Their precipitation, says Pouvarot, in the tubes to which they belong, cannot be regarded as a simple separation; since it is accompanied by a modification in the properties, nature, and composition of each. Thus the cerebral pulp is not exactly the same albuminous matter as that in the serum of the blood; the gelatine is not isolated in this fluid, as in the membranes thin; the mucular fibre is not completely identical in its character with that which exists in the blood; and the phosphat of lime is not assimilated in the latter to the gelatine substance, which unites its parts.
cles in the bony system. Hence secretion always implies some change or modification in the matter which results from its exercise. Commoill, Chir. sect. 8, ord. 4, art. 5.

Another notion, as distinct of all solid foundation as the former, is, that the blood undergoes certain changes as it arrives at the glands; that it affixes a peculiar composition before it penetrates the organ. It has been asserted that the blood-vessels are so arranged as to produce particular modifications in the contained fluid, and that this is a disposition preparatory to the final process. The hepatic secretion has been considered to afford the clearest example of such previous changes. The structure and number of the vessels which surround and enter the organ, the proportion of those which carry blood or white fluids, the different temperatures supposed to depend on these proportions, in a word, all those points of organization which can possibly influence the nature of the blood, are said to be sufficiently diversified in order to produce in the chemical properties of the fluids a disposition favourable to the formation of saliva in the neighbourhood of the salivary glands, or urine in that of the kidney, &c. This disposition, depending on the vascular apparatus, has been represented to consist particularly in a retardation, acceleration, cooling or warming of the blood, or in the loss, by absorption, of some of its principles. But what feasible cause can produce these effects? Does not the blood flow through the trunks which are going to the glands just as in other vessels? In short, what is the change? The supposition in question is a complete assumption; not supported by a single fact, and contrary to observation as far as our knowledge hitherto extends. For we can detect no difference in the blood drawn from the carotid, spermatic, hepatic or renal arteries. We have been surprised to find this opinion adopted and supported by Proucroy; but the whole of his remarks on the subject in the "Système des Connoissances Chimiques," sect. 8, ord. 4, art. 5, do not contain a single proof, and afford an example of vague and entirely illogical statements. We do not mean to deny that there may be particular conditions of the whole mass of blood favourable to certain secretions. Thus, after drinking copiously of watery fluids, we find a much larger portion of urine secreted; and the cutaneous exhalation is often augmented from the same cause.

In our endeavours to discover the mechanism of secretion, it will be best for us to select the most simple mode of this function. Now the exhalation from ferous membranes, and the mucous fluid covering the surface of most cavities in the body, are examples of this kind. We can discover nothing in these organs but vascular ramifications united by cellularsubstance. Injected fluids in the dead body follow the same route which the secreted liquors follow in the living state. And the same observation may be applied also to the case of secretions in some of the more complex infusions. "Water," says Haller, "tinted with colouring matter, fluid film, or oil of turpentine, thrown into the arteries of a young subject, and occasionally even fuel, in the experiments of Raync and Albinus, have excited in numerous small drops from the skin, after the removal of the cuticle in warm water, so as to imitate very closely the proceedings of nature. I have also repeatedly seen water, coloured with blue, and injected into the lungs through the interior cava, run out with much froth from the trachea. In the kidney, water, air, or fuel will pass through excretory tubes continuous with the arteries into the infundibula and pelvis. Oil of turpentine and quicksilver have passed into the chamber of the aqueous humour from the arteries: in the same way injected water imitates the course of the tear, and exudes abundantly from the whole internal surface of the eyelids." Memo. Physiol. t. 2, p. 374. Physiologists have indulged in considerable disputes concerning this kind of secretions. "Some," says Blumenbach, "affirm that all separation of fluids from the mass of blood is accomplished merely by pores in the blood-vessels, and that, as they say, of an inorganic nature; while others deny altogether the existence of secretory pores. I suspect that this difference of opinion need be resolved into a verbal difference. On the one hand, I must confess, unequivocally, that I know not what notion to form of inorganic pores in an organized body, since all the openings in such bodies must belong to their organic nature, and be regulated by their vital properties. On the other side I do not conceive that the orifices or pores in the coats of the vessels, the existence of which cannot be doubted, differ essentially, in regard to their functions, from the cylindrical ducts, in which secretion is performed in the conglomerate glands, and in the glandular vesicles: since it is probable that the separation of fluids depends more on the vital properties than on the forms of the secretory organs." Inst. Physiolog. sect. 32, § 469, note b.

However simple the process of secretion may be deemed in the case just specified, and however closely the proceedings of nature may be imitated by the experiments with injections, we shall find ourselves entirely ignorant of the essential circumstances of the process; i.e., we cannot explain the formation of the new product from the blood, and the formation of such totally different new combinations in organs where no difference of structure can be detected.

Those, who wish to see the various attempts at explaining the mechanism of secretion, may find ample gratification in the third section of the seventh book of Haller's great work: where he gives his usual detail of all that has been written on the subject. The reader will be very willing to spare us the task of recounting all these dreams, and the still more disgusting toil of refuting them. We shall merely mention one opinion, on which physiologists lay some stress even in the present day. This refers the difference of the secreted matters to the peculiar arrangements of the minute arteries of the glands. Ruyfch, who excelled in the art of making anatomical preparations, was led to remark, in his employment of injections, that the ultimate arterial ramifications differ in the different secretory organs, and indeed that there are characteristic differences in this respect in all the structures of the body. This explanation may possibly be true, and we cannot perhaps completely overthrow it: but this is all that we can say in its behalf. We must observe, in the first place, that a correct account of the facts, and an exact description of the different vascular networks, is yet a desideratum; for the question concerns the very smallest capillaries, from which the tubes conveying the new product commence. Now the larger ramifications, such, for instance, as will admit several globules, do not differ sufficiently from each other to account for the diversity of the fluids produced in the various organs. Indeed similar vessels often produce the most opposite products. The structure of the cortex cerebr. of the liver, and of the placenta, is very much alike with the most dissimilar results. The veins, too, are arranged like the arteries, as we should conclude, certainly not for the purposes of secretion. Very different arrangements of blood-vessels may be seen in various membranes which produce the same kind of exhalation.

Recover has been had to the science of chemistry, in order to explain the function of secretion, but no affinity has been
hitherto derived from this source in unfolding the mystery. That the changes, by which the new products constituting the animal fluids are produced from the blood are purely chemical, cannot be doubted, but we are equally in the dark as to the circumstances which determine or modify these alterations. We cannot doubt indeed that the whole essentially depends on a vital power of which chemistry can neither detect the nature, nor appreciate the force. If, however, we cannot be very sanguine in expecting from this science a development of the immediate agent by which secretion is effected, much light may, probably, be thrown on some parts of the subject by accurate chemical investigations. We may apply generally the observation of Dr. Thomson concerning the kidneys: the changes operated on the blood in the kidneys are at present altogether unknown; but they must be important. Provided the method of analyzing animal substantia was so far perfected as to admit of accurate conclusions, considerable light might be thrown upon this subject, by analyzing with care a portion of blood from the emollient artery and vein separately, and ascertaining precisely in what particulars they differ from each other. 

Fourthly, too, in considering how far secretion admits of explanation on chemical principles, speaks rather of what may be done than of what has been effected in this way. Hitherto chemistry can only furnish some general statements on this subject; and, if we look to this science for an explanation of the causes and products of the secretions, and for a demonstration of what passes in every kind of secretion in particular, we must wait till the experiments are much more numerous, the investigations more exact, and the animal analyses considerably multiplied. We must determine the temperature, confidence, and nature of the cerebral blood, of that in the vena portorum, and in the renal arteries, before we can understand the mechanism of the secretions performed in the brain, liver, and kidneys.

We should always bear in mind, in our attempts at chemical explanations of the animal functions, that the effects of the vital power are more particularly observable in counteracting and preventing the exertion of those affinities, by which dead animal matters are regulated; and consequently, that if secretion be an example of chemical affinity, it is so modified by the vital powers, that we can have very little hope of imitating it by experiments out of the body.

In what manner, and to what extent, are the secretions influenced by the nerves? The fact that glands have a supply of nerves, leads us to expect a priori that the effects of their operation will be very obvious; but the laws, which regulate this matter, are litherto by no means clearly ascertained, and even the kind of influence is very obscure. There is a want of direct evidence, from experiment, on this subject. As I divided,” says Bichat, “the nerves of the trachea in a fowal; the gland inflamed and suppurred; but the latter occurrence shows that nervous influence is not necessary for secretion, since suppuration is accomplished in a manner analogous to that of the latter functions. Physicians know very well that paralytic limbs may inflame and suppurate. Erection and evolution of the femur may occur, when the lower part of the body is paralyzed; and when the nerves of the prostate at least must have entirely lost their influence. An example was related to me of a soldier, who contracted a gonorrhoea in this state. In complete paralysis of the bladder, mucus is still secreted in sufficient abundance. The noril of the affected side is as moist as usual in hemiplegia; and an equal quantity of cerumen is produced in the meatus auditorius of the same side. The glands of the uvula

Vol. XVI.

do not cease to act where that organ is paralyzed. After cutting the nerve of the eighth pair on one side in a dog, the air-veils are equally full of mucus on that side. In the convulsed state of such parts as pofts glands, where the nerves of these organs must consequently be unusefully excited, there is no augmentation of the secretion.” Anatomic Generale. tom. 4. p. 604. We may observe further, that when the influence of the brain on the organs of the animal life is completely suspended in apoplexy or convulsion, where fection and voluntary motion are lost, the secretions continue undisturbed. On the other side we may adduce numerous phenomena, which can be accounted for only through the agency of the nervous system. Under this head we may mention the flow of saliva on the sight of food, the increased lacrimal secretion produced by various affections of the mind, the suppressed discharge from the skin from the same cause. The urinary secretion is often suddenly affected in hypochondriacal persons; distressing news will occasion it to be secreted in great abundance, and of a very pale colour; and many remarkable instances have been recorded, where the biliary secretion has been decidedly and suddenly affected by mental emotions. It has been asserted, but we know not on what authority, that a cow, after being milked by the same individual for a long time, will give much less milk, if the operation be performed by a stranger. These and other analogous facts have led many physiologists to admit of a nervous influence in the affair of secretion; the mode and degree of this action have been variously estimated. De Bergey conceives that the tone of the secretory organs was kept up by the nervous fluid; De Natura Humana. p. 122. Quennay referred the differences of the secreted fluids to various degrees of sensibility in the secretory vessels. L'Environ. Anim. t. 3. p. 437. De Bordeus ascribed great influence to the nerves on the secreting arteries; Recherches sur les Glandes. p. 532. Stahl and his followers, who ascribed the power of guiding the vital motions to the soul (anima), conceived that it governed the functions of secretion also; and A. F. Hoffman ascribed the difference of the fluids entirely to the anima, which regulates the secretory orifices by sphincters and valves, now closing them to prevent the entrance of particles heterogeneous to the fluid intended to be formed, and now opening them for the entrance of the suitable molecules. Nov. Hypothet. Physiol. p. 13. After recounting these opinions, Haller observes that they ascribe too great an influence to the nerves, and reminds his reader that secretions of various kinds are performed in plants, without the influence of nerves; and that balsams, ointments, gums, and coloured milky fluid is formed from the common liquid taken in by the roots of the vegetable. On this subject we may observe, with Bichat, that the expression nervous influence has generally been used by physiologists in a very indefinite manner. When the irritation, division, or paralysis of a nerve supplying a voluntary organ interrupts, or entirely destroys its functions, we can observe and appreciate the influence of the nerves on such organs; but, with what propriety can we employ the same term to designate the power, which the nerves may possibly have over the secretory organs, when their division or paralysis does not at all disturb the functions of the part? The secretions may be affected by the direct action of external irritants, although mechanical or chemical irritation in the living body produces no sensible motion or contraction of the organ. Thus, any acid matter will augment the flow of mucus from these surfaces which secrete it; and the slightest irritation of the conjunctiva increases the secretion of
of the biliary gland. The presence of food in the mouth excites the salivary organs; and the act of suckling or milking produces a secretion of milk, &c. &c.

The same powers by which secretion is effected accomplish the passage of the fluid, when produced, through its respective tubes; it is the sensible organic contrariety by which this is effected. Experiments on the ducts of glands in living animals, show that they are not affected by chemical or mechanical irritation, and hence many have concluded that they possess no power of contraction; but the phenomena render it necessary to allow them such a property, which may exist in parts, although the trials just mentioned should not render it obvious. External prelapses and extraneous influence of other kinds have been resort to, in order to account for the expulsion of the fluids contained in excretery tubes, on the idea that these canals possess no contractible powers in themselves. Such explanations are quite gratuitous assumptions in all cases; and in many instances are totally and manifestly inadequate, because the organ is exposed to no agency of the kind.

The secreted fluid in some instances is not conveyed immediately to the point of its ultimate definition; but is either retained in the excretery tubes, or kept in particular resevoirs; and it has been supposed that various changes take place in its nature and properties under these circumstances. "Frequent urines," says Haller, "are mechana ou natura urinar, ut humorem seque pertinere, persecut, ad determinant. Hahs contemperz, legitima occasione effundat." Elen. Physiol. t. ii. p. 155. The urinary and gall-bladders are the most remarkable instances of this description: we may mention also the vesicular feminales, and the mucous ducts of the urethra and female organs of generation. That the secreted fluids in these, and in several other instances, are considerably altered after the time of their first production, cannot admit of a doubt, as mere inspection is sufficient to prove it; the particular changes produced in each case will be considered in the account of the various organs. The opinions entertained concerning the general effects of these resevoirs, are, that the fluids are impregnated by an adsorption of these aqueous parts, that they are depurated, or rendered more perfect, and variously mixed together; it is added, that their retention in the heat of the living animal body in many instances renders them acrimonious, and that this change, in many cases, as in the bile and feamen, promotes the views of nature. These notions are not very consonant with each other, nor very clear in themselves; the latter hypothesis, concerning the acrimonious tendency of the fluids, is founded on the observation of the changes occurring out of the body, and is not at all warranted by observation of the living subject, in which chemical alterations are reduced by the vital powers.

We have every reason to suppose that much of the secreted fluids is taken up and carried into the circulation by the absorbers; but our knowledge does not enable us to determine the exact extent or nature of the modification, which the function of secretion undergoes from this cause. The experiments of Bichat prove that the various animal products, even those which we should at first have regarded as the most noxious, may be introduced into the venous system without essential injury to the animal; so that the blood may be deemed a common fluid, receiving and retaining various principles, which may vary according to circumstances. "I injected," says Bichat, "into the jugular veins of several dogs, the bile taken from other dogs opened at the same time. During the first days they appeared weary, did not eat, were very thirsty, had a dull look about the eyes, and were constantly lying down; in a little time, however, they gradually recovered their original vigour. I have often employed human bile in similar experiments; the results were the same, except that hicouche and vomiting took place soon after the experiment. In one instance the animal died three hours after the injection; here I had used bile of an extremely deep black colour, like thick ink, such as is occasionally seen in the gall-bladder, and seems to form an essential part of the black vomitings observed in certain cases. When similar trials were made with saliva, the consequent languor was less sensible. I then tried mucus of the nose suspended in water. Lastly urine itself, not of the aqueous kind, but that of coition, was employed; the consequent ill-necess was more severe, but one animal only died, and I suspect that this fatal event happened from the unguarded introduction of a little air at the time of the experiment." Anatomie Generale, t. 4. p. 858. He observes afterwards that the injection of any animal fluids into the carotid artery is immediately fatal, from the effects produced on the brain; but they may be thrown with impunity into other parts of the arterial system, as, for instance, into the crural artery.

Sympathies of the glandular system—These may be divided into the passive and active. The glandular tissue is very readily influenced by various excitements, either in the natural state, or in different, which constitute its passive sympathies. The cases in which the excitation of other organs augments glandular action, are particularly observable in the mucous system. Most of the excretery ducts open on surfaces of this nature; and examples of the observation occur in the flow of saliva determined by the presence of food in the mouth; in that of urine produced by catheters retained in the bladder; in the seminal excretion produced by iritation of the glans; the flow of tears from irritation of the conjunctiva or pituitary membrane; and in that of bile during the passage of the food into the small intestine.

The glandular system frequently exhibits passive sympathies in disease; the organic properties are brought into action under these circumstances, the animal sensibility being very seldom developed for the purpose of producing pain. The innumerable varieties in the quantity or quality of fluids separated by the glands under circumstances of disease arise principally from sympathetic influence. Thus the salivary apparatus moistens the mouth, or leaves it dry; fills it with a viscid or a thin fluid, &c. The mucous organs cover the tongue with matters of most varying consistence, thickened, and colour; and this occurs from sympathy with various states of the stomach. The liver, kidney, and pancreas are influenced in very numerous ways; wherever any organ in the animal economy is affected, these are deranged; their secretion is increased, diminished, or altered, and frequently even inflammation and suppuration supervene. The affections of the liver from injuries of the head are well known; and the lacrymal secretion is variously modified in inflammatory and malignant fevers, so as to produce various appearances of the eyes. Weeping in various mental affections is another example of sympathetic influence. The teardrops and prolate exhibit fewer instances of such sympathies, probably because their functions are so much more isolated. The relations which connect the breasts and uterus are remarkable, and frequently observed. In the sequel of consideruble acute chills, particularly fevers, the action of the glands is often considerably affected, and copious evacuations, called critical, the nature of which is not yet clearly explained, take place.

The active sympathies are less frequent than those of the
preceeding clas: but diseases exhibit influence of them. inflammations of the liver, kidney, salivary systen, &c. new various phenomena produced sympathetically in other systen.

Bichat, in his Anatomie Generale, gives the following view of the characters which distinguish the vital properties of the glandular system.

1. Peculiar vitality (vita propria) of each gland — The vitality of the glands, resulting from the preceding powers combined in a state of action, is not uniform in the whole system; because the structure varies in every instance, and each tissue possesses a particular modification of vitality. Hence refult many phenomena noticed by Bichet.

1. There are certain matters on which alone each gland can act in the natural state. Thus the salivary apparatus does not form bile, the liver does not separate urine, &c.; and on this principle the difference of the secretions is founded. In the same way cachetaries act particularly on the urinary organs; mercury on the salivary glands, &c. 2. Each gland has its particular mode of sympathy. Thus the liver acts especially on the brain, the kidney influences the fleshes, the uterus and breasts affect each other, &c. 3. Each glandular inflammation has a peculiar character: that of the inflamed prostate has very different symptoms from the tooth in such a condition. 4. Every gland has peculiar difeases, or fome at least to which it is more exposed than others. Hydatids, which are very common in the liver, are never seen in the salivary glands or saccus. Sarcocole is extremely common, while nothing is more unfrequent than an enlarged parotid. The liver alone exhibits that peculiar alteration, which constitutes the fatty state; and is the moft frequent of all feptic tumours. Physicians, who have not been converfant with the inspection of morbid eaxes, use the vague and insignificant terms of obftrufion and induration for every kind of glandular enlargement. The increafe of fire is the only common character of fuch affections, while the nature of the tumour is entirely different. 5. Every gland presents fome peculiar modifications in what are called the chronic eruations, occasionally confequent on acute difeases. 6. The different vitality of the glands occasions them to re-act at very different intervals, in confequence of direct irritation, or sympathtic excitation. The lacrymal gland, for example, pours out suddenly an abundant fecretion, when irritated; while the kidneys or pancreas can be excited only very slowly.

2d Character. Inactive state of the vital powers. — The glands are fubjeét to habitual alternations of increafed and diminifhed action. The animal functions are especially influenced by sleep, which completely fuppreds them. The action of the glands is only partially diminifhed at certain times, except in fleep, when it is sometimes completely fuppressed. Bichet compares the fleep of the animal life to the intervals of intermittent fevers, where the apetite is complete; and the fleep of the glands to that of remittent fevers, where the symptoms are merely diminished in degree. Salvia flows into the mouth abundantly during malnutrition; it merely moistens the cavity at other times. The pancreas and liver pour out their fecretions profusely, while the food is in the duodenum: they act much less intenfly during the state of abstinence. The kidney is particularly excited fome little time after a meal. The intermitting in the action of the fluids are almost as complete as theofe of the organs of animal life. Every mucous gland has its particular period of fecretion: it is, when the surface, on which the duct opens, is in contact with any subsance either retained in the cavity, or paffing through it. We muft, therefore, form this notion of the office of the glands: that they constantly separate a fluid from the blood, but that they are more active at certain periods, and confequently furnish a more abundant supply.

This remittance of the glandular action, says Bichet, depends on a caufe analogous to that of sleep, which arises, in the animal life, from the fatigue experienced by the organs of sensation and locomotion, after a continuance of action. The latitude, of which the glands are infusceptible, is not generally marked by any painful feeling; yet there is in the bread, after long fuffering, a kind of dragging sensation, and actual pain is felt in the teeth after emission has been repeated two or three times.

3d Character. — The vitality of the glands is never extinguished at the fame time in the whole system. When one is in action, the others are in a state of remission. We might conceive, fays Bichet, that there is only a determinate quantity of vital powers for the whole, and that one cannot be exercised unanimously without a corresponding diminution in the ref]. The digestive apparatus is accommodated to this law. At fift the salivary fystem produces an abundant fecretion; then the fomach comes into action; thirdly, when the chyme enters the duodenum, the liver and pancreas are principally excited; at the fourth period, the mucous glands of the large intestine act; and laftly, the kidney exercises its peculiar office to evacuate the refuse of the fluids. All the glands cannot act at once; as, in the external movements, certain muscles are always in a condition of repose, while others are contracted. The moft improper time for coercion is during digestion, because the mucous, pancreatic, hepatic fecretions, &c. muff then be performed at the fame time with that of the tefticle. In difeases, the fecretion of one gland is extinguished at the expense of others. This character of the glandular fystem is only an example of the general character belonging to all the vital powers, by which, when increafed at one point, they are proportionally diminished in the other fation. Hence large abscesses, confequent tumours, and dropsies are always attended with debility of the glandular action. On the fame principle is founded the use of blisters, feetons, moxa, cauteries, &c. which do not act, as old physicians fuppofed, by evacuating any morbid matters, but by putting an end to the irritation in the difeased part, by means of that which they determine in some other organ.

4th Character.— Influence of climate and the feasons on the vitality of the glands. From the preceding character is derived another phenomenon, which may be considered peculiar to the glandular fystem: viz. that it is in general more active in winter than in summer, in cold than in warm climates. Warmth, by relaxing the integuments, increases the cutaneous discharge at the expense of that of the glands; while the action of cold is the inverse of the preceding. Hence the fame fluid, introduced into the body, is expelled in winter by the skin, in summer by the kidneys.

5th Character. — Influence of sex on the vital properties of the glands. Is the vitality of these organs more active in the male than in the female? In those which are subervient to digestion, the lacrymal and urinary fecretions, &c. the two sexes exhibit very little difference. In the generative fystem, the male produces the addition of tefticles and prostate, the female of mammary glands; so that here there is a compensation. But the influence of the former on the animal economy very much exceeds in its force that of the latter.

Development of the Glandular System.

1. State of this system in the fetus. — Although the fecretions
GLA

GLA

vations possess very little activity in the fetus, the glands in
general are large. The salivary glands and pancreas are
larger than in the sequel; the bulk of the liver is enormous;
and the kidneys considerably exceed their adult volume.
It is not yet ascertained whether the same observation ap-
pplies to the mucous glands. The form and colour are dif-
different in several from what they afterwards exhibit. The
texture partakes of that softness and delicacy, which are
common to the whole body; and they abound with fluids.
In respect of their secretions, they seem to be in a con-
dition analogous to that of remission in the adult; indeed,
they produce still less than at that time. In fact, all the re-
servors would not suffice to contain the produce of their se-
cretion, if these were as much produced in a given time, as
after birth. Is this because the black blood, which they
contain, does not furnish suitable materials, or rather, be-
cause the actions concerned in the composition of the body
predominate so remarkably over those of the other kind?
All the matter brought to the organs remains in them, and
affords the materials of the rapid growth, which is then
taking place; consequently, the secretions, which are de-
digned chiefly to get rid of the refuse of nutrition, are
then inactive. Moreover, digestion introduces into the
blood none of those principles, which, not being required
for nutrition, are expelled nearly as they enter, without
having belonged to the composition of the organs; such as
the greatest part of the drink.

2. State of the glands during growth.—This system ac-
quires a sudden increase of energy at the time of birth.
Red blood now circulates through its vessels; and the ex-
trinsics of the excretories are stimulated in various ways,
as, by the food in the cafe of those which open on the al-
imentary canal, by the air in the respiratory apparatus, &c.
The organs are so much the more sensitive to this sudden
excitation, in proportion as they were before unacquainted
with it. Yet many of the secretions are carried on with less
activity during the first years of life, than in the sequel, as
those of the salivary glands, liver, &c. Affections of the
glomerular system are not the leading ones in the first years
of life. The lymphatic glands, as they are called, and not
the parotids, form the swellings so frequent about the neck.
Hepatic affections are rare at this time. All the secretions
connected with the generative process hitherto do not exist.
The organs, which are particularly employed at any age,
are chiefly affected by acute and chronic diseases at that
time; while those, by which no important function is ex-
ercised, seem to be overlooked. All affections of the testis
and chord are unfrequent before puberty, while the process
of nutrition alone is carried on in these organs. The glan-
dular tissue is for a long time soft and delicate in the child;
and it has not that property of becoming hard in con-
sequence of boiling, which we have mentioned as belonging
to it in the adult.

3. State of the system after growth.—We have already
spoken, in the article GENERATION, of the organs which
come into activity at puberty, and of the influence which
they exert on the frame. At this time all the system ac-
quires a greater firmness in its texture. Towards the for-
tieth year the digestive glands seem to be predominant in
the economy, and the liver is especially observable among
those. Now bilious affections are most numerous; and the
influence of those passions, to which the bilious tempera-
ment seems to difpofe, is most observable.

4. State of the glands in old age.—At this time the organs
gradually become more hard in their texture; but their col-
cour changes les than that of most parts. The liver, kid
ey, &c. are nearly as full of blood as in the adult;
while the mucus, pale and colourless, contain a smaller
proportion than before. It seems that this fluid first quits
the skin and mucus, which are far from the heart, and
is concentrated in the nearer organs; thus the secretions are
still abundant in old perons, while the muscular and nervous
powers are considerably weakened. The kidneys and liver
still separate their particular secretions in large quantity.
The activity of the generative system has long ceased. The
active exertion of the glands which are thus employed may
be referred to two causes. The decomposition of the body
is very marked at this time, and much matter is consequently
thrown out by certain glands. The decay of the old sub-
ject is a phenomenon exactly opposite to that of growth in
the fetus. The skin, shrivelled and hardened, ceases to
throw out the products of decomposition, and the glands
supply its place.

Generally speaking, life ceases most gradually in the
glomerular system. In the bodies of old persons we see the
gall and the urinary bladders still full of their respective
fluids. Compression of any gland, even of the prostate,
shows that it contains much fluid; even more than we ob-
serve in the young subject. It is also a remarkable pheno-
menon that all the chief internal organs, as the liver, kidney,
heart, lungs, &c. still preserve a considerable share of vi-
ability, while the parts subjacent to the stomach and small
bowels are nearly exhausted, and the ties, which connect the
individual to surrounding objects, are consequently nearly
destroyed. Haller, Element. Physiolog. tom. 2. Dumas,
Principes de Physiologie, t. 4. Bichat, Anatomie Gene-
rale, t. 4.

GLAND, in VEGETABLE PHYSIOLOGY, (gladiola, a little kernel)

defined by LINNAEUS as a "small tumour, discharging a
fluid." This fluid is always some peculiar secretion. The
calyx and flanks of the Mofs Roe, and of many other
Roes in some degree, are covered with prominent glands,
discharging a virfud aromatic liquor. Between the flanks of
the leaf of SALIS pamandra, the Bay-leaved Willow, is a
series of such glands, whose exudation is a highly fragrant
yellow gum-resin, to which the fine-rect of that leaf is
chiefly owing, and several other Willows are provided with
similar, though less perfumed, secretions. On the footstalks
of the Guelder-rofe, Viburnum Opulus, are very large and
elaborate glands, whose discharge however is comparatively
trilling, while various Species of Paffion-flower bear cup-
shaped glands, on their footstalks, producing a considerable
quantity of very sweet honey. These therefore bear more
analogy to those glands, appropriated to some flowers, and
called, from their produce, nectariferous glands, or nec-
taries. Such occur in GERANiUM, and in the Cruci-form plants,
constituting the Linnaean class TRichodynia. In the latter
the nectariferous glands occasionally exhale a powerful
scent, especially in SyphiIum tenuifolium, Eng. Bot. t. 525.

The kinds of glands above-menioned, being of a secre-
tory nature, certainly bear a great analogy to the glands
of the animal body; but it appears that the more general
and important secretions of vegetables are accomplished
through membranes, whose organization and physiolog are
inertible to our powers of investigation. S.

FISH.

GLANDEN, in Geography, a town of Prussia, in Na-
tangen; 30 miles E. of Brandenburg.

GLANDERS, in Veterinary Science, a filthy disease in
a horse, so called, probably, from the swelling of the sub-
maxillary glands that accompanies it; and consisting in a

corrupt
corrupt slimy matter, running from the nose, of a different colour, according to the degree of the malignity, or as the infection has been of a shorter or longer continuance; being white, yellow, green, or black, sometimes tinged with blood.

Authors ascribe it to various causes: some to infection; some to a disorder of the lungs; others to the spleen; some to the liver; and others to the brain. After it has been of so long standing, that the matter is of a blackish colour, which is usually in its last stage, they suppose it to come from the spine; and hence they call it the warning of the death.

Kernels and knots are usually felt under the caud in this disorder; and as these grow bigger and more inflamed, to the glands increase more. The progres of the disease is extremely uncertain; as some horses will endure it for many years, without any other obvious inconvience than a slight discharge and the enlargement of the glands under the jaws; and instances have occurred in which these symptoms have disappeared for several weeks, and returned, perhaps, with no augmented virulence. In most cases, however, the course of the malady is more rapid; the bones and cartilages of the nose are speedily eroded by the malignity of the ulcer, from which an abscission commences, and conveys the poison into the circulation, gradually and fatally contaminating the whole frame. Neither the appetite nor the condition of the glandered horse suffers materially in the early or mild stage of the complaint. When, however, it has fixed its dominion over the thoracic viscera, forming ulcers in the substance of the lungs and in the waist-pipe, great pain and difficulty of respiration are experienced, the discharge becomes very considerable, the appetite is injured, and the body of the unfortunate animal exhibits a picture of extreme distress; and unless the humanity of the owner does not induce him to terminate his sufferings, the disease will, by tardy steps, afford relief to the wretched animal by dissolution.

M. La Foffe, farrier to the King of France, has taken great pains, by repeated dissections, to discover the source and cause of this disorder, and to ascertain the proper and effectual method of cure. He has distinguished seven different kind of glanders, four of which are incurable. The first proceeds from ulcerated lungs, the purulent matter of which comes up the trachea, and is discharged through the nostrils, like a whitish liquor, appearing sometimes in lumps and grumes; the second is a watery humour, that usually seizes horses at the decline of a disease caused by too hard labour, and proceeds from the lungs: the third is a maliglant discharge, which sometimes attends the pleasure, falls upon the lungs, and is discharged at the nostrils: the fourth is when an acrimonious humour in the farcy seizes these parts: the fifth arises from a horse's taking cold; the sixth is a discharge from the sinuses, which sometimes vents itself at the nostrils: the seventh, or real glanders, is that above described.

M. La Foffe, after examining, by dissection, the carcase of glandered horses, and making a strict scrutiny into the state of the viscera, affixed in his enquiry by ingenious anatomists for the space of ten years, affirms this disease to be altogether local, and that the true seat of it is in the purulent membrane which lines the partition along the inside of the nose, the maxillary sinuses or cavities of the cheek-bones on each side of the nose, and the frontal sinuses or cavities above the orbits of the eyes; that the viscera, as the liver, lungs, &c. of glandered horses are, in general, very found; and, therefore, that the seat of the disorder is not in those parts, as many authors have affted.

He found these cavities more or less filled with a viscid slimy matter: the membrane, which lines both them and the nostrils, inflamed, thickened, and corroded with forbid ulcers, which, in some cases, had eaten into the bones. He observes, that, when glandered horses discharge matter from both nostrils, both sides of the membrane and cavities were affected; but when they ran at one nostril only, that side only was found disfigured; and if one gland only was affected the horse discharged from one nostril only: but if both were affected, the discharge was from both. It has been observed, that the glanders in horses very much resembles a disorder in men, called abscess.

In this disease, if the matter sticks to the inside of the nostrils, like glue or stiff paste, if the inside of the nose is raw, and appears of a livid or leaden hue, and the matter becomes bloody, fetid, and of an ablab colour; these symptoms are very unfavourable: but when only a limpid fluid is first discharged, and afterwards a whitish matter, the gland under the jaw does not much increase, and the disorder has been of no long continuance, a speedy cure may be expected. The cure of the milder kind of glanders may first be attempted by injections and fumigations. When these latter symptoms appear, the horse should first be bled, and treated as in the common disorder of cold; and then, let an emollient injection, prepared with a decoction of linden, marsh-mallows, elder, chamomile flowers, and honey of roses, or such like, be thrown up as far as possible with a strong fire, and repeated three times a day: if the running is not lessened or removed in a fortnight by these means, a refraining injection may be prepared with treacle of roses, honey-water, &c. and the nostrils fumigated with the powders of frankincense, mastic, amber, and chambar, burnt on an iron heated for that purpose, the fumes of which may easily be conveyed through a tube into the nostrils. When the disease is irrevocable, recourse must be had to the operation of trepanning, which M. La Foffe performed on three horses, two of which discharged from one nostril only, and the third from both: he trepanned the two hell on that side of the head which was affected, and the other on both sides, and found that the wound and perforation filled up with good flesh in twenty-six days, and the horses suffered no inconvenience from the operation. The method of performing this operation will be understood by means of Plate XIX. “Illustrations,” fig. 1, and the following explication: B, B, are two lines representing the bounds of the cerebellum, or back part of the brain, which commences from the line D. C C is a line, where the superior part of the fissus frontalis commences, together with a view of the bottom of the sinus, terminating between the lines D and E, where appears a subabundance in the form of a pear, which is the os ethmoidis, or sieve-like bone through which the olfactory nerves pass, communicating sensibility to the pituitary membrane. E represents the beginning of the maxillary sinus, terminating at M: the shaded space between these lines represents the great cavities. F is a bony partition, separating this sinus into two parts that have no communication: of which partitions there are sometimes two, represented by F and G. Some horses have neither of these. N shows the place of the canals or horns; O, the doubting; P, their middle part; Q, the lower part of them; and M, the bony pipe or canal which guards the maxillary nerve: A A is the leptomarium, dividing the nose from top to bottom, and separating the two nostrils. I, shows the place where the trepan should be applied, when there is reason to apprehend that the glanders is spread to the frontal sinus; E is the place where it should be applied.
to cleanse the maxillary fissus, though the round spot between D and E is preferable, because one orifice in this place will serve to wash all the parts, both above and below, with one injection. It flows the place where another perforation should be made, as a drain for discharging the foul matter washed away by the injection; and this hole, kept open by a hollow leaden pipe, would, in all recent cases, be sufficient. I represents the injection thrown in by the syringe, which flows out by the orifice and the nostril K; and, during this part of the operation, the nostrils should be held close. If there should be two holes in the maxillary fissus, it is absolutely necessary to pierce through both, with a filletto or sharp-pointed tack, as in the figure. The trochan should be directed towards the interior part of the nose, to continue being obstructed by the roots of the teeth. R is the trochan, S the handle which turns it, and T the few-part to be applied to the bone. The surgeon's trephine will suffer the purpose for this operation; but the instrument is applied, a circular piece of the skin, of about the size of half a crown, should be first cut off with the membrane which covers the bone. The syringe should be large enough to hold a pint of injection. The injection first used should be of a different nature, as a decoction of birth-wort, gentian, and centaury, to a quart of which may be added two ounces of Egyptianum and tincture of myrrh; and when the discharge abates, and the matter becomes of a thick consistence and white colour, this injection may be changed for barley-water, honey of roes, and tincture of myrrh; and for completing the cure, Bates's alum-water, or a solution of colocynth, vitriol, lapis medicamentosus, and such like, in line-water, will serve to dry up the moisture, and to relieve the tone of the relaxed glands. For this purpose Dr. Bracken recommends the following mixture: Take of alum and white vitriol powdered, of each four ounces; calcine them in a crucible; when cold, powder the cakes, and mix it with a gallon of line-water and a quart of vinegar, and decant the mixture clear for use. The perforations that are made in this operation should be kept open, after the use of the injection, by fitting to the upper one a piece of cork waxed over, and a hollow leaden tent to the lower, through which there will be a constant drain of matter from the fixture, and both may be secured by a proper bandage. The growth of the flesh should be also checked by rubbing with caustic medicines, or applying the actual cautery. The cure will be expedited, by giving every day a quart or three pints of a strong decoction of gualacum chips, by purging at proper intervals, and putting a rowel into the horse's chest; and if these fail, mercerials may be administered with the physic, and the alternative powders with lime-water may be given and continued for some time.

The following remedy is said to have succeeded, in fifty cases out of sixty, for curing the glanders, without trepanning. Keep the horse a day or two with small quantities of choice hay, and scalded bran; then blow up his nostrils as much as possible, in fine powder, as will lie on a fixed-pence, evening and morning, giving him for drink small line-water, during four or five days; then boil two ounces of elecampane roots in a quart of drink, till they mix, and give it once a day during three or four days more; then boil two handfuls of the white masts that grows on oaken pales, in two quarts of milk, till one is cowed; strain it and squeeze the masts, and give the milk half warm: repeat this for four or five days. About an hour after the horse has had his drink each day, take a piece of sweet butter, about the size of an egg, and about half an ounce of brimstone finely powdered, and work them well together; then take two clean goose feathers, as long as they can be procured, and make a hole in each of the quill ends; in which take four long threads; then anoint the feathers well with the mixture, and roll them in dry flour of brimstone; open the horse's nostrils, and thrust the feathers up into his head, fastening the threads to the top of his head, to prevent their dropping out; ride him an hour or two morning and evening, and let him stand half an hour after he returns to the stable before the feathers are taken out: pursue this course eight or nine days, bathing his head with camphorated spirits of wine, and afterwards confining his head over a frcb of hot grains, that he may breathe the steam. A rowel may prevent a relapse.

After all that has been said, it is now generally allowed, that no effectual remedy for the glanders has yet been discovered. The operation of trepanning has never been attended with permanent success; and whatever relief has been obtained from the use of various medicines, it has been merely temporary, and the disease has been pronounced incurable. But though all attempts for curing the glanders have hitherto proved ineffectual, the inquiry should be pursued, and efforts for this purpose should be renewed till the veterinarian's ingenuity and perseverance are crowned with success. The analogy subsisting between the glanders and the venereal disease has led some practitioners to recur to the use of mercury, but the successes attending it has been very partial. Professor Coleman mentions a single case which occurred at the Veterinary College, in which the glanders yielded to the treatment employed, which was that of repeated and long continued doses of calomel, carried to the extent of salivation. This solitary case led to many trials of a similar nature, but, unhappily, without the success which was hoped for by the professor, who exerted his utmost ingenuity to improve the hint which this single instance afforded. Others have made similar efforts in this way, with only a temporary abatement of the symptoms, but without ultimate success. Some years ago, great expectations were formed, from the use of the mineral acids in the venereal disease; and trials were made with their in some cases of glanders, which were ineffectual. The late professor of the Veterinary College, M. St. Bel, made a variety of experiments for ascertaining the nature of this disease, and for investigating an effectual remedy, whilst he was professor of the veterinary school at Lyons; he has recorded the cases that fell under his notice, with his method of treatment, which was very diversified and multifarious; but he concludes with observing, "notwithstanding my failures, I think that a remedy may be found for the glanders." Many circumstances convinced M. St. Bel, that the virus of the glanders has greater activity in Southern than in Northern countries; and that its progress is more rapid in the male and the afes, than in the horse; but that the former are not so subject to receive it by infection or contact as the horse is. The use of verdigris having been recommended by a professor of the veterinary art, Mr. Lawton, surgeon to the Oxfordshire light dragoons, gave this medicine a trial in two cases, those of a horse and mare, beginning with one drachm daily, and gradually increasing it to one ounce. But no beneficial effect was produced. Diffusion of the horse after three months' trial showed no disease in the brain, but it was altogether confined to the fentum of the nose and nostrils.

As the glanders is a disease of such virulence, known to be contagious in a high degree, and hitherto found to be incurable, it is of importance to distinguish it from other diseases to which the horse is subject. A cold, which has been sometimes mistaken for the glanders, may be easily distinguished from them. In cold, there is generally a
GLANDULA, in Anatomy, the name as gland.

The word is a diminutive of the Latin glans, acorn; and is here used on account of some external relation between the glands of the body and the fruit of the oak.

GLANDULA Glandis, among Surgeons, is a tumor resembling a gland; soft, lumpy, movable, with roots, and separate from the adjacent parts.

GLANDUS, as in Anatomy, a name sometimes given to an excrecence near the anus.

GLANDULOSUS, or Glandular, something composed of glands, or that abounds with glands.

The breasts are glandulous bodies. The cortical substance of the brain is commonly reputed to be glandulous; though Ruyfch, from the discoveries made by his admirable injections, holds, that there is no such thing as a gland therein.

The ancients distinguished a particular kind of flesh, which they called carp glanulosus, or glandulatus flesh.

Glandosus Divus, glandulosum corpus, more particularly denotes the profite.

Glandulosus Roots, among Botanists, such tuberous roots as are affiliated together in large numbers by small fibres or threads.

GLANIS, in Ichthyology, a species of Silurus, which fe.

GLANOVENTA, in Ancient Geography, a place of Britain, in the 10th Iter of Antoninus, inpitoted by Horfley to be Lancaster, in the county of Durham.

GLANS, in Natural History, a fruit contained within a smooth but hard bark, including a single seed; its hind-part being covered with a kind of cup, and the forepart bare. See Acorns and Oak.

GLANS Marina, a name given to a genus of shell-fish, more usually called Lutum, and in English the centre shell.

GLANSE, as in Anatomy, a name given by Guigner, and some of the Physicians, to a kind of figured shell, found usually among the trochitide and entrichi, and evidently appearing to have in some manner belonged to them. All the writers, who have these bones examined, are the names of glanses trochiliformes, others under less determine etes. Agricola.
calls them lapides informes; and Lifter, after him, rude stones, having impressions of the entrench. See farther Philosophical Trans. No. 100.

GLAS Palus, in Anatomy, the rounded extremity of the organ. See Generation, organ of.

GLASHAMMAR, in Geography, a town of Sweden, in the province of Nerica; seven miles N. E. of Oboeo.

GLANVILLE, John, in Biography, was born at PlymOUTH in the year 1636, where he probably received the early parts of his education: but he pursued his mature studies at Exeter college, Oxford. He took his first degree in the year 1655, and removing to Lincoln college, he graduated master of arts in 1658, and was, about the same time, appointed chaplain to Francis Rous, eqq. provost of Eton college. The death of his patron induced him, after a very short time, to return to Lincoln college, where he spent his time in literary and philosophical studies, till the restoration of king Charles II. He became acquainted with the writings of Richard Baxter, and was an ardent admirer of his teaching and religious principles. He is said to have been an eager reformer in politics, but, whether this be the real fact, has been much doubted. Upon the re-establishment of monarchy and episcopacy, he conformed to the national church, a circumstance which did not in the least abate the esteem which Baxter had before manifested for him. He became a zealous convert to the principles of the new philosophy, in opposition to the system of Aristotle, and published a work in their justification, entitled "The Vanity of Dogmatizing or Confidence in Opinions," &c. This piece introduced him to the acquaintance of many of the persons who afterwards formed the Royal Society. About this time Mr. Glanvil entered into orders, and was presented to the rectory of Wimbish, in the county of Essex, and in 1662 he was inducted into the vicarage of Frome-Selwood, in Somersetshire. He published in the same year, but anonymously, a discourse on the fundamental doctrine of the ancient eastern philosophers, which he endeavoured to prove was not incompatible with revealed religion. It was entitled "Lex Orientalis; or an Enquiry into the opinion of the Eastern Sages concerning the Pre-existence of Souls; Being a Key to unlock the grand Mysteries of Providence in relation to Men's Sin and Misery." Upon the establishment of the Royal Society, he published his former treatise, corrected and enlarged, under the title of "Seepis Scientifica; or confessed Ignorance in the way of Science, in an Essay on the Vanity of Dogmatizing and confident Opinion." This work was dedicated to the Royal Society, and the author was almost immediately admitted one of its members. In 1666 he published his work, entitled "Some Philosophical Considerations touching the Being of Witches and Witchcraft." This performance, which is still regarded as a curiosity, though very little creditable to the judgment of the author, engaged Glanvil in a controversy which lasted as long as his life. He was now presented to the rectory of Bath, in which city he fixed his residence. Here he met with many opponents, who were apt to treat him but roughly, on account of his adherence to the new philosophy, which led him to draw up a small but elegant treatise, entitled "Iis Ultra; or the Progress and Advancement of Knowledge since the Days of Aristotle." In an account of some of the most remarkable late improvements of practical useful learning, to encourage philosophical endeavours, &c. The author was violently attacked on this occasion, but he defended himself with spirit and success. His reputation was now firmly fixed, and he was frequently called upon to preach on public occasions. At a visitation of the diocese, he delivered a discourse which met with general approbation, and which was frequently re-printed: it was a defence of reason in the affairs of religion, against infidelity, scepticism, and fanaticism of all sorts. He next attempted to shew the corroboration between religion and the new philosophy, in a discourse concerning the religious temper and tendency of the experimental philosophy which is professed by the Royal Society. "While," says one of his biographers, "he was enlisting himself to the particular acknowledgments of the members of that body, by defending the reformation and useful tendency of their pursuits, he also contributed to their collection of instructive and entertaining papers, some observations on the mines in the Mendip hills, and on the natural history and springs of Bath, which were well received, and inserted in the Philosophical Transactions." In the year 1672, Mr. Glanvil exchanged his rectory of Frome for that of Streteh, in the same county, with the chapel of Walton annexed; and about the same time was made one of the king's chaplains. In 1675, he published his "Essays on several important Subjects in Philosophy and Religion," containing the principal of his former pieces, revised and improved, with a treatise, entitled "Antifanatic Theology, or the Free Philosophy." Two years after this, his "Essay concerning Preaching" came out; it was written for the purpose of dissuading the younger clergy from that affectation of wit and fine speaking, which began to be fashionable in those times, and to recommend and enforce a plain and practical method of enforcing the moral duties of the gospel, as the true eloquence of the pulpit. The last work of this worthy divine, was entitled "The zealous and impartial Protestant, shewing some great but lost heeded Dangers of Popery." Mr. Glanvil died of a fever at the early age of forty-four, and Dr. Hornecke published a quarto volume of Discourses, &c. after his death, to which is prefixed an account of the author. As a preacher, Mr. Glanvil was eloquent and pathetic; in private life he was truly amiable and praiseworthy. He was author of various other tracts besides those already noticed, the titles of which are given in the Biographia Britannica. To this work the reader is referred for further particulars.

GLAZEANA, in Ornithology, the name of a bird described by Gmelin from the figure, and suspected to be no way different from the pipiota, a kind of buck, the Alauda campbelli; which see.

GLAREOLA, a species of Tringa; which see.

GLAREOLA, in Ornithology, a genus of the Grallinæ order, founded on the natural family called by Dr. Linnaeus "Perdix de Mer," and also Glareola. The name character of this genus consists in the bill being strong, short, straight, and turned down or hooked at the tip; nodifer linear, and placed in an oblique position at the base of the bill; gape of the mouth large; feet four-toed, the toes long, slender, and connected at the base by a membrane; tail fuscated, and containing two feathers. The number of species, according to Gmelin, are three, namely, Glareolæ, Seneagalensis, and Nebra, the first of which, however, comprises several remote varieties. Linnaeus described this as a species of hirundo, the second kind is a tringa of the same author, and the third, gallinula of Ray.

Species.

The length of this bird is nine inches; the bill black, with the base red; upper wing-coverts white, quill and tail-
tail-feathers dusky, the outer side of the first tail-feathers white; and the legs and naked part of the thighs in general red. The species inhabits chiefly the south of Europe, and the milder parts of Asia; towards the north it becomes more sparingly diffused, and is very rarely seen to remote from the southward as Britain. It shuns most in the plains of the defects towards the Caspian sea, in the neighborhood of the rivers, its food consisting of aquatic insects and worms.

One of the varieties of this species is called by Brehm Glareola toxopta, and by Buffon, "Perdix de mer a collier." The plumage beneath is white; the front black, with a white spot on each side, and the collar brown. Its face is rather inferior to the former, and the legs blackish instead of red. This, like the other, is a noisy restless bird, and frequents the banks of the rivers, aquatic insects constituting its principal food. The eggs are oblong, and usually about seven in number in each nest.

The bird called "Perdix de mer" by Sonnert is another variety of this species; the lower part of the plumage, and also the rump, are white; and the chin streaked with black, and surrounded by a black curved line. This was caught in the open sea, in the latitude of the Maldives islands, and lived a month on fish, and bread soaked in water.

Two other varieties occur in the East Indies, on the coast of Coromandel, and are likewise described by Sonnert; the feet of this is brown, the under parts, with the rump and base of the tail white; in the second, the tail-feathers are brown, having the outer ones marked with a white band.

**Gmelin.** Entirelyfuscous. Gmel. Glareola Senga-

**Tringa rufa, Br.** "Perdix de mer brune, Buff. Senga-

**ponticula."** Scearsely exceeds the former in size, being nine inches and a half in length, and inhabits Sengal. The same variety is found also in Siberia.

**N. varius.** Brown, spotted with white; lower part of the belly and vent reddish-white, with black spots; bill and legs black. Gmel. "La perdix de mer tarda," Bril. "Gal-

**limba melanopsis, Rothm. Ray. Gmelins, Buff. Spotted prati-

tch." Size of Glareola audiaca. This variety is met with in Germany.

**GLARINUS, HENRICUS, LoIRITUS, in Geography,** famined Glarianus, from the town of Glar, in Switzerland, where he was born, in 1458. He rendered himself famous by his knowledge of music, and belles lettres; but he may more properly be ranked among dilettanti theorists in music, than a musician by profession; and his abilities, as a scholar and critic, have been much less diffused by the learned, than his knowledge of music, by musicians.

He studied at Colom, Bafl, and Paris; his preceptor in music was John Coelhus; and in literature, Erasimus, with whom he lived in strict friendship, and by whom he was warmly recommended, in a letter till extant, to the archbishop of Paris. He is called by Walther a philosopher, mathematician, historian, geographer, theologian, and poet; indeed, he distinguished himself in most of these characters. Gerard Vossius calls him a man of great and universal learning; and for his poetry, the emperor Maximilian I. honoured him with the laurel crown.

His famous treatise on music, entitled **APOLLOPONOS**; which includes twelve modes; to which number he wished to augment the ecclesiastical tunes, which had never before exceeded eight, from the time of St. Gregory. Zarlini, and a few more, adopted the opinion of Glarianus, but soon reestablished it, on finding that they had made no converts. Indeed, the whole twelve modes of Glarianus contain no other intervals than those to be found in the key of C and A natural, or in the different species of octaves, in these two keys; and though his augmentation extends the currents of sounds used in the modes, it offers no new arrangement of intervals, as may be seen by his third stage, when it tells us that the authentic modes are D, E, F, G, A, C, and the plagal, B, C, D, E, G; where we perceive that A, C, E, G, are repeated, by being made both authentic and plagal.

If, instead of twelve modes, Glarianus had augmented the eight to twenty-four, by assigning two to each fractio of the octave, he would have done real service to the music of his times; but his contemporaries were not yet ready for such an innovation. Being told he had fallen in the trapnels of the church, to dare to any other fancies than those that time had consecrated, and authority admitted within its pale.

His book, however, contains many curious anecdotes and compositions of the greatest munificence of his time, which were excellent studies for his contemporaries and posterity, and, if feared, would be still very instructive and useful to young contrapuntists. Glarianus died 1563, aged 75.

**GLARIS, or GLARUS, in Geography, a canton in Switzerland, formerly subject to the abbots of the convent of Leckbingen, in Swabia, but possessing a democratical form of government, under a mayor, appointed by the abbots, but chosen by the inhabitants; till towards the latter end of the thirteenth century, the emperor Rudolph I. obtained the exclusive administration of justice; and from afterwards his son Albert purchased the majority, which had become royal, and reunited in his own person the whole civil and judicial authority. The government of Albert, and of his descendants, the dukes of Austria, was arbitrary and oppressive; and therefore, in 1525, Switzerland, reunited by Zlere, Lucerne, Uri, and Unterwalden, expelled the Austrians from the canton of Glarus, and re-established the democracy. Glarus then entered into a perpetual alliance with its deliverers, and was received into the Helvetian confederacy, with some restrictions, which were not abolished till 1837.

It was then the 6th canton, but afterwards became lost in rank of the eight ancient cantons, as they were called. The people of Glarus enjoyed their liberties unimpaired till 1538, when the Austrians made an inroad into the canton, and pillaged the country and massacred the inhabitants. At this time 350 troops of Glarus, aided by 500 Bernese, repulsed the whole army of the Austrian prince, and compelled them to retire. In the 16th century the reformation was introduced into this canton; but the Protant and Catholic had been accustomed to live together on terms of mutual toleration. The government of this canton, similar to that of the French revolution, was entirely democratical; every person at the age of 16 had a vote in the "Landsgemeinde," or general assembly, which was annually held in an open plain. This assembly ratified new laws, laid contributions, entered into alliances, declared war, and made peace. The "Landhausman" was the chief of the republic, and was elected alternately from the two seats, with the president, that the Protestant remained three years in office and the Catholic two. The other great officers of state, and the bailiffs, were taken also by lot from a certain number of candidates proposed by the people. The executive powers were vested in the council of regency, composed of 48 Protestants and 15 Catholics; and each had its particular court of justice. The canton comprehends 350 square miles; and its population is estimated
the handsome only this and subject it inferiour its 26'.

Lat. from Glaris, According mere the was great mountains, place tb? 11

Glarus, Wallenstadt, the Glar. bedroom, Uznac, and Rappenfchweil, forms the eighth canton, and

deputes five representatives to the diet.

This canton is entirely enclosed by the Alps, except towards the north; and there is no entrance but through this opening, which lies between the lake of Wallenstadt and the mountains separating this canton from that of Schwettz. At this entrance, the canton reaches from the banks of the Linth to the farthest extremity of its Alps, about 30 miles; forming a valley, which becomes narrower as you advance, and is feared more than a humidfil foot in breadth at the burch of Glarus. It afterwards opens by degrees, and, about a league from this burch, is divided by the Freiburg mountains; at the point of this division, the two rivers, Linth and Sernfta unit. The hillock of the Peak in Derbyshire, says Mr. Coke, are mere mole-hills to the Alps of Glarus. These tremendous chains of rocks are absolutely perpendicular, approach one another so near, and are so high, that the sun may be laid to rest, even in summer, at four in the afternoon. On each side are a number of waterfalls, which excite attention. The valley terminates in an amphitheatre of mountains, and the glaciers of the canton close the view. (See Linth.) All the houses in this canton, like those of Appenzel, are built of wood, large, solid and compact, with great pent-house roofs, that hang very low, and extend beyond the area of the foundation. The police in this democratical state is well regulated; nor does liberty often degenerate into licentiousness. Cattle, cheese, and butter constitute the principal commerce of the canton. The cattle are fed in summer upon the Alps; it is computed that 10,000 head of large cattle, and 4000 sheep, are fattened during that season upon the mountains belonging to the canton. The inhabitants also manufacture linen and muffins. Among the exports, a considerable article is flax, with which the canton abounds; the principal quarry being in the region of Sernfta, where large plates are dug up that serve for tables. These quarries once furnished Great Britain with plates for writing; but this branch of trade has been superceded by the great slate quarries in Caernarvonshire. A great part of this canton consists of mountains, rocks, inaccessible forebats, and barren heaths, covered with snow; and it is subject to frequent inundations, and to the devastations occassioned by tempets and falling rocks.

GLARNISH, a mountain of Switzerland; 7 miles W.S.W. of Glarus.

GLARUS, or GLARS, the capital of the above-described canton, situated upon the Linth. The town is large and populous; and the town-house is a hardstone structure; 32 miles E. of Luzerne. N. lat. 26° 50'. E. long. 9° 3'.

GLASENDORF, a town of Bohemia, in the circle of Konigigratz; 6 miles N.W. of Trautenau.—Alice, a town of Silefia, in the province of Neisse; 11 miles S.W. of Pafchekan.

GLASGOW, a very populous, handsome, and regularly built city, in the county of Lanark, in Scotland; situated on the north bank of the river Clyde, which is navigable for vessels of 100 tons and upwards. In ancient times, and during the prevalence of the Roman Catholic religion, Glasgow was chiefly distinguished as an archiepiscopal see, and was of course principally under the influence of the archbishop and his inferior clergy. Their power seems in those days to have been civil as well as ecclesiastical, for the charters of the most ancient corporate bodies are held by this tenure, the civil magistrates being only noticed as of subordinate rank and authority, and the freedom lines, and other emoluments are expressly appropriated to ecclesiastical purposes. The revenue of the diocese of Glasgow, if it may be estimated by the extent of lands subject to the payment of tythes, or (as they are called in Scotland) teneus, must have been very great; for these barthens extended over almost the whole of the counties of Lanark, Renfrew, Dumfartone, Ayr, Dumfries, and Galloway, comprizing the whole south-west district of Scotland, and perhaps a moiety of the most fertile land in the whole kingdom. This enormous revenue, since the reformation a small part, but now of great value, has been appropriated for the support of the university of Glasgow, some part for the payment of the parochial stipends, and a great part has reverted to the freeholders or their dependants, and these are constantly fluctuating as in other parts of the kingdom. The interferences and civil wars, which devasted Scotland subseqently to the reformation, and previous to the revolution, having divested Glasgow of all that attraction which it had acquired as the archiepiscopal and occasionally as the royal residence, it appears to have been only remarkable as the occasional scene of those fantastic and furious contentions for which the age was conspicuous. It fell into the hands of the regent upon the defeat and flight of the unfortunate Mary Stewart at the battle of Langside, two miles south of the city. It was long afterwards battered and taken by Cromwell's army, and it was the refuge of the defeated party, after the battle of Bothwel bridge, fought between the regent (afterwards James II.) and the Covenanters. After the revolution it seems for many years to have been a place of little importance, poifessing neither a sufficient degree of wealth or refinement to render it conspicuous for elegance or luxury, nor such security or strength as to make it defirable or important as a military poit. At the time of the Union with England, its whole population was estimated at only 14,000, a fact ratified in the house of commons by Mr. Secretary Dundas, (now lord Melville,) in one of the debates when the Irish Union was in contemplation. Subsequently to the Union, the rise of Glasgow in commercial importance, even under the successive checks of the two civil wars in 1715 and 1745, of the valley of greater commercial embarrassments and the consequent fall of the manufactories of Glasgow, and of its colonial trade during the American contilels, and all the subacient hostilities produced by the French revolution, has been perhaps unequalled by any other place in the empire, or perhaps in the world. Its population, under the act of 1754, including its numerous suburbs, was returned at 94,000, and from the concealment which was practised from the idle fears of ignorant people, many of whom foolishly imagined that caius to be the precursor of a military confection, that number is supposed to be at least 30,000 short of the actual amount.

Different histories of Glasgow have been published. Of these, one published many years ago by Mr. M'Ure, one of the city clerks, was much esteemed, but is now considered as obsolete. Others have subsequently been written by Mr. Gibbon about 1774, and recently by Mr. Denholm, about 1796.

The limits of this article necessarily preclude the possibility of entering much into detail, nor would it be either amusing or instructive to the general reader. We shall therefore infer what remains concerning the present state of this
this great commercial and manufacturing city under the following general heads.

1. Situation and general state of the adjacent country.—

Glasgow is situated on the north bank of the river Clyde, in N. lat. 55° 52′, and W. long. from the meridian of Greenwich, 4° 30′. The extreme length from E. to W., including two suburbs, is nearly two miles, and its breadth from the cathedral or high church to the river about one mile. The lower part of the city is nearly level, and the rest is upon the southern declivity of a hill. Perhaps no city or town in Europe is, upon the whole, more regularly planned, for all the principal streets are either parallel or at right angles to each other. The chief streets are better paved than those of London, and generally wider; all the front buildings are of fine free-stone, which is found in great abundance in the immediate neighbourhood. The granite, or cobia stone, for paving the carriage ways, is also very plentiful close by the town. The houses are very large and lofty, being more generally upon the French plan, where every floor forms a separate lodging, accessible by a common staircase, than upon the English, where one person occupies the whole premises. The more wealthy inhabitants, however, have almost universally adopted the English style in building.

In the old part of the town it is indeed much to be regretted that there are too few public streets, so that an immense number of buildings are crowded together, many of which are accessible only by narrow passages, which are very ill calculated either for free circulation of air, admission of light, or domestic cleanliness. In the modern buildings these inconveniences are avoided, and whatever inconvenience may remain, must rather be attributed to the habits or negligence of the occupant, than to want of facilities on the part of the architects.

There are many very fine public buildings in Glasgow, the most prominent of which we shall very briefly enumerate.

Churches.—The cathedral or high church is perhaps the finest specimen in Scotland of that species of architecture, generally denominated Gothic. It was founded in the year 1123, and consecrated in the presence of king David I. in 1136. This building is more similar to that of Litchfield, than to any other of the English cathedrals, but it does not appear to have ever been completely finished, and certainly until lately little care has been used for its preservation.

After the reformation it is said to have narrowly escaped demolition from the misguided zeal of the people, who confounded the building itself with the religious or superstitious ceremonies which they had exploded. It now contains two churches adapted to the Presbyterian form of worship, and the choir is used as a place of interment. The burying vaults, or cemetery, were formerly occupied as another place of worship for the harony or country parish of Glasgow; but lately a new church has been erected for this purpose at the opposite extremity of the church-yard. The great spire is very lofty, and in some degree resembles that of Salisbury. The church was dedicated to St. Mungo, or Kentigern, whose burying-place in one of the vaults is still shown.

The remaining churches profess in general little claim to architectural embellishment or description. They are fix in number, viz., the college, St. Andrew's, North Well, Iron, St. Enoch's, and St. George's.

St. Andrew's church is a handsome modern building, of Corinthian architecture, and is very similar in appearance to the church of St. Martin in the Fields, Westminster.

St. Enoch's and St. George's are also handsome modern buildings. Besides the established or parochial churches, there are many dissenting chapels and meeting houses, some of which are very handsome and commodious.

Priests.—This is a large and very strong building, situated in the centre of the city, adjoining to the Exchange. The lower part is occupied by the council-chambers, and rooms for the magistrates and the city clerks; the middle portion of the building contains the close or lock-up rooms for those imprisoned upon criminal charges; and the two upper floors are allotted for the reception of civil debtors. The roofs are lofty, the apartments airy, and the building, upon the whole, commodious; but it is in contemplation to erect a new prison, with an enclosed space round it, where the prisoners may have the benefit of fresh air and exercise, from which they are at present precluded.

Bridewell.—This is a large building which serves as a house of correction, or penitentiary house, for persons of depraved habits convicted of petty offences. It is very well regulated, and every means of encouragement afforded for reclaiming the prisoners from their vices, and promoting habits of industry. Many, at the period of their confinement, have thus acquired and received considerable sums, besides the expense of their subsistence, which is deducted from their earnings.

Town Hospital.—for the reception of poor persons unable to maintain themselves. The expense of this establishment is defrayed by a tax or assessment on the inhabitants, and by the proceeds of the labour of those admitted, who are supplied with work suited to their respective abilities. The inmates are aged and infirm persons and destitute children; the latter are well educated, and when arrived at a proper age, the boys are apprenticed to trades and the girls sent to service. The economy of the house is superintended weekly by gentlemen who act in rotation. The whole is very well managed.

Royal Infirmary—a very fine modern building, from a plan of Mrs. Adams. From 90 to 120 patients are generally under cure, but the house contains accommodation for a much larger number when required. It is supported by donations, legacies, and annual subscriptions; the funds at present amount to 10,000l. or 12,000l., besides what has been annually expended; the annual disbursement is about 180l. or 200l.; the direction is vested in the lord provost, the dean of guild, convener of the trades, professors of medicine and anatomy, president of the faculty of physicians, member for the city, and eighteen directors, ten of whom are elected by the contributors, and the others by various public bodies. The directors elected by public bodies are, one by the council, one by the merchants, one by the trades, one by the university, one by the ministers of Glasgow, and three by the faculty of physicians and surgeons. The medical assistance is afforded gratuitously.

Theatre Royal.—This splendid house was erected a few years ago by voluntary subscriptions, upon transferable shares of 25l. each. The total cost was upwards of 15,000l., part of which still remains as a debt upon the property, the whole annual rent being appropriated for its gradual liquidation. The direction of the property is in sixteen directors, four of whom go out annually, in rotation, but may be re-elected. It is unquestionably the largest and most magnificent provincial theatre in Britain. The managers are merely lessees, and the lease is always given for a short period, seldom exceeding two or three years.

Concert and Assembly Rooms.—These rooms are also very splendid, and, like the theatre, were erected by voluntary subscription, upon transferable shares.

University.—The buildings of the university have been erected at various times, and in very different styles, cannot
be appreciated by any specific scale of architectural taste; but the whole has certainly an air of imposing grandeur, and is very well adapted in every respect to the purposes for which it is designed. It consists of four distinct courts, which communicate with each other, and is accessible from the high street by three gateways. Behind is a very large garden laid out in grass and shrubbery, with very fine walks; it is divided into three parts, of which one is appropriated as a botanical garden, another is open as a place of exercise and recreation for the students, and the third, in which the astronomical observatory is situated, is generally referred as a place of retirement for the professors, or of amusement for their families and friends.

The university of Glasgow was founded in the year 1451, by William Turnbull, bishop of the diocese, and now consisted of a chancellor, a dean of faculty, a principal, who was also professor of theology, and three professors of philosophy.

The professorships and lectures are now as follow:

A lord chancellor: an office now honorary, and held for life.

Lord rector: also honorary—electively annually.

Dean of faculties: chosen by the professors or regents.

Principal: by the crown—present incumbent, Rev. Dr. Taylor.

Fou. Senor.

Divinity, — appointed by the university.

Church history, — crowned.

Oriental languages, — university.

Natural philosophy, or physics, — do.

Mathematics, — do.

Moral philosophy, or ethics, — do.

Logic, — do.

Greek, — do.

Humanity, or Latin, — do.

Civil law, — crowned.

Medicine, — do.

Anatomy and botany, — do.

Practical astronomy, — do.

Lectures.

Materia medica, — university.

Chemistry, — do.

Midwifery, — do.

Natural history, — do.

Elocution, — do.

Painting and drawing, — do.

The funds for the support of the university are in a very flourishing and prosperous state. Independently of the emoluments derived from the students, salaries and commodious houses are allotted to every professor, and these expenses are defrayed from the funds at various times granted to the university; of these, the funds or tythes of the parish of Govan, form a very prominent part. The students of the five junior classes, viz. natural philosophy, moral philosophy, logic, Greek and Latin, are distinguished by wearing gowns of scarlet fringe; the students of the senior classes have no particular distinction of dress. The resident members of the university claim an exemption from all civil burthens and services, and generally from the jurisdiction of the city magistracy, but acknowledge that of the sheriff of the county, and of the supreme courts of Scotland.

The internal government of the university is vested in the principal and professors, who, in their judicial capacity, assume the title of regents. Their supreme court is a general assembly of the whole faculty, who, at a remote period, afforded the power even of capital punishment. The most severe sentence, however, which has been passed for many years, is that of expulsion, and even this has been very rarely exercised. An inferior court is the "Jurisdiction ordinaria," consisting of at least three regents, who determine offenses against the general order and peace of the university, and punish by a pecuniary fine. Each professor also possesses the power of levying small fines in his own class for negligence, contumacy, or irregularity.

The number of students in the university was estimated at 500 thirty years ago, and this number is now greatly increased. The professors and students, when assembled for the election of a rector or any other general purpose, are divided into four nations, according to the places of their respective births, viz.

Glesga—comprehending the natives of Clyde-side, and the adjacent districts of Scotland south of the Forth.

Transportani—the natives of Scotland, on the north of the Forth.

Rothfiani—the natives of the west highlands of Scotland and of Ireland.

Lochdoniani—those of the eastern districts of Scotland, of England, America, and the colonies. The votes of these nations are decided by a majority, and the majority of nations decides the question. In cases of parity the decision is in the regents.

The university of Glasgow has recently received a most valuable acquisition, by the bequest of the museum of the late Dr. William Hunter, of London. For the reception of this valuable legacy, a very handsome building has been erected, where it is now arranged. The museum consists of a valuable collection of paintings, chiefly original; a very fine collection of anatomical preparations; a cabinet of medals, and a fine library. The medals are accounted of such value, that the trustees of the British museum are paid to have offered 25,000£ for them, besides furnishing such duplicates as they possessed, and defraying the expense of an application to parliament for an act, to far to dissolve the tellator's will. This liberal offer, however, was declined.

The public library of the university is also a collection of uncommon value. It consists of upwards of 6000 volumes, and many very rare and valuable manuscripts. In the faculty hall are some valuable paintings, particularly one of the "Martyrology of St. Catherina."

Among the celebrated literary characters, which have belonged to this seminary, the names of Dr. Cullen, Dr. Adam Smith, and the late professor Miller, are most recently conspicuous.

There are many other public buildings in Glasgow, of which it will be necessary to confine ourselves to very brief notices.

The Trades-hall is a fine modern building from a plan of Messrs. Adams'. It is used for the general meetings of the fourteen incorporated trades, and is also occasionally occupied for concerts, balls, and other public amusements.

Merchants' Hall—an old building, remarkable for nothing but the spire, which is a very fine one. It is used by the body to which it belongs, in the same manner as the Trades-hall.

Public Markets—These are very commodious, and consist of square-paved courts, surrounded by the walls where the meat is exposed to sale. No cattle are slaughtered here, and they are kept very clean and regularly inspected.

Barracks—These are situated in a large area walled round, and consist of three very large buildings, one of which is appropriated for officers, and two for non-commissoned officers and privates. Their complement is 1072 men, but they will lodge, on emergency, 4 or 500 more.
GLASGOW.

Town-House—A fine old building adjoining to the prison. Only one hall is retained by the body corporate. The remainder contains the Tontine Hotel, which was enlarged by subscription upon lives. The coffee-room, in particular, the largest and finest in Europe. It is supported by annual subscription, the subscribers amounting to upwards of 2000, who pay one pound per share each.

Brigade—Three of these are at home, and a fourth was actually built in the year 1795, when the river rising rapidly, in consequence of excessive rains, it was swept away in one night when nearly finished. The arches being very thin, and the extremities not sufficiently secured, the accident was attributed, by professional persons, to the lateral pressure. Its place has since been supplied by a very handsome wooden bridge for foot passengers. The two bridges higher up on the river are plain, but very well built and paved. The lowest, or new bridge, is very finely executed, and is deemed one of the most complete specimens of this species of architecture in Britain.

Waters-works.—The city of Glasgow, until lately, was supplied with water by pit-wells, and the water, though abundant in quantity, was of inferior quality both for washing and culinary purposes, as beside other impurities, it holds in solution a considerable portion of marine acid, by which it is rendered hard and brackish. To remedy this inconvenience a public company was formed, who, at the expense of upwards of £50,000, brought water filtered from the river into every part of the city and suburbs by cast iron pipes, and from these pipes into every house, upon receiving a moderate annual payment from the proprietor or lessee. The capital necessary was raised by transferable shares of 5s. each. The rapidity with which these shares were bought induced others to form a separate establishment, and to raise water also from the river for the supply of the city. The first water driven from the Clyde by two large steam engines, into a reservoir about two miles to the outfall of the town. From this reservoir it is filtered into another, and thence conveyed by the pipes to a third, immediately contiguous to the town. The whole lower part may be supplied from this without further forcing, but to supply the higher parts, a portion is again forced by another smaller engine to a cistern on a higher elevation, which commands every part above the former level.

The eastern water-work company draw their supply from the river, to cisterns situated on an eminence about one mile west of the town, where it is filtered, and conveyed by pipes, without requiring to be forced a second time. The inhabitants are left to their own free choice from which company to take their supply.

River Clyde.—The Clyde takes its rise about 45 miles to the southeast of Glasgow, in the same mountain which forms the sources of the Tweed and the Ayr. Near the county town of Lanark, about 24 miles above Glasgow, it has three remarkable falls or cataracts, much visited by strangers. From Lanark to Glasgow it passes through a fine valley, richly wooded in many places, fertile and highly cultivated. From the new bridge or Glasgow, where it becomes navigable, until it terminates in St. George’s, or the Irish channel, about 80 miles distant. About thirty years ago, Mr. Goldburn, an eminent engineer, was employed by the city of Glasgow to deepen the river, from the Broomhall or harbour, to the sea-port towns of Port Glasgow and Greenock, the former fretted 21, and the latter 24 miles below the city. This he effected in a very judicious, although gradual and economical manner. The beneficial effects of his plan became soon apparent, have been, every successive year, improving, and must continue so for many years to come. He began by constructing, on either bank, projecting dykes, or jetties, into the river, at right angles to the banks on either side, and placed at small distances from each other along the whole course of the navigation. These jetties intercept much of the earth and gravel washed down by successive floods, and thus supply the materials for ultimate contraction, without the expense of carriage. Besides this, a number of labourers are employed every summer to throw the bottom between the projecting jetties. By the constant repetition of this plan, a great part of the river is now contracted to less than one-half of its original breadth, and has gained above four feet of additional depth. As the townage dues, the greater part of which is paid for this purpose, now exceed the 10,000 per annum, there is every reason to hope that this will probably be continued on a more extended scale than ever, and it is probable that in a few years vessels of large burden may be brought up to the city. The largest bitts which brought are about 150 tons, the depth of the channel being about nine feet at high water. The gentleman who now directs these improvements thinks, that in a few years the depth may be increased to 14 feet by the present plan.

It was lately proposed to improve the harbour by the construction of wet docks; but a difference of opinion having arisen respecting the measures under which these improvements were to be placed, the scheme has been suspended, but it is hoped not finally relinquished. The townage dues are one shilling per ton on merchandise, eightpence on foreign produce, and fourpence on coal, brick, and other building materials. Muir, carried upon the river for the improvement of the adjacent country, is exempted from any tax.

The country stretching along the banks of the Clyde, for a number of miles, both above and below the city, is generally fertile, and, in most places, highly cultivated, and well enclosed. The parish of Govan, situated on the south bank of the river, is, perhaps, as highly improved as any district in Britain. Besides the natural fertility of the soil, this may be accounted for by the plentiful supply of coal, lime, and sand is often brought at a very cheap rate by water-carriage. It must also be greatly promoted by the circumstance of there being many landed proprietors, whose estates, although abundantly sufficient to maintain themselves and families in comfort and affluence under their personal superintendence, are not so large as to induce them to relinquish the profits and emoluments of cultivating their own property, which, of course, derives the united benefit of their personal skill, industry, and capital, besides that emulation which a laudable spirit of rivalry excites among them to surpass each other. The higher lands, both to the north and south, are considerably inferior, both in soil and cultivation, to those in the valley. In every direction round Glasgow, coal, lime, and iron-stone are found in great plenty, and give great advantages to the agricultural and manufacturing classes of the community.

The suburbs of Glasgow, which form the chief refuges of the operative tradesmen, are the following:

CAIRN—a very populous village, immediately adjoining to the city on the north-east, and bordering on the Green of Glasgow. This village contains upwards of 20,000 inhabitants, with many manufactories, dairies, &c. The green serves both for pasturage and for the purposes of walking and bleaching. There are a considerable walking-place, and fine walks for the recreation of the inhabitants. The dues of walking and pasturage form part of the city revenue. The green contains upwards of 100 acres of ground.

Bridgegate—
Glasgow.—Another suburb adjoining to the former, and similar in every respect.

Gorbals.—A village on the opposite bank of the Clyde, governed by a chief magistrate, appointed by the council of Glasgow, and two resident bailies.

Anderton, Broomiel, Finnieston, and Partick.—These four villages lie to the north of Glasgow, on the north bank of the Clyde; they are also residences for operative tradesmen, and contain several extensive manufactories, viz. three large cotton mills, an extensive putting-field, and porter brewery, at Anderson; a large and flourishing glass-work at Finnieston, and the very large flour-mills belonging to the incorporation of bakers at Glasgow, at Partick, where are also the remains of an ancient castle, formerly belonging to the archbishop.

Municipal Government of Glasgow.

This, as formerly remarked, in ancient times, was almost exclusively vested in the archbishop and chapter. Since the reformation, it underwent various changes during the successive alterations of government in Scotland at large. The last arrangement made by royal and parliamentary authority, was early in the 18th century, under William and Mary. It has since been modified by the authority of the Scottish convention of royal burgesses, who exercise this power without dispute. As at present constituted, the government of the city is vested in the lord provost, three merchants, and two trades bailies, the dean of guild, or president of the merchants, the convenor, or president of the trades, the city treasurer, and master of the public works, twelve counsellors from the merchants, and eleven from the incorporated traders, in all 33 counsellors. To this body the regulation of all the public business belongs; the lord provost being president, with the casting or deciding vote in cases of parity. The courts of justice within the city are the following:

1. The circuit court of judicature, for the cognizance of criminal actions, which is held twice a year at Glasgow, for the counties of Lanark, Renfrew, and Dumfriesshire, generally before two of the lords commissioners, although any one of their number is competent. This court also decides appeals in civil causes from any of the inferior courts within the district.

2. The magistrates or town court. This court is held under the authority of the magistrates, assisted by the town clerks as legal advisers. The jurisdiction of this court extends to any amount subject to an appeal to the court of seisin.

3. The confidence court, for the decision of petty causes under twenty shillings, where the formality of an oath is dispensed with, or any written pleading.

4. The sitting magistrate also decides daily trifling claims under five shillings. The magistrates also exercise a criminal jurisdiction in petty crimes, and punish by imprisonment, pillory, and sometimes public whipping and banishment from the city.

5. The sheriff court, for the under-ward of Lanarkshire, is also held at Glasgow, before the sheriff subtitute. His jurisdiction is equal to that of the magistrates, not only within the city, but the district. The decisions of this court are subject by appeal to the sheriff depute and to the court of seisin.

6. The justice of peace court also decides civil causes to a limited amount, and regulates disputes between masters and servants. The appeal from this court is to the quarter sessions, and from the quarter sessions to the court of seisin.

7. The small debt court is held by two or more justices, for the decision of causes under 10s. No professional lawyer is heard here, and the pleadings are verbal. They review their own decisions upon appeal, provided the sum demanded be lodged with the clerk of court.

8. The commissary court is the remnant of the bishop's court. It decides for sums under 3l. 6s. 8d., and also in cases of detention. Its jurisdiction extends over all the ancient bishopric.

Police Establishment.—This establishment was constituted a few years ago under the authority of a special act of parliament. The commissioners named in the act are, the lord provost and bailies, and twenty-four commissioners elected by twenty-four wards, into which number the city is divided. The qualification of a commissioner is, the occupation of a dwelling house valued at 5l. or upwards of yearly rent; and of a voter, that of any house at 10l. or upwards. The business of this establishment is the lighting, cleaning, and guarding of the streets, and suppression of quarrels, riots, and other breaches of the public peace. For this purpose a master, or intendant of police officers, and watchmen are employed. A magistrate sits every morning at the police office to decide upon those who have been apprehended during the night. Where the charge is serious, he generally remits the cognizance of it to the town court, and punishes petty delinquencies by a small fine. The expense is defrayed by a tax on the valued rents of shops, warehouses, and dwelling houses, by fines levied in the course of the year by the sale of manure, from cleaning the streets, &c. The maximum of the tax is from 6d. to 1s. 5d. per pound of valued rent, but much less has been generally found sufficient. This institution has been always hitherto conducted with the most vigilant attention to economy, and is very popular even among those of the citizens, who formerly opposed its original adoption.

Commerce and Manufactures.—The commercial importance of Glasgow only began to rise subeutaneously to the Union, and had attained no very important extent until the colonization of North America opened a wide field for the exportation of British commodities and the importation of American produce in return. Previous to the commencement of the American war in 1775, it had, however, engaged very extensively in the tobacco trade, for it appears that of 90,000 bales. of tobacco imported into Britain in 1772, 49,000 bales. were brought into the Clyde alone, and, in 1775, the importation was 52,143 bales.

The operations of the war necessarily put a stop to this intercourse, to the great loss of the merchants engaged in it; many of whom have never been able to recover their debts. Upon the restoration of peace in 1783, the trade with America revived, and continued again in a flourishing state, until again suspended by the American non-intercourse act. In 1783, the registered vessels of the Clyde, were 386, and their tonnage 22,896, and in 1803, the number cleared outwards and inwards was as follows:

GLASGOW.

From this note some idea may be formed of the extent of the trade; but many of these vessels having probably made several voyages in the course of the year, it is not to be inferred that this number of vessels actually belongs or trades to the Clyde. The articles of exportation are chiefly British manufactured goods, coals, fish, &c. and the imports European, American, and colonial produce.

The city of Glasgow had also a very considerable commercial intercourse with the eastern parts of the island, and with the northern states of Europe, until this was suspended by the events of the war. This intercourse is carried on by means of the Forth and Clyde canal, which interlacks Scotland, and forms a junction between the eastern and western seas, some account of which has already been given under the article Canal.

The manufactures of Glasgow had obtained no very great extent previous to the commencement of the American war, although they had been progressively advancing during the whole course of the eighteenth century. So far back as the reign of Charles II. indeed, some attempts had been made to introduce the manufacture of soap, refining of sugar, and some other branches, all of which proved abortive, and were discontinued. The linen manufacture was the most extensive of the various attempts made, and the most successful during the time that it lasted. It commenced about the year 1725, and continued progressively advancing until it was almost entirely superseded by the cotton towards the close of the century. The cotton manufacture, which is now unquestionably the staple trade of Glasgow, was prosecuted to very small extent until after the year 1784, but when once introduced it advanced with unprecedented rapidity. It is impossible to ascertain with any precision its actual amount either in quantity or value at any given period for want of proper data. A computation in 1791 makes the number of looms employed 15,000, and the persons who earned their subsistence by various parts of the processes of spinning, weaving, bleaching, &c. 135,000. It also estimates the total value of the goods made yearly at 1,000,000l. The grounds of this calculation are not flated, and little reliance can be placed on it, for the value of cotton goods has fluctuated as remarkably as the quantity has extended.

Two manufacturies of earthen ware are carried on in Glasgow, but neither of them extensively. Indeed a much greater quantity of Staffordshire ware is used in the city itself than of the produce of either. Two or three rope works are also carried on, but to no great extent.

The printing of calicoes and other goods is, however, a very extensive branch of the manufacture of Glasgow and its vicinity. The most extensive of these works, are those situated upon the water of Leven, in Dumbartonshire, about 18 miles distant. The extension of the cotton trade has also greatly improved and enlarged the number of dye-works, and the manufactures of chemical preparations for the various processes of bleaching, dyeing, and printing. These works are situated in the vicinity of the city, chiefly on the banks of the river.

Of the chemical works carried on in Glasgow, some are peculiar to it. The manufacture of Cudbear was introduced by Messrs. Mackintosh so long ago as the year 1777. It is prepared from rock-mofs, and above 2000 gallons of human urine are daily consumed in the process. The cudbear gives a dark reddish colour, and is used in the dyeing of leather, woollen fluffs, &c. The processes is kept profoundly secret.

Discharging of the Turkey red dye is also peculiar to Glasgow. This process is particularly described under the article Discharging of Colour.

The manufacture of the oxy-murate of lime, in a dry form, for the purposes of bleaching, &c. is also almost peculiar to Glasgow. Its object is to decrease the expense of bleaching by the substitution of lime for potash. This article is made to great extent by Mr. Tennent the inventor.

Iron liquor, for the use of printers, is made here by various persons, and large alum works are established in the neighbourhood. Manufactures of red and white lead are also carried on.

Miscellaneous Remarks.

It will appear that the city of Glasgow has undergone three remarkable changes. Its first was the refuge of a great archbishop and, consequently it was for many ages entirely under clerical influence and control. Its first eminence as a commercial place arose from its favourable situation for commerce with the American and West Indian colonies, and through this traffic it made rapid advances in commercial importance during the whole course of the eighteenth century. One branch of this traffic being at least for the present far ended, it now depends chiefly on the other, and upon its manufactures for support. From the facilities of acquiring a good education, the inhabitants of Glasgow have generally added a considerable title for literary attainment even to their commercial habits, and this style prevails, perhaps, in a degree superior to any other commercial place in Britain. The system of education is, however, rapidly adapting itself to the modern pursuits of the inhabitants, and more pains are now taken to qualify the rising generation for eminence in the counting-house than the cloister. However desirable a thorough knowledge of the principles of commercial economy, and the details of business may be in a commercial community, it is still to be hoped, that all the benefits arising from intellectual attainment will not be deemed altogether nugatory, and consequently neglected. In every situation of life, they are sources of rational and innocent amusement, and, in the salutary to which commercial enterprise is peculiarly exposed, may often prove of real benefit and utility to the possessor.

The city of Glasgow returns a member to the British parliament, conjointly with the neighbouring burghs of Rutherglen, Renfrew, and Dumbarton.

GLASGOW, Port, situated on the river Clyde, about 22 miles below the city, is a handsome small town, and was projected by the magistrates of Glasgow at the request of the merchants as a harbour for their ships and vessels. It is said that the first plan was to improve the harbour of Dumbarton for this purpose, but Dumbarton being a royal borough, the consent of its magistrates became necessary, and that when made, it was rejected by that body, who preferred the full enjoyment of their chartered privileges to the idea of linking into the more sea-port of Glasgow, however much their wealth, revenue, population, and general prosperity might be benefitted by such an union. If this were the case, it is one among the numberless instances where comfort and prosperity have been sacrificed to a mere empty title. The harbour of port Glasgow is good but shallow. The disadvantage of the bank, noticed in the article Greenock, is also much against it as a haven. At port Glasgow there is a cullion-house, where the general customs of the Clyde are collected. There is here also a fine graving-dock built by the merchants of Glasgow long before that of Greenock was executed, and this circumstance alone brought many ships up to that port which now come no further than Greenock. The situation of port Glasgow is more pleasant than that of Greenock, the country more level, and better adapted for cultivation. In other respects it is certainly
GLASS calculated for the general purposes of maritime traffic than its rival, and therefore there is little probability of its extension. Indeed the shipping belonging to Glasgow is certainly on the decrease, the foreign merchants finding it more for their advantage to freight or charter vessels for any purpose than to build or buy vessels of their own, which both continue to find a considerable portion of their capital, and may from the many calamities and fluctuations to which commerce in this eventful age is exposed, prove rather burdens than advantages, while the mere shipowner, if deprived of a freight or charter-party at one port, may with greater facility seek it at another, than the person with whom freight is only a secondary and inferior consideration.

Port Glasgow is governed by magistrates, appointed by the council of Glasgow, and some resident magistrates. Its exports and imports have been already given and compared with those of Greenock under the article GLASGOW, which indeed furnishes by far the greater part of the freight to and from both ports.

There are no manufactures here of any extent, excepting those which are to be found at almost all sea-port towns, viz. ship building and rope spanning. Both of these are carried on to a very considerable extent. A work was erected four years ago for refining of sugar, and also a small cotton-mill, but neither have ever been prosecuted to any great extent.

A plan has been formed, and its execution is now begun, which in time may produce a great effect, both on this town and Greenock. This plan has for its object the formation of a more direct communication between Glasgow and the west sea, than the present circuitous navigation of the Clyde, by means of a navigable canal to be carried from Glasgow to Ardrossan, near Irvine, which is about thirty miles farther down the river than the present canals. This canal was projected under the sanction and patronage of the present earl of Eglinton, lord Ardrossan of Great Britain, a part of whose estates lie in that neighbourhood. Its objects are two-fold. First, to facilitate the maritime intercourse of Glasgow and Paisley with the New World, by a more direct channel and better harbour. Second, to improve the agricultural and internal state of Renfrewshire, and the northern district of Ayrshire, by affording means for the cheap conveyance of coal, lime, manure, and other heavy articles by means of the canal. Ardrossan is situated not more than thirty miles from Glasgow, by the line of the projected canal, and therefore the carriage of goods will not be more expensive or tedious than by the Clyde, for the canal being free from the constant interruptions arising from the operation of wind and tide upon the river, the time of arrival and departure may be depended upon at all feasons and in all weathers. A considerable sum has already been subscribed for the canal, and also for the harbour, and from the well-known energy and activity of his lordship's general character, there is no reason to doubt that every exertion for its speedy completion will be used.

It is natural to expect that every opposition will be given by those whole local interests will suffer by the facilities of this undertaking, and these comprehend many wealthy and powerful classes; but whilst some oppose, others will find its interest to promote it, and the competition must be ultimately advantageous to the general body, however it may terminate, as to those more immediately interested.

The other part of the plan is the formation of an excellent and finished harbour at Ardrossan, capable of receiving ships of large burthen, and this also is begun. The subscriptions for the two undertakings are conducted separately. The coal here is in some places reckoned dangerous during the prevalence of strong gales from the north-west, when vessels are making the land; but it is said that the bay of Lamlash, in Arran, will afford a safe and easy shelter within a few hours' sail, when this may prove to be the case. The surveys, plans, and estimations for the canal and basin of Ardrossan were made under the superintendence of Mr. Telford. It must be perfectly evident that this canal will in all events produce much benefit as it passes through the most populous and flourishing manufacturing district in Renfrewshire.

GLASGOW, a new county of America, in Newber district, North Carolina, taken from Dubbs's county; bounded N. by Edgrom, S. by Leon, E. by Pitt, and W. by Wayne.—Also, a town of New York, on the E. coast of lake Cayuga; eight miles S. of Cayuga.

GLASS, in the general acceptation of this term among Ch. myr., denotes any substance or mixture, earthly, saline, or metallic, which is reduced by igneous fusion to the state of a hard, brittle, uniform mass, which breaks with a conchoidal fracture, falling into splinters, and with a high degree of luster. Most glasses of this kind are also transparent.

See VITRIFICATION.

GLASS, Pήρημ, a more restricted term, and as the term is commonly used in the arts and manufactures, signifies that transparent, solid, brittle, fictitious substance, produced by the vitrification of silicious earths with various lots and metallic oxides, which is applicable to innumerable purposes of ornament and comfort, as well as of scientific investigation and research.

As to the antiquity of the term glās, Tacitus (Ger. c. 45) and Pliny (l. xxxvii. c. 5) inform us, that amber was called among the ancient Gauls or Germans by the name of glabum or glāibus and from the similarity which glās bore to amber with respect to transparency and brightness, it acquired a name, which was, in all probability, originally the same. The word glās denoted, without doubt, a thinnest or transparent substance, as glāsum expreses at present in the German language to thin; and our English word to glase is derived from it, and has nearly the same signification. Ducange says that some critics were of opinion, that the word glaself itself implied glasses rather than amber. The ancient Greeks, as it has been observed, applied the same term (σαρκίων) both to glass and amber. The herb with which the Britons painted their bodies had also the name of glāsium, perhaps from the flashing appearance it might give to their skins, or possibly because its ashes might be used in the making of glases. The Latins called the famous paint by the name of vitrum, the word they used to signify glases. (Cicero, Bell. Gall. I. v.)

We find frequent mention of this plant in ancient writers, particularly Cæsar, Virgilus, Pliny, &c. who relate, that the ancient Britons painted or dyed their bodies with glutam, guanam, vitrum, &c. i.e. with the blue colour procured from this plant. And hence, as from having been used, the fictitious manner we are speaking of, came to be called glases, as having always somewhat of this kind in it.

Mercurie (Not, in Aut. Nicii de Art. Vitrum.) gives us the several characters or properties of glases, by which it is distinguished from all other bodies, viz. 1. That it is an artifical cocerote of salt and sand, or bones. 2. Fusible by a strong fire. 3. When fused, transparent and coherent. 4. It does not melt or confine in the fire. 5. When melted, it changes to iron. 6. Dustible, when red-hot, and fusible in any way, but not malleable; and capable of being blown into a hollowness, which no mineral is. (See Ductility of Glases.)

7. Frangible when thin, without annealing. 8. Fusible when cold. 9. Always inflammable, whether hot or cold. 10. Flexible and cartilaginous. 11. Diffusible by cold and moisture. 12. Only capable of being drawn, or cut with a
GLASS.

diamond or other hard stones, and emery. 13. Receives any colour or dye, both externally and internally. 14. Not dissolvable by aquafortis, aqua-regia, or mercury. 15. Neither aed juices, nor any other matter, extract either colour, taste, or any other quality, from it. 16. It admits of polishing. 17. Neither loses of weight nor substance, by the longest and most frequent use. 18. Gives fission to other metals, and softens them. 19. The most pliable thing in the world, and that which best retains the fashion given it. 20. Not capable of being colored. 21. An open glass, filled with water in the fummer-time, will gather drops of water on the outside; just as far as the water on the inside reaches; and a man's breath blown upon it will manifestly moisten it. 22. Little glasses balls, filled with water, mercury, and other liquor, and thrown into the fire, as also drops of green broken, fly asunder, with a loud noise. 23. Neither wine, beer, nor any other liquor, will make it muddy, nor change its colour, nor ruff it. 24. It may be cemented as stones and metals. 25. A drinking-glass, partly filled with water, and rubbed on the brim with a wet finger, yields musical notes, higher or lower, as the glass is more or less full; and this makes the liquor frisk and leap. See Arnonica. For the electrical properties of glasses, see Electric, &c.

Glass, origin and history of. De Neri will have glasses as ancient as Job; for that writer, chap xxviii. ver. 17. speaking of wisdom, says, "gold and glasses cannot equal it." This, we are to observe, is the reading of the Septuagint, Vulgate Latin, St. Jerom, Pineda, &c. for in the English version, instead of glasses, we read crystal; and the same is done in the Chaldee, Arias Montanus, and the king of Spain's edition. In other versions, &c. it is read stone; in others beryl: in the Italian, Spanish, French, High and Low Dutch, &c. diamond: in others, carbuncle: and in the Terzaghi, looking-glass.

In effect, the original word is χυαβιθ, (717; 71) which is derived from the root χυατιναι, to purify, cleanse, stone, white, transparent; and the same word (Exod. xxx. 34.) is applied to frankincense; and rendered in the Septuagint πάρις. Hence the reason of so many different renderings; for the word signifying beautiful and transparent, in the general, the translators were at liberty to apply it to whatever was valuable and transparent.

Herodotus (i. iii.) is, according to Dr. Falconer (Manchester Memoirs, vol. ii.) the most ancient writer (B.C. 440) who used the word παρίς, which is generally understood to signify glasses. But he evidently does not mean artificial glasses, nor glass paint, but most probably, some of the talecy kind, or lapis specularis, which might readily be framed in such a manner, as to form a convenient transparent cafe, such as the ancient historian has described. Aristophanes (B.C. 420) seems to be the next writer who mentions glasses: that poet, in his comedy called the Clouds, scene I. act. 2, uses the word λυαλθ, (352,) which is now ordinarily rendered glasses. He there introduces Strepsiades teaching Socrates a new way to pay old debts, viz: "by placing a fair transparent stone, fold by the druggists, from which the fire is struck, between the fun and the writing, and so melting away the letters thereto." This stone Socrates calls λυαλθ, which the Scholiast on Aristophanes derives from ειναι, to rain, from the likenesses it bears to ice, which is rain, or water congealed; though, it must be owned, the word λυαλθ is ambiguous, and signifies crystal as well as glass: and Gorrinus observes, that the ancients had a kind of yellow amber, transparent as glasses, called by some λυαλθ.

Aristotle (B.C. 350) has two problems upon glasses: the first, Why we see through it? The second, Why it is not malleable? If these problems be Aristotle's, which the learned Vol. XVI.
again melted, and tinged of the colour required. Some of these pieces are brought to the shape required by blowing with the breath; some are ground on a lathe, and others are embossed in the same manner as silver. Sidon was formerly famous for these manufactories, as specular or looking-glasses were first invented there; "liquidum etiam specula excogitaverat." Such is the ancient method of making glafs, decribed by Pliny. In his time, it was made with sand found at the mouth of the river Vulturnus, upon the shore, for six miles between Cumae and the Lucrane bay. This sand was very fine, and was ground to powder with a ball or sphere and a mill. It was then mixed with three parts of the fojil alkali, either by weight or measure; and being fused, was conveyed in a liquid state to other furnaces, where it was formed into a mass, called "ammonium," (or sand combined with the fojil alkali,) which mass was melted, and became then pure glafs, and a mass of white vitriof matter. The same method of making it prevailed in Spain and Gaul. Glafs was likewise made to imitate the lapis Obsidians, a substance found by a person of the name of Obsidius, in Egypt and Ethiopia. This substance was of a black color, but yet obtainable, transparent, and often placed among specula in the walls of rooms, to reflect the shadow of objects. It was also used for the same purpose as gems (probably for engraving upon) and even for statues. Pliny mentions, that he saw solid statues of the emperor Augustus made of this material; and the same emperor dedicated four elephants made of the same substance in the temple of Concord. It seems to have been used from great antiquity; but in the time of Pliny the artificial imitation of it by glafs was used instead of the native material; and he intimates that the black colour was produced by some coloring ingredient. The Romans had likewise an opaque red kind of glafs, used for plates and dishes for the table, called "hematium," one of various colours, called "myrhum," a white, a clear red, a blue, and indeed molt other colours. Pliny observs, that no substance was more manageable in receiving colours, or being formed into shapes, than glafs. The perfectly clear glafs, which bore the greatest resemblance to crystal, was, however, most valued. Nero gave for two cups, with two handles to each, and of no extraordinary size, 6000 s. lidders, or nearly 50,000 l. lidders. The inferior kinds were not uncommon, as Pliny informs us, that the use of glafs cups had nearly superceded those of gold and silver. We shall here add, that Pliny knew the power of a hollow glafs globe, filled with water, in concentrating the rays of light, so as to produce flame in any combustible substance upon which the focus fell; and he also mentions, that some surgeons in his time made use of it as a cautery for ulcers (l. xxxvii. c. 3.). He was likewise acquainted with the comparative hardines of gems and glafs, as he observes, that the lapis Obsidians would not scratch the true gems; and he also mentions (l. xxxvii. c. 13.), the counterfeiting of the latter, in his time, as a very lucrative art, and brought to great perfection. He also says, that glafs might be cut or engraved upon by means of diamonds, which art is evidenced by the antique gems so frequently found. (See Gem.) Josephus, d. ii. c. 10.) mentions the fund of the river Belus, in Galilce, as fit for making glafs.

The first time we hear of glafs made among the Romans was in the reign of Tiberius, when Pliny relates that an artist had his house demolished for making glafs mallenable, or rather flexible; though Petronius Arber, and some others, assure us, that the emperor ordered the artist to be beheaded for his invention. In the time of Martial, (A.D. 84) glafs was not only brought to great perfection, and in common use for drinking vessels, but was employed (as it seems) for bottles in which wine was kept, and likewise for pots to hold flowers. (Epig. i. i. ii. 22. 40. i. iv. 86.) Galen (A.D. 143) frequently mentions glafs in several parts of his works, and seems to have been well acquainted with the method of making it. Apuleius (A.D. 161) mentions the manufacture of glafs cups, in his time, as highly wrought and carved in various ways, and of great value. Alexander Aphrodisius (A.D. 214) a Greek writer, and a commentator on Aristotle, has several remarks on glafs respecting both its brittleness, especially on change of temperature, and its transparency.

The manufacturers of glafs formed a company at Rome, and had a street assigned them, in the first region of the city, near the Porta Capena. A tax was laid upon them by Alexander Severus (A.D. 220) which subsisted in the time of Aurelian, and probably long after.

Mr. Nixon, in his observations on a plate of glafs found at Herculanum, which was destroyed A.D. 79, on which occasion Pliny lost his life, offers several probable conjectures as to the ufe to which such plates might be applied. Such plates, he supposes, might serve for specula, or looking-glases; for Pliny, in speaking of Sidon, adds, "liquidum etiam specula excogitaverat;" the reflection of images from these ancient specula being effected by reflecting them behind, or tinging them through with some dark colour. (See Mirror.) Another ufe in which they might be employed, was for adorning the walls of their apartments by way of wainscot, to which Pliny is supposed to refer by his mira coxae (lib. xxxvii. cap. 25. § 64.). Mr. Nixon farther conjectures, that these glafs plates might be used for windows, as well as the lanae of lapis specularis and phengites, which were improvements in luxury mentioned by Seneca, and introduced in his time. Ep. xc. However, there is no positive authority relating to the ufeage of glafs windows earlier than the close of the third century: "Maneullis et," says Lactantius, "mentem effe, per ocules ea quae sunt opposita, transmittit, quam per fenstrulas lucente vitrum spectari lapidem obseotum." De Oplifici Dei, cap. 5. See Phil. Trans. vol. l. art. 80. p. 601, vol. iii. art. 23. p. 123.

St. Jerome (A.D. 422) speaks of windows formed of glafs, melted and cast into thin plates, as being used in his time. Paulus Silentiarius, a poet and historian of the 6th century (about A.D. 554), speaks of the brightness of the sun's rays, passing through the eastern windows of the church of St. Sophia, at Constaninople, which windows were covered with glafs. Gregory of Tours (A.D. 571) laments the devastations frequently committed on the windows of the churches by the ravages of war. Johannes Philoponus, who lived about the year 650, or, as some say, a century earlier, not only speaks of glafs, but of the panes being fastened in with plaster, much in the same way as at present.

If the opinion of Pennant, suggested under the article ANGUINUM, be well founded, we have reason to believe, that, long before the conquest of Britain by the Romans, the art of manufacturing glafs into such ornaments as beads and amulets was known among the Druids; and if the art was thus applied, it is not improbable to suppose, that it was employed for more important and useful purposes, as in the manufacture of glafs vessels. Nor is it likely that the Britons derived this art from the Romans, who preferred silver and gold to glafs for the composition of their drinking vessels. Besides, the glafs that was commonly used by the Romans was of an inferior quality, and appears from some remains of it discovered at their flats but.
and houses to have consisted of a thick, sometimes white, but mostly blue-green, metal.

According to venerable Bede, artificers skilled in making glass were brought over into England, in the year 674, by abbot Benedict, who were employed in glassing the church and monastery of Weremouth. According to others, they were first brought over by Wilfrid, or Wigfrid, bishop of Worcester, about the same time, or, as others think, at a later period, A.D 726. Till this time the art of making glass, or at least of applying it to this purpose, was unknown in Britain: though glass windows did not begin to be used before the year 1180: till this period they were very scarce in private houses, and considered as a kind of luxury, and as marks of great magnificence. Italy had then first, next France, from whence they came into England.

Leo Olifens (A.D. 760) speaks of the windows in his time being made with glass-plates fixed in lead, and fastened together with iron. Ananiaus, an historian of Rome, who was librarian to the pope, mentions, that in the pontificate of Leo III. who became pope about the year 800, painted glass in windows was in use. The statues of the church of Trugier, in Lower Britain, about the year 1156, speak of the windows of churches and chapels being ornamented with arms and military emblems painted upon the glasses in them. A charter of Richard II. of England, quoted by Rymer, (A.D. 1386), contains a paragraph in which is mentioned glass, together with the manufacture of it for windows.

Venice, for many years, excelled all Europe in the fineness of its glasses; and in the thirteenth century, the Venetians were the only people who had the secret of making crystall looking-glasses, and which they performed by blowing, much in the same manner as a considerable quantity of the common mirror-glass is now manufactured. The great glass-works were at Muran, or Murano, a village near the city, which furnished all Europe with the finest and largest glasses.

The glass manufacture was first begun in England in 1557: the finer sort was made in the place called Crotchted Friars, in London; the fine flint glasses, little inferior to that of Venice, was first made in the Savoy-house, in the Strand, London. This manufacture appears to have been much improved in 1655, when it was carried on with sea-coal or pit-coal, instead of wood, and a monopoly was granted to Sir Robert Manfield, who was allowed to import the fine Venetian flint glasses for drinking, the art of making which was not brought to perfection before the reign of William III. But the first glass plates, for looking-glasses and coach windows, were made in 1673, at Lambeth, by the encouragement of the duke of Buckingham; who, in 1670, introduced the manufacture of fine glasses into England, by means of Venetian artificers, with amazing success. So that within a century past, the French and English have not only come up, but even surpassed, the Venetians, and we are now no longer supplied from abroad.

The French made a considerable improvement in the art of glasses, by the invention of a method to cast very large plates, till then unknown, and scarce practised yet by any but themselves and the English. That court applied itself with a laudable industry to cultivate and improve the glass manufacture. A company of glass-men was established by letters patent; and it was provided by an act, not only that the working in glasses should not derogate any thing from nobility, but even that none but nobles should be allowed to work therein.

It was in the year 1665, under the ministry of the great Colbert, that a company for "blown-mirror-glasses" was first established near Cherbourg, in Normandy, on the plantation of the Venetian manufacture; but the beautiful art of making flint glasses was invented in France about the year 1688, by a person of the name of Abraham Theyart; and a company was soon established for this branch of manufacture. This window glass first carried on at Paris, and soon after removed to St. Gobin, where it still excels in full activity, and undiminished reputation. An extensive manufacture of this kind was first established among us near Prefcat in Lancashire, about the year 1723, by a respectable body of proprietors, who were incorporated by an act of parliament. They struggled for a considerable time with difficulties; but being nobly relieved and encouraged by government, they have succeeded in producing plates rivaling, if not surpassing in fire, quality, or brilliancy, the most celebrated continental manufacturers. This company furnishes, at Albion Place, London, plates of various dimensions, from 12 to 144 inches in length, and from 10 to 72 inches in breadth; and also convex and concave mirrors, from 12 to 36 inches in diameter.

Glass, Ingredients of. The materials used in the composition are some saline fulness and some sort of silicious earth.

1. The first ingredient we shall specify is flex or flue. The best is that which will melt, and which is white and transparent. It is this that gives confidence and firmness to the glass. This is found principally in Italy, being a sort of dirty fulness called tarso: the next is peaces, or conglodes, a sort of pebbles found at the bottom of rivers, and gathered for the Venetian manufacture out of the river Po, which are faid not to be inferior in whiteness to albaster.

Indeed, nothing makes finer and clearer glasses than common flint, distinguished for this use by its clear transparency, black colour; this, before it is used, must be heated red hot, and then immediately quenched in cold water. The heat whitens it, and the water cools it to split in every direction, and facilitates the grinding of it. The charge of preparing this deters the glasses-men from using it. The rounded fragments of quartz, found in the banks of rivers among mountains, are sometimes used in foreign countries, being first heated and ground to powder. Indeed, the preparation necessary for flint, in general, is to calcine, powder, and mix it.

Ant. Neri observes, that all white transparent flours, which will not burn to lime, are fit to make glasses; and that all flours which will strike fire with steel, are capable of being employed in making of glasses. But this latter rule, Dr. Meret observes, does not hold universally. Where proper flue cannot be had, sand is used; and it is now almost the only kind of fulness employed in the British manufactures of glasses. The best for this purpose is that which is white, small, and fining; examined by the microscope, it appears to be small fragments of rock crystal. For green glasses, that which is of a soft texture, and more gritty; it is to be well washed, which is all the preparation it needs. Our glass-houses are furnished with white sand for their crystal glasses from Lynn in Norfolk, and Maidstone in Kent, and from the western extremity of the Isle of Wight; and with the coarser, for green-glasses, from Woolwich.

2. The second ingredient in the manufacture of glasses is an alkali, which is either soda, or potash. It is always used at first in the flake of carbonate, though the carbonate acid flies off in the process. For the method of preparing each, see CARBONATE. These alkalis are used in different degrees of purity according to the required quality of the glasses. The finest sort of glasses requires the boil purities, purified by solution and evaporation, to dry; but for inferior glasses cheaper alkalis, such as barbital,
GLASS.

wood-ashes, and kelp, are employed. The ashes of fern will also yield a salt, which will make excellent glass; and, moreover, the ashes of the cobs and flakes of beans, as also those of coleworts, bramble bulbs, millet-flakes, rushes, cyr-eyes, and many other plants, may be used for the like purpose, and after the same manner.

There are other fluxes used for different kinds of glass, and for various purposes. Lime, in the form of chalk, is employed in the manufacture of glass; but this must be used only in small proportions; for an excess would act powerfully on the sides of the glass-pot, in consequence of the escape of the carbonic acid from the chalk during the fusion; and besides, it would render the glass opaque and milky in cooling, however clear it might be when hot. It is known by experience, that to 100 parts of flux and the requisite quantity of alkali, no more than about six or seven parts of quick-lime, or chalk, can be added, without affecting the cleanness of the glass. Borax is another very valuable flux; but its high price restricts the use of it to the finest kinds of glass, and to those which are required to be free from specks and bubbles. A very small quantity of borax will correct any deficiency of strength in the glass.

Of the oxides of lead, litharge and minimum are found to be of singular use in the manufacture of glass. Litharge is a powerful flux, and imparts to the glass the valuable qualities of greater density and greater power of refracting the rays of light, and of bearing sudden changes from heat to cold, without becoming liable to crack, and also greater tenacity when red-hot, so that it is more easily wrought. A considerable quantity of this oxide is contained in the finer glasses; such as the London finit glasses, and which is used for the table, for hilites, for artificial gems, and for most optical purposes. Glass, however, that contains much lead, is extremely soft; and liable to be injured by hard bodies that come into contact with it; and it is also very fusible. It is also liable to be corroded by very acid liquors. Besides, the use of lead renders it difficult to unite the flux and alkali, that a piece of glass shall be throughout of uniform density. Another ingredient occasionally used in glass is the black oxide of manganese, called "glaes-fosp," from its use in clearing the glass from any accidental foun- nes of colour, and more especially from the green tinge, owing to the presence of iron. Scheele and Bergman in their respective "Essays," have illustrated many curious circumstances that attend the use of manganese in glasses, which are particularly detailed in Aikin's Dictionary. The manganse should be chosen of a deep colour, and free from specks, of a metallic appearance, or a lighter cast: and it requires to be well calcined in a hot furnace, and then to undergo a thorough levigation. The effect of manganese in destroying the colours of glasses is accounted for by M. Montany, in his "Traité des Couleurs pour la Peinture en Email," in the following manner; the manganese destroys the green, olive, and blue colours of glass, by adding to them a purple tinge, and by the mixture producing a blackish brown colour: and as blackness is caused merely by an absorption of the rays of light, the blackish tinge given to the glass by the mixture of colours, prevents the reflection of so many rays, and thus renders the glass less coloured than before. But the black produced by this substance suggests an obvious reason for using it very sparingly in those compositions of glasses, which are required to be very transparent.

This purple colour may be corrected by charcoal, or in the glaze-house, by thrusting a billet of wood down into the melted glass, which becomes charred by the intense heat, and causes the purple hue to vanish, with a slight effervescence of the glass, and escape of numerous small air-bubbles. Or, the other hand, if a small quantity of nitre is added to glasses containing manganse, the purple colour is restored, or, if present, the discolouring effect of the charcoal is prevented, till the nitre becomes alkaliized by the heat, and mixes with the other ingredients of the crucible. For the explanation of these phenomena, it is observed, that the oxide of manganse gives the purple colour only so long as it remains in its higher state of oxidation; but when in contact with charcoal, the latter partially decomposes it, and the carbonic acid gas formed, the cause of the bubbles observed on this occasion, and the colour is now lost. Nitre, on the other hand, is known to give out oxygen largely as soon as red-hot; and hence the manganese immediately retakes from this source the oxygen of which the charcoal had deprived it, and restores its colouring power. The other substances which take away the colour from glasses, tinged red with manganese, are all the salts with the basis of fulphuric acid, such as gypsum, fulphat of soda, &c. and also sulphur itself; likewise the oxys of tin and iron, and of some other metals. Nevertheless these substances have this power only when in contact with charcoal. The tingling power of manganese is perfectly destroyed by the addition of arsene in any form. Thus, a mixture of oxide of cobalt and oxide of manganese, in the colouring flate, is of a dark purple; but on the addition of any arsene, or of white arsene, the manganese is made inactive, and the proper cobalt-blue alone appears. Hence we perceive the necessity, when the red colour of manganese is wanted, to avoid any thing arseneal; and nitre is also generally added to keep the manganese always at the proper flate for imparting its colour. The oxide of man- ganeser is a very powerful flux for all earthly matters; and this, as well as lead, gives a great density to glasses. The white oxide of arsene is another powerful and cheap flux in the making of glass; but it should be very moderately used; for it takes a longer time to mix intimately with glass, and to allow it to be perfectly clear, than any other of the additions commonly employed. For want of this the glass has a milky hue, which increases with age; and when the arsene is in excess, the glases becomes gradually soft, and is decomposed. Besides, glasses of this kind is unsafe to be used in the form of drinking vessels.

Nitre is also used, in small quantities, in the manufacture of glass, and is designed to answer particular purposes, some of which we have already specified. It not only serves to destroy the strong tinge of yellow which is found in glases, prepared with lead as a flux; but in eaine glases, it is requisite, in a smaller proportion, to render it sufficiently transparent, as in the case of looking-glasses, and other kinds of plates. For an account of Mr. Dollond's excellent contrivance for destroying the colours in the object-glasses of tele- scopes, &c. see ABBERRATION.

With regard to the several fluxes above enumerated, we may observe, in general, that the more calx of lead, or other metallic earth, enters into the composition of any glases, so much the more fusible, soft, coloured, and dense this glass is, and reciprocally.

The colours given to glases by calcis of lead are shades of yellow: on the other hand, glases that contain onlyeline fluxes partake of the properties of fales; they are less heavy, less dense, harder, whiter, more brilliant, and more brittle than the former; and glases, containing both ealine and metallic fluxes, partake of the properties of both these substances. Glases too, in which glass is safely fusible, capable of alteration by the action of air and water; efficaciously those in which alkalis prevail; and these are also liable to be injured
GLASS.

by acids. Those that contain too much borax and arsenic, though at first they appear very beautiful, quickly tarnish, and become opaque when exposed to air. By attending to these properties of different fluxes, phlogilic or felsic, the artist may know how to adjust the proportions of these to feldspar or powdered flints, for the various kinds of glaze.

GLASS, proportion of ingredients in. Different kinds of glass require different proportions; nor have these been precisely ascertained. We shall here, and in subsequent articles, state several of the most usual and approved mixtures that have been proposed. When felsic is melted with twice its weight, or more, of dry carbonated alkali, either potash or soda, the result is a very soft deficient vitreous mass, always more or less opaque, strongly alkaline to the taste, and which, on exposure to moist air, or more speedily in water, totally dissolves into a clear liquor, which is a solution of fels in alkali. When the felsic alkali is equal to the fels in weight, or does not much exceed it, the glaze is now transparent, but it is still soluble in water. It is not till the alkali is diminished to about one-half of the weight of the fels, that the glaze becomes perfectly hard and infusible in any corrosive liquors, (the fluoric acid excepted,) and, in short, acquires the character of a perfect glaze. This proportion, therefore, of two parts of fels to one of alkali, is usually the datum on which the doses of the alkalies actually used are regulated. Thus, if common wood ashes of (which the alkali part is reckoned at no more than 10 per cent.) are employed, 100 lbs. of these would require no more than about 20 lbs. of fels. If the belt Spanish barilla, containing from 45 to 50 per cent. of carbonate of soda, be used, an equal weight of fels may be added; but if purified pearl-ash be taken, it will melt down perfectly twice its own weight of fels. But glazes composed merely of pure alkali and fels, require a very strong fire for their fusion, and are hard, hard, and difficult to break: they are therefore never used alone. As one half the weight of the fels is reckoned an abundant allowance of alkali, it follows of course that when litharge, arsenic, borax, or any other fluxes are employed, the quantity of alkali will be proportionally diminished.

The following proportions are extracted from Macquer's Chemical Dictionary: If a glaze be required that is dense, fusible, and not fustine, one part and a half of red lead or leady, may be mixed with one part of fels, and fused together: if equal parts of fels and of calc of lead be employed, a glaze somewhat less dense and harder will be produced: if a glaze be required of very little density, only fustine fluxes must be employed. A glaze of this kind may be composed of five parts of fels of tartar, or of potash, or of pure soda, mixed with eight parts of fels or of fints; or of four parts of any of the above-mentioned alkalies, mixed with two parts of nitre or of borax, and eight parts of vitrifiable earth. When a crystal glaze is required, which shall be of an intermediate quality between the metallic and fustine glazes, it may be made from a mixture of one part of the above mentioned fints, one part of calc of lead, and two parts of fels or other vitrifiable earth. By varying the proportion of these ingredients, many different kinds of glazes may be produced, each of which may be good, if the quantity of each of the fluxes employed be proportionate to its vitrifying power.

GLASS, instruments for manufacturing. These are sub-divided into two different purposes, viz. the levigation and mixture of the ingredients, and the fusion or vitrification of them. To the former class belong hobs or hand-mills, mortars and pestles, flat stones and millars, and shears or seizers. The other sort of utensils are furnaces, with the proper iron work, pots for containing the composition when put into the fire, and iron instruments for shifting the matter out of one into the other, in case of accidents; and for taking out small portions, in order to judge of the progress of the vitrification, and the qualities of the glaze, &c. See the following articles. See also GLASS-BOGEY, FURNACE, and GLASS-POTS.

GLASS, fritting of. When the ingredients are selected and properly proportioned, they are first calcined for a longer or shorter time, before they are put into the glaze-pots. This operation is called "fritting," and is performed either in small furnaces adjoining to the proper glaze-furnace, and heated by the same fuel after its chief force has been spent upon the glaze-pots, or else in small furnaces or ovens constructed for this purpose. The uses of fritting are, to expel all moister from the ingredients, by which the glaze-pots would be endangered; to discharge part of the carbonic acid from the alkalies and chalks, and thus to moderate the swelling in the glaze-pots, and especially to cause an adhesion, or commencement of chemical union, between the alkali and fels, and metallic oxides. This operation should be performed gradually, and carried to the point of semi-vitrification, in which the materials strongly adhere, and begin to become pasty, but are still opaque and not homogeneous. This operation serves also to destroy any carbonaceous matter. When the ingredients are sufficiently fritted, they are thrown with clean iron shovels through the side-opening of the furnace into the glaze-pots, the fire having been previously raised to its greatest intensity, to prevent the furnace from being chilled and to fire time. The pots are charged by two or three successive portions, the preceding one being thoroughly melted down before another portion is thrown in. When filled, the side-opening is closed up with wet clay, excepting a small hole for examining the work, which is pulled down when the glaze is well refined and about to be worked off. As soon as the frit begins to feel the action of the fire in the glaze-pots, which is immediately raised to its greatest pitch, it links down into a soft pally state, increasing in tenacity till the fusion is complete. However, it is still opaque, from the rising of a white porous fume, known by the name of "fandiver," or "glaze-gall." This fustance appears to be a confounded mass, consisting of all those faults contained in common alkalies, which readily melt at somewhat less than a glaze-melting heat, and are either naturally soluble in a considerable degree, or have little, if any, affinity for fels, and not uniting in the composition of glazes, but being lighter, rise to the top. Another heterogeneous fustance, called "fandiver," is sometimes found at the bottom of the pots. This is quite different from the other, and seems to consist of a vitriified mass of arienic and other impurities. But the fume, or proper"glaze-gall," is almost entirely fustine. When laked out and cooled, it forms a crumbly mass, sometimes white, at other times brown and foulish, and strongly fustine, but not uniform in its composition, being sometimes merely fust, often very bitter, probably as common falt and sulphate of potash predominates. It is so volatile in a strong fire, that it is constantly Siberating from the surface of the glaze in a dense vapour, which is first thick and black, afterwards white, and which corrodes the top of the crucible in its passage. With long continued fusion it would entirely escape in this state, if it were not fumed off with long lades, and sold to metal refiners as a powerful flux. Abundance of this glaze-gall is attended with one of the greatest inconveniences to the maker of glaze, as it requires a considerable expence of strong
strong heat to dissipate the whole of it, or otherwise the glass would be full of bubbles, unbound, and having a cloudy gelatinous appearance. It is observed, that glasses from potash is more likely to suffer from glass-gall than the soda-glasses is, because the potash glasses are harder, and do not run so thin as the other, and the glass-gall from them does not easily dissipate in the fire.

During this process samples for examination are drawn out of the pots with an iron rod; and the glasses gradually becomes more and more flexible, dense, and less brittle, and at last the glass-gall is entirely dissipated. Whilst the heat is continued, the glass which was full of specks and bubbles is refined, and becomes beautifully clear, transparent and colourless; and this process, which goes on from the evaporation of the vapour of the glass-gall and its entire removal to the time when the glass is altogether clear and free from bubbles, is called the "refining." After this the glasses is complete; but being too thin for working, it is cooled, by dropping the draught of fire round the pot which contains it, and in cooling it thickens to a fit flate for being wrought. For glasses that is call into plates, its cooling is necessary, as it is required to flow very thin and hot. On an average it takes about 48 hours for the fine flint glasses, from the time when the pots are first filled till the glass is ready for working; in which state it is of a very full red colour, and possesseth a singular kind of condition and tenacity. It is just soft enough to yield with ease to any external impression, even to the force of the breath urged pretty strongly in the centre of the glowing mass, and may be bent and shaped in every possible way; and such is its tenacity, that it extends uniformly without any cracks or fissures; but when stretched out to the utmost, it forms a fold, the diameter of which is constantly decreasing till it separates from the mass in a thin expiaphy thread. It thickens as it cools, and becomes perfectly brittle and also transparent. As melted glasses adheres very feebly to polished metal, it is very easily wrought with bright iron tools.

Glass, working or blowing round.—Every kind of glass, plate-glasses excepted, is formed from a hollow globe that has been produced by blowing. For this purpose the operator takes his blowing-iron, which is a hollow tube, about four or five feet long, and dipping it in the melting-pot, turns it about the tube till the metal adheres to the iron like some glutinous or clammy juice; he then holds it near the ground, so that the mass is extended by its own weight, and blows strongly into the tube. With his breath thus penetrating into the centre of the red-hot mass, he enlarges it into an uniform hollow globe of the requisite thickness and bulk, keeping the force of his breath upon it for a few seconds till it thickens by cooling, and thus preventing its sinking by the compression of the denser external air. This globe, adhering by a neck to the iron rod, is formed by the dexterity of the workman, and by a variety of ingenious manoeuvres into all the common utensils. As a specimen of his art, we may imitate a common tumbler. The hollow globe already mentioned is taken off the iron rod by the following simple procés: An affilant dips the end of a short solid iron rod into the glass-pot and, bringing out at its extremity some of the melted glasses, thrusts it immediately against the hollow of the globe at the part directly opposite to the neck, to which it firmly unites, and thus the glass is cemented by the melted glasses to the second rod. The workman then wets a small piece of iron with his mouth, and lays it on the neck of the globe, which is extremely hot, and this, in a second or two, cracks it round; so that with a little pull it comes off and detaches the hollow rod, leaving the globe open at the neck, and transferred to the second rod at the opposite side. The open globe is again softened by holding it a few seconds over the mouth of the glass-pot, and is cut away from the spout, and so to the form of a cup by iron tongs. The operator, when employed in fashioning the globe, usually sits upon a kind of arm-chair, with its arms disposed forwards and covered with a flat smooth iron-plate; and by laying the iron rod straight before him, resting on both the arms of his seat, and twirling it backwards and forwards, the hot glasses at the end is made to revolve like clay on a potter's lathe, and thus is opened, widened, or compressed at pleasure by any simple iron instrument that is prefixed against it. The chuck is thus extended easily into a cylinder, or made into the shape of a barrel, if this form be required, and is smoothed up at the edges. In order to separate it from the iron-rod, it is wetted as before at the point of attachment, and the tumbler drops off complete. This last operation leaves that burr or roughness, with sharp fragments, which is seen at the bottom of all glasses-vessels, unless it be taken off by polishing. The next operation is that of cooling the vessel very gradually, called "annealing." See Annealing of Glass.

Glass, different kinds of. The manufactured glasses now in use may be divided into three general kinds; white transparent glass, coloured glasses, and common green or bottle glasses. Of the first kind, there is a great variety; as the flint glasses, as it is called with us, and the German crystal glasses, which are applied to the same uses; the glasses for plates for mirrors or looking-glasses; the glasses for windows and other lights; and the glasses for plates and small vessels. And these again differ in the substances employed as fluxes in forming them, as well as in the corendelic or fineses of each as are used for their body. The flint and crystal, mirror, and bell window glasses, not only require such purity in their fluxes, as may render it practicable to make the glass perfectly from all colour; but for the same reason likewise, either the white Lynn sand, calcined flints, or white pebbles, should be used. The others do not demand the same nicety in the choice of the materials; though the second kind of window glass, and the bell kind of phials, will not be so clear as they ought, if either too brown sand, or impure fatts, be suffered to enter into their composition.

Of coloured glasses there is a great variety of sorts, differing in their colour, or other properties, according to the occasions for which they are wanted. The differences in the latter kind depend on the accidental preparation and management of the artih by whom they are manufactured.

Glass, Crystal. Foreigners use this term for our flint glasses, and for making it they give the following directions: Take of the white talc, pounded small, and leared as fine as flour, two hundred pounds; of the salt of boron, a hundred and thirty pounds; mix them together, and put them into the furnace, called the calcar, first heating it. For an hour keep a moderate fire, and keep stirring the materials with a proper rake, that they may incorporate and calcine together; then increase the fire for five hours; after which take out the matter; which, being now sufficiently calcined, is called frit. From the calcar put the frit in a dry place, and cover it up from the dust for three or four months.

Now, to make the glasses, or crystal: Take of this crystal frit, called also bollis; set it in pots in the furnace, adding to it a due quantity of manganese: when the two are fused, call the flour into fair water, to clear it of the salt, called fassa, which wets otherwise the crystal obscure and cloudy. This lution must be repeated again and again, as often as needful, till the crystal be fully purged; or, this fema may be taken off by means of proper ladles. Then set
GLASS.

It to boil four, five, or six days; which done, see whether it have manganese enough; and if it be yet green, add more manganese, at discretion, by little and little at a time, taking care not to overdry it, because the manganese inclines it to a blackish hue. Then let the metal clarify, till it becomes of a clear and shining colour; which done, it is fit to be blown or formed into vessels at pleasure.

GLASS, Flint, as it is called in our country, is of the same general kind with that in other places is called crystal glass. It has this name from being originally made with calcined flints, before the use of the white sand was understood; and retains the name though no flints are now used in the composition of it. This flint glass differs from the other, in having lead for its flux, and white sand for its body; whereas the fluxes used for the crystal glasses are felspar or arsenic, and the body consists of calcined flints, or white river pebbles, tarso, or fine stones. This glass, on account of the quantity of litharge, which enters into its composition, is the heaviest, the most brilliant, the softest and most easy to work, and also the most expensive. It is that fine glass, of which the common and most valuable articles of white glasses in domestic or ornamental use are manufactured; and besides, many optical instruments are made of this substance. To the white sand and lead a proper proportion of nitre is added, for the purposes specified in a former part of this general article, and also a small quantity of manganese, and in some works they use a proportionate quantity of arsenic to aid the fluxing ingredients. The most perfect kind of flint glasses may be made by fusing with a very strong fire a hundred and twenty pounds of the white sand, fifty pounds of red lead, forty pounds of the bell pearl-ashes, twenty pounds of nitre, and five ounces of manganese.

From others we have the following composition for glasses of this kind, said to be of the best quality, viz. 120 parts of fine clear white sand, 40 of pearl-ashes well purified, 35 of litharge or minium, 13 of nitre, and a small quantity of black oxyd of manganese. The following composition for a fine crystal glass is given by Loyola: 100 pounds of white sand, 86 to 85 of red oxyd of lead, 25 to 30 of pearl-ashes, 3 to 4 of nitre, and one ounce of manganese. The specific gravity of this glass, and of the common London flint-glasses, is about 3.2.

Another composition of flint glasses, which is said to come nearer to the kind now made, is the following: a hundred and twenty pounds of sand, fifty-four pounds of the bell pearl-ashes, thirty-six pounds of red lead, twelve pounds of nitre, and eight ounces of manganese. To either of these a pound or two of arsenic may be added, to increase the flux of the composition. A cheaper composition of flint glasses may be made with a hundred and twenty pounds of white sand, thirty-five pounds of the bell pearl-ashes, forty pounds of red lead, thirteen pounds of nitre, five pounds of arsenic, and four ounces of manganese; or, instead of the arsenic, may be substituted fifteen pounds of common salt; but this will be more brittle than the other. The cheapest composition for the worst kind of flint-glasses, consists of a hundred and twenty pounds of white sand, thirty pounds of red lead, twenty-five pounds of the bell pearl-ashes, ten pounds of nitre, fifteen pounds of common salt, and five pounds of arsenic. The bell German crystal glass is made of a hundred and twenty pounds of calcined flints, or white sand, seventy pounds of the bell pearl-ashes, ten pounds of salt-petre, half a pound of arsenic, and five ounces of manganese. And a cheaper composition is formed by a hundred and twenty pounds of calcined flints, or white sand, forty-six pounds of pearl-ashes, seven pounds of nitre, fix pounds of arsenic, and five ounces of manganese.

A glass, much harder than any prepared in the common way, may be made by means of borax in the following method: take four ounces of borax, and an ounce of fine sand; reduce both to a subtile powder, and melt them together in a large close crucible set in a wind-furnace, keeping up a strong fire for half an hour; then take out the crucible, and when cold break it, and there will be found at the bottom a pure hard glass, capable of cutting common glases like a diamond. This experiment, duly varied, may lead to several useful improvements in the arts of glases, enamels, and fustifications, and forms an expedient method of making glases, without any fixed alkali, which has been generally thought an essential ingredient in glases; and it is not yet known whether calcined crystal, or other sublunaries, being added to this salt instead of sand, might not make a glas approaching to the nature of a diamond. Shaw's Lectures, p. 426.

GLASS, Crown, is the best sort of window-glas, and differs from the flint-glasses in containing no lead, nor any metallic oxyd, except manganese, and sometimes oxyd of cobalt, in minute doses, not as a flux, but for correcting the natural colour. This glass is much harder and harder to the touch than the flint-glasses; but when well made it is a very beautiful article. It is compounded of sand, alkali, either potash or soda, the vegetable athes that contain the alkali, and generally a small portion of lime. A small dose of arsenic is often added to facilitate the fusion. Zaffre, or the oxyd of cobalt, with ground flint, is often used to correct the dingy yellow of the inferior sort of crown-glasses, and by adding the blue, natural to glases coloured with this oxyd, to convert the whole into a soft light green. One ounce of zaffre is sufficient for 1000 lbs. But when the sand, alkali, and lime are very fine, and no other ingredients are used, no zaffre nor corrective of bad colour is required. A very fine glasses of this kind may be made by 200 parts of pretty good soda, 300 of fine sand, 35 of lime, and from 270 to 300 of the ground fragments of glass. We had formerly in London two kinds of crown glasses, distinguished by the places where they were wrought: viz. 1. Ratcliffe crown glasses, which is the best and clearest, and was first made at the Bear-garden, on the Bank-side, Southwark, but since at Ratcliffe: of this there are twenty-four tables to the cafe, the tables being of a circular form, about three feet six inches in diameter.

2. Lansell crown glasses, which is of a darker colour than the former, and more inclining to green. The following composition has been recommended for the best window or crown glasses, viz. white sand, fifty pounds; of purified pearl-ashes, thirty pounds; of salt-petre, fifteen pounds; of borax, one pound; and of arsenic, half a pound. If the glass should prove yellow, manganese must be added. A cheaper composition for window glasses consists of sixty pounds of white sand, twenty-five pounds of unpurified pearl-ashes, ten pounds of common salt, five pounds of nitre, two pounds of arsenic, and one ounce and a half of manganese. The common, or green window glasses, is composed of sixty pounds of white sand, thirty pounds of unpurified pearl-ashes, ten pounds of common salt, two pounds of arsenic, and two ounces of manganese. But a cheaper composition for this purpose, consists of a hundred and twenty pounds of the cheap white sand, thirty pounds of unpurified pearl-ashes, sixty pounds of wood-ashes, well burnt and sifted, twenty pounds of common salt, and five pounds of arsenic.

The manufacture of the common window glasses, though made by blowing, is conducted differently from that of the flint glasses articles; as it is the object to produce a large, flat, very thin plate of glases, which is afterwards cut by the glazier's
GLASS.

Glass, French, as also called Normandy glass, and formerly Lorraine glass, because it was made in those provinces: though it has since been made wholly in the nine glass works; five of which were in the forest of Lyons, four in the country of Eu: the last at Beaumont, near Rouen. It is of a thinner kind than our crown glass; and, when laid on a piece of white paper, appears of a dirty, greenish colour. There are but twenty-five tables of this to the cafe.

Glass, German, is of two kinds, the subite and the green: the first is of a whitish colour, but is subject to those small curved breaks, observed in our Newcastle glass, though free from the spots and blemishes thereof. The green, besides its colour, is liable to the fame breaks as the white; but both of them are straighter, and less warped, than our Newcastle glasses.

Glass, Dutch, is not much unlike our Newcastle glasses, either in colour or price. It is frequently much warped, like that, and the tables are but small.

Glass, Newcastle, is that most used in England. It is of an ash-colour, and much subject to specks, flaws, and other blemishes; and, besides, is frequently warped. Leyburn fays, there are forty-five tables to the cafe, each containing five superficial feet; some fay there are but thirty-five, and six feet in each table.

Glass, Phila, is a kind of glass between the flint glasses and the common bottle, or green glasses. The best kind may be prepared with a hundred and twenty pounds of white sand, fifty pounds of unpurified pearl-ashes, ten pounds of common falt, five pounds of arfene, and five ounces of manganef. The compofition for green or common phila glasses, consists of a hundred and twenty pounds of the cheapest white sand, eighty pounds of wood-ashes, well burnt and sifted, twenty pounds of pearl-ashes, fifteen pounds of common falt, and one pound of arfene.

Glass, common green bottle, is made almost entirely of sand, lime, and sometimes clay, alkaline ashes of any kind, as cheapness or convenience direct, and more especially of help in this country, of barilla, vase, and the other varieties of soda in France, and of wood-ashes in many parts of Germany, and the like. To these ingredients is sometimes added the earth remaining from flint glasses, after the alkali and falt have been extracted by lixiviation, and in England flags from the iron furnaces. Bottle-glasses is a very hard well-vitrified glasses, which refits the corrosive action of all liquids much better than flint glasses. It is used, not only for wine-bottles, but for very large retorts, subliming vessels, and other articles of the chemical apparatus; and it has for this purpose the advantage of bearing as much as a pretty full red heat without melting or sinking down into a harp-lefs lump, as the lead-glasses would do. The following composition is given by Loycelf as a good and cheap material for bottle-glasses: viz. 100 parts of common fand, 50 of varece (a kind of coarse help made on the western coasts of France), 160 of the lixiviated earth of ashes, 50 of frith wood-ash, or any other kind of ash, 80 of brick-clay, and any quantity, generally about 100, of broken glasses. This composition yields no glafs-glost. This kind of glafs is made of sand of any kind, mixed by the ashes of burnt wood, or of any other part of vegetable; to which may be added the feorize or clinfers of forges. When the fift glafs is made, two hundred pounds of wood-ashes will suffice for a hundred pounds of fand, which are to be ground and mixed together. The composition with the clinfers consists of a hundred and seventy pounds of wood-ashes, a hundred pounds of fand, and fifty pounds of clinfers, or feorize, which are to be ground and mixed together. If the clinfers cannot be ground, they must be broke into small pieces, and mixed with the other matter without any grinding.

A good bottle-glasses, but nearly black and opaque, has been made in France of the decomposed pulverulent basaltic earth found in the valleys of all basaltic countries. In France it abounds in the Vivara, in Langedoc, and Auvergne. The first glases of this kind appears to have been made in 1780 by a M. Ducros at the fuggestion of Chapital, who almoft melted some of this basalt without addition in a glas-pot, and formed of it two very light, black, or rather deep yellow, thinning, perfect bottles. In subsequent trials by another artiz, a mixture of equal parts of basalt and fand was employed, as preferable to the basalt alone; but notwithstanding a considerable demand for bottles of this ma-terial, the manufacture was abandoned for want of uniformity in the ingredients, which made them often fail. The colour of this glases was of a green-olive.

The green colour, transmitted by bottle-glasses, when in its perfect state, is owing to the iron contained both in the vegetable ashes and in the fea-fern, which enter into its compofition. This glas affords an infalce of a femipellucid fubftance, which exhibits a blue colour by incident light, and a yellow or orange colour by that which is transmitted. See Delaval on the caufe of the permanent colour of opaque bodies.

Glass, Plate, is the most perfect and beautiful glases, of which all the kinds of mirrors and looking-glasses are com-posed. The materials of which this kind of glases is made are much the fame as those of other works of glases, viz. an alkali falt, and fand.

To prepare the falt, they clean it well of all foreign ma-teries; pound or grind it with a kind of mill, and finally fift it pretty fine.

Pearl-ashes, properly purified, will furnish the alkali falt requisite for this purpofe: but it will be neceffary to add borax, or common falt, in order to facilitate the fution, and prevent the glases from flifitting in that degree of heat, in which...
which it is to be wrought into plates. For purifying the pearl-ashes, dissolve them in four times their weight of boiling water, in a pot of cast iron, always kept clean from rust. Let the solution be removed into a clean tub, and remain there twenty-four hours, or longer. Having decanted the clear part of the fluid from the dregs or sediment, put it again in the iron pot, and evaporate the water till the ashes are left perfectly dry. Prefer them in stone jars, well secured from air and moisture.

Pearl-ashes may also be purified in the highest degree, so as to be proper for the manufacture of the most transparent glasses, by pulverizing three pounds of the best pearl-ashes, with six ounces of salt-petre, in a glass or marble mortar, till they are well mixed, and then putting part of the mixture into a large crucible, and exposing it in a furnace to a strong heat. When this is red-hot, throw in the rest gradually, and when the whole is red-hot, pour it out on a moistened stone or marble, and put it into an earthen or clean iron pot, with ten pints of water; heat it over the fire till the ashes be entirely melted; let it then stand, cool, and filter it through paper in a pewter callender. When it is filtered, put the fluid again into the pot, and evaporate the salt to dryness, which will then be as white as snow; the nitre having burnt all the phlogistic matter that remained in the pearl-ashes, after their former calcination.

As to the sand, it is to be sifted and washed, till such time as the water come off very clear; and when it is well dried again, they mix it with the salt, passing the mixture through another sieve. This done, they lay it in the annealing furnace for about two hours; in which time the matter becomes very light and white; in this state they are called frit, or fritte; and are to be laid up in a dry clean place, to give them time to incorporate. They lie here for at least a year.

When they would employ this frit, they lay it for some hours in the furnace, adding to some of the fragments or shards of old and ill made glasses; taking care first to calcine the shards by heating them red-hot in the furnace, and thus casting them into cold water. To the mixture must likewise be added manganeze, to promote the fusion and purification.

The bell composition for looking-glass plates is said to consist of sixty pounds of white sand, cleansed, twenty-five pounds of purified pearl-ashes, fifteen pounds of salt-petre, and seven pounds of borax. If a yellow tinge should affect the glass, a small proportion of manganeze, mixed with an equal quantity of arlene, should be added. An ounce of the manganeze may be first tried: and if this proves insufficient, the quantity should be increased.

A cheaper composition for looking-glass plate consists of sixty pounds of the white sand, twenty pounds of pearl-ashes, ten pounds of common frit, seven pounds of nitre, two pounds of arlene, and one pound of borax.

The materials of the finest plate glasses, such as that of French manufacture, are white sand, soda, and lime, to which are added manganeze and zaffre, or any other oxyl of cobalt for particular colouring purposes. The sand is of the finest and whitest kind, which should be previously passed through a wire sieve, moderately close, into water, in which it should be well stirred about and washed. The sharpest grained sand is preferred, and it is found that grains of moderate size melt with the alkali sooner, than the very fine dust or the larger fragments. The alkali is always soda, which is preferable to potash, as glasses made with soda are found to be softer and to flow thinner when hot, and yet to be equally durable when cold. Besides, the neutral salts with the bulky of soda which confitute the glass in this instance, such as the muriat and sulphate of soda, appear to be dissolved more readily by the fire than the corresponding salts of potash. The soda that is used is considerably pure, or such as is separated from the rough ashes of harissa, and other soda plants by lixiviation. Lime adds to the fineness of the other materials, supplying the use of lighthouse in the fine-glasses; but excess of it would impair the colour and solidity of the glass. About 1-15th of the whole is as much as can properly be used; but some reduce the quantity to 1-24th. The decolouring substances are azure, or cobalt blue, and manganeze. Besides these, there is always a great quantity of the fragments of glasses, collected from the walls of the manufacture, which are made friable by quenching in water when hot, and used in this state together with the fresh materials. As to the quantities and proportions of the ingredients, much latitude is allowed. The following are said to produce a very fine glass; viz. 300 lbs. of sand; 200 lbs. of soda; 55 lbs. of lime; 32 ozs. of manganeze; three ozenes of azur; and 300 lbs. of fragments of glasses. In the manufacture at St. Gobin the purity is observed with regard to the materials; but it is affirmed, and with much probability, that borax is used in small quantity.

Of the materials now enumerated the sand, soda, lime, and manganeze are first mixed together with more care than for ordinary glasses, and they are sifted in small furnaces built for this purpose, the heat being gradually raised to a full red-white, and then kept with frequent stirring till the materials undergo no further change, nor yield any kind of vapour. The azure and glasses fragments being already in a state of perfect vitrification are not added till just at the end of the process, which lasts about six hours. When the materials are thus prepared, they are fit for plate-glasses, to be formed either by blowing or casting. The largest glasses at St. Gobin are run; the middle-sized and small ones are blown.

Blowing looking-glass plates. The work-houses, furnaces, &c. used in the making of this kind of plate-glasses are the same, except that they are smaller, and that the earthen-ware are disposed in a large covered gallery, opposite the furnace, as tho’ in the following article, to which the reader is referred.

After the materials are vitrified by the heat of the fire, and the glass is sufficiently refined, the workman dips his blowing iron, six feet long, and two inches in diameter, sharpened at the end, which is put in the mouth and covered at the other, that the matter may adhere to it. By this means he takes up a small ball of matter, which sticks to the end of the tube by constantly turning it. He then blows into the tube, that the air may swell the annexed ball; and carrying it over a bucket of water, which is placed on a support at the height of about four feet, he sprinkles the end of the tube to which the matter adheres, with water, still turning it, that by this cooling, the matter may coalesce with the tube, and be fit for finishing a greater weight. He dips the tube again into the same pot, and proceeds as before; and, dipping it in the pot a third time, he takes it out, loaded with matter, in the shape of a pear, about ten inches in diameter, and a foot long, and cools it at the bucket; at the same time blowing into the tube, and, with the assistance of a labourer, giving it a balancing motion, he shapes the matter to the length; which, by repeating this operation several times, affinches the form of a cylinder, terminating like a ball at the bottom, and in a point at the top. The afflent is then placed on a floor three feet and a half high, and on this floor there are two
GLASS.

upright pieces of timber, with a croft beam of the same, for supporting the glass and tube, which are kept in an oblique position by the affidavit, that the mather workman may with a punchen set in a wooden handle, and with a mallet make a hole in the mafs; this hole is drilled at the centre of the ball that terminates the cylinder, and is about an inch in diameter. When the glass is pierced, the defects of it are perceived; if it is tolerably perfect, the workman lays the tube horizontally on a little iron treffel, placed on the support of the aperture of the furnace. Having exposed it to the heat for about half a quarter of an hour, he takes it away, and with a pair of long and broad scissors, extremely sharp at the end, widens the glass, by infusing the scissors in the hole made with the punchen, whilst the affidavit, mounted on the floor, turns it round, till, at half, the opening is so large as to make a perfect cylinder at bottom. When this is done, the workman lays his glasses upon the treffel, at the mouth of the furnace, to heat it; he then gives it to his affidavit on the floor, and with large scissors cuts the mafs of matter up to half its height. There is at the mouth of the furnace an iron tool, called pontil, which is now heated, that it may unite and coalesce with the glass just cut, and perform the office in which the tube did before it was separated from the glass. This pontil is a piece of iron, fix feet long, and in the form of a cane or tube, having at the end of it a small iron bar, a foot long, laid equally upon the long one, and making with it a T. This little bar is full of the matter of the glass, about four inches thick. This red-hot pontil is presented to the diameter of the glass, which coalesce immediately with the matter round the pontil, so as to support the glass for the following operation. When this is done, they separate the tube from the glass, by striking a few blows with a chisel upon the end of the tube, which has been cooled; so that the glass breaks directly, and makes this separation, the tube being discharged of the glass now adhering to the pontil. They next present to the furnace the pontil of the glass, laying it on the treffel to heat, and redden the end of that glass, that the workman may open it with his scissors, as he has already opened one end of it, to complete the cylinder; the affidavit holding it on his floor as before. For the last time, they put the pontil on the treffel, that the glass may become red-hot, and the workman cuts it quite open with his scissors, right over against the fore-mentioned cut; this he does as before, taking care that both cuts are in the same line. In the mean time, the man who looks after the carquasses, comes to receive the glass upon an iron shovel, two feet and a half long without the handle, and two feet wide, with a small border of an inch and a half to the right and left, and towards the handle of the shovel. Upon this the glass is laid, flattening it a little with a small flack a foot and a half long, so that the cut of the glass is turned upwards. They separate the glasses from the pontil, by striking a few gentle blows between the two with a chisel. The glass is then removed to the mouth of the hot carquasse, where it becomes red-hot gradually; the workman, with an iron tool, fix feet long, and widened; the end in form of a club at cards, four inches long, and two inches wide on each side, very flat, and not half an inch thick, gradually lifts up the cut part of the glass, to unfold it out of its form of a flattened cylinder, and render it smooth, by turning it down upon the hearth of the carquasse. The tool, already descried, being immersed within the cylinder, performs this operation, by being pushed hard against all the parts of the glass. When the glass is thus made quite smooth, it is pulled to the bottom of the carquasse, or annealing furnace, with a small iron raker, and raised there with a little iron hook. When the carquasse is full, it is stopped and cemented as in the case of run glasses, and the glass remains there for a fortnight to be annealed; after which time, they are taken out to be polished. A workman can make but one glasses in an hour, and he works and rolls for six hours alternately.

It may be observed, that looking-glasses, thus blown, should never be above forty-five, or at most fifty inches long, and of a breadth proportionable. These exceeding these dimensions, as we frequently find among the Venice glasses, cannot have the thickness sufficient to bear the grinding; and, besides, are subject to warp, which prevents them from regularly reflecting objects. Whereas plates as large as nine feet in length and proportionally wide, have been manufactured by casting.

Casting or running large looking-glass plates. This art, as we have observed in the History of Glass, is of French invention. It is owing to the Sieur Abraham Thewart, who first propitiated it to the court of France, in 1688.

It is performed much like the casting of sheet-lead among the plumbers; and by means hereof we are not only enabled to make glasses of more than double the dimensions of any made by the Venetian way of blowing; but also to call all kinds of borders, mouldings, &c.

The furnaces for melting the materials of this manufacture are of large size, being about 18 feet long and 15 wide; and those for annealing the glasses, when formed, are much more so. Round a melting-furnace, there are at least twenty-four annealing furnaces or ovens; each from twenty to twenty-five feet long; they are called carquasses; each carquasse has two tills, or apertures, to put in wood, and two chimneyes. Add, that beside the annealing furnaces, &c. there are others for making of frit, and calcining old pieces of glasses.

All these furnaces are covered over with a large lid; under which are like wise forges, and work-houses for smiths, carpenters, &c. continually employed in repairing and keeping up the machines, furnaces, &c. as also lodges, and apartments for the workmen, and the other workmen, employed about the glasses, and keeping up a perpetual fire in the great furnace; so that the glass-houses, as that in the castle of St. Go-bin, in the forest of Pere, in the Soiflonois, appears more like a little city, than a manufactory.

The inside of furnaces is formed of a feet of baked earth, or refractory clay, proper to fulfill the action of fire; and the fame earth serves also for melting-pots, cisterns, &c. The furnaces seldom last above three years; after which they are to be rebuilt, from bottom to top, and to keep them good, even for that time, the inside must be refitted every six months, at which time the fire is extinguished. The melting-pots are as big as wine hogheads, about three feet in height, and in diameter; and contain above two thousand weight of metal. They are in the form of an inverted and truncated cone. The cisterns, or pans, called "euvettes," are much smaller, being about thirty-six inches long, eighteen inches wide, and many deep; and serve for the conveyance of liquid glasses, which is drawn out of the pots to the casting tables. They do not contain much more than a sixth, or when large plates are cast, a third of the pots.

When the furnace is in condition to receive the pots and cisterns, they heat it red-hot, which requires fifty cords, or a hundred cart-loads of wood. That kind of wood which emits the largest and brightest flame, without much refrums smoke, is preferred. This done, they fill the pots with the materials, or fosa and sand, which is done at several times, to facilitate the fusion. When the matter is sufficiently vitrified, refined, and settled, which usually happens in thirty-
GLASS.

Thirty-six hours, they fill the cisterns, which are in the same furnace, and which are left there about six hours longer, till such time as they appear all white through the excessive heat.

To get the cisterns with the metal out of the furnace, they make use of a large iron chain which opens and shuts with hooks and eyes. From the middle of this, on each side, arise two massive iron pins, by which, with the assistance of pulleys, the cisterns are raised upon a kind of carriage of a proper height; and thus conducted to the table where the glais is to be run. The cistern is then raised above the tables with an engine, in form of a crane, by means of two iron bars, so contrived as to throw the cistern into an inclined position, which discharges a torrent of matter, all on fire, with which the table prepared for this purpose is presently covered.

The table on which the glais is to be run, is of smooth thick copper-plate, about ten feet long, and fix feet broad. It is supported on a wooden frame, with truckles, for the convenience of removing from one carquaise, or annealing furnace, to another, in proportion as they are filled.

Or, when each pot has a caiing table, it is strongly supported by masonry, and contiguous to each table on the same level are the annealing ovens, upon which, being flat, the glais, when cast and sufficiently cooled, may be slid off the copper-table without much difficulty. The tops of the flat ovens and the tables are on a level with the corresponding opening of the furnace, whence the cuvettes or cisterns are withdrawn. When the glais is melted and fixed in the manner already stated under the article Flint Glass, the cuvette or cistern, previously made hot in the furnace, is filled out of the pot with a copper ladle, about ten inches in diameter, fixed to an iron handle seven feet long, properly supported on an iron stay by two workmen; and after remaining in the furnace for some hours, till the samples taken out for trial appear to be quite clear and limpid, the door of the furnace is opened, and the cuvette is pulled out and removed to the side of the copper table. It is then returned with an instrument consisting of a copper blade set in iron, and horsed for the discharge of its contents on the table, in the manner already mentioned.

To form the thickness of a glais, and to make the surface smooth and even, there are two iron rollers or rims, placed round the edge of the table; and on these roll the two extremes of a kind of roller, or hollow heavy cylinder of copper, turned after being cast, and about five pounds in weight, which serves to drive the liquid matter before it to the end of the table, or mould. The iron rollers being moveable, and capable of being set closer, or farther apart, at pleasure, determine the width of the glais, and retain the matter, that it does not run off at the edges. The waste glais, if any, falls into a vessel of water, and is reserved for the next melting.

As soon as the matter is arrived at the end of the table, and the glais is come to a consistence, examined by the directors of the manufacture, and approved, they shove it off into the annealing furnace, with an iron raker, as wide as the table, that has a handle two fathoms long; being assisted by workmen on the other side of the carquaise, who, with iron hooks, pull the glais to them, and range it in the carquaise, which holds fixed large glais.

What is most surprising throughout the whole of this operation, is the quickness and address with which such many cisterns, filled with a flaming matter, are taken out of the furnace, converted to the table, and poured on it, the glais spread. It. The whole is inconceivable to such as have not been eye-witnesses of that surprising manufacture.

As fast as the cisterns are emptied, they carry them back to the furnace and take fresh ones, which they employ as before. This they continue to do, so long as there are any full cisterns; laying as many plates in each carquaise as it will hold, and stopping them up with doors of baked earth, or clay, and every chink with cement, as soon as they are full, to let them anneal, and cool again, which requires about fourteen days.

The first running being dispatched, they prepare another by filling the cisterns anew, from the matter in the pots; and after the second, a third, and even a fourth time, till the melting pots are quite empty.

The cisterns at each running should remain at least six hours in the furnace to whiten; and when the first annealing furnace is full, the casting table is to be carried to another. It need not here be observed, that the carquaises, or annealing furnaces, must first have been heated to the degree proper for them. It may be observed, that the oven full, or the quantity of matter commonly prepared, supplies the running of eighteen glaises, which is performed in eighteen hours, being an hour for each glais. The workmen work six hours, and are then relieved by others.

When the pots are emptied, they take them out, as well as the cisterns, to scrape off what glais remains, which otherwise would grow green by continuance of fire, and spoil the glaises. They are not filled again in less than thirty-six hours, so that they put the matter into the furnace, and begin to run it every fifty-four hours.

The manner of heating the large furnaces is singular enough; the two tilters, or percons employed for that purpose, in their shirts, run round the furnace without making the least stop, with a speed scarse inferior to that of the lighted courier: as they go along, they take two billets, or pieces of wood, which are cut for the purpose; these they throw into the first tillator, and continuing their course do the fame for the second. This they hold without interruption for six hours successively; after which they are relieved by others.

It is surprising that two such small pieces of wood, and which are consumed in an instant, should keep the furnace to the proper degree of heat; which is such, that a large bar of iron, laid at one of the mouths of the furnace, becomes red-hot in less than half a minute.

It is computed, that a furnace, before it he fit to run glais, costs above three thousand and one hundred pounds; that at least six months are required for the building it anew, and three months for the retouching it; and that when a pot of matter bursts in the furnace, the loss of matter and time amounts to above two hundred and fifty pounds.

The glais, when taken out of the melting-furnace, needs nothing farther but to be ground, polished, and polished. But before these operations are performed, they cut and square the edges of the plates; which is performed with a rough diamond, pulled along the surface of the glais, upon a square ruler, like that of the glaisers, and made to cut into the substance of the glais to a certain depth. This cut is then opened by gently knocking with a small hammer on the under side of the glais, just under it; by which means the piece comes off, and the roughness of the edges are removed by pincers. The plates are then laid by for grinding.
GLASS.

Looking-Glass.

Glass, Annealing or Nealing of. The operation of annealing of glases is performed in a peculiar furnace called the anneal, which consists of two parts, the tower and hearth. The vessels, as soon as made, are placed by the workmen on the floor of the former to anneal: which done, they are drawn slowly in a sort of pan, called a frakter, by an operator called the hard-man, all along the latter, the space of five or six yards, to give them time to cool gradually; so that when they reach the mouth of it, they are found quite cold. Merret, Not. to Neri, p. 243, seq.

This annealing is generally performed in a hot chamber, built for the purpose, at the top of the glases-house, above the crucibles, and a little below the chimney. Without this precaution, the glases would be liable to fly and break, by the least change of heat and cold, by the smallest scratch, and sometimes without any apparent external cause. The hard glases, and those especially that are made with alkali and earths, require much more annealing than the softer and more fusible glases, containing in their composition much litharge.

The particles of glases by annealing are supposed to lose part of their springiness, and their brittleness at the same time. A gradual heating or cooling of glases, according to Dr. Hook, anneals or reduces its parts to a texture more loose, and can to be broken; but withal more flexible than before. And hence in some measure the phenomena of glases drops.

Some of the phenomena depending on the fragility of unannealed glases deserve the attention of the curious. Those of the lacrymæ, or glases-drops, were among the first taken notice of; and it has also been observed, that hollow bells made of unannealed glases, with a small hole in them, will fly to pieces by the heat of the hand only, if the hole by which the internal and external air communicate be stopped with a finger. Phil. Trans. No. 477. § 3. See Rupert's Drops.

But lately some vessels made of such unannealed glases have been discovered, which have the remarkable property of refilling very hard brokes given from without, though they shiver to pieces by the shocks received from the fall of very light and minute bodies dropped into their cavities. Of this kind is the "Bologna phial." These glases may be made of any shape; all that needs be observed in making them, is to take care that their bottoms may be thicker than their sides. The thicker the bottom is, the easier do the glases break. One whole bottom is three fingers breadth in thickness, filled with as much eafant leaff as the thinnest glass. Some of these vessels have been tried with brokes of a mallet sufficient to drive a nail into wood tolerably hard, and have resist'd fracture. They also refill the shock of several heavy bodies let fall into their cavities, from the height of two or three feet. For instance, market-balls, pieces of iron, or other metal; pyrites, jasper, wood, bone, &c.; but this is not surprizing, as other glases of the same fize do the fame. But the wonder is, that taking a flierten of flint of the fize of a small pea, and letting it fall into the glases only from the height of three inches, in about two seconds the glasa flies, and sometimes in the very moment of the shock; any a bit of flint, no larger than a grain, drop into several glases successively, though it did not immediately break them, yet they all flew, being set by, in less than three quarters of an hour. Phil. Trans. ibid. p. 509.

Some other bodies produce a like effect with flint: for instance, sapphire, porcelain, diamonds, hard tempered iron, as also marbles, such as boys play with; to which add pearls from the animal kingdom.

The experiment succeeded also when the glases were held in the hand, reflect on a pillow, put in water, or filled with water. It is also remarkable, that the glases broke upon their bottoms being slightly rubbed with the finger, though some of them did not fly till half an hour after the rubbing.

If the glases be every where extremely thin, they do not break in these circumstances.

Some have pretended to account for these phenomena, by saying, that the bodies dropped into these vessels cause a concussion, that is stronger than the cohesion of the parts of the glases, and that consequently a rupture of the same must ensue. But why does not a ball of gold, silver, iron, copper, or several other bodies, even a thousand times heavier than a fliver of flint, equally cause this concussion, and break the glases?

Mr. Euler has endeavoured to account for these appearances from his Principles of Percussion. He thinks this experiment entirely overthrows the opinion of those who measure the force of percussion by the vis viva; and he thinks the principles he has established give a clear solution of this phenomenon. According to these principles, the extreme hardnes of the flint, and also its angular figure, which makes the space of contact with the glases veffel extremely small, ought to cause an impression on the glases vastly greater than lead or any other metal; and this may account for the flint's breaking the veffel, though the bullet, even falling from a considerable height, does no damage. Mem. Acad. Berlin, 1745. p. 47.

Hollow cups, made of the green bottle-glasses, some of them three inches thick at bottom, were instantly broken, by a fliver of flint weighing about two grains, though they had refilled the shock of a musket ball from the height of three feet. Phil. Trans. ibid. p. 515.

"The specific mechanical cause of this disposition to crack in unannealed glases, is very difficult to explain," says Aikin (Dià.), "but generally speaking, it is suppos'd to be the forcible contraction of the outer part by fuddled cooling, whilft the inner portion is still soft and half-fluid, fo that the whole fixes with a permanent strain or inequality of preffure, on one part upon the other; and as glases is extreme-ly elaftic, though brittle, any force which teares ofnder a portion, however small, of the teafe part, communicates a strong and fudden impulfe over the whole mafs." "This mott singular phenomenon," (of the Rupert's drop) says the fame ingenious chemist, in confequence of his own experiments, "is obviously owing to some permanent and very strong inequality of preffure, for when they are heated fo red, as to be loft and merely let to cool of themselves, this property of bufting is entirely loft, and, at the fame time, the specific gravity of the drop is increas'd. The peculiar brittlenes of the Bologna phial is also removed by again heating and cooling slowly." The common window-glasses, when badly annealed, is cut by the diamond with difficulty, and the cut often flies in a direction different from what was intended, or the glases entirely breaks.

Among other more common defects of glases, we may mention its liability to be acted upon by corrosive liquors, as is the case when too much fulminate has been used. As imperceptible as glases is to the common meultrums, we find it eaten by the air in length of time, when exposed in old windows; but the effects of its being kept in a subterraneous place are much more strange. Borrichius tells us, that at the
the time when he was at Rome, there was dug up a whole house from under the kitchen garden of a citizen. The house had been buried there ten ages, and there were found in it several glafs urns, or lacrymatories. The glafs of these had no holes made in it, as our old glafs in chamber-windows has, but still retained its smooth surface and transparency; but it was split into a vast number of thin laminae, which were as pellucid and fine as Muscovy glafs; and in some places were tinged with all the beautiful colours that art could have given. We are not acquainted perfectly with the ancient way of working their glafs; but it is not probable there could be any thing particular in the formation of the vessel, to determine it to split thus into flakes; but that glafs of the fame kind, in any form, would have done the fame. Borrich, de Ortu Chemicz.

There are other visible imperfections in glafs, materially injuring its foundness and beauty, and enumerated by Aikin (Dict. art. Glafs) under the denominations of friza, threads, tears, and knots. The former are undulating waves in the glafs, arising from the imperfect mixture of the materials, and their different specific gravities. Accordingly, we may observe, that the most transparent glafs is subject to bubbles and veins, the methods of preventing which are yet little known; and this is an inconvenience by which Mr. Dollond's excellent discovery is affected; for the flint-glafs which he uses is peculiarly subject to small veins, that disturb the rays entering their passage, and render the vision confused. This effect is owing to the density of these veins being greater than that of the rest of the glafs, as appears from their image received on white paper, when the glafs is hold between the paper and a candle, or other luminous object; for this image of a vein, thus received, is a line brighter than the rest of the image of the glafs, and this bright line is defined by a dark edge on each side. But the bright line evidently shows a convergency of rays, which can only be effected by the veins being denser than the medium in which they are placed. The reason why flint glafs is more subject to veins than other glafs is, says the translator of Macquer's Chemical Dictionary, because it is compos'd of materials of more different densities.

Mr. Macquer, with a view of improving the manufacture of this glafs, proposes to facilitate the union of the calx of lead and sand, of which it is compos'd, by depriving the calx of lead, as much as possible, of its phlogiston, which may be done by combining the vitriolic acid with nitre, or red-lead, and exposing this composition to the operation of fire, to difengage it from the acid; and also by giving these two substances the greatest possible degrees of fluidity and mobility, which may be done by mixing with the composition of them a considerable quantity of solvents. Hill. Acad. Science, for 1773.

Threads in glafs, are those fleery filaments which arise from the vitrification of the clay; being generally green, and rendering the glafs more liable to crack at these parts. But one of the worst defects (says Aikin, uti supra), is tears, or drops of vitrified clay falling down from the furnace into the pots, and entangled with the glafs. Articles made of glafs with this defect, are always very brittle, and generally break of themseles by slight changes of heat and cold. Small bubbles appear in glafs not sufficiently refined by a continuance of the melting heat; and these may be owing to a deficiency of flux, so that the glafs is less fusible, and the bubbles cannot easily be disengaged. "Hence," says the author now cited, "the soft fusible glafs with much lead are much liable to this fault than the hard, green bottle-glafs, which is made only of alkali and earth." The last in glafs "are either from a portion of sand that has escaped vitrification, and remains entangled in the glafs, or from a remaining quantity of glafs-gall; or from bits of the crucible which may be accidentally knocked off by the iron instruments used in the working."
hard of shining: for, in this case, the strong fire will destroy
the colouring substance before the glass melts, and he has
found the following compositions to be nearly the best: viz.
face two parts, alkali three parts; or find two, alkali
three, calcined borax one; or, instead of alkali, two, alkali
two, calcined borax one: and though salt-petre is hardly
used at all, or very sparingly, for yellow glasses, as
it too much volatilises the colouring substance; yet here
for the most part a certain proportion of it, easily determined
by trial, is very necessary; for without it, the concentrated
colouring matter is apt to make the glass too dark, and even
of an opaque pitchy blackness. It does not certainly appear
that there is any material diversity in the effects of different
colours, the difference being probably owing to the different
quantities of the inflammable matter which they contain;
so that a little more shall be required of one kind than of
another, for producing the same degree of colour in the glass.
Nor does the fluidness or stickiness of the wet appear to be in
any respect necessary.

Gold-coloured spangles may be diffused through the sub-
fstance of glasses, by mixing the yellow tinctures with powdered
glasses, and bringing the mixture into fusion. See Lewis’s
Com. Phil. Techn. p. 222, 626, &c.

Glass resembling gold. See Orf. and G M s.

Glass, Ruby. The way to give the true fine red of the
ruby, with a fair transparence, to glasses, is as follows. Cal-
cine in earthen vessels gold dissolved in aqua regia, the men-
struum being evaporated by distillation, more aqua regia added,
and the abstraction repeated five or six times, till it becomes
a red powder. This operation will require many days in a
hot furnace; when the powder is of a proper colour, take it
out; and when it is to be used, melt the skillful crystal-glass,
and purify it, by often canceling it into water; and then add,
by small quantities, enough of this red powder to give it
the true colour of a ruby, with an elegant and perfect tran-
sparence. Neri. See Gems.

The process of tinging glasses and enamels by preparations
of gold, were first attempted about the beginning of the 17th
century. Libavius, in one of his tracts, entitled Alchemia,
printed in 1626, conjectures that the colour of the ruby pro-
cedes from gold, and that gold dissolved, and brought to red-
fens, might be made to communicate a like colour to facitious
gems and glasses. On this principal Neri, in his "Art of Glafs," dated 1611, gives the process above rectified. Gla-
aber, in 1648, published a method of producing a red colour
by gold, in a manner which is of the vitreous kind, though not
perfect glases. For this purpose he ground powdered flint or
sand with four times its weight of fixed alkaline salt; this
mixture melts in a moderately strong fire, and when cold
looks like glass, but exposed to the air runs into a liquid
state. On adding this liquor to solution of gold in aqua regia,
the gold and flint precipitate together in form of a yellow
powder, which by calcination becomes purple; by mix-
ing this powder with three or four times its weight of the
alkaline solution of flint, drying the mixture, and melting it
in a strong fire for an hour, a mass is obtained, of a transparent
ruby colour, and of a vitreous appearance, which nevertheless
is soluble in water, or by the moifure of the air, on ac-
count of the redundancy of the salt. The honourable Mr.
Boyle, in a work published in 1682, mentions an experiment,
in which a like colour was introduced into glasses without
fusion; for, having kept a mixture of gold and mercury in
digression for some months, the fire was at last immediately
increased, so that the glass burst with a violent explosion;
and the lower part of the glasses was found tinged throughout
of a transparent red colour, hardly to be equalled by that of
rubies. See Porphyry of Bodies, in Shaw’s Abridgment of
Boyle’s Works, vol. i. p. 459; and Appendix to the Skep-
tical Chemist.

About the same time Caffius is said to have discovered the
preparation of gold by tin, and that glasses might be tinged of
a ruby colour by melting it with this precipitate: though
he does not appear, says Dr. Lewis, from his treatise De
Auro, to have been the discoverer of either. He describes
the preparation of the precipitate and its use, but gives no
account of the manner of employing it; only that he says,
one dram of gold, duly prepared, will tinge ten pounds of
glasses. See Gold precipitate with tin.

This process was soon after brought to perfection by
Kunckel; who says, that one part of the precipitate is sufficient
to give a ruby colour to 120 or parts of glasses, and a feitible
red to upwards of 1500 parts; but that the success is by
no means constant. Kunckel also mentions a purple-gold
powder, resembling that of Neri, which he obtained by ini-
nitrating solution of gold to dryness, abstracting from it
fresh aqua regia three or four times, till the matter appears
like oil; then precipitating with strong alkaline leys, and
washing the precipitate with water. By diffusing this pow-
der in spirit of salt, and precipitating it again, it becomes,
he says, extremely fair; and in this state he directs it to be
mixed with a due proportion of Venice glasses.

Orfekl in his treatise entitled Sol solm Velle, gives the
following process for producing a very fine ruby. He di-
 rects the purple precipitate, made by tin, to be ground with
fix times its quantity of Venice glases into a very fine powder,
and this compound to be very carefully mingled with the frit
or vitreous composition to be tinged. His frit consists of
equal parts of borax, nitre, and fixed alkaline salt, and
times as much calcined flint of each of the salts; but he
gives no directions as to the proportion of the gold precipi-
tate, or mode of fusion. Heliot describes a preparation,
which mixed with Venice glases, was found to give a beau-
tiful purple enamel. This preparation consists of equal parts
of solution of gold, and of solution of zinc in aqua regia,
mixed together with the addition of a volatile salt pre-
pared from sal ammoniac in quicksilver, in sufficient quantity
in order to precipitate the two metals. The precipitate is then
gually heated, till it acquires a violet colour. However,
though a purple or red reed, approaching to that of ruby,
may, by the methods above rectified, be baked on glasses or
enamels, and introduced into the mass by fusion, the way of
equally diffusing such a colour through a quantity of frit
or glass is still, says Dr. Lewis, a secret. The following pro-
cesses for making the ruby glasses was communicated to Dr.
Lewis by an artist, who ascribed it to Kunckel. The gold
is directed to be diffused in a mixture of one part of spirit
of salt, and three of aqua-fortis, and the tin in a mixture of
one part of the former of these acids with two of the latter.
The solution of gold being properly diluted with water (see
GOLD precipitate, &c.) the solution of tin is added, and
the mixture left to stand till the purple matter has settles to
the bottom. The colourless liquor is then poured off, and
the purple sediment, while moist and not very thick, is thorou-
ghly mixed with powdered flint or sand. This mixture is
well ground with powdered nitre, tartar, borax, and arsene, and
the compound melted with a suitable fire. The proportions
of the ingredients are 2560 parts of sand, 384 of nitre, 240 of
tartar, 240 of borax, 28 of arsene, 5 of tin, and 5 of
gold. Lewis’s Com. Phil. Techn. p. 171, 621, &c.

Glass, white-opaque, and semi-transparent, may be made of
ten pounds of either of the compositions for hard glasses, and
GLASS.

One pound of well calcined horn, ivory, or bone; or an opaque whiteneifs may be given to glasses, by adding one pound of very white arsenic to ten pounds of flint glass. Let them be well powdered and mixed, by grinding them together; and then fused with a moderate heat, till they are thoroughly incorporeted. A glass of this kind is made in large quantities at a manufactury near London, and used only for differant kinds of vessels, but as a white ground for crystal in dishes, plates and snuff-boxes, which do not require finishing with much fire, because it becomes very white and fusible with a moderate heat.

Glass. Yellow. See Golden-coloured Glass.

Glass-balls, which are circular or otherwise shaped hollow vesels of glasses, may be coloured within, so as to imitate the semi-opaque gems. The method of doing it is this: make a strong solution of ichthyocolla, or safas, in common water, by boiling; pour a quantity of this warm into the hollow of a white glass vesel; shake it thoroughly about, that all the fides may be wetted, and then pour off the rest of the moisture. Immediately after this, throw in red lead, shake it and turn it about, throw it into many places with a tube, and the moisture will make it stick and run in waves and pretty figures. Then throw in some of the painter's blue earth, and make it run in waves in the ball as the red-lead; then do the same with verdigris, next with orpiment, then with red lake, all well ground; always casting in the colours in different places, and turning the glass, that the moisture within may run them into the waves. Then take fine plaster of Paris, and put a quantity of it into the ball; shake it also nimby about; this will even when fick firmly to the glasses, and give it a strong inner coat, keeping all the colours on very feaily and strongly.

These are set on frames of carved wood, and much embellished as ornaments in many places. Neri.

Glass-strops. See Rupert's glass.

Glass-gall, or sandiver, is the flour of the glasses pots, which arises during the vitrification of the frit. See Glass, super.

Glass, gilding of. See Gilding of enamcl and glasses.

Glass, grinding of. See Grinding.

Glass-house Furnaces, is the place in which the ingredients or materials of glasses are fused and vitrified. There are three kinds of furnaces used in the glass-marts. The firt, called the "calcur," serves for preparing or calcining the frit. It is made like an oven, 10 feet long, seven broad, and two deep. The fuel, which is sea-coal, is put in a trench, on one side of the furnace; and the flame reverberates from the roof back upon the frit. The coals burn in an iron grate, and the ashes fall thence into holes underneath.

The second is the "working furnace," in which the ingredients are melted, and the glasses is made. Its figure is round, resembling a domed, three yards in diameter, and two high, supported on arches, beneath which is a large space for a brick and copious draught of cold air from without: round the inside there are arranged eight or more pots, on these piling-pots, every where chould except at one side opening, which communicates with a small recess formed by the alternate projections of the masonry and lines of the oven or kiln, which rests on the stone-bench. The furnace has two partitions; the lower, terminating the pots from the fire-places, has a circular hole in the centre covered with a grate, through which the fames pass from the fire-place into the furnace, being afterwards reverberated from the arches fides and roof to the melting-pots, and passing out with the fume through the top of the dome, which is lengthened into a chimney for the space of a few feet. The second partition divides this from the hearth or annealing furnace; through the beccas, or working holes, when there are more than one, the metal is taken out of the pots, and the pots put into the furnace; these beccas are stopped with moveable covers, made of slate and brick to screen the eyes of the workmen from the fire; and sometimes on each side of the becca is a round end, out of which coloured glasses, or finer metal is taken from the piling-pot. To the furnace likewise occasionally belong ovens, or holes near the hearth, for the calcining of tartar, iron, &c.

The hearth, which furnishes to anneal and cool the vessels, and which Agricola makes a particular furnace, consists of a tower, before the becca; the hearth lies directly over the melting furnace, with a partition between them about a foot thick, having an aperture called "cella," or "fumella," through which the flame or heat ascends out of the furnace into the tower; or on the floor or bottom of this tower, the vessel, fashioned by the artist, is set to be annealed; and as the flame has here a less degree of intensity than that which is fertilized by the pots, the vessels, after they have been formed, cool slowly and gradually. This has usually two beccas, or mouthes, by which the glasses are put in with a fork, and placed on the floor. The hearth is an avenue, five or six yards long, continued to the tower; through this the glasses, when annealed, are drawn in iron pots, called scrapes, by which they come to cool by degrees, being quite cold at the time they reach the mouth of the hearth, which enters the "farcilo," or room where the glasses are to be fet.

The third is the "green-glass furnace," which is a kind of compound of all the former. It is made square, (the two former being circular,) having an arch at each angle for annealing and cooking the glasses. The metal is wound on two opposite sides, and on the two others they have their Calcs, into which are made linnet-holes for the fire to come from the furnace, to bake the frit, and also to discharge the flame. Fires are made in the arches to anneal the vessel, so that the whole process is done in one furnace.

The materials with which the inside of these furnaces are constructed are not ordinary brick (which would soon melt down into glasses, as would also all the other fumes,) but hard and sandy kinds, called by Imperators "pyramida." But when bricks are used, they should be formed of an earth which coalesces in the highest degree the qualities of density and inertibility, for retaining the fire, which continues to act upon them, without combustion for a long time; as the fires in a glass-house are seldom suffered to go out, from the time when the furnace is first employed till it needs repair, and the interval may be two or three years: the walls of the furnace, for this reason, as well as the pots, are constructed chiefly of clay, mixed with sand, and other materials of a refractory kind, in due proportion. See Glass-pots.

Glass of lead, a glass made with the addition of a large quantity of lead, of great use in the art of making counter-gems. The method of making it is thus: put a large quantity of lead into a potter's kiln, and keep it in a state of fusion with a moderate fire, till it is calcined to a grey, lumpy powder; then spread it in the kiln, and give it a greater heat, continually stirring it, and by frequent passages into lamps, continue this several hours, till the powder becomes of a yellow, and then take it out and sift it fine: this is called calcined lead.

Take of this calcined lead fifteen pounds, and crystalline, or other frit, twelve pounds; mix these as well as possible together; put them into a pot, and let them in the furnace for ten hours; then cool the whole, which will be now perfectly melted, into water; separate the loose lead from it, and return the metal into the pot; and after standing in fusion.
fusion twelve hours more, it will be fit to work. It is very tender and brittle, and must be worked with great care, taking it slowly out of the pot, and continually wetting the marble it is wrought upon. Neri.

It is well known, that ceraüs, or white lead, minimum, litcharge, and all the other preparations and colours of lead, are easily fused by a moderate fire, and formed into a transparent glass of a deep yellow colour. But this glass is so penetrating and powerful a flux, that it is necessary to give it a greater confidence, in order to render it fit for use. With this view, two parts of calc of lead, i.e. minimum, and other parts of fand, or powdered flints, may be put into a crucible of refractory clay, and baked into a compact body. Let this crucible, well closed with a luted lid, be placed in a melting furnace, and gradually heated, for an hour, or an hour and a half; and afterwards let the heat be increased, so as to obtain a complete fusion, and continued in that state for the same time: let this crucible remain to cool in the furnace, and when it is broken, a very transparent yellow-coloured glass will be found in it. Some add nitre and common salt to the above mixture, because these salts promote the fusion and the more equal distribution of the fand. This glass of lead has a considerable specific gravity, and its lowest part is always the heaviest. It is an important flux in the alloys of ores to facilitate their scorifications.

Glas of lead is capable of all the colours of the gems in very great perfection. The methods of giving them are these: for green, take poverine frit twenty pounds, lead calcined sixteen pounds; sift both the powders very fine; then melt them into a glas, separating the unmixed lead, by plunging the mass in water; after this return it into the pot, and add brass threes calcined fix ounces, and one penny-weight of crocus martis made with vinegar; put this in at six different times, always carefully mixing it together; let it finally settle an hour; then mix it together, and take a proof of it; when the colour is right, let it stand eight hours, and then work it. If instead of the calcined brass the same quantity of the caput mortuum of the vitriolum veneris be used, the green is yet much finer.

For topaz-colour take crystal frit fifteen pounds, calcined lead twelve pounds; mix them well together, by siftting the powders through a fine sieve; then let them in a furnace not too hot, and separate the superfluous unmixed lead, by calling the whole into water; repeat this twice; then add half gold yellow glas, and let them incorporate and purify, and they will be of the true and exact colour of the original topazes.

For sea-green, take crystal frit sixteen pounds, calcined lead ten pounds; mix them well together, and let them in a pot in a furnace; in twelve hours the whole will be melted; then call it into water and separate it from the loose lead; put them into the furnace again for eight hours; then separate the loose lead by washing a second time, and return it to the pot for eight hours more. Neri. See Gems.

Glass, Painting in. The primitive manner of painting in glas was very simple, and of consequence very elegant; it consisted in the mere arrangement of pieces of glas of different colours, in some fort of symmetry; and constituted a kind of what we call Mosaic work.

Afterwards, when they came to attempt more regular designs, and even to represent figures raked with all their nuances, their whole address went no farther than to the drawing of the contours of the figures in black, with water colours, and hatching the draperies, after the same manner, on glases of the colour of the object intended to be painted. For the carnations, they chose glases of a bright red; upon which they designed the principal lineaments of the face, &c. with black.

At last the taste for this sort of painting being considerably improved, and the art being found applicable to the adorning of churches, basilicas, &c. they found means of incorporating the colours with the glas itself, by exposing them to a proper degree of fire, after the colours had been laid on.

A French painter at Marfilles is said to have given the first notion hereof, upon going to Rome, under the pontificate of Julius II. But Albert Durer, and Lucas of Leyden, were the first that carried it to any height.

The colours used in painting on glas are very different from those used either in painting in oil, or water.

The black is made of two-thirds of flakas, or scales of iron, beaten up, and mixed with another third of rocaile, or little glas beads. White, with fand, or little white pebbles, calcined, pounded in a mortar, and afterwards ground on marble; with one fourth-part of salt-petra, added thereof, and the mixture calcined and pulverized over again: to which, when they are ready to use it, is added little gypsum, or plaster of Paris well ground, &c. For yellow, they use lead-silver ground, mixed up in a crucible, with sulphur or salt-petra; then well beaten and ground on a porphyry stone; and, at length, ground over again with nine times as much red ochre. Red is made of litharge of silver, and scales of iron, gum Arabick, feret, glas-beads, and blood-ore, nearly in equal quantities. This is one of the most difficult colours, and the preparation only to be learned by experience. Green is made of azutum, one ounce; as much black lead, and four ounces of white fand, incorporated by the fire. After calcination, they add a fourth part of salt-petra: after a second calcination, a sixth part more: after which they make a third coction before it is used. Aures, purple, and violeta, are prepared like green, only leaving out the azutum, and in the lien thereof using sulphur for azure; perigueux for purple; and both these drugs for violet. Carnations are made of feretta and rocaile. And lastly, colours for the hair, trunks of trees, &c. are made of feret, rocaile, &c.

This account of colours we have from M. Felibiens excellent work Des Principes d'Architecture, &c. though it must be owned, that all the painters on glas do not use them; there being few artists of that kind but have invented their own particular ones, whereas they usually make secret colors. But this is certain, that those above described are sufficient for the best paintings of all sorts; provided the perfon has but the skill to manage them.

In the windows of divers ancient churches, chapels, colleges, &c. we meet with the most beautiful and lively colours imaginable; such as far exceed any used among us: but it is not that the secret of making those colours is lost; but that the moderns would not go to the expense of them; nor take all the necessary pains; because this sort of painting is not now so much esteemed as formerly.

Mr. Walpole, in his Anecdotes of Painting in England, has traced the history of this art from the reformation, when misguided zeal destroyed most of the monuments of it in our churches, through a seies of profilers to the present time. Among the later proficients in this art were Isaac Oliver, who painted the windows at Christchurch, Oxford, in 1709; William Price, who in the same year painted the windows in Merton chapel; William Price, the fon, to whose art we owe the windows at Queen's, New-college, and Maudlin, of whom Mr. Walpole says, that his colours are fine, his drawing good,
GLASS.

good, and his taste in ornaments and Mosaic far superior
to any of his predecessors, and equal to the antique.
In 1761, Mr. Pateron, an antiquary late of Exell-house
in London, exhibited the two first auctions of painted glases
imported from Flanders; and undertook also to establish a
manufacture of painted glases: several of the pieces of this
ingenious artist exhibited colours vying in perfection with
the old paintings.

Thefe beautiful works, among the painters in glases, which
were made in the glase-house, were of two kinds: in some,
the colour was diffused through the whole body of glases;
in others, which were the more common, the colour was
only on one side, scarce penetrating within the substance
above one-third of a line; though this was, more or lefs,
according to the nature of the colour; the yellow being al-
ways found to enter the deepest.

Thefe last, though not fo strong and beautiful as the
former, were of more advantage to the workmen: becaufe,
on the fame glases, though already coloured, they could
now other kinds of colours, where there was occasion to embroider
draperies, enrich them with foliages, or repreff other or-
naments of gold, silver, &c.

In order to this, they made ufe of emery; grinding, or
wearing down the surface of the glases, till fuch time as
they were got through the colour, to the clear glases: this
done, they applied the proper colours on the other side
of the glases. By this means the new colours were pre-
vented from running and mixing among the former, when
the glases came to be expos'd to the fire, as will hereafter
be fhewn.

When the intended ornaments were to appear white, or
filvered, they contented themselves to bare the glases of its
colour with emery, without applying any new colour at all;
and it was in this manner that they wrought the lights and
heightenings on all kinds of colours.

The painting with vivid colours on glases depends en-
tirely on the fame principles as painting in enamel; and
the manner of executing it is likewise the fame; except
that in this the transparency of the colours being indif-
penfibly requisite, no fubfiances can be ufed to form them
but fuch as vitrify perfectly; and, therefore, the great
object is to find a fett of colours, which are composed of
fuch fubfstances, as, by the admixture of other bodies,
may promote their vitrification and fufion; are capable of
being converted into glases; and melting, in that flate,
with lefs heat than is fufficient to melt fuch other kinds
of glases as may be cho'en for the ground or body to be
painted; to temper these colours, fo as to make them
proper to be worked with a pencil; and to burn or reduce
them by heat, to a due flate of fufion, without injuring
or melting the glaces which confiitutes the body painted.
The firft thing to be done, in order to paint on glases,
in the modern way, is to defign, and even colour, the
whole subject on paper. Then they make choice of pieces
of glases proper to receive the feveral parts, and proceed
to divide or diftribute the defign itself, or the paper it is
drawn on, into pieces suitable to thofe of glases; having
always a view that the glases may join in the contours
of the figures, and the folds of the draperies; that the
emotions and other finer parts may not be damaged by
the lead wherewith the pieces are to be joined toge-
ther.

The distribution being made, they mark all the glases,
as well as papers, with letters, or numbers, that they
may be known again; which done, applying each part
of the defign on the glases intended for it, they copy or
transfer the defign upon this glases, with the black colour,
diluted in gum-water; by tracing and following all the
lines and strokes, as they appear through the glases, with
the point of a pencil.

When these firft strokes are well dried, which happens
in about two days, the work being only in black and
white, they give it a glact wash over, with urine, gum
Arabic, and a little black; and this feveral times repeated,
according as the shades are defired to be heightened:
with this precaution, never to apply a new wash, till the
former is sufficiently dried. This done, the lights and
shadings are given, by rubbing off the colour in the refpe-
tive places, with a wooden point or the handle of the
pencil.

As to the other colours above-mentioned, they are ufed
with gum-water, much as in painting in miniature; taking
care to apply them lightly, for fear of effacing the out-
lines of the defign; or even, for the greater fecurity, to
apply them on the other side, efpecially yellow, which
is very pernicious to other colours, by blending the-
with.

And here too, as in pieces of black and white, parti-
cular regard must be always had, not to lay colour on co-
our, or lay on a new lay, till fuch time as the former are
well dried. It may be added, that the yellow is the only
colour that penetrates through the glases, and incorporates
therewith by the fire; the red, and particularly the blue,
which is very difficult to ufe, remaining on the surface,
or at leaft entering very little. When the painting of all
the pieces is finifh'd, they are carried to the furnace or
oven, to anneal or bake the colours. The furnace here
ufed is small, built of brick, from eighteen to thirty inches
square: at fix inches from the bottom is an aperture, to
put in the fuel, and maintain the fire. Over this ap-
erture is a grate, made of three fquare bars of iron, which
traverse the furnace, and divide it into two parts. Two
inches above this partition is another little aperture, through
which they take out pieces, to examine how the coaction
goes forward.

On the grate is placed a fquare earthen pan, fix or seven
inches deep; and five or fix inches lefs, every way, than
the perimeter of the furnace. On one side hereof is a
little aperture, through which to make the trials, placed
directly opposite to that of the furnaces defined for the
fame end.

In this pan are the pieces of glases to be placed in the
following manner: firil, the bottom of the pan is covered
with three ftrata, or layers of quicklime, pulverized;
thefe ftrata being feparated by two others, of old broken
glases: the defign whereof is to secure the painted glases
from the too intense heat of the fire. This done, the glases
are laid horizontally on the lab, or uppermost, layer of
lime.

The firil row of glases, they cover over with a layer of
the fame powder an inch deep; and over this they lay an-
other range of glases: and thus alternately, till the pan is
quite full; taking care that the whole heap always ends
with a layer of the lime-powder.

The pan thus prepared, they cover up the furnace with
tiles, or on a fquare table of earthenware, closely luted
all round; only having five little apertures, one at each
corner, and another in the middle, to serve as chime-
neries.

Things thus disposed, there remains nothing but to give
the fire to the work. The fire for the two firft hours muft
be very moderate; and must be increased in proportion
as the coaction advances, for the space of ten or twelve
hours; in which time it is ufually completed. At laft,
GLASS.

the fire; which at first was only of charcoal, is to be of dry wood: so that the flame covers the whole pan, and even flares out at the chimneys.

During the first hours, they make affays from time to time, by taking out pieces laid for that purpose, through the little aperture of the furnace, and pan, to see whether the yellow be perfect, and the other colours in good order. When the annealing is thought sufficient, they proceed with great haste to extinguish the fire, which otherwise would soon burn the colours, and break the glasses. See Painting.

GLASS; painting on, by means of prints. See Back-printing.

GLASS; polishing of. See Polishing; and Grinding.

GLASS; porcelain, the name given by many to a modern invention of imitating the china-ware with glafs. The method given by M. Reaumur, who was the first that carried the attempt to any degree of perfection, is delivered by that gentleman in the Memoirs of the Academy of Sciences of Paris, to this effect. This change of glafs was first taken notice of by Neumann, who, in distilling milk in a glafs retort, observed, that the bottom of the vessel acquired the appearance of porcelain, which he attributes to the fine white earthy matter of the milk forced into the glafs by heat. Neum. Chem. Works, by Dr. Lewis, p. 57.

The mixing of glafs reduced to powder, with other lefs easily vitrifiable substances for forming a paste, to be afterwards made into a fort of porcelain, has been a contrivance long practised, but it is very troublesome, and the result subject to many faults; but this new ware is made of glafs alone, and that with much less trouble, and without the reducing it to powder. By this art, vessels of glafs are changed into vevels of a fort of porcelain, without altering their form, and the meanest glafs made only of sand, lime, and flaine ashes, serves as well as the best for that purpose: our common coarse green quartz-bottles, or the great bell glafs with which gardeners cover their melons, &c. being by this means changeable into a beautiful white fort of porcelain ware; and this is to be done in so easy a manner, and with so small expense, that it requires no more trouble or charge, than that of baking a common vevel of our coarse earthen-ware; and for this reason the vevels of this fort of ware may be afforded extremely cheap.

It is very certain, that all porcelain ware is a suffibance in the flate of semi-vitrification; and in order to bring glafs, which is a wholly vitrifiable substance, into the condition of porcelain, there requires no more than to reduce it to a lefs perfectly vitrified flate.

The question which would naturally be started on this occasion, is, whether it be possible to reduce glafs to a lefs vitrified flate, it having already undergone what is esteemed the last change by fire. But when we consider, that the mats of antimony, the vitrifications of many of the metals, as the glafs of lead, and the counterfeit gems coloured by the metals, are more or lefs easily reduced again by chemicity to metals, &c. the reducing of sand, flints, &c. after they are vitrified, at least a little way back toward their native or primitive flate, may appear not wholly impracticable, and the attempts which M. Reaumur made on this occasion, were what gave him the first hints of the glafs-porcelain; called from his name "Reaumur's porcelain."

The method of making it is this. The glafs vevels to be converted into porcelain are to be put into a large earthen vevel, such as the common fine earthen dishes are baked in, or into sufficiently large crucibles; the vevels are to be filled with a mixture of fine white sand, and of fine gysph or glider-Rose burnt into what is called flatter of Paris; and all the interfaces are to be filled up with the fame powder: so that the glafs vevels may no where touch either one another, or the sides of the vevel, they are baken in. The vevel is to be then covered down and liuted, and the fire does the rest of the work; for this is only to be put into a common potter's furnace, and when it has stood there the usual time for the baking of the other vevels, it is to be taken out, and the whole contents will be found no longer glafs, but converted into a white opaque subflance, which is a very elegant porcelain, and has almost the properties of that of China. Memoirs Acad. Sciences Par. 1739.

The powder which has served once, will do again as well as fresh, and that for a great many times: nay, it seems, ever so often. The caufe of this transformation, says Macquer, is probably that the vitriolic acid of the gypsum quits its hairs of calcareous earth, and unites with the alkaline flant and sialine earth of the glafs, with which it forms a kind of falt or saline, differing from the calcareous salines, by the interception of which matter the glafs acquires the qualities of porcelain. Dr. Lewis, from a variety of experiments on the nature and qualities, and method of producing this porcelain, has deduced the following conclusions: 1. Green glafs cemented with white sand received no change in a heat below ignition: in a low red-heat, the change proceeded very slowly; but in a strong red-heat, approaching to whitening, the thickest pieces of glafs bottles were thoroughly changed in three hours. 2. The glafs sustained the following progression of changes. Its surface first became blue; its transparency was diminished, and when laid between the light and the eye, it appeared of a yellowish hue: afterwards it was changed a little way on both sides into a white subflance, externally full blackish: and as this change advanced, still further and farther within the glafs, the colour of the visible part in the middle approached nearer to yellow: the white coat was of a fine fibrous texture, and the fibres were disposed nearly parallel to one another, and transverse to the thickest of the pieces: by degrees the glafs became throughout white and fibrous, the external bluefkins at the same time going off, and being succeeded by a dull whithit or dun colour: by a full longer continuance in the fire, the fibres were changed gradually from the external to the internal part, and converted into grains; and the texture then was not unlike that of common porcelain. The grains, at first fine and somewhat glossy, appeared afterwards larger and diller, and at length the substance of the glafs became porous and friable, like a mass of white sand slightly cohering. 3. Concerning the qualities of the converted glafs Dr. Lewis observes, that the whitenss of the internal part was not inferior to that of porcelain, but that its surface was the most beautiful; that the thick pieces were quite opaque, and that several thin pieces were semi-transparent: that while it remained in a fibrous state, its hardness became greater than that of glafs or of the common kinds of porcelain; it was capable of sustaining sudden changes of heat and cold better than any porcelain; and in a moderate white heat, it was friable into a subflance not fibrous, but vitreous and smooth, like white enamel: that when its texture had been carefully granulated, it was now much softer and unfultable; and, lastly, that when some coarsely granulated unfizable pieces which, with the continuance of a moderate heat, would have become porous and friable, were suddenly exposed to an intense fire, they were rendered remarkably more compact than before; the solidity of some of them being superior to that of any other ware. 4. No differences appeared in the internal colour, hardness, texture, or the regular succession of changes, from the use of different cementing substances; though
GLASS.

though in external appearances the differences were considerable. All the pieces which had been surrounded with charcoal or with foot were externally of a deep black colour, which did not disappear by exposure to a strong fire during an hour, with free access of air. Coloured sands and founds communicated different shades of a brown colour; and white earths gave whitish, greyish, or brownish tinges. White sand, calcined flints, and gypsum, gave in general the greatest whiteness, and tobacco-pipe clay the greatest glisnness and brightness. Glasses composed of earths without alkaline salt, glas of lead, flint-glas, crown-glas. looking-glas plates, a glass prepared with calcined flints and a fixed alkaline salt, and even green glas which had been fused together with a ninth part of alkaline salt, suffered none of the above alterations by cementation. Green bottles-glas and common window-glas were most susceptible of these alterations. 6. The changes produced by cementation could not proceed from any absorption of matter from the cementing substance; because no increase of weight was given, and became the same changes were produced upon a piece of glas merely by heat, without any cementing substance. See Com. Phil. Techn. p. 250—255.

Mr. Gregory Watt, in his valuable paper on basalt (Phil. Trans. for 1804, cited by Alken) alleges this porcellaneous change of glasses as an illustration of his important principle, viz. that bodies which have a natural tendency to a crystalline arrangement, or a polarity, when vitrified by a sufficient heat and cooked hastily in the vitreous state, are able subsequently to return to their natural crystalline arrangement of fibres, when exposed to a heat merely sufficient to soften the texture, though not enough for fusion. This, in the instance of basalt, he shows by the singular crystallizations formed in the cells of fused basalt, long after it had lost the liquidity of fusion. The circumstance of no material change occurring in the weight of glasses by this conversion into the fibrous state, he shows incontrovertibly that it cannot be owing either to any thing gained during the process, nor to any material loss of the alkali; and this is also rendered manifest by its return to the vitreous state and vitreous qualities when again melted. This too may again be porcellanized in the same way, and again be melted into glas, and so on alternately." See Porcelain.

Glas-pots, the vessels in the glasses manufacture used for melting the glases. Those for the white glasses works are made of a tobacco-pipe clay, brought from the Isle of Wight, which is first well washed, then calcined, and afterwards ground to a fine powder in a mill; which being mixed with water, is then trod with the bare feet till it is of a proper consistence, to mould with the hands into the proper shape of the vessels. When these are thus made, they are afterwards annealed over the furnace. Those for the green glases work are made of the non-fuch, and another sort of clay from Staffordshire; they make these so large as to hold three or four hundred weight of metal. And besides these, they have a small sort called pluming pots, which they set upon the larger, and which contain a finer and more nice metal fit for the nicest works. Neri.

The clay that is used for this purpose should be of the purest and most refractory kind, and well censed from all sandy, ferruginous, and pyritic matters; and to this it will be proper to add ground crucibles, white sand, calcined flints duly levigated, or a certain proportion of the same clay baked, and pounded not very finely. The quantity of baked clay that ought to be mixed with the crude clay, to prevent the pots from cracking when dried, or exposed to a great heat, is not absolutely determined, but depends on the quality of the crude clay, which is more or less fit. M. D'Antic, in a memoir on this subject, proposes the following method of ascertaining it: the burnt and crude clay, being mixed in different proportions, should be formed into cakes, one inch thick, and four inches long and wide. Let these cakes be slowly dried, and exposed to a violent heat, till they become as hard and as much contracted as possible, and in this state he examined; and the cake, he says, which has suffered a diminution of its bulk equal only to an eighteenth part, is made of the best proportions. He observes, in general, that most clays require that the proportion of the burnt should be to the fresh as four to five.

It is of great importance that the material of which the pots are made should be carefully selected, as they are exposed to the action of a very fierce fire, and also to the solvent activity of the glasses with its powerful forces. They should also be made very thick and strong, as they are intended to last for many months. When milled, they are placed in a warm room in order to discharge their moisture, and any small fissures arising from the unequal shrinking of the clay are closed by gently beating with a mallet. They are afterwards gradually heated in a small oven, constructed for this purpose, and slowly brought to a red heat; and after remaining for some time in this state, they are removed to the furnace, and fixed down in their places by fire-clay. Here, on account of a further shrinking, they remain for a day or two before they are fit for receiving the glas materials. Pots of this kind are said to last, on an average, about a year.

GLASS TUBES are of various lengths, diameters, and forms, according to the purposes to which they are applied. These are often formed with the lump and blow-pipe, in the manner described under the article Lamp-blowers. In this way tubes are sealed hermetically (see HERMETICAL SEAL), tubes are bent, others are joined, bulbs are annexed to tubes for thermometers, &c., and glass is drawn out into threads.

It has been observed, that glasses tubes laid before the fire in an horizontal position, and with their extremities supported, have had a rotary motion about their axes; and also a progressive motion towards the fire, even when their supports are inclined from the fire, so that the tubes will make a little upwards. See Phil. Trans. N. 476, § 1.

When the progressive motion of the tube is stopped by any obstacle, its motion about its axis will still continue. When the tubes are placed in a nearly upright posture leaning to the right hand, the motion will be from east to west; but if they lean to the left, the motion will be from west to east; when the nearer they are placed to the perfectly upright posture, the left the motion will be either way. If the tube be placed horizontally on a glass plane, the fragment, for instance, of coach window-glasses, instead of moving towards the fire, will move from it, and about its axis, in a contrary direction to what it had done before. Nay, it will recede from the fire and move a little upwards, when the plane inclines towards the fire.

Neither the draught of air up the chimney, nor attraction or repulsion, are the causes of these phenomena. It seems rather owing to the swelling of the tube towards the fire; for allowing such dwelling, gravity must pull the tube down, when supported near its extremities horizontally; and a fresh part being exposed to the fire and swelling out again, must fall down again, and so on successively; which will produce a rotary motion towards the fire.

If the tube be supported by two other tubes, and these be brought near to each other, and to the centre of the supported tube, then its parts hanging over on each side, being larger than the part which lies between the supporters, will.
by their weight, pull downwards, and consequently force the middle part, resting upon its two props, upwards: and being left advanced towards the fire, as being heated, will, by their oblique situation, pull the middle part backwards also from the fire, which will cause a rotatory regressive motion, quite contrary to what the tube had when supported near its extremities. And when a single tube lies inclining opposite to the fire, either to the right hand or to the left, out of a plane perpendicular to the surface of the fire, gravity will not permit the curved part to rest, but pull it down till it coincides with a plane perpendicular to the horizon; and consequently, as new curves are generated, new motions will fo too; that is, the tube will be made to move about its axis, with this difference, when the tube inclines to the right hand, the motion will be from east to west; when to the left hand, from west to east. The justness of this reasoning is made manifest, by bending a wire, and supporting it first near its extremities, then near its centre on each side, afterwards inclining it to the right and to the left; the bending in every case representing the curved part of the tube next the fire. This solution of the phenomenon is rendered the more probable from hence, that when four supporters were made use of, one at each extremity, and two near the middle, there was no motion at all, either backward or forward. Nor does the increase of contact hinder the motion, because the plate of glass was so broad as to have a much greater contact with the tube, and yet both the rotatory and regressive motions were manifest.

These experiments succeeded best with tubes about twenty or twenty-five inches long; and the diameter about one-tenth of an inch; and they had in each a pretty strong pin fixed in cork, for an axis to roll with on the supporting tubes.

Phil. Trans. N. 426.

Glass receivers, how to cement the cracks of. See Cement and Receiver.

Glass, how to take the impression of antique gems in. See Gem.

The property which glass possessest in common with other substances of being expanded by heat, and contracted by cold, was long ago observed and evinced by Mr. Hook. See Birth's Hill of the Royal Society, vol. i. p. 411. See Thermometer.

Glass, Laws relating to. No glass shall be imported into Ireland, other than the manufacture of Great Britain, on pain of forfeiting the same, and ship, and 102 a pound. 19 G. II. c. 12. If any foreign glass shall be landed or unshipped before entry and payment of the duties, or without warrant from the proper officer, the same shall be forfeited, or its value; and the master or other person having command of the vessel, and every other person concerned in such landing or unshipping, shall forfeit 100l. 17 G. III. c. 39. And by 38 G. III. c. 33, for preventing the fraudulent importation of glasses, every package containing any plate or plates of glasses unframed, being plate, crown, or flute glasses, which shall be imported, or brought into this kingdom for exportation, shall be marked on the outside in Roman letters four inches long at least, with the word Glass, on pain of forfeiture, together with the package, and all goods contained in it. The matter of the vessel importing such package, shall, in reporting his cargo, express every such package of glasses, on pain of forfeiting the same, and also 100l. Nor shall any such package be imported, which shall not contain 500 weight, on pain of forfeiture; but not extending to any part of glasses 60 inches in length or upwards, on account of the package not being marked. By 43 G. III. c. 69. For every 100 weight of materials, &c. that shall be made use of in Great Britain for the making of plate or finer glasses, or enamelled, stained, or paste glasses, or phial glasses, shall be paid by the maker thereof 1l. 12s. 6d.; for every hundred weight of materials used in making spread window glasses, commonly called broad glasses, 8s. 2d.; for every hundred weight of materials used for making all other window glasses (not being spread glasses), whether flatted, or otherwise manufactured, commonly called crown glasses, or German fluted glasses, 1l. 4s. 6d.; for every hundred weight of materials used in making common bottles (not being phials), and of vessels used in chemical laboratories, and of garden glasses, and of all other vessels or utensils made of common bottle metal, 4s. 7d.; and for every hundred weight of plate glasses, and of all other glass manufactures, which shall be imported into Great Britain, the same not being flaked, in which wine or oil is imported, nor foreign green glasses bottles, nor Irish glasses, or glasses manufactures imported directly from Ireland, to be paid by the importer before the landing thereof, 2l. 2s. 2d. And any glassmaker shall take out a licence, for which he shall pay 5s., to be renewed annually ten days at least before the end of the year, on the penalty of 50l. 24 G. III. c. 41. 43 G. III. c. 69. The place of making glasses shall be entered, before the commencement of manufacture, and all work-houses, furnaces, pots, annealing arches, &c. shall be on pain of forfeiting 200l. 19 G. II. c. 12. 17 G. III. c. 39. 35 G. III. c. 114. Officers may enter and survey, and mark pots; and any person counterfeiting or altering such mark, or contriving at its being done, shall forfeit 500l.; or defacing, or causing to be defaced or obliterated such mark, incurs a forfeiture of 200l. 35 G. III. c. 114. Notice of beginning to work shall be given in writing, on pain of forfeiting 200l. 19 G. II. c. 12. And notice of filling every pot shall be given twelve hours before the operation is begun, on pain of 50l. 19 G. II. c. 12. 17 G. III. c. 39. Annealing arches are to be made of a certain form, and numbered, on pain of forfeiting 100l. Annealing arches are to be locked, except at certain times; and breaking such lock, &c. incurs a forfeiture of 200l. 35 G. III. c. 114. The same act comprehends several other provisions, enforced by certain penalties. Bottles are not to be removed till they are weighed, (penalty 100l.) which are to be kept separate from those that are unweighed, on pain of forfeiting 50l. No phials, &c. are to be made in places entered for making common glasses bottles, on pain of forfeiting 200l. Entry shall be made of the glasses manufactured every month within the bills, and elsewhere every six weeks, on pain of 20l. The maker, within the bills, shall, in four weeks, and elsewhere in six weeks after entry, pay off the duties, on pain of double duty. If glasses, shipped for exportation, shall be re-landed, it shall be forfeited, and every person concerned therein shall forfeit 100l. 17 G. III. c. 39. For the drawbacks on exportation of glasses, see 43 G. III. c. 69. Obstructing officers in curing the duties incurs a forfeiture of 50l. 19 G. II. c. 12. 17 G. III. c. 39. Penalties are appropriated, half to the use of the king, and half to him that shall sue.

Glass-Carrick Point, in Geography, a cape of Ireland, on the eastern coast of the county of Wexford. N. lat. 52° 35'. W. long. 6° 12'.

Glass-Cfes, in Gardening, a light fort of erection formed with glasses fences in proper framework, mostly upright in the front part and ends, but sloping at top from a back wall, or other convenient building, to the fore-part; the front, top, and both ends being of glass-work. The situation for this purpose should face the south, in order to have the full influence of the sun. Constructions of this nature are useful for protecting many sorts of curious tender plants in winter which want it only occasionally from severe frost, and other similar causes.

Buildings
GLASS.

Buildings of this kind may be constructed, occasionally, either against some ready-built south wall, which serves for the back, or all the other parts forward being wood-work and glafs; or detached in a similar situation, so that the whole front may blend to the south; the back being framed of brick-work, &c. or of wood double planked; but the former is preferable; the whole being generally ranged lengthways, nearly in an east and west direction.

The dimensions may be from five or fix, to eight or ten feet in width, by ten, fifteen, or twenty feet in length or more, as may be required; and from six or eight, to ten feet high behind, by five or fix to seven or eight in the front, both ends in proportion with the top, sloping gradually, as just noticed, from the back, having an entrance, or door, in front, or at one end. The glafs-work should be made to slide readily backwards and forwards.

Sometimes fire-flies are carried along the back and front internally, proceeding from an external furnace, for occasional fire-heat in winter, which renders them more convenient and useful for different purposes.

These cafes, as mentioned above, are used as preparatory departments, in which to winter many sorts of curious exotics of the harder green-house kinds, which only want protection from severe cold, as well as many choice kinds of the open ground, which are rather tenderer in their minor growth, or may other particular or curious hardy plants, whether flowers, shrubs, or young trees, especially the choice evergreen kinds, which require effectual protection from the ravages of rigorous frosts or cutting winds, in winter or early spring; and, at the same time, in mild open weather, to enjoy the full air by opening the glases; all which, being in pots, can be readily placed in this preparatory at the approach of severe weather, and be thus kept in good condition till settled weather in spring, &c.; then removed into the full air. In summer and autumn, when unoccupied in this way, these cafes may be of some utility to place some curious kinds of tender plants in, when in flower for seeing, to guard them from heavy or incessant rain, or cold night dews in autumn, which, in many forts retard, or sometimes wholly frustrate their production of good feed, as in many forts of curious tender annuals; particularly the fine double ballans, cock's-combs, tricolors, double flammoniums, diamond ficoides, and various others.

They are also capable of being used in spring and the early part of summer, as in April, May, and June, as a kind of drawing-frames, for some particular sorts of curious annuals to bring them to a tall growth, such as the large or giant cock's-combs, tricolors, double flammoniums, double-striped ballans, egg-plants, &c. the plants being first raised in hot-beds, under garden-frames, till of twelve or fifteen inches growth, then a hot-bed made in the glass cafe, earthed at top, and the plants in pots, finely plunged into the earth of it; the glases, in these cafes, should be shut close, only a necessary admission of fresh air being given every day, by which they run up to a tall stature in the best perfection of strength for flowering. See Annual Plants.

These sorts of glass-cafes are also sometimes made use of as a kind of appertainances to hot-houses, or boxes, detached from them, having, as observed above, internal fluxes for fireheat, when necessary, serving as preparatory for many sorts of exotics, which are tenderer than common green-house plants, but do not require the constant full heat of the more tender hot-house kinds, but only the assistance of moderate fire-heat in winter, in cold nights, or when very damp, cloudy, foggy-weather and severe frosts prevail. They are sometimes used in the business of forcing different kinds of flowering plants and efluent, either by means of an internal bark-bed, or fluxes for fire-heat.

When intended for this purpose, it is convenient to have both an internal pit for a bark-bed, and fluxes for fire-heat, in order to use either separately, or sometimes both, as may be found necessary. See Hot-House.

GLASS-FLACKS, in Mining, is a term for the polished surfaces, or sicken-fides, which are found in some of the mineral veins in Derbyshire, something like the polishing which is seen often on the sides of faults. See Slickenside.

GLASS FLAX, called also Stakelby, in Geography, one of the Hebrides, near the N.E. extremity of Harris. It is a small, low, round island, covered with heath, and indented by the sea. Near its western extremity are two good natural harbours, and on its east point a light-house was erected A.D. 1788. It lies at the entrance of East Loch Tarbot. N. lat. 57° 50'. W. long. 6° 40'.

GLASS-LEAD, in Mining, according to Mr. Mawe, "Mineralogy of Derbyshire," p. 105, is an opaque waxy lead-ore found in that county: sometimes allo it is transparent and crystallized, appearing as though it had undergone the action of fire.

GLASS-LEUGH, in Geography, a lake of Ireland, in the county of Meath, near a village of the same name, about five miles from the town of Meath. The lake contains 120 acres; and a wood, spreading over a fine bold hill, hangs down to the water in one deep thistle, the effect of which is remarkably beautiful. The county around is very fine. Young.

GLASSES are distinguished, with regard to their form, use, &c. into various kinds, as drinking-glasses, optical-glasses, looking-glasses, burning-glasses, &c.

GLASSES, Drinking, are simple vessels of common glafs or cryflal, usually made in form of an inverted cone. Each glas consists of three parts, viz. the calyx or bowl; the bottom, and the foot; which are all wrought or blown separately.

Nothing can be more dexterous and expeditious than the manner wherein these parts are all blown; two of them opened, and all three joined together. An idea is only to be had thereof, by seeing them actually at work.

The glases chiefly used in England are made of the ashes of fern; cryflal glases being less frequent in use. The exceeding brittleness of this commodity, notwithstanding the very rate of each glas, renders the consumption thereof very considerable. For the method of fudging the edges of drinking-glasses, see Gilding on Enamel and Glass.

GLASSES, Metallic, in Chemistry, are the oxyds, or sometimes the sulphured oxys of the different metals, vitrified by heat.

GLASSES, Optic, are those made use of to strengthen, improve, or preserve the Hght. See Optic Glasses.

GLASSES, Convex. See Convex.

GLASSES, Concave. See Concave.

GLASSES, Infernal. See Infernal.

GLASSES, Lenticular. See Lenses.

GLASSES, Meniscus. See Meniscus, &c.

GLASSES, Plain. See Plain Glass.

GLASSES, Plano-Concave. See Plano-Concave.

GLASSES, Plano-Convex. See Plano-Convex.

GLASSES, Telescop. See Telescope.

GLASSES, Object. See Object-Glases.

GLASSES, Eyes. See Eye-Glases.

GLASS, Pole of a. See POLE.
GLASS, Hour. See Hour-Glafs.
GLASS, Tin. See BISNITH.
GLASS, Watch. See WATCH.
GLASS-Wor. See KALE.
GLASS-Worr, Berry-Bearing, in Botany. See ANARASIS.
GLASS-Wor. Jointed. See SALICORNIA and KELF.
GLASSHATTEN, or GLADTEN, in Geography, a town of Hungary, celebrated for its hot-baths, and having near it some rich gold mines; 7 miles from Schenmitz.
GLASS-HOUSE BAY, a bay on the E. coast of New Holland, between cape Moreton, and the Glafs-houes, which are three hills, so called by captain Cook in 1770, situated in S. lat. 26° 28'.
GLASSHUTTEN, a town of Saxony, near which is a silver mine; 8 miles S. of Drefden.
GlaSSUS, Solomon, in Biography, was born in the year 1593, and it is supposed he was educated at Jena, where he was admitted to the degree of doctor of divinity, and for some time filled the theological chair with distinguished reputation. He was appointed superintendent of the churches and schools in the duchy of Saxo-Gotha, and exercised the duties of his function with prudence, equity, and impartiality. He died at Gotha in 1645, and left behind him, as a memorial of his fame and learning, a work published in quarto in 1623, entitled "Philologia Sacra," which is pronounced by Mothem an ineffable and immortal work, in which none can be more useful for the interpretation of Scripture, as it throws much light upon the language and phrenology of the inspired writers, He was author, likewise, of "Onomatology Melfie Prophetica," "Chriftologia Mafaica et Davidica;" "Exegesis Evangeliorum et Epiphanorum," and some other pieces. Morei.
GLASSNEVIN, in Geography, a village near Dublin, in Ireland, remarkable for the very extensive and valuable botanical garden belonging to the Dublin Society. See Dublin Society.
GLASSY HEMOUR. See EYE and VITREOUS.
GLASTONBURY, in Geography, a market town in the hundred of Glaston, and county of Somerset, England, is situated on the great road from Wells to Exeter. The site occupied by it was originally called Ynyswytryn, or the Glas Islan, and in Latin Avalonia.
A town is said to have been built here, and largely endowed by king Ina about the year 708: in the next century it was laid waste by the Danes, and rebuilt by king Edmund, who granted it many additional privileges. In 1184 it was destroyed by fire, and was again restored by the munificence of Henry II. The chief celebrity attached to the town was derived from its abbey; which, during six centuries, far surpassed in authority and revenues every other in England, excepting that of Westminster. The abbots enjoyed a state of regal splendour, with an income of nearly 40,000l. per annum, and held the title of lords, and sat at table with the peers in parliament. The abbey and its offices occupied an area of land of nearly sixty acres within the walls.
The last abbot, Richard Whiting, who was the sixteenth in succession, refusing to surrender his abbey to king Henry VIII., was, with two of his monks, drawn on a hurdle to the Torr, near the town, and there hanged: the abbot's head was set on the gate of the abbey, and his quarters were sent to Bath, Wells, Bridgewater, and Helston.
It being traditionally recorded, that this was the burial place of king Arthur, Henry II. ordered a search to be made, when a Ironen crofs was discovered with a Latin inscription in rude characters, thus translated: "Here lies the famous king Arthur, buried in the isle of Avalon." Beneath was found a coffin hollowed out of the field rock, wherein were the bones of a human body, supposing to be those of Arthur; which were then deposited in the church under a monument. Scarcely any vestige remains of these extensive buildings, except some ruins of the church, part of a chapel dedicated to Joseph of Arimathea, and the abbots kitchen, which seems to be of a more recent structure than the other offices.
Among the religious relics with which the town and its environs abound, the most conspicuous is the Torr, or St. Michael's Tower (on which abbots Whitting was executed,) standing on an eminence called the town, where was formerly a small oratory, dedicated to St. Michael the archangel.
The town of Glastonbury consists of two principal streets, and is divided into two parishes, St. John's and St. Benedict's. It was formerly a parliamentary borough, but was disfranchised on the confiscation of the abbey in 1539. A charter of incorporation was granted by queen Anne, by which the civil government was vested in a mayor, a justice, eight aldermen, and sixteen burgesses. The principal buildings are the two parish churches, two meeting-houses, two almshouses, and a free school. The George, a respectable inn, was anciently a hospital for the accommodation of pilgrims returning to the shrine of St. Joseph. In the centre of the town was formerly a large flone crofs, originally appropriated to shelter persons who attended the market. It was taken down about five years ago; but a plate and description are prefixed in the first volume of the Architectural Antiquities of Great Britain. Glastonbury is 130 miles distant from London, has a market on Tuesdays, and four annual fairs; the population returned, in 1801, was 410 houses, and 2033 inhabitants, of whom only 104 were employed in trade, which is chiefly that of manufacturing woollen stockings.
South-west of the town is Wearyall hill, so called from a tradition that St. Joseph and his companions, weary with their journey, halted here; and that St. Joseph struck his hawthorn staff in the earth; it took root, and constantly budded on Christmas day. This famous thorn had two trunks, of which one was destroyed in queen Elizabeth's reign, the other in the great rebellion; but there are trees, originally from the old rock, still growing in the gardens of Glastonbury, and in various other parts of the kingdom. Collinson's Hill, Somersetshire, 3 vols. 4to. Maton's Western Counties, 2 vols. 8vo.
Glastonbury, a township of America, in the county of Bennington, and State of Vermont; having only 48 inhabitants.—Also, a handsome little town in Hartford county, Connecticut, situated on the E. side of Connecticut river, opposite to Westfield; containing 2718 inhabitants.
Glastonbury Thorns, in Botany. See Mespilus.
GLASTUM, from the German word glafl, an old name for Wood (see Isatis.) Hence several plants have the specific name of glasfolid, on account of the fineness of their leaves to that herb.

GLATT,
GLATT, in Geography, a river of Germany, which runs into the Neckar, 2 miles N. from Salz in Wurttemberg.

GLATZ, or Glätzen, a town of Germany, in the county of Frąger; 4 miles E. of Dornfetten.

GLATZ, a river of Switzerland, which runs into the Rhine; 2 miles below Eglfau.

GLATZEN, a mountain of Switzerland; 10 miles S.S.W. of Glarits.

GLATZ, a principality of Silesia, bordering on Bohemia, and surrounded by mountains. The internal territory is mountaneous, intersected with valleys, meadows, corn-fields, woodlands and small rivers. It produces wheat, generally sufficient for its inhabitants, and has pastures for a great number of cattle. It contains quarries of mill-stones, freestone, and marble; as well as a great variety of precious stones. It has also mines of coal, copper, and silver; and several mineral springs. From 1561 to 1742, Glatz was annexed to the crown of Bohemia; in 1742 it was ceded by the empress Maria Theresa to Frederick II. king of Prussia, and his heirs. It forms one circle, divided into six districts.

Glatz, the capital of the principality above-mentioned, is seated on the Neisse, and built on the side of a mountain, having upon its summit a strong castle. The town contains about 450 houses within the walls, and as many in four faubourgs. It is a place of considerable trade. It has been frequently pillaged and burnt; 54 miles E. of Breslau. N. lat. 50° 16'. E. long. 16° 26'.

GLATZ, Kogel, a mountain of Austria; 12 miles S. of Steyr.

GLAVACIA, a town of Walachia; 35 miles W. of Bucharest.

GLAUBER, JOHN RODOLPH, in Biography, a celebrated chemist of Amsterdarm, who was esteemed the Paracelsus of his age, was born in Germany in the beginning of the sixteenth century. He travelled much in the pursuit of chemical knowledge, and collected many secret processes; and his experiments contributed to throw much light on the composition and analysis of the metals, inflammable substances, and salts. In fact he passed the greater part of his life in the laboratory. He did not always see the proper application of his own experiments, and vainly fancied that he had discovered the panacea, and the philosopher's stone, which were at that time objects of pursuit; and the disappointment of many persons, who had been seduced by his promises, contributed to bring the art of chemistry into contempt. His theory is full of obscurity; but his practice has perhaps been misinterpreted by those who listened to his vain and pompous pretensions; and who accuse him of a dishonourable traffick, in selling his secrets to chemists at an enormous price, of again dispossessing them to other persons, and lastly, of making them public in order to extend his reputation. Glauter published about twenty treatises; in some of which he appears in the character of physician, in others in that of an adept or metallurgist; in the latter he most particularly excelled. However, it would be unjust not to give him the praise of acute men of mind, of facility and address in the prosecution of his experiments, and of extensive chemical knowledge. He was the inventor of a salt, which to this day retains his name in the shops of our apothecaries. The works of Glauter have appeared in different languages; the majority of editions are in German, some in Latin, and others in French. A collection of the whole of the Latin was published at Frankfort in 1628, in 8vo, and again 1659 in 4to. An English translation was published by Christopher Pack, London, 1689, in 8vo. Elyh. Dict. Hill.

Glauber Salt, native or natural, in Mineralogy, the sulphate of soda of chemists, was discovered by baron Born in the salt mines of Upper Austria; after which Momet, Volta, Suckow, Gmelin, Bredfield, Pallas, and others have added to the list of the localities of this saline substance, which is more frequently found in a native state than has been supposed by some writers. It generally occurs as neatly efflorescent; sometimes matted, seldom flat, flake-like or crystallized; in which latter case the crystals are described as acicular and as flat-foated prisms, more or less flatly acuminate by three planes, set on the lateral edges, or sometimes on the lateral planes: they are fibrous: their internal lustre is vitreous. Crude of the crystals small conchoidal. It varies from transparent to opaque according to its freshness. It is brittle. Its taste is a mixture of salt and bitter. Besides in the above forms, it occurs also, and most frequently, dissolved in certain mineral waters, in the neighbourhood of salt-mines and salt lakes, where also the efflorescence is mostly found on moist ground, and flat stone, and new walls. For the chemical character of this salt, see Soda, Sulphate of.

Bromnart has given the most complete list of the localities of Glauber salt. In solution it occurs in the waters of several lakes of Austria and Lower Hungary, especially in that of Neuhof, between the counties of Oedenburg and Worfelburg. It is met with in Switzerland; in Spain; round a source in the neighbourhood of Aranjuez, and near Vacha-Madrid, as efflorescence, at the bottom of a ravine: the source which issues from the mine contains a great proportion of this salt. Also the water of the Tagus is held to hold it in solution. In France it has been found near Grenoble. The deep fissures of the Sallatara of Fontaine yield this salt, in one place, on the north side. It is common in the lakes of Siberia; and it has been observed that the bottom of the lake Gumikof, between Tsjomil and Ilyasofy, is covered with a crust of Glauber salt as soon as the temperature is below the freezing point. Pallas tells us that the apothecaries of Orenburg annually collect a quantity of this salt, which is deposited in autumn at the bottom of a lake between the Tobol and Mius. It is also found in a lake near Courif; in another between Utoiska and Minkiakia, in the neighbourhood of Esuffey; likewise at the foot and in the middle of the chains of the Ural mountains, near Tchebikof; in the last of these places, the salt issues in the spring seet out of the earth in the form of efflorescence or froth. The chayey soil of that neighbourhood does not contain any Glauber salt; whence this is supposed to be formed, in the same manner as salt-petre is, at the surface of the earth, and by the action of the atmosphere. Lastly, this salt is also obtained from the alum-flate of Dittweiler, near Saarbrück, in the department of Sarre, and from the aluminiferous waters of Freyenwald, in Brandenburg.

Glauber's Salt, in Chemistry and Materia Medica. See Sulphate of Soda.

Glauber's Spirit of Marine Salt. See Muriatic Acid. Glauber's Spirit of Nitre. See Nitric Acid.

GLAUBERITE, a lately discovered mineral, belonging to the class of salts, and of which M. Bromnart has given the description and analysis. This substance (called glauberite by its discoverer, both in honour of the well-known Glauber, and on account of its containing a considerable quantity of the salt which bears the name of that alchimist) was found among pieces of rock-salt brought from Ocean in New Cadile, in crystals resembling those of thumus, or arsenite. They were chiefly on a count of their made of occurring) mistaken in Spain for pyrite.

The form of these secondary crystals, that of an ellipse very
very short proflinate with rhomboidal base. The planes of
the bafe are generally smooth and shining; the lateral planes
flattened parallel to the edges of the bafe. Cleavage double,
the one parallel to the bales, the other less distinct and par-
allel to the edges of the bafe; in all other directions the
fracture is vitreous. Hence the primitive form is an oblique
prism with rhomboidal base, the obtuse angles of which cor-
respond with the obtuse angles of the secondary prismatic. The
crystals are from topaze yellow to nearly colourless; they are
transparent, and, provided they are kept dry, preserve their
transparency and solidity though exposed to the air. Their
hardness surpasses that of sulphat, but is inferior to that of
carbonat of lime.

Exposed to an intense heat, the glauberite decrepitates and
melts into a white enamel. Immered in water, its surface
is covered by a milk-white crust, which penetrates deeper
and deeper, till the whole crystal is white and opaque
throughout; taken out of the water and dried, the white
crust crumbles into dust, leaving the nucleus, if there be
any remaining, untouched and perfectly transparent. Specific
gravity about 2.73.

From M. Brongniart's experiments it appears that
glauberite is essentially composed of anhydrous sulphat-of
lime and of sulphat of soda, equally anhydrous. 2. That
these two salts exist in this substance nearly in the following
proportions:

| Anhydrous sulphat of lime | 0.49 |
| Anhydrous sulphat of soda  | 0.51 |

A trace of water, indicated by the calcination, is not
brought into account, as little as the accidental admixture
of a feebly perceptible quantity of iron, to which the yellow-
whitish colour of this substance appears to be owing.

Mr. B. adds the following observations: the above-menti-
oned pieces of salt from Oceana, which contain this sub-
stance, have generally some clay adhering, which penetrates
into the flies of the surfaces, but seldom into the substance
of the glauberite.

The efflorescence on glauberite, when moistened, and the
property this salt possesse of becoming opaque in water,
proceed from this, that the water, by dissolving the sulphat
of soda, transforms the sulphat of lime into a fupongy sub-
stance, and thus produces a phenomenon which is the reverse
of that exhibited by the hydraphane.

The existence of native sulphat of soda, or Glauber salt,
is well known to mineralogists, and, indeed, it has been met
with in the neighborhood of beds of rock-falt; but this
was only as solution in the water of salt-springs, or as efflo-
rescence near salt-mines: in a solid and crystallized flate,
entirely destitute of water of crystallization, and intimately
united with saltpetre, it had never before been observed. Even
the anhydrous sulphat of soda was almost entirely unknown,
until Berthier proved that it constitutes nearly the fifth part
of those hard scales found at the bottom of the pans in which
the sea-falt is obtained by evaporation.

It remains to be ascertained, under which circumstances
the rock-falt occurs which contains the glauberite, and particu-
larly in what relation this latter stands to it, and whether
it occurs in the sands or on the surface of the beds. See
Journal des Mines for 1808.

Hauty places the glauberite separately at the end of the
substances acidifera; and it appears to this mineralogist, that
the integrant molecules of the two salts of which it is com-
pounded exist together in the glauberite. He refers, for an
analogous combination, to Leblanc's experiments, according
to which a solution of sulphat of copper and sulphat of iron
mixed, yielded crystals composed of these two substances,
while their primitive form proved to be that of the latter,
which had impressed on this mixture the character of its par-
cular crystallization. The question, therefore, is, whe-
ther the glauberite be in a similar case. Its form has, indeed,
nothing in common with that of the anhydrous sulphat of
lime; but we are totally unacquainted with the cry-
alline form of the anhydrous sulphat of soda. But
even if it should be found that in this case the two molecules
combine in such a manner as to produce a third of a differ-
ent form from either, this circumstance could, according to
Hauty's opinion, not be adduced as an objection against
the theory of crystallization, and must be considered as a pro-
blem, the solution of which is more interesting to the chemist
than to the mineralogist.

GLAUBOTTE, in Geography, a town of Prussia, in
Natangen; 14 miles S.E. of Bartenhelm.

GLAUCEDO, in Surgery. See GLAUCOMA.

GLAUCHA, in Geography, a town of Saxony, in
the lordship of Schomburg, on the Mulda, containing about
600 houses; the inhabitants are employed in the manufac-
ture of fluffs; 46 miles W. of Dresden. N. lat. 50° 45'.
E. long. 12° 25'.

GLAUCHE, a town of Germany, in the duchy of
Magdeburg, adjoining to the town of Halle, but governed
by its own magistrates; in which are four fermaries, where
the languages, theology, mathematics, music, &c. are taught
by 120 preceptors.

GLAUCION, in Ornithology, a species of Antha, the
grey-headed duck. See DUCK.

GLAUCIUM, in Botany, is so named from its glaucous,
or sea-green, colour. Whether the plant intended by Pliny
be the Yellow Horned Poppy, according to the opinion gen-
erally received, or any maritime species of Eschscholtzia,
seems a point not easily determined. GLAUCION of Dioscorides
appears to be the juice of the first-mentioned in its wild state,
though he compares it to his ΑΙΙΑΛΟΧΟΝ, (which is evidently
the Yellow Horned Poppy itself,) saying the plant which yields
the φαλαχανή, and grows at Jerusalem, has almost the leaves
of the ΑΙΙΑΛΟΧΟΝ, but thicker, and spread on the ground,
strong smelling, and more bitter, yielding plenty of yellow
coloured juice. Possibly this may refer to one of our other
species of Glaucium, if not to the common wild lettuce.
Most commentators have taken Argemone mexicana for the
plant of Dioscorides; but that is a tropical production,
unknown in Europe, as we presume, previous to the disco-
ey of America, though now naturalized in the East Indies;
see Eschscholzia. Neither does the above description suit this
plant, for its leaves are much thinner than those of the
Horned Poppy, and their juice pale yellow; nor are they
spread on the ground. Matthioli seems to take the drug
Gamboge for φαλαχανή, but this does not at all help us, as to
the botanical question, nor has it any probability in its
Mill. Dict. v. 2.)—Clas and order, Polyandra Monogynia.

Gen. Ch. rul. Parthen inferior, of two ovate, conca
tent, blunthilt, deciduous leaves, often tipped with a point near the
summit. Cor. Petals four, large, roundil, slightly concave,
nearly equal, with a thinning spot near the base. Stam.
Plaments numerous, shorter than the corolla, flat, incurved,
rather dilated upwards; anthers erect, roundish, of two
lobes. Pist. German nearly cylindrical, curved, longer than the
the flamen; style none; stigma with two or three lobes, downy. Peric. Pod linear, curved, very long, of two or three cells, and as many concave valves. Seeds numerous, globular, dotted. Receptacle linear, fimbriate, parallel to the valves, its surface cellular to receive the seeds.

Eff Ch. Calyx of two leaves. Petals four. Pod superior, linear, of two or three cells and two or three valves. Seeds numerous, dotted.

Obf. This genus is very naturally distinguished from Chelidonium by its habit, and essentially characterized by having more than one cell in its pod, and no crested to its cells.

2. G. fulvum. Orange Horned-Poppy. Scmp. Exot. Bot. v. 1. 11. 1. 7. (G. glabrum, flore phoeniceo; Tourn. Imit. 254. Chelidonium cornutum; Donn. Cant. ed. 5. 131.)—Stem smooth. Stem-leaves rounded, waved. Pods rough. Flowers nearly sessile. Supposed to be a native of the south of Europe, but we know it as a garden plant only. This differs from the former in the rather more blue cast of its herbage, nearly or quite sessile, flowers, and smaller petals of a rich tawny orange-colour. We have thought the root annual, but we find it will survive a mild winter, about as well as the first species, which indeed is often killed, and never lives many years, at least in a garden. The G. fulvum, whether a distinct species or only a permanent variety, propagates itself by seed and remains unaltered. Its flowers, contrasted with the leaves, have a singularly elegant effect. Their petals fall, in hot weather, before noon, but in the autumn will endure till the next morning, or longer, which is also the case when they are gathered and placed in a room.

3. G. rubrum. Red Horned-Poppy. Scmp. Prodr. Fl. Grac. v. 1. 357. (G. orientale, flore magni rubro; Tourn. Cor. 18.)—Stem hairy. Stem-leaves pinnatifid, cut. Pod strongly hairy. Gathered by Dr. Sibborth by the way-side between Smyrna and Barfa, as well as in the isle of Rhodes. The root seems to be annual. Stems spreading, or nearly prostrate, clothed with soft expanded hairs. Stem-leaves elongated, and deeply pinnatifid, by which it essentially differs from both the preceding, as it does from the following in the soft hairs, instead of rigid bristles, which clothe the pods and its stem. The flowers are stalked, with obvate petals, narrower and flatter than in either of the former, of a tawny red, with a violet spot on the claw. Lööv's Papaver cornutum phoeniceum alterum, t. c. 271, f. 2, agrees with this rather than with the last in its petals, and somewhat in its leaves; but if Tournefort be correct, it cannot be designed for the present species, which he gives in his Corolla as different from all he had previously enumerated, including Lööv's plant.

Vol. XVI.

4. G. phoeniceum. Scarlet Horned-Poppy. Scmp. Fl. Brit. t. 9/94. Prodr. Fl. Grac. v. 1. 357. Engl. Bot. t. 145. (G. lutea, flore phoeniceo; Tourn. Imit. 254. Chelidonium; Curt. Land. fait. G. t. 32. Chelidonium phoeniceum; Linn. Sp. Pl. 724. Papaver cornutum, phoeniceum; Lob. Ic. 271. 1.)—Found in cultivated fields in the south of Europe; a do jelly native of England, though easily naturalized in a garden. It is a tall, flowering in summer and autumn, and grows rather more erect and bushy than the last, from which it differs in the rigid close-preffed bristles which clothe the pods. The pods moreover are larger, rounder, and of a rich tawny, though each marked with a violet spot like the last; and the remaining bristles on the flabellum are very different from the flat hairs of that species.

GLAUCIUM, in Ornithology, a name given by Brilison to the Anna Caudex of tufted duck. See Deck; and also to the Anna Marilis, or scmp-duck. See Deck.

GLAUCOMA, or Glaucoma, a term, in Surgery, imparting, according to Mr. Samuel Sharp, what the Latin writers understood by sufflatum, and what we call a cataract. This defect, as we have often when explained, is an opacity of the crystalline lens. (See CATARACT.) Maitre-Jean, St. Yves, and other oculists, however, think, that glaucoma is a cataract complicated with the want of a sero, or an insensible film of the retina and optic nerve. (See GlaTTA SCLERA.) The word is derived from glaucos, blus, the pupil frequently having this colour. Some writers have regarded glaucoma as a defect of light, originating from an opaque, scattered turbid flat of the vitreous humour. Such a case is uncommon; but were an opacity of this kind to impede vision, an endeavor should be made to diffuse it with small doses of calomel, and by exposing the eye to the vapour of ether. In the event of these means failing, the opacity might be broken and disturbed with a coughing-meedic. The fuses hematodes of the eye must be determined. See Fuses.

GLAUCOPIS, in Ornithology, a genus of the order Pic. The bill is incurved and arched; the lower mandible shorter, and carunculate beneath at the base; the nostrils depressed, and half-covered by a fleshy cartilaginous membrane; tongue flesh-cartilaginous, divided at the end, and ciliated; legs formed for walking; toes three before and one behind.

The only species of this extraordinary genus at present known, is the wattle-bird of Dr. Fed., described by the Voyages of Captain Cook, and which appears to be a posterior. Observed in some naturalists, in the Australian regions. It is from the length of the leg, the length from the bill to the tail, and the length of the tail. The bill remarkably strong, and a little square at the back. The nostrils are situated in a hollow at the base of the bill, and are half-covered by a fleshy cartilaginous membrane which falls over as a cover to the ramus.
are pendent from the base of the lower mandible on each side, and the texture resemble the wattle of the common cock; the colour at first blue, and afterwards fine orange. The iris is fine blue. From the forehead to the eye the colour is deep black; the other parts of the plumage dark ash-colour. The tail long, wedge-shaped, and composed of twelve feathers. Legs long, and the hind claw much longer than the red.

This bird inhabits New Zealand, where it subsists on berries and insects, and is sometimes seen perched on trees, though rarely, as it is usually seen walking on the ground; its note is a kind of whistling or rather murmuring noise; and the flesh savoury and delicate.

GLAUCUM, in Ancient Geography, a promontory of the Libyan name, on the confines of Marmarica and Egypt, upon which was a town of the same name. Ptolemy.

GLAUCUS, a river of the Peloponnesus, in Achaea, near Patras. Pauchanius—Alfo, a river of Asia Minor, in Lycaea, having its mouth N. E. of the town of Tymithis, in the gulf of Glauces.—Alfo, a river of Asia, in the territory of Cocius, where it discharges itself into the Phasis. Pliny.—Alfo, a gulf of Asia Minor, in a direction from N.W. to S.W. More anciently this gulf was denominated the gulf of Tymithis, from the name of the town, situated near its termination in the eastern part of it.

GLAUCUS, in Ichthyology, a species of Chidodon; which see.—Alfo, a species of Smolner. —Alfo, a species of Falks, which see respectively.

Gen. Ch. Cal. none; unless the corolla be considered as such. Cor. of one petal, five-cleft, bell-shaped, crept, permanent, with obtuse revolute lobes. Stem. Filaments five, awl-shaped, crept, the length of the corolla; anthers roundish. 2. Pfl. German ovate; style filiform, as long as the stamens; stigma capitata. Peric. Capsule globose, pointed, of one cell, with five valves. Seeds five; roundish; receptacle very large, globose, hollowed for the seeds.

Ell Ch. Calyx of one leaf. Corolla none. Capsule of one cell, with five valves and five seeds.

1. G. muririma. Black Salt-wort. Linn. Sp. Pl. 501. Engl. Bot. t. 13. This is the only species known, being very frequent in salt-marshes throughout Europe, and flowering in summer. The root is perennial and creeping. Stem about four inches high, erect, somewhat branched, thickly covered with ovate, leathery, and felt-coloured, pubescent, or whitish flowers. Dr. Withering has remarked that cows eat this herb, and that it is used for a pickle, being found everywhere from Lapland to the Archipelago.

The description in Dioscorides, book 4. chap. 141. is so exact that it is impossible to be mistaken; yet we do not find this plant in the Prodromus Florae Graecae, because Dr. Sibthorp did not himself observe it in his journey.

GLAZIC, in Geography, a small island in the English Channel, near the coast of France. N. lat. 47 26. W. long. 2 56.

GLAZIER, an artificer or dealer in glass.

GLAZING. The Roman method of glazing some of their urns might give our workmen a hint toward a method greatly superior to any thing now in practice for the glazing of earthen-ware. There is a sort of red urns found in Yorkshire, which are, instead of glazing, covered all over inside and out with a fine cornal-coloured varnish, that gives them a beauty, which no earthen-ware of our times can attain; and is not only far more durable than our way of doing it with lead, which is apt to crack and fly, both with wet and with heat, but far more safe and wholesome; and being well known to be a vapourable metal, and its fumes very noxious, there is great reason to suspect that it must be unwholesome when brought to the fire. This ancient glazing seems to have been done either by the brush, or else by dipping, for both the inside and outside are varnished with equal regularity; and something may be guessed at as to the materials they used in it, from what Pliny has left us. This author occasionally observes, that such earthen-ware as was painted with bitumen never lost its beauty; and afterwards, that it was a custom to cover over whole statues with this fort of glazing, which he observes did not only make a smooth coat, but sunk into the matter of the foam or earth, and therefore this could not be likely to crack and fly off like our lead-coats on plates, &c. which is merely a crust laid over them. Hook's Philof. Collect. p. 89.

A common glazing for any kind of earthen-ware may be made of white sand forty pounds, of red-lead twenty pounds, of pearl-ashes twenty pounds, and of common salt twelve pounds. Powder the sand by grinding it, and then add it to the other ingredients and grind them together; after which calcine them for some time with a moderate heat, and when the mixture is cold, pound it to powder; and when wanted for use, temper it with water. The proportion of these ingredients may be occasionally varied. We may observe, in general, that lead ought to be excluded from the composition of glazings, and other fluxes substituted in its stead. See Colica Diamontiam.

A transparent glazing may be prepared, without lead, by calcining forty pounds of white sand, twenty-five pounds of pearl-ashes, and fifteen pounds of common salt; and proceeding as before: and a more perfect transparent glazing may be made of sand forty pounds, of wood-ashes perfectly burnt, fifty pounds, of pearl-ashes ten pounds, and of common salt twelve pounds. The following recipes are taken, for the most part, from Kunckel, who says that they are the true glazings used at Delft, and other Dutch manufactories.

GLAZING. Black, is made of eight parts of red-lead, iron filings three, copper-ashes three, and zaffre two measure.

This, when melted, will make a brown black; and if you want it blacker, add more zaffre to it.

GLAZING. Blue, is thus prepared: take lead-ashes, or red-lead, one pound, clear sand, or powdered flints, two pounds, common salt two pounds, white calcined tartar one pound, Venice or other glas half a pound, zaffre half a pound, mix them well together, and melt them several times, quenching them always in cold water. If you would have it fine and good, it will be proper to put the mixture into a glass furnace for a day or two.

Another blue glazing may be formed of one pound of tartar, a quart of a pound of red-lead, half an ounce of zaffre, and a quart of a pound of powdered flints, which are to be fused and managed as in the last recipe. Or, take two pounds of calcined lead and tin, add five pounds of common salt, five pounds of powdered flints, and of zaffre, tartar, and Venetian glas, each one pound. Calcine and fuse the mixture as before.

Or, again, take of red-lead one part, of sand three parts, and of zaffre one part. For a violet blue glazing, take four
GLAZING.

ounces of tartar, two ounces of red-lead, five ounces of powdered flints, and half a dram of manganese.

GLAZING, \textit{Brown}, is made of red-lead and flints, of each fourteen parts, and of manganese two parts, fused: or, of red-lead twelve parts, and manganese one part, fused. A brown glazing, to be laid on a white ground, may be made of manganese two parts, and of red-lead and white glafs, of each one part, twice fused.

GLAZING, \\textit{Gold-coloured}, is made of twelve parts of lead-ashes, and one of white glafs.

GLAZING, \textit{Gold-coloured}, to make gold-coloured glazing, take of litharge three parts; of sand, or calcined flint, one part; pound, and mix these very well together; then run them into a yellow glafs with a strong fire. Pound this glafs, and grind it into a fiffble powder, which moisten with a well faturated solution of silver; make it into a paste, which put into a crucible, and cover it with a cover. Give at first a gentle degree of fire; then increase it, and continue it till you have a glafs, which will be green. Pound this glafs again, and grind it to a fine powder; moisten this powder with some beer, fo that by means of an hair pencil you may apply it upon the vessels, or any piece of earthen ware. The vessels that are painted or covered over with this glasing, must be first well heated, then put under a muffle; and as soon as the glafs runs, you must foonk them, by holding them over burning vegetables, and take out the vessels.

Mr. Heinfius of Petersburg, who sent this receipt to the Royal Society, ufe the words \\textit{affigere deos suum}, which is rendered \textit{imanab them}, in the Transactions, Phil. Trans. No. 465, \textit{p. 6}.

Kunckel gives several preparations for a gold-coloured yellow glazing. This may be produced by fusing a mixture of three parts of red-lead, two parts of antimony, and one part of fparifh of Mars; by again melting the powdered mafs, and repeating the operation four times; or, by fusing four or five times a composition of red-lead and antimony, of each an ounce, and of fcales of iron half an ounce; or by calcining and fusing together eight parts of red-lead, six parts of flints, one part of yellow ochre, one part of antimony, and one part of white glafs. A transparent gold-coloured glazing may be obtained by twice fusing red-lead and white-flints, of each twelve parts, and of filings of iron one part.

GLAZING, \textit{Green}, may be prepared of eight parts of litharge, or red-lead, eight parts of Venice glafs, four parts of brafs-duft, or filings of copper; or, of ten parts of litharge, twelve of flints or pebble, and one of \textit{azylum}, or copper-ales.

A fine green glazing may be produced by using one part of the Bohemian granate, one part of filings of copper, one part of red-lead, and one part of Venetian glafs; or by fusing one part of white glafs, the fame quantity of red-lead, and alfo of filings of copper; powdering the mafs, and adding one part of Bohemian granate to two parts of this powder. A fine green may be obtained by mixing and grinding together any of the yellow glazings with equal quantities of the blue glazings; and all the shades and tints of green will be had by varying the proportion of the one to the other, and by the choice of the kind of yellow and blue.

GLAZING, \textit{Iron-coloured}, is prepared of fifteen parts of lead-ashes, or red-lead, fourteen of white fand, or flints, and five of calcined copper. This mixture is to be calcined and fufed.

GLAZING, \textit{Liver-coloured}, is prepared of twelve parts of litharge, eight of fand, fix of pebble or flint, and one of manganese.

GLAZING, \textit{Purple-brown}, conifts of lead-ashes fifteen parts, clear-fand, or powdered flints, eighteen parts, manganese one part, and white glafs fifteen measures; to which fond add one measure of yellow.

GLAZING, \textit{Red}, is made of antimony three pounds, litharge, or red-lead, three, and ftrut of iron; grind them to a fine powder. Or take two pounds of antimony, three of red-lead, and one of calcined faffron of Mars, and proceed as before.

GLAZING, \textit{Sea green}, is made of five pounds of lead-ashes, one pound of tin-ashes, three pounds of flint, three quarters of a pound of fand, half a pound of tartar, and half a pound of copper duft.

GLAZING, \textit{White}. A fine white glazing for earthen-ware is thus prepared: Take two pounds of lead, and one of tin; calcine them to ashes: of this take two parts, calcined flint, white fand, or broken white glafs, one part, and fand one part: mix them well together, and melt them into a cake for use. The trouble of calcining the tin and lead may be prevented, by procuring them in a proper flate.

The white glazing for common ware is made of forty pounds of clear fand, twenty-five pounds of litharge, or lead-ashes, twenty-six of pot-ashes, and ten pounds of fand: these are three times melted into a cake, quenching it each time in clear cold water. Or, it may be made of fifty pounds of clean fand, twenty of lead-ashes, thirty of wood-ashes, and twelve of fand.

A very fine white glazing may be obtained by calcining two parts of lead, and one part of tin; and taking one part of this, and of flints and commom fand, of each one part, and fufing the mixture. See \textit{Delf-ciw}.

A white glazing may be prepared by mixing one hundred pounds of mallicot, fifty pounds of red-lead, twenty pounds of calcined tin or putty, and ten pounds of common fand; and calcining and powdering the mixture several times.

GLAZING, \textit{Tellow}, is prepared of red-lead, three pounds; calcined antimony and tin, of each two pounds: or, according to fome, of equal quantities of the three ingredients. These must be melted into a cake, then ground fine; and this operation repeated several times: or, it may be made of fifteen parts of lead-one, three parts of litharge of silver, and fifteen parts of fand.

A fine yellow glazing may be procured by mixing five parts of red-lead, two parts of powdered brick, one part of lead, one part of the white glazings, and two parts of antimony, calcining the mixture, and then fufing it. Or, take four parts of white glafs, one part of antimony, three parts of red-lead and one part of iron feals, and fufe the mixture: or, fuse fourteen parts of flints, one part of iron-filings, and twenty-four parts of litharge. A light yellow glazing may be produced with ten parts of red-lead, three parts of antimony, and three of glafs, and two parts of calcined tin. See \textit{Gold-coloured Glazing}.

GLAZING, \textit{Citrone-yellow}, is made of fix parts of red-lead, seven parts of fine red brick-dust, and two parts of antimony. This mixture must be calcined day and night for the space of four days, in the afi-hole of a glafs-boule furnace, and at laft urged to fufion.

GLAZING of \textit{Delf-ware}. See \textit{Delf-ciw}.

GLAZING of \textit{Porcelain}. See \textit{Porcelain}.

GLAZING of \textit{Stone-ciw} and Queen's ware. See \textit{Porcelain}.

GLAZING for Tobacco Pipes. See \textit{Tobacco-pipes}.

GLAZING, in \textit{Painting}, a term of the art, expressive of a peculiar mode or variety in the practice of it. It consists in laying a transparent colour, made very thin by a great quantity of oil, or other vehicle, over a fixed body of opaquethe;
GLAZING.

colour; and its intent is, to give a greater degree of clearness and brilliancy to the colour produced by this process, than can be obtained by mixing together in suspension the two colours thus employed. In this mode their hues are blended, without disfigurement of each other; whereas, in mixing them in the ordinary way, a certain diminution of their brilliancy takes place, produced by the dissimilar nature of their qualities.

Glazing appears to have been practiced very early in oil-painting; and probably the use of varnishes over pictures painted with water-colours may have first shown its utility. Indeed it could not fail to be the case, if the varnish employed happened to be tinged with any colour; for the latter pictures acquired by that circumstance must be strikingly engaging; a harmony and sweetness are thereby gained, which all other means are vainly employed to obtain. It is therefore surprising that all those who practiced the art of painting after the discovery of the use of oil, should not have given it to the application of it. Yet it is certain that the Roman School is remarkably deficient in the knowledge of the value of this practice, and most frequently neglected to use it; owing probably to the employment painting found in fresco. The Venetian and Dutch schools, on the other hand, employed it in perfection, and it is in their works that a knowledge of it may best be acquired.

The principal difficulty attending the use of glazing, is to avoid the too common application of it; as it does not suit the representations of all Substances, in its more immediate sense; though one general glaze over a picture, completed in its forms, will at all times benefit the work; if it happens not to be too low, or tinted, in its tones of colour.

All kinds of gems and polished substances, such as metals, filks, velvets, &c. are imperfectly wrought to effect, when it is not employed; and fleh, which is in nature compounded of a great variety of colours, is seldom quite perfect in its hue, when glazing is not employed to finish with. It is a species of it, produced by the yellow varnish being but partially removed from old pictures, which gives them their peculiar and brilliant luire. It is quite impossible to make any effect exactly like it with fresh colours, unless force and care be used to furrow the effects of time; such as rubbing in dirt, and then partially removing it, &c. tricks which picture dealers are perfectly conversant with; and by which many an ingenious copy is passed off upon the unskilled amateur, to the enrichment of the dealer, and the future annoyance of the buyer, when time and improved information let him into the secret.

Glazing is the most valuable part of the practice of painting, when judiciously employed; as it produces clear broken tones of colour, which have no reminiscence of the palette, but deceive the eye by the variety of hues, and dazzling effect of light, produced by one colour shining through another in different degrees of illumination; much more like the effects of natural objects, than the use of opaque colours can possibly produce. But then great dexterity and judgment are required to use it properly in a general manner. A well-informed and scientific artist knows the tone which one colour glazed over another will produce; and without that knowledge, a dirty dunhef may be the effect, instead of the cleanliness required; and if not successful, it is always injurious; there is no medium in the application of it. If the under colour is not improved, it is sure to be deteriorated; and it will require repainting, to restore its original freshness. So that when a painter has prepared a work for glazing, (which should always be done with great cleanliness and precision,) the most extreme caution is requisite in adapting the tone of the glaze which he proposes to use to the general hue of the picture before he applies it. It is not possible to give rules more explicit on this matter; the indefinite subdivisions of hues which all colours are capable of, must for ever leave to the feeling and judgment of the artist their peculiar application. It is hardly necessary to state that a glaze of red, over blue, will produce purple; of blue, over yellow, green; and of red, over yellow, orange; but it may aid the student in his practice, if he considers, that all the varieties of tone the original colours are capable of, will, when equally employed, produce a corresponding compound; and, of course, if his picture be of too red a hue, though of a light tone, a corresponding one of yellow, will change it to the end he may require; and if he use the blue and yellow together as a green, it will produce a negative colour; totally destroying the red; but the varieties are too complicated and numerous to follow.

GLAZING of Cloth. The process of glazing is used for all the flout fabrics of cotton goods, and sometimes for those of linen. It is a part of the general processes of finishing goods for the market, and which is carried on by those who are generally called cloth-hatters, or calender-men. The glazing is done by putting on the cloth a small quantity of white wax, such as that used in the manufacture of wax candles, and the glofs is afterwards effected by the friction of any smooth body on the surface of the cloth. By the ordinary process the apparatus is very simple, consisting merely of a smooth table, a little inclined towards the operator, like a common writing desk, upon which the cloth to be glazed is spread smoothly, and drawn over, as occasion requires, from one end of the piece to the other. Above this is a lever, suspended from any convenient fixture to the roof, the lower end hanging in contact with the cloth, and by moving this backward and forward, the necessary friction is produced. The end of the lever next to, and in contact with the cloth, is faced with a smooth piece of flint or pebble, finely polished, and of a cylindrical form, the under surface of which is in contact with the cloth. This lever being drawn backward and forward by the operator's hands, the whole cloth is polished or glazed in succession, the joint at the top of the lever being fitted into a horizontal slider, which allows the polisher or flint to be moved from one side of the cloth to the other. In this way of glazing, the whole is performed by the power of a man's arms and hands; and, from the position of his body being constantly inclined over the table, is found to be a very laborious and fatiguing operation. The great number of people necessarily employed by this operation, and the difficulty of getting large quantities of goods rapidly glazed to answer the demands of hurried shipments for exportation, suggested lately the idea of a more speedy and efficacious manner of performing the operation of glazing by an improvement and alteration in the construction of the common five-howl calender. This improvement was planned and executed at the extensive works of the late Mr. John Miller of Glasgow, who furnished the inventor with the means of carrying his plan into effect, and upon a proof of its efficacy on trial, his majesty's royal letters patent for its exclusive use to the inventor or his assignees within Scotland were obtained in the usual form. Two or three machines were then constructed for his own works, to which, as far as we know, they are still confined; and these machines have given the most universal satisfaction to all who have had their goods glazed by them, while at the same time an immense reduction of labour has been effected by this process.

The patent glazing machine, like the common calender, consists of five bowls, or cylinders, four of which are of cast
GLA

call iron, smoothly turned, and finely polished on the surface, and the large or intermediate cylinder is generally of plate
board on an iron axis. In the common operation of smoothing
by means of the calender, the velocity of the cylinders
revolving upon their own axes, is in the ratio of their respec-
tive diameters, so that an equal quantity of superficies is con-
stantly exposed of each. In the calendering-mill, or machine,
it is only necessary that the motions of one of the cylinders
should be so much accelerated as to produce the friction
corresponding to the glazing by rubbing against the other
cylinders with which it is in contact, so as not to be liable to
wear or otherwise injure the fabric. This motion is pro-
bred by means of wheels placed in the following manner:
On the axis of the main cylinder, A, is a call iron wheel of
any convenient diameter and number of teeth. This wheel
works into the fluid-wheel, B, the number of whose teeth is
not material to the speed, and whose diameter may be regula-
ted so as to pitch well into the remaining wheels. The
wheel is placed to revolve loosely on an iron fluid, screwed
into the frame-work of the machine. The fluid-wheel B
gives motion to the second fluid-wheel, C, and it continues
the motion to the wheel, D, which is fastened on the axis of
the first iron cylinder. The upper cylinder works merely
by friction, as in a common calender, and when the intermediate
fluid-wheel is removed by being taken off the fluid, the
whole cylinders will revolve exactly as in the common ma-
chines, without producing any glazing effect. The simpi-
city of this machine, the regularity of the gloss which it
gives, and the immense saving of labour, are powerful
recommendations in its favour. The great quantity alo which
may be effected by it in a very limited time, renders it pe-
larly adapted to meet the occasional exigencies of the
experimenter; and the additional advantage of its facility of adapta-
tion to the purposes of the common calender, when glazing is
not required, adds to its value and utility. Upon uniform
occasions, one of these engines, by being constantly em-ployed
even by day and night, will glaze from 600 to 800 pieces of cloth,
in 28 yards each, weekly.

Those employed in the late Mr. Miller's works are driven
by means of a steam engine, by which various other kinds
of machinery, adapted to the various operations of the bus-
iness, are set in motion. Should any machinery of this de-
scription be contracted in works where there may be a gen-
eral necessity of keeping them constantly employed for the
purpose of glazing, it will be very necessary that care should
be taken that the moving power, whether water, steam, or
horse, should be ample; as it must be evident, even to those
who are not practically conversant with the calculation of
power and resistance, that this calender, when employed to
glaze, must require considerably greater force to keep it in
motion, than when the cylinders revolve in the ratios of their
diameters, for the mere purpose of common calendering or
smoothing.

We are not in possession of sufficient data to enable us to
ascertaim, with any tolerable precision, the quantum of re-
stistance added by the friction; nor are we aware that any ac-
curate experiments have been made for that purpose. But it
is evident that it must be very great in all calenders. It is reas-
able also to infer, that it may be considerably increased or
diminished by the texture or fabric of the flint upon which the
glazing operation is performed. Hence, if these machines
are employed incessantly in large works, and let in motion by
the same power, which also drives machinery adapted to other
purposes, care must be taken that the power be sufficient to
effect all the various purposes to which it is applied. And
should this be attempted, under the impression that the glazing
might be performed by the same power as common calender-
ingen, a deficiency would be found, which must render it ne-
cessary to disengage part of the machinery, in order to give
sufficient momentum to the rest. This is perhaps, one of the
most common, and at the same time, most obvious errors
into which the projectors of large works, who are not mechan-
ics, are apt to fall. In the first instance, detours that a
large establishment should be to fire at the ball possible
expense, they too frequently calculate too barely, and are
then obliged either to abandon their whole scheme at a great
loss, to work it under serious and ruinous inconvenience, or
to repair, at a triple expense, what they have left deficient
at first.

GLAZOV, in Geography, a town of Russia, in the
government of Viatka, on the Tchetsva; 56 miles E.S.E. of
Viatka. N. lat. 58° 5'. E. long. 51°.

GLEAG, or GLAIL, in Ornithology, a name used in the
northern parts of the kingdom for the milke, or kite. See
FALCONS.

GLEAM is popularly used for a ray or beam of light.
Among falconers, a hawk is said to glean, when the cats
or thrown up filth from the gore.

GLEAM, in Geography, a river of England, which rises
about four or five miles N. of Stanfordin Lincolnshire, and
ranst into the estuary called the Wash, five miles N.E. of
Spalding.

GLEAMING, the act of gathering or picking up the
eras of corn left behind, after the field has been reaped, and
the crop carried home.

By the customs of some countries, particularly those of Me-
lun and Ebalpes, all farmers and others are forbidden, either
by themselves or servitors, to put any cattle into the fields, or
prevent the gleaners in any manner whatever, for the space
of twenty-four hours after the carrying off the corn; on penalty
of confiscation, &c. It hath been said, that by the com-
mon law and custom of England the poor are allowed to en-
ter and glean upon another's ground after the harvest, without
ch. 15. 438. This humane provision seems to be borrowed from
the Mosaic law. Levit. xix. 9. xxiii. 22. Deut. xxiv.
19, &c.

Gleaning is a practice that is little heard of in the more
northern parts of the kingdom, but which prevailed greatly in
some of the southern districts. The custom is of great anti-
quity; and whether it is not the poor have any legal right
in this country, to glean, except by the express permission of the
farmer, it has however been so long sanctioned by its con-
venience, that it is but rarely interrupted or put a stop to by
him. In some places where it is carried on to excess, it would
then become necessary for the farmers to make regulations in respect to
it, that should not be broken through on any account
whatever. If this be not the case, the abuse is frequently
so great that they are much injured by it, "as the poor glean
among the sheaves, and too often from them," as is notorious
to those who have attended to the practice. It has been
therefore suggested to make it a rule not to hinder a gleaner to en-
ter a wheat field until it is wholly cleared of the crop, which
would, no doubt, prove a very beneficial regulation. It
does not, however, upon the whole, appear that much bene-
fit is derived to the poor from the custom, while it con-
dently leads to idleness, immorality, pilfering, and a number
of disadvantages.

GLEBA ALANA, a name by which some call the yel-
lowish white tripoli.

GLEBE, Addit. In the civil law, fases were held to be
annexed to the glebe; i.e. they went with it; were held with
it, &c.

The right of patronage should be annexed to a glebe.

GLEBE,
GLEBE, GLEBA, in *Natural History, Chemistry, &c.* a clod, or piece of flone or earth, frequently containing some metal, or mineral.

The glebe is carried to the forges to be wrought, purified, and melted, &c.

GLEBE, or *Glebe-land,* is properly used for church-land;

"Dos vel terra ad ecclefsiam pertinent."GLEBE-land is most commonly used for land belonging to a parish-church, beside the tithes.

Thus, Lindwood: "Glebe et terra in qua consitit dos eccleſiae; generaliſter tamen finitur pro folo, vel pro terra culta." Though in the most general, and extensive use of the word, glebe is applicable to any land or ground belonging to any benefice, fee, manor, inheritance, or the like.

If any parson, vicar, &c., hath caufed any of his glebe lands to be manured and fowed at his own cofls, with any corn or grain, the incumbents may devise all the profits and corn growing upon the faid glebe by will. (Stat. 28 H. 8. cap. 11.) And if a parson fows his glebe and dies, the executors shall have the corn fowed by the teftator. But if a glebe be in the hands of a tenant, and the parson dies after feverance of the corn, and before his rent due; it is faid, neither the parfon's executors nor his fucceffor can claim the rent, but the tenant may retain it and alfo the crop, unless there be a fpecial covenant for the payment to the parfon's executors proportionably, &c. Wood's *Infl. 163.*

GLEBE, in Geography, a town of America, in the flate of Virginia; 10 miles S.E. of Tappanville.

GLEBOUS, in Rural Economy, a term sometimes provincially signifying the turf or gravity surface.

GLEBOW, in Geography, a town of the duchy of Courland; 18 miles S. of Miottaw.

Gen. Ch. Car. Persianth of one leaf, tubular, cylindrical, frilled, very small, permanent; its mouth having five sharp unequal teeth. Cor. of one petal, ringent; tube flender, compressed; upper lip erct, oblong, lower lip spreading, larger than the upper one, obtuse, three-cleft, its middle lobe larger, emarginate. Stam. Filaments four, under the upper lip, two of which are shorter; each pair of anthers forming themselves into a crofs. *Pijf.* Germen four-cleft, style thread-shaped, bending under the upper lip; stigma cleft, acute. *Peric.* none; the calyx nonrigidly four, ovate in its bizon.

1. *G. hederacea.* Ground-ivy. Linn. Sp. Pl. 827. Engl. Bot. t. 823.—"Leaves kidney-shaped, crenate."—Found in woods and hedges, flowering in April and May. Root perennial, and creeping. Leaves on foot-flats, dotted beneath with glandular points. *Flowres* axillary, about three to each leaf, prettily speckled with white and blue. *Calyx* dilated. *Anther* white. Ground-ivy has been so long and so generally known, that it has obtained various appellations, such as *Ale-hoof,* Gill, Robin-run-in-the-hedge, Cat's-foot, &c. Before the introduction of *Hops* its leaves feem to have been used for flavouring and clarifying ale. Gerarde has enumerated a long train of "Vertue" supposed to be possessed by this plant; and when infused into tea or honey, it is still a favourite medicine with the common people for coughs. Many animals eat it, though it is faid to injure horses if taken too copiously. The specific character is now superfluous, as two species enumerated in the first edition of the *Species Plantarum* are now referred to other genera.

GLECOMA *Hederaecea, ground-ivy or gill,* in the *Materia Medica,* is a well known plant, growing commonly under hedges and flowering in April. Ground-ivy has a peculiar strong smell; the leaves, according to Dr. Withering, being bent beneath with hollow dots, in which are glands secreting an effential oil, and above with little eminences, which do not secrete any odoriferous oil; for this surface, when rubbed, yields no peculiar scent, whereas the under surface affords a pleasant reviving scent. The tafe is bitter, and somewhat aromatic. This plant was formerly supposed to posses great medicinal powers, not discovered by former experience; accordingly it is omitted in the materia medica by the London college. Its qualities have been described by different authors, as pectoral, detergent, aperient, diuretic, vulnerary, corrodorant, eruline, &c. and it has been recommended for the cure of those disfresses to which these powers seem to be most adapted, but chiefly in pulmonary and nephritic complaints. In obstinate coughs it is a favourite remedy with the poor, who, probably deriving benefit from it, perfitin its ufe. Ray, Mead, and others, speak of its being usefully joined with fermenting ale; but Dr. Cullen obferves, "it appears to me frivolous. In fhort, in many cafes where I have feen it employed, I have had no evidence either of its diuretic or of its perifical effects. In common with many others of the verticillate, it may be employed as an eruline, and in that way cure a head-ache, but no otherways by any specific quality." It is usually taken in the way of infusion, or decoction, as tea. Woodville Med. Bot.

GLEANONITAS, a name given by the ancient *Phvfcus,* to a fort of wine impregnated with penny-royal, much recommended in all obftructions. It takes its name from *gleos,* the Greek name of penny-royal, or *pulegium.*

Female, on a separate plant, Car. Persiathan like the male, but of five leaves. Car. Petals five, long, acute, rather spreading. Nectaries two, short, like abortive filaments. *Pijf.* Germen superior, broad, compacted, longer than the corolla; style short, reflexed; stigma thick, the length of the style, to which it is longitudinally affixed, downy in the upper part. *Peric.* Legume very large, broad, compreded quite flat, divided by numerous tranverse partitions, and filled with pulp. Seeds solitary, roundifh, hard, and polished.

At the summit, generally, of the male spike is an united flower, with four calyx-leaves and as many petals, with a nectary and flammes like the male, but with a pillif, producing perfect fruit, as in the female. Hence Linnaeus referred this genus to his clas *Pulegium,* but if it remains there
GL E

there it must rather be on account of the difference of structure in its male and female flowers, than for their flight sexual anomalies. Even for this difference of structure we should rather place it in *Diosca.* See Sm. Introd. to Botany, 478, 485.

Obf. This genus has considerable affinity with *Ceraonia,* especially in the fruit. We cannot apply the term actinomy to its inoffensiveness, which is a spike.

Female, Calyx of five leaves. Petals five. Nectaries two. Pilif one. Legume.

Some flowers united, four-cleft.

The species of *Gladiola* are as yet a mass of confusion. *G. trianum.* Linn. Sp. Pl. 1509, the original one, a native of North America, was cultivated by bishop Compton in 1506, and is a tall handline tree, which bears our climate well, except being sometimes broken, like *Rheum* *Pilea* *sativa,* by strong winds. It is remarkable for its large frond or compound spines, which grow to the length of six or eight inches, from a very slender base. The leaves are deciduous, bipinnate, large, consisting of innumerable elliptical, slightly toothed, nearly smooth leaflets, half an inch or nearly an inch long. Flowers greenish, in axillary spikes. Some leaves appear to be finely pinnate, but we know not whether this is a specific difference or not.

A very distinct species is cultivated with us by the name of *G. cambria,* which Linnæus also had at Upsal, but he does not seem to have described it. The spires are compound. Leaves finely and abruptly pinnate, of seven or eight pair of thin, squarish, unequal-sided, crenate leaflets, gradually larger upwards, the terminal pair being sometimes twice the dimensions of the next.

In Summer's garden, belonging to the duke of Northumberland, is a tree of another species, of which we find no mention. Its leaves are finely pinnate like the leaf, and the leaflets also gradually larger upwards, but they are coriaceous, elliptical, their sides very seldom unequal. The calyx-leaves and petals are narrower, shorter, and blunter than in *G. trianum.* Of its spires we have no account, but the leaves and flowers were communicated to us by Mr. Mayo, in August 1796, as a *Gladiola* not in the *Hortus Kewensis,* where, indeed, all that are known are made varieties of the *trianum.* From the new edition of this valuable work perhaps more information may be expected.

*G. inermis,* first mentioned by Linnæus in the second edition of Sp. Pl. 1509, seems to have been adopted without a specimen, from Plukenet's t. 123 f. 2, to which is added Miller's t. 5, which last represents a *Mimosa,* nor does any subsequent writer appear to know any thing of this species.

It would be a tedious and unprofitable task to attempt a determination of the synonyms of this genus, even if the species were defined. The letter is a defibrable object, and worthy the attention of those who have perpetual access to the old botanical gardens about London, and can observe these trees at different periods of growth. It is necessary to determine whether the simply or doubly pinnated leaves mark a specific distinction; whether the spires vary according to the age of the tree; and whether the legume is, in any species, constantly single-fed, or merely from accidental abortion. Travellers in America can scarcely be expected to throw any light on such botanical questions as these, though a careful observer, resident there, might render highly important services to botany, and to the most useful arts of life, by determining first the specific differences, and then the economical qualities, of all the American trees, among which the *Gladiola* claim a distinguished place. The labours of a Lambert among the Pines, and a Michael among the Oaks, are models for future enquirers.

*Gleditsia,* in *Gardening,* comprehends a plant of the deciduous tree or shrub kind, of which the species usually cultivated is the three-thorned acacia (*G. tricantus*), which seldom rises higher than a shrub in this country.

There are several varieties with different numbers of spines, and with stronger and weaker spines.

Method of Culture.—These trees are capable of being increased by fowling the seeds, which are obtained fresh from America, in a bed of light earth, in the early spring season, watering them occasionally when the season is dry. It is, however, a much more expeditious practice to sow them in pots, and plunge them in a moderate hot-bed. The plants should be kept clean during the first summer after they appear, and in the succeeding winter be well protected from severe frosts, especially such as are in pots.

The young plants may, most of them, in the following spring, be removed and set out into nursery rows, at a foot or eighteen inches distant from each other, and eight or ten inches in the rows. Such small plants as remain, may be put out in the same manner in the next autumn or spring.

The plants should continue in this situation till they have had two or three years growth, after which they may be transplanted into the situations in which they are to remain any time towards the latter part of the spring season.

These plants are found to succeed best in situations where the soil is of the more light deep kinds, and rather inclined from the inclement of the atmosphere.

They are all very ornamental trees, and well adapted to large shrubberies, plantations, and pleasure grounds. When planted alone, on lawns, and large open spaces that are kept in short grass, they produce a fine appearance. They have, however, the disadvantage of putting forth their leaves at rather a late period.

*G. Lee,* a musical term derived from Skinner, Junius, John-son, and all the etymologists, from *glie,* Saxon, joy, mirth, sport.

His merry men commanded he
To make him both game and glee.

Chaucer, Rin. S. Tap. v. 126.

The term, we believe, is not to be found in music-books, or musical writers, before the middle of the 17th century. The first time it appears in the title of a collection of canons, rounds, and catches, is in a publication by John Playford, 1657, under the title of "Dialogue, Glis, Ayres, and Ballads, of two, three, and four Voyces."

A glee in music implies nothing more in its original sense, in our printed music-books, than a song of three or more parts, upon a gay or merry subject, in which all the voices begin and end together, singling the same words." When subjects of fatigue or imitation occur, and the composition is more artificial than simple counterpoint, it leads resembles a glee than a madrigal, which it might, with more propriety, be called, if the words are serious; for a serious glee forms a complection, and a direct contradiction in terms. The word glee, in Saxon, German, and English dictionaries, ancient and modern, implying *mirth,* *merriment,* and in Chaucer, and other old authors, *muse* itself.

*Glee,* in *Surgery,* commonly signifies the continuance of a thin discharge from the urethra, after the inflammatory symptoms of a clap have for some time ceased. However, the running which takes place from the urethra, in cases of strictures, diseased prostate gland, &c. is also frequently called a gleet. A mere gleet, unattended with any other difcase of the parts, is not accompanied with the remarkable

pain.
G LEET.

pain and discharging inflamnation in making water, which are produced by gonorrhoea. The latter affection may be considered as acute, while the gleet is quite of a chronic nature. It was one of the opinions of Mr. Hunter, that a gleet differed from a gonorrhoea, likewise, in not being infectious. It is well known that it was one of the doctrines of this eminent surgeon, that the poison of gonorrhoea, and that which is productive of lues venerea, are of the same quality, and that the different effects are owing to the different structure of the parts concerned in the two diseases. We need not here enter into an investigation of this part of the subject. All that we wish to observe is, that if Mr. Hunter means, when he states, that a gleet differs from a gonorrhoea in not being infectious, that a gleet is not capable of communicating the general disease, no one can question the accuracy of the observation. But, on the contrary, if the affection implies that the matter of a gleet, when applied to the pudenda, will not bring on a pain in making water, a discharge, &c., then we differ from the opinion altogether. We have known an influence, in which a gentleman, who had had a gleet upon him for upwards of a year, and who, on the presumption that it was not infectious, ventured to have connection with a young woman, of whose continence, with regard to other men, we ourselves entertain no doubt. However, there may be gleets of various kinds, and none of them may be infectious, and others not so. When, after a gonorrhoea, a thin discharge continues for a long while, to take place from the urethra, the complaint may depend upon a weakness of the viscid, or, as Mr. Hunter expresses it, upon a habit of action, which the parts have contracted. When a gleet arises from a fluxure in the passage, or from a disease of the prostate gland, the cause must be referred to irritation, and the cure depends on the removal of the original complaint.

Gleets, which are the consequences of gonorrhoea, are often exceedingly difficult of cure, and what is very curious, it frequently happens, that, after they have received every sort of remedy, and after the patient has long given up the use of medicines and injections, a sudden cure spontaneously occurs. Many gleets undergo a temporary disappearance under particular modes of treatment; but, as soon as this is remitted, regularly return again. A vast number of gleets depend upon the presence of a fluxure in the urethra, and of these are not curable by injections. We have often thought that in all cases of gleets, it should be the invariable custom of the surgeon to introduce a bougie, for the purpose of ascertaining whether there is any obstruction in the passage; for, when the discharge depends on a fluxure, the patient might make use of balms, turpentine, and bougies, for years, and yet receive no benefit whatever. At all events, whenever a gleet yields ordinary means, the state of the urethra and of the prostate gland ought to be examined. See Prostate Gland, Disease of; and Stricture.

Mr. Hunter was of opinion, that the spontaneous disappearance of a gleet, after a long resistance to every sort of medicine and application, very frequently depended upon accidental changes in the patient's constitution. It was another sentiment of this celebrated surgeon, that some gleets were connected with rheumatism. This idea is founded on the circumstance, that more gleets may be cured by sea bathing, than any other kind of bathing. It is also supported by the fact, of sea water being sometimes an effectual means of cure, when employed as an injection. We have always found faith with this plan of judging of the nature of diseases. If a disorder yields to mercury, practitioners are apt to decide immediately, that the complaint is venereal. If a malady, like a gleet, gives way to sea bathing, which benefits febrifugal complaints, such surgeon, as reason on Mr. Hunter's principles, will immediately set down the case as febrifugal. It is never remembered in this calculation, that mercury cures many diseases besides the venereal; and to do sea bathing many complaints besides those which are of a febrifugal nature.

Gleets have also been represented as always connected with a relaxed constitution, though we think we have seen the complaint in subjects, who were strong, robust, and young, with every appearance of general health, and whose state seemed to us a striking contradiction to the foregoing observation.

Gleets, as we have before stated, are often exceedingly difficult of removal. Sometimes, indeed, they may be got rid of with tolerable ease; but in other instances, they completely frustrate the most skilful surgery, and the patient, tired of the incessant trial of different remedies, relinquishes the trial of all. In slight cases, and occasionally in invertebrate ones, a cure may be effected by exhibiting internally the balsam of copaiva, the oleum terebinthii, or the tincture of bylze (catharines). It is well worthy of notice, that when a cure can be accomplished by these means, benefit is often derived from their employment. For this reason, when they neither disappoint, nor remove the gleet in the course of five or six days, Mr. Hunter made it a rule never to continue their use any longer, but have recourse at once to other methods. We have already remarked the great tendency of many gleets to return, after being for a time stopped by different modes of treatment. Hence practitioners should never discontinue the successful plan immediately the discharge ceases, but persist in its adoption for ten days or a fortnight, after all the symptoms have entirely gone off.

In relaxed habits, gleets are very likely to be cured by the cold bath, sea bathing, barks and fleshy medicines. Cold bathing indeed often succeeds in every kind of constitution, when other methods are of no avail. We have known strong young men labouring under gleets, who could not get rid of them in many ways in London; but who got well almost immediately on going to the sea side and bathing there. There can be no doubt also, that some beneficial resolution in the flux, arising from the change of air, might have a considerable share in the cure. We lately had under our care a gentleman with a gleet, which had lasted nine months, but disappeared all at once on the patient going for a short time to a part of the country which was not near the sea.

There are two principal kinds of injections in use for the cure of gleets, viz., astringent and irritating ones. The astringent ones are, for the most part, such as the decoction of barks, and solutions of zincum vitriolatum, chlor, or nitric of lead. An injection of proper strength, containing cuprum vitriolatum, balsum gallicum, and camphor, is also an exceedingly eligible one.

The bell irritating injection which we know of, is that made by dissolving two grains of the hydrargyrum muriatus in eight ounces of distilled water.

Bougies may also be considered as acting on the urethra as irritating applications, and hence they are occasionally recommended to be worn for the cure of gleets. In general, common bougies are employed; but sometimes others, medicated with camphor or turpentine, are used.

In irritable constitutions, the latter kind of injection and the bougies may exercise a good deal of irritation, pain, fluxure, &c. so that some circumspection is necessary in the employment of such means. We may state, indeed, that no endeavour should ever be made to cure a gleet, by exciting irritation in the urethra with stimulants injections, or bougies, before mildest means have failed. We have found a weak
weak injection of the hydrargyreum muriatus more frequently successful than any other. One grain to fix ounces of water is quite strong enough to begin with, and the strength may be gradually augmented, in proportion as the urethra appears capable of bearing it. The practitioner must not leave off the injection as soon as the discharge ceases; for if he does so, the gleet will generally recur. The plan should still be followed up for about a fortnight.

When gleet are to be cured by bougies, it is necessary to wear these instruments about a month or six weeks before any dependence can be put in the permanence of the cure.

Neither the surgeon nor the patient should be deterred from profiting in the trial of irritating injections or bougies, by the circumstance of their appearing to increase the discharge at first. This they always do.

Mr. Hunter thought that moderation and regularity in diet were conducive to the cure of gleet. So is a quiet kind of life in the generality of cafes, but there are instances in which gleet seem to be benefited and cured by rough exercise on horseback.

A return or an increa of a gleet is very apt to be the consequence of intercourse with women, and the patient often thinks that he has received a fresh infection. Mr. Hunter thought that the cafee might be discriminated by the short time which intervenes between the connection and the reappearance of the discharge. Gleet are often too exceedingly obilinate, that the surgeon cannot be informed of too many modes and principles of cure. On this account we deem it right to mention that gleet seem to be curable on the principle of counter-irritation. Hunter has seen a gleet flop on the breaking out of two chances on the glands penis, and the discharge has been known to stop as soon as a blisters was applied to the under part of the penis.

Gleet have likewise been cured by electricity.

Women are liable to gleet, and the disease being situated in less irritating parts, whatever injections are used, may be made stronger than for male patients.

It is almost unnecessary to remark, that halfmen and turnitines, internally given, can have no specific effect on the parts affected in women, as they have on the urethra in men. Hence it would be absurd to prescribe such medicines for female patients.

GLEBERG, or GLITZBERG, in Geography, a town of Germany, in the principality of Nassau Weilburg; eight miles N.E. of Wetzlar.

GLEICHEN, a county of Germany, in the principality of Gotlia, divided between the princes of Gotlia, Hohenlohe, Hatzfeld, and Schwartzburg; situated on the banks of the Ohr, between Erfurt and Gotlia.

GLEICHEN, Frederick von, in Biography, was born in the year 1714. He was intended and educated for the profession of arms, and spent the early part of his life as an officer in the service of Bavenoth, and was distinguished by his attention to military discipline. He rose to the rank of lieutenant-colonel, and obtained the favour of the margrave. His honour did not sit easy upon him, for he retired, and in 1756 his wishes were accomplished; he obtained a commission from the service with a handsom pension, to which was afterwards added the rank of privy councillor. He now had leisure to distinguish himself as a philosopher, a naturalist, and a writer. His attention was accidentally excited to microscopical observations, and not satisfied with the instruments already in vogue, he constructed an universal microscope, with which he combined the polar microscope. His principal observations relate to seminal animalcula, and infuion animal: he would fit day after day at his glass, and was always displeased if he experienced any interruption while engaged in his favourite pursuit. By daily practice he had acquired a vivid recollection of minute acuteness of sight, which was of the greatest advantage to him in his researches. Though he had an ardent attachment to science for the love of it, yet he devised various economical plans, from which he expected to derive great emolument, but they were the schemes of a dreamer, and did not prove of real advantage either to himself or the world.

He died in June 1783, leaving behind him numerous works in natural history, as "Observations on the Parts of Fruittification in Plants when in bloom, and on the Insects found in them;" "History of the Common House Fly;" "Treatise on seminal Animalcula and infuion Animalcula;" "A Essay towards the History of the Tree-louse from the Elm;" this insect, the aphus ulmi campeli, call our author the labour of eight years; it is the caule of the bladders on the leaves of the elm-tree during the spring. Gen. Biol.

GLEICHENBERG, in Geography, a town of the duchy of Stirm; 10 miles N. of Ruckhill.

GLEICHENBERGAN, or GLEICHENBERG, a town of Germany, in the county of Henneberg; four miles N. of Ronnhild.

GLEICHENIA, in Botany, named by the writer of this article in honour of Philip Frederick Baron von Gleichen, author of a splendid microscopical work on the structure and physiology of the parts of fruitification in several plants, published at Nuremberg, in folio, with coloured plates, in 1764. As the seeds of ferns were among the subjects to which Baron Gleichen paid great attention, a genus belonging to this curious tribe was judged peculiarly proper to commemorate him. Smith in Mem. de l'Aced. de Turin, v. 5. 419. t. 9. f. 10. Tracts. 258. t. f. 16. Swartz. Fil. 165. Brown. Prod. v. 1. 160. (Mertensia; Wilden. in Àet. Holm. ann. 1821. 165. t. 45. f. 5. Swartz. Fil. 165.)—Cliff and order, Cryptogamia Filiæ; sect. Annulata. Nat. Ord. Filiæ dorsiæ.

Eff Ch. Capsules in a simple, concentric, orbicular feries; each feries constituting a round separato dot, on the back of the leaf. Cover none.

This genus was first founded on the Onclea palposdica of Linnaeus, an elegant and singualr fern, native of the Cape of Good Hope. In this the capules are usually three, rarely four together, half immerse in the under side of the frond, and as each berries by a longitudinal fissure, they all together have exactly the appearance of a single capsule, of three cells, and three valves, the partitions seeming to originate from the centre of each valve. Traces of a jointed ring appear upon some of the valves only, and rather resemble the corrugations of those ferns termed *paciens* inundates. Several other species, strictly allied to the original one in habit and appearance, so as to be at first sight scarcely distinguishable from it, have been found in New Holland, and have been described by Dr. Swartz and Mr. Brown. In these the capules are not immerse in the leaf, though each feries stands in a light depression. In Gleichia of Brown there are only two together; in others three, four, or even six. These new discovered species evince the propriety of Mr. Brown's measure, of reducing the *Mertensia* of Willd. into Swartz to Gleichia, as their frettations exactly agree. *Diacoptera* of Bernhardi does not in our opinion as well afford us, having an irregular accumulation of flaked capules in each dot, though its habit is precisely that of *Mertensia*. Mr. Brown, having examined these ferns alive, determines them to be furnished with a complete, frillated, transverse, rarely oblique, ring.
This genus naturally divides itself into two sections. The original Gladiolus, of which there are five species, have the ultimate branches of their repeatedly forked stem pinnate, their leaflets or pinnae deeply pinnatifid, with short, triangular, or rounded segments, each segment bearing a single dot or series of capsules. The Meriania have their ultimate branches deeply pinnatifid, the segments linear, with a row of numerous dots on each side of the midrib of each segment, especially at its lower half. Of these we are acquainted with five or six species, all natives of the East or West Indies, or of New Holland and its neighbourhood.

GLEICHENSTEIN, in Geography, a town and castle of Germany, in the territory of Lichfield; seven miles S.E. of Heiligenlindt.

GLEINSTOLLEN, a town of the duchy of Sturia; 14 miles S. E. of Voitberg.

GLEISS, a town of Switzerland, in the Valais; 26 miles E. of Sion.

GLEIWITZ, or Gliwice, a town of Silesia, in the principality of Oppeln; 20 miles N. E. of Ratibor. N. lat. 53° 17'. E. long. 18° 35'.

GLEN RIVER, a river of Lincolnshire, which rises near Reepley, and pursues a course nearly S. S. E. to Brackn-le-Knowle, then, suddenly turning N. N. E., it plunges to Gates bridge and through the Tens, by Surfleet, to the sea at Foddyke Water; for the greater part of its course through the Tens this river is navigable for barges, a circumstance which was overlooked in compiling the alphabetical list of inland navigations in our article CANAL. The small river or drain called the Bourne, which branches from the Glen and proceeds up to Bourne town, is also navigable for some distance upwards. The South Forty-foot navigable drain commences very near this river, below the mouth of the Bourne, and proceeds by a circuitous route to Bolton. See South Forty-foot.

GLENAA, a mountain in the county of Kerry, Ireland.

See KILLARNEY.

GLENAN ISLANDS, a cluster of small islands in the Atlantic, near the coast of France. N. lat. 47° 43'. W. long. 3° 55'.

GLENARM, a post-town of the county of Antrim, Ireland, on the coast of it, adjoining which is Glenarm castle, the seat of the counts of Antrim. The town is pleasantly situated on the seashore, near the bay of the same name. It is 104 miles N. from Dublin, and 24 N. from Belfast.

GLENAVY, a post-town of the county of Antrim, Ireland, situated near the eastern border of Lough Neagh. It is 77 miles N. from Dublin on the road to Antrim.

GLENCOE, a vale of Scotland, in the county of Argyll, near Loch Leven, where, in the year 1691, the inhabitants were massacred contrary to the faith of a royal proclamation; 17 miles N. of Inverary.

GLENDALOUGH, Gleandelough, or Glendellach, commonly called the Seven Churches, an interesting object to travellers in the county of Wicklow, Ireland, 22 miles S. from Dublin, and about seven or eight miles west from Rathdrum. Its name is derived, according to Mr. Ledwich, from its being situated in a valley with lakes, from glein, a valley, and lac, a lake. That this was the true origin of the name seems to be confirmed by Hoveden, who was chaplain to Henry II., and who calls it equivalently in Latin, Episcopus Bilaganecus, the bishopric of the two lakes. Glendalough is surrounded on all sides, except to the east, by stupendous mountains, whose vast perpendicular height throws a gloom on the vale below, well suited to inspire religious dread. From these, many mountain-streams fall into the valley, and, forming a junction, assume the name of Avonmore. One of these streams, called St. Kevin's keeve, is still an object of superstitition; weak and sickly children being dipped in it every Sunday and Thursday before sun-rise, and on the third of June, which is St. Kevin's day. The two lakes in the vale are divided from each other by a rich meadow; the rent of the soil is so rocky as to be incapable of tillage by the plough. The names of the adjoining mountains, in which the word Derry often occurs, are supposed to denote that they were formerly covered with wood; at present they have only brown heath, or more fertile peat. Between the cathedral and upper lake is a group of thorns of great size; and near the cathedral the trunk of an aged yew, which measures three yards in diameter. From the remains of walls above, and the traces of foundations below the surface of the earth, the town is supposed to have been once pretty large, but the only flet appearing is the road leading from the market place into the county of Kildare. It is in good preservation, being paved with stones placed edgewise, and ten feet in breadth. There are seven churches of considerable antiquity, and some chapels which appear to be of later construction. St. Kevin was the patron saint, and his name consequently is given to many of the surrounding objects. He is said to have founded the town or monastery in the fifth century; but Ledwich attributes the erection to the Olmenn, who infelated Ireland, in the ninth century. Some figures in a chapel, containing the tomb of St. Kevin, furnish some plausible arguments in support of this opinion. There are two round towers at Glendalough, both of which are adjoining churches, but neither the cathedral nor abbey has such an addition, though if a belfry were the object of these buildings, the preference would probably have been given to them. These towers were also, in Mr. Ledwich's opinion, the work of the Olmenn. The arguments for and against this opinion will be considered under the article ROUND TOWERS. A monastery having been founded here, and the supposed miracles of St. Kevin having been proclaimed, numerous footles to his shrine; as Girald Cambrenensis saies, in what had been a barren wilderness, were to be found, after a few years, not only churches and good houses, but much wealth. According to the Irish annals, the town thus founded was often plundered by the piratical freebooters of the north, who, as they fulfilled solely by depredations, without reluctance, frequently pillaged their own countrymen. In 1162, Laurence O'Toole, afterwards archbishop of Dublin, was elected abbot; and in a few years after earl Strongbow granted the abbey and parsonage to Thomas, the nephew of Laurence. The charter is one of the most valuable and ancient in Ireland, as it protects the possessions, privileges, and immunities of the abbey. Previous to this, Glendalough had also had a bishop; but, in 1152, Cardinal Paparo endeavoured to unite it to the see of Dublin. This was refused, and, in 1179, pope Alexander III. confirmed the city to its bishop, saving the rights of the abbot. A letter, written in 1214, is quoted by Ledwich, to shew that Glendalough was at that time become a nest of thieves and robbers. In the reign of king John, the see was united to that of Dublin; but the see of the O'Toole's, who were very powerful, kept it, in some degree, independent until 1497, when the bishop formally surrendered his right and claim in the Chapter-house of St. Patrick, Dublin. The Seven Churches, when approached by the bridge of Derrybown, form a very picturesque and pleasing scene. The bridge is thrown over the Avonmore, and is composed of three elliptic arches. Derrybown, covered to a great extent with an oak coppice on one side, and the huge broccoli on the other,
GLI

other, confines the view up the river to the valley; at the end of which the great round tower, and the other ruins, appear to great advantage. As the new military road has made Glendalough easily accessible, it is frequently visited by travellers. Ledwich's Antiquities.

GLEN, properly signifies the cavity orocket of the eye.

GLEN more frequently used by anatomists for the shallower cavities of bones, into which some other bone is received and articulated.

By which it stands distinguished from cotyle or acetabulum, which is a deeper cavity, intended by nature for the like purposes.

GLENHEAD, in Geography, a cape of Ireland, in the peninsula of Inis Lowen, county of Donegal. W. long. 7° 41' from Greenwich, N. lat. 55° 29'.

GLENGARRY, a harbour of Ireland, in the county of Cork, on the north-eastern part of Bantry-bay. The arbutus grows in this neighbourhood in great perfection.

GLENARY, the name of a county in Upper Canada, bounded on the E. by the line which separates Upper from Lower Canada; on the S. by the river St. Lawrence; and on the W. by the township of Cornwall, running N. 24° W., until it intersects the Ottawa or Grand river, thence descending the said river till it meets the fore-mentioned separating line. Glengary county comprehends all the islands contiguous to it in the river St. Lawrence.

GLENICZA, a river of the deely of Warfaw, which runs into the Obra, near Kolon.

GLENKEN'S CANAL, is the parliamentary name of an inland navigation, made since the year 1802, in Kirkcudbright county in Scotland. See CANAL.

GLENLUCY, a town of Scotland, in the county of Wigtion, which sprang from an abbey of Clifertians, founded in 1195, called *Vallis Lucis.* It is situated at the northern extremity of a large bay to which it gives name; 18 miles W. of Wigtion. N. lat. 54° 58'. W. long. 4° 27'. The bay extends on the S. coast of Scotland from the Mull of Galloway to Burrowhead. N. lat. 54° 50'. W. long. 4° 50'.

GLENMORE, a small island on the W. coast of Scotland, at the mouth of Loch Sturt. N. lat. 56° 38'.

GLEN, in Anatomy, from γλυκόν, the articular cavity of a bone, and ως, form, a term applied to certain articular surfaces, particularly where the hollow is not deep.

GLERS, in Geography, a town of Germany, in the county of Tyrol; 21 miles W. of Bolzano.

GLESE, a river of Louisiana, which runs into the Mississippi, N. lat. 37° 15'. W. long. 90° 14'.

GLESUM, or Glesum, in Natural History, a name given by many of the ancients to the common yellow amber or succinum. The word seems to have been originally German, and to have been adopted by the Romans in their conquests in that part of the world. They seem to have used the word in general for any transparent substance, and thence to have applied it to amber as a transparent stone. See GLASS.

GLETHERHORN, in Geography. See JUNGERHOF.

GLIANY, a town of Poland, in Galicia; 20 miles E. of Lemberg.

GLI, a town of Sweden, in West Bohemia; 25 miles W. N. W. of Torna.

GLIGV, a town of Asia, in Daghestan; 50 miles N. of Teshin.

GLIKIEN, a town of European Turkey, in the province of Epirus; 26 miles W. of Arta.

GLINS HOLM, one of the small Orkney islands, which affords pastures; 2 miles S. of Pomona, between that and Burray.

GLIMMER, or CAT-SILVER, in Mineralogy, according to Dr. Woodward, *Method of Fossils,* p. 14, are names for *Mica,* which feef. Glim, spangles, daze, and silver, are other names by which the miners and quarrymen designate the shining plates of this substance which they meet with dispersed in the earths and stones in their works. The late Mr. William Martin observes, *Outlines,* p. 141, *Glimmer is frequently dispersed through the sand-stones and clay, forming vegetable petrifactions, but never contains their whole substance.* In Derbyshire, it is not uncommon to find nodules, or round nells or mafes of mica, in thin and separate plates, in the first, or millstone grit, which fall out on exposure, and leave spherical holes, a circumstance which has, according to Mr. Farcy, given rise to, rock-baths or holes on the tops of large loose blocks of stone where the water flows in many infulances after rain, but not perfectly, as the vulgar opinion is. See ROCK-BASIN.

GLINA, in Geography, a river of Croatia, which runs into the Save; 12 miles W. of Patrini.

GLINNOUGH, a lake of Ireland, in the northern part of the county of Leitrim, from which a small river flows to Sligo bay.

GLINNOVO, a town of Russia, in the government of Novgorod, on the Milla; 12 miles S. E. of Borovitch.

GLINSK, a town of Russia, in the government of Tchemîgof, on the river Sol'; 80 miles S. E. of Tchemigof.

GLINUS, in Botany, derives its name from γλύκον or γλυκόν, a word used by Theophrastus, and denoting a kind of maple, though we cannot trace any similitude between this tree and the little herbaceous plant, to which the name was applied by Lodetling; but it was adopted by Linnaeus.

Gen. Ch. Cal. Perizanth inferior, of five ovate, acute, concave leaves, coloured within, permanent, and downy, Corn: none; neectaries about five, resembling narrow petals, shorter than the calyx, and unequally two or three-cleft.

Stam. Filaments about fifteen, awl-shaped, flat, as long as the calyx; anthers incumbent, oblong, compressed, two-lobed. Pét. Germen of five fides; styles five: short; figmas, simple. Peric. Capsule ovate, with five cells, five fides, and five valves. Seeds numerous, roundish, in a single row at the base of the valves, tubedged, each attached by a long thread-like flalk.

G. lodhi. Linn. Sp. Pl. 663. Bawm. Ind. 112. t. 36. f. 1. *Stem hairy. Leaves ovate.* -Native of Spain, and found by Locellin in a gravelly soil near Toledo on the Tiber. Also on a dried-up rivulet between Merida and Trotullo. Rect annular. Stems procumbent, jointed, hairy. *Leaves ovate, on foot-stalks. Flowers nearly five, crowded together, sometimes on very short hairy stalks. A figure of this species is defined to appear in the Flora Graeca, t. 473, from a drawing made at Smyrna, and from which it appears that what Gartner considered as petals are more probably scale-leaves, as not being external to the flowers, after all, they ought perhaps to be called
barren filaments. They feem, from the dried specimens, to be ranged alternately with the real filaments.

2. G. distansnls. Wildl. Sp. Pl. v. 2. 929. Pluk. Amal. 16. 1. 336. f. 6. — Leaves round, hairy. Stem thrubby, prostrate. Leaflets of the calyx lanceolate. — Native of India. It seems doubtful whether G. distansnls be not merely a variety of Mantiska; but as Willdenow did not keep them separate, on the authority of a dried specimen, we have retained the species.

3. G. setiferus. Wildl. Sp. Pl. v. 2. 929. Vahl. Symb. 3. 64. — Leaves obovate, plaited. Stem thrubby. Leaflets of the calyx ovate. — Native of wooded plants in Arabia Felix during the rainy season. The whole plant is hairy, from very thick hairs, which are longer than in G. ioata. This species was first described by Vahl, from Forlkal's specimen which we have examined. The pubescence is beautifully flecked and very dentate.

GLINUS, in Ichthyology, a name by which Bellonius and some other authors have called a small sea-fish, more commonly known by the name of the eel-canculus.

GLIS. In the common acceptance of the word, this only signifies the dormouse; but Linnæus has used glise in a larger sense: and, in his Syllan of Zoology, makes it the name of the fourth order of the mammalia class of animals. The characters of the creatures of this class are, that they have only two fore-teeth in each jaw; they have no dentes canini, or dog-teeth; and the feet have toes, and are formed for leaping when they run. The animals of this class are the several species of the Icthyis, Gopor, Muro, Arctonyx, Sciuros, Myurus, Didelph, Lagctis, and Hareus; which see respectively.

Glis, a name given to several species of Myurus; of Didelphs; of Mus; and of Arctonyx; which see respectively.

GLIS; Pedans. See Vespertilo Spafens.

GLISCHROMICTHES, in Natural History, the name of a genus of compound earths. The word is derived from grs, touch, and injus, mixed. The bodies of this genus are loams composed of sand and a more viscid clay, and are of a tough and firm texture.

The earths of this genus are used in making bricks, and on some other occasions; and are of several distinct species.

GLISSA, in Ichthyology, the name of a sea-fish of the tunny kind, but of a perfectly smooth skin, and wholly free from scales. It usually grows to the length of two or three cubits, and the thickness of a man's body: it is of a very round body, and has very rough jaws, but no distinct teeth; its tail is forked, but not so arched or bentuated as that of the tunny; it lives in deep water, and is a fish of very delicate taste. Gefen. De Pisc. p. 153.

GLISSON, Francis, in Biography, was born at Rampisham, near Dorsethore, in the year 1597, and educated at Caius college, Cambridge, of which he became a fellow, and in 1627 was incorporated M. A. in Oxford. He then applied himself to the study of physic, in which faculty he took his degree of doctor at Cambridge, and in that university was made regius professor of physic, which office he held about 40 years. He settled in London for the practice of his profession, and was admitted a fellow of the College of Physicians in 1633. In 1639 he was chosen reader of anatomy in the college, and in that department acquired great reputation by his lectures "De Morbis Partium," which he was particularly requested by his col leagues to make public. During the civil wars he retired to Colchester, where he practised with great credit in those times of confusion, and was in the town at its memorable siege by the parliametary forces in 1648. He was one of that small, but illustrious society, who instituted a weekly meeting in London about the year 1645, for the purpose of promoting inquiries into natural and experimental philosophy, which, after having removed to Oxford during the troubles, was augmented in London after the restoration, and became ultimately the Royal Society. He was afterwards several years president of the College of Physicians, and died in 1677, in the parish of St. Bride's, London, aged 80. Glisson left the following works: 1. "Tractatus de Rachitide, seu morbo puerili Rickets dieéto," first published in 1650; it went through several editions abroad, and two translations into English the year after its publication, by Philip Armin, and Nicholas Culpepper. 2. "Anatome Hepatis, &c." London, 1653; afterwards reprinted at Amsterdam and the Hague. This work contains a much more exact description of the liver than had before appeared. The caputle of the venas portaara was first discovered by him, and has ever since borne his name; but Wallis and Pequet had seen it a short time before, and he has only the merit of having first examined and described it with accuracy. Dr. Glisson's largest work is a metaphysical piece, viz. 3. "Tractatus de Natura Substantum Energetica, seu de Vita Naturae, ejufque tribus primis Facultatibus," Lond. 1672, in 4to., a profound and laborious performance, in the very depths of the Aristotelean philosophy, with all its numerous divisions, and an extraordinary effort of the understanding in a man of an advanced age. — 4. His last publication, "Tractatus de Ventriculo et Intestinali, cui primum alterius partium continens in genere, et in specie, de illo Adbominis," Lond. 1679, in 4to., Amst. 1677, 12mo., contains every thing at that time known concerning the alimentary canal, arranged in a clear manner, with various new observations. In a word, Glisson was exceeded in judgment and accuracy by none of that group of English anatomists, who followed the steps of Harvey with great ardour and success; infomuch that Boerhaave terms him "omnium anatomiearum excjllentissimum," and Haller speaks in praise of all his writings. Aikin Biog. Mem. of Med. Elyg. Dict. Hist.

GLISTER, See CLIVER.

GLITNESS, in Geography, one of the smaller Shetland islands, on the E. coast of Shetland; 11 miles N. of Lerwick. N. lat. 60 22'. W. long. 1° 16'.

GLIJEBEN, a town of European Turkey, in Dalmatia; 18 miles S.E. of Moloar.

GLIZADE, in Fencing, an operation performed by dextrously making your blade slip along that of your adversary by a movement of the wrist, and a quick forward extension of the arm, without deviating from the line of direction. This is a simple, and at the same time a masterly movement in fencing.

Gen. Ch. Cal. Paranther superior, of one leaf, tubular, permanent; its border three-lobed. Cer. of one petal; tube long, cylindrical, slender; outer limb in three, nearly equal, ovo-lobed, spreading lobes; inner of two similar lobes, and a central
central, vertical, prominent lip, cloven at each extremity. Stam. Filament one, prominent, long, linear, channelled, divided at its summit; anther oblong, of two distinct parallel lobes, attached by its back to the dilated part of the filament. Pist. German inferior, roundish; style thread-shaped, the length of the filament and embraced by it; stigma capitate. Peric. Capsule roundish, of three cells and three valves. Seeds numerous.

Eff. Ch. Aster in two parts. Filament elongated, incurved, bearing a lobed appendage. Style thread-shaped, the base, embraced by the anther. Corolla with three outer lobes and three inner, the middlemost vertical and cloven.

1. G. marantiana. Linnaeus Mant. 2. 170. Sm. Exot. Bot. v. 2 85 t. 103 (Colebrookia bulbifera; Donn. Cant. 1.)—Appendage of the filament four-lobed, divaricating, terminal. Spike not taller than the leaves. Bracts elliptical, broad, longer than the calyx—Native of Bengal, from whence it was sent by Dr. Roxburgh to the late Lady Amelia Hume in 1820. It flowers in the flower in July and August. Root perennial, tuberous. Stems several, herbaceous, about two feet high, simple, leafy. Leaves elliptical, acute, entire, with one rib and numerous parallel simple veins; smooth above; soft and finely downy beneath; their footstalks long, sheathing, bearded at the top, which is extended upwards into a pair of rounded auricles. Spike terminal, solitary, simple, erect, more or less lax, about as tall as the leaves, or rather under that height. Bractlets alternate, sessile, elliptical, broad, concave, many-ribbed, somewhat downy, minutely dotted; the lower ones each bearing one ovate bulb; the upper ones a cluster of several flowers, each of which is accompanied by its own smaller bract. These flowers are very transient, slender, orange-coloured, with a deeper spot in the centre of the lip.

G. marantiana Sm. Exot. Bot. v. 2. 115 t. 117. (Decorum of the inhabitants of Nepal.)—Appendage of the filament arrow-shaped, narrower than the anther. Clutter elongated, cylindrical. Bracts shorter than the calyx, deciduous.—Gathered by Dr. F. Buchanan in the woods of Upper Nepal, flowering in June. Habit of the leaf, but taller, with larger more pointed leaves. The inflorescence is much more likinking, and consists of a long terminal racemes of numerous orange-coloured flowers, which are twice the size of the former, and essentially distinguished from that by the arrow-shaped form of the appendage to their filament, which does not extend beyond the anther, except at its rounded termination.

3. G. verifolius. Sm. Exot. Bot. v. 2. 116 t. 117; o, b, c. (Hara Siamenium; Koenig in Retz. Obs. s. 3: 49.)—Appendage of the filament four-lobed, divaricating. Clutter somewhat corybiform. Bracts shorter than the calyx. Lip towards the middle of the filament—Found by Koenig plentifully in grassy shady parts of the island called Young Cayon, in the East Indies. The calyx of flowers is shorter and more corybiform than in G. racemosa, and the corolla is variegated with orange, white, and different shades of violet. The appendage of the filament nearly resembles that of G. marantiana, but the situation of the lip, thril, as it were, half way up the filament, above the other lobes of the corolla, is altogether peculiar. For this, however, we depend on a drawing made by Mr. Sidney Parkinson, and communicated to us by Dr. Joseph Banks, of the accuracy of which we have no reason to doubt. Koenig mentions a mere dwarf variety, found near the town of Madaca. Can this be what has lately been introduced into the flower about London by Dr. Roxburgh, and which we have seen and examined at Sir Abraham Hume's, and at Meffrs. Lee and Kennedy's, flowering in June 1820? It is figured in Curtis's Magazine, t. 1325, where Dr. Sims has, we think, justly made this pretty plant a new genus, by the name of Mandra sativaria. It differs from Globba in having a radical, not terminal, inflorescence, which, as far as we know, is an infallible indication of a generic difference in this natural order, and therefore the flower affords, as was necessarily to be expected, different characters of distinction, in the two long linear appendages to the three valves. Seeds numerous.

GLOBE, in Geometry, a round or spherical body, more usually called a sphere; which see. The earth and water together are supposed to form a globe; hence called the terraqueous globe. The planets, both primary and secondary, are supposed, as well as our earth, to be solid globes. The earth is, in a particular sense, called the globe, or globe of earth; though it is now well known that this is not its true figure. See Figure of the Earth.

GLOBE, Restfulness of a. See Resistance. Globe is more particularly used for an artificial sphere of metal, plaster, paper, or some other matter; on whose convex surface is drawn a map, or representation, either of the earth or heavens, with the several circles conceived thereon.

Globes are of two kinds, terrestrial and celestial: each of very considerable use, the one in astronomy, and the other in geography, to perform many of the operations thereof in an easy, feasible manner, so as to be conceived without any knowledge of the mathematical grounds of these arts.

The fundamental parts, common to both globes, are an axis, representing the polar axis, and a spherical shell or ccover, which makes the body of the globe, on whose external surface the representation is drawn.

Globes, we have observed, are made of divers materials, viz. silver, brass, paper, plaster, &c. Those commonly used are of plaster and paper; the construction whereof is as follows.

Globes, Construction of. A wooden axis is provided, somewhat less than the intended diameter of the globe; and into the extremes hereof two iron wires are driven for poles: this axis is to be the hcm or halves of the whole structure.

On the axis are applied two spherical, or rather hemispherical caps, formed on a kind of wooden mould or block. These caps consist of pasteboard and paper, laid, one by another, on the mould, to the thickness of a crown piece; after which, having fixed to dry and embody, make an incision along the middle, the two caps thus parted, are clipped off the mould.

They remain now to be applied on the poles of the axis, as before they were on those of the mould: and to fix them in their new place, the two edges are found together with peckthread, &c.

The rudiments of the globe thus laid, they proceed to strengthen and make it smooth and regular. In order to this, the two poles are helped in a metallic semi-circle of the size intended; and a kind of plaster, made of whiting, water, and glue, heated, melted, and incorporated together, is daubed all over the paper surface. In proportion as the plaster is applied, the ball is turned round in the semi-circle, the edge whereof passes off whatever is superfluous, and beyond the due dimension, leaving the rest adhering in places that are short of it.

After such application of plaster, the ball hardens to dry: which done, it is put again in the semi-circle, and fresh

matter...
GLOBE.

matter applied: thus they continue alternately to apply the composition, and dry it, till such time as the ball everywhere accurately touches the semi-circle; in which state it is perfectly smooth, regular, firm, &c.

The ball thus finished, it remains to paste the map or description thereon: in order to this, the map is projected in several gores or gullets, all which join accurately on the spherical surface, and together cover the whole ball. To direct the application of these gores, lines are drawn by a semi-circle on the surface of the ball, dividing it into a number of equal parts corresponding to those of the gores, and subdividing those again answerably to the lines and divisions of the gores.

The papers thus pasted on, there remains nothing but to colour and illuminate the globe, and to varnish it, the better to reflect dull, moisture, &c.

The globe itself thus finished, they hang it in a brass meridian, with an hour circle and quadrant of altitude, and thus fit it into a wooden horizon.

GLOBES, Description of the. The things common to both globes are either delineated on the surface, or added as appendages without it.

Without the surface are, 1. The two poles whereon the globe is turned, representing those of the world. (See Pole.) 2. The brass meridian, which is divided into degrees, and passes through the poles. 3. The wooden horizon, whose upper side represents the horizon, and is divided into several circles; the innermost whereof contains the twelve signs of the zodiac, falsified into their degrees; the next the Julian; and the third the Gregorian calendar; without side of all these, are drawn the points of the winds. 4. A brass quadrant of altitude, divided into 90 degrees, to be fastened on the meridian at the distance of 90 degrees from the horizon. 5. The hour-circles, divided into twelve hours, and fitted on the meridian, round the poles, which carry an index pointing to the hour. A mariner’s compass is sometimes added on the bottom of the frame, and sometimes a semi-circle of position.

On the surface are delineated, 1. The equinoctial line, divided into 360 degrees, commencing from the vernal interfections. 2. The ecliptic, divided into twelve signs, and these subdivided into degrees. 3. The zodiac. 4. The two tropics. And, 5. The polar circles. All which are under their proper articles.

What else belongs to globes, either as to construction or description, is different as the globe is either celestial or terrestrial.

Our common globes, though instructive instruments for explaining the first rudiments of geography and the spherical doctrine of astronomy, yet labour under several defects: as they do not show how the phenomena, illustrated by them, arise from the motion of the earth, which is the principal thing beginners especially should have in view, and as they are only formed for the present age, and do not serve the purposes of chronology and history, which they might be made to do, if the poles, whereon they turn, were contrived to move in a circle round those of the ecliptic, according to its present obliquity.

Mr. John Senex, F.R.S. invented a contrivance for remedying these defects, by fixing the poles of the diurnal motion to two shoulders or arms of brass, at the distance of 23° from the poles of the ecliptic. These shoulders are firmly fastened at the other end to an iron axis, which passes through the poles of the ecliptic, and is made to move round with a very still motion; so that when it is adjusted to any point of the ecliptic, which the equator is made to intersect, the diurnal motion of the globe on its axis will not be able to disturb it. When it is to be adjusted for any time, past or future, one of the brass shoulders is brought under the meridian, and held fast to it with one hand, whilst the globe is turned about with the other, so that the point of the ecliptic, which the equator is to intersect, may pass under a degree of the brass meridian: then holding a pencil to that point, and turning the globe about, it will describe the equator according to its position at the time required; and transferring the pencil to 23°, and 66° on the brass meridian, the tropics and polar circles will be so described for the same time. By this contrivance, the celestial globe may be so adjusted, as to exhibit not only the risings and settings of the stars, in all ages and in all latitudes, but likewise the other phenomena that depend upon the motion of the diurnal axis round the annual axis. Senex’s celestial globes, especially the two greatest, of fourteen and twenty-eight inches in diameter, have been constructed on this principle: so that by means of a unit and screw, the pole of the equator is made to revolve about the pole of the ecliptic. Phil. Trans. N. 447, p. 201, 202, or Martyn’s Abr. vol. viii. p. 217, and N. 493, art. 16 in Phil. Trans. vol. xi. p. 290.

Mr. Joseph Harris, late almanack-maker of the mint, contrived to remedy the former of the defects above-mentioned, by placing two hour circles under the meridian, one at each pole; these circles are fixed upright between two brass collars placed about the axis, so that when the globe is not turned, they are carried round with it, the meridian serving as an index to cut the hour divisions. The globe, in this state, serves readily for solving problems in north and south latitudes, and also in places near the equator; whereas, in the common construction, the axis and hour circle prevent the brass meridian from being moveable quite round in the horizon. This globe is also adapted for shewing how the visibilities of day and night, and the alteration of their lengths, are really occasioned by the motion of the earth; for this purpose, he divides the brass meridian, at one of the poles, into months and days, according to the sun’s declination, reckoning from the pole. Therefore, by bringing the day of the month to the horizon, and rectifying the globe according to the time of the day, the horizon will represent the circle separating light and darkness, and the upper half of the globe the illuminated hemisphere, the sun being in the zenith.

Mr. Harris also gives an account of a cheap machine for shewing how the annual motion of the earth in its orbit causes the change of the sun’s declination, without the great expense of an orrery. Phil. Trans. N. 456, p. 321, &c. or Martyn’s Abr. vol. vii. p. 332.

The late Mr. George Adams, mathematical instrument maker to his majesty, has made some useful improvements in the construction of the globes. His globes, like others, are suspended at their poles in a strong brass circle, and turn therein upon two iron pins, which are the axis. They have besides a thin brass semi-circle, moveable about the poles, with a small, thin, sliding circle upon it. On the terrestrial globe, the thin brass semi-circle is a moveable meridian, and its small sliding circle the visible horizon of any particular place to which it is set. On the celestial globe, the semi-circle is a moveable circle of declination, and its small annexed circle an artificial sun or planet. Each globe hath a brass wire circle, placed at the limits of the twilight, which, together with the globe, is set in a wooden frame, supported by a neat pillar and claw, with a magnetic needle at its base. On the terrestrial globe the division of the earth into land and water is laid down from the latest discoveries; there are also many additional circles, as well as the rhumb-lines, for solving all the necessary geographical and nautical
nautical problems. On the celestial globe, all the southern constellations, lately observed at the Cape of Good Hope by M. de la Caille, and all the stars in Mr. Flamsteed's British Catalogue, are accurately laid down and marked with Greek and Roman letters of reference, in imitation of Bayer. Upon each side of the ecliptic are drawn eight parallel circles, at the distance of one degree from each other, including the zodiac; and these are crofled at right angles with segments of great circles at every fifth degree of the ecliptic, for the more readily noting the place of the moon, or of any planet upon the globe. The author has also inferred, from Uligh Beigh, printed at Oxford in 1665, the mansions of the Moon of the Arabian Astronomers, so called, because they observed the moon to be in or near one of these every night during her monthly course round the earth, to each of which the Arabian characters are fixed. On the strong brass circle of the terrestrial globe, and about 234 to each side of the north pole, the days of each month are laid down according to the Sun's declination; and this brass circle is so contrived, that the globe may be placed with the north and fourth poles in the plane of the horizon, and with the south pole elevated above it. The equator, on the surface of either globe, serves the purpose of the horary circle, by means of a semi-circular wire placed in the plane of the equator, carrying two indices, one of which is occasionally to be used to point out the time. For a farther account of these globes, with the method of using them, the reader may consult Adams's Treatise on their Construction and Use, &c. 1769.

GLOBE. Celestial, is an artificial sphere, on whose convex surface the fixed stars are laid down, at proportionable distances, together with the principal circles of the sphere.

The surface of the celestial globe may be esteemed a juf representation of the concave expanse of the heavens, notwithstanding its convexity; for if the eye were placed in the centre of it, and the globe made of glass, the stars that are drawn upon it would appear in a concave surface, exactly corresponding to those in the heavens. The use of these globes is to exhibit the phænomena of the motions of the Sun and stars, in an easy and obvious manner; which, though somewhat inaccurate, is yet exact enough for the common uses of life, and may save the trouble of trigonometrical calculations.

To exhibit the stars, circles, &c. on the surface of a given sphere, and fit for the uses of astronomy. — 1. Allume any two points diametrically opposite to each other, as P and Q (Plate XIV. Astronomy, fig. 117.) and in these fix up arcs, PA and QC, for the ball to turn round on. The points P and Q, or A and C, will exhibit the poles of the world.

2. Divide a brazen circle A B C D into four quadrants, A E, E C, C F, and F D; and subdivide each quadrant into 90 degrees, numbered from the points E and F, towards the poles A and C.

3. Exploy the globe in this circle, as in a meridian, at the points A and C, so as it may freely turn therein.

4. Apply a style or pin to the surface of the globe, in the first degree of the meridian, and turn the ball round; by this means will a circle be described on the surface, representing the equator to be divided into degrees.

5. From the pole of the world P towards M, and from the other pole C towards N, number 234 degrees; the points M and N will be the poles of the ecliptic.

6. Apply a style to the meridian, in the point M, and turn the globe round; by this rotation will the arctic polar circle be described; and after the same manner is the antarctic polar to be described about the point N.

7. Number 234 deg. from the equator towards the poles P and Q, and note the points H and I; then applying a style to the meridian, as before, two circles will be described parallel to the equator, whereas that drawn through H will be the tropic of Cancer, and the other through I the tropic of Capricorn.

8. Hang the globe within the meridian, in the poles of the ecliptic, as before in the poles of the world; and applying a style to E, turn it round: by this means will the ecliptic be delineated, which remains to be divided into twelve signs; and each of these, again, divided into thirty degrees.

9. While the globe remains thus suspenfed, bring the degree of longitude of any star under the meridian; and in the meridian, number as many degrees towards the pole as is the degree of latitude of the place; the point of intersection is the place of that star on the surface of the globe. After the like manner may the place of the star be determined from the right ascension and declination given.

10. All the stars of a constellation thus laid down, the figure of the constellation is to be designed; after which it may either be coloured or engraved.

11. Place the globe with the meridian, in a wooden frame or horizon, D B L, supported on four feet, in such manner as to be divided thereby into two hemispheres, and that the pole A may be raised or depressed at pleasure.

12. On the limb or edge of the horizon describe a circle, which divide into 360 degrees, and insert the calendars and winds.

13. Lastly, To the pole A fit a brazen circle, divided into twenty-four horary parts, and numbered twice twelve, so that the line of division of XII may be in the plane of the meridian, on either side the pole; and on the pole itself apply an index, to turn round with the globe. See Horary Circle. Thus is the globe complete.

It may be here observed, that as the longitude of the stars is continually increasing, a common globe does not remain of perpetual use; but the increase in seventy-two years only amounting to a degree, the whole will make no considerable error in a hundred years; the design of a globe being only to represent things something near the truth.

GLOBE, to make a celestial. This method is that most frequently used; and we only premise the former as being the most easily conceived, and leading more naturally to this.

1. From the given diameter of the globe, find a right line A B, fig. 118, equal to the circumference of a great circle, and divide it into twelve equal parts.

2. Through the several points of division, 1, 2, 3, 4, &c. with the interval of ten of them, describe arches, mutually intersecting each other in D and E: these figures or pieces, duly pullel or joined together, will make the whole surface of the globe.

3. Divide each part of the right line A B into thirty equal parts, so that the whole line A B, representing the periphery of the equator, may be divided into 360 degrees.

4. From the poles D and E, fig. 119, with the interval of 234 deg. describe arches, a, b; these will be twelve parts of the polar circles.

5. After the like manner, from the same poles D and E, with the interval of 66 deg. reckoned from the equator, describe
GLOBE.

describe arches \(a, d\); these will be twelfth parts of the tropics.

6. Through the degree of the equator \(e\), corresponding to the right ascension of any given star, and the poles \(D\) and \(E\), draw an arch of the circle, and taking in the compass the complement of the declination from the pole \(D\), describe an arch intersecting it in \(i\); this point \(i\) will be the place of that star.

7. All the stars of a constellation being thus laid down, the figure of the constellation is to be drawn according to Bayer, Hevelius, or Flamsteed.

8. Lastly, the same manner are the declinations and right ascensions of each degree of the ecliptic \(d, g\) to be determined.

9. The surface of the globe thus projected on a plane is to be engraved on copper, to face the trouble of doing this over again for each globe.

10. A ball, in the mean time, is to be prepared of paper, plaster, &c. after the manner above directed, and of the intended diameter of the globe; on this, by means of a semi-circle and style, is the equator to be drawn; and through every 30th degree a meridian. The ball thus divided into twelve parts, corresponding to the segments before projected, they are to be cut from the printed paper, and nailed on the ball.

11. Nothing now remains but to hang the globe, as before, in a brazen meridian and wooden horizon; to which may be added a quadrant of altitude \(H, I\), fig. 120. made of brass, and divided in the same manner as the ecliptic and equator.

If the declinations and right ascensions of the stars be not given, but their longitudes and latitudes in heaven, the surface of the globe is to be projected after the same manner as before: except that, in this case, \(D\) and \(E\), fig. 121. are the poles of the ecliptic, and \(f, h\) the ecliptic itself; and that the polar circles and tropics, with the equator \(g, d\), and the parallels thereof, are to be determined from their declinations.

One of the fullest catalogues of the stars is that of Mr. Flamsteed; wherein the right ascensions and declinations, as well as the longitudes, latitudes, &c. are everywhere expressed.

GLOBE, use of the ecliptic. The use of this instrument is very extensive; there being scarcely any thing in the spherical astronomy but may be exhibited thereby.

The principal points are contained in the following problems, with their solution; which will let the reader enough into the nature and reason of this noble instrument, to apply it, of his own accord, in any other cases.

To find the right ascension and declination of a star, represented on the surface of the globe.—Bring the star to the graduated side of the brazen meridian; then the number of degrees intercepted between the equator, and the point on the meridian cut by the star, gives its declination; and the degree of the equator which comes under the meridian, together with the star, is its right ascension.

To find the longitude and latitude of a star.—Apply the centre of the quadrant of altitude over the pole of the ecliptic in the same hemispheres with the star, and bring it in a meridional edge to the star; the degree on the quadrant cut by the star is its latitude, reckoned from the ecliptic; and the degree of the ecliptic cut by the quadrant its longitude.

To find the sun's place in the ecliptic.—Seek the day of the month in the proper calendar on the horizon, and against the day in the circle of signs is the sign and degree the sun is in for that day; this done, find the same sign upon the ecliptic, on the surface of the globe; this is the sun's place for that day.

To find the declination of the sun.—The sun's place for the day given being brought to the meridian, the degrees of the meridian intercepted between the equinoctial and that place, are the sun's declination for that day at noon.

To find the place of a planet, with its right ascension and declination; its longitude and latitude for the time being given.—Apply the centre of the quadrant of altitude on the pole of the ecliptic (the pole, we mean, of the same demonstration with the latitude), and bring it to the given longitude in the ecliptic; this point is the planet's place; and bringing it to the meridian, its right ascension and declination will be found, as already shewn of a star.

To rectify the globe, or adjust it to the place, &c. so as it may represent the present state or situation of the heavens.—

1. If the place be in north latitude, raise the north pole above the horizon; if in south, raise the south pole; till the arch intercepted between the pole and horizon be equal to the given elevation of the pole. 2. Fix the quadrant of altitude on the zenith, &c. on the latitude of the place. 3. By means of a compass or meridian line, place the globe in such a manner as that the brazen meridian may be in the plane of the terrestrial meridian. 4. Bring the degree of the ecliptic the sun is in to the meridian, and set the horary index to twelve; thus will the globe exhibit the face of the heavens for the noon of that day. 5. Turn the globe till the index come to any other given hour: thus will it shew the face of the heavens for that time.

To know all the stars and planets by means of the globe.—

1. Adjust the globe to the state of the heavens for that time. 2. Look on the globe for some one star which you know, e. g. the middle off star in the tail of the Great Bear. 3. Observe the positions of the other more conspicuous stars in the same constellation; and by transferring the eye from the globe to the heavens, you easily note the place there. 4. After the same manner may you proceed from this to the neighbouring constellations, till you have learned them all.

If the planets be represented on the globe, after the manner above described, by comparing them with the neighbouring stars you will likewise know the planets.

To find the sun's oblique ascension, his ephemerid, amplitude, and azimuth, with the time of rising.—1. Rectify the globe for the hour of twelve, and bring the sun's place to the ephemerid side of the horizon; then the number of degrees, intercepted between that degree of the equator now come to the horizon and the beginning of Aries, is the sun's oblique ascension. 2. The degrees on the horizon, intercepted between the ephemerid point thereof and the point wherein the sun is, is the ortive or rising amplitude. 3. The hour, pointed to by the index, is the time of the sun's rising. 4. Turning the globe till the index points to the present hour, lay the quadrant to the sun's place: the degree cut by the quadrant, in the horizon, is the sun's azimuth.

To find the sun's oblique declension, ephemerid amplitude, and azimuth, with the time of setting.—The solution of this problem is the same as that of the former; excepting that the sun's place must be here brought to the western side of the horizon, as in the former it was to the ephemerid.

To find the length of day and night.—1. Find the time of the sun's rising, which being numbered from midnight, the double thereof gives the length of the night. 2. Subtract the length of the night from the whole day, or twenty-
To find the rising, setting and culmination of a star; its
continuance above the horizon for any place and day; to-
gether with its oblique ascension and declension, and its equa-
tor and western amplitude and azimuth. —1. Adjust the globe
of the sun to the place of the heavens at twelve o'clock that day.
2. Bring the star to the eastern side of the horizon: thus will the western amplitude and azimuth, and time of
rising or setting be found, as already taught of the sun.
3. Bring the east to the western side of the horizon: thus will the western amplitude and azimuth, and the
time of setting, be found. 4. The time of rising, substracted from that of setting, leaves the continuance
of the star above the horizon. 5. This continuance
above the horizon, substracted from twenty-four hours, leaves the time of its continuance below the horizon.
6. Lastly, the hour to which the index points, when the
star is brought to the meridian, gives the time of its cul-
mination.

To find the altitude of the sun, or star, for any given hour
of the day or night. —1. Adjust the globe to the position
of the heavens, and turn it till the index point at the
given hour. 2. Fix on the quadrant of altitude, at 90 degrees from the horizon, and bring the sun's or star's
place; the degrees of the quadrant, intercepted
between the horizon and the sun or star, is the altitude
required.
The altitude of the sun by day, or of a star by night, being
given, to find the time of that day or night. —1. Rectify the
globe as in the preceding problem. 2. Turn the globe
and quadrant, till such time as the star or degree of the
ecliptic the sun is in, cut the quadrant in the given degree
of altitude; then does the index point at the hour
fought.
The azimuth of the sun or a star given, to find the time of
the day or night. —Rectify the globe, and bring the quad-
rant to the given azimuth in the horizon; turn the globe,
till the sun come to the fame: then will the index show
the time.
The separation of time between the risings of two stars,
or the continuations. —1. Raise the pole of the globe for
many degrees above the horizon, as is the elevation of
the pole of the place. 2. Bring the first star to the
horizon, and observe the time the index points to. 3. The
same do by the other star; than substracting the former
time from the latter, the remainder is the interval between
the risings.

After the like manner is the interval between two cul-
minations found, by bringing both stars to the meridian.
The day of the month being given, to find when any star will
come to the meridian. —Rectify for the sun's place; turn the
point till the sun becomes the meridian; then the
index will show the time fought.
To find when any given star will come to the meridian, at any
given hour of the night. —Bring the given star to the
meridian; set the index to twelve at noon; then turn the
globe eastward, till the index points to an hour as far
distant in the forenoon from twelve as the given hour is
in the afternoon, observe the degree of the ecliptic then at the
meridian, over-against which degree, in the calendar, is
the day of the month, when the given star will be upon the
meridian at the given hour.
By observation of a star upon the meridian, to find the hour
of the night. —Rectify for the latitude and the sun's place;
bring the given star to the meridian, and the index will
flew the hour of the night.

Vol. XVI.

To find the beginning and ending of the crepuscular or twi-
light. —1. Rectify the globe, and set the index to the
twelfth hour, the sun's place being in the meridian.
2. Note the sun's place, and turn the globe westward, as
also the quadrant of altitude, till the point opposite the
sun's place cut the quadrant of altitude in the eighteenth
degree above the horizon: the index will then show the
time when the twilight commences in the morning. 3. Taking
the point opposite to the sun, bring it to the easterly hemi-
sphere, and turn it, till it meet with the quadrant of altitude
in the eighteenth degree: then will the index show the time
when the twilight ends.

Given the sun's longitude and the obliquity of the ecliptic, to
find the sun's right ascension and declination. —Find the sun's
longitude or place on the ecliptic, and bring it to the
brazen meridian. Then the arc of the equator, between
the first point of Aries and the brazen meridian, shows the sun's
right ascension; and the arc of the brazen meridian between
the equator and the ecliptic shows the declination.

Given the obliquity of the ecliptic and the sun's declination, to
find the sun's longitude and right ascension. —Mark the sun's
decimation on the brazen meridian, and turn the globe till
the ecliptic comes under the figure; then will the distance
from the meridian to the first point of Aries show the sun's
longitude on the ecliptic, and its right ascension on the
equator.

Given the obliquity of the ecliptic and the sun's right ascension,
required the sun's declination and longitude. —Bring the sun's
right ascension in the equator to the brazen meridian, then
will the intercepted arc of the ecliptic to Aries show the sun's
longitude; and the arc of the meridian, that is between the
sun's right ascension and longitude, will show the declination.

To find on what day the sun begins to shine constantly at any
given place in either of the frigid zones, and how long he con-
tinues to shine without intermission at the same place. —Subtract
the latitude of the given place from 90°, and find in what
two days of the year the sun's declination is exactly equal to
the remainder, and of the fame kind as the latitude of the place;
then on the first of those days in the spring quarter, the
sun ceases to set at the given place, and shines without
intermission till he arrives at another point of the ecliptic, as many degrees on the other side of the summer
solstice, when his declination is again equal to the comple-
ment of the latitude: the space of time between those two
days is the length or duration of the longest day.

To find the latitude of those places in the north frigid zone,
where the sun begins to shine constantly on any day between
the natural equinox and the summer solstice, or in the south frigid zone on any day between the autumnal equinox and the winter solstice.

Find the sun's declination for the given day: subtract it
from 90°, and the remainder will be the latitude of those
globe on the south frigid zone where the sun begins to shine constantly the latitude
is of the fame kind as the sun's declination.

To determine under what latitude two given stars rise or set at
the same instant. —Bring one of the stars to the horizon, and,
keeping it there, raise or depress the pole till the other is on
the horizon at the same time, observing whether this is
affected on the east or west position of the horizon; then
the degrees of the meridian, intercepted by the horizon, will
be the latitude of the place required.

To find at what place a given star is vertical at any given hour
at London ; e. g. at what place will Capella be vertical
the 21st of March at 10 o'clock afternoon, at London time.

N.B. —This problem requires the assistance of both the
terrestrial and celestial globes.

1. Find, as above, the time of the meridian passage of the
GLOBE.

In the present instance Capella passes about 6 o'clock in the afternoon.

2. Find under what meridian they reckon 6 o'clock when it is 10 with us, which will be four hours to the west.

3. Observe under this meridian the place whose latitude is equal to the declination of the star, which, in this example, is nearly 45°; and this place, which is near Louisburg, in North America, will be the place required.

To explain the phenomena of the harby-moon by the globe, see Morex.

Globe. Terrestrial, is an artificial sphere, on whose surface are delineated the principal places of the earth, in their proper situations, distances, &c. together with their circles imagined on the surface of the terrestrial sphere. The use of the terrestrial globe, is to exhibit the several affections and phenomena of the different places of the earth, depending on magnitude, &c. in an easy obvious manner, without the trouble of trigonometrical calculations.

Globe. To construct a terrestrial,—The construction of a terrestrial globe, whether of metal, plaster, paper, &c. is the same as that of a celestial. The same circles are delineated on both; and as for the places, viz. cities, towns, &c. they are laid down from the longitudes and latitudes given, as the stars are from their right ascensions and declinations.

Hence all problems, depending on the circles, may be equally wrought on either globe; as the affections, declinations, amplitudes, azimuths, risings, settings, altitudes, &c. of the sun; the lengths of day and night; hours of the day and night; crepuscula, &c.

We shall here, therefore, only give what is peculiar to the terrestrial globe.

Globe. Use of the terrestrial. To find the longitude and latitude of any place delineated on the globe.—Bring the place to the graduated side of the hemis meridian: the degree of the meridian it cuts is the latitude required; and the degree of the equator, at the same time under the meridian, is the longitude required.

The longitude and latitude given, to find the place on the globe.—Seek, in the equator, the given degree of longitude, and bring it to the meridian: then count from the equator on the meridian the degrees of latitude given, towards this or that pole, as the latitude is either north or south: the point under this is the place required.

The hour being given at any place, to find what hour it is in any other part of the world.—Bring the given place to the meridian, and let the hour-index to the given hour; then, by turning the globe, bring any place to the meridian, and the index will point to the hour of that place.

To find the anteri, posteri, and antipodes of any place.—1. The given place being brought to the meridian, count as many degrees on the meridian from the equator towards the other pole: the point which is thus arrived at is the place of the antecedent. 2. Note the degree of the meridian over the given place and its antecedent, and turn the globe till the opposite degree of the equator come under the meridian; or, which amounts to the same, till the index, which before stood at twelve, come to the other twelve: then will the place, corresponding to the former degree, be the posteri; and the latter, that of the antipodes.

To find what place of the earth the fun is vertical to at any time given.—1. Bring the fun's place found in the ecliptic to the meridian, and the index to the hour of twelve, noting what point of the meridian corresponds thereto. 2. If the given hour be before noon, subtract it from twelve hours, and turn the globe towards the west, till the index points at the hours remaining; thus will the place required be under the point of the meridian before noted. 3. If the hour be after noon, turn the globe in the same manner towards the west, till the index points at the given hour; thus, again, will the place required be found under the point of the meridian before noted.

If, at the same time, you note all the places which are under the same half of the meridian with the place found, you will have all the places to which the fun is then in the meridian; and the opposite half of the meridian will show all the places in which it is then mid-night.

A place being given in the torrid zone, to find the two days in the year wherein the fun is vertical in the fun.—1. Bring the given place to the meridian, and note the degree of the meridian corresponding thereto. 2. Turn the globe about, and note the two points of the ecliptic passing through that degree. 3. Find on what days the fun is in these points of the ecliptic: for on those days he is vertical to the given place.

To find those places in the torrid zone to which the fun is vertical on a given day.—Bring the fun's place in the ecliptic to the meridian; then turning the globe round, note all the places which pass through that point of the meridian; these are the places required.

After the same manner may be found what people are afei for any given day.

The day and hour at any place being given, to find where the sun is vertical at that hour.—Bring the fun's place to the meridian, and the degree over it is the sun's declination at that time; then bring the given place to the meridian, and find the index to the given hour; turn the globe till the index points to twelve at noon, and the place on the globe which lies under the degree of the sun's declination has the fun then vertical.

A place being given in the frigid zone, to find the time when the fun begins to appear above the horizon, and when it begins to disappear; and also the length of the longest day or night in that place.—Rectify for the latitude, bring the ascending part of the ecliptic, i. e. for latitudes north of the tropic of Cancer the fenidere intercepted between Capricorn and Cancer, to the north point of the horizon; observe the degree of the ecliptic which cuts that point, and find when the fun enters that degree, and this will give the time when the fun begins to appear in that latitude. Bring the descending part of the ecliptic to the same point on the horizon, and the calendar will show when the sun leaves that latitude and disappears. Again, bring the ascending part of the ecliptic to the north point of the horizon, and the degree, as before, will show in the calendar when the longest day begins; and by bringing the descending part of the ecliptic to the same point, we shall find, in the same manner, when the longest day ends.

To find the latitude of the places wherein any given day is of any given length.—1. Count so many degrees from the next tropic, towards the equinoctial point, as there are units in half the number of the given days; because the sun, in its proper motion, goes nearly a degree every day. 2. Bring the point of the ecliptic, thus found, to the meridian; and its distance from the pole will
GLOBE.

will be equal to the elevation of the pole, or latitude of the places required.

Any hour of the day or night being given, to show all those places to which the fun rises and sets; where it is noon or midnight; and where day or night.—1. Find what place the fun is at that time vertical to, as already taught. 2. Let this place be brought to the zenith of the wooden horizon, i. e. elevate the pole as the latitude of that place requires; then will the places on the eastern side of the horizon be those the fun is setting to; and on the western side, those he rises to: those under the upper semi-circle of the meridian have it noon; and those under the lower, midnight. Lastly, to those of the upper hemisphere it is day; and to those in the lower, night.

Hence, as in the middle of an eclipse, the moon is in that degree of the ecliptic opposite to the fun's place; by the present problem it may be known what places of the earth then see the middle of the eclipse, and what the beginning or ending.

To find what places of the earth a planet is at to any day of the year.—1. Mark the planet's place on the globe, as above taught. 2. Bring this place to the meridian, and note the degree over it. 3. Turn the globe round, and the places which pass under the point are those required.

The declination of a star, or any other phenomenon, given, to find what parts of the earth the fun is vertical to.—Count as many degrees in the meridian, from the equator towards one pole, as are equal to the given declination; viz. towards the north, if the declination be to the northward; and towards the south, if the declination be south. Then turning it round, the places that pass through the extremity of this arch in the meridian are the places required.

To determine the place of the earth where any star, or other celestial phenomenon, will be vertical at a given hour.—1. Elevate the pole according to the latitude of the place, from whose noon or midnight the hours are numbered. 2. Bring the fun's place for that day to the meridian, and set the index at twelve o'clock. 3. Determine the place of the fun on the surface of the globe, and bring it to the meridian; this index will then show the difference of time between the impulse of the fun and star to the meridian of the place: note the point of the meridian over the place of the fun.

4. Find in what places of the earth it is then noon, and set the index to twelve o'clock. 5. Turn the globe towards the west, till the index has passed over the interval of time between the culmination of the fun and star. Then, under the point of the meridian, before observed, will the place required be found. And hence may always be found what place a star, or other phenomenon, rises or sets at any given time.

To place the globe in such manner, under any given latitude, as that the fun shall illuminate all those regions which he actually illuminates on earth.—1. Rectify the globe, i.e. elevate the pole according to the latitude of the place; bring the place to the meridian, and set the globe north and south by the compasses; thus, the globe having the same situation with regard to the fun as the earth has, that part thereof will be illuminated which is illuminated on earth. Hence also the globe being situate in the same manner, when the moon shines, it will shine what parts are then illuminated by the moon.

And in the like manner, we may find when the fun and moon rise and set at any given time.

To find the distance of two places on the globe.—Take the given places in the compasses, and apply them to the equator; the degrees which there subtend being reduced into miles, leagues, or the like, give the distances required.

The same may be done, and that more commodiously, by laying the graduated edge of the quadrant of altitude over the two places, and noting the degree intercepted.

To find how any one place bears from another.—Bring one place to the meridian, and lay the quadrant of altitude over the other, and it will shew the horizon the point of the compass on which the latter bears from the former.

Problems on the terrestial globe may sometimes be advantageously solved, by considering the horizon as the circle of illumination, and bringing the fun's place to the zenith.

To find for any given day and hour those places where the fun is rising or setting; those places where it is noon, and in particular those place under the fun is vertical; those places where the fun is rising or setting; and those places where it was midnight.—Find the fun's place in the ecliptic for the given day, bring it to the brazen meridian, and mark its declination.

Elevate the (north or south) pole, as many degrees above the horizon as are equal to the fun's declination (north or south). Bring the given place to the meridian, and set the index to the given hour, then turn the globe on its axis, till the index comes to the upper twelve, and fix the globe in that position. All these places along the western edge of the horizon have the fun rising, and those along the eastern edge have the fun setting: it is noon to the places under the brazen meridian, and amongst them is the fun is vertical to that place, which stands under the degree of the fun's declination.

Those places that are within 18° of the western semi-circle of the horizon have morning twilight, and those within 18° of the eastern semi-circle have evening twilight: and it is midnight at all those places under that part of the brazen meridian which is below the horizon. In short, it is day to all places above the horizon, and either twilight or dark night to all those which are below it.

The day and hour of a lunar eclipse being given, to find those places where it will be visible.—Find the place where the fun will be vertical when the eclipse begins, and rectify the globe, in respect to latitude, for the antipodes of that place. Then bring the antipodes to the upper part of the brazen meridian, and fix the globe in that position; and the beginning of the eclipse will be visible to all places which are then above the horizon.

To find the proportion which the land bears to the sea.—For this purpose Dr. Long proposes to take the papers of a large terrestrial globe, and after separating the land from the sea with a pair of scissors, to weigh them carefully in scales. This method supposes the globe to be exactly delineated, and all the papers of equal thickness. By an experiment on the papers of Mr. Senex's seventeen inch globe, he found that those comprehending the sea weighed 249 grains, and the others only 123; whence he infered, that almost three-fourths of the surface of our earth between the polar circles are covered with water, and that little more than one-fourth is dry land. Dr. Long omitted weighing the papers within the polar circles, because the proportion which the land bears to the sea within them is not ascertain'd. Long's Alston. vol. I. p. 163. See Magnitude of the Earth.

Globe. To confirm all by the. See Dial.

The celestial globe has been improved by Mr. Ferguson; in this globe, (Plate XV. Astronomy, fig. 122,) an arch MKH, of 23°, is fixed on the north pole of the axis, above the hour circle; and at the end is fixed an upright pin HG, flaring
flanking directly over the north pole of the ecliptic, and perpendicular to that part of the surface of the globe. On this pin are two moveable collets at D and H, to which are annexed the quadrantal wires N and O, carrying two little balls representing the fun and moon. The collet D is fixed to the circular plate P, on which are engraved the 39½ days of the moon's age, beginning under the wire N, which wire, as it turns round, carries with it the plate F. These wires are fixed or slackened by the screw G, and the two little balls are made to rise and set at the same time and on the same point of the horizon, for the day to which they are rectified, as the fun and moon do in the heavens. The ball representing the moon may be screwed as many degrees to either side of the ecliptic, as its latitude amounts to at any given time; and for this purpose, S is a small piece of palteboard, the curved edge of which at S is to be set upon the globe at right angles to the ecliptic, and the dark line over S to stand upright upon it: from this line, on the convex edge, are drawn the 5½ degrees of the moon's latitude on both sides of the ecliptic; and when this piece is set upright on the globe, its graduated edge reaches to the moon on the wire O, by which means she is easily adjusted to her latitude found by an ephemeris. The horizon of this globe is supported by two semi-circular arches, because pillars would float the progres of the balls, when they go below the horizon in an oblique sphere. This globe is rectified by elevating the pole to the latitude of the place, bringing the fun's place in the ecliptic for the given day to the brazen meridian, and setting the hour-index to twelve at noon; then, setting the fun directly over his place in the meridian, and the moon over her place in the ecliptic, by fixing her wire under the number that expresses her age for that day on the plate F; and, lastly, laying the curved edge of the palteboard S over the ecliptic below the moon, and adjusting the moon to her latitude over the graduated edge of the palteboard. Having thus rectified the globe, turn it round, and obverse on what point of the horizon the fun and moon balls rise and set; for these agree with the points of the compas on which the fun and moon rise and set in the heavens on the given day; and the hour-index shews the times of their rising and setting, and also the time of the moon's passing over the meridian. This globe is also contrived for exhibiting the phenomena of the harvest-moon, &c. Phil. Trans. No. 483, art. 21. in vol. xlv. p. 535; or Ferguson's Altnon. p. 251.

Globe, Dialling. See Dialling.

Gloves, Painted, are those with the improvements of Mr. Neale, for which he obtained his majesty's letters patent, by means of which he solves several astronomical problems, which do not admit of solution by the common globes.

Globe, Planetary, is a machine contrived and described by Mr. Ferguson; in which T (Plate XV. Altnon.) is a terrestrial globe fixed on its axis standing upright on the pedestal C D E, on which is an hour-circle, having its index fixed on the axis, which turns somewhat slightly in the pedestal, so that the globe may not be liable to shake: to prevent which, the pedestal is about two inches thick and the axis goes quite through it, bearing on a shoulder. The globe is hung in a graduated brazen meridian, much in the usual way: and the thin plate N, N E, E, is a moveable horizon graduated round the outer edge, for laying the bearings and amplitudes of the fun, moon, and planets. The brazen meridian is grooved round the outer edge; and in this groove is a Bender semi-circle of brahs, the ends of which are fixed to the horizon in its north and south points: this semi-circle slides in the groove as the horizon is moved in rectifying it for different latitudes. To the middle of the semi-circle is fixed a pin, which always keeps in the zenith of the horizon, and on this pin the quadrant of altitude q turns; the lower end of which, in all positions, touches the horizon as it is moved round the fame. This quadrant is divided into 90 degrees from the horizon to the zenithal pin on which it is turned, at 90. The great flat circle or plate A B is the ecliptic, on the outer edge of which the signs and degrees are laid down; and every fifth degree is drawn through the rest of the surface of this plate towards its centre. On this plate are seven grooves, to which seven little balls are adjusted by sliding wires, so that they are easily moved in the grooves, without danger of starting out of them. The ball next the terrestrial globe is the Moon, the next without it is Mercury, the next Venus, the next the Sun, then Mars, then Jupiter, and lastly Saturn; and in order to know them, they are separably rapped with the following characters: Φ, θ, Φ, θ, θ, 24, 1. This plate or ecliptic is supported by four strong wires, having the lower ends fixed into the pedestal at C, D, and E, the fourth being hid by the globe. The ecliptic is inclined 23½ degrees to the pedastal, and is therefore properly inclined to the axis of the globe which stands upright on the pedestal.

To rectify this machine.—Set the Sun, and all the planetary balls, to their geocentric places in the ecliptic for any given time, by an ephemeris; then set the north point of the horizon to the latitude of your place on the brazen meridian, and the quadrant of altitude to the fourth point of the horizon; which done, turn the globe with its furniture till the quadrant of altitude comes right against the Sun, viz. to his place in the ecliptic; and keeping it there, let the hour index to the XII. next the letter C.

By this machine the following problems, as well as many others, may be resolved.

To find the amplitude, meridian altitude, and times of rising, culminating, and setting of the fun, moon, and planets.—Turn the globe round eastward, or according to the order of the signs; and as the eastern edge of the horizon comes right against the fun, and any planet, the hour-index will shew the time of its rising; and the inner edge of the ecliptic will cut its rising amplitude in the horizon. Turn on, and as the quadrant of altitude comes right against the fun, moon, or planets, the ecliptic cuts the meridian altitudes in the quadrant; and the hour-index shews the times of their coming to the meridian. Continue turning, and as the western edge of the horizon comes right against the fun, moon, or planets, their setting amplitudes are cut in the horizon by the ecliptic; and the times of their setting are shewn by the index on the hour-circle.

To find the altitude and azimuth of the fun, moon, and planets, at any time of their being above the horizon.—Turn the globe till the index comes to the given time in the hour-circle; and keep the globe steady, and moving the quadrant of altitude to each planet respectively, the edge of the ecliptic will cut the planet's mean altitude on the quadrant, and the quadrant will cut the planet's azimuth, or point of bearing on the horizon.

The fun's altitude being given at any time either before or after noon, to find the hour of the day, and the variation of the compas, in any known latitude.—With one hand hold the edge of the quadrant right against the fun; and, with the other hand, turn the globe westward, if it be in the forenoon, or eastward if it be in the afternoon, until the fun's place at the inner edge of the ecliptic cuts the quadrant in the fun's observed altitude; and then the hour-index will point out
the time of the day, and the quadrant will cut the true azimuth, or bearing of the sun for that time; the difference between which, and the bearing shown by the azimuth compass, shows the variation of the compass in that place of the earth. Ferguson's Alton. p. 292, &c.

GLOBE Amaranth. See Gomphrena.

GLOBE Animalcula, in Natural History, is a singular, minute, aquatic animal, whose form seems exactly globular, without either head, tail, or fins. It moves in all directions, either rolling like a bowl, or gliding along smoothly without turning itself at all. Its whole body is transparent, except where it is covered with circular black spots; some of which have fix or five, some one, two, three, four or five, and others no spots at all. These spots are probably the eggs or young ones of the animal. The general appearance of the body exhibited a kind of short movable hairs or bristles, by means of which it is conjectured the motions of the animal may be performed. Baker's Microf. 1753, p. 322, &c.

GLOBE Daisy. See Globularia.

GLOBE Fijb, in Ichthyology, a name by which some species of the order are called. See Ostracion.

GLOBE Flower, in Botany. See Sphagneticus.

GLOBE Ranunculus. See Trollsii.

GLOBE Thistle. See Echinops.

GLOBULAR CHART, a representation of the surface, or some part of the surface, of the terraqueous globe upon a plane; wherein the parallels of latitude are circles nearly concentric, the meridians, curves, bending towards the poles; and the rhomb-lines also curves.

The merits of this chart consist in this, that the distances between places on the same rhumb are all measured by the same scale of equal parts; and the distance of any two places in the arch of a great circle, is nearly represented in this chart by a straight line. Hence hand-maps, made according to this projection, would indispensably have great advantages above those made in any other way. See MAP.

But for sea charts, and the use of navigation, it is yet controverted, whether the globular chart be preferable to Mercator's, whereby the meridians, parallels, and particularly the rhomb-lines, are all straight lines; inasmuch as straight lines are found more easy to draw and manage than curves, especially such as rhomb-lines on the globular chart are. This projection is not new, though not much taken notice of till late. It is mentioned by Ptolemy in his Geography; as also by Blundeville, in his Exercises. See CHART.

GLOBULAR Projection. See Projection.

GLOBULAR Sailing. See Great-circle Sailing.

Gen. Ch. Cal. Common perianth imbricated, with equal scales, the length of the disk; proper perianth of one leaf, tubular, five-cleft, acute,permanent. Cor. General one nearly equal; proper one of a single petal, tubular at the base; limb in five segments; the upper lip very narrow, cloven, shorted; the lower consisting of three larger, equal segments. Stam. Elements four, simple, as long as the proper corolla; anthers distinct, incumbent. Pijf. German superior, ovate; style simple, the length of the stamens; stigma obtuse. Peric. none; proper calyx, flutting up and enclosing the solitary, ovate flower. Common receptacle elongated, divided by scales. Eff. Ch. Common calyx imbricated; proper one tubular, inferior. Partial corolla with the upper lip cleft; under one three-cleft. Receptacle chaffy.

1. G. longifolia. Long-leaved Globularia. Willd. Sp. Pl. v. 1. 539; (Allysum five Herba terrabilis; Sloan. Jan. v. 1. 19. t. 5. f. 3.)—"Stem shrubby. Leaves linear-lanceolate, entire. Heads of flowers axillary."—This green-house shrub is a native of Madeira, flowering in July and August. The wood of this plant is hard and white, with a very large pitch, and an unequal light brown or grey bark. Leaves growing very thick towards the ends of the branches. Flowers consisting of several spherical heads, of a bluish color. Seed pappus, all over downy.

2. G. Alypum. Herb Terrible. Linn. Sp. Pl. 139. (Allysum montis Ceti; Ger. em. 526.)—"Stem shrubby. Leaves obovato-lanceolate, three-toothed or undivided. Heads of flowers terminal."—A green-house shrub, found in various parts of the south of Europe, flowering from August to November. Root woody. Leaves alternate, fascicled in the lower axils, near an inch long, glaucous, some are undivided, others three-toothed. Flowers blue or purple. The whole plant is bitter, and purgative in a violent degree.

3. G. biflagella. Linn. Sp. Pl. 139. (Scabiosa biflagella five Frutecfes: Pluk. Amalt.h. t. 58. f. 5.)—"Stem shrubby. Radical-leaves wedge-shaped, abrupt; stem-leaves lanceolate."—Native of the woods of India. Stem of many straight, hard, leafy branches, each about five or six inches high. Flowers in a blue terminal head.

4. G. vulgaris. Blue Daisy. Linn. Sp. Pl. 139. (Aphyllanthes anguillara; Camer. Hort. t. 7.)—"Stem herbaceous. Radical-leaves three-toothed. Stem-leaves lanceolate."—A hardy perennial, common in some parts of Europe, and flowering in May and June. Root woody. Stem a span high, terminated by a head of deep blue flowers. Willdenow mentions two varieties of this species, one with a leafless stem, the other with slender flowers.

5. G. frigida. Linn. Sp. Pl. 139.—Radical-leaves crinate; petiole; stem-leaves entire, pointed."—Native of Spain, Albinus having gathered it in Granada. It flowers in May.

—Radical-leaves numerous, small, fluff and notched, each sepal ending in a prick. Flowers composing an oblong sphere, hairy.—We are not acquainted with any figure of this species.

6. G. cordifolia. Linn. Sp. Pl. 139. Jacq. Anfr. t. 245.—"Stem nearly naked. Leaves wedge-shaped, with three points; the middle one very small."—Native both of hills and vales in Hungary, Austria, and Switzerland, flowering from April to July. Root creeping, each joint throwing out a cluster of leaves, from the centre of which springs a smooth purplish stem about four inches long, terminated by a head of blue flowers.

7. G. nutans. Willd. Sp. Pl. v. 1. 542.—"Flower-talks naked, very short, leaves spatulate, somewhat ovate, entire."—Found in the south of France, and on the Pyrenees, where our dried specimen was gathered by Dr. Noeben.

Root woody and very thick, bearing numerous tufts of little leaves, among which arise the short, solitary flower-talks. Flowers forming a terminal head.—It has never been figured.

FLOWER.-Flower-flask about six inches long, smooth, filleted, purplish towards the top, bearing a roundish head of blue flowers.

GLOMERULAE, in Gardening, contains plants of the herbaceous, flowery, perennial kind; of which the species chiefly cultivated are the three-toothed globularia (G. ajupum); and the common globularia or blue daisy (G. vulgaris); but others may be easily raised.

There are two varieties of the half fort, one with a white flower, and another that has a leaves item.

Method of Culture.—In the first it may be effected by planting cuttings of the young branches in April, July before they begin to flower, in pots of light earth mould, plunging them in a very moderate hot-bed, and giving them due water and shade, till they have fully rooted. After this they should be removed from the bed, and be gradually hardened to the open air, being protected during the winter months.

The second fort may be readily increased by parting the roots, as in the common daisy, planting them out in the early part of the autumn, in moister situations. They succeed best in such loamy soils as are rather moist in their quality.

The first affords variety among potted plants, and the latter in the fronts of the more moist and shady borders and clumps of pleasure-grounds.

GLOBULE, GLOBULUS, a little globe; otherwise called a sphenoe.

Thus the red particles of the blood are called globules of the blood, on account of their redness and fineness. (See Blood.) The Carteians call the particles broken off the matter of the first element, globules of the second element. See CARTEIAN, &c.

GLOBULARIS, NASS, is used for the lower, flexible, cartilaginous part of the nose.

GLOCHIDION, in Botany. See Braulia.

GLOSETZI, in Geographical, a town of Walachia; 50 miles N. of Bucharest. N. lat. 49° 13'. E. long. 26° 16'.

GLOGAU, a principality of Silelia, on the 8th side of the Oder, bordering on Poland; producing corn and wine, in abundance, in some parts affording mines of iron. The pastures feed many sheep, and the wool is wrought into different manufactures. It is divided into six circles. In the year 1241, it was governed by its own princes; but afterwards belonged to the king of Poland, to the king of Bohemia, to the emperor, and last of all to the king of Prussia.

GLOGAU, Great or Great, the capital of the principality of the same name, built in 1110 on the S. side of the Oder, taken by the Prussians in 1741, and strengthened by new fortifications. It is the seat of a governor, a commandant, divers tribunals, and a bishop's court, &c. It contains two Catholic churches, of which one is collegiate, three convents, a Lutheran church and school, and a chapel for Calvinists; 62 miles N.W. of Breslau. N. lat. 51° 37'. E. long. 16° 5'.

GLOGAU, Ober, or Little, a town of Sileilia, in the principality of Oppeln; 19 miles S. of Oppeln. N. lat. 53° 16'. E. long. 17° 48'.

GLOGNITZ, a town of Austria; 28 miles S. of Vienna.

GLOKEN-SPESSE, in Mineralogy, a term used by the Germans to express a sort of impure regular of bifinith, obtained by accident, sometimes in the making of found'. The bifinith ores are often so intimately mixed with the cobalt, that they cannot be separated from them. In this case, the arsenic being raised in the flowers, there remains at the bottom, instead of the fixed vitrifiable earth of the cobalt, a sort of impure regular of a reddish colour. This is bifinith, with an admixture of the earth of cobalt, and other extraneous matter. They sometimes call this whole matter by the common name of especific; but more usually they separate it into two parts, and call the under part, which is most solid, gloken-specific, and the upper part they distinguish by the name of as caladurn.

GLOMERELLS, in our Old Writers, comminatories appointed to determine differences between scholars of a school or university, and the townsmen of a place. In the edict of the bishop of Elly, anno 1276, there is mention of the matter of the glomerells.

GLOMMES, or GLOMEN, in Geography, called also the Star Els, or great river, the chief river of Norway, springs from the lake of Osefond on the north of the Farnund, and after running a course nearly south about 500 British miles, discharges itself into the Northern Ocean near Frederikshafi, to which town about 50,000 trees are annually floated upon it. This river, being full of cataracts and shoals, is not navigable. Before it receives the Warne, which issues from the lake Miof, it is about as broad as the Thames at Henley. In its course it presents a broad surface, sometimes watering pleasant valleys, sometimes intercepted by sand-banks, over which it frequently shifts its course, sometimes winding between rocky cliffs, and precipitating itself in frequent cataracts. Near Kongsvinger it is as broad as the Thames at Putney. Its rugged course, however, must render it a tremendous torrent.

GLOM, a river of Bavaria, which runs into the Ammer, near Cranzberg.

GLOS, a town of France, in the department of the Ouren, and chief place of a canton, in the district of Liege. The place contains 1,560, and the canton 8,550, inhabitants, on a territory of 1075 square kilometres, in 23 communes.

GLORE-FAT, in Rural Economy, a term applied to animals that are extremely fat.

GLORIA PATRI, in the Liturgy, a formula of words repeated at the end of each Psalm, and on other occasions, to give glory to the Trinity; called also the Doxology. It is thus denominated, because it begins in the Latin office with these words; Gloria Patri, q. d. Glory be to the Father, &c.

Pope Damasus is commonly said to have first ordered the rehearsal of, or rather, singin the Gloria Patri at the end of Psalms. Baronius, indeed, will have it to have been used in the times of the apostles; but its use, then, he allows to have been more obscure, and that it did not become popular till after the rise of Arrianism, when it was made a kind of symbol of orthodoxy.

The fifth canon of the council of Vaison, held in 529, decrees, * that the name of the pope shall always be rehearsed in the churches of France, and after the Gloria Patri shall be added sanctus in principio, as is done at Rome, in Africa, &c. on account of the heretics, who say,
fay, that the Son of God had his beginning in time."—Pleury.

GLORIA in excelsis is also a kind of hymn rehearsed in divine service, beginning with the words Gloria in excelsis Deo, & in terra pax hominibus, &c: Glory be to God on high, on earth peace, &c.

GLORIOSA, in Botany, so named on account of the splendour and magnificence of its flowers. Tournefort, objecting to the name given by Linnaeus because it is an adjective, called this genus Methonia, in which he has been followed by Jussieu, and indeed by all French botanists, though the Linnean school have refused to adopt this barbarous name.—Linn. Gen. 164. Schreb. 220. Willd. Sp. Pl. v. 2. 95. Ait. Hort. Kew. v. 1. 343. Mart. Mill. Dict. v. 2. Germs. t. 18. Jaff. 48.—Clas. and order, Hexandria Monoicy. Nat. Ord. Sarmentosae, Linn. Lilia, Juss.

1. G. superba. Superb Lily. Linn. Sp. Pl. 437.—Res. Lilac t. 26. "Leaves furnished with tendrils."—Native of Malabar and Guinea. It was introduced into Kew Garden in 1690 by the first earl of Portland. A tender herbaceous plant, flowering in July and August. The stem is herbaceous, about a fathom high, round, having two opposite lateral branches, and putting forth a flower-stalk from the base of each leaf. Leaves alternate, smooth, each ending in a tendril. Flowers pendent, of a most beautiful red and yellow colour. Petals lanceolate, long, waved at the edge, reflexed near the base. This remarkably handsome plant requires excessive heat to make it flower.

2. G. simplex. Linn. Mant. 62. Willd. Sp. Pl. v. 2. 96. "Leaves pointed."—Native of Senegal. The leaves are not furnished with tendrils. Flowers blue. There is no figure of this species known. It was merely taken up from Miller, nor has any thing been found which answers to the description.

Obf. This very beautiful genus is nearly allied to Erythro-rium.

GLORIOSA, in Gardening, comprises a plant of the herbaceous, flowering perennial kind; of which the species cultivated is the superb-lily (G. superba).

Method of Culture.—It is capable of being increased by planting the offsets from the old roots, either in the autumn after the lemons decay, or in the early spring before they shoot, in pots filled with light earth, plunging them in the bank of the flume. The old roots, when taken out of the ground, should be preserved in dry sand during the winter in the flume, or in a dry warm room. It is the practice of some to let the roots remain during the winter in the mould, keeping the pots in the tan-bed; planting out the offsets early in the spring. In either way they should have very little water given them.

When the lemons appear they should be supported by sticks, and in hot dry weather a little water should be sparingly given, as there may be occasion. And the pots in which they are planted should be small, that they may be confined, and put forth stronger lemons. Two-penny pots will be large enough for the roots of the greatest fixed plants of this nature.

The plants afford much effect by their beautiful flowers among those of the flume kind, when properly intermixed with them.

GLORIOUS ISLANDS, in Geography, two small islands in the Indian sea. S lat. 11° 35'. E. long. 27° 15'.

GLOSAR, a small island in the Baltic, E. of Aland. N. lat. 60° 20'. E. long. 20° 15'.

GLOSAR, a comment on the text of any author, to explain his sense more fully and at large, whether in the same language, or in any other. See Commentary.

The word, according to Rumphius, comes from sphenos, tongue; the office of a gloss is to explain the text, as that of the tongue is to discover the mind. Others derive it from the Latin glossa, a fletter or note; which among lawyers sometimes stands for litter; the gloss being, as it were, litter to the text.

Nic de Lyra compiled a polit or gloss on the Bible, in six volumes folio. The French fay, proverbially of an ill comment, that it is gloss d'Orleans, plus obscure que le texte.

Gloss is also used for a literal translation, or an interpretation of an author in another language, word for word. Young scholars need an intermediary gloss for the understanding of Junvenal, Horace, Sallust, Persius, &c.

Gloss is also used in matters of Commerce, &c. for the further, bulky, or the like.

GLOSSARY, GLOSSARIUM, a kind of dictionary for explaining the obscure, ancient, and barbarous words and phrases of an altered, corrupted, or refined language.

Spelman's glossary, entitled Archaeologicum, is an excellent work; though that author did not begin to study in this way till fifty years of age. M. Du Cange's Latin Glossary in six volumes, Paris, fol. 1735. Bald, fol. 1762, is a work in high estimation, and containing a fund of the most curious and amusing intelligence. Charpentier's supplement to this work, in 4 volumes, fol. Paris, 1766, is necessary to render this set of books complete. Du Cange's Greek Glossary in two volumes, fol. Lugd. 1688, is an excellent performance, full of uncommon erudition.

The Greek, Latin, and French glossaries of Du Cange form a series of the most instructive articles in the study of jurisprudence and belles lettres. There is an abridgment of this work in 6 vol. 8vo.; which, however, contains some matter not common to either of the preceding. This abridgment is exceedingly rare. At a caution to the purchasers of the Greek Glossary, we inform them that in the article "Moneta" (coins, vol. iv. p. 924.) there should be 10 plates of engravings of coins, and monograms of various princes and sovereigns of Europe, which are sometimes wanting, and thus the value of the edition is materially depreciated.

Lindenburg has a Glossary on the laws of Charlemagne, &c.

GLOSSOCATOCCHOS, in Surgery, an instrument for depressing the tongue. It is described by Paulus Aegineta, and the term is derived from γλωσσα, the tongue, and κατεχω, to hold.

GLOSSOCELE, denoting a swellling and protrusion of the tongue. The word comes from γλώσσα, the tongue, and κελε, a tumour.

GLOSSOCOMA, a retraction of the tongue.

GLOSSOCOME, in the Instrumental Music of the Greeks; a name given by the ancients to a kind of cithara for the glottides or tongues of their flutes, which probably were lutanists, and, consequently, their glottis was a reed. See Glottis.

GLOSSOCOMON, in Mechanics, is a name given by Hip-
ero, to a machine composed of divers dented wheels, with pinions serving to raise huge burdens.

Glossoscolex, a term in Surgery, derived from γλωσσ-, the tongue, and κεκαλωμενος, to guard; originally a caife for the reed of a hawthorn, but used metaphorically to signify a caife for a fractured limb.

Glossodia, in Botany, (ξυγονειδες), having the form or appearance of a tongue; in allusion to the peculiar appendage to the internal part of the flower, which resembles the tongue of a serpent, and affords the essential character. Brown Prod. Nov. Holl. v. 1. 325.—Chafis and order, Gynandra Monogynia. Nat. Ord. Orchides.

1. G. major. Brown 326.—' Appendage cloven half way down, its lobes spreading, acute.'

2. G. minor. Ibid.—' Appendage cloven to the base; its lobes parallel, obtuse.'

Both species are natives of the country near Port Jackson, New South Wales. Their fums are undivided, with a laminated coat, and grow in the earth, not parasitically. Herb hairy. Leaf folfary, radical, its base enclosed in a membranous sheath. Stalk radical, bearing generally one blue flower, rarely two, and furnished with one bradca besides what accompanies each flower. Brown.

Glossoides, in Natural History, a name given by some authors to a species of flocne, resembing the figure of the human tongue. This is a mere accidental configuration of a common flint or pebble, perfectly indeterminable in size and colour, and owing its form to no animal mould, as the fiones found in fheels usually do, but is a mere lufus nature in the concretion of the fione.

Gen. Ch. Cal. Perianth superior, of one leaf, turbinate, four-toothed, permanent. Cor. Petals four, equal, lanceolate, acute, much longer than the calyx, recurved. Nectary a ring round the base of the style. Stam. Filaments four, very short; anthers oblong, nearly united into a cylinder, elongated at the top into a membranous lanceolate expansion of two cells, opening inwardly. Pijf. Geren inferior, obovate; styie thread-shaped, as tall as the flamen: fignias four, acute. Peric. Drupae pear-shaped, of one cell, crowned by the calyx. Seed follicary, ovate, flariated.

Obf. The above characters appear to be taken by Schreber from Aulebit, nor have we any better materials. The only species known is,

1. G. arborefoeue; Willdenow. (Votomita guianensis; Aubl. v. 1. 91. t. 35.)—A shrub of a middling size, whose trunk is five or six feet high, and five or six inches thick; the wood yellow, hard and compact. Branches knotty, spreading variously, leafy. Leaves opposite, elliptical, pointed, entire, six inches long, thick and firm, of a shining green, placed on short stalks, with a deciduous fruip at each side of their base. Flowers white, on short, umbellate, axillary stalks, their petals about half an inch long. This plant is found in the extensive forests of Guiana, about the habitation of the natives. Nothing is recorded respecting its qualities or uses.

Gen. Ch. Cal. Perianth inferior, of one leaf, minute, five-toothed, permanent. Cor. Petals five, lanceolate, spreading, acute, much longer than the calyx, each bearing at its point a linear-lanceolate, abrupt appendage, almost of the length of the petal, bent back and lying upon it. Stam. Filaments five, very short; anthers roundish. Pijf. Geren roundish, encircled by a glandular ring, which bears the petals and flamen: styie none; fignias five, acute. Peric. Berry roundish, with five furrows, of one cell. Seeds five, angular.

Eff. Ch. Ca//y: half inferior, with five teeth. Petals five, each bearing an inflexed longitudinal appendage. Berry with five feeds.

Obf. Schreber, p. 826, suspects this genus not to be distinct from Atrala, but the habit confirms Jullien's opinion, which separates them widely. Two species are described by Aublet.

1. G. glabrum. (Goupia glabra; Aubl. v. 1. 296. t. 116.)—' Leaves smooth.'—Native of the forests of Guiana, 30 leagues from the sea, bearing flowers and fruit in November. The trunk is 60 feet or more in height, and two or three feet in diameter, serving to make canoes; the bark smooth and grey; the wood white and light. Branches drooping, furnished with alternate leaves of an ovate, pointed, somewhat unequal figure, entire, rigid, shining, and smooth, with a branching rib, and five transverse veins at the back. Flowers yellow, small, many together in foliary axillary umbels. Berry black, globular.

2. G. tomentosum. Willd. Sp. Pl. v. 1. 1522.—' Leaves downy.'—Native of the forests of Cayenne and Guiana. Not half so lofty as the former. The bark is wrinkled and dark-coloured. Leaves clothed on both sides with some short hairs. Their juice, which, as well as the bark, is bitter, is used to cure inflammations of the eyes.

Glossopetra, or Giottopetas, in Natural History, called also ixibonunada, sbarb's teeth, dog-sifs teeth, &c. a kind of extraneous fossil, somewhat in form of a serpent's tongue; frequently found in the island of Malta and divers other parts. Some of them are in a high state of preservation, having their enamel and points perfect, and their sharp edges finely ferrated as in the recent teeth.

Naturalists have been much divided as to the nature and origin of these bodies. Steno, De Corpore solido intra solido, content; Ol. Wormius, Diert, de Glofopeira; and Reyfehius, De Glofopetis Lunebergenfibus, treat of them at large.

The vulgar notion is, that they are the tongues of serpents petrified; and hence their name, which is a compound of γλωσσ-, tongue, and φηνες, stone. Hence, also, their traditional virtue in curing the bites of serpents.

The general opinion of naturalists is, that they are the teeth
teeth of fishes, left on land by the waters of the deluge, and since petrified.

They even specify the very kind of fish, and take it to be that which Theophrastus and the Greek writers call *exypus,* and the moderns the *shark or sea-dog.*

Camarius cannot persuade himself that the glosophetra found in England, Malta, and round Montpellier, were ever the teeth of a sea-dog, or any other fish. The chief difficulty, he suggests, is the small quantity of volatile salt and oil which they afford by distillation. To which Dr. Woodward answers, in defence of the common system, that having him so long buried under ground, it is no wonder they should have lost the best part of their volatile principles. It is certain, that human bones and flints, long interred, do not afford nearly the quantity of those principles that they would have done immediately after the person's death.

Another fable, proposed by Camarius is, that the glosophetra, when exposed to the naked fire, turn to a coal; and not to ashes; contrary to what is affected by Fabius Columa. Dr. Woodward answers, that it is likely enough the glosophetra, in burning, may assume the form of a coal, before it arrive to that of a calx.

The several sizes of the teeth of the same species, and those of the several different species of sharks, afford a vast variety of these fossil substances. Their usual colours are black, blue, white, yellow, or brown; and in shape they usually approach to a triangular figure. Some of them are simple; others are tricuspit, having a small point on each side of the large one; many of them are quite straight, but they are frequently found crooked, and bent in all directions; many of them are serrated on their edges, and others have them plain; some are undulated on their edges, and slightly serrated on these undulations. They differ also in size as much as in figure; the larger being four or five inches long, and the smaller of less than a quarter of an inch.

They are most usually found with us in the strata of blue clay, though sometimes also in other strata, and are frequent in the clay-pits of Richmond and of Sheppy Island, and in other places. They are very frequent also in Germany, but nowhere so plentiful as in the island of Malta. In the British strata they rarely occur. Mr. Farey has found them in these strata only in five places, viz., in the London clay, probably obtained from the clay-pits above-mentioned; in a bed of the soft or upper chalk in Kent, at Hærefield, near New Malton, &c.; in a green sandy stratum below the chalk, N. of Dumfriëths, &c.; in the Stonesfield and Collywellen flints series, above the Bath free-lime rocks, at Elstone in Oxfordshire, where Woodward procured specimens of these teeth in the jaw, &c.; and in the thick grey limestone rock which lies under and surrounds the South-Wales coal basins (Phil. Trans. N. 334.) Glosophetra are sometimes found in gravel-pits and other collections of alluvial matters. It is seldom possible to determine to what place in the series of strata these belong, and they should therefore be carefully distinguished from such as are actually found in the strata.

The Germans attribute many virtues to these fossil teeth; they call them cordials, Fowler's, and alephormans: and the people of Malta, where they are extremely plentiful, hang them about their children's necks to prevent dentition. They may possibly be of as much service this way as an anodyne necklace; and if suspended in such a manner that the child can get at them to its mouth, may, by their hardness and smoothness, be of the same use as a piece of coral. See *Serpent's Tongue.*

GLOSSO-PHARYNGEUS, in *Anatomy,* from *exypus,* the tongue, and *exypus,* a name given to those fibres of the constrictor pharyngis superior, which arise from the side of the tongue.

GLOSSO-SPATHA, in *Surgery,* an instrument, called by some *speculum linguae,* and used to depress the tongue, in order to look into the fauces.

There are many inflammatory disorders of the mouth, fauces, and palate, which require a depression of the tongue, while they are inspected and treated with proper remedies. The handle of a silver spoon is made to supply the place of this instrument in most cases, and answers the purpose very well. Whichever is used, care should be taken to depress very gently, to avoid giving the patient pain, as also to avoid irritating the mouth and inflamed parts.

When injections are to be made into the mouth, this instrument or the spoon should also be applied, and the syringe should be conveyed into the mouth over it.

GLOSSO-STAPHYLINEUS, in *Anatomy,* from *exypus,* the tongue, and *exypus,* another name for the constrictor pharyngis superior. See *Dilatation.*

GLOTTIDES, from *glosa,* the tongue; it is the opening through which the air passes to and from the lungs in respiration. In this passage the voice is formed. See *Dilatation and Larynx.*

Julius Pollux makes the glosis a joint or part of a flute, and Helychius says that the glosis were little tongues, acted upon by the breath of the player. This description of Helychius seems to confirm the idea of the ancient nomadic flutes being a kind of hautboys.

GLOTTIS, in *Ornithology,* a name given by many authors to a bird of the long-legged kind, approaching to the nature of our red-shank, but larger and longer legged, and generally known by the name limaja. See *Scolopax Limaja.*

GLOUCESTER, in *Geography,* a city in Gloucestershire, England, is situated in a vale, on a gentle eminence, rising, on the east side, from the river Severn. This opulent city appears to have originated in a Roman station which was situated at King's Holm, near the north-eastern extremity of the present city. The Romans continued to occupy this spot till the dislocations of their own empire occasioned them to quit the island. Its government then reverted to the British princes, under whose domination it continued till about the year 577, when, according to the Saxon Chronicles, it was surrendered to the West Saxons, and was reputed one of their principal cities, it was afterwards subjugated by the Mercians, who also obtained possession of the other part of the county. Under the Saxons it acquired the appellation of Gloce-cilcum. The strength and consequences of the city rendering it an object of frequent enterprise, its vicissitudes several times the scene of actions between the Britons and Saxons. By these conflicts, its buildings were nearly ruined, and the whole place might have sunk into complete decay, if Wolphere, son of king Penda, had not enlarged and adorned it, about the year 670. This restoration was so perfect, that Bede informs us, it was embellished, about the commencement of the 8th century, as one of the noblest cities in the kingdom. Its early importance is evinced by its having been the residence of various Saxon monarchs; and hence it was denominated a royal city, as it is expressly termed in a grant made by king Edgar to the monks of Worceler, dated at Gloucester in the year 964. By this monarch a battle was fought here with the Danes, who had twice plundered the city in the preceding ages, and who again ravaged, and partly consumed it by fire, in that of his son Ethelred. Several of the
the Norman and English kings also occasionally resided and transacted public business in this city. A memorable era in the eventful history of Gloucester originated in a contest between Henry III. and the barons. That monarch, in 1263, appointed Sir Maci de Beauf, a French knight, sheriff of the county, and constable of the castle within the city. The preference thus given to a foreigner was violently resented by the indignant nobles, who immediately made choice of Sir William Tracy, a native of the Shire. He accordingly proceeded to exercise the duties of his office in holding a county court, but was suddenly interrupted by De Beauf, who, entering with a party of the king’s troops, seized the knight, and, with circumstances of peculiar cruelty, hurried him to the castle, where he was committed to close confinement. After this outrage, the barons deputed Sir Roger de Clifford, and Sir John Giffard, with their dependants, to besiege the castle, for the double purposes of refuge and revenge; in a few days they obtained an entrance, and compelled De Beauf to retire to the keep; he afterwards surrendered, and was sent as a prisoner to Erfedey castle, in the marches of Wales. In the year 1278 Edward I. assembled a parliament here, and several laws, connected with the statute of Quo Warranto, were enacted, and have, from that period, been known under the general appellation of the Statutes of Gloucester. In course of the two next centuries, four parliaments were held here. The opposition of the Glouchestrans to the royal cause, during the reign of Charles I., is generally supposed to have operated fatally against his interest throughout the kingdom; so early as the year 1641, they declared for the parliament; raised a company of volunteers, which they added to their trained bands; procured cannon from London and Bristol, and repaired and strengthened the fortifications: though frequently besieged by the royalists, they successfully resisted every attack.

The ecclesiastical state of Gloucester, during the Roman and former part of the Saxon period of its history, is involved in much obscurity: but in the year 657, Edwy, king of Northumberland, having subdued Mercia, erected Litchfield into a bishop’s see, and included Gloucestershire within its diocese. This bishopric was soon afterwards divided into the five smaller of Litchfield, Dorchesteth, Hereford, and Worcester; to the last of which this district was annexed, and continued subject, till the reign of Henry VIII., who, by letters patent, dated September 30, 1539, erected afterwards episcopal by act of parliament, erected “the city of Gloucester, the county of that city, and all the county of Gloucester, into a bishopric, with a dean and chapter, by the name of the diocese of Gloucester; and ordained that such part of the then vil and county of Bratford, as formerly was in the diocese of Worcester, should be from thenceforward in the diocese of Gloucester for ever.”

The church appointed for the cathedral of the new see, was that belonging to the abbey, founded by Wolphierce, first Christian king of Mercia, and Ethelred, his brother and successor, in the year 681. The New Minster, as it is termed in the records, was burnt, with the monastery, in 1087 or 1088; probably at the same time that the city was partly destroyed by the adherents of Robert, brother to William Rufus. Serle, then abbot, began a new church in June, 1089; the first stone was laid by Robert, bishop of Hereford; and on the completion of the edifice, in the following year, it was dedicated to St. Peter, by the bishops of Worcester, Rochester, and Bangor. The abbey was again destroyed by fire in 1101 or 1102, but the church was saved. The present magnificent and interesting edifice has been erected at different periods, and consequently displays various specimens of ancient ecclesiastical architecture, in the Saxon, Norman, and English styles. The conversion of the abbey church into a cathedral was the chief cause of its preservation at the reformation; and, to the honour of the inhabitants of Gloucester, it became the object of their peculiar care during the civil wars, after which they obtained a grant of it from Oliver Cromwell. Hence the cathedral has been transferred to the present age, as nearly perfect in all its parts, with regard to its general construction, as it was left by the mostfavoured of its architects. The era of erection of the principal parts are known; and hence the characteristic styles of each can be satisfactorily ascertained. The lower part of the nave, the chapels that surround the choir, and the crypt, are preferred to have belonged to the building erected by bishop Aldred, before 1089; the roof of the nave obtained its finishing and form in 1248. In 1310 the south aisle was begun; and part of the south transept was added in 1330. The building of the north transept and choir commenced about the same year; the latter was completed in 1457. Between the years 1551 and 1590, the elaborate claustra were finished. The chapel of our Lady was built between the years 1457 and 1498; and the centre tower between 1457 and 1516. The interior of this splendid fabric consists of a nave, choir, side aisles, and transepts, with a chapel of our Lady, and several smaller chapels or oratories. From the intercession of the nave and transepts rises a high tower, and on the south side is a handomе projecting porch. The roof is finished on twenty-eight columns, which extend in two rows from the west end to the high altar, where the presbytery forms nearly a semi-circular sweep; the transepts have no isolated pillars. The chapel of our Lady is, as usual, attached to the presbytery; and there are chapels in the north-east and south-west angles of the transepts and choir, with two others projecting in the sweep between those and the chapel of our Lady. The outline, or ground plan of the cathedral, is probably the same at present as designed by bishop Aldred previous to the year 1089; and the crypt remains almost as perfect as the masonry left it. The architecture of this subterraneous and gloomy place is marvelly alive, and united to the immense weight resting on the arches, which are turned upon huge short pillars, and strengthened by groins of proportionate solidity. The nave is an interesting specimen of the style which continued to prevail for nearly two centuries after the Norman conquest. The arcade of ponderous round columns, and the rows of semi-circular arches above, impreses the mind with ideas of the strength, solidity, and profound solemnity which must have accompanied its original state. The architecture of the west end is very different from the other parts of the nave; and the vault is covered by intersecting ribs, and ornamented key-stones; but the remainder is of the plainest description, with three ribs only to each pillar; yet the key-stones are carved. On each side are eight massive columns; the arches between them are bounded by large mouldings, carved into zig-zag and other ornaments. Directly over each column, and at some distance, is a range of heads of various characters; some serpents, and others terrible. These serve as brackets to claustra of short pillars, whose capitals display the most beautiful variety of foliages, on which zig-zag strigings extend, serving as a base to other clustered pillars with equally elegant capitals; from these the ribs of the vault commence. The gallery windows, pierced through the wall above the arches, are divided by short thick pillars, and bounded by others, with zig-zag arches; a twisted string separates them from the clerestory windows. The north and south aisles of the nave are nearly in the style of the west end, with pointed windows, rich ramifications in the arches from the mullions, and fillet-
ed vaults. The arch of entrance to the cloisters from the north aisle is most elaborately and exquisitely adorned by pillars, buttresses, niches, pinnacles, foliage, and pendants, and the singular ornament of twisted pinnacles under the arch. In the south aisle, nail-headed mouldings are introduced as embellishments on each side of the windows. An advanced gradation of style is exhibited in the interior of the south transept; but the most perfect and ornamental degree is displayed in the chapel of our Lady. The choir is divided from the nave by a screen, designed by Kent.

The dimensions of the cathedral and its several parts are as follows: entire length, in feet, one hundred and thirty-five; breadth, forty-four feet two inches; height, fifty-seventh feet seven inches; breadth of the north aisle, twenty feet ten inches; height, forty-four feet six inches; breadth of the south aisle, twenty feet ten inches; height, forty-two; length of the south transept, fifty-six feet; breadth, thirty-four feet five inches; height, eighty-five feet; length of the north transept, forty-six feet; breadth, forty-three feet five inches; height, seventy-eight feet; length of the nave, three hundred and sixty three feet; breadth, thirty-four feet; height, thirty-four feet; length of the east front, forty-eight feet; breadth, forty-three feet; height, seventy-eight feet; length of the west front, thirty-four feet five inches; breadth, forty-one feet; height, thirty-four feet.

This cathedral contains several curious specimens of monumental sculpture. On the tomb of Edward III., which was erected by his son and successor, and exhibits great perfection of art, is a recumbent figure, in albaliaster, of the deceased monarch, regally robed and crowned. Another monument, worthy of notice, is that to the memory of alderman Blackleach, and his wife, whose figures, in white marble, lie on a table tomb, dated 1639, and seem accurate copies of the portraits by Vandyke: they are evidently the work of a skilful artist. A third, deserving observation for its design and classy style, displays a group by Flaxman, erected to commemorate Mrs. Morley, who died at sea, in childbirth: the figure is represented as rising from the waves with her infant in her arms, and conducted by two angels. Between the north aisle and the choir is a monument, erected by abbots Perker to perpetuate the memory of king Osfie: and in a chapel nearly opposite, is a figure, supposed to represent the unfortunate Robert Curthos, duke of Normandy, and eldest son of William the Conqueror.

The walls that surrounded Gloucester are mentioned in the ancient history, attributed to Merlin; and tradition ascribes them to Cisfa, the second king of the south Saxons. The Norman conqueror caused them to be strengthened and embattled: and they were again repaired in the twentieth of Edward III. Leland describes Gloucester as "well-built of stone, and strongly defended with walls, where its is not fortified with the deep lime of five years. The walls were completely demolished after the Reformation; and the only memorial of their former strength now remaining is the Well Gate: this is embattled; and was erected in the time of Henry VIII. The castle, was probably built about the period of the Norman invasion; the remains were lately destroyed; and on its site was built the county gaol, which was completed in 1701; it consists of three divisions, respectively named the Penitentiary House, the Bridewell, and the Sheriff's Prison: these all have their distinct and appropriate regulations. The gaol contains 200 separate cells; 164 for men, and 30 for women.

In this city and its suburbs were formerly eleven parochial churches; but only five are now standing: those of St. Michael, St. Mary de Crypt, St. Nicholas, St. Mary de Lode, St. John, and St. Aldate; the others having been either destroyed at the siege in 1643, or since taken down. In St. Michael's parish is a Blue Coat hospital, so called from the similarity of its regulations to those of Christ Church, London, founded and endowed in 1666 by Sir Thomas Rich, bart. Among other benevolent establishments that confer honour on the inhabitants of Gloucester, may be mentioned the county infirmary, erected by voluntary contributions, and opened in the year 1755. Its annual receipts, arising from donations and the interest of funded property, amount to between two and three thousand pounds.

The principal trade of Gloucester results from the navigation of the Severn, from the hemp and flax-dressing busses, and from the pin manufacture. The latter, which is the principal source of labour to the inhabitants, appears to have been introduced into this city by John Tilliby, in the year 1626, and is now carried on to a far greater extent than at any other place in England; there being nine manufactories, which furnish employment to about 1500 persons. The pins conveyed annually to the metropolis, are said to amount to the value of £5,000; but the principal demand is from Spain and America. A bell-foundry has been established here above three hundred years. The clothing trade, formerly the chief support of the inhabitants, is now nearly lost; on fulling mill only remains.

Various and important privileges have been granted to Gloucester by several monarchs; it was erected into a borough by charter from king John; Henry II. granted the burgesses the same liberties and customs as had been enjoyed by the citizens of London; by the act 33 Hen. VIII., which established the bishopric of Gloucester, it is ordered that the town should thenceforth be termed a city. It is also privileged as a county within itself. The corporation, acting under a charter of Charles II., consists of a mayor, twelve aldermen, a high steward, recorder, town clerk, two sheriffs, common-council, &c. The title of mayor still occurs in the year 1483. The high rewards have generally been perquisites of great eminence. Two representatives to parliament are elected by the inhabitants and freemen; the number of voters is about 3,000; the earliest return was made in the twenty-third year of Edward I. The elections are carried on in an ancient structure, called the Booth-hill, which is also appropriated to the aldermen and other county business. The public affairs of the city are transacted at the Thofley, a building supposed to have derived its name from the toll formerly received in it by the lords of the manor. Very considerable improvements have been made, within the last seventy years, in the appearance and buildings of this city. It consists, principally, of four spacious streets, meeting each other at right angles, and taking their names from the function of the gate which originally stood at the bottom of each, as East Gate street, Well Gate street, North Gate street, and South Gate street. At the intersection of the streets, formerly stood a large and beautiful church; but falling to decay, and impeding the passage of carriages, it was removed in 1752; its site still retains the name. The city is well paved and lighted, and its elevated situation, with a gradual descent on every side, greatly contributes to health and cleanliness. The markets had long been established by prescriptive right; but those now held, on Wednesdays and Saturdays, were chartered by Henry III. Three fairs are held annually and much frequented. The fairs
GLOUCESTER.

houses and population have varied considerably in different ages, according to the degree of security or danger which the inhabitants experienced; the progress has been several times interrupted by fires and civil commotions. Since the siege in 1643, the incarce has been regular. On the left entrance, under the act of 1804, the houses, in the city alone, amounted to 1,368, the population to 7,265; the inhabitants of the suburbs being 1,500 more. Gloucester is situated 166 miles W. from London.

Among the more eminent natives of this city is Robert of Gloucester, who wrote a chronicle of Britain in verse, from the age of Brut, to his own time, the reign of Henry III.

On the north-west side of Gloucester is the celebrated isle of Alney, a small tract, formed by the separation of the stream of the Severn into two channels. This was the scene of a combat between Edmund Ironside and Canute the Dane, in the year 1016.

In the southern frufts of Gloucester are the remains of Lanthea priory, founded in 1187. After the dissolution, the monastic buildings were converted into the offices of a farm. The only parts now left are a large barn, and the principal entrance, or gateway; on which are the arms, among others, of the Bohuns, earls of Hereford, who were great benefactors to the priory. Ruddor's History, &c. of Gloucester. Beauties of England and Wales, vol. v.

GLOUCESTER and Berkei Canals is the parliamentary name of a canal of very large dimensions, following the E. side of the Severn river between Berkeley and Gloucester, of which Mr. Robert Mylne and Thomas Dafford were the engineers; the other particulars will be found in our article CANAL.

GLOUCESTER, or Cape Ann, a township of America, in Essex county, Massachussetts, whose east point forms the N. side of the bay of Massachussetts. It contains 5,133 inhabitants, and is divided into five parishes, besides a society of Universalists. It is a port-town and a town of entry. The harbour is open and accessible to large ships, and it is one of the most considerable fishing towns in the commonwealth. At the harbour, properly so called, are fitted out annually from 60 to 70 bankers, and from Squam and Sandy bay, two small out-ports, the bay fishery is carried on with great spirit, and to a large amount. Thatcher's island, on which are two lights, lies close to the S.E. side of the township, which is itself joined to the continent by a bank of sand, that is rarely overflowed with the water. Here is a fine white sand, fit for the manufacture of glass. The harbour is defended by a battery and citadel erected in 1705:—16 miles N.E. by E. of Salem, and 34 N.E. of Boston.

GLOUCESTER, the N. westernmost township, and the largest, in Providence county, Rhode island, being 114 miles square, containing 4009 inhabitants.

GLOUCESTER, the name of a county in New Jersey, bounded N. by Burlington county; S. by Salem, Cumberland, and Cape May counties; E. by the Atlantic ocean, and W. by Delaware river. Its length on the Delaware is about thirty miles, and on the sea it is about 22 miles. Great and Little Egg harbour rivers are both navigable for vessels of about 200 tons about 20 miles from their mouths. The streams which fall into Delaware river are navigable for small vessels, a few miles up from their mouths, and afford some fish, eel, perch, parr, and perch. Its adjacent islands are Red Bank, Pett, and Old Man's creek. The full of the county is a mixture of sand and loam, and the tract bordering on the Delaware is in a high state of cultivation. The chief productions are beef, pork, fish, bay, corn, lumber, butter, cheese, &c. It is divided into ten townships, viz. Woodbury, Waterford, Newtown, Gloucester township, Gloucester town, Deptford, Greenwich, Woodwicb, Egg harbour, and Galloway. Malicus river divides the county from Burlington, and is navigable 20 miles for vessels of 60 tons. Maurice river runs southly about 40 miles through Cumberland county into Delaware bay, and is navigable for vessels of 150 tons 15 miles, and for flat-boats 10 miles further. It contains 16,115 inhabitants, of whom 61 are slaves. In this county are found quantities of bog-iron ore, which is manufactured into pig and bar iron, and hollow ware. Here is also a glass-house. The chief town is Woodbury, nine miles S. of Philadelphia.

GLOUCESTER, a small town in the above-mentioned county, on the E. side of Delaware river, three miles below Philadelphia,—Also, a port-town in Virginia, in the county of its own name, on a point of land on the N. side of York river, 17 miles distant from York town.

GLOUCESTER, a county in Virginia, fertile and well cultivated, bounded N. by Rappahannock river, which separates it from Middlesex, E. by Matthews county and Cheapsake bay, N.W. by King and Queen, S. and S.W. by York river, which divides it from York county. It is about 55 miles long and 20 broad, and contains 357,260 free inhabitants, and 4909 slaves. The low lands produce excellent barley, and Indian corn, the flax produce of the county.

GLOUCESTER HANY, a plantation belonging to the Hudson company, situated in New South Wales, on the N. side of the waters which form a communication through a chain of small lakes, between Winnipeg lake and Albany river. Henley house lies N.E. of this, nearer the mouth of Albany river in James's bay. N. lat. 54°. W. long 87° 30'.

GLOUCESTER, a township in the county of Dundas in Upper Canada, which is the seventh in ascending the Ottawa river; E. of, and contiguous to, the river Rondeau.

GLOUCESTER, Cape, a cape on the S. coast of Terra del Fuego.—Also, a high promontory on the E. coast of New Holland. S. lat. 19° 51'; E. long. 148° 11'.—Also, a cape on the coast of New Britain. S. lat 5° 54'; E. long. 148° 15'.

GLOUCESTER ISLAND, an island in the S. Pacific ocean, about five miles long, and from one to a quarter of a mile broad, discovered and so called by captain Wallis in 1767. It is surrounded by rocks, full of trees, and inhabited by persons who appeared armed with long pikes or poles, but deficient of canoes. S. lat 19° 11'; W. long 146° 4'.

GLOUCESTER, Duke of, ISLANDS, two islands in the S. Pacific ocean, discovered and so called by captain Carteret in 1767, which were covered with trees, but appeared to be uninhabited. The situation of them was a lip of land in the form of a half-moon, low, flat, and sandy; the appearance of it was pleasant, but it had neither vegetables nor water; but it abounded with birds, so tame that they might be taken by hand. The other island very much resembled this, and is distant from it about five or six leagues; they lie W.N.W. and E.S.E. of each other. One of them is in S. lat. 20° 38'; W. long. 146°; the other in S. lat. 20° 34'; W. long. 146° 15'; the variation 5° E. These islands are probably the land seen by Quivo, as the situation is nearly the same.

GLOUCESTERSHIRE, one of the western counties of England, is surrounded by Herefordshire, Oxfordshire, Berkshire, Wilts, Somersetshire, and Monmouthshire. It comprehends an area of nearly seventy miles in one direction, by forty in a transverse line. This district, during the Roman domination in Britain, was much occupied
pied by the Romans. Mr. Fosbrooke (one of the historians of the county) observes, "from the ruins which have at various times been excavated, it is evident that this county, from Cirencester to Painswick, Bibury, Sapperton, Woodchester, Uley, Kingscote, and other adjoining places, was much peopled with Romans, or Romanized Britons; that Cirencester was the great metropolis, or resort of pleasure and amusement; while Gloucester, and the hills about the Severn, were the great military positions; the city, on account of the river, having peculiar advantages with respect to commerce." The principal Roman roads which passed through this county, were the Icknield street, the Erming or Erming street, the Foshs-way, and the Via Julia. Under the dominion of the Saxons, Gloucestershire formed part of the Mercian kingdom, and Winchcombe and Kingstanley are mentioned as residences of the Anglo-Saxon monarchs. On the division of Mercia into five biophilips, after the conversion of the Saxons, the greatest part of this county was included under that name Wicceca, and from this appellation the Dobuni, the early inhabitants of this part of Britain, were afterwards termed Wicceca.

Gloucestershire is separated into four divisions; these are subdivided into twenty-eight hundreds, containing 320 parishes, one city, and twenty-eight market towns. The number of houses, as returned under the population act, amounted to 375,276; of inhabitants, 187,162; of which 90,237 were males, and 96,927 females. The whole county, with the exception of the chapelry of Iscomb, and Cowleyborne, is included within the diocese of Gloucester; which comprehends one arch-deanery, and ten deaneries. The number of representatives returned to parliament are eight; two for the shire, two for the city, two for Tewkesbury, and two for Cirencester. The principal aspect of Gloucestershire is greatly diversified; nature having divided it into three districts of very dissimilar character, respectively named the Hill, the Vale, and the Forest. The Hill district, including the Cotswolds, and the Stroudwater hills, may be regarded as a continuation of the central chain proceeding south from Derbyshire, and passing through this country with a smaller elevation into Wiltshire; there swelling into the Salisbury Downs, and afterwards running west towards the Land's End in Cornwall. The extent of the Cotswold hills, from Broadway hill to near Tetbury, is thirty miles; and from Birdlip hill to Burford, about twenty miles; the area they include is estimated, by Mr. Marshall, to contain nearly 202,000 acres. The surface is hilly; and the climatic, considering the natural elevation of the land, unusually mild. The sides of the hills abound with springs; and almost every dip has its rill, and every valley its brook. The principal object of the Cotswold habitancy is sheep; these have been long famous; and it is a prevailing tradition, that the Spaniards originally procured their breed of fine woolled sheep from these hills, though this tradition is contradicted by several modern writers. The inclosures are chiefly stone walls, about four feet and a half high, exclusive of a coping of flat stones. The Vale district includes the entire tract bounded on the east by the Cotswold hills, and by the river Severn on the west; and is usually subdivided into the Vales of Eyemah and Gloucester, and the Vale of Berkeley; the latter of which is separated from the former by a natural interjection, and is very different in produce and rural management. The Forest district is separated from the rest of the county by the river Severn; and is principally comprehended by the Forefield of Dean, which was formerly of particular value, for the goodness and strength of its timber. Its oaks were so greatly renowned that Evelyn observes, that in Elizabeth's reign, an ambassador was purposely sent from Spain to procure its destruction, either by negotiation or treachery. It also abounds in bees; and the soil is considered as peculiarly favourable for the growth of the Stire apple. Its principal minerals are iron, ore, and coal; iron appears to have been wrought here even in the time of the Romans; and so early as the reign of Edward I. seventy-two furnaces, for melting iron, are recorded to have been built here. In a survey made in the seventeenth year of Charles I. the forest is estimated as originally containing upwards of 45,000 acres, of which above 14,000 were woodland. Several thousand acres have, however, been granted away, by different sovereigns, and disafforested. The names have distinct courts, and, like those of Derbyshire and Devonshire, are governed by their own customs.

The principal rivers connected with Gloucestershire, are the Severn, the Frome, the Wye, and the Isis or Thames. The canals that intersect the county are distinguished by the names of the Thames and Severn, the Stroudwater, the Berkeley, and the Horsey and Gloucester. The Severn, the second commercial river in England, renders essential service to a large portion of the county. It enters Gloucestershire near the ancient town of Tewkesbury, where, uniting its waters with the Upper Avon, and pursuing a south-westerly course, it traverses a wide vale, which is rich in pasturage, and in some places abundantly wooded. About one mile above Gloucester, it divides into two streams: these again unite a little below the city, forming the tract of land called Alney island. In the course of its passage through the county, it receives the streams of the Upper Avon, the Chelt near Wainscoat, the Leden near Over's bridge, the Frome at Framilode, the Avon at Berkeley, and the Lower Avon below Bristol. The Wye separates part of this county from Monmouthshire and Herefordshire, and forms the grand natural western boundary to the forest of Dean, whose noble wooded eminences constitute many fine features on its meandering banks. The Thames, the most important of the British rivers, has its source in this county, at a place called the Thames-head, near the village of Cotes, about two miles south-west of Cirencester. Near this place the Thames and Severn canal emerges from under ground, and receives a considerable quantity of water, occasionally from this spring. The junction of the Thames and Severn was an object of favourite speculations with the Londos and Bristol merchants for many generations; but was not completed till near the close of the last century, an act for that purpose was obtained in 1783, and the design was brought to perfection in 1792, when the first vessel passed from the Severn into the Thames. This canal begins at Wallbridge, near Stroud, (at the place where the Stroud navigation ends,) and proceeds in a devours course through the county to Lechlade, where it joins the Thames. This course includes a distance of thirty miles, seven chains and a half. The water, in its progress from Stroud to Sapperton, (seven miles three furlongs,) is raised by means of locks 241 feet 3 inches; between Sapperton and Lechlade it falls 120 feet 6 inches. The Stroudwater canal encounters many obstacles; yet in defiance of all opposition, an act was obtained in 1777, under the operation of which it was finished.

The manufactures of Gloucestershire are numerous: clothing, linens, blankets, rugs, carpets, drokings, &c. are made in different parts of the county. Bar iron, edge tools, wire, nails, and many other articles, are also manufactured in large quantities. Near Bristol are some extensive furnaces, as well as different works for making bricks and wire, vitreil, redlead, Cornishmenes, &c. At Gloucester, vast quantities of pins are made, and at Frampton Cotdes is a considerable

GLOVE: Chirotheca, a habit or covering for the hand and wrist, used both for warmth, decency, and as a shelter from the weather. Gloves are distinguished, with respect to commerce, into leather gloves, silk gloves, thread gloves, cotton gloves, worsted gloves, &c.

There are also gloves of velvet, satin, taffety, &c. Leather gloves are made of shamoyn, kid, lamb, doe, elk, buff, &c. There are also perfumed gloves; washed, glazed, waxed gloves; and white, black, uncolour, &c. gloves; single, lined, topped, laced, fringed with gold, silver, silk, fur, &c.

It is a proverb for a glove to be good and well made, three kingdoms must contribute to it; Spain to drefs the leather, France to cut it, and England to sew it. But, of late, the French seem to have appropriated the functions of the other two; the gloves of the French manufacture being now said to have the advantage, in point of dreesing and sewing, as much as of cutting.

By 34 Geo. III. c. 10, the British duty on gloves and mittens imposed by 25 Geo. III. c. 55, is repealed, except the duty on licenced; and by 36 Geo. III. c. 80, the said duty on licences is also repealed. By 6 Geo. III. c. 19, and 25 Geo. III. c. 55, foreign manufactured leather gloves or mitts shall not be imported, under the penalty of forfeiture; and the importer or seller incurs, besides forfeiture, a penalty of 200. with double costs.

Glove, to throw, was a practice or ceremony very usual among our forefathers, being the challenge whereby another was defiled to single combat. It is still retained at the coronation of our kings, when the king's champion calls his glove in Westminster-hall. Fawyn supposes the custom to have arisen from the eastern nations, who, in all their sales and deliveries of lands, goods, &c. used to give the purchaser their glove by way of livery or investiture. To this effect he quotes Ruth iv. 7 where the Chaldee paraphrase calls glove what the common version renders by shoe. He adds, that the rabbinis interpret by glove, that passage in the eviuth Phalim. "In Idumean extendam calencaum tov marb, Over Edom will I call out thy shoe." Accordingly, among us, he who took up the glove, declared thereby his acceptance of the challenge; and as part of the ceremony, continues Fawyn, took the glove off his own right hand, and call it upon the ground, to be taken up by the challenger. This had the force of a mutual engagemnt on each side to meet at the time and place which should be appointed by the king, parliament, or judges.

The fame author afferts, that the custom which obtained of helling gloves, in the coronation of the kings of France, is a remain of the ealern practice of giving possession with the glove. Lib. xvi. p. 1017, &c.

The delivery of a glove was in frequent use formerly, as a symbol of investiture. See Du Cange, Gloff. Lat.

GLOVES were also used to signify the reward's or bailiff's fee, or part of the price of the invelliture or purchase-money of the land. "Si aliquam territorii partem vendendi contigi, domini venditiones habebunt; hellacet, tot demaries quot venefor inde habuerit solidis. Major vero terro illius pro exitu recipient duo dariarios." Where quake signifie gloves, or, in French, gants.

Hence the common custom, in many bargains, of giving ferrants money for a pair of gloves.

"Anciently it was prohibited the judges to wear gloves on the bench; and at present, in the fables of most princes, it is not safe going in without pulling off the glove."

GLOVER, Richard, in Biography, was born at Lon- don in 1712. He received the elementary instructions in classical learning at Chalm, and exhibited a considerable talent for the classics, and an attachment to science. When he was only 16 years old, he wrote a copy of verses "To the memory of Sir Isaac Newton," which is prefixed to Dr. Pemberton's view of the Newtonian philosophy. He engaged in commercial pursuits, and became eminent in the mercantile world, to which he was introduced by his father. In 1737, he married a lady with a handsome fortune; and in the same year he published his epic poem of Leonidas. Glover had joined the opposition of the day, at the head of which was Frederic prince of Wales, and his poem, founded on the struggles of free Greece against Asiatic despotism, was calculated in a high degree to serve a generous caufe. It abounds in noble sentiments, and is considerably varied by incident and description. Its plan is admirably adapted for poetical effect: it was received by Lyttlet- ton and others with high applause, and very soon passed through three editions. "But it labours," says the critic, "under that want of interel which attends all modern epics, especially such as are built up on some of the fabulous events of ancient history; and its poetry is not of a character sufficiently elevated to engage the reader by the beauty of detached passages." The reputation which it first acquired soon fubstituted, and it now lives rather in memory than in the actual acquaintance of readers. He published in 1739, his poem, entitled "London, or the Progress of Commerce;" and the ballad of "Hofier's Gloff." Mr. Glover was not only a poet but an ardent politician, and was distinguished in various instances for his eloquence in the cause of freedom. His talents gained him great credit, and he was appointed by the merchants of London, to conduct an application to parliament, complaining of the neglect with which their trade had been treated. The speech which he pronounced at the bar of the house of commons on this subject, in January 1742, was greatly admired, and was published. His celebrity as a public character, did not favour his pro- gress in commerce; his affairs became embarrassed; he was, to use a modern fashionable phrase, obliged to suspend his payments, and at length retreated from active life, to pacific commerce in an obscure situation. The duchess of Marlborough bequeathed him, and Mallet, five hundred pounds each on condition of their joining to write the history of the great duke. Glover renounced the task, and Mallet never executed it. He now wrote several pieces for the stage, which being successful to a considerable degree his circumstances became so much improved, that he ventured to return to public life, and sat as member for Wey- mouth, in the parliament of 1761. His commercial knowl- edge made him extremely useful on several important occasions. In the year 1775, he took an active part in an application to parliament on behalf of the West India merchants, and for his zeal and ability he was complimented with a valuable present of plate. He died in November.
November 1785, and left behind him another poem, entitled the ‘Athenaeid,” relating, in thirty books, the wars between the Greeks and Perians. This was published in 1788, in three volumes 12mo., but it failed completely in attracting public attention.

GLOW-WORM, in Entomology. See Cicindela. Catharisi and Cicindela have been often used, indiscriminately, for the glow-worm; but they form two distinct genera of the same order in the Linnean system. See Cantharis.

The glow-worm is often seen in the day time. The male and female differ greatly in this species of insect. The male has wings, and is a small fly; the female has no wings, but is a large crawling worm.

The body of the male is oblong, and somewhat flattened; the wings are shorter than the body; the head is broad, dun, and flat; the eyes are large and black. This has no light issuing from it, and is not commonly supposed to be at all of kin to the glow-worm.

The female is what we expressively call by this name; this is a very slow-paced animal, without wings, and somewhat resembling a caterpillar; the head is small, flat, hard, and black, and sharply towards the mouth; it has short antenna, and fix moderately long legs; the body is flat, and is composed of twelve rings, whereas the body of the male consists only of five; it is of a dusky colour, with a streak of white down the back. It is often seen in the day-time, but it is not known except in the dark; at which time it is easily distinguished by the glowing light, or lambent flame, that is seen near the tail, issuing from the under part of the body.

The common glow-worm is frequently met with under our hedges, and, if carefully taken up, may be kept alive many days on fresh tufts of grass; all which time it will continue to shine in the dark.

The light of this little insect is so strong, that it will shew itself through several substances, in which the creature may be put up; a thin pillow easily shews it through, and even though lined with paper, the light is not impeded in its passage by both. The creature is sluggish, and appears dead in the day-time, and its light is not distinguishable, even if carried into a darkened room, unless the creature be turned upon its back, and disturbed, so as to be put in motion, and then it is but very faint; after some the light begins to return, and with it the life and motion of the animal. The motion and light of this creature seem, in some measure, to depend upon one another; it never shews when the body is not in some sort of action; and when it shews most, the body is extended to one third more than its length in the day-time. In the time of brightest shewing, it will sometimes on a sudden turn its body about, and the light will not be larger than the head of a pin; and, on being touched, it will then immediately extend itself, and the light will become as large and bright as ever. Phil. Trans. N. 71.

Two points seem to be agreed upon by naturalists, with regard to the light issuing from the tail of a glow-worm; first, that it is phosphoric, and secondly, that its use is to attract the male insect. Should the singularity, if any such there be, in the natural history of this animal, which should render a provision of this kind more necessary for the glow-worm, than for other insects, be a subject of inquiry; it may be observed that this singularity seems to be the difference, which subsists between the male and the female, which difference is greater than what is found in any other species of animal whatever. The glow-worm, as we have observed, is a female caterpillar, the male of which is a fly; lively, comparatively small, differ from the female in appearance, probably also as did the fish from her habits, pursuits, and manners, as he is unlike in form and external constitution. Hence it appears, that the caterpillar cannot meet her companion in the air. The winged rover dreads the ground. They might never therefore be brought together, did not this radiant torch direct the volatile mate to his sedentary female.

In this example," says the ingenious author now cited, "we see the sources of art anticipated. One grand operation of chemistry is the making of phosphoric; and it was thought an ingenious device, to make phosphoric matches supply the place of lighted tapers. Now this very thing is done in the body of the glow-worm. The phosphoric is not only male, but kindled; and caused to emit a feady and genial beam, for the purpose which is here stated, and which I believe to be the true one." Paley’s Natural Theology, p. 563.

Glow-worm, Flying, cicindela volans. In the warmer months of the year, this creature is sometimes caught in our houses flying to the flame of a candle, and when examined in the dark, it is found luminous at these times, though perhaps less, or not at all fo, at others; which may be a reason of its not being known, though caught in the fields; and to this it may be owing, that many who have described it have thought it not a native of England. Without wings it is frequently enough found in form of the common glow-worm, and then always shews. Aldrovand has very well described the cicindela volans, and says, that it lays eggs which hatch into small worms, and that these after a time become flies, by the same sort of change which happens to caterpillars and other reptiles which become butterflies, and other species of winged insects. Moufett, and Thomas Bartholin, both describe the animal much as Aldrovand has done, but they allow the male only to have wings; but Julius Scaligier contradicts this, and says, that he has caught them both winged in the act of generation; this is a plain proof that both sexes are winged; yet it has not happened that both sexes have been acknowledged to be so, even by those who have quoted this passage. And Mr. Walker, who gives an account of them in the Philosophical Transactions, observed them in the same manner in the act of copulation both winged, and with no other difference between them but that the female was the larger of the two, which is the case in regard to many insects. Julius Scalig. Exerc. 191. Phil. Trans. N 167. p. 841.

The male and female in this winged state both shew in hot weather, and their light is so vivid as to be easily seen even while there is a candle in the room; the vibrations of it are irregular and its colour greenish. The luminous parts are two small specks under the tail at the end, and the light continues in these some time after the tail is cut off, but then gradually goes out.

The parts of insects continue alive in some degree for a considerable time after they are cut off, and probably the light in the tail of this animal continues just as long as that fort of life remains in it. Moufett, cap. 15.

The use of this light seems to be to direct the animal in its course, and in the taking of its prey, and to this purpose it is admirably placed. The tail is easily bent under the belly, and then throws the light full upon any object about or under the head of the animal, and the eyes are placed not on the upper part but on the under side of the head; so that they have all
The native and its oblique flowers. 1785, a anthers 9. this mucli and enemies. Thomas Barthol. de Luce Anim. lib. ii. cap. 12.

This insect is of the beetle kind, of a brown and dirty colour. It has hard cape or shell wings, as the other beetles have, and when these are expanded, there appear a pair of very large membranous ones; its head is covered with a fort of shield or broad-brimmed hat; under this hat are placed the eyes, which are black and large, and are moveable, so that the creature can, upon occasion, thrill them forward: it has two hairy antennas, and its legs are like those of the common fly, hard, sly, and hairy. Its eyes afford an elegant object for the microscope, being composed of an infinite number of lenses, as those of the libelle and other insects. Aldrovand. de Insect. lib. i. cap. 8.

Gen. Ch. Cal. Perianth superius, of five oblong, spreading, nearly equal leaves. Car. of one petal, obliquely bell-shaped; gibusious at the base: its border in five rounded obtuse lobes, the four uppermost recurved, the lower one prominent, concave and inflected. Stem. Filaments four, much shorter than the corolla, with the rudiment of a fifth; inferted into the receptacle, connected with the base of the corolla, incurved, downy, converging laterally in the upper part, two after the shortest: anthers ovate, pale, two-celled, cohering together, their lobes diverging. Pyl. Germen inferior, turbinate, furrowed: style cylindrical, as long as the flaments: stigma capitate. Peric. Capsule imperfectly two-celled, with two valves, and two lateral divided receptacles. Seed numeros.

Eff Ch. Calyx superior, of five leaves. Corolla bell-shaped, with an oblique irregular border. Filaments, with the rudiment of a fifth, inserted into the receptacle. Capsule with many seeds, inserted into lateral receptacles. 1. G. maculata. Curt. Mag. t. 1191. (Martynia perennis; Linn. Sp. Pl. 862. Hort. Cliss. t. 18. Ehret. Dict. t. 9. f. 2. Mart. Mill. Dict. v. 3.—Native of South America; the seeds having been sent from Carthagena by Mr. Robert Millar, before 1739. It requires with us the confiant heat of a dark flow, by means of which it flowers late in autumn. It is propagated abundantly by the little tuberous roots, which are perennial. The flamen herbaceous, fimple, leafy, round, very smooth, spotted with purple. Leaves large, opposite, recurved, filated, broad-ovate, acute, ferrated, smooth and shining, pale at the back, with prominent veins. Flowers axillaries from the diminished leaves, or bracées, at the upper part of the flamen, folicit. filated, large, drooping, of a fine blue with a dark spot at the bottom within. Their fcent is very peculiar, refumbling mint, which no writer seems to have noticed.

GLUBOKAYA, in Geography, a town of Ruffia, in the government of Kolyvan; 72 miles E. of Semipolatnoi.

GLUCHOV, or Glukhov, a town and district of Novgorod Severoff, situated on the river Yefma, falling into the Seim; 40 miles E.S.E. of Novgorod Severoff.

GLUCK, le Chevalier Christopher, in Biographe, a musical composer of great fire and originality, who, during the last 30 or 40 years of the preceding century, acquired great renown, but chiefly in France, by a species of composition, congenial to the national taste, which Lulli and Rameau had formed, and in which the short and simple airs required no great abilities in the fingers; but the dramas being written in the language and made being regarded as more important performance than the composer of the mufe, the several characters required great actors rather than great fingers.

This eminent composer was born in the Palatinate, of a poor family, about the year 1716. His father, during the infancy of his son, removed into Bohemia, where he died, leaving his offspring in early youth, without any provision, so that his education was totally neglected; but nature had given him an instinctive love for music, which he himself used to practice with the greatest skill and taste, by reason of his father's instruction in the second degree of singing, which he acquired with the greatest facility.

This was the ease with the young Christopher, who travelled about from town to town, supporting himself by his talents till he had worked his way to Vienna, where he entered the service of a nobleman, who became his patron, took him into his service, carried him into Italy, where he procured him leons in counterpoint, at Naples, by which he profited so well, that before he left Italy he composed several dramas for different theatres, which acquired him reputation sufficient to be recommended to lord Middlesex as a companion to his lyric theatre in the Haymarket, then under his lordship's direction. But, unhappily, arriving in England in 1745, after his first opera of "Artamene" had been performed ten nights, in which the famous air "Raffarena il mesto" sung by Montefilli, was constantly encored, the rebellion broke out, and the great Operabanche was shut up, on account of the popular prejudice against the performers, who, being foreigners, were chiefly Roman Catholics. Nor was the Opera-banche allowed to be opened again, till January 7th, 1746, when "la Caduta de Giganti," fet by Gluck, was performed before the duke of Cumberland, in compliment to whom the whole was written and composed. The fingers were Montecelli, Jozzi, and Ciacci; with figuro Inier, Pompeggi, afterwards better known by the name of madame Cornelle, and Frai. The first woman, Inier, never surpassed mediocrity in voice, fafe, or action; and the Pompeggi, though nominally second woman, had such a masculine and violent manner of singing, that few female symptoms were perceivable. The new dances by Auretti, and the charming Violette, afterwards Mrs. Garrick, were much more applauded than the faults, which, however, for the time, had considerable merit. The first air in G minor is of an original call, but monotonous. The second air's genius and excellency in it. Then a duet, in which he hazarded many new passages and effects. The following air, for Montecelli, is very original in symphony and accompaniments which a little disturbed the voice-part in performance, we well remember, and Montecelli called it oria tedeo. His contemporaries in Italy, at this time, fancied too much filed down; and when used afterwards in that country, made him one of the greatest composers of his time. The next air printed, is in a very peculiar manner,
fure, and like no other that we recollect: it has great merit of novelty and accomplishment; the voice-part wants only a little more grace and quiet. The following song, set for Jozzi, a good musician with little voice, is full of new and ingenious passages and effects; we should like much to hear this air well performed at the opera; it is kept alive from beginning to end. Something might be expected from a young man able to produce this opera, imperfect as it was. It had, however, but five representations.

From London he returned to Italy, and composed several operas in the style of the times, such as that of Termeoegus, Galuppi, and Jomelli; and we heard little of him till he joined with the Italian poet Calzabigi, with whom he joined in a conspiracy against the poetry and music of the melo-drama then in vigour in Italy and all over Europe. It is extraordinary that Calzabigi, editor of the beautiful Paris edition of the works of Metastasio in 1755, in the preface to which there is the highest and seemingly most cordial praise of the works of the imperial laureate, should be the first, ten years after, to find them so defective; writing his "Orofello" in a different style, and joining with Gluck in doubly exciting the lyric style both of the music and poetry of the Italian opera.

In 1764, the year in which the late emperor Joseph was crowned king of the Romans, Gluck was the composer, and Guadagni the principal singer. It was in this year that a species of dramatic music, different from that which then reigned in Italy, was attempted by Gluck in his famous opera of "Orfeo," which, with Guadagni's admirable action, succeeded so well, that it was soon after attempted in other parts of Europe, particularly at Paris and Vienna. This is not the place to discuss its merit; we shall here only observe, that the simplifying dramatic music in Gluck's manner, in favour of the poet, at the expense of the composer and singer, is certainly very rational, when an opera is performed in the language of the country, and the singers have not great abilities to display, as in France; but in England, where we have frequently fingers of uncommon talents, and where so small a part of the opera audience understands Italian, by abridging the symphonies, and prohibiting divisions and final cadences, in favour of an unintelligible drama, we should lose more than we should gain.

After its successes at Parma and Paris, "Orfeo" was exhibited at Bologna, Naples, and in 1760 in London; when the principal parts were filled by Guadagni and Graffo, afterwards Mrs. Bach. The unity, simplicity, and new dramatic excellence, which Vienna, and afterwards at Paris, rendered this drama so interesting as to make the audience think more of the poet than the composer, were greatly diminished here, by the heterogeneous mixture of music of other composers in a totally different style.

In 1765, Calzabigi and Gluck, encouraged by the successes of "Orfeo," produced "Alceste," a second opera, on the reformed plan, at Vienna, which received even more applause than the first. In 1771, the same poet and musician brought a third opera, "Paride ed Elena," on the stage at Vienna, written and composed in the same new, or rather old, French style, with better music, in which Millico was the principal singer, and which afforded the audience such pleasure as seemed to have impressed the lovers of music in the imperial capital with a partiality for that species of dramatic music, which was not likely to be soon obliterated.

In 1772, Gluck set to music an opera taken from Racine's "Iphigenie," in which he so far accommodated himself to the national taste and style of France, as frequently to imitate and adopt them. And as this opera was intended for Paris, his friends feared for its success, as there was frequently mistrust, and always jealousy, in his music; though set to French words, and for a facile French opera.

But the year 1774 was rendered a remarkable era in the annals of French music, by the arrival of the chevalier Gluck at Paris, whose operas, by his conforming to the genius of the French language, and flattering the ancient national taste, were received with acclamation. He began his career in this capital by his celebrated opera of "Orphee," of which the reputation was already established; and this was followed by "Iphigenie," taken from one of Racine's best tragedies, which did all the successes that may be imagined from the force of his genius applied to a favourite drama, set in the style of their favourite composers, Lulli and Rameau.

In his operas of "Cythere Alligée," 1775, where much delicacy and tenderness, than force, were required in the composition, he was not so successful. Nor was his "Alessandro," the year following, received with the same rapture as at Vienna. Indeed his "Armide," in 1777, did not quite fulfill the ideas of grace, tenderness, and pathos, which some of the scenes required, and auditors accustomed to Italian music expected; however, his operas were excellent preparations for a better style of composition than the French had been used to; as the recitative was more rapid and the airs more marked, than in Lulli and Rameau; there were likewise more energy, fire, and variety of movement, in his airs in general, and infinitely more force and effect in his expression of grief, fear, remorse, vengeance, and all the violent passions.

Gluck's music is so truly dramatic, that the airs and scenes, which have the greatest effect on the stage, are cold, or rude, in a concert. The situation, context, and interest, gradually excited in the audience, give them their force and energy.

Indeed, he seems so much the national musician of France, that since the best days of Rameau, no dramatic composer has excited so much enthusiasm, or had his pieces so frequently performed. It has been said in the "Journal de Paris," that each of his pieces had supported two or three hundred representations. The French, who feel very enthusiastically whatever music they like, heard with great rapture the operas of Gluck, which even the enemies of his genius allowed to have great merit of a certain kind; but though there is much genuine and intrinsic worth in the dramatic compositions of this master, the congeniality of his style with that of their old national favourites, Lulli and Rameau, was no small merit with the friends of that music. The almost universal cry at Paris was now, that he had recovered the dramatic music of the ancient Greeks; that there was no other worth hearing; that he was the only musician in Europe who knew how to express the passions; these and other encomiums preparatory to his apotheosis, were uttered and published in the journals and newspapers of Paris, accompanied with constant and most unmeaning encomiums of Italian music, with which specious, admiring, and humble names were added to the titles of his operas.

This admirable composer, the delight and pride of Naples, as Gluck of Vienna, had no sooner erected his triumphal arch in France, than all the friends of Italian music, of Rameau's doctrines, and of the plan, if not the language, of Metastasio's dramas, enlisted in his service. A furious war broke out, all Paris was on the qui vive? No door was opened to a visitor, without this question being asked previous to his admission: "Monseigneur! estes vous Piccinni ou Gluckelet?" These disputes, and those of musical critics, and rival artists throughout the kingdom, seem to us to have flourished and diminished the pleasure arising from music in proportion as the art was advanced to perfection. When every paper or magazine in a new composition is to be analyzed and dissected during performance, all delight and enthusiasm
The chevalier Gluck, after returning to Vienna from Paris, and being rendered incapable of writing by a paralytic stroke in 1784, only lingered in a debilitated state till the autumn of 1787, when he died at the age of seventy-three.

Gluck had great merit as a bold, daring, nervous composer; and indeed, in his French operas, he was unrivalled. But he was not so universal as to be exclusively admired and praised at the expense of all other composers ancient and modern. His style was peculiarly conducive to France, where there were no good singers, and where no good singing was expected or underlived by the public in general; and where the poetry was set up against music, without allowing equality, or even an opportunity of manifesting her most captivating vocal powers.

It is, however, allowed by an exclusive admirer of Gluck, in the Encyclopaedia Meth., that "the Italians have the glory of having furnished examples of almost every kind of beauty of which music is susceptible, and of having disseminated their taste in every part of Europe;" but adds, that "France will owe to the celebrated Gluck the having first conceived the system of a music truly dramatic, and our theatre will furnish true models of it to other nations, and to posterity. Let us hasten to hail from the Italians and the Germans the glory of laying the true foundation of a musical system and of transforming the most amiable and touching of arts, into a science as interlacing as it is fertile."

Gluck, in a moment of frangible, over a bottle, said "the French are a very good sort of people, who love music, and want forg in their operas; but they have no fingers." And Sacchini, being asked how his operas were executed at Paris, said, "God forbid I should ever go to hear them performed!" And these are the people who are to furnish models of dramatic music to Italy, and to all the rest of Europe!

GLUCKSBURG, in Scania, a town of Denmark, with a fortress, in the duchy of Sleidw; nine miles E. of Flensburg.

GLUCKSTADT, a sea-port town of Germany, in the duchy of Holstein, belonging to Denmark, situated on the Elbe. This town is regular and well-built, and its market place commands the chief streets. Several canals run through it, and the principal one crofles near the market place, and is here connected with another, which divides the town into two nearly equal parts. On the land side it may be laid under water. Gluckstadt is the seat of the king's regency, and of the offices and courts connected with it. Here is also a grammar-school. The Calvinists are permitted to have a church, the Roman Catholics a chapel, and the Jews a synagogue. In 1738 a commercial college was instituted here by King Christian VI., as it was a place of trade; and in 1750, king Frederic V. established an office for keeping the harbour, adjoining to which is a basin for the reception of vessels, in good condition. Gluckstadt was built in 1692 by permission of Christian IV. in a walle called the Wildenefs, and in the patent granted to it, he ordered that it should be called Gluckstadt, or the Fortune Town; he also conferred upon it many customs, rights and privileges, such as were enjoyed by the town of Willem; and it was soon after invested with the Lubeck and Hamburg rights. It is distant 28 miles N.W. from Hamburg. N. lat. 53° 51', E. long. 9° 20'.

GLUE, GLUTEN, a viscid, tenacious matter, serving as a cement to bind or connect divers things together. There are divers kinds of glues made use of in the divers arts; as the common glue, globe glue, parchment glue: but the two last are more properly called false.

The common or strong glue is a commodity used by numerous kinds of artificers; as joiners, cabinet-makers, cafe-makers, hatters, book-binders, &c. and the consumption thereof is very considerable. The best is that made in England, in square pieces of a ruddy brown colour: Flanders glue, which is white and transparent, is held the next after the English. The most ordinary glue of France is black and opaque.

Glue is made of the skins of all kinds of beasts; as oxen, cows, calves, sheep, &c. The older the beast is, the better is the glue that is made of its hide. Indeed, it is rare they use whole skins for this purpose; these being capable of being applied to better purposes: but they make use of the flaving, parings, or scabs of the hides, and also horns; and sometimes they make it of the feet, sinews, nerves, &c. of heads; and also of the pelts obtained from furriers.

That made of whole skins is the best: and that of sinews, &c. the worst: and hence, chiefly, arises the difference of glue, and the advantage of English and Flemish glues.

GLUE, method of making.--Mr. Clowes, in the Monthly Magazine for 1822, gives the following extract of the general mode of its manufacture. The materials above enumerated are first digested in lime-water, to cleanse them from grease or dirt; they are then steeped in clean water with frequent stirring, and afterwards laid in a heap and the water pressed out. They are then boiled in a large brash cauldron with clean water, fumming off the dirt as it rises, and it is further cleansed by putting in, after the whole is dissolved, a little melted alum or lime finely powdered. The fumming is continued for some time, after which the mass is strained through badders, and suffered to settle, that the remaining impurities may subside. It is then poured gradually into the kettle again, and further evaporated by boiling and fumming, till it becomes of a clear dark brownish colour. When it is thought to be strong enough, it is poured into frames or moulds about six feet long, one broad, and two deep, where it gradually hardens as it cools, and is cut out when cold by a spade into square cakes. Each of these is placed in a sort of wooden box open in three divisions to the back; in this the glue, while yet soft, is cut into three pieces, by an instrument like a bow, with a brads wire for its string. The pieces are then taken out into the open air, and dried on a kind of coarse net-work, fastened in moveable frames four feet square, which are placed in rows in the glue maker's field. When perfectly dry and hard it is fit for sale. That is thought to be the best glue which retains considerably without melting by three or four days' immersion in cold water, and recovers its former dimensions and properties by drying. Glue that has got froth, or that looks thick and black, should be melted over again. To know good glue from bad glue, the purchaser should hold it between the eye and the light, and if it appears of a strong dark colour, and free from cloudy and black spots, the article is good. When glue is used by the carpenters, they break it and soak it for about 24 hours in cold water; and then melt the forged pieces, causing it to simmer for a quarter of an hour over a slow fire and frequently stirring it. When cooled it becomes a firm jelly, which may be cut by any instrument. It is merely warmed for use, and in this state spread over the surface of the wood with a flint brush. In an interval from one
one to three days the pieces of wood will be so perfectly cemented, that boards, thus adhering, will as readily break in any part as separate at the junction. Glued boards will not set in a freezing temperature; the stiffening being occasioned by the evaporation of the superfluous matter of the glue, which is prevented by a considerableness degree of cold.

GLUE, Res. See WAX.

Glu, rift, is a sort of glue made of the nervous and mucilaginous parts of a large fish, found chiefly in the Russian seas.

These parts, being boiled, bear a near resemblance to that worship matter found on the skin of cod-fish. When boiled to the consistency of a jelly, they spread it on a leaf of paper, and form it into cakes; in which state it is sent to us.

Glu is of considerable use in medicines, and divers others arts; where it is better known under the name of sedgeglue and ichthromen. See Isinglass.

A strong and fine glue may be prepared with sedgeglue and spirit of wine thus; steep the isinglass for twenty-four hours in spirit of wine or common brandy. When the menstruum has opened and mollified the isinglass, it must be gently boiled together, and kept stirring till they appear well mixed, and till a drop thereof, suffered to cool, presently turns to a strong jelly. Then strain it, while hot, through a clean linen cloth, into a vessel to be kept close stopped.

A gentle heat suffices to dissolve this glue into a transparent and almost colourless fluid, but very strong; so that pieces of wood, glued together with it, will separate elsewhere than in the parts joined. Boyle's Works abridg. vol. i. p. 130.

A strong compound glue may be made by infusing a mixture of common glue, in small pieces, with isinglass glue, in as much spirit of wine as will cover them, for about twenty-four hours; then melt the whole together, and add as much powdered chalk as will make it an opaque white.

A strong glue, that will retain moisture, may be obtained by dissolving gum lambardae and mastic, of each two ounces, in a pint of spirit of wine, and adding about an ounce of clear turpentine: then take equal parts of isinglass and parchment glue, and having pounded them into small pieces, pour the solution of the gums upon them, and melt the mixture in a covered vessel, with a heat less than that of boiling water; then strain the glue through a coarse linen cloth, and putting it again over the fire, add about an ounce of powdered glafs.

Or, a strong glue, that will retain water, may be made by adding half a pound of common isinglass glue to two quarts of skimmed milk, and evaporating the mixture, a due consistency.

A glue, that will hold against fire and water, may be made by mixing a handful of quick-lime, with four ounces of linseed oil, boiling them to a good thickkness, and spreading the mixture on tin plates in the shade: it will thus become exceeding hard, but will easily be dissolved over a fire, and be fit for use. See CEMENT.

GLUMA, a Buffy, in Botany, is the peculiar calyx of graffes and graff-like plants, and indeed their corolla, at least what is so termed by Linnaeus, is of the fame chaffy nature. Hulks or Glumes are usually comprized, embracing each other at the base: more rarely they are depressed, flattened vertically, as in Quaking-grafts or Briza. To the hulk belongs the arija or awn, (see ARISTA) which is a bristle-shaped appendage, usually spiral, and possessing the properties of an hygrometer. It originiates from the midrib or keel of the hulk, and is either terminal or dorsal, being in the latter case placed sometimes very far down the back of the hulk, in many species of Arvena, and in these instances it belongs to the glumes that constitute the corolla, not the calyx. The arija, though so remarkable, is by no means always confluent in the same species, though nearly invariably so in the flowers of the same individual plant.

Hulks are mostly furnished with one central longitudinal rib, though the inner glume of the corolla in graffes have two nearly marginal ones. They have in most instances, besides the central rib, a greater or lesser number of lateral ones, all likewise longitudinal, of great use in distinguishing species of Poa and other difficult generas. Their margin is commonly thin and more or less membranous or fragile. Some glumes always remain separate and distinct from the leaf which they commonly enfold; others are closely incorporated with that part as it ripens, of which a curious example may be seen in Briza.

Some sorts of viviparous graffes exemplify the transformation of glumes into leaves in a remarkable manner, the same remaining at the summit being perhaps the only indication of their original nature. See Aro Luscenta, Eng. Bot. t. 2102. The same metamorphosis of a petal into a leaf is indeed not rarely seen in a Tulip and other cultivated flowers. We have a wild specimine of a similar change in the Arenaria alpina, part of whose leafy involucrum is become a perfect petal.

Glumes are, we believe, invariably permanent, never deciduous, till the seed ripens, when those of the corolla fall off among with the seed, serving the purpose of a pericarpium.

GLUMACEOUS Flowers, a term applied by botanists to the flowers of the natural order of graffes, expressive of their chaffy nature.

GLUMMEN, in Geography, a town of Prussia, in the province of Natangen; 24 miles S. of Konigberg.

GLURANTZ, or GLUS, a town of the county of Tyrol, situated on the river Adige, built in 1562, and surrounded with walls in 1550. It was taken by the French in 1799; 36 miles W. of Brixen. N. lat. 46° 38'. E. long. 10° 26'.

GLUS, in Surgery, a species of dyuria, attended with a copious quantity of mucus in the bladder. Hence, the ma-

GLUT, among Falkmers, the fliny substance that lies in a hawk's pouch.

GLUT, in Rural Economy, a term sometimes provincially applied to a large wooden wedge.

GLUTA, in Botany, so called by Linnaeus, from the Latin word glatus, thrith close together, in allusion to the close application of the claws of the petals to the stalk which elevates the organs of fructification. Professor Martyn seems not to have been aware of this derivation. We are led to it by the repeated indication of the circumstance in Linnaeus, and his use of the word adflablatina, even in the generic character, as well as in his subsequent observations. Lin. Mant. 2. 160. Syll. Veg. Ed. 14. 821. Schreb. 146. Willd. Sp. Pl. v. 1. 1120. Mart. Mill. Dict. v. 2. Jussi. 427. Glaf and order, Pentandria Moneypia. (Linnaeus refers it to Gynandra Pentandria.) Nat. Ord. Capparidae. Juff.?

Gen. Ch. Cal. Perianth inferior, of one leaf. Membranous, bell-shaped, obtuse at the base, with a crown half way down into two lobes, deciduous. Cor. Petals five, equal, lanceolate, bluntish, somewhat oblique, four times the length of the calyx; their upper part spreading horizontally; their claws cohering round the flake of the germen, and attached to it. Stam. Filaments five, bell-shaped, rather shorter than the petals, inserted into the summit of the flake of the germen; anthers versatile, rather oblong. Pyt German, obovat.
G L U

Globate, standing on a cylindrical stalk, which is rather longer than the calyx; style thread-shaped, equal to the filaments; stigma simple, obtuse. Peric. and Secos unknown.

Eff. Ch. Calyx bell-shaped, cloven, deciduous. Petals five; their claws cohering round the stalk of the germen. Stamens inserted into the top of that stalk, below the germen.

1. G. Benghæs. Linn. Mant. 2. 293. Native of Java, where it is called Benghæs, and, if we mistake not, in the Malay language Dodec. This plant is unknown to all botanists except Linnaeus, by whose herbarium alone it can be determined. His remarks have led the students of natural orders wide of the truth concerning it, for nothing can be more unlike Puffflora. To Sterculia it has some resemblance, and we have been much inclined to refer it to Jullien's Malvocea, especially from its likeness in some respects to the Aflonia of that author and of Cavanneills; but on examination this likeness proves fallacious. The most probable place for it is amongst or near the Capparidáceae, but the fruit being unknown, leaves this matter in great doubt. After all, it may be thought to belong to some new order, which the students of natural arrangement are but too prone to make on every emergency, and the French in particular fond to think they threw their skill by their refinements on this head; whereas it is but an easier fault, though a more fatal one, than that of making too many genera, and ought to be watched with tenfold care.

The Gluta Benghæs appears to be a shrub or tree, with slightly pubescent branches and buds. Leaves scattered, most numerous about the ends of the branches, from three to ten inches long, elliptico-lanceolate, bluish, entire, tapering down at the base into a short footstalk; they are smooth on both sides, furnished with one rib and many transverse veins connected by innumerable reticulations. Stipulas none. Flowers nearly the size of Clamatis Flammula, or, as Linnaeus says, of a cabbage blossom, in a corymbose panicle; whether terminal or axillary cannot be determined from the specimen, though he affirms the former. There is some appearance of a glandular depression at the back of the footstalk where it joins the leaf. S.

GLUTEA, Arteria, in Anatomy, a large artery distributed chiefly among the glutei muscles. See Artery.

GLUTEN, Animal, in Chemistry. See Animal Fibre and Blood.

GLUTEN, Vegetable, a substance resembling the former, and found in several vegetables. (See Vegetable Fibre.) Beccari first found that wheat-flour contained gluten in considerable quantity, and from this it is obtained by the following process. (Aikin's Dict.) "Moisten any quantity of wheat-flour with a little water, and knead it with the hand into a tough dough-like paste, then let a very flender stream of water keep dropping on the paste, while it is incessantly worked about with the hands, and the water will run off white and turbid, owing to the feacula or flour which it carries off. The paste in the mean time gradually becomes more of a grey and almost semi-transparent appearance; and when the water runs off quite clear, nothing is left in the hands but pure gluten. No other precaution is required in this preparation but that of not drenching the flour at first with water, but only using a very small quantity with much kneading, that the gluten may not be carried off along with the flour. Good wheat-flour will yield in this way about a fourth of its weight of gluten, and no other flour but that of wheat will yield it, except in a very small proportion, and hence probably the peculiar property of wheat-flour to make bread without any other addition than a ferment." See Bread.

Gluten is contained in small quantity in several vegetable juices and other parts, and may be separated from them. Bird-lime is supposed to be chiefly gluten, and the greenfocus of plants abounds with it. See Bird-lime and Fecula.

GLUTEUS, in Anatomy, a name given to three large muscles, concerned in the motions of the pelvis and thigh, and distinguished from each other by the epithets magnus, medius, and minor. They occupy the outer and posterior part of the pelvis, from which they arise, and form the large fibrous prominences named the buttocks.

The glutæus magnus, or maximus, is grand fossier, illiac-faco-femoral, is a very broad, thick, and bulky muscle, composed of large fasiculi loosely connected together, and separated to a considerable depth by adipose and cellular substance, of an irregularly quadrilateral figure, and situated obliquely at the outer and back part of the hip. The rounded felling, which forms the outline of the buttock at its back-part, and the projection of which hides the termination of the large ilio-femur, is formed entirely by this muscle. Its external surface has the same degree of convexity as that of the buttock; the internal, which covers the tuberosity of the ischium, and the great trochanter, is proportionally concave. It arises, 1st. By short aponeurotic fibres, from about one inch of the posterior extremity of the crista ili, where the bone extends beyond the facrum, and from the neighbouring part of the immediately subjacent notch. At this origin an aponeurosis may be observed, continuous with that of the thigh, and of the vertebral muscles. 2dly. From the ligament connecting the posterior end of the iliac crista, to the back of the facrum; and here it is continuous with the tendinous origin of the latilius dorsi, longilius dorsi, and facro-lumbialis. 3dly. From the external margin of the facrum, near its lint foramen, from the tubercle at the side of the termination of the canal containing the medulla spinales, and from the articulation between the facrum and coccyx. 4thly. From the posterior surface of the coccyx. 5thly. From the surface of the great facro-facieous ligament. From these points the fibres all proceed obliquely downwards and outwards, nearly parallel to each other; the muscle is at first rather thinner and narrower, and grows broader and thicker as it proceeds. Its upper margin is closely attached to that part of the femoral facia which covers the glutæus medius. The superior fibres, having turned over the great trochanter, join the upper part of the common tendon. The latter is most intimately connected to the facia lata, so that, on the first inspection, the glutæus magnus appears to be inserted into this facia, throughout the whole line of its front edge; we cannot, however, easily distinguish these parts by cutting through the muscle, and turning it aside. The common tendon receives the muscular fibres from above the trochanter, to below the quadratus femoris, where it begins to be attached to the bone. It is very firmly attached to the rough line, which commences at the root of the trochanter, and joins the linea aspera, occupying by its insertion a space of about three inches; it is situated here between the vastus externus and adductor magnus, to the former of which it is connected by tendinous and muscular fibres.

The exterior convex surface of this muscle is covered for a small space towards its upper part by a thin plate of the facia lata, and is every where else immediately subjacent to the integuments. The inner surface covers the ossinnationum, the facrum and coccyx, the origin of the vertebral muscles, the glutæus medius, the pyramidales, the gemini, the obturator internus, the quadratus femoris, the tuberocity of the
the ribs, the origins of the semitendinosus and biceps, the adductor magnus, the sciatic nerve, and the great trochanter. A large synovial membrane, placed between this muscle and the fact-named eminentia, favours their reciprocal motions. The cavity does not in general contain much fluid; and it sometimes shows internal folds.

The gluteus medius, le moyen felleur, illo-trochanterian, is a thick and broad muscle, flattened and triangular, partly covered by the preceding, but placed more at the side of the pelvis. It arises by very short aponeurotic fibres from the external surface of the os innominatum, immediately under the crista ili. running forwards to the front as far as the anterior superior spine, and backwards to the facro-sciatic notch: downwards it is bounded by the curved line, which marks the circumference of the gluteus minimus. Another origin of this muscle is from the facia lata, where that aponeurosis is fixed to the crista ili, and where it separates this muscle from the tenor vaginae. From this double origin the fibres all take their course: downwards, the anterior or shortest being at the same time directed obliquely backwards; the middle, which are longer, passing perpendicularly, and the posterior or longest, coming obliquely forwards. In this way they all converge to meet in a broad aponeurosis in the radiate fibres, beginning in the substance of the muscle, higher behind than before, and defending, as it receives the musculi fibres successively, to the great trochanter, to be fixed to the upper and anterior part of that eminence. Many of the anterior fibres are mixed with those of the gluteus minor; so that the two cannot be completely separated without dividing some of the muscular substance.

Its external surface is covered behind by the gluteus magnus, in front by the facia lata. The inner surface covers the gluteus minor, the gluteal artery, and the surface of the bone. Its front edge is in contact with the tenor vaginae; the posterior with the pyramidalis.

Gluteus minor, or minimus, le petit felleur, ilio-sciatic-trochanterian. This is the smallest of the three glutei, and covers the os innominatum by its whole inner surface, being equally covered on the outside by the preceding muscle. It is thick and flattened, and has a triangular figure. It arises from the surface of the os innominatum by very short aponeurotic fibres; beginning at the anterior superior spine, and following a curvilinear line, which extends from the latter proceeds to the facro-sciatic notch. From this line, of which the convexity is turned upwards, it covers the bone as far as the edge of the acetabulum. These musculi fibres all descend in a converging manner; the middle taking a perpendicular course, while the anterior are directed backwards, and the posterior forwards. They are all implanted in a broad radiated aponeurosis, which lies on the external surface of the muscle, except towards the front, where it is covered by a few fibres of the preceding muscle. This aponeurosis, as it descends, forms a strong tendon implanted immediately within the former, in the upper and anterior portion of the great trochanter. It has some connection to the capsular ligament of the hip; and a small synovial membrane is interposed between it and the trochanter. It is covered by the gluteus medius, and very slightly by the pyramidalis; it lies on the bone, on the capsular ligament of the hip, and the origin of the rectus cruris.

Actions produced by the glutaei. — The muscles, which we have just described, move the thigh and pelvis reciprocally on each other. Their action on the pelvis may be observed both in standing and walking. When we support the trunk in the erect attitude on both feet, the glutei magni fix the pelvis firmly behind, and counteract that tendency which the body naturally has to fall forwards. Hence the bulk and power of these very muscles in the human subject afford a clear proof that man was designed for the attitude on two feet; this gives to the human frame the buttocks, which are seen in no other animal, because man is the only biped among the mammalia. In the case now under consideration the glutaei magni are assisted by the femi-tendinosi, femi-semimembranosus, and biceps; and antagonized by the psoas and ilacus, which perform a force much inferior to that which opposes them behind, because they are aided by the weight of the trunk. When the pelvis has been bent forwards, the glutaei magni will rest it, and if the circumstances admitted of this part being carried backwards, the same muscle would produce that motion. The other two glutaei are not effectually concerned in the attitude of leaning on both feet, but they are the principal agents in supporting and balancing the trunk on one foot, by inclining the pelvis over the head of that thigh bone on which the body rests, so that the centre of gravity of the trunk may be in a line drawn through that lower extremity. In this case their exertion counteracts the tendency of the trunk to fall on that side which is not supported. These muscles are further employed in the same kind of way in procreation: the glutaeus magnus balances the pelvis while one leg is carried before the other, and brought to the ground; and the two others support the trunk laterally, while the limb of the opposite side is in the air. In the attitude one leg, the glutaeus magnus can rotate the pelvis on the thigh bone of its own side, so as to turn the lymphatics pubis towards the opposite side. When the glutaei move the thigh on the pelvis, the magnus restores the bone to its former position, where it had been previously bent; and, if the pelvis be carried forwards, it may move the former still farther in the direction of extension; the medius and femi-medius move the thigh away from the opposite limb. The glutaei magni has the effect also of rotating the thigh outwards; while the anterior fibres of the two smaller muscles will rotate it inwards. The former is a tenor of the facia lata.

GLUTTON, in Zooncity. See URUS Gaul.

GLYCAS, Michael, in Biography, a Greek historian, who is supposed to have flourished in the 12th or 13th century, though by some others he is referred to the 15th. He was a native of Byzantium, and spent a great part of his life in the island of Sicily. He is principally known by his "Annales," in four parts, containing the history of the world, from the creation to the birth of Christ, and that of the Byzantine emperors down to the death of Alexius Comnenus in 1118, interspersed with a number of theological, philosophical, and physical discourses. An edition of the "Annales" in Greek and Latin was given to the public by father Labbe, in 1660. The third part has been published separately by Meurinus, with a version and scholia. Several letters of Glycas have been published in different collections. He was undoubtedly a very learned man, and the correspondance which he maintained with the literati of his age shew that he stood in very high reputation. Moreri.

GLYCERIA, in Botany, from γυετις, fluid, the seeds being eaten in Germany, and called Mannseeds, on account of their sweet taste. Brown Prod. Nov. Holl. v. 1. 179. — Claws and order, Triandra. Gynae. Nat. Ord. Gramma. This new genus of grasses is founded by Mr. Brown on the Novi-glauses of Linnaeus, Post glauces, Sm. Pl. Brit. 95, with the following characters.

Glene (Calyx) of two valves, containing many flowers. Spiket cylindrical, awnless. Perianth (Corolla) headless, its valves of equal length. Scale under the germin solitary, fetid, like a half fluid. Stigmas double compound. Seed uncon-
unconnected, oblong, with a furrow at one side. Flowers somewhat panicked.

We cannot but apply to the property of separating the graviola from the flowers, as far as habit is concerned, but we are very certain that *Pseudiscus*, *maritimus*, *punctatus*, and *Rosa Brit. and Ceylonensis* of Linnaeus cannot fail to go along with it, though we fear the characters given by the vagabond writer above quoted will not be held to hold good in all, if any, of these. Perhaps the following definition of *Glycine*, formed on simple and obvious Linnaean principles, may be unexceptionable, as embracing them all, and preferring an analogy with genera already established.

Glycine, from *triplus*, *tour*, the particular application of which is not very obvious, having originated merely from the sweet taste noticed by Cornuti in the leaves and tuberous roots of *G. Apios*. This indeed is the original, and perhaps the only true *Glycine*, the numerous affinities of species ranged under this genus, by recent writers, being very anomalous in fructification, especially those of New Holland, as will appear by Mr. Brown's definitions when the second part of his valuable work appears.—Linn. Gen. 374. Schreb. 495. Willd. Sp. Pl. v. 3. 1553. Mart. Mill. Dict. v. 2. Att. Hort. Kew. v. 3. 34. Juss. 357. Lamarck Illutr. t. 699. Garto. t. 154. Chas. and order, *Diosphyllum Decandria*. Nat. Ord. *Papilionaceae*, Linn. *Leguminosae*, Juss.

Gen. Ch. *Cal*. Perianth inferior, of one leaf, compreßed, two-angled; upper lip notched, obtuse; lower longer, three-angled, acute; its middle tooth longest. Cor. papilionaceous. Standard incurve heart-shaped, dilated at the apex, gibbous at the back, emarginate at the top, and straight, till driven back by the keel. Wings small, oblong, ovate towards the extremity, bent downwards. Keel linear, falcate, curved upwards, precluding the standard upward by its obtuse and dilated extremity, *Stam. Filaments in two sets, (one simple, the other in nine divisions,) slightly separated at the top, revolute; anthers simple, *Pist.* Gernon-aped, style cylindrical, rolled spirally; stigma obtuse. *Peric. Legume oblong. Seeds kidney-shaped.*

Eff. Ch. Calyx two-angled. Stamens in distinct sets. Keel of the corolla forcing back the standard with its point.

Obs. *Glycine Apios* and *fruticosus* have a two-celled legume. *G. monocotis* is a singular instance of a separation of the sexes in flowers of this tribe.

This genus has accumulated from two species (*G. Apios* and *fruticosus*) in the Hortus Cliffortianus, nine in the second, fifteen in the fourteenth, and last edition of *Systema Vegetabilium*, and finally to forty-four in Willdenow. These now form a very heterogeneous affinities, and the New Holland ones constitute a distinct genus, the *Kamunda de Ventenat*, distinguished by its spontaneously reflexed standard, and legume of many cells. The whole requires a thorough revision. Some are of opinion that *G. Apios* is generically distinct from all the others, and if so, it should be most convenient, though this is one of the original species, to give it the generic name of *Apios*, retaining *Glycine* for such more common and more numerous ones as may answer to the usual idea of the genus, an essential character being selected to combine them together.

*Glycine*, in *Gardening*, contains plants of the shrubby climbing kind; of which the species cultivated are the

GLYCINE.

Suspended and exposed by an extent of surface to the action of the alkalies. If the treatment described is properly conducted, the fused mass, when softened with water, will be entirely dissolved by muriatic acid, and while it is being distilled, the muriatic solution thus procured must be evaporated in a still. A large quantity of water will dissolve the soluble salts, and leave the principal part of the fixed, which is to be separated and well washed on a filter. The filtered solution is to be precipitated by carbont of potash. The precipitate, consisting principally of alum, is to be dissolved in dilute sulphuric, and precipitated to the proper conclusion to afford crystals of alun. If the precipitate produced by carbont of potash has been well washed, it is necessary to add a little potash to the sulphuric solution. When the solution, on a second or third evaporation, and addition of potash, ceases to yield any more crystals of alun, the mother liquor is to be mixed with a solution of carbont of ammonia, greatly exceeding the quantity necessary to saturate the acid, and to be transferred to a bottle having a ground flintle: the mixture is to be well agitated, and carbont of ammonia is to be added till the precipitate which first appears is redissolved, or no longer diminished by fresh portions of the carbont of alum. The solution of the triple compound of glycine carbonic acid and ammonia is to be filtered in order to separate the small remaining quantity of alumine, and then boiled till the vapour cæases to change the colour of turmeric paper, or till it no longer has a ammoniacal smell; when all the carbont of ammonia being drive off, the whole of the glycine will be found precipitated in the form of a white granular powder, combined with carbonic acid. This powder is to be washed in a filter, till the water ceases to afford a precipitate with muriatic barytes and lime-water; it is then to be dried, and heated to redness: by this means, the water and carbonic acid, amounting to about half the weight of the whole, will be expelled, and the glycine, if it does not effervesc with acids, will be left in a perfectly pure state.

Glycine thus procured, is a snow-white powder, soft and somewhat unctuous between the fingers, very adhesive to the tongue, and deliquescent both of smell and taste. Its specific gravity is 2.976. It produces no change in the colour of vegetable blues. Neither oxygen nor nitrogen has any action on it, nor does it suffer any change by exposure to the atmosphere; as carbonic acid and moisture do not appear to be absorbed by it. It forms, with a small quantity of water, a slightly dulce paste, that possesss much less tenacity than that of alumine. Glycine has not yet been fused; it neither contracts nor hardens when heated, nor is it altered by exposure to the most intense fire. With borax it forms a white transparent glass, which does not become opaque on cooling. It refutes to combine directly with sulphur or phosphorus, but it appears from Fourcroy that a fulphat may be formed by decomposing the fulphat of glycine by charcoal. Glycine is soluble in a saturated solution of fulphurat hydrogen. A hydro-sulphat of this earth, it is likewise said, may be obtained by dissolving the fulphat in water. In these properties it approaches the alkaline earths, and constitutes apparently the link of union between them and the clafs to which it belongs. It is dissolved by both the fixed alkalies in their liquid state, but in a less degree than alumine, and, like alumine, is not taken up by ammonia. It is dissolved in a solution of carbont of ammonia, as has already been mentioned. It very readily unites with acids. All its soluble salts produce, when first titrated, the sensation of sweetness, which gradually becomes astringent.

In relation to its affinity for acids, glycine appears to be intermediate between alumine and magnesia, for it decomposes only the salts of alumine, yttria, and zirconium. And the order of its affinities is much the same, according to Fourcroy, as that of the other earths, sulphuric acid holding the first place, antimonious, muriatic, phosphoric, fluoric, boric, and carbonic following. No experiments have been undertaken yet, to ascertain what combinations glycine is capable of forming with the earths and metallic oxydes.

Yttria and alumine are the only earths for which glycine is liable to be mistaken: the properties in which it resembles them are, rather unfortunately, of a most striking kind, but it has a number of other characters which are very distinct, and fully demonstrative of its peculiar nature. Glycine is similar to alumine, in being soluble in caustic solutions of the fixed alkalies, and in some of its physical qualities; but it differs from alumine in affording with acids sweet astringent salts in not yielding alum with sulphuric acid and potash; in possessing a greater affinity for acids; in being entirely soluble in carbont of ammonia; and lastly, in not being precipitated from its solutions by oxalate, tartrate, or prussiate of potash. It is to be distinguished from yttria, by its greater solubility in carbont of ammonia, the latter requiring for its solution five times as much carbonated alkali as glycine, by its salts occasioning a precipitate, when added to any of the succinates, by the insolubility of yttria in fixed alkaline solutions, and by the precipitate which the salts of yttria afford with prussiate of potash.

Glycine was considered as a simple body till the important discoveries of Mr. Davy gave rise to new analogies; and though the compound nature of this earth is not yet fully demonstrated, yet there is every reason to believe that glycine, like the alkalies and alkaline earths, is a metallic oxide; and the results of the experiments which Mr. Davy made on this body are explained both on such a supposition. This gentleman negatively electrified glycine, slightly moistened in contact with an amalgam of potassium, under naphtha, by a battery of 500 plates. After an hour the amalgam was thrown into water, and an alkaline solution was produced, which became cloudy when neutralized by acid, thus indicating the presence of the earth. Mr. Davy, following the nomenclature which he has adopted in respect to the new metals, has proposed glucine for the name of the metal of glycine, when its existence is no longer doubtful.

Carbonat of glycine, as well as all the other salts of this earth, has not yet been discovered ready formed in nature. It is procured by precipitating the sulphat, nitrat, or muriat of glycine, by either of the carbonated fixed alkalies. The precipitate, which is the salt fought after, being well washed and dried, appears in the form of soft white powder, having a greasy feel and great lightness. Carbonat of glycine is insoluble in water, and it is unaltered by exposure to the air. It is decomposed by all the acids; and by the action of a red heat: moli probably all the alkaline earths deprive it of carbonic acid in the moist way. According to Klaproth it is composed of

| Glycine | 53 |
| Carbonic acid and water | 47 |

Phosphat of Glycine.—Phosphat of soda, added to a neutral solution of nitrat of glycine, throws down this salt either in a white pelluculent form, or in a mucilaginous state. It is insoluble in water, inpho and uneryllizable. It is not decomposed by a violent heat, but it fuses into a white transparent glass, that does not become opaque on cooling. Phosphat of glycine is soluble in phosphoric acid. The sulphuric and nitric acids first dissolve this kalt, and
and afterwards decompose it. Muratic acid produces a
similar effect, but in a less degree. It is likewise readily
decomposed by the carbonated alkalies and by all the car-
bonated earths, except carbonat of magnesia. With the sul-
phat, nitrat, and muriat of alumine, it suffers decomposi-
tion, a mutual exchange of acids taking place between the
two earths.

**Sulphat of Glycine.**—Glycine, both in its pure and car-
bonated state, dissolves very readily in dilute sulphuric acid.
The solution by spontaneous evaporation affords octahedral crys-
tals, composed of two oblique four-sided pyramids joined base to base, with their edges and solid angles trun-
cated. It also, but with difficulty, yields when evaporated on
a sand bath small needle-form crystals. The solution, when evaporated nearly to dryness, assumes a fyruppy con-
finence. Sulphat of glycine, has a remarkable sweet and astringent taste. It is very soluble in water. Heated,
it intumesces, suffers the watery fusion, and becomes pul-
vorous when it leaves of its water. It is completely de-
composed by a strong red heat, the acid being expelled and
the earth left in its pure state. It has been already ob-
erved that sulphat of glycine is converted, when heated with
charcoal, into a sulphuret; but this sulphuret, according to
Fourcroy, does not become a pyrophorus, like alum
thus treated, though sulphat of potash be present. A solu-
tion of nut-galls, added to this salt dissolved in water, pro-
duces immediately a white precipitate. Previous to the
knowledge of this fact, such a property was conceived to
be peculiar to metallic salts.

Sulphat of glycine, slowly evaporated with a small
quantity of sulphat of potash, forms minute crys-
talline grains, which divide with ease in seven or eight times
their weight of cold water. Glycine, added to a solu-
tion of alum, precipitates the alumine, and most probably pro-
duces a compound, similar to the preceding one. Sulphat of
glycine is decomposed by all the alkalies and earths, ex-
cepting alumine, yttria, zircon, and felines.

**Nitrat of glycine** is procured by faturating nitric acid
with glycine. The solution of this salt does not afford crys-
talline by evaporation, but produces a duftile and adhesive
mafs, which, when further dried, falls into powder. It
is very soluble in water and deliquescent in the air. It attrac-
ts moisture strongly, that it might, if easily procured, be ad-
antageously employed for abhorbing the hygrometrical
water of gases. Its taste is saccharine and astringent.
Tincture of galls dropped into a solution of this salt pro-
duces a yellowish brown precipitate. Nitrat of glycine
fuses at a low heat, but if the heat is increased, the acid is
expelled. It is decomposed in the moist way by sulphuric acid,
and by the same alkalies and earths as the sulphat.

The proportions of its component parts are not known; but
Vauquelin has observed that a given quantity of nitric acid
requires rather more glycine than alumine for its complete
furation; yet the former earth, though in combination with
nitric acid more soluble than the latter, decomposes with
the affilience of heat, nitrat of alumine, precipitating the
alumine, and forming nitrat of glycine.

**Muriat of glycine** is procured by dissolving glycine in
muratic acid. It is in some respects similar to the nitrat,
but differs in its solution, according to careful management
small crystals, the form of which, on account of their fine,
have not yet been determined; and in not being subject to
deliquescence on exposure to the atmosphere. Its taste is
similar. A solution of this salt in dilute alcohol is said to
be an agreeable sweet liquid. When distilled per fl, the
acid flies off, and leaves the earth in a flake of purity. It
is also decomposed when heated with phosphoric acid. The
fame effect is produced by sulphuric and nitric acids, and
by the alkalies, and by all the earths that decompose the nitrat.

**Acetat of glycine,** which is prepared by dissolving
the earth in acetic acid, has not yet been procured in a crys-
talline form. Its solution, when evaporated, acquires a glutinous
confidence, and the salt becomes brittle as it flowly

dries.

**Succinat of Glycine.**—Any of the succinates added to
the nitrat, muriat, or sulphat of glycine, precipitate the salt in question. Its properties have not yet been enquired
into.

We are indebted for the imperfect knowledge we have of the
combinations of glycine, with the several acids above-men-
tioned, principally to the celebrated discoverer of this earth.
Glycine, in no form as yet, has been usefully employed; yet
Vauquelin conceives that the earth itself and some of its
salts, when they can be procured with facility, may admit
of such an application in chemistry, in medicine, and the
arts. Its marked attraction for animal and vegetable col-
ouring substances induced him to think that there was
a probability of its being serviceable as a mordant; and
the peculiar taste of some of its salts gave rise to the hope
that these combinations might produce salutary effects on
the animal fytem. If his expectations should be realized, we
must agree with Vauquelin, that these salts will be some of
the most agreeable medicines that exist. Ann. de Chem.
part. i. 1808. p. 352.

**GLYCONIAN, GLYCONUS.** in Greek and Latin
poetry.

A Glyconian verse is that consisting of two feet and a
yllable; at least this is Scaliger's opinion; who adds, that
the Glyconian verse was also called the Euripidean verse.
See VERSE.

Others hold, that the Glyconian verse consist of three
feet, a spondee and two dactyls; or rather a spondee, cho-
riambus, and an iambus or pyrrhic: which opinion is the
most followed.

"Sic te diva potens Cypris," is a Glyconian verse.

**GLYCOSRRHIZA, in Botany, Liquorice, Glycyrrhiza
of Dioscorides, who describes the plant very faithfully and
accurately; but it is remarkable that he lays the flower is
like a hyacinth which can allude to the colour only, whether
his χιονίς δές; be the Delphinium or Hybridius of modern
botanists. The word is composed of γλυκός, sweet, and χιος,
a root; and the name in apothecaries' Latin, liquiritia,

as well as the English one, liquorice, the French 
 OVERRIDE, the Italian regolada, &c. with all their corruptions, originate
t. 215. Germn. t. 148.—Chas and order, Dianella Dem-

Gen. Ch. Col. Perianthus inferior, of one leaf, tubular,
two-hipped, permanent; upper lip in three deep segments,
of which the lateral ones are linear, the central one broad-
cle and cloven; lower perfectly simple, linear. Cor.
papillosous. Standard ovato-lanceolate, bright, longoval. 
Wings oblong, very like the keel, but rather larger. Keel of
two petals, acute, its claw the length of the calyx. Stam.
Fila-
ments in two feet, (one simple, the other in nine divisions).
Flag. German shorter than the calyx; style awl-shaped, as long as the flaments;
 stigma obtuse, ascending. Petio. Legume ovate or oblong,
compressed, acute, of one cell. Seed very few, kidney-
haped.
GLYCYRRHIZA.

Eff. Ch. Calyx with two lips; the upper three-crested; lower simple. Stamens in different sets. Legume ovate, compressed, of one cell. Seeds one or two.

1. G. ellenbana. Linn. Sp. Pl. 1045. "Native of Italy, as well as of Tartary and the confines of China; also abundantly, according to Dr. Sibthorpe, on the sandy shores of Crete, Samos, and Greek islands, where it still retains its ancient name unchanged. The long plant perennial roots, deeply defending into the ground in a favourable soil, are cultivated for their sweet taste and pectoral virtues, and are sufficiently well known. The stems are two or three feet high, nearly simple, leafy, round and fruticated. Leaves of several pair of equal, elliptical, entire, acute leaves, the odd one on a little stalk only like the rest, not on an elongation of the main stalk. Stipulas lanceolate, acute. Flowers several, in axillary, solitary, flattened heads; their colour a dull purple. Legumes clothed, in their upper part especially, with numerous long rigid prickles, resembling the fruit of Xanthium strumarium. Dioecious differs them to that of the Plane-tree. The whole herb is delicate of substance, but somewhat clammy to the touch.

2. G. fetida. Desfont. Atlant. v. 2. 170. t. 159.—Legumes prickly. Flowers spiked. Stipulas lanceolate. Leaflets sessile beneath; the terminal one nearly so. Found by Derfontaine on mount Atlas, and in cultivated fields near Maimene in Africa. We have it from Aixfar. Whole plant extremely fragrant. Leaves much like the leaf in size and shape, but the flowers are pale yellow, in long spikes. Legumes crowned with the permanent style, which is longer in this than in the former. The film as well as both sides of the leaves, is besprinkled with minute scales.

5. G. gurneana. Linn. Suppl. 330. Pallas. Reis. v. 3. t. G. g. 1. t. 1. 2. (G. labrida; ibid. 754.)—Legumes smooth, beaded. Flowers spiked. Stipulas lanceolate. Leaflets rounded, prickly beneath. Stem and stalks prickly.—Found by professor Pallas in sandy ground between the river Wolga and the Taman. Pallas MSS. The root is extremely sweet, especially in the spring. Stems usually two, rarely three, ascending, a fain high, nearly square, leafy, rough with numerous little rigid prominent prickles, as are the isoetals, and backs of the isofets. The latter are roundish or ovalish, obtuse with a little point, from and very above. Flowers longish, pale violet, with whitish wings and keel, in one or two thicks spikes about the top of each stem. The isofets are drawn by Pallas above an inch long, recurved, of a necklace-like form, and smooth, containing many seeds. The calyx is oblong, purplish, rather hairy. It has the habit of a Glycyrhriza, flowers of an Ageratum, and fruit apparently of a Coriandrum; nor does the calyx answer to the generic character, being five-crested.

6. G. leucophaea. Linn. Sp. Pl. 1054. (G. orientalis, filisquis lariscifolius; Tourn. Cor 26.)—Legumes hairy. Leaves oblong-lanceolate, the terminal one on a long stalk. Flowers spiked. Found by Tournefort in the Levant. Root perennial. Of this we have seen neither a specimen, nor any further description.

GLYCYRRHIZA, in Gendier, furnishes a plant of the herbaceous perennial kind, the common liquorice (G. glabra). It is a plant which has the roots running very deep into the ground, and creeping to a considerable distance, especially where they remain long unremoved.

Method of Culture.—A light sandy soil is the most adapted to the growth of this fort of crop, as its goodness consists in the length of the roots. The ground in which it is intended to be planted should be well dug and trenched the year before planting, that it may have become perfectly mellow, and the dung well rotted, and mixed with the earth; otherwise it will be apt to keep the roots from running down, and being properly supported, and immediately before planting it should be well dug again to the depth of three fingers, and be laid very light and open.

When the land is thus prepared, fresh plants taken from the sides or heads of the old roots should be provided, care being taken that they have each a good bud or eye, being about ten inches long and perfectly sound.

The operation of planting them should be performed about the middle of March, which is done in this manner: a line is first laid across the ground, then, with a long dibble made at purpose, the shoots or cuttings are put in, so that the whole plants may be set into the ground, with the heads about an inch under the surface, in a straight line about a foot asunder in the rows, and a foot and a half or two feet row from row.

When the whole spot of ground has been thus planted, a thin crop of shoots may be sown over the land. These must be kept perfectly clean by the hoe, care being taken not to cut off the top shoots of the liquorice plants, as it would greatly injure them. All the shoots which grow near the heads of the liquorice should also be removed. In October, the shoots of the liquorice should be removed, and a little very rotten dung spread upon the surface.

In the following spring, about March, the ground should be slightly dug between the rows of liquorice, burying the remaining part of the dung, being very careful not to cut the roots.

During the summer they must be kept quite clean by occasional hoeing. The face operations must be annually performed, so as to keep the ground and plants in perfect order.

These plants will remain three years from the time of planting, when they will be fit to take up for use, which should be done when the shoots are perfectly decayed; as, when taken up too soon, the roots shrink greatly, and lose in weight.

In taking up the roots the ground is trenched over, row after row, to the full depth, and the young shoots taken from the old roots cut into sets for new plantations; which should be made annually, in order to keep a constant succession of roots fit for being taken up.

The great art in this culture is to have the earth well trenched to a proper depth, to have good sets, and to keep

Vol. XVI.
the ground afterwards quite clean by hoeing and other proper means.

The liquorice is a native of the south of Europe, but it has been cultivated in Britain ever since the time of Turner. (See Tourn. Herb. p. 2. fol. 12. published in 1562.) The chief places in which it has been long propagated for sale are, Pontefract, in Yorkshire; Workhop, in Nottinghamshire; and Godalming, in Surrey; but it is now planted by many gardeners in the vicinity of London, who supply the metropolis with the roots.

GLYCIRRhiza, in the Materia Medica. The root of the common liquorice, boiled slightly in a little water, gives out nearly all its sweetness. The decoction, pressed through a drainer, and infused with a gentle heat, till it will no longer stick to the fingers, affords a better extract than that brought from abroad, and particularly from Spain, whence our shops are chiefly supplied with it, and its quantity amounts to near half the weight of the root. The extract that is prepared here, is made by macerating, for four hours, liquorice root sliced, a pound, in a gallon of boiling water; then boiling down to four pints, skimming off the hot liquor, and evaporating it to a proper consistence. A purer extract may be made by a repetition of the process of solution and evaporation; and it is kept in the shops under the name of "refined liquorice." Rectified spirit takes up the sweet matter of the liquorice equally with water; and as it dissolves much less of the inebriating mucilaginous substance of the root, the spirituous infusions and extracts are proportionably sweeter than the water. This root contains a great quantity of saccharine matter, leaves disposed to run into fermentation than that of other vegetables, which is joined with some proportion of mucilage, and hence has a virulent sweet taste. From the time of Theophrastus it has been a received opinion that it very powerfully extinguishes thirst; accordingly it was named \textit{adiabatic}, and the root directed to be chewed in dropsies and other disorders where great thirst prevailed. If this fact be true, it is the more remarkable, as sweet substances in general have a contrary effect. Accordingly Dr. Cullen observes, that the sweet of liquorice, separated from the root, does not quench thirst more than other sweets: and he observes the error respecting it to this circumstance, that if a piece of the root is chewed till the whole of the sweetness is extracted, farther chewing brings out the acrid and bitterish matter, which stimulates the mouth and faints, so as to produce an excretion of fluid, and thereby takes off the thirst which the sweetnees had produced. Liquorice is in common use as a pectoral or emollient in catarrhal defluxions on the breast, coughs, hoarseness, &c. Infusions or extracts from it afford likewise very commodious vehicles for the exhibition of other medicines. Lewis's M.M. Cullen M.M. Woody, Med. Bot.

GLYMN, in Geography, a county in the lower district of Georgia, in the United States, bounded E. by the ocean, N. by Atlantic, which separates it from Liberty county, and S. by Camden county. It contains 1734 inhabitants, including 1052 slaves. Its chief town is Brunswick.

GLYPH, in Architecture or Sculpture, is any canal or cavity used as an ornament. The Greek word is \textit{πλυς}, which literally signifies growing, incising. Treba is properly a notch or indenture made in graving; or, more properly, it is the notch in the end of an arrow, in which the string goes.

GLYPHTIC ART, the art of engraving precious stones. See Gems.

GLYSTER. See GLYSTER.

GEMIN, JOHN GEORGE, in Biography, a physician and eminent botanist, was born at Tubingen on the 12th of August, 1709. He was distinguished by his diligence and early attainments at school, and at the age of fourteen was deemed ready for entrance upon the academical studies of his native place. In 1727, he took the degree of doctor of physic, and went to Peterburgh, whether some of his teachers had been invited. Here he gained many favours from Blumentoell, the director of the academy, and was so highly esteemed, that, in 1729, he was elected one of the members of the academy, and in 1731 was appointed professor of chemistry and natural history. In 1733, he was selected for the department of natural history, in a commissary formed by the Russian government, for the purpose of exploring the boundaries of Siberia; and set out on the 15th of August, with G. F. Muller, and Louis de L'isle de la Croyere, and a party of twenty-eight persons, consisting of draughtsmen, masons, hunters, land surveyors, and twelve soldiers, with a surgeon and drummer. In the month of February, 1741, Gmelin returned safe to Peterburgh, after having employed nine years and a half in this long and dangerous journey, which proved highly interesting to the sciences, and he returned the offices which he had before filled. In the year 1749, he entered upon a new professorship, to which he had been appointed, on the death of Baehmeiter, while on a visit to Tubingen. He died of a fever in May, 1755, in the forty-sixth year of his age. The works, which were the result of his travels through Siberia, obtained for him a considerable celebrity, especially his "Flora Siberica, seu Historia Plantarum Siberiarum," Peterburgh, 1747, 1749, in two parts, large 4to. with one hundred plates: the third and fourth parts were published by S. G. Gmelin. He also published his "Reise durch Sibirien," &c.; or Travels through Siberia between the Years 1733 and 1745, Göttingen, 1751, 1752, in four parts, 8vo. with plates. Gen. Biog.

GEMLIN, SAMUEL GOTTLIEB, son of Philip Frederick Gmelin, was born at Tubingen in 1743; where he obtained both his scholastic and academical education, and graduated M. D. in 1765. He gave early proofs of genius, and during his travels in France and Holland distinguished himself so much by his knowledge of natural history, that he was appointed professor in the Academy of Sciences at Peterburgh. Like the subject of the preceding article, he spent several years in travelling through the distant provinces of the Russian empire, for the purposes of scientific investigation; but ultimately with a less fortunate result. He was appointed, together with professor Guldenstadt, to explore the province of Afiacman, at the time that the transit of Venus over the sun's disk was expected, and set out in June, 1768. Having examined the countries on the western side of the Don, the Persian provinces on the south and south-west side of the Caspian sea, the banks of the Volga, and, lastly, the eastern side of the Caspian, so dangerous to travellers, he was recalled to Peterburgh. But when he had arrived within three days journey of Killar, a fortress on the Russian borders, he was seized by the chief of Chaitaks; who plundered him of all his property, treated him with great barbarity, and imprisoned him. The health of Gmelin suffered considerably at this time, and he laboured under a flux, brought on by improper food and the effects of climate; yet the barbarian chief intercepted the provisions sent to him from Killar. The emperors gave orders that he should be refuted by force; but this was rendered impossible at that time by the rebellion of Pugalchef; and Gmelin died in confinement, on the 27th of July.
July, 1774. His death was much regretted by Catherine II., who made a liberal provision for his widow.

His works are: "Historia Fucorum," printed at Petersburg in 1768, 4to.; a subject to which botanists had paid little attention before him. "Reichen nach Russland, &c." or, Travels through Russia, for the purpose of exploring the three kingdoms of nature. This work was published in separate parts, as follows:—Part I. Journey from St. Petersburg to Tcherkass, in the years 1768 and 1769. Petersburg 1771 with thirty-two plates. Part II. Journey from Tcherkass to Alfracan, from August 1769 to June 1770; ibid. 1774, with forty plates. Part III. Journey through the northern districts of Persia, from that period to April 1772; ibid. 1774, with fifty-one plates.—Part IV. edited after the author's death, by professor Pallias. Journey from Alfracan to Czarizyn: and also a second Persian Journey, 1772-74; ibid. 1786, with eighteen plates. The various and important information, contained in these publications, renders the imperfections of the style of this author of little moment. Gen. Biog.

Gmelina A., in Botany, received its name from Linnaeus, in honour of John George Gmelin, a native of Turbingen, professor of chemistry and natural history at Petersburg, who spent ten years in travelling through Siberia, at the expense of the Russian government, and whose Flora Siberica, in four vols., quarto, with plates, is a book of great reputation and merit. The first and second volumes were published in his lifetime; the third and fourth long after his death, which happened in 1755, at the age of 46. He took his arrangement from Van Royen. Hallay says the plates are unworthy of the beautiful drawings, which he himself had seen.—This genus also serves to commemorate four or five more botanists of the same family, especially Samuel Theophilus Gmelin, nephew of the former, and his successor in the professorship, who published a Historia Fucorum, with plates, in 1768, one of the most popular books on submarine botany, and which died in 1764, aged 31.

Gen. Ch. Cal. Peraianth very small, inferior, of one leaf, nearly globular, with four small unequal teeth, permanent. Cor. of one petal, ringent, inflated; its limb four-cleft; the upper segment large and vaulted; lower, and lateral ones, smaller, oblong, rounded, spreading. Stam. Filaments four; the two uppermost thicker and shorter; two lowermost curled upwards; anthers two-lobed; two of them sometimes smaller and simple. Pfl. German superior, roundish or obvate; style as long as the longer filament, attenuated; stigma acute. Peric. Drupa ovate, of one cell. Nut obvate, smooth, of three cells, the lowermost abortive. End. solitarious.

1. G. spicata. Linn. Sp. Pl. 873. Burm. Ind. v. 132. (Jambhato sylvestris parvifolia; Rumph. Anth. v. 1. 139. t. 40.)—Leaves roundish, somewhat three-lobed, acute, downy beneath.—Native of Java, Amboina, and other parts of the East Indies. A tree, with straight, roundish, slightly downy branches. Leaves opposite, scarcely two inches long, of a roundish or elliptical form, acute, or sometimes furnished with a short broad lobe at each side, entire; smooth above; pale and downy beneath; the midrib bearing off two principal lateral ones, that above its base, and ve
eral smaller ones higher up, all which are branched. Feet. flanks downy, various in length, often nearly equal to the leaf, each with a small hairy bud above its infection, and above that usually a straight, downy, horizontal sipe. Flowers in a short, simple, downy, terminal racemus. Calyx downy, besprinkled with several large, shield-like, smooth glands. Corolla large, yellow.

Rumphius's figure unquestionably belongs to this plant, but his description seems that of an Eugenia. Plukkenet's t. 305. f. 5. is certainly Gardenia dulcamora, and refurnishes our Gmelina only in being thorny; his t. 97. f. 2. may possibly be intended for Gmelina parvifolia, but is of no use as to determining it.

2. G. elliptica.—Leaves elliptical, undivided, obdome, downy beneath. Thorns none.—Native, we presume, of the East Indies, confounded in the Linnean herbarium with the foregoing, from which it differs in having rather larger leaves, which are exactly elliptical and blunt, more densely downy beneath, and not lobed. There are no traces of thorns. The inflorescence is rather more compound, but the remarkable glandular calyx is the same. If a variety it is a very extraordinary one.

3. G. parvifolia. Roxb. Corom. v. 2. 31 t. 162. (G. coromandelica; Burm. Ind. 132.)—Leaves obovate, undivided or three-lobed, smooth on both sides. Common in every forest and uncultivated place on the coast of Coromandel, flowering in October and November. Roxb. It is often intermixed with G. equita, from which it differs in its more humble size, larger and constant thorns, and especially in its smaller leaves, which are smooth on both sides. Their flowers and fruits are alike, the latter being yellow, obovate, the size of a small cherry. We perceive on one calyx in our specimen a solitary gland, like those described in the two former.—Dr. Roxburgh mentions that cold water, thick with a leafy branch of this shrub, becomes thick, from the abundant mucilage of the leaves, and is used in that state as a remedy for the heat of urine which accompanies gonorrhœa. Water thickened with branches and leaves of Pedulium Murus becomes in like manner mucilaginous, and is used for the same purpose, but soon loses its consistency, which is not the case with such as is prepared with this Gmelina. The Telingas call the plant Stichin guoomadeo. It may possibly be Plukkenet's Lyriticus Madrastifastum, t. 97 f. 2. as Burman takes it to be, but Sloane's Rhamnus, Hist. of Jamaica, v. 2. t. 207. f. 1, cannot be the same, though his figure affords no distinct indication of what he means.

4. G. arboria. Roxb. MSS. (Cumbula; Rheede Hort. Mal. v. 1. 75 t. 41.)—Leaves heart-shaped, undivided, pointed, downy beneath; their lateral ribs cloven. Thorns none.—Grows from the coast of Coromandel by the Rev. Dr. Rottler, with the above name of Dr. Roxburgh. Gartner has most fully pointed out the Cumbula of Rheede as a Gmelina, though quoted by Linnaeus, doubtfully indeed, for his Bignonia Catalpa. This is a tall and upright tree, growing in sandy ground, with downy branches, and large, opposite, flaked, heart-shaped, entire leaves, downy and veiny beneath. Thorns none, as far as we can learn. The flowers are numerous and handsome, yellow, growing in compound, hairy, terminal clusters. Fruit yellow, obovate, rather small.

5. G. indica. Burm. Ind. 132 t. 39 f. 5. (Dory Zakia of the Malays.) Leaves alternate, heart-shaped, crenate, smooth on both sides.—Native of Java. Herb. Linn. A shrub or tree, with round, somewhat zig-zag, slightly downy branches. Leaves from half an inch to an inch long, alternate, on short hairy stalks, veiny, bluntly crenate. Thorns 3 c 2 straight.
straight, slender, acute, mostly longer than the leaves. The flowers and fruct are known. We have only
Burnian's very feeble authority for making this a *Gnidia*,
which its alternate crinate leaves strongly disencourage,
but did Linnaeus ever venture to adopt it? S.

GMUND, in Geonaphy. See GEMUNDEN.

GNA, a town of the duchy of Styria; 24 miles S.E.
of Graz.

GNADENHUETTEN, a settlement of the Moravi-
as in America, situated on Multhiingam river, opposite to
Salem, in the lands which belonged to the Mahican Indians.
—Also, the name of a Moravian settlement, on the S.W.
bank of Lehigh river, in Pennsylvania, about 25 miles N.W.
of Bethlehem.—Also, a Moravian Settlement, called Acca
Gnaadhuettten, on Huron river, about 22 miles from lake St.
Clair, in the county of Wayne, and 28 N.W. of Detroit.

GNAPEZI, a town of Birmah, on the Irawaddy;
sometimes called from Gaape, or Napes, a fort of soap, half
picked and half putrid, used as a dye by the Birman,
and forming an extensive branch of trade: 116 miles N.N.W.
of Rangoon.

GNAPHALIUM, in Botany, γνάφαλιον, an ancient Greek
name, from γνάφαλος, soft down or seed, such as is plucked
from both in forming it, alluding to the woolliness of
the herbage. Many writers have contended that *Santolina mari-
tina* of Linnaeus, and *Sm. Fl. Brit. 869*, is the true * gland-
as* of Dioscorides, an opinion extremely difficult to esta-
lish or to contradict, as all he says of it is, that *its leaves
are white and soft, useful for stuffing.* However this may
be, Tournefort, and lately Gartner, have retained that
plant, as the true and only species of *Gnaphalium*. The
*Gnaphalium* of Linnaeus however is a very extensive and
comprehensive genus, from which some species have of
late been separated. See *Eichhorn—Card-weed.*—Linm.
*Sm. Fl. Brit. 867*. Jaff. 1759. (Eichhorn; Garn. t. 166.
Antennaria; Garn. t. 165. Anacoton; Garn. t. 165. Fili-
Guergiu. Garn. t. 166. See Filiagn.) Claff and order,
*Sygoepalio Polygammia*; *Garn*., Nat. Ord. Compositae Noce-
montes, Linm. *Corymbiura, Juff.*

Gen. Ch. Comun calyx imbricated, rounded; scales
numerous, the marginal ones rounded, scariofe, coloured.
Cor. compound; florets of the disk perfect, tubular, funnel-
shaped, in five equal reflexed marginal segments; some
female ones, without a corolla, are often intermixed towards
the margin. Stam. (in the perfect flowers) Filaments five,
very short, capillary; anthers forming a cylinder. Pist. (in
the same flowers) German ovate; style thread-shaped, the
length of the filaments; stigma cloven. In the female ones
the same. Peric. now, except the permanent disodium
(style) German ovate; style thread-shaped, the length of the
filaments; stigma cloven. In the female ones the same.
Peric. now, except the permanent disodium
(style) German ovate; style thread-shaped, the length of the
filaments; stigma cloven. In the female ones the same.
taceous); the plantain-leaved everlasting (G. plantagineum); the common shrubby everlasting, or Ichecas. (G. oxechas). Many of these are curious plants.

Method of Cultures. — The first four sorts may be increased by slips from the heads or cuttings; by planting them in pots of light earth in the spring or summer months, and plunging them in a moderate hot bed, and then in the open air when the weather is settled without water. When they have taken full root, they may be removed into separate pots, and be placed among other plants of the garden. They require the protection of a frame in the winter season.

The fifth species may be increased in the same manner, being placed at once where it is to remain, in a shady sheltered place, or other place that is proper. The fifth and sixth sorts may be easily raised by dividing and planting their creeping roots where they are to grow, either in the autumn or spring months.

These three last are sufficiently hardy to stand the open air in warm situations.

They are all ornamental plants, the former in the greenhouse collection, and the latter in the open ground.

GNAPHEUS, in Entomology, a name given by Authorities and others of the Greek writers to the tench.

GNARP, in Geography, a town of Sweden, in the province of Helsingland; 20 miles N. of Hudwrickov.

GNAT, in Entomology. See Culex.

There is no species of insect that we have so much reason to dislike in regard to the injury it does us as the gnat. Others indeed give us more pain with their stings, but it is but by accident that we are struck by them; the gnats thirst for our blood, and follow us about in the open air for us. There are many marshy places where the legs and arms of the motto swelled to an enormous size by the repeated bitings of these insects, and in many other countries they are much more troublesome than with us.

But as trouble-some enemies as these little creatures are to us, there is that about them which is extremely worthy our admiration; nor can we indeed fail greatly to admire even the very instrument of the mischief they do. They have bestowed this many very observable particulars in the course of their lives.

All the naturalists of late years have applied the microscope to the examination of the parts of this little animal, and it is a production of the Hook, Bonnami, Leeuwinkoek, &c, have given very good accounts, and very valuable drawings of the creature.

There is a great number of very small species of gnats, and though some are considerably large, yet none of these approaches to the size of the tipula, or father long-legs, as commonly called. The larger tipulae are therefore easily distinguished from the gnats; but Swammerdam, Goedart, Lister, and others, have very often given us the smaller tipula among the species of gnats. Both have long slender bodies, and both prominent corselets, which make them look lump-backed; but when either of the kor insects are taken into the hand it is very easily known, the gnat having a very long trunk, and the tipula no trunk at all.

There is a prodigious number of species of the gnat kind, comprehending the smaller ones: Dr. Derham observed near forty different species about Upsinifer in Essex; but of those of a size to be remarked with ease, and without the help of glasses, there are three principal kinds: the one has its body variegated with white and black; this is the larger kind, and its corselet is treated with black or deep brown, and white lines or greyish ones; these have brown eyes; another is smaller than this species, and has a plain brown body, the colour of the corselet, and that of the eyes is the same as in the larger or first species; the third kind is the smallest of the three and the most common, has its corselet red, or of a faded reddish yellow, and the body whiteness, and on the under part of the belly every ring has one single brown spot; the rest is grey; the eyes of this species are of a very pleasant green.

All the gnats have a long cylindrical body composed of eight rings; their corselet is short but large, in proportion to the size of the fly, and to this are fixed the fix legs, which are hairy, with fix joints to each, and at the end two little claws, the wings, and the balances: four fixstomata are also found here, as is the case in other flies; the two fixst of these are placed near the head, and have been mistaken for ears.

The antennae of gnats are extremely worth observation, and differ much from one another. Some of them are elegantly feathered; these belong to the males of certain species, for the antennae of the females are not so beautiful. The bristl-horned or male gnat has two pairs, one of which is surrounded, at small distances, with long hair, passing out circularly, each circle forming a series of the extremity of the antenna; the other pair are longer and much thicker, and hairy from end to end. In the great hellied or female gnat, the first pair of antennae, though of the same figure as the male's, has hairs not near to long, and the second pair is shorter than the first by at least three parts in four.

GNATS, Eggs of See Eiga.

For the Eggs of Gnats, see Eggs of Flies.

GNAT-worm, in Natural History, a small water insect, produced of a gnat, and which is, after its several changes, transformed into a gnat again.

From the eggs, deposited by the gnat on the surface of the water, proceed a number of minute worms, which hatching to the bottom of the water, form for themselves coverings of fine sand or earth, cemented together with a spot of glue, but open at both ends, that they may come out and enter as occasion requires.

These worms do not frequent rivers; but ditches, ponds, and other standing waters, afford them in vast abundance, from the middle of May till toward the beginning of winter. This is the reason why watery and marshy places are found most to abound with gnats, and why the wet fummer's are found to produce the greatest numbers of them; because in dry seasons, the ponds and ditches, where they are to pass their worm-state, are dried up, and the worms killed. These are creatures, however, that one need not go far to seek, since a vellcy of water, exposed in any open place in the summer months, will not fail to afford plenty of these worms in a little time.

Before these worms are arrived at their full growth, though they are then but small, they are easily found, because they are under a necessity of coming frequently to the top of the water, by having occasion for frequent respiration; and to do this, they are obliged to keep the end of a small pipe they are furnished with, from the bottom of their body, above water. The end of this pipe is hollowed and indented, and forms a sort of funnel on the surface of the water: it is of the length of about three rings of the body, and is somewhat thicker at its insertion than at its extremity.

As there is a vast number of species of gnats, there is no list of the worms from whence they are produced; and to this is a great measure owing the variety in the figures given of
of the worms by the authors who have treated of them; which may also be not a little added to by the particular views in which those druggists have been taken. Notwithstanding all the variations of these figures, the general form of the animal is however the same in all, and the species cannot but be known from any of them. While the worm is young, the body is whitish or greenish; but when it is at its full growth, and draws near the time of its changes, it becomes greyish. The great transparency of the body of this worm gives a fine view of what passes within it; it is at any time easy to see into the memoir of the intellines, by which the food is pushed on towards the anus. The two principal tracheae are also seen very distinctly in this creature; they are two white tubes placed in a parallel direction one to another, and run from the first ring to the tube of respiration.

The great worm several times changes its skin in the course of its life. After three changes of this kind, which usually happen in the space of three weeks, or thereabout, it undergoes a fourth, where the old skin is as easily thrown off as in the rest, but the animal now appears in a new form, that of a nymph; it is now shorter and rounder than before, and the body is so bent that the tail is applied to the under part of the head; this, however, is only its form in a voluntary state of rest, for it can yet move, and when it pleases extends its tail, and swims about as swiftly as when in its other state.

When the creatures have quittd their first habitations and the figure of worms, they recede to the top of the water, inclosed in a kind of shell, with a large head and mouth, two black eyes, two horns, several tufts of hairs on different parts of the body, and a tail with a brist of hair at the end of it, which, being smeared over with an oily fluid, serves to keep them above water; their heads being sometimes lifted in the air, and sometimes plunged into the water, while the tail slides along the surface; and when the oil on the tail begins to dry, they sink from their mouth a fresh supply, which renders it capable of steering where they please, without being wetted and damaged by the water.

All the parts of the future gnat may be seen in this nymph; the skin of it is extremely thin and transparent, yet sufficiently tough and firm for the use it is intended for. It is uncertain how long exactly the animal lives in this nymphal state; but after some time is accomplished, its change into a gnat is very quick, and is attended with great danger to the animal, since multitudes are drowned in the act of getting out and springing into the air.

Gnat, in Rural Economy, a small well-known insect, which is said to destroy the leaves of some tender vegetables as soon as they appear, such as the turnip, &c.

GNEISS, in Mineralogy, a primitive rock, composed of feldspar, quartz, and mica; ingredients which are likewise those of granite, from which it differs in the arrangement of those parts; for while in the latter rock they usually appear as granular aggregations, those of gneifs are disposed in such a manner as to exhibit a more or less flatly structure. This structure passes through various degrees of distinctness; on one hand it approaches to near the granular texture, that the distinction between gneifs and granite ceases to exist, while, on the other hand, when its peculiar texture is very obvious, and becomes what is termed thin flatly, a pallage is formed into the primitive rock, next to it in antiquity, called micacr-flate. In its progress towards the nature of granite, the feldspar is generally predominant with regard to the mica; while those varieties approaching mica-flate gradually exhibit a smaller proportion of feldspar and much mica. Sometimes, however, the mica is only apparently predominant, owing to the circumstance, that on breaking a mass of gneifs, the line of separation will more frequently pass through the mica than through the other layers, and display a whole surface of that substance; but another fracture, perpendicular to the first, will, in this case, soon deceive the observer. Though feldspar, generally speaking, the predominant ingredient of gneifs, yet the proportion of mica in this rock is, upon the whole, greater than what we see it in granite: and if this is the case, the more the maa appears granular, and the more it approaches to granite. It is often a matter of difficulty, in viewing small specimens only, to distinguish some kinds of gneifs from the last-mentioned primitive rock; when the inspection of the former in their natural situation, and on a large scale, would have left but little doubt in the mind of the observer.

Gneifs, viewed in the large, as a mountain mafs, always exhibits thick and distinct strata, whose outgoings, or upper terminations, are generally lower than the subjacent granite, and higher than those of the superincumbent mica-flate.

Werner (to whom we owe more correct ideas respecting this rock,) distinguishes four kinds of gneifs, viz. that approaching the granular structure, the waved or undulated, the common, and the thin flaty gneifs. As particular varieties of these, we have 1. The striped gneifs, in which the quartz is disposed in narrow bars, surrounded by feldspar, producing, on its longitudinal fracture, a striped appearance, not unlike that of some kinds of petrified wood; while its transversal fracture exhibits a granular disposition of the parts. This striped variety generally occurs together with the waved; such as at Ober-Newhonberg, Reilland and Hartmannsdorf, near the Bohemian frontier. 2. The sprinkled, or that kind of gneifs in which the feldspar and mica exhibit themselves in the form of small neifs; such as that found at Hartmannsdorf and Bobrith, near Freiburg, and at Kuffenberg in Bohemia. 3. The short lamellar or flaky variety, as it is found at Marienberg.

The colour of the ingredients of gneifs is not subject to great variation. The feldspar is generally of a greyish, yellowish, and reddish-white colour, feldom yellowish-grey, or deep fells-red, as it appears in many varieties of granite, upon the whole, its tint resembles that of the quartz with which it is accompanied, and which feldspar appears fioke-grey or brown. The colour of the mica is generally black or brownish-black, sometimes brownish, yellowish, and ash-grey, and rarely silver-white or of a golden hue.

These component parts are found to vary also in regard to their freshness: in general the feldspar is perfectly foliated and shining; but sometimes it appears in incipient decomposition, or even converted into petzime; in the same manner as the mica is now and then seen passing into a greenish substance resembling flake. Dr. Reuuf found that the porceain earth dust at the Galgenberg, near Puchwiszitz, in the Saatz district of Bohemia, where it is used for white- washing walls, is the result of the highest stage of decomposition of gneifs; it forms thick strata, and contains a great quantity of small greyish white, light grey, and pale clove-brown grains of quartz. In the same manner this mineralogist observed in that country frequent proofs of the conversion of the feldspar of gneifs into a ferruginous clayey mass. Near Klostery it is seen converted into bunt-iron or variegated clay.

Besides the more essential feldspar, quartz, and mica, the following accidental ingredients are now and then met with in gneifs. 1. Sylor: both the common and black tourmaline sylor, sometimes occur in the gneifs of Freiburg, and particularly of Spain. 2. Garnet; rarely, but much more frequently than in granite; it occurs at Wielenthal-in Saxony, in Norway, in the island of Zealand, in Morocco, &c.
GNEISS is but seldom found, and only in the thin flatly variety of gneisfs, which pass into mica and hornblende slate. 4. Steatite: occurs principally in the gneisfs forming the walls of the metallasiferous veins in the Freiberg district; it is considered by some as mica thus transformed by sulphuric acid. 5. Actinote: is said sometimes to constitute an ingredient of gneisfs in Switzerland and Hungary. Metallic substances that are sometimes found disseminated in gneisfs, in the vicinity of veins, cannot properly be enumerated even as accidental component parts of this rock.

Gneisfs abound in metals more than any other rock, as may be seen from the richness of the Saxon and Bohemian mines, those of Saltburg, &c. There are but few among the known metals that are not found in it, either in veins or beds.

"The oldest gneisfs in the Saxon Ertzgebirge," says Mr. Jameison, "that with reddish-coloured feldspar, is the least productive in ores; but the newer, with white coloured feldspar, is the most productive; and the veins, though small, are numerous. The oldest venigerous formation appears to be that which contains titan-foce. The titan-foce is accompanied with wolfram, molybdenum, arsenic-pyrites, fluorspar, chlorite, topaze, and opal. The second venigerous formation appears to be a lead-glance formation. The third formation consists principally of copper, and the ores are grey copper-ore, copper-glance, copper-pyrites, and variegated copper-ore. The fourth formation, which is very extensive, contains ores of cobalt. The fifth formation is that which contains ores of silver. Veins containing antimony, and red iron-foce occur in gneisfs, and these are supposed to be newer than any of the preceding. The metallasiferous beds that occur in this rock contain argentiferous lead-glance, blende, copper and iron-pyrites. It sometimes also contains formations of gold."

There are three considerable beds of rocks subordinate to, and synchronous with, gneisfs, and which are therefore not seen in granite, viz. granular limestone as it is observed; for instance, near Freiberg; primitive trap, such as hornblende-slate, at Kutenberg in Bohemia, at Kongberg in Norway, &c; and the older porphyry. (See LIMESTONE, TRAP, AND PORPHYRY.) Also small beds of common gargets, actinote, with magnetic iron-foce, iron-pyrites, galena, &c. now and then occur in gneisfs.

Gneisfs being generally superincumbent on granite, is hence considered as next to this primitive rock in point of age; there is, however, also a difference in the relative antiquity of the different kinds of gneisfs, and on the whole it may be said that the nearer it approaches in its texture to Mica-foce, (see that article,) the more recent is its origin. From this does it not, however, follow, that there should not be found kinds of gneisfs which forage in antiquity even some kinds of real granite. (See GRANITE.) The very thick flaky varieties of gneisfs, with black mica and a small proportion of mica, may, in general, be said to be of more ancient formation.

Gneisfs, though far less widely distributed than granite, has still a considerable range; it extends over the greatest part of the Saxon Ertzgebirge: the country about Freiberg, Glaubitz, Marienberg, Ehrenfriedersdorf, confiding almost entirely of it. In the same manner it is the characterizing rock of the Bohemian mountains mining district. It is also found in Silhesia, Carinthia, in some parts of the Black Forest in Suabia; nor is it wanting in the Taurisian mountains, in Salzburg, in the Swiss Alps, the Pyrenees and Volgse, in Scandinavia, Greece, &c. In Great Britain it has been observed particularly in Scotland, in the islands of Coll, Tiree, Rona, and in the Shetland islands. It should however be observed, that frequently other rocks have been described as gneisfs by topographical writers.

The economical use made of gneisfs is that for paviug, and for the conduction of walls; for both which purposes it is extremely well calculated, by reason of the facility with which it is wrought by the mason. Hence in the Saxon mining district not only almost all buildings are constructed of gneisfs, but also the scaling of the shafts and levels is most advantageously executed in this useful rock.

GNEISON, in Bedoin, a town so called in the island of Terragia and others of the Moluccas, which is named in the Malay language Mengoe, or Mengoe, a word apparently of the same derivation, whatever that may be. See GNETUM.

GNERDEN. in Geography, a town of Persia, in the province of Irak; 150 miles E. of Hafzan N. lat. 32° 20'. E. long. 55°

GNERKOUTEGH, a town of Birmail, on the Pra-waddys; 60 miles N. E. of Peshawry.

GNERSEN, or GNESEK, a city of Poland, in the duchy of Warsaw, built, as it is said, by king Lechus I. founder of the monarchy, and called Gnozy, from an eagle's nest found there, denominating in the Polish language Gnezdn. The kings of Poland were crowned in this city, and the regalia were kept here till, in the year 1320, they were removed to Cracow. During the independent existence of Poland, it was famous as the see of an archbishop, who was primate of Poland, and who acted as interrex or regent upon the king's demise; and who also announced the event, convoked the diets and districts of convocation, and performed the functions of royalty. Gneza is 160 miles N. E. from Breslaw, and 150 W. from Warsaw. N. lat. 52° 26'. E. long. 17° 42'.

Gen. Ch. Col. Cattoon composed of several remote, calous, thickened whorls, each subtended by a small partial calyx, which is poliat, orbicular, flat, entire, containing several scaly florets, the male ones inferior, the females superior, in the same whorl. Periacth of the male a minute, ovate, coloured scale. Cor. none. Stem. Filament one, thread-shaped, longer than the scale; anthers in pairs, connected.

Obf. Linnaeus observes that Rumphius makes his plant diocious, but he found it monocious, and even few one catkin entirely male, standing on its own footstalk, near a female floret. The Thoa of Aublet, though somewhat differently described, is undoubtedly the same genus, and indeed so like the original Gnetum in foliage, that it is not very easy to distinguish them.

1. G. German.
1. *G. Guenon*. Linn. Mant. 125. (Guenon domesticus; Rumph. Ambobin. v. i. 181. t. 71. 72. Beroentis fruticus; Clus. Exot. 55)—Lateral veins of the leaves prominent, inter-branching archwise half way towards the margin. Catkins opposite, axillary, on simple flanks.—Native of the Molucca islands, and other parts of the East Indies. We have it from Java. A tree, with straight, round, slender, smooth branches, swelling at each joint, under the infection of the leaves, and somewhat forked at the ends. Leaves opposite, flalked, ovate, inclining to lanceolate, pointed, entire, smooth and shining, three or four inches long, furnished with a midrib, channelled above, prominent beneath, sending off several alternate, spreading, prominent though slender veins, which meet rather more than half way towards the margin in one common arching vein, whence numerous reticulations originate. *Stipula none*. Fruit flalks half an inch long, channelled and keeled. Catkins axillary, shorter than the leaves, two together from each opposite leaf, on simple flanks, their whorls when young crowded, but four becoming digitate and bead-like, every whorl bearing numerous females as well as male flowers. What *Linneas* describes as a torn fede in the former, seems rather a very dense assemblage of short tufted fibres. Fruit the size of an ordinary acorn or filberd, its coat thin, sweetish according to Rumphius, but with too much certain to be eaten raw; as is also the case with the leaves, which, when fried, are in almost daily use among the natives of Ambonays, though thought mauvish and inuspid by Europeans.

2. *G. Theo*. (Thoa urens; Aubl. Guian. v. 2. 874. t. 356.)—Lateral veins of the leaves obsolete, inter-branching archwise. Catkins on simple flanks, from the repeated forks of the branches.—Gathered by Aublet in the woods of Guiana, where the natives call it *Thoa*. His own specimen in our possession has no justification or incoherence, so that we have been obliged to take part of our character from his figure. The leaves seem in general to be rather shorter and broader than in the former, but the chief distinction is observable in their lateral veins, which though they do in a similar manner run into one common arching vein, above half way towards the margin, are all together far more flat and less prominent than in the first species. The fruit is like the former, reddish, and elliptical. Aublet says that when its outer skin is taken off, a dry substance is found underneath, composed of stiff deforced hairs, which easily separate from each other, and if any of them fall upon the human skin, they cause a great itching. The kernel of the nut, boiled or toasted, is good to eat. Birds of the fowl or pleasant tribe feed in the woods upon this fruit, which they swallow whole. The same author affirms us that a clear gum issues from the bark and branches, but that when the main trunk or great branches are cut, a clear tafteless watery liquor runs out, which may be drank by those who are defirfed for water. This tree is almost always in flower and fruit. Aublet describes the catkins as male, with two female flowers at their base. This is so different from our specimens of *G. Guenon*, that it might almost afford a specific character, but Rumphius describes the same circumstance in what he terms his male *Guenon*, and Linnaeus adverted to something like it. It should seem therefore that in the first, if not in every species, the genus is imperfectly distinct, one tree bearing catkins with female flowers, with perhaps less perfect males; in every whorl, while on another are found more efficient males in every whorl, with females at the base only, as in Aublet's *Thoa*. Such examples throw great light on the physiology of vegetable generation, and confirm the Linnaean theory.

3. *G. fuciculare*. Buchanan MSS. (Guenon fuciculare; Rumph. Ambobin. v. 5. 12. t. 8. Ula; Rheed. Hort. Mal. v. 7. 41. t. 22.)—Lateral veins of the leaves separate to the margin. Catkins opposite, axillary, on branched flanks.—Native of Ambonays and other places in the East Indies. This is a long trailing branching smooth *fureus*, turning black in drying, which the two former do not. The leaves are four or five inches long, various in breadth, pointed, firm, shining, distinguished by their veins continuing distinct to the edge of the leaf. The flower-flanks are axillary, in pairs, more or less branched and forked; each catkin being about an inch long, composed of numerous orbicular imbricated scales concealing the flowers, and not unlike compared to the Hortus Malabaricus to Long Pepper. Each flanks on a partial leaf, of about its own length. The fruit refines that of the foregoing, and is rounded over the fire, which renders the kernel edible. The tender leaves serve for a pot-herbs, like thole of *G. Guenon*. The bark of the young twigs, split into thread, serves to make nets.

Rumphius's vol. 5. t. 17, which he calls *Fruits Guenoniiformis*, but of which he seems not to have known the flowers, may possibly be that male plant of our half-described species, bearing only one or two female flowers at the bottom of the flanks of the male catkins, according to the analogy observed in the foregoing ones. 8.

GNIADA, in Geography, a town of Hungary; 7 miles W.S.W. of Pestoa.

GNIDIA, in Botany, from Gnidos, where Venus had her temple. A seed, reported to be brought from thence, had been called *Convolvulium*, and there is a *vitis*, or *Kisse*, supposed to be a kind of Orache; but Linnaeus probably had not the least idea of the affinity of this genus to *Pafferia*, named after a favourite bird of the goddess, in allusion to which it was first named *Sternia* by Van Royen. It is moreover akin to *Daphne*, one species of which, *Daphne Guidentia*, has been taken for the ancient *yanoos*.

Gen. Ch. Cal. Perianth inferior, of one leaf, funnel-shaped, coloured; its tube thread-shaped, very long; limb flat, in four deep segments. Cor. Petals four, subelliptic, flat, inferted into the edge of the tube of the calyx, and shorter than its limb. Stam. Filaments eight, bristle-shaped, erect, inserted into the tube in two rows, the uppermost reaching nearly to the top; anthers roundish, erect, simple, of two cells. Pfl. Germin ovate, superior; style thread-shaped, as long as the tube, inferted laterally into the germin; stigma capitulate, hispid. Peric. a dry berry, with a thin coat. Seed solitary, ovate, obliquely pointed.

Eff. Ch. Calyx funnel-shaped, four-cleft, withering, including the framents. Petals four, inserted into the calyx. Style lateral. Seed coated.

Obf. It differs from *Pafferia* only in having petals; which are often rather of a glandular appearance. The habit is altogether that of *Daphne* and *Pafferia*. Willdenow enumerates sixteen species, but of these *G. parciflour* and *radiata* are one and the same, and *G. disphacophila*, Linn. Suppl. 255, seems rather to belong to *Dios*.

All the genuine species are natives of the Cape of Good Hope, of a humble flabby growth, with white or yellowish sweet-scented flowers.

GNIEWE, or Mave, in Geography, a town of Prussia, in the province of Pomerania, on the Vistula; 50 miles S.S.E. of Danzig.

GNOIEN,
GNOIEN, a town of the duchy of Mecklenburg; 21 miles E.S.E. of Rottlock. N. lat. 53° 59'; E. long. 12° 52'.

GNOll RAIL-WAY. This is an establishment in Glamorganshire, in South Wales, which we had not heard of at the time of compiling our article Canal; it is called an iron waggon-way, the flanch being on the wheels of the waggon, instead of being on the tram-plates, as is more common in that district. It commences at the shipping-place 200 yards below Neath bridge, on the Neath river; crosses the Neath canal on a wooden bridge, and proceeds about one and a half a-mile to the late Sir Herbert Mackworth's Gaol collieries, of run coal, which are driven up forty fathoms, to be loaded into the waggon on this waggon-way, which has so far regular a descent, as to require no inclined planes, or other considerable works.

Gnomes, Gnomi, a name which the Cabbalists give to certain invisible people, whom they suppose to inhabit the inner parts of the earth, and to fill it to the centre. They are represented as very small of stature, tractable, and friendly to men; and are made the guardians of mines, quarries, hidden treasures, &c. Vigener calls them Gnomoni: the females of this species are called Gnomides.

Vigenel de Marville, in his Melange de Histoire et de Literature, tom. i. p. 230, gave a relation of a conference with a philosopher of this class, who held, that an infinity of spirits inhabited each of the four elements, fire, air, water, and earth, under the denomination of Salamanders, Sylphs, Oudins, and Gnomes; that the Gnomes are employed in working or actuating the machines of brutes upon earth.

He added, that some philosophers of that sect held that these spirits were of two sexes, for the two sexes of beasts or moving machines; that they were more or less perfect as the brutes were; and that there was an infinite number of exceedingly small ones, to actuate the infinite number of animals and animalcules, both those that are visible, and those which are too small to come under our senses: that all these spirits, in general, govern their respective machines according to the disposition of the parts or organs, the humours, temperaments, &c. that they do not lay hold of all machines indifferently, but of those suited to their own character, element, &c. that a haughty one, for instance, feizes a Spanish gennet; a cruel one a tyger, &c.

Gnome, Gnomon, or chrise, is also used for a short, pity, and sententious observation, reflection, or the like, which is worthy to be treasured up and remembered.

Such is that of Juvenal, "Orandum est ut fit mens fana in corpore ratio." The writers of rhetoric distinguish several kinds of gnomes, according as they turn on words, on actions, or both; denominating them verbal, affure, and mixed gnomon or chrise. See ARGUMENT.

GNOMON, in Dialling, is the style, pin, or cock of a dial, the shadow wherein points out the hours.

The word is Greek, γνωμων, which literally imports something that makes a thing known; because the style or pin indicates or makes the hour, &c. known.

The gnomon of every dial is suppos'd to represent the axis of the world; and therefore the two ends or extremities thereof must directly answer to the north and south poles. See DIAl and DIALLING.

GNOMON, in Geometry. If a parallelogram be divided into four lesser ones, by two lines intersecting each other, and one of these parallelograms be retrenched or taken away, the other three will make a gnomon, ordinarily called a square.

Or, a gnomon, in a parallelogram, may be said to be a figure formed of the two complements, together with either of the parallelograms about the diameter. Thus, in the parallelogram $\Delta ABC$, Plate VIII., Gnomen $= x^2 + y^2 + z^2$. If $\phi = \delta$, the gnomon is $M + x + z = N$; or $M + N = X + Z$.

GNOMON, in Astronomy, the name given to any upright pillar, when used for the purpose of determining the altitude of a celestial object, but particularly the sun.

The extreme simplicity of this instrument renders it very probable, that it was the first ever used for astronomical purposes. It fortunately happened for the science, that it was capable likewise of being a very exact one; and all the knowledge the ancients had of the solar theory seems to have been derived from this instrument. The principle of it is so simple, as hardly to require explanation. If the height of a vertical pillar be compared with its shadow on a horizontal plane, the altitude of the sun may be deduced by trigonometrical calculation, since these two quantities are to each other, as the tangent to the radius, or as the sine to the cosine of the altitude required. The ancient obelisks found in Egypt and the East were probably instruments of this kind: it would be too much to conclude that every one was erected for astronomical purposes, but this was probably their original destination; and the figure of an obelisk being rather pleasing to the imagination, it was adopted as an ornament to pubic squares and buildings. As practical astronomy advanced to accuracy and perfection, however, the gnomon appeared to be subject to considerable defects. The shadow is found to be generally ill defined, so that its length cannot be very accurately measured; and to obviate this, the gnomon must be of greater height than is easily practicable. In modern Europe, therefore, the original gnomon has been almost entirely abandoned, and a new one substituted upon principles nearly similar, but of a somewhat different construction.

The gnomons of modern Italy are usually constructed in very large edifices; a small aperture is made in the upper part of the building, which permits a luminous circular image of the sun to be formed on the pavement, on which a meridian line is accurately traced; a plumb line is suspended from the aperture to the floor, and thus both the height of the aperture, and the distance of the solar image from the point immediately beneath it, is very accurately ascertained.

There are upon record some very ancient observations made with instruments of this kind, particularly of Pythias, who observed the solstices at Megaleses about three centuries before the Christian era. Pliny mentions an obelisk erected by Auguslus: this obelisk was brought from Egypt, and was said to have been made by Scopolius, near a thousand years before Christ. It was used by Manlius for the fame purpose for which it was originally designed, namely, to measure the height of the sun.

The Chinese have from the earliest time been in the constant practice of making use of a gnomon.

In the year 1278, a gnomon 40 feet high was erected at Pekin, by the Chinese emperor Co-čhew King.

Ulugh Beig, in the year 1437, observed the solstices at Samarcand by the shadow of a gnomon 165 feet high; and similar instruments are even said to have been used by the ancient inhabitants of Peru.

The gnomons to which modern astronomy is the most indebted, are chiefly those of France and Italy.

Paul Tufenelli constructed a gnomon in the cathedral of Florence, whose height was 280 feet. Ximenis required this, and published an account of it in 1757.
Gnomic

Gnomic Column. See Column.

Gnomic, Polyhedron. See Polyhedron.

Gnomonic, or Gnomonical Projection, which that represents the circles of a hemisphere, upon a plain touching it in the vertex, by lines or rays from the centre of the hemisphere to all the points of the circles to be projected.

In this projection, all the great circles of the sphere are projected into right lines. Any lesser circle parallel to the plane of projection is projected into a circle. And any lesser circle not parallel to the plane of projection, is projected into a conic section.

The gnomonic projection is also called the "horologigraphic projection," because it is the foundation of dialing. In other respects it is not much used, because the circles of the sphere are projected into conic sections, which are difficult to be described. However, this projection has its conveniences in the solution of some problems of the sphere, on account of the great circles being all projected into right lines.

Mr. Emeron, known by an ingenious Treatise upon Fluxions, and a variety of other publications, has given the theory and practice of the gnomonic projection, in his Treatise on the Projection of the Sphere, Lond. 1749, 8vo. See Projection.

Gnomonica, Art. Gnomon, or Gnomonics, the art of dialing, or of drawing sun and moon-dials, &c. on any given plane.

It is thus called, as it shews how to find the hour of the day, &c. by the shadow of a gnomon or hyle.

Gnosimachi, in Ecclesiastical History, an ancient hand in religion, whose distinguishing character was, that they were professed enemies of all studied knowledge in divinity. The word is gnos维奇, q. d. an enemy of wisdom or knowledge.

Damascenus says, that they were perfectly averse from all the graces of Christianiety, i.e. all the science or technical knowledge thereof. They held it an unfeels labour to seek for graces in the holy scriptures; and said, that God requires nothing of men but good works; that it were, therefore, much better to walk with more simplicity, and not to be so folicitous about the dogmata of the gnostic life.

Gnosus, in Antiquities, a town of the island of Crete, more anciently called "Ceratius," from the name of the river which watered it. It was the fixed residence of Minoes, once the capital of the island, and, according to Strabo, a wealthy and populous place, being 30 furlongs in compass, and full of inhabitants. This writer places it 20 furlongs from the Aegean or Archipelago, and 60 from the African sea. Its port, called Herakleum, was at a considerable distance, according to Oliver about four or five leagues to the eastward. Paulinianus (Attic) says, that it had a lake. From this town Arion, so much celebrated by the poets, derived the name of Grus. When the island was reduced by the Romans, Gnozus was humbled, and Gortyna, her rival, raised upon her ruins. Somnian says, that a small village, Cnis, near Candia, would recall to mind the site of the ancient town, were it not discoverable, in a manner no

Gnostic's, in Ecclesiastical History, ancient heretics, famous from the first rise of Christianity, principally in the East.

It appears from several passages of the sacred writings, particularly 1 John i. 18; Tit. vi. 20, and Col. ii. 8, that many persons were infected with the Gnostic heresy in the first century; though the doubt did not render itself conspicuous, either for number or reputation, before the time of Adrian, when some writers erroneously date its rise.

The word is formed of the Latin gnostics, and that of the Greek γνωστικος, knowing, or γνωσης, I know.

The name Gnostic was adopted by all of this fact, as if they were the only persons who had the true knowledge of Christianity. Accordingly they looked on all the Christians as simple, ignorant, and barbarous persons, who explained and interpreted the sacred writings, in a too low, literal, and unedifying signification.

At first, the Gnostic's were only the philosophers and wit's of those times, who formed for themselves a peculiar system of theology, agreeable to the philosophy of Pythagoras and Plato; to which they accommodated all their interpretations of scripture. These enthusiastic and self-sufficient philosophers boasted of their being able to restore mankind to the knowledge (gnostic) of the true and Supreme Being which had been lost in the world. They also forecast the approaching defeat of the evil principle, by whom they attributed the creation of this globe, and declared, in the most pompous terms, the destruction of his associates, and the ruin of his empire. But

Gnostics afterwards became a general name, comprehending divers sects and parties of heretics, who rove in the first centuries, and who, though they differed among themselves as to circumstances, yet all agreed in some common principles. They were such as corrupted the doctrine of the gos pel by a profane mixture of the tenets of the oriental philosophy, concerning the origin of evil and the creation of the world, with its divine truths.

It was one of the chief tenets of the philosophy of the Christian Gnostics, that rational souls were imprisoned in corrupt matter, contrary to the will of the Supreme Deity. In conformity to the opinion of the oriental sages, who expected an extraordinary messenger from the Most High, endowed with wisdom and invested with authority to communicate to miserable mortals just notions of the Supreme Being, and to deliver them from the chains of the tyrants and usurpers of this world, they believed, when Christ appeared and wrought miracles of the most astonishing and marvelous kind, that he was the expected and wished-for messenger. Accordingly they imagined that he would relieve men from the power of the malignant genii, or spirits, to which, agreeably to their doctrine, the world was subject, and so free their souls from the dominion of corrupt matter. Having admitted this supposition, they interpreted, or rather corrupted, all the precepts and doctrines of Christ and his apostles, in such a manner as to reconcile them with their own erroneous tenets.

Such were the Valentinians, Simonians, Carpocratians, Nicolaitians, &c.

Gnostics, a denomination sometimes also more particularly attributed to the successors of the first Nicolaitans and Carpocratians, in the second century, upon their laying aside the names of the first authors. Such as would be thoroughly acquainted with all their doctrines, theories, and visions, may consult St. Ireneus, Tertullian, Clemens Alexandrinus, Origen, and St. Epiphanius; particularly the first of these

writers, who relates their sentiments at large, and confesses them at the same time; indeed, he dwells more expressly on the Valentinians than any other sort of Gnostics; but he shews the general principles wherein all their mistaken opinions were founded, and the method they followed in explaining scripture. He accuses them with introducing into religion certain vain and ridiculous genealogies, i.e. a kind of divine precessions or emanations, which had no other foundation but in their own wild imagination.

In effect, the Gnostics confounded, that these xenos or emanations were no where expressly delivered in the sacred writings; but inferred, at the same time, that Jesus Christ had intimated them in parables to such as could understand him. They built their theology not on the gospels and the epistles of St. Paul, but also on the law of Moses and the prophets.

These last laws were peculiarly serviceable to them, on account of the allegories and allusions with which they abound; which are capable of different interpretations.

However, their doctrine, concerning the creation of the world by one or more inferior beings of an evil or imperfect nature, led them to deny the divine authority of the books of the Old Testament, which contradicted this idle fiction, and filled them with an abhorrence of Moses and the religion he taught; alleging, that he was actuated by the malignant author of this world, who confounded his own glory and authority, and not the real advantage of men. Their persuasion that evil refixed in matter, as its centre and source, made them treat the body with contempt, discourage marriage, and reject the doctrine of the resurrection of the body and its re-union with the immortal spirit. Their notion, that malevolent genii presided in nature, and occasioned diseases and calamities, wars and desolations, induced them to apply themselves to the study of magic, in order to weaken the powers or supplant the influence of these malignant agents.

The Gnostics confounded Jesus Christ as the Son of God, and, consequently, inferior to the Father, who came into the world for the refuge and happiness of miserable mortals, oppressed by matter and evil beings; but they rejected our Lord's humanity, on the principle that every thing corporeal is essentially and intrinsically evil; and, therefore, the greatest part of them denied the reality of his sufferings. They set a great value on the beginning of the gospel of St. John, where they fancied they saw a great deal of their xenos or emanations under the Word, the Life, the Light, &c. They divided all nature into three kinds of beings, viz. lyic, or material; psichic, or animal; and pneumatic, or spiritual.

On the like principle they also distinguished three sorts of men: material, animal, and spiritual. The first, who were material, and incapable of knowledge, inevitably perished, both soul and body; the third, such as the Gnostics themselves pretended to be, were all certainly saved; the psychic, or animal, who were the middle between the other two, were capable either of being saved or damned, according to their good or evil actions.

With regard to their moral doctrines and conduct, they were much divided. The greatest part of this sect adopted very antient rules of life, recommended rigorous abstinence, and prescribed severe bodily mortifications, with a view of purifying and exciting the mind. However, some maintained, that there was no moral difference in human actions; and that, confounding right with wrong, they gave a leafy ruin to all the passions, and averted the innocence of following blindly all their motions, and of living by their tumultuous debates. They supported their opinions and practice by various authorities: some referred to fictitious and apocryphal writings of Adam, Abraham, Zeruiaher, Christ,
and his apostles; others boasted that they had deduced their sentiments from secret doctrines of Christ, concealed from the vulgar; others affirmed, that they arrived at superior degrees of wisdom by an innate vigour of mind; and others affirmed, that they were instructed in these mysterious parts of theological science by Thendas, a disciple of St. Paul, and by Matthias, one of the friends of our Lord. The tenets of the ancient Gnostics were revived in Spain, in the fourth century, by a sect called the Prisillianists.

(See Moheim's Ecc. Hist. vol. i.)

The appellation Gnostic sometimes also occurs in a good sense, in the ancient ecclesiastical writers, and particularly in Clemens Alexandrinus, who, in the person of his Gnostic, describes the characters and qualities of a perfect Christian. This point he labours in the seventh book of his Stromata, where he shews, that none but the Gnostic, or learned person, has any true religion. He affirms, that were it possible for a knowledge of God to be separated from eternal salvation, the Gnostic would make no scruple to choose the knowledge; and that if God would promise him impunity in doing of anything he has once spoken against, or offer him heaven on those terms, he would never alter a whit of his measures.

In this sense the father uses Gnostics, in opposition to the heretics of the same name; affirming, that the true Gnostic is grown old in the study of the holy scripture; and that he preserves the orthodox doctrine of the apostles, and of the church; whereas the false Gnostic abandons all the apostolical traditions, as imagining himself wiser than the apostles.

At length the name Gnostic, which originally was the most glorious, became infamous, by the idle opinions and dissolute lives of the persons who bore it; much as, in the present age, it has fared with the name gnostik, piastis, &c.

GONI, in Zoology, a species of Antelope, having horns thick, rough, and bent much forwards at the base, then suddenly turned backwards, a ferruginous body, a neck with a mane, and a tail white. This animal inhabits the country of the great Namaquas, to the north of the Cape of Good Hope. It feeds in large flocks in the plains: is exceedingly fierce, very swift, and fights with its horns; it frequently drops on its knees, runs quickly in that posture, furrowing the ground with its horns and legs. It is a singular animal, having the body like a horse, with a thick bull-like head, elegant taper legs like a deer, and the lachrymal furrows of the Antelope tribe. It is about 6 ft. long, and 3 ft. high at the shoulders; of a rusdy brown colour, having its hair tint with white, but on the breast and fore-legs long and black; the head is large and clumsy, with a square mouth and broad flaps over its nostrils; on the chin and gullet is a long hanging beard, or bunch of white hairs; the neck is short, thick, and somewhat arched, with an erect ash-coloured mane; the tail is long, white, and flowing like that of a horse; the feet have only one spurious hoof on each. The flesh is reckoned very good.

GOA sometimes used in Law, in a special signification. Thus, to go without dry, and to go to God, denote as much as to be dismissed the court, and to be acquitted.

GOA, in Geography, an island in the East Indian sea, near the west coast of Hindostan, separated from the continent by a river called "Mandova;" about eight leagues in circumference. The soil, especially in the valleys, is fertile; the trees are always covered with leaves, flowers, and fruit; and springs in abundance issue from the mountains. The rainy season continues here from June till September or October; and the land-floods bring down such quantities of mud and sand as flout up the haven and impede the navigation. In the months of April and May the weather is sultry, but from October to March it is very moderate.

GOA, a city and capital of the Portuguese settlements in India, the seat of a vicerey, and seat of an archbishop, taken by the Portuguese general Albuquerque in 1513 from a prince of Sarscan extraction. The port of Goa is naturally, and still more by the improvements of the Portuguese, one of the best in India; it is fortified with many castles and towers, and furnished with abundance of good cannon. Beyond these castles the channel becomes narrow, threatening sometimes to one, sometimes to two miles, and its banks are planted with the best fruits and finest trees which India affords. Eight miles up the channel is the town of Goa. About the middle of this distance is a palace, now serving as a barrack for the garrison; and here begins a strong broad wall, two miles in length, which is a foot walk when the country is overflowed, and in the vicinity of it a great quantity of salt is collected. This channel, which forms so excellent a port, runs many miles into the country, dividing it into several fruitful islands and peninsulas, which plentifully furnish the city with necessaries. Adjoining to this port is the haven of Murmagon, formed by the other channel, that runs between the island of Goa and peninsula of Saffle, and affords a safe retreat to the Portuguese and other ships, when they are shut out of the port by the sands which are brought down by the river Mandava, in consequence of the high tides of June, and till the passage is opened in October. This port of Murmagon is defended by a castle on the island of Saffle, and a good garrison. At the fouthern entrance into the channel are the ruins of Old Goa; and from thence to the new city is a commodious road, elegantly adorned with trees for fruit and shade. The walls of the new city, which is decaying, include a space of 12 miles in circuit; and the public structures which remain sufficiently evince its former grandeur as well as extent. The number of inhabitants is said to be about 20,000; they consist of native Portuguese, Melitzos, and Canarians, or natives, who are black as jet, with long black hair, and fine features; here are also many negro slaves, and Pagans of different nations. As to the character of the inhabitants, the men are said to be, for the most part, proud, indolent, jealous, revengeful, and indigent; the women lazy, lascivious, and as well skilled in poisoning as any in the world;... 215 miles S.S.E. from Bombay. The inquisition, formerly existing in this place, is now abolished. N. lat. 15° 28' 20''.

GOA, or Goa, a kingdom on the west and south-west coast of the island of Cebes, which, after various conflicts and revolutions, is now dependent on the kingdom of Boni. The capital of the same name stands on a little island, on the banks of a river, whence the kingdom derives its denomination. It was built about the same period as Samboupo and Telia; and was taken by the Dutch in 1775. S. lat. 5° 12'. E. long. 119° 11'.

GOACHO, a town of Peru, in the diocese of Lima, near the Pacific ocean; 65 miles N.N.W. of Lima. S. lat. 11°.

GOAD, in Rural Economy, a term applied to a pointed instrument, by which oxen are driven when employed in teamlabour. It has frequently, like a, a leather thong attached to the contrary end of it, so as to form a sort of whip.

GOAFFI, in Geography, a town of Africa, in the kingdom of Mandinga, on the Senegal.

GOAHIROS, a nation of South America, situated between the jurisdiction of Maracaibo and the Rio, or river
de la Hache: they occupy the coast for more than 30 leagues, and extend equally far into the interior part of the country. They have at all times been considered as the most ferocious of the maritime Indians. The Spaniards never even attempted to conquer them. Some missionaries have made efforts for instructing and profiting them to the Christian faith, but without any permanent effect. Their number amounts to 30,000. They are governed by a cacique, for whom they have erected a citadel upon a small eminence, called "La Tata," the Pap at the distance of some leagues from the sea. They breed horses upon which they ride with incredible rapidity. Their troops are all mounted, each soldier carrying a carbine, cartridge-box, bow and quiver. They experience much friendship from the English of Jamaica. They afford them with advice, and supply them with arms. These marauders have rarely any communication with Maracaibo, because, as its jurisdiction is the principal scene of their robberies and atrocities, the inhabitants are obliged to be continually on their guard, so as to be always ready to repel the aggregations of such troublesome neighbours. The Spanish city to which they chiefly resort is Rio-de-la-Hache, depending upon the vice-royalty of Santa Fe, where they barter their commodities. They set out in bands, most commonly preceded by their wives, who carry their children upon their backs, besides other loads, too heavy even for beams of burden. Dreading imposition, they have never adopted the use of specie, but barter their horses and oxen chiefly for spurious liquors, to the use of which they are much addicted. Urged by their necessities they recur to arms, and threaten the nearest city or village. After some hostilities, the Spaniards sue for peace, and obtain it in consideration of some pipes of brandy and other smaller articles. Although these Indians are well received in the Spanish cities, they will not admit any Spaniard into their country; and yet some Spanish smugglers contrive, for pecuniary considerations, to obtain a passport and escort for traversing the country of the Guahios, and they have thus acquired many partizans among the Spaniards themselves; but their principal and most useful connection is formed with the English of Jamaica. By them they are supplied, not only with arms and ammunition, but with the fluffs that clothe them. Their drefs is ornamented by a great variety of feathers, fragments of shining metals, and gold ridiculously fixed to their ears, nose, and arms. The articles with which they furnish the English in exchange for the merchandise they receive are pearls, which they fish in their own ports, and horsetails, muses, and oxen. Their ferocity is such, that even the English will seldom go far from them in order to venture on shore, but the business of bartering is transacted on board, and the ships hafien to depart. The ships that are accidentally cast upon the coast, immediately become the prey of these cannibals, who massacre the crew and devour their flesh; dividing the cargo among those who are present on the occasion. The Guahios are said to be a formidable nation, well mounted, armed, and disciplined; and able to bring into the field 40,000 effective men.

On the eastern part of the territory of the Guahios are the "Cocinas" Indians, who live like savages, but are so cowardly and pusillanimous as to allow the Guahios to exercise an authority, which the bold always acquire over the timid. These savages are, in fact, merely the slaves of other savages. Depots's travels, vol. iv.

GOAL. See GAOL.

GOAL-PARAH, in Geography, a town of Hindoostan, in Bengal, situated on the Burhampootor, and on the borders of Assam; where the Europeans have factories, who carry on a considerable trade with Assam, Bootan, Thibet, &c.; 32 miles E. of Rangamathy.

GOAN, the name of a Persian tree, of the ashes of which they make a sort of antidote, or medicinal powder, for dizziness of the eyes.

GOANOOGOOGA, in Geography, a town of Hindoostan, in Marawar; 8 miles N. of Tripolore.

GOANADA, a naked, savage and ferocious race, who inhabited the extensive and unexplored wild-ness, E. of Nagpour, in Hindoostan, which is pervaded by the great river Bain, or Buun Gongo, and terminates in the mountains bounding the English circuits.

GOAR, St. a town of France, in the department of the Rhine and Moselle, and chief place of a canton, in the district of Simmers, situated on the west side of the Rhine, in which there is, near this place, a water-fall; 16 miles S. of Coblenz. N. lat. 50° 8'. E. long. 7° 43'.

Goat-vetch, a name sometimes applied to the summer vetch. See TARE and VETCH.

GOARING, on Shipboard. The foremen by a sail is cut going, when it is cut foaping by degrees, and is broader at the chaw than at the ear-ang, as all top-fails and top-gallant-fails are.

GOAS, in Geography, a town of Bengal; 11 miles E. of Moorshedabad.

GOAT, in Zoology. See CAPIA.

GOAT, in Rural Economy, is an animal, that in particular situations may be kept with advantage by the farmer, as where the country is rocky and barren, and there is but little keep for any other sort of animal. The goat is capable of climbing the steepest rocks, and of browsing upon the briers, heath, and shrubs of several different kinds, which are rejected by other sorts of animals. When turned into pastures, they should consetually be prevented from nipping the young shoots of trees and other woods, as they prefer them to the grasses.

They are beneficial in several different points of view, as in their milk, which they afford plentifully, and which is of a very excellent quality. In some cases, this and cow's milk are mixed together, and a highly valuable cheese prepared from them.

The young kids are likewise very excellent food, and two or three are frequently brought forth at a time, often twice in the course of the year.

The hair of the goat is also very valuable for different purposes, as the making of ropes to be used in the water, which are extremely durable. A sort of fluff is also formed from it in some places. It may be sheared in the same manner as wool from the sheep.

The fleece of the goat is excellent, the animals being in some places, as in Caarmovonsiro, killed merely for the object of their fleece; which is capable of being made into candles of a superior quality to those of the common kind.

Their horns constitute valuable handles for tucks and pen-knives. The skin of the young kid is well suited to the glove manufacture, from its taking on a dye better than any other sort of skin. The old skin is highly useful also, being in many cases preferred to that of the sheep; besides, the flesh affords a cheap and abundant food for the winter months, especially when the kids have been fed early to market. The calves of the goat are often salted and dried, and supplied all the uses of bacon; and are known by the Welsh under the name oeub yr wedden, or hung venison.

In choosing goats for keeping, the following directions should
should be attended to. The male should have a large body, with long hair, and straight fluff legs, the neck should be plain and short, the head small and flender, the horns large, the eyes prominent, and the beard long.

The female ought to have a large wadder with well fixed teats, and with none or very small horns.

Goats are kept in flocks, in order that they may have the use disposition to struggle; and they should have good shelter both for summer and winter, great heat and cold being equally injurious to them.

The period of coupling them is about December. They are mostly kept without litter in the winter season, in clean paved yards or other places.

The kids may be prepared for the table in a manner familiar in some degree to that of the lamb. They have been vulgarly supped useful in stables from the disagreeable odour that issues from the males at particular seasons, but there are probably no real grounds for such a conclusion.

Goat-fish, Caprius, in Ichthyography, the name of a fish, called also by some caper. It is a species of Ballistes. In the middle of its back it has three very strong and large prickles, the first of which is three times as large as any of the others, and all are connected by a membrane.

The whole fish is covered with a scaly skin; but the scales have more the appearance of those of a salmon than those of the fish; for they are placed in cancelled lines intersecting one another, and are so well fixed, that they can only come off; and wood or ivory may be polished with the skin, as with the common fish-skin used by the turners, &c. It is of a blue-green colour, spotted with a fine blue, and the back and belly fins are black, with some blue and red spots. Its whole figure is very broad and flat, as well as short, so that it approaches to a round form. It seldom exceeds two pounds in weight. It is caught in the Mediterranean, but not commonly. The skin of it is frequently found in the cabinets of the curious.

Goat Islands, in Geography, two small islands near the S. coast of Jamaica, they are denominated Great and Little; the former is situated in N. lat. 17° 53'. E. long. 76° 51'; and the latter about a mile N. W. from it.

Goat Field, the southermost of the Bashee islands, in the East Indian sea. N. lat. 20° 6'. E. long. 121° 30'.—Allo, a small island among the Philippines, near the S. W. coast of Luzon. N. lat. 13° 57'. E. long. 120° 13'.—Alfo, a small island of America, in the latitude of Rhode Island, opposite to the town of Newport, and on which is Fort Washington.

Goat’s Beard, in Botany. See Tragopogon.

Goat’s Eye, in Surgery. See Eye.

Goat’s Horn, petrified. In Dr. Grew’s “Rarities of Gra- fiham College,” p. 257, a Tephrites hurtii, or goat’s horn, in that collection, is described as broken at both ends, about six inches long, and 2½ inches across at the broadest part, the belly an inch over and furrowed, the back somewhat edged, of an ashen colour, inwardly blue grey, outwardly mixed with oblique and white streaks, bended, one end thicker than the other; it is added, that such are found in Germany, Moravia, Silesia and other parts, and effervesce with nitric acid.

In the Analysis of the Labours of the French national Institute for 1809, it is mentioned that M. Cuvier in the alluvial soils near Etampes has discovered horns, some of which do not seem to differ essentially from the horns of the existing species of goats. The evidence in neither of the above cases, or any other which we have seen, is sufficiently strong to prove the fossil horns of this clafs to have really belonged to goats; and analogy would justify us rather, in referring them to the extinct race of animals, fish, and vegetables with which the strata are so abundantly flored, in some parts of the series.

Goat’s Rue. See Galega.

Goat’s Suckers. See Caprimulgus.

Goat’s Stones, greater. See Lithrolphus.

Goat’s Stones, lesser. See Orchis.

Goat’s Thorns. See Anthriscus.

GOATFIELD, in Geography, a mountain of Scotland, in the island of Arran; the summit of which is 2842 feet above the level of the sea.

GOAVE, GRAND, a town of the island of Hispaniola; 10 miles S.W. of Leogane.

GOAVE, Petit, a sea-port town of the island of Hispaniola, with a harbour capable of receiving vessels of the largest size safe from winds; in its environs are plantations of sugar, coffee, indigo, and cotton. The town is the emporium to which the inhabitants of Grand Goave, and other places, fend their commodities; 26 miles W.S.W. of Leogane. N. lat. 18° 26'. W. long. 73° 37'.

GOBAN, a town of Persia, in the province of Chufidan; 75 miles S. of Sujur.

GOEB, or Geob, a small island in the mouth of the Euphrates, or Shat el Arab, at the entrance into the gulf of Peria, with a town upon it; 50 miles E.S.E. of Baffora. N. lat. 35° 10'. E. long. 48° 25'.

GOBANNIUM, in Ancient Geography, a town of Brit- ain, placed in Antionius’s itinerary between Burrim or Ukle, and Magnus or Kencheller, 12 miles from the former and 22 from the latter, and supped to be Abergavenny, which was.

GOBI, in Geography, a country of Africa, between that of Camma, and cape Lopez Gonfalvo; the chief trade of which consists in elephants and ivory. The chief town is about a day’s journey distant from the Atlantic. N. lat. 1° 30'. See Camma.

GOBBINS, in Mining, is a name with the colliers of several districts for the hole-ling fluff and other refuse of their works; also for the hollows or spaces behind them, into which they throw the refuse coal, earth, and stones: which latter are also called waffles and old-hollows.

In the coal-pits about Wednesbury in Staffordshire, and at Donifhorpe, Danby-Hall, &c. in Derbyshire, the gobbins take fire spontaneously after some time, unless the air is excluded from them, owing to dunes, tow, taw or cat-dirt, a thin stratum found near the coal, which heats, fires, and spontaneously inflames, by the contact of air and moifure. At Donifhorpe they encase their gobbins in walls of tempered clay at certain distances, for excluding the air.

GOBBS, otherwise Cobblers, are pieces of coal from the size of walnuts to that of a man’s fist or larger, which are occasionally picked or raked out of the deck or refuse small coals at the collieries, either by poor persons, who are allowed to do so, or for sale. These are what in London, and many places in the east and south of England, would be called round-coals and highly valued on account of the absence of very small or dust coals among them. When the situation among the buyers and dealers is for large coals, as about Wednesbury in Staffordshire, and the Crewe vale in Derbyshire and Nottinghamshire, an inconceivable waste is made of cobbles and fiek: in working the thick coal about Wednesbury a heap of such, six or seven yards thick, is said to be left and wafted on the floor of their works; and
and to occasion a further waste of a rib or wall of solid coal, round each hall or chamber, for excluding the air, which would otherwise fire the walls of its. See Gobelin.

GOBELINS, a celebrated manufactury, established at Paris, in the Faubourg St. Marcel, for the making of tapestry, and other furniture for the use of the crown. The house where this manufactury is carried on was built by two brothers, Giles and John Gobelins, both excellent dyers; and the first that brought to Paris, in the reign of Francis I., the secret of dyeing that beautiful scarlet colour still known by their name; as well as the little river Biere, on whose banks they fixed their dye-house; and which is now known by no other name than that of the river of the Gobelins.

It was in the year 1667 that this place, till then called "Gobelins' Folly," changed its name into that of "Hotel Royal des Gobelins," in consequence of an edict of Louis XIV. Mon. Colbert having re-established, and with new magnificence enriched and completed the king's palaces, particularly the Louvre and Thalieries, began to think of making furniture suitable to the grandeur of those buildings; with this view he called together all the ablest workmen in the divers arts and manufactures throughout the kingdom; particularly painters, tapestry-makers, sculptors, goldsmiths, enamellers, &c. and by splendid offers, pensions, privileges, &c. called others from foreign nations.

And to render the intended establishment firm and lasting, he brought the king to purchase the Gobelins, for them to work in, and draw up a system of laws, or policy, in fourteen articles.

By these it is provided, that the new manufactury shall be under the administration of the superintendent of the king's buildings, arts, &c. that the ordinary masters thereof shall take cognisance of all actions and proceedings brought against any of the persons in the said manufactury, their servants and dependants; that no other tapestry work shall be imported from any other country, &c.

The Gobelins has ever since remained the first manufactury of this kind in the world. The quantity of the finest and noblest works that have been produced by it, and the number of the best workmen bred up therein, are incredible; and the present flourishing condition of the arts and manufactures of France is, in a great measure, owing there-to.

Tapestry work, in particular, is their glory. During the superintendence of Mr. Colbert, and his successor M. de Louvois, the making of tapestry is said to have been practiced to a degree of perfection, hitherto inferior to what was before done by the English and French.

The battles of Alexander, the four seasons, four elements, the king's palaces, and a series of the principal actions of the life of Louis XIV. from the time of his marriage to the first conquest of Franche Comte, done from the designs of M. le Brun, director of the manufactury of the Gobelins, are master-pieces in their kind.

GOBEMOUCHE, the fire-creater lizard, a species of American lizard that is always employed in catching of flies. It is the smallest of all the lizard kind, and is very beautiful, its skin often appearing as if covered with leaf-gold, or leaf-silver, and in some others of a green, or red and gold, wonderfully bright and beautiful. They are not at all shy or fearful of men, but as they do not hurt, so they seem to dread none; they enter chambers and closets, and do no sort of damage, but destroy the flies and other troublesome vermin they find there. Their whole lives seem spent in the chase of these insects, and it is a very pleasing thing to observe the various ways they have of catching them. They are very cleanly creatures, and may be suffered to run over the table at meal times; where, if they see a fly, they will pursue it over the very hands and clothes of people, or over the dishes, without doing the least hurt.

Notwithstanding their great beauty while alive, they are only of a duncky grey when dead, all their other colours immediately vanishing.

GOBEMOUCHE, in Ornithology, a name given by Buffon to several species of Lanius, Todas, Turdus, Muscicapula, and Motacilla, which he describes.

GOBIN, St., in Geography, a town of France, in the department of the Aine; celebrated for its manufacture of plate-glass; 4 miles S. of la Fere. See GLASS.

GOBIO, in Ichthyology, a species of Cotops; and also of Cyprinus, which he describes.

GOBIUS, a genus of the thoracic order, polliing, according to Linnaeus, the following essential character. Head small, eyes approximated, with two punctures between; gill-membrane four-rayed; body small, compressed on each side, covered with small scales, and furnished with a small tubercle behind the vent; the ventral fins united into an oval or funnel shape; and the dorsal fins two in number.

At the time Linnaeus wrote his Systema Naturae, the above character was probably found sufficiently explicit to embrace, in a correct and lucid order, all the species of this natural tribe of fishes, with such proficiency of the period known. This, however, it must be confessed, is not precisely the case at present. The number of species has been materially augmented by the recent discoveries of naturalists, and among these are certain kinds which exhibit differences essentially different from each other; though small, in the idea of the Linnean student, they can be only referable to the genus Gobius; while others, no less intimately allied, cannot, without a palpable innovation on the order of nature, be confounded to that genus. The later French writers, as Latreille, Bosc, and others, after the example of Lacépéde, divide the Linnean Gobius, and their natural affinities, into four distinct genera, namely, Gobius, Gobioneis, Gobionapus, and Gobionemobius, an extension perhaps requisite, or at least admissible. This extension is indeed, in our own opinion, rather defensible, and we refrain from adopting it only to avoid that degree of perplexity which might probably result from the dispersion of the species into the several distinct articles, which would then become necessary. For this reason, we propose to concentrate the whole in one point of view, observing only to refer the species respectively to their different genera, as we proceed, and by this means leave it to the judgment of the reader, whether the recently established genera ought to be in reality considered essentially distinct, or only constituting the natural subdivisions of the Linnean genus Gobius.

The habits of these fishes in general appear to correspond; they are chiefly inhabitants of waters contiguous to the shores, and its concealed among the rocks, under stones, or in the sand and mud of seas and rivers; they feed on worms, insects, and the spawn and fry of fishes; and adhere firmly to the rocks or other hard substances by means of their central fins.

Species.

Genus Gobius—Ventral fins united; dorsal fins two.

† Section. Pectoral fins attached close to the body.

BODDAERT. Rays of the anterior dorsal fin cirrionate, the third very long. Pallias.

Anno.
G O B I U S.

A native of the Indian seas, in common about six inches in length, and never exceeding eleven or twelve inches. The head thick, blunt, and somewhat convex, with spots of brown and white; crown convex, and gradually sloping down; jaws of nearly equal length; lips thick and fleshy; eyes vertical and oblong; gill-membrane livid. The body is rather convex, tapering slightly towards the tail, and covered with small and soft scales; the colour blueish brown above, beneath pale yellow, inclining to whitish; the back marked with a longitudinal series of seven brown spots, beneath which, on the sides, are seven other spots of the same colour; but these latter are speckled with white; the vent, which is situated rather nearer the head, is surrounded by a black circle, behind which is a conic peduncle. The dorsal fins are blueish black, the first including five rays, has the membrane spotted with white; the membrane of the second is remarkable in having six white lines between each ray, these rays are fetaeous, and amount to twenty-five in number; the pectoral fin is roundish, and includes twenty-one rays; ventral, thirty-four; and, twenty-five; and the tail, which is blueish white, eighteen rays.

L A G O C E P H A L I S. Upper jaw hemispherical; no tongue and lateral line. Pallas.

The native place of this species is uncertain; it was first described by Kolreuter, in the Transactions of the Royal Academy of Peterburgh, and afterwards by Pallas in his "Spicilegia Zooloigica." The head is short, thick, and delimited of scales, the mouth transverse; eyes dilated, small, and covered with a common skin; upper jaw very thick, the lower with a few larger teeth, which are a little hooked; the lips ekef in the middle, doubled, the upper fleshy and very thick, and also reaching much beyond the jaw; palate with numerous crowded teeth of small size on the margin. The body round, compressed towards the tail, of a grey or brown colour, and covered with minute scales; vent in the middle of the body. The first dorsal fin contains six rays of a simple form, the rays in the second fin, like those of the tail, are brachial, and amount in number to eleven; the pectoral fin lanceolate oval, with fifteen rays; ventral, with eight short crowded rays; anal, ten rays; and, caudal, twelve. The total length of this fish about three or four inches.

C Y P R I N O I D E S. Body covered with large sub-ciliated scales; tail rounded; the membrane connecting the rays tefollute with brown. Pallas.

About the size of a finger, the body of a compressed form, thickish, convex, grey brown above, beneath whitish; skin soft and ciliated with fine lines; teeth minute and nearly equal; tongue flat, soft, and obtuse; eyes lateral and between them a blackish semi-lanceolate crest; rays of the fins mostly branched; lateral line obfolete. The species inhabits Ambôna.

Inhabits the brooks and rivers of Martinico, where Plu- nier saw it in great abundance. The body is oblong, and covered with round imbricated scales, which are larger on the posterior part. The head is long and truncate; the eyes vertical with black pupil, and golden iris; jaws equal; tongue soft and acute; cheeks blueish edged with red; lateral line in the middle of the body, and the vent nearer the head; dorsal and anal fins with simple, soft, dilate rays, connected by a thin membrane; rays of the first dorsal membrane extended far beyond the membrane; between the dorsal fins on each side a brown spot; pectoral fin yellow edged with blue; tail at the base greenish yellow, the edge violet. The flesh excellent.

MINUTUS. Whitish, spotted with ferruginous: rays of the dorsal and caudal fins obscurely streaked with the latter. Donov. Gobius minutus; albicans ferrugineo-marainalis, radix dorsofalse, et caudalis ferrigino osse4e, forestis, Pallas. Mi nutus or spotted goby. Pennant.

"The minute or spotted goby is a pretty, delicate, little creature, whose usual length very rarely exceeds two inches and a half, or at the utmost three inches. Pallas, who describes this species, defines its character with much precision; he speaks especially of the oblique streaks across the rays of the two dorsal fins and tail, which are sufficiently distinct, except when the fins happen to be considerably expanded, at which time they indeed appear as so many series of connected dots. These streaks, or dots are uniform and confluent in all the specimens of the fish that have fallen under our observation, varying a trifle only in the tint or density of colour.

"Bloch does not include this species in either of his works on fishes. Pennant considers it as the Gobius aphya of Linnaeus, in which particular later writers are mistaken; it must however be confessed, that there still remains some little doubt as to the precise difference between the aphya and minutus; Linnaeus tells us the former has the body and fins barred with brown, and this will, in a certain degree, apply to the characters of minutus. That the spotted goby is the minutus of Pallas cannot admit of doubt.

"It has been imagined, on the authority of Mr. Pennant, that the spotted goby appeared on our coasts only during the summer months, and was besides extremely local. This idea is certainly unfounded, for we have received them from various parts of the sea-coast in all seasons of the year. In the wide sweep of sands, called Traeth Levan, which extends along the south-fide of Beaumaris bay; upon the shores of the Severn; and also many other of our sandy coasts, this diminutive fin has attracted our remark swimming or lurking among the shrimps in the shallow pools left by the sea at ebb-tide. The same species is likewise not infrequently captured with the sprats, at a short distance from the shore.

"In the first dorsal fin are fin rays, in the second eleven; the pectoral fin contains twenty rays; the ventral, nineteen; anal, eleven; and tail sixteen.

We have been the more explicit in detailing the character and history of the spotted goby, in order to enable the reader to comprehend the precise difference between this and the following species.

A P H Y A. Body and fins barred with brown. Linn. Muf. Ad. Fr. Gobius uniculus, pinnar dorso fuscatae ocularum 17; Art. Described as a very small species found in the Nile and some parts of the Mediterranean; the length about an inch. The first dorsal fin, as in minutus, contains six rays, the second fifteen or seventeen; pectoral, according to Linnaeus, eighteen, or one less, as Artedi mentions. Linnaeus states the number of rays in the ventral fin at twelve, Artedi at only six, and in describing those of the anal fin they differ again, these being, as Artedi informs us, no more than eleven, though Linnaeus says they amount in number to no less than fourteen.

This is an inhabitant of the European and Mediterranean seas; its length is from four to five inches; the body above brown, beneath whitish, and the whole covered with scales. The head is compressed; pupil of the eye black with the iris white; the back slightly arched; jaws of equal length, and armed with numerous small teeth; the lateral line straight.
straight, blackish, and placed in the middle of the body. The colour of the fins, which is blue, constitutes, according to Bloch, the characteristic distinction of this particular species. Its haunts are the sandy shores of the sea, and its food telsaceous animals, crabs, and other marine creatures. Though highly prolific, it is observed not to multiply very fast; its eggs being eagerly sought after by the larger kinds of fishes. The flesh is indifferent, being hard and meagre.

Whitish, covered with large, round, and smooth scales, and marked on the back near the gill-covers with an ample violet spot; both the dorsal fins of equal length, the first containing five rays, the second eleven; pectoral fin twenty; ventral, ten; anal, nine; and tail ten. The species inhabits China.

A fish of small size found in China: the first dorsal fin contains five rays, the second twenty-six; pectoral, nineteen; central, twelve; anal, twenty-five; and caudal, fifteen.

**Bicolour.** Fusce; all the fins black. *Linn.—Brinii pice.

Length from three to four, or rarely exceeding six inches, and inhabits the Mediterranean sea. The rays of the fins project very considerably above the connecting membrane.

**Cuvier.** Mouth plicate with red; rays of the dorsal fins reaching above the membrane. *Brinii*.

About a span in length, the mouth, gill-covers, chin, and fins plicate with fangulous red spots; beneath the eyes a transverse membrane-like line, and two others placed longitudinally before the dorsal fin; fins generally brownish, with fleshy rays; pectoral rounded; ventral blue, with the rays split at the end; tail pointed and slightly banded with black. *Gmelini* is inclined to think this may be only a variety of the species *Jozoi*.

**Pagonellus.** Tail and second dorsal fin purplish at the base; the first dorsal fin edged with a yellowish line. *Linn.* *Gobius pagellus*, Halieuton.

Length three, four, or six inches; the body slightly compressed and whitish, with a green tinge, and marked with blackish dots or small spots. Native of the Mediterranean.

**Arabicus.** Five posterior rays of the first dorsal fin terminating in a red filament twice the length of the membrane. *Forsk.*

Native of Djidda in Arabia. The body is about the size of the little finger, and of a greenish-brown colour, with numerous confluent violet spots and speckles of blue; skin soft and covered with minute firm scales; fins spotted; tail cuneated.

**Nebulosus.** Second ray of the first dorsal fin ending in a black filament twice as long as the body. *Forsk.*

Inhabits the same sea as the former, and nearly the same size; body whitish, with brown clouded confluent spots, beneath white without spots; scales rhombic and rigid; pectoral fins glaucous; with oblique brown spots at the base; ventral; dorab fin and tail transparent, dotted with brown; anal fin hyaline, with the outer edge black. *Pleuranus.* Upper jaw prominent. *Forsk.*

This, according to Plummer, inhabits the rivers of the Antilles in great numbers, and is in much esteem for the table, its flesh being of good flavour, and very wholesome. The body is round, fleshy, above tawny, yellow on the sides and white beneath; the whole covered with small scales; head large; vent in the middle of the body; lateral line straight.

**Genus Gobius.**

Ventral fins united; dorsal fin one; head small; gill-covers close nearly throughout their contour.

**Melanurus.**
GOB

**Section. Pectoral fins attached or placed on a free or elongation.**

KOELEUTER. Ventral fins divided; first dorsal fin with eleven rays. Pallas.

Length about nine inches, the body soft, fat, and whitish-grey; head long, thick, and convex in front; eyes on the top of the head; lips doubled and fleshy; teeth unequal, conic, the anterior ones larger, and one larger on each side above; aperture of the gills limited; lateral line impressed; vent about the middle of the body with a peduncle behind; fins soft; the first on the back large and brown, with a black terminal band, the rays finous; the second narrower, yellowish, with a longitudinal deep brown band, and branched rays; pectoral fan-shaped or oval, and placed on a broad pedicle; tail oval and lanceolate, with ramose rays.

Genus Gobionurus.

Head small, with the eyes approximated; gill-covers closed nearly throughout their contour; dorsal fin two.

PISONIA. Ventral fins divided; lower jaw longer. Gmel. Amare pisum, P.fo. A small species found in South America. The head is depressed and covered with scales in size equal to those on the back; the mouth furnished with several rows of teeth; and the tail rounded.

Genus Aper, a name given by Geofner and others to a species of perch called by many after piceiulis, a name confounding it with many other different fishes, and by Liuaus perca. It is distinguished among the perch tribe by Artedi under the name of the perch with eight or nine black lines on each side. See PERCA.

Genus Fluviatus, or Gudgeon. See Cyprinus Gobio. Genus Marius, O. Gob. Gobius Niger. Goble, or Gobelet, a kind of drinking cup, or bowl; ordinarily a round figure, and without either foot or handle.

The word is French, goblet; which Salmasius, and others, derive from the barbarous Latin cupa. Budens deduces it from the Greek μελλον, a sort of cup.

Goplets, made of the wood tamaliik, are ranked among medicinal drugs; because the liquors infused a while therein, are supposed to acquire a quality which renders them good in diseases of the spleen.

GOBONE, or Gobony, in Heraldry, the same as con.

GOBYANGAN, in Geography, a town of Bengal; eight miles 8. E. of Goragot.

GOCEY, a town of Hindoojtan, in Allahabad; 30 miles N. of Gazypour.

COCH, a town of France, in the department of the Roer, and chief place of a canton, in the diocese of Cleves, situated on the Niers, surrounded with walls in 1291, and containing three churches; 12 miles 8. of Cleves. The place contains 2412, and the canton 12,728 inhabitants, in 19 communes.

GOCHELINUS, RODOLPHUS, in Biography, a physician, was born at Wittenberg in 1572. His father was professor of logic at Marburg, where he subject of this article studied medicine, and obtained the degree of doctor in May, 1601; and was himself elected professor of philosophy in 1665, and also professor of mathematics in 1612. He died on the 2d of March 1621, at the age of 40. Although his life was not long, by extreme industry he had written a considerable number of treatises, in which he evinced much of the spirit of Paracelsus, of whom he was a zealous follower. It is unnecessary to enumerate the long list of titles to his works, which relate to philosophy, mag-
M. Hallenberg, a Swedish writer, in a work published at
Stockholm in 1796, and entitled "Dissertatio historica et
philosophica de origine nominis Dei," &c. suggests
that the names given by different nations to the deity
might denote unity; as the word God itself, by which in all
the Teutonic dialects the Supreme Being is
denominated.

Philologists have hitherto considered the word God
as being of the same signification with God; and this
is not denied by M. Hallenberg. But he thinks, that
both words originally denoted unity; and that the root is
유 in Hebrew, whence the Syr. Chait and Goda; the Arab.
א and God; the Persic cedu and cedu; and the Greek
α and αι; and the Teutonic God; and the German Gotz; and
our Saxon God. The other names of God, this author
thinks, are referable to a similar origin.

By his immateriality, intelligence, and freedom, God
is distinguished from all finite, perfect, and
free; as of good nature, wisdom, and power; who
made the universe, and continues to support it, as well as
to govern and direct it by his providence.

The Rabbins and Hebraists, particularly St. Jerom, and
the interpreters, reckon up ten different names of God
in Scripture; which are א, ב, ג, ד, ה, י, ק, ל, מ, נ,
Elohim, or in the singular, א, ב,ג, ד, ה, י, ק, ל, מ, נ,
Eloah, or in the singular, א, ב,ג, ד, ה, י, ק, ל, מ, נ,
Shaddai, or Jebovasb; but it is wrong to
divide א, ב,ג, ד, ה, י, ק, ל, מ, נ, " by one name
thenbeitah, i.e. God of hosts. Of these
names there are three which express the essence of God,
and are proper names; א, ב,ג, ד, ה, י, ק, ל, מ, נ,
Jebovasb: the others are only names of attributes. St. Jerom
gives a particular explanation of these ten names, in his
epistle to Marcella; and Buxtorf the younger has an express
dissertation on the same, "Dissertatio de Nominibus Dei." The
Jesuit Socquet has three several discourses on the three
names, א, ב,ג, ד, ה, י, ק, ל, מ, נ, Shaddai, and Jebovasb,
printed at Paris, 1715.

The Hebrews call the name of God י and the
Greeks, after this example, Τυραννους, as consisting
of four letters, which it is observed to do in most
languages: thus, in the Hebrew God is called י, Jebovasb,
in the Greek, Θεός; in Latin, Deus; in Spanish, Dios; in
Italian, Dio; in French, Dieu; in the ancient Gaulish,
Dios; in ancient German, Diet; in the Slavonic,
Bog; in Arabic, Alla; in the Polish, Bóg; in the Pannonian,
Jha; in the Egyptian, Tnu; in the Persian, Sir; in the
language of the Magi, God. But a distinction ought here
to be made between the name God, and the name of God;
it being the latter, not the former, that in the Hebrew
consists of four letters. The name or word God, in the
Hebrew, is י, Eloah, which consists but of three letters;
or in the plural, י, Elohim, which consists of five.
The name of God is י, Jebovasb, which is the true
name of God, or the name of four letters among
the Hebrews and Greeks. But it is not this name that answers
to the Greek Θεός, Latin Deus, English God, &c. It
is, as י, Jebovasb, is in the Hebrew.

GOD

GOD
G O D.

It is confessed, that God exists necessarily; and by the
same necessity he exists always, and every where. Hence,
also, he must be perfectly familiar; all eye, all ear, all brain,
al arm, all the power of perceiving, understanding, and
acting; but after a manner not at all corporeal, after a man-
ner not like that of men, after a manner wholly to us un-
known.

He is definite of all body, and all bodily shape; and
therefore cannot be seen, heard, or touched; nor ought to
be worded under the representation of any thing corpoe-
real.

We have ideas of the attributes of God, but do not
know the substance even of any thing: we see only the
figures and colours of bodies, hear only sounds, touch only
the outward surfaces, smell only odours, and taste tastes; and
do not, cannot, by any sense, or any reflex act, know their
inward substances; and much less can we have any notion of
the substance of God.

We know him by his properties and attributes; by
the most wise and excellent structure of things, and by final
causes; but we adore and worship him only on account of
his dominion; for God, setting aside dominion, Providence,
and final causes, is nothing else but fate and nature." Newt.

An ingenious divine has wrought these thoughts of that
admirable philosopher into form, and ripened them into a
more express syllum, in a discourse on this subject. Max-
well's Difc, concerning God.

We shall here subjoin a compendious abstrakt of the prin-
cipal arguments that have been alleged in proof of the ex-
itence of God. The admirable metaphysician and divine,
Dr. Clarke, has demonstrated this truth, with that clearness
and force of reasoning, for which he is so eminently dif-
tinguished, by a series of propositions, mutually connected
and dependent, and forming a complete and unanswerable
argument in proof both of the being and attributes of the
Deity. 1. Something has existed from all eternity; for,
free something now is, something always was: otherwise the
things that now are must have been produced out of nothing,
absolutely and without cause; which is plain contradiction
in terms. 2. There has existed from eternity some one un-
changeable and independent being: or else, there has been an
infinite succession of changeable and dependent beings pro-
duced one from another in an endless progression, without any
original cause at all. From without, this series of beings
can have no caufe of its existence, because it includes all
things that are or can ever were in the univerfe: nor is any one
being in this infinite succession self-existent or necessary, and
therefore it can have no reason of its existence within itself
and it was equally possible, that from eternity, should
never have existed any thing at all, so that a succession of
such beings should have existed from eternity. Consequent-
ly, their existence is determined by nothing; neither by any
necessity of their own nature, because none of them are self-
existent; nor by any other being, because no other is sup-
posed to exist. 3 That unchangeable and independent be-
ing, which has existed from eternity, without any external
da of its existence: must be self-existent, i.e. it must exist
by an absolute necessity originally in the nature of the thing
itself, and antecedent in the natural order of our ideas to our
supposition of its being. For whatever exists must either
have come into being out of nothing without cause; or it must
have been produced by some external cause; or it must
be self-existent: but the two former suppositions are contrary
to the two first propositions. From this last proposition it
follows, that the only true idea of a self-existent, or necessi-
tively existing being, is the idea of a being, the supposition
of whose non-existence is an express contradiction; and this
idea is that of a most simple being, absolutely eternal and in-
finite, original and independent. It follows also, that noth-
ing is so certain as the existence of a supreme independent
cause; and likewise that the material world cannot possibly
be the first and original being, uncreated, independent, and of
itself eternal; because it does not exist by an absolute nece-
nity in its own nature, so as that it must be an express con-
tradiction to suppose it not to exist. With respect both to
its form and matter, the material world may be conceived
not to be, or to be in any respect different from what it is,
without a contradiction. 4 and 5. The subsistence or essence
of the self-existent being is absolutely incomprehensible by
us; nevertheless, many of the essential attributes of his na-
ture are strictly demonstrable, as well as its existence. The
self-existent being, having no caufe of its existence but the
absolute necessity of its own nature, must of necessity have
existed from everlasting, without beginning, and must of
necesity exist to everlasting, without end. 6. The self-
existent being must of necessity be infinite and omnipotenti.
Such a being must be everywhere, as well as always, unal-
terably the same. It follows from hence, that the self-exist-
ent being must be a most simple, unchangeable, incorruptible
being; without parts, figure, motion, divisibility, and
other properties of matter, which are utterly inconsistent
with complete infinity. 7. The self-existent being, must of
necesity be but one, because in absolute necessity there can
be no difference or diversity of existence; and, therefore,
it is absolutely impossible, that there should be two indepen-
dent self-existent principles, such e.g. as God and matter.
8. The self-existent and original cause of all things must be
an intelligent being. This proposition cannot be demon-
strated strictly and properly a priori; but a posteriori the
world affords undeniable arguments to prove that all things
are the effects of an intelligent and knowing cause. The
cause must be always more excellent than the effect; and,
therefore, from the various kinds of powers and degrees of
excellence and perfection, which visible objects posses from
the intelligence of created beings, which is a real distinct
quality or perfection, and not a mere effect or composition of
unintelligent figure and motion; from the variety, order, beau-
ty, wonderful contrivance, and fitness of all things to their
proper and respective ends; and from the original of motion;
the self-existent creating being is demonstrated to be intelli-
gent. 9. The self-existent and original cause of all things
is not a necessary agent, but a being endued with liberty and
choice. Liberty is a necessary concomitant of intelligence:
without liberty, no being can be said to be an agent, or
cause of any thing; since to act necessarily is really good
and proper not to act at all, but to be acted upon. Besides,
if the supreme cause be not endued with liberty, it will follow,
that nothing which is not could possibly have been; that
nothing which is could possibly not have been; and that
no mode or circumstance of the existence of any thing could
possibly have been in any respect otherwise than it now actu-
ally is. Further, if there be any final cause in the universe,
the supreme cause is a free agent; and on the contrary sup-
position, it is impossible that any effect should be finite;
and in every effect, there must have been a progression of
causes in infinitum, without any original cause at all. 10. The
self-existent being, the supreme cause of all things, must of
neceshty have infinite power; since all things were made
by him, and are entirely dependent upon him; and all the
powers of all things are derived from him, and perfectly sub-
ject
God.

ject to him; nothing can resist the execution of his will.
11. The supreme cause and author of all things must of necessity be infinitely wise. This follows from the propositions already established; and the proof a priori, of the infinite wisdom of God, from the consideration of the perfect and consummate excellency of his works, is no less strong and undeniable. 12. The supreme cause and author of all things must of necessity be a being of infinite goodness, justice, and truth, and all other moral perfections such as become the supreme governor and judge of the world. The will of a being, infinitely knowing and wise, independent and all-powerful, can never be influenced by any wrong affection, and can never be misled or opposed from without; and, therefore, he must do always what he knows to be done; that is, he must act always according to the strictest rules of infinite goodness, justice, and truth, and all other moral perfections, and more particularly, being infinitely and necessarily happy and all-sufficient, he must be unalterably disposed to do and to communicate good or happiness. See Clarke's Demonstration of the Being and Attributes of God, passim.

To this more abstruse argument a priori, for the existence of God, we may add another, more generally obvious, and carrying irresistible conviction, which is deduced from the frame of the universe, and the traces of evident contrivance and fitness of things for one another that occur through all the parts of it. These confine to prove that the material world, which in its nature is originated and dependent, could not have been the effect of chance or necessity, but of intelligence and design. The beautiful, harmonious, and beneficial arrangement of the various bodies that compose the material system; their mutual dependence and subserviency; the regularity of their motions, and the aptitude of these motions for producing the most beneficial effects; and many other phenomena resulting from their relation, magnitude, situation, and use, afford unanswerable evidences of the creating power and wise disposal of an intelligent and almighty agent. The power of gravity, by which the celestial bodies persevere in their revolutions, detects our particular consideration. This power penetrates to the centres of the sun and planets, without any diminution of its virtue, and is extended to immense distances, regularly decreasing, and producing the most tender and important effects. Its action is proportional to the quantity of solid matter in bodies, and not to their surfaces, as is usual in mechanical causes and therefore, seems to surpass mere mechanism. But however various the phenomena that depend on this power, and may be explained by it, no mechanical principles can account for its effects; much less could it have produced, at the beginning, the regular situation of the orbits, and the present disposition of things. Gravity could not have determined the planets to move from west to east in orbits nearly circular, about in the same plane; nor could this power have projected the comets with all the variety of their directions. If we suppose the matter of the system to be accumulated in the centre by its gravity, no mechanical principles, with the assistance of this power, could separate the large and unwieldy mass into such parts as the sun and planets; and, after carrying them to their different distances, project them in their several directions, preferring still the equality of action and reaction, or the state of the centre of gravity of the system. Such an exquisitely fine structure of things could only arise from the contrivance and powerful influences of an intelligent, free, and most potent agent. The same powers, therefore, which at present govern the material universe and conduct its various motions, are very different from those which were necessary to have produced it from nothing, or to have disposed it in the admirable form in which it now presents.

But we should far exceed the proper limits of this article, if, confining our observation to the earth, our own habitations, we were to enumerate only the principal traces of design and wisdom, as well as goodness, which are discernible in its figure and constituent parts, in its diurnal and annual motion, in the position of its axis with regard to its orbit, in the benefit which it derives from the light and heat of the sun, and the alternate vitiolitude of the seasons; in the atmosphere which surrounds it, and in the different species and varieties of vegetables and animals with which it is replenished. No one can survey the vegetable productions of the earth, so various, beautiful, and useful, nor the various gradations of animal life, in such a variety of species, all preferred distinct, and propagated by a titled law, each fitted to its own element, provided with proper food, and with instincts and organs fitted to its rank and situation, and especially with the powers of sensation and self-motion, and those immediately or remotely subservient to the government and use of man, without admiring the skill and design of the original创建者; for we find there are more signally manifested in the structure of the human frame, and in the noble powers and capacities of the human mind; more especially in the moral principles and faculties, which are a distinguishing part of our constitution, and lead to the perception and acknowledgment of the existence and government of God. In those instances that have now been recited, and a variety of similar instances suggested by them, or naturally occurring to the notice of the curious and reflecting mind, contrivance is manifest, and immediately, without any nice or subtle reasoning,suggests a contriver. It strikes us like a sensation; and artificial reasoning against it may puzzle us, without shaking our belief. No person, for example, that knows the principles of optics, and the structure of the eye, can believe that it was formed without skill in that science, and therefore, Sturmius held that the examination of the eye was a cure for atheism; and another excellent writer, cited below, observes, that if there were no example in the world of contrivance, except that of the eye, it would be alone sufficient to support the conclusion which we draw from it, as to the excellency of an intelligent creator; nor can it be supposed that the ear was formed without the knowledge of sounds; or that the male and female, created and preserved in due proportion, were not formed for each other, and for continuing the species. All our accounts of nature are full of instances of this kind. The admirable and beautiful structure of things for final causes exist outside of the contriver; and the unity of design shows how to be one. The great motions in the system, performed with the same facility as the leaf, suggest his almighty power, which gave motion to the earth and the celestial bodies, with equal ease as to the minutest particles; the subtility of the motions and actions in the internal parts of bodies, shows that his influence penetrates the immost recesses of things, and that he is equally active and present everywhere. The simplicity of the laws that prevail in the world, the excellent disposition of things, in order to obtain the best ends, and the beauty which adorns the works of nature, far superior to any thing in arts, suggest his consummate wisdom. The usefulness of the whole scheme, so well contrived for the intelligent beings who enjoy it, with the internal diffuseness and moral structure of those beings, shows his unbounded goodness. These are arguments which are sufficiently open to the view of cababilities of the unlearned, while at the same time...
fame time they acquire new strength and lucidre from the discoveries of the learned. The Deity's acting and interposing in the universe shew that he governs it as well as formed it; and the depth of his counsels, even in conducting the material universe, of which a great part surpasses our knowledge, tends to preserve an inward generation and awe of this great being, and depiozes us to receive what may be otherwise revealed to us concerning him. His essence, as well as that of all other substances, is beyond the reach of all our discoveries; but his attributes clearly appear in his admirable works. We know that the highest conceptions we are able to form of them are still beneath his real perfections; but his dominion over us, and our duty towards him, are manifest. See Maclaurin's Account of Sir I. Newton's Phil. Disc. Book iv. chap. 9.

Those who wish to see the argument, which has been now stretched out in some of its leading outlines, more fully illustrated and urged, may consult the works of Ray, Newton, &c. and more especially archdeacon Paley in his "Natural Theology, or Evidences of the Existence and Attributes of the Deity, collected from the appearances of Nature." This admirable work, if our limits would allow it, would enable us very much to enrich this article. One atheistic way, says this much approved and popular writer, of replying to our observations upon the works of Nature, and to the proofs of a Deity which we think we perceive in them, is to tell us, that all which we see must necessarily have some form, and that it might as well be its present form as any. Let us now apply this answer to the eye.—"Something or other must have occupied that place in the animal's head; must have filled up, we will say, that socket; we will say also, that it must have been of that sort of substance, which we call animal substance, as flesh, bone, membrane, cartilage, &c.; but that it should have been an eye, knowing as we do what an eye comprehends, viz. that it should have consisted, first, of a series of transparent lenses, (very different, by the bye, even in their substances from the opaque materials of which the rest of the body is, in general at least, composed; and with which the whole of its surface, this single portion of it excepted, is covered); secondly, of a black cloth or canvas (the only membrane of the body which is black) spread out behind these lenses, so as to receive the image formed by pencils of light transmitted through them; and placed at the precise geometrical distance at which, and at which alone, a distinct image could be formed, namely, at the concourse of the refracted rays; thirdly, of a large nerve communicating between this membrane and the brain; without which the action of light upon the membrane, however modified by the organ, would be lost to the purposes of sensation. That this fortunate combination of the parts should have been the lot, not of one individual out of many thousand individuals, like the great prize in a lottery, or like some singularity in nature, but the happy chance of a whole species; nor of one species out of many thousand species, with which we are acquainted; but of by far the greatest number of all that exist, and that under various, not casual or capricious, but bearing marks of being suited to their respective exigences; that all this should have taken place, merely because something must have occupied these points in every animal's forehead; or that, all this should be thought to be accounted for by the short answer, "that whatever was there must have had some form or other," is too absurd to be made more fo by any argumentation."—Nor does it mend the answer to add, with respect to the singularity of the conformation, that after the event, it is no longer to be computed what the chances were against it. This is always to be computed, when the question is, whether an useful or imitative conformation be the produce of chance or not. I define no greater certainty in reasoning than that by which chance is excluded from the present disposition of the natural world. Universal experience is against it. What does chance ever do for us? In the human body, for infancy, chance is the operation of causes without design, may produce a wen, a wart, a mole, a pimple, but never an eye. Among inanimate substances, a cloud, a pebble, a liquid drop, might be; but never was a watch, a telescope, or organized body of any kind, answering a valuable purpose by a complicated mechanism, the effect of chance. In no assignable instance hath such a thing existed, without intention, somewhere. Some have said "that the eye, the animal to which it belongs, every other animal, every plant, and every organized body which we see, are only to many out of the possible varieties and combinations of being, which the lapse of infinite ages has brought into existence; and that the present world is the result of that variety."—But "there is no foundation whatever for this conjecture in any thing which we observe in the works of nature; no such experiments are going on at present! No such energy operates as that which is here supposed, and which should be constantly pushing into existence new varieties of beings; nor are there any appearances to support an opinion that every possible combination of vegetable or animal structure has hitherto been tried." Should it be said that the parts of animal bodies were not intended for the use, but that the use arose out of the parts; this distinction is intelligible."—But "there is little place for it in the works of nature. When roundly and generally affirmed of them, as it has sometimes been, its amounts to such another stretch of aertion, as it would be to say, that all the implements of the cabinet-maker's workshop, as well as his fifh-akin, were substances accidentally configured, which he had picked up and converted to his use; that his adzes, saws, planes, and gimlets, were not made, as we suppose, to hew, cut, smooth, shape-out, or bore wood with; but, that these things being made, no matter with what design, or whether with any, the cabinet-maker perceived that they were applicable to his purpose, and turned them to account." If this kind of solution be applied to those parts of animals, the action of which does not depend upon the will of the animal, it is fraught with still more evident absurdity. It is possible to believe that the eye was formed without any regard to vision, that it was the animal itself which found out, that though formed with no such intention, it would serve to see with; and that the use of the eye, as an organ of fight, resulted from this discovery, and the animal's application of it? The same question may be asked of the ear; the fame of all the fenes, none of which depend upon the ejection of the animal, nor consequently upon its fagicity or experience. Others have chosen to confer every thing to a principle of order in nature. A principle of order is the word; but what is meant by a principle of order, as different from an intelligent creator, has not been explained either by definition or example; and without such explanation, it should seem to be a mere substitution of words for reasons, names for causes. "Was a watch ever produced by a principle of order; and why might not a watch be so produced as well as an eye?"—The confidence," continues the author now cited, "which we place in our observations upon the works of nature, in the marks which we discover of contrivance, choice, and design, and in our reasoning upon the proofs afforded us, ought not to be shaken, as it is sometimes attempted to be done, by bringing forward to our view our own ignorance, or rather the general imperfection of
our knowledge of nature."—"True fortitude of understanding confounds in not suffering what we know to be disturbed by what we do not know. If we perceive an useful end, and means adapted to that end, we perceive enough for our conclusion. If these things be clear, no matter what is obscure. The argument is fulfilled."—"Our ignorance of many points need not suspand our assurance of a few."—"Contrariness," says our author, "if establisht, appears to me to prove every thing which we wish to prove. Amongst other things, it proves the personaliy of the Deity, as distinguished from what is sometimes called nature, sometimes called a principle; which terms, in the mouths of those who use them philosophically, seem to be intended, to admit and express an efficacy, but to exclude and deny a personal agent. Now that which can contrive, which can design, must be a person. These capacities constitute personaliy, for they imply consciousnes and thought. They require that which can perceive an end or purpose; as well as the power of providing means, and of directing them to their end. They require a centre, in which perfections unite, and from which volitions flow; which is mind. The acts of a mind prove the existence of a mind; and that, whatever it be, in which a mind refles, is a person. — "Whenever we see marks of contrivance, we are led for its cause to an intelligent author. And this transition of the understanding is founded upon uniform experience, and a belief, that there may be many second causes, and many causes of second causes, one behind another, between what we observe of nature and the Deity; but there must be intelligence somewhere; there must be more in nature than what we see; and amongst the things unseen, there must be an intelligent designing author;"—"after all the struggles of a reluctant philosophy, the necessary resort is to a deity. The marks of design are too strong to be got over. Design must have had a designer. The designer must have been a person. That person is God." But we must content ourselves with earnestly recommending the works from which these detached extracts are made, to the perusal of our readers; for we cannot do justice to the author's admirable reasoning.

Another argument to prove the existence of God, as the creator and governor of the univerfe, may be deduced from the universal confluent of mankind, and the uniform tradition of this belief through every nation and every age; it is impossible to conceive, that a falhacy fo perpetual and universal, should be imposed on the united reason of mankind. No credible and satisfactory account can be given of this universal confluent, without ascribing it to the original constitution of the human mind, in consequence of which it cannot fail to deter the existence of a deity, and to the undeniable traces of his being, which his works afford. Fear, flate-policy, and the prejudices of education, to which the confluence of mankind in this principle has been sometimes resolved, are founded on this universal principle, suppose it being and influence, and are efculated by it. It is much more reasonable to imagine, that the belief of a God was antecedent to their operation, than that it should have been produced by them; and that it was dictated by reason and experience, independent of the passions and policy of men. The uniform and universal tradition of this belief, and of the creation of the world by the divine power, affords ceurerence evidence both of the principle and of the fact.

The existence of God is also farther evinced by these arguments which have been usually alleged to prove, that the world had a beginning, and, therefore, that it must have been created by the energy of divine power. In proof of this, the history of Mofes, considered merly as the most ancient historian, deserves particular regard. His testimony is confirmed by the most ancient writers among the heathens, both poets and historians. It may be also fairly alleged, that we have no history or tradition more ancient than that which agrees with the received opinion of the world's beginning, and of the manner in which it was produced; and that the most ancient histories were written long after that time. And this conformation is urged by Lucrectius, the famous Epicurean, as a strong presumption that the world had a beginning.

"———Si nulla fuit genitalis origo
Terrarum et cord, femperque externa fueru :
Cur supra bellum Thibaranum, et funera Trojé,
Non alias ali quoque res ecceoares poeta?"

Befides, the origin and progress of learning, and the most useful arts, confirm the notion of the world's beginning, and of the common era of its creation; to which also may be added, that the world itself, being material and corruptible, must have had a beginning; and many phenomena occur to the observation of the astronomer and natural historian, which furnish a strong presumption that it could have had no long duration, and that it gradually tends to dissolution. From all these considerations we may infer the existence, attributes, and providence of God. If we admit miracles, as facts authenticated by credible history, these, considered as deviations from the established course of nature, afford independent evidence of the being of God. See MIRACLE.

God is also used in speaking of the falfe deities of the heathens, many of which were only creatures to which divine honours and worship were superflitiously paid.

The Greeks and Latins, it is observable, did not mean by the name God, an all-perfect being, whereof eternity, infinity, omnipotence, &c., were essential attributes; with them, the word only implied an excellent and superior nature; and, accordingly, they gave the appellation gods to all beings of a rank, or class, higher and more perfect than that of men; and especially to those who were inferior agents in the divine administration, all subject to the one supreme.

Thus men themselves, according to their fystem, might become gods, after death; inasmuch their souls might attain to a degree of excellence superior to what they were capable of in life.

The first divines, father Busius observes, were the poets: the two functions, though now separated, were originally combined; or rather, were one and the same thing. Now the great variety of attributes in God, that is, the number of relations, capacities, and circumstances, wherein they had occasion to consider him, put the poets, &c., under a necessity of making a partition, and of separating the divine attributes into several persons: because the weakness of the human mind could not conceive so much power and action in the simplicity of one single divine nature. Thus the omnipotence of God came to be represented under the person and appellation of Jupiter; the wisdom of God under that of Minerva; the justice of God under that of June.

The first idols, or falfe gods, that are said to have been adored, were the llars, sun, moon, &c., on account of the light, heat, and other benefits which we derive from them. (See IDOLATRY.) Afterwards the earth came to be deified, for furnishing fruits necessary for the subsistence of men and animals. But fire and water became objects of divine worship, for their usefulness to human life. In proof of time, and by degrees, gods became multiplied to infinity; and there was scarce any thing but the weaknesses, or caprices of
GOD

Some devotees or other, elevated into the rank of deity; things
insects, or even defunctive not excepted.

The principal of the ancient gods, whom the Romans
called divi majorum genii, and which Cicero calls civilis
gods, Varro felet gods, Ovid nobles deos, others confrater deos,
were Jupiter, Juno, Vesta, Minerva, Ceres, Diana, Venus,
Mars, Mercury, Neptune, Vulcan, and Apollo. Jupiter
is considered as the god of heaven; Neptune as god of the
sea; Mars as the god of war; Apollo of eloquence, poesy,
and physic; Mercury of thieves, Bacchus of wine, Cupid of
love, &c.

A second sort of gods, called demi-gods, semi-divi, divi mino-
rum genii, indigetes, or gods adopted, were men canonized
and deified. As the greater gods had possession of heaven
by their own right; these secondary deities had it by right
and donation; being translated into heaven because they
had lived as gods upon earth.

The heathen gods may be all reduced to the following
classes:

1. Created spirits, angels, or daemons: whence good and
evil gods; Gemini, Laries, Lemures, Typhoons, guardian
gods, infernal gods, &c.

2. Heavenly bodies: as the sun, moon, and other planets:
also the fixed stars, constellations, &c.

3. Elements: as air, earth, ocean, Ops, Vesta; the ri-
vers, fountains, &c.

4. Meteors: Thus the Persians adored the wind: thou-
der and lightning were honoured under the name of Gery-
on; and several nations of India and America have made
themselves gods of the same. Caltor, Pollux, Teleusa, and
Iris, have also been preferred from meteors to be gods; and
the Pheas has been practiced in regard to comets: what
which appeared at the murder of Caesar. Socrates deified
the clouds; if we may give credit to Ariliophanes; and the
primitive Christians, Tertullian affords us, were reproached
with the same thing.

5. They erected minerals, or follies, into deities. Such was
the Batyllus; the Finlanders adored fomes; the Scythians
iron; and many nations silver and gold.

6. Plants have been made gods. Thus licks and onions
were deities in Egypt; the Selavi, Lithuanians, Celtas,
Vandals, and Persians, adored trees and forests; the ancient
Gauls, Britons, and Druids, paid a particular devotion to the
oak; and it was no other than wheat, corn, feed, &c.
that the ancients adored under the names of Ceres and Pro-
serpina.

7. They themselves gods from among the waters.
The Syrians and Egyptians adored fishes; and the Tri-
tons, Nereids, Syrens, &c. what were they but fishes? Se-
vveral nations have adored serpents; particularly the Egyp-
tians, Puffins, Lithuanians, Samogitians, &c.

8. Insects, as flies and ants, had their priests and votaries:
these among the Thelidans, and those in Armenia, where
bullocks were offered to them.

9. Among birds, the fowl, raven, the sparrowhawk, ibis,
eagle, griffin, and lapwing, have had divine honours; the lift
in Mexico, the relf in Egypt, and at Thebes.

10. Four-footed beasts have had their altars: as the bull,
dog, cat, wolf, baboon, lion, and crocodile, in Egypt, and
elsewhere; the hog in the island of Crete; rats and mice in the
Transal and at Tenos; weasels at Thebes, and the porcupine
throughout all Greece.

11. Nothing was more common than to place men amon-
g the number of deities; and from Besus or Baal, to the Roman
emperors before Constantine, the influences of this kind are
innumerable; frequently they did not wait so long as their
deaths for the apotheosis. Nebuchadnezzar procured his fature
to be worshipped while living; and Virgil shews that Augus-
tus had altars and sacrifices offered to him, Eclog. i. 6, 7
As we learn, from other hands, that he had priests called
Augufalea; and temples at Lyons, Narbona, and several
other places; and he must be allowed the first of the Romans,
in whose behalf idolatry was carried to such a pitch. The
Ethiopians deemed all their kings gods: the Velleda of the
Germans; the Janus of the Hungarians; and the Thau,
Woden, and Afia, of the northern nations, were, indis-
putably, men.

12. Not men only, but every thing that relates to man,
has also been deified: as labour, rest, sleep, youth, age, death,
virtues, vices, occasion, time, place, numbers, among the
Pythagoreans; the generative power, under the name of
Priapus. Infamy, alone, had a cloud of deities; as Vage-
tanus, Levana, Ruminia, Eduba, Potina, Cuba, Cuminia,
Carna, Offaligo, Statulimus, Fabulimus, &c.

They also adored the gods health, fever, fear, love, pain,
indignation, flame, impudence, opinion, renown, prudence,
science, art, hideity, felicity, calmnety, liberty, money, war.

Lastly, nature, the universe, or so a/, was reputed a
great god.

Heothol has a poem under the title of Deipara, i.e. the ge-
genation of the gods; wherein he explains their genealogy and
decent; feds forth who was the first, and principal; who
next descended from him, and what issue each had; the whole
making a sort of fylum of heathen theology.

Beside this popular theology, each philosopher had his
fylum; as may be seen from the Timaeus of Plato, and
Cicero De Natura Deorum.

Justin Martyr, Tertullian in his Apologieges, and in his
book Contra Gentes; Arnobius, Minutius Felix, Laclau
tius, Eufebius, Prepar. & Demontil. Evangel. St. Augustine De
Civit. Dei, and Theodoret Adverf. Gentes, shew the vanity
of the heathen gods.

It is very difficult to discover the real sentiments of the
heathens with respect to their gods: they are exceedingly in-
tricate and confused, and even frequently contradictory.
They admitted so many inferior and inferior gods, who shared
the empire, that all was full of gods. Varro reckons upon
 gods among a small extent of ground, and yet
their number was every day growing. The way to be-
\n
heaven was so easy for the great men of those days, that Juvenal
brings in Atlas complaining he was ready to sink under the
load of such a number of new gods as were daily placed in
the heavens: yet father Maugues seems to have proved that
all the philosophers of antiquity have acknowledged in
that there was but one God. Plan. Theol. des Sct. Scavans.

GODAGARY, in Geography, a town of Bengal; 18
miles N. of Moommedabad.

GODALMING, a market town and parish in the
county of Surrey, England, contains 474 houses and 3435
inhabitants. The town is built in a valley, on the banks of
the river Wey, which is divided into several small streams
here. The chief of these is navigable to Weybridge, where
it unites its waters with the Thames. In the vicinity of
the town are some corn-mills, and paper-mills. Here are several
manufactories for weaving stockings, patent fleece hony
cloth, and coarse woollen cloths; wool-combing and spinning
of worsted also constitutes part of the trade of the place. The
parish
parish of Godalming is divided into nine tythings, and the whole is governed by a warden, eight assistants, and a bailiff. The church is distinguished by its handsomc frieze. In the town are a Quaker's meeting-houfe, two chapels for dissenters, a charity school, and in the immediate vicinity is an hospital for the accommodation of ten poor men. A singular impostion on public credulity and curiosity was practiced in this town about the year 1726. A female, named Mary Tofts, circulated a report that she was pregnant with rabbits, and also excited a very general belief that she had actually been delivered of some of these animals. The impostion, like that of "the Cock-lane ghost," was supported by so much cunning and address, that many persons, among whom were some of the faculty, were deceived, and, for some time, credited the tale. Godalming has a weekly market on Saturday, and two annual fairs. Manning's History and Antiquities of Surrey, folio.

GODAMA, GODEMA, GOAUNA, GOANA, or GONAM, in Indian Mythology, different names applied in various parts of India, and particularly in the Birman empire, to their deity Budha, or Bouddh. (See Bouddh.) Godama or Godama is the most common appellation among his worshipers in India beyond the Ganges; it seems also to be common among the Hindoos, who, according to the account of the Sanerit, write it Gotamans. This name, as some say, literally signifies cow-herd, but metaphorically king; and, according to others, the meaning of Godama is eminently wife, or a fagc. Many other appellations are given to this deity derived from the pastures in which his various images represent him. Godama was probably an Indian prince, deified by superstitition; and in an ancient treatise, giving an account of the religion of Godama, entitled "Zaralaa," Godama is said to have attained divinity at the age of 35 years, to have preached his law for 45 years, and to have brought salvation to all living beings. Dr. Buchanan, who cites this treatise (Af. Ref. vol. vi.) places the death of Godama 546 years B. C. The doctrine and laws, laid in this treatise to be delivered by Godama, consist chiefly in observing the five commandments, and in abjuring from the ten sins. The five commandments are as follow: 1. From the meanest infect up to man, thou shalt not kill any animal whatever. 2. Thou shalt not steal. 3. Thou shalt not violate the wife or concubine of another. 4. Thou shalt tell nothing false. 5. Thou shalt drink neither wine, nor any thing that will intoxicate; thou shalt not eat opium, or any other inebriating drug. The perfon who keeps these five commandments shall attain high rank, and shall not be liable to poverty, nor to other misfortunes and calamities. The ten sins are the killing of animals—thrift—adultery—falsehood—idol—harsh and indignt language—idol and superfluous talk—the coveting of your neighbour's goods—envy and the desire of your neighbour's death, or misfortune—and the following of the doctrine of false gods. Every one who abhors from these sins, will successively increase in virtue through all his five finer transmigrations, till at length he will become worthy of beholding a God, and of hearing his great voice; and he will be exempted from the four human miseries, viz., weight, old age, disease, and death. The good works required are giving alms, and thoughtfully pronouncing three words. Whoever dies without the abstinence and good works here prescribed, will certainly pass into one of the infernal states, and be doomed to certain transmigrations. The priests of Godama are called Rahans in the Birman language, and they have also bestowed upon them the title of Somona or Samana, which is likewise applied to the images of the divinity when he is represented, as he commonly is, in the priestly habit. (See Rahans.) Godama commanded his images and relics to be worshipped. The largest and most celebrated temples are generally in the form of a pyramid; and contain some of these relics, such as a tooth, a bone, a hair, or a garment. To these temples the prayers of the devotees are addressed, and their offerings presented. The images of the god are of various materials; clay, copper, silver, and alabaster. Many of them are richly gilt, and adorned with paintings of flowers; they are of different sizes, some being not above six inches high, and others of a colossal stature. Other objects of great veneration among the worshippers of Godama are stones of large dimensions, carved with various hieroglyphics, and said to represent, or to be the impreffions of his feet. The principal deificales of Godama are by his followers considered as saints; and many images of these, in a priestly habit, accompany that of their master. Every true worshipper of Godama prays before he goes to sleep, and before he rises in the morning, which is generally at the dawn of day.

Besides their private devotions, which are numerous and regularly performed, it is customary to make offerings at the temple; the feasts for which are those of the four phases of the moon, especially the full and change, which may be considered as the Burma fiffhathis. Friday is with them reckoned an unfortunate day, and therefore on this day they undertake no business; but they keep holy no particular day of the week. The tea of Godama effecrs the opinion of a divine being, who created the universe, to be highly impious; and accordingly the flowers of Godama are, strictly speaking, atheistic, as they feep every thing to arise from fate; and their gods are merely men, who by their virtue acquire supreme happiness, and by their wisdom become entitled to impose a law on all living beings. See Birman Empire, and Bouddh.

GODANA, in Geography, a town of Peria, in the province of Irak; 105 miles E. of 11pahan.

GODAVERY, or GONGA GONOWAY, a river of Hindoostan, sometimes called the Gang in Perihtta's History, was, till very lately, considered as the same with the Cottack river, or Mahanadi; but it is now ascertained to be a different river, which has its source about 70 miles N. E. of Bombay; on the western Goutts, more properly called the Sreekien mountains; and, in the upper part of its course, at least, is esteemed a sacred river by the Hindoos; that is, ablutions performed in its stream have a religious efficacy superior to those performed in ordinary streams. The Godavery, after traversing the Dowlatabad boufah, and the country of Tellingana, from west to east, turns to the south-east; and receiving the Bain Gonga, about 90 miles above the sea, besides many smaller rivers, separates into two principal channels at Ramundry; and hence dividing again, they form altogether several tide harbours, for vessels of moderate burden. Ingeram, Caringa, Yanam, Bandarmeines, and Naraposun, are among the places situated at the mouth of this river, which appears to be the most considerable one between the Ganges and cape Comorin. Extensive forests of teak-trees border on its banks, within the mountains, and supply ship-timber for the use of the ports above-mentioned. The Kistnnah and Godavery rivers, however remote at their fountains, approach within 80 miles of each other in the lower parts of their course; and form an extensive track of country, composed of rich vegetable mould, such as is usually found at the mouths of large rivers. Rennell. See Delta.

GOD-BOTE, in our Author Saxon Catalog, an ecclesiastical or church fag, for crimes and offences committed.
G O D

against God. These, according to Blackstone, are opacy and deoey; which fee.

G O D D A R D, JONATHAN, in Biography, an eminent
physician and chemist, was born at Greenwich in the year 1617. After studying for four years at Oxford, he lent out on his travels, and, on his return, settled in practice in London, having taken his degree at Cambridge. He was elected a fellow of the College of Physicians in 1646, and in 1647 was appointed lecturer on anatomy. In conjunction with some friends, he formed a society for experimental
inquiry, which met at his lodgings in Wood-street, and in promoting the objects of which he was extremely affiduous. Having gained considerable reputation, and having, with the rest of his party, sided with parliament, he was appointed by Cromwell chief physician to the army, and in this capacity accompanied the ufferer to Ireland in 1649, to Scotland in the following year, and thence returned with his master, who, after the battle of Worcester, rode into London in triumph, September 28th, 1641. He obtained many favours from Cromwell, who first made him
warden of Merton college, Oxford, afterwards sole representative of that university in the Short Parliament in 1653; and in the same year one of the council of state. These favours were sufficient to procure for him the displeasure of Charles II.; and, being driven from Oxford, he removed to Oriel college, where he had been chosen professor of phy-
sic in November 1655. Here he continued to frequent those meetings, which gave birth to the Royal Society, and was nominated one of the first council of that institution in the charter. Dr. Goddard was a conscientious and able
practitioner. Partly from the love of experimental chem-
istry, principally from a diffidence in the knowledge of apo-
thecaries, he prepared his own medicines, and recommended the practice to be adopted by physicians in general. Finding numerous
obstacles, however, in his way, he published
“A Difcourse, fetting forth the unhappy condition of the practice of physic in London,” 1669. But this was of no avail. He died on the 23d of March, 1674, being feized
with an apoplectic fit in Cheapside, when returning from one of the philosophic meetings. Two papers of his were published in the Philosophical
Transactions, N. S. 137, 138; and many others in Birch's History of the Royal Society.

G O D D E S S, Dea, Diva, a heathen deity, to whom
they attributed the female sex.

The ancients had almost as many goddesses as gods.
Such were Juno, the goddess of air; Diana, the goddess
of woods and charity; Proserpina, the goddess of hell;
Venus, of beauty; Thetis, of the sea; such also were
Victory, Fortuna, &c.

Nay they were not contented to make women gods, and
admit both sexes into the roll; but they had also herma-
phrodite gods. Thus Minerva, according to several of the
learned, was both man and woman, and worshipp'd both
under the appellation of Lomus and Luna. Mithras, the
Persian deity, was both god and goddess, and the sexes of
Venus and Vulcan are very dubious: whence, in the invo-
culation of those deities, they used this formula; “Be thou
god or goddess,” as we learn from A. Gallus. It was
a privilege peculiar to goddesses, that they might be rep-
resented, on medals, naked. The imagination, it was sup-
pofed, must be sav'd, and kept from taking liberties, by
the consideration of the divine character.

G O D E A U, ASTRIDY, in Biography, was born at the
city of Dreux in the year 1625. He was educated for
civil and active life, but having met with a disappointment
in the object of his affections, he repaired to Paris, where
he cultivated the society of men of letters, and was one of the first of those who eblam'd the French academy of
belles letters. This society suggetted to the cardinal
Richelieu the foundation of the French academy, of which M. Godau was an original member. He took orders in
the year 1735; and having enriched his own mind with the
knowledge of Christian morality, he taught them
from the pulpit with much eloquence, and he is said to have
practised them in all his actions. In the year 1636 he was,
by the influence of cardinal Richelieu, nominated to the
bishops of Grafs, and from this time he divided his time
between his studies, and the diligent discharge of his episcopat functions. He found the state of ecclesiastical discipline exceedingly relaxed, and fell about its reformation; he
personally examined the qualifications of the clergy, and
enquired in what manner they discharg'd the important
duties of their office; he frequently preached in different
parts of his diocese, and exhibited in his own life an admi-
able model of those virtues which he was anxious to re-
commemorate the attention of his flock. He was in high
favour with pope Innocent X., who granted him bulls of
union of the bishopric of Venice with that of Grafs, but
when he found that the people and clergy opposed the mea-
sure, he chose rather to give up his pretentions, than break
in upon the peace of the church. He died in 1672, at the
age of sixty-seven years. He was a considerable writer,
chiefly on subjects connected with his profession, but his
most important work was “The History of the Church from
the commencement of the World to the end of the Ninth
Century,” in three volumes, folio. This is the first ecle-
siastical history written in the French language; and though
composed with less precision than that of the Abbé Freuxy; it
possesses considerable merit. It is characterized by Dupin
as “exact, faithful and agreeable;” he further adds, that
always will have a merit, which neither time, nor any other
history will be able to efface. Besides the history, we may
notice M. Godau's “Paraphrases on the Epistles of St.
“The lives of St. Paul, St. Augustine, and St. Charles
Borromeo, &c.” Moreni.

G D E F R O I, D E N Y S, a very learned jurist, was born at Paris in
1549. He studied at Louvain, Cologne, and Heidelberg, and upon his return to France acquired a high
reputation in the parliament, in which he was nominated to a
counsellor's place. In 1580 his religious principles obliged
him to seek a refuge at Geneva, where he was admitted a
burgher, and a professor of the law. In 1580 Henry IV.
created him bailiff of some villages at the foot of
Mount Jura, and a supernumerary counsellor in the parliament
of Paris. After this he was deprived of his employment and
his valuable library by the invasion of the duke of Savoy,
and in 1594 he accepted the professorship of the law in
the university of Strafburg. In 1604, at the invitation of Frede-
rick, elector-palatine, he went to settle at Heidelberg, and in
1618 that prince lent him on an embassy to Lewis XIII.,
who received him with marks of high esteem. He died at
Straburg in 1622, leaving behind him many works that testify
to his great learning. The titles of these are enumerated by
Moreni and others, and a few of the principal may be
mentioned here, “Codex Juris civilis ex antiquis et recentioribus
scriptoribus;” this treatise has been frequently reprinted; the best edition is paid
be to that from the Elzevir press in two volumes folio.

“Note in IV. Libros Institutionum;” “Praxis Civilis ex
antiquis et recentioribus Scriptoribus.”

G D E F R O I, THEODORE, the eldest son of the preceding,
was born at Geneva in 1582. He pursued his studies first
in
in that city; then at Strasbourg, and afterwards at Paris, where he embraced the Catholic religion. In 1643 he obtained the office of counsellor of state, and acted during the last half of his life as counsellor and secretary to the French embassy for the general peace at Munster. Here he died in 1649. He was particularly vered in the genealogical and ceremonial history of France, and published several learned works for its illustration; such as "Le Ceremonial de France," 4to. "Mem. concernant l'Annexion des Rois de France sur les Rois d'Espagne," "De la veritable Origine de la Maison d'Auvergne," "Traite touchant les Droits du Roi, tres-chretien fur plusieurs Etats voisines," &c. Moreri.

GODEFROI, James, brother to Theodore, was born at Geneva in 1537. He followed the steps of his father by a strict adherence to the reformed religion, and by pursuing the studies of law, history, and philosophy. In 1560 he was created professor of the law at Geneva, and was called to a seat in the council in 1569. He filled with the greatest zeal and ability every public office with which he was entrusted. He was five times elected syndic of the republic, and was made secretary of state. He was chosen as a fit person to conduct various negociations in France, Piedmont, Switserland, and Germany: and, at the same period, he devoted all his leisure to public lectures in jurisprudence, and composed a variety of learned works. He maintained a correspondence with the most learned men of the age, by whom he was greatly respected. He died in 1572, and his works bear testimony to his profound erudition, and to his great and unwearied industry; among them may be mentioned "Fragmenta Dodecim Tabularum," "Animadversiones Juris Civilis," "De Jure Precedentiarium," "Codex Theodonianus," a posthumous work, regarded as a most valuable monument of ancient jurisprudence. He edited the works of Cicero, "cum notis Lambini et Gothofredi." He had likewise made large collections for the history of Geneva, which were afterwards used by Spire. Moreni.

GODEFROI, Denis, son of Theodore, born at Paris in 1515, was an able French historian. He was author of "Memoires et Instructions pour servir dans les Negociations et les Affaires concernant les Droits du Roi," a work, which has sometimes been attributed to the chancellor Seguier, by whose order it was compiled. He re-edited many of his father's works, adding to them new illustrations with learned notes. He continued to his own time Feron's "Histoire des Officiers de la Couronne." As a public man he was appointed in 1668 the director and keeper of the chamber of accounts at Lille in Flanders, where he died in 1681. Moreni.

GODEFROI, John, son of the preceding, succeeded his father in the direction of the chamber of accounts at Lille, where he died, much advanced in years, in 1732. He published an edition of the "Memoirs of Philip de Comines," in five volumes 8vo. "The Journal of Henry III." "The Memoirs of Queen Margaret." He is said to have contributed more than any other writer to the elucidation of the affairs of the League. Moreni.

GODERVILLE, in Geography, a town of France, in the department of the Lower Seine, and chief place of a canton, in the district of La Havre; 9 miles N.E. of Montmartier. The place contains 670, and the canton 15,359 inhabitants, on a territory of 150 kilometres, in 31 communes.

GODESCHALC, in Biography, a Benedictine monk, who flourished in the ninth century, was born in Saxony, and was brought up, contrary to his own inclination, to the profession, in the convent of Fulda. He was ordained priest when he was about forty years of age, and in 846 we find him at Rome visiting the holy places there; hence he proceeded to Pannonia and Dalmatia, where he commenced preaching the doctrine of predetermination with much fervor, which it is supposed he imbibed from the works of St. Augustine. Upon his return to his own country he had a conference with Nothingus, bishop of Verona, before whom he maintained that God, from all eternity, had pre-ordained some to everlasting life, and others to everlasting punishment and misery. Nothingus, astonished and terrified at this daring, and, as he thought, impious a position, complained of it to Rabanus, archbishop of Mentz, who undertook to refute his error, in writing. Difficulties, perhaps, with his own arguments, Rabanus summoned a council to meet at Mentz, in the year 848, to which, however, Godeschalke presented a justification of his opinions, and resolutely persisted in maintaining them to be consistent with the scriptures and the sense of the orthodox fathers. The council passed sentence of condemnation upon him, and sent him prisoner to Hincmar, archbishop of Rheims, within whose jurisdiction he had received the priesthood. Hincmar, who was devoted to the interest of Rabanus, assembled a council in 849, in which the monk was a second time condemned, and rendered liable to a punishment repugnant to all the principles of religion and humanity. Godeschalke, however erroneous his sentiments might be, was not to be intimidated; he believed what he alleged, and he firmly adhered to the doctrine in spite of the higher powers. Hincmar accordingly proceeded to put the sentence into execution, degraded the monk from the priesthood, and ordered him to be scourged with the utmost severity. It appears that he was not prepared for so grievous a trial of his fortitude; the force of the pain inflicted on him obliged him, in compliance with the dictates of his prudent, to throw into the fire the justification of his opinions which he had delivered into the council. The infamous persecutors were not contented with this triumph; they committed him to the prison of Hautvilliers, in the diocese of Rheims. In this, as in every other case of a similar kind, the sufferings of Godeschalke gained him followers and adherents, and many became advocates for his cause. A considerable schism was produced in the Latin church. Some confined themselves to the defence of his person and conduct, while others employed all their zeal and talents in the vindication of his doctrine. The spirit of the controversy ran so high between the contending parties, that Charles the Bald, in 853, summoned the council to meet at Quiercy. Here the suffering monk was again condemned, but the decrees of this council were declared null and void, and Godeschalke and his doctrine vindicated and defended, in a council at Valence, in Dauphiny, in 855; the decrees of which were confirmed in the council of Langres, and in that of Tourn. Such was the origin of the disputes concerning the doctrines of predetermination and grace, which, from time to time, have divided the Catholic world into two parties, and which have subsisted in full force among the Protestants. The unfortunate Godeschalke died in prison about the year 869, maintaining with his last breath the doctrine for which he had suffered. The only writings of this monk that have come down to the present times are, two "Controversiae de Fide," inferred in archbishop Ulfer's "Hiscoria Godeschalch," printed at Dublin in 1644; an epitola to Rutmanus, published in Celio's "Hiscoria Godeschalch," at Paris, in 1655; and some fragments of other pieces, noticed by Uvar. Godeschalke has immortalized his name by setting on foot the controversy.
God

controversy to which we have referred, and by his sufferings in vindication of his favourite doctrine. In the year 1650, the celebrated Magini published at Paris, in two volumes 4to, a collection of the early treatises produced on both sides of this controversy, entitled "Veterni Auctorum qui nono Ante Baptem de Predestinatione et Gratia peripferant, &c."

GOD-FATHERS, and GOD-MOTHERS, persons who direct and attend at the baptism of infants, or other persons, who give the name, and who become sureties for the faith and good conduct of the infant baptized. Hence they are called ponsors, or more commonly sponsors. To this purpose Dr. Nichols, (Def. part ii. p. 273.) says, that the sureties in baptism religiously engage for the faith of the baptized; that they shall sincerely believe all that is revealed in the gospel, and shall direct the subsequent actions of their lives by the laws of Christ." Against this practice Protestant divines have alleged, that the parents, to whom both God and nature have committed the education of their child, are the proper persons to stand forth at baptism, and take upon them this great and important trust; and to bind themselves by a solemn vow faithfully to discharge it. They object to the order and practice of the established church, that without sufficient authority from reason, or scripture, or the ancient practice of the Christian church, parents are set at issue in this solemnity, and forbidden to stand forth, and take upon them this great charge to which God hath called them. For the 29th canon expressly commands, "that no parent shall be urged to be present at his child's baptism, nor be admitted to answer as godfather for his own child." They also object, that the forms of the church should require other persons to appear instead of the parents, and to take upon them this important trust, and will solemnly to promise before God and the church the performance of that, which few of them ever do, or perhaps ever intended to perform, or are capable of performing. It has been pleaded, and generally allowed, that sponsors in baptism were not known or thought of in the primitive apostolic church. Tertullian, who lived about A.D. 200, seems to have been the first of all Christian writers who mentions persons of this description: "What necessity is there," says he, (De Baptism.) "that sponsors should expose themselves to danger, who, through death, may fail of the performance of their promises, or may be deceived by the wicked imposition of those for whom they promise?" Whether the use of sponsors was from the apostles' days, (says lord King, in his Enquiry into the Constitution, &c. of the Primitive Church.) "1 cannot determine, unless the negative may be conjectured from Justin Martyr, Tertullian's senior by 50 years, who, when he enumerates the method and form of baptism, says not one word of sponsors or godfathers, as may be seen in his second apology, p. 553, 54.) St. Austin, one of the earliest of Christian writers who mention sponsors, who lived about A.D. 390, informs us when, and upon what occasion, these sponsors were admitted: "A great many," says he, "are offered to baptism, not by their parents, but by others, as infant-sons are sometimes offered by their masters; and sometimes when the parents are dead, the infants are baptized, being offered by any who can afford to shew this compassion to them. And sometimes infants, whose parents have cruelly exposed, to be brought up by those who light on them, are now, and then, and taken up by the holy virgins, and offered to baptism by them who have no children of their own, nor design to have any." Upon these words of Austin, Dr. Wall ingeniously confesses, (Hist. Inf. Bap. vol. i.) "Here we see the ordinary use there was for parents to answer for the children; but yet that this was not counted so necessary, as that a child could not be baptized without it." Hence it has been inferred, that parents were never set aside, when they were capable and willing to offer their children; and that only in cases of the incapacity of parents, were sponsors admitted; and in all such cases, provided that the practice be not enforced as a Christian institution, and as absolutely indispensable, the divines, we conceive, could not reasonably object to it. Mr. Wheatly, a well-known writer on the Common Prayer, observes, that the godfathers and god-mothers of persons baptized at riper years "are only appointed as witnesses of the engagement, and undertake no more than to remind them hereafter of the vows and profession, which they made in their presence." And yet our church catechism expressly affirms, and repeats the affection, that the sponsors, engaging for infants, engage that they shall believe and repent; for the infants are said to promise both these things by their sureties. Free and Candid Disquisitions, p. 131.

The number of godfathers and god-mothers is now reduced to three in the church of England, and two in that of Rome: anciently, they had as many as they pleased.

The Romanists have also godfathers and god-mothers at their confirmation. They even give god-fathers, &c. to bells, at their baptism.

Among the ancients it was the custom for persons of quality to have others of like quality cut their children's hair the first time; by which they became reputed a fort of godfathers: and the like was practiced with regard to the hair of the beard.

God-father was also a name anciently given to a kind of seconds, who attended and assisted the knights in tournaments, or single combats.

The godfathers of dukes were a kind of advocates, who were chosen by the two parties, to represent the reasons of their combat to the judges.

Something of this kind was long retained at solemn carousals. There were two or more in each quadrell. See Quadrell.

The institution of godfathers and god-mothers, patrini and matrini, is originally Roman. They are said to have been people who, in the games of the Circus, attended the chariots, flowers, and images, of the gods. Cicero makes mention of them, in his oration De Haruspiciis Repofpin. Their office was much like that of the children in some Roman ceremonies, who are drest in the habit of angels, to draw flowers, bear incense-pots, lights, &c. and accompany the relics and images of saints.

Godfrey of Bouillon, in Biography, celebrated for the part which he took in the first crusade, and king of Jerusalem, was the son of Eulace II., count of Boulogne. The appellation of Bouillon was derived from his lordship of that name in the Ardennes. In his youth he served in the armies of Henry IV., who, as a reward of his valour and fidelity, conferred upon him the title of duke of Lorraine. When the religious enthusiasm of the times set on foot an expedition for the recovery of the Holy Land from the possession of the Saracens, Godfrey was one of the earliest and most illustrious of the princes who took the cross. The command of the principal army was entrusted to his care, and it is agreed that none among the leaders were actuated by purer motives than Godfrey. He gave a distinguishing proof of the disinterestedness of his conduct, by sacrificing almost all his property to defray the necessary expenses of the expedition. Godfrey set out in the autumn of 1096, and proceeded with his host through Germany and
and Bulgaria, taking care to abate from those acts of hostility and rapine which characterized, and had caused the destruction of the fanatics of Peter the Hermit. It was not until June 1199, that Godfrey was able to lay siege to the renowned city, and though his army was greatly diminished in point of numbers, he was able to succeed, and on July 13th Jerusalem was taken by storm. The fanaticism and madness of the victors indulged themselves in a horrible massacre of the vanquished, which, it is believed, his general and leader was unable to prevent. Godfrey was almost immediately proclaimed sovereign of the new acquisition, but he refused to assume the title and enigmas of royalty in the place where Christ, in whose name he was acting, had been crowned with thorns, and he governed under the modest appellation of "Defender and Baron of the Holy Sepulchre." He was soon after attacked by the Sultan of Egypt, but the Christians soon put him and his numerous forces to flight, and the whole of Palestine was reduced under the power of Godfrey. He established the feudal institution in his kingdom; and a code of jurisprudence, under the title of "The Assize of Jerusalem," gave a model of the purest forms of European liberty in the midst of Asiatic despotism. He died, after he had fat on the throne about a year, and was succeeded by his brother Baldwin. The celebrity of Godfrey is immaterial as the hero of Tasso's "Jerusalem Delivered," one of the noblest of epic poems; nor has the bard found it necessary to borrow the colours of fiction, in order to throw splendour round a character so truly estimable: "Godfrey," says the historian in describing his character, "was the first who ascended the walls of Rome, and his fide, or perhaps his remorse for bearing arms against the pope, confirmed an early resolution of visiting the holy sepulchre, not as a pilgrim, but as a deliverer. His valour was matured by prudence and moderation; his piety, though blind, was sincere, and in the tumult of a camp he practised the real and fictitious virtues of a convent. Superior to the private fictions of the chiefs, he revered his enmity for the enemies of Christ; and though he gained a kingdom by the attempt, his pure and disinterested zeal was acknowledged by his rivals."—Gibbon Univer. Hist. See also the article Crusade.

Godfrey of Viterbo, an Italian historian of the 12th century, was chaplain and secretary to the emperors Conrad III., Frederick I., and Henry IV. According to his own account he was a great traveller for knowledge; and was conversant in several languages. His principal work was a "Chronicle," entitled the "Pantheon," as treating on the "Gods of Earth," is dedicated to pope Urban III., and is a general historical record from the creation of the world to the year 1186. It is written in the Latin language, and is deemed very worthy of the events of his own time. It was first printed at Basil in 1559; then at Frankfort in 1583, and afterwards at Hanover in 1613; in the collection of German historians, edited by Pillorius. Godfrey was author of a work intitled "Speculum Regnum, five de Genealogia omnium Regnum;" the MS. is preserved in the Imperial library of Vienna.

God-Gild, in our Ancient Customs, that which is offered to God, or for his service.

God's Mercy, Islands of, three or four small islands at the N.W. extremity of Hudson's straits. N. lat. 63° 45'. W. long. 73°.

Godwin, Earl, in Biography, a powerful Saxon baron, was the son of Wulfnoth, governor of Suffolk, and he himself, at the accession of Canute, was earl of Kent, and lord of very great possessions. When the Danish possessions of Canute were attacked by the king of Sweden, Canute took over as auxiliaries a body of English commanded by the earl of Godwin, who obtained a complete victory, which so delighted the king, that he bestowed his daughter in marriage upon him, made him large grants of land, and admitted him to the close of confidence. After the death of Canute, the succession being disputed between Harold Harefoot and Hardicanute, Godwin espoused the part of the latter, and was instrumental in preventing a civil war. It is reported that he afterwards concurred with Harold, in a plan for destroying the two English princes, sons of Ethelred II. and Emma, and the murder of one of them, viz. Alfred, is imputed to the vassals of Godwin. In the reign of Hardicanute the surviving prince Edward preferred an accusation against the earl for the murder of his brother, and loudly demanded justice for the crime; Godwin, to appease the king, made him a present of a galley finely gilt and decorated, rowed by four score men, each of whom wore on his arm a gold bracelet, weighing sixteen ounces, and they were all armed and clothed in the most sumptuous manner. Hardicanute, delighted with the spectacle, forgot his brother's murder, and on Godwin's own testimony he was allowed to be acquitted. In 1041, he was so completely reconciled to Edward, that on the death of Hardicanute he was the chief instrument of promoting him to the succession of the crown: he now acquired much influence in the state, and was created duke of Wessex, and the counties of Kent and Sussex were annexed to his government. The friendship between Godwin and the king was not of long continuance. Upon his refusal to act against the inhabitants of Dover, who had incurred Edward's displeasure, he was threatened with the royal vengeance. The earl, feeling his own power, actually excited a rebellion against his sovereign. Edward now summoned to his aid thedukes of Northum-
GODWIN.

which was in the gift of the college, to resign his fellowship. He retired to this situation in 1549, and having married, continued there peaceable and happy during the reign of King Edward, devoting what time he could spare from the duties of his office to the study of theology and physic, and on the accession of Mary, he became an object of Bonner's fury, and was obliged to resign his school, and turn his attention to physic. By the practice of this, he maintained his family till Elizabeth ascended the throne. He now resolved to follow the bent of his inclination, devoted his whole time to theological studies, was admitted to holy orders, and appointed chaplain to the bishop of Lincoln. He was shortly after introduced to the queen, who made him one of the Lent preachers. This post, which was probably attended with little emolument, he filled eighteen years, with very high reputation, during which he received no preferment in the church; but, in 1564, he was promoted to the deenery of Christchurch, Oxford, and in the same year a prebend was conferred on him. In 1566, he was advanced to the deenery of Canterbury, and attended the queen in her visit to the university of Oxford, on which occasion he took his degree of D.D. with great applause. In 1584, after eighteen years residence at Canterbury, he was nominated by the queen to the vacant fee of Bath and Wells. This honour did not augment the happiness of Dr. Godwin: in resettling the unjust claims of one of Elizabeth's favourites, he lost the favour of the queen herself, which aficioned his mind, as to render him incapable of performing his episcopal functions. The affairs of his diocese, being left to the management of others, fell into such disorder, that his metropolitan, archbishop Whitgift, thought proper to visit it in the year 1587. At this time Dr. Godwin's health was in a very bad state, and he gradually became worse till he sunk under the effects of disease, in his seventy-third year. He is highly spoken of for learning and unaffected piety, and was beloved and respected for his cheerful hospitality, benevolence, and charity. Biog. Brit.

GODWIN, FRANCIS, the son of the preceding, was born at Haddington, in Northamptonshire, in the year 1561, and having been carefully educated in grammar, he was sent to Christ-church college, Oxford, where he resided for his first six years, and in 1578 he was elected a scholar of that institution. In 1580, he took his degree of B.A., and three years after he proceeded to his degree of M.A. About this time he wrote an entertaining philosophical fiction, which he did not at that period publish, because it contained ideas at variance with the sentiments then prevalent in the schools. It was given to the world five years after his death, under the title of "The Man in the Moon, or a Discourse of a Voyage thither by Domingo Gonzales." The hints, conjectures, &c. contained in this piece, prove that the author was not ignorant of the writings of Copernicus, and was probably a convert to his doctrines. In 1587, he was a canon in the cathedral church of Wells, and promoted to the deenbury of Exeter. The history and antiquities of his country became favourite subjects of his enquiries, and in the year 1590 he accompanied the celebrated Camden into Wales, in search of objects to illustrate them. In 1595, he took the degree of doctor in divinity, being in possession of very considerable and lucrative preferment in the church. He published, in 1601, "A Catalogue of the Bishops of England, since the first Planting of the Christian Religion in this Island, together with a brief history of their Lives and memorable Actions, so far as can be gathered out of Antiquity." As a reward for the great diligence used in the composition of this catalogue, the queen promoted him, the same year, to the vacant fee of Landaff; being allowed to retain, in connection with the bishopric, the subdeanery of Exeter, and a good rectory in the diocese of Bath and Wells. He now employed himself in improving his "Catalogue," and in making collections relative to civil and ecclesiastical history. In 1615 he published a new edition of his "Catalogue," to which he prefixed a discourse concerning the first conversion of our Britains unto the Christian Religion. It was afterwards republished in Latin, under the title of "De Pre-fulibus Anglicis Commentarius." In the same year he published "Rerum Anglicarum Henrici VIII., Edvardo VI., et Mariae, regnantis, Annalcs," which was much admired for the elegance of the style. By King James he was translated from Landaff to the bishopric of Hereford in the year 1619, and from this period, he devoted such time as the discharge of his episcopal functions would permit, chiefly to the improvement of his former works; but in 1629 he published a discourse on the several methods of conveying secret and speedy intelligence, with the title of "Nuncius Imnatus, Utopia." It has been suggested that this was written in obscure and enigmatical language, with a design of concealing the author's secret; but from certain expressions, it should seem, that the hints contained in it might have led to an earlier establishment of public telegraphs. Besides several editions of the Annals, and a translation into English of the same work, we have a learned dissertation by the bishop, on the value of the Roman fable and attic talent, which was printed at the end of Hakewell's "Apology of Divine Providence." This was his last labour in the field of literature. He died in 1633 in his seventy-sixth year. Of his learning and classical taste, his works bear most decisive evidence, and they exhibit him as a zealous friend to the establishment of the English language, of which he was a member. According to Anthony Wood, "he was a good man, a grave divine, a skilful mathematician, an excellent philosopher, a good preacher, and a strict lawyer; but so much employed in his studies and matters of religion, that he was a stranger to the world and the things thereof." Biog. Brit.

GODWIN, THOMAS, a learned English divine and writer on Jewish antiquities, was born in Somerfetshire in the year 1564. In his fifteenth year, he was sent to the grammar-school at Magdalen-hall, in the university of Oxford, where he was entered a scholar. Here, in due course, he took his degrees, and soon after was chosen master of the free-school at Abingdon, in Berkshire. In this situation he distinguished himself by his diligence and affability in forming good scholars, who afterwards became eminent in various departments of literature, and in poets of honour and emolument in the church and state. In 1613 he published "Romane Histories Anthologiæ," an English exposition of the Roman antiquities, which went through several editions. Shortly after this, he entered into orders, and was appointed chaplain to Dr. James Montague, bishop of Bath and Wells, and in 1615 he was admitted to the degree of bachelor of divinity, and published a work, entitled "Synopsis Antiquitatum Hebraicarum ad Explicationem utriusque Talmudis Valde necessaria," &c. lib. 3. 4to. About this period he resigned his school, upon obtaining a presentation to the rectory of Brightwell, near Wallingford, in Berkshire. In the year 1625, he published the work by which he is chiefly known, viz. "Moses and Aaron; civil and ecclesiastical Rites, used by the ancient Hebrews, observed, and at large opened, for the clearing of many obscure Texts, throughout the whole Scripture." This work was immediately regarded as a standard book in our places of academic education, and has been repeatedly printed. In 1656 Mr. Godwin was admitted to the degree of doctor of divinity. He died..."
in 1642. Besides the works already noticed, Dr. Godwin was the author of "Florilegium Paralipomenon,"—or A Survey of the Latin Tongue. And Three Arguments to prove election upon the ground of faith. Gen. Dig.

Godwin, in Geography, in Geography, in Geography, in Geography, in Geography, a bank in the sea, about five miles from Dool, near the coast of Kent, England, were formerly part of the estate of the celebrated earl Godwin, but were separated and overwhelmed by a sudden inundation of the sea, about the end of the eleventh century. These sands are frequently fatal to mariners, but, notwithstanding, are of considerable use, as is it by them alone that the Downs are constituted a road or harbour for shipping. In all calmer winds they serve as a pier, or breakwater, and greatly mitigate the force and immensity of the waves, which, in stormy weather, would otherwise roll upon this shore with unabated fury. The sands extend in length about ten miles; the north end-head being nearly opposite to Ramigate, and the south end-head to Kingdown. The danger of flitting upon them arises from their nature, which Mr. Shaw describes as that of a quick-flood, clean and unconnected, yet lying so close, as to render it difficult to work a pointed bar to the depth of more than six or seven feet. Their ingurgitating property is so powerful, that even the largest vessel driven upon them would, in a few days, be swallowed up, and seem no more. At low-water they are in many parts dry, and parties frequently land upon them; but when the tide begins to flow, the sand becomes soft, and is moved to and fro by the waves. The largest portion of this bank which becomes dry, is known to leaven the name of the Jamaica island. Some years ago, in order to prevent the many accidents which occur in shipping on these sands, the Corporation of the Trinity-house formed the design of erecting a light-house on them; but after the sand had been penetrated by boring augers to a great depth, the scheme was given up as impracticable, as no solid foundation could be obtained. Floating lights have, however, been placed off these sands, consisting of three distinct lights in the form of a triangle, of which the middle-one is considerably the highest; when they are obscured in hazy-weather, a bell is kept constantly ringing.

GOELANS, Point Au, in Geography, a promontory on the N. side of lake Ontario; about 33 miles S. W. of fort Frontine.

GOELHEIM, a town of France, in the department of Montélimar, and chief place of a canton, in the district of Kaiferlautern. The place contains 800, and the canton 4999 inhabitants, in 16 communes.

GOELICKE, Andrew, in Biography, a German physician, who acquired considerable reputation at the beginning of the eighteenth century, and taught the science of medicine at Halle, in Saxony, and at Franckfort on the Oder, with distinction. His writings were in high estimation among the followers of the doctrines of Stahl, of whom he was one of the ablest defenders. Nothing more is known respecting his life. He left several works, which relate principally to the history of anatomy, of ancient and modern surgery, and of medicine. His "Histoire Medicinale Universelle, qui celebrorum quorumque Medicorum, qui a primitis Artis natalibus ad nostra usque tempora inclamerunt, viae, nomina, dogmata singulare, ratiociniis, hypotheseis, facta, &c. accuratissime pertractata," was printed in six different portions or epochs, between the years 1717 and 1720. The first four brought down the history to Hippocrates; the fifth treated of the Hippocratic medicine alone; and the last part included a sketch of the descendants of the father of medicine, until the time when, according to his, was divided into three professions. Ebor. D. It.

GOELL, in Geography, an island of Denmark, in Lymford gulf, about 10 miles in circumference; on which are a town and a village of two; 6 miles W. of Aalborg. N. lat. 57° 5'. E. long. 9° 49'.

GOELMA, a port of Egypt, in the Red sea, capable of accommodating only small vessels.

GOELWARA, a cove of Hindostan, in Guzerat, on the W. coast of the gulf of Cambay.

GOEREEL, William, in Biography, who flourished in the 17th century, was born at Middleburg, in Zealand, in the year 1655. He had a decided turn for literature, but by the death of his father while very young, he was confined to the care of an illiterate step-father, who would not permit him to pursue the bent of his mind. Being obliged to fix upon a trade, instead of studying for one of the learned professions, he fixed on that of a book-seller, as that which he imagined best adapted for the improvement of his leisure hours in the acquisition of knowledge. His various works will show how well he filled his time, and to what advantage he turned those intervals from occupation, which are too frequently spent in little-kisses or devoted to pleasure. He died at Amsterdam in 1711, leaving his "Jewish Antiquities," in two volumes, folio. "The History of the Jewish Church," in four volumes folio. "History Sacred and Profane," "An Introduction to Painting," "A Treatise on Architecture," and some other useful works. More.

GOERZEL GHEEZEK, in Geography, a town of Asiatic Turkey, in Notola; 25 miles S. of Smbb.

GOES, a town of Portugal, in the province of Beira; 9 miles E. of Coimbra.—Alto, a town of Holland, in Zealand, called "Ter-Goes," situated on the N. coast of the island of South Beveland, on an arm of the Scheldt, with which it is connected by means of a canal. The great church is a handsome structure; and though the town is not large, it carries on a considerable trade, particularly in salt and grain; 10 miles E. of Flushing. N. lat. 51° 33'. E. long. 4° 46'.

GOETIA, Goezia, a species of magic, opposed to Theurgia, the object of which was mischief; and accordingly it invoked only the malevolent genii.

GOEZ, DAMIAN, in Biography, a learned Portuguese, of the 16th century, was born at Alencer, and educated in the court of the king Emanuel, to whom his brother was gentleman of the chamber. He was, as he advanced in life, employed in various negotiations from his court to the court of France, Germany, Poland, and the Low Countries. In 1534, we find him at the university of Padua, in which he studied some years under Buonamico, and contracted a friendship in Italy with Benmo, Sadolet, and other great men. He carried forward his studies at Louvain, where he fixed his residence after his marriage, and was the principal means of defending the city against the attack of Martin von Roffen. He was, however, seized by the enemy, under the pretext of a violation of the truce, and obliged to return him. He was after this recalled by the king of Portugal, who wished to employ him to write the history of that country. The materials put into his hands were in so confused a state, and so scanty in regard to quantity, that he was able to perform but a small part of the task. He was malignant, accused, arrested, and thrown into prison. At length, as there was nothing found against him, he was liberated, and returned.
ed to his own dwellings, where he was shortly after found burnt to death, the confederacy, probably, of an apoplectic fit. His works are, "Legatio magi in Domum Emperor ad Emanualem Lateinian Regem," "Fides, Religionis, Mor" "Ethiopiam," "Etyphonii Laudent." "Iuris Lanovanii Obfudio," "Commentarii Gebrarum in Judic. Lateinian." "Urbanii Syllophonii Decriptio," "Historia del rey Dom. Manuel," "Chronica de Principe D. Jusas II." Moreri.

GOEZE, JOHN AUGUSTUS EMBLEM, was born at Alchiper in the year 1731, where he received the elements of a learned education. He was afterwards sent to Halle to pursue his studies preparatory to the exercise of the profession of preacher. In 1751 he settled in that capacity at Quedlinburg, which he retained till the period of his death. It was not till he was about forty years of age that he turned his attention to the microscope and natural history, for his skill in which he afterwards became famous. At first he made use of his microscope only for amusement, but in a short time he perfected himself of the very best instruments of the kind that had been manufactured, and his researches led him to the study of the natural history of insects. Baker's description of a certain insect which he described to explore the ditches, rivulets, and ponds. He wrote down his observations for his own private use, and caused many of the objects which he saw to be delineated. The facts thus collected he published in the Hannoverian magazine, which attracted the notice of the learned, from whom he received many flattering and highly complimentary letters on the subject. He translated Buffalo's treatise on insectology, which met with a very favourable reception from naturalists. He felt out without regard to style or order, but soon found that systematic knowledge was necessary in his pursuits; and completely acquainted himself with the Linnean arrangement; and his "Entomological Collections" were intended as a supplement to the works of the Swedish naturalist. The next considerable work of Goede was on the natural history of intestinal worms, which he published in quarto in 1782. This work contributed greatly to encrease his reputation as a naturalist, and entitles him to an honourable place among the dilettomists of modern times. The interest which he took in the education and improvement of his own children led him to publish some works on natural history, intended particularly for young professors in general, and being a very agreeable as well as learned writer, his productions were all well received, and to his honour it must be spoken that he never forgot to inculcate the duties of religion and morality while he was defending on the wonders of the natural world. After he had communicated to the public the result of his observations on intestinal worms, he sent his collection to Pavia, where it was sold for a thousand dollars. His fame, however, had extended much beyond his own country, and within a very few weeks after he had parted or at least agreed to part with his curious collection for the above named price, he received a letter from Dr. Hunter, offering him nearly double the fun for it. He died in June 1786.

GOFABAD, in Geography, a town of Persia, in the province of Irak: 55 miles E. of Isphahan.

COFFEE. See GEFF.

GOFFSTOWN, a town of America, in Hillsborough county, New Hampshire, situated on the western bank of Merrimac river, 3 miles from Amoskeag falls, or 60 miles W. of Portsmouth. It was incorporated in 1761, and contains 1612 inhabitants.

GOG and Magog. In Scripture History, are names given to Great Tribulation. They are connected in the sacred writings. (See Ezek. xxxviii. 2, 3, &c. xxxix. 1, 2, Rev. xx. 8.) Mofes (Gen. x. 2) speaks of Magog, the son of Japheth, but says nothing of Gog. According to Ezekiel, (ibid. 27) Gog was prince of Magog; the latter signifying the country or people, and the former, the king of it. The ancients generally represent Magog as the father of the Scythians, or Tartars; and traces have been found of the name in the provinces of Great Tartary. Others say that the Persians are descendants of Gog; and to these purpose people have been found there called Magians, and philosophers called Magi or Magi. Some have imagined that the Goths were descended from Gog and Magog, and that the wars described by Ezekiel, and undertaken by Gog against the saints, are those which the Goths carried on, in the 5th century, against the Roman empire. Bochart has placed Gog in the vicinity of Caucasus; and he derives the name of this celebrated mountain from the Hebrew אָגָּם, gog-casus, the desert of Gog. He also says, that Promethus, kid to be chained to Caucasus, is Gog; and it may be observed, that there is a province in Iberia S. of Caucasus, called the Gogarens. The Jews, in Scripture, are of opinion, that Gog and Magog, in Ezekiel and the Revelations, are taken allegorically, for such princes as were enemies to the church. Accordingly many, by Gog in Ezekiel, understand Antiochus Epiphanes, the persecutor of the Jews; and Gog in Revelations, they suppose to represent Antichrist. Calmet apprehends that the Gog of Ezekiel and Carbyces, king of Peris, were the same persons. The Arabian historians are of opinion that the descendants of Gog and Magog inhabit the northern parts of Asia, beyond the Tartars and Scythians; and hence it is probable that Gog and Magog, according to the notions of the Arabs, formerly inhabited the mountains of the Hyperboreans, and that they were known to the ancients by this name. This nation is unquestionably famous in antiquity, and there is reason for imagining, that they were some of the Scythians, and confounded among the Great and Little Tartars, and perhaps among the Muscovites, and other northern people. Calmet.

GOG-MOGG Hills, in Geography, hills so called, about three miles from Cambridge, remarkable for the interments and other works found there, and supposed by some to be a Roman camp, and by others, a work of the Danes.

GOGA, a town of Abyssinia: 30 miles S. of Gendar — also, a small town of India, on the western side of the gulf of Cambaya, about 28 or 30 leagues from Cambaya, abounding with hians and feamen.

GOGARDE, a town of Sweden, in Est. Gotland, 23 miles N.N.W. of Linkoping.

GOGARENA, in Antiqu Geography, a country of Asia, in Armenia. Strabo.

GOGARY, in Geography, a town of Bengal: 24 miles N.W. of Boghniar. N. lat. 25° 26'. E. long. 86° 30'. — also, a town of Hindoostan, in Bhar; 12 miles N. of Monghir.

GOGAVINUS, ANTONIUS GRAVINUS, an Antonius GOGAVIN DE GRAVE, in Biography, a learned writer, who, according to the informations of the famous Farlisse, published in corps all the ancient authors on music, at Venice, 1562, 410. His compilation contains the books of Aristoxenus and Ptolemy, and the fragment of Aristoil, with the Commentary of Peripty., the whole enriched with notes by Botugrand. See MEHUNUS, and BOTUGRAND.

GOGET, in lzbolology. See GENTIS ANON.

GOGGLES, in Rural Economy, a paired effection in 3G. see.
GOGO

sheep, which is sometimes extremely destructive to them. It is faggotted in the Bath papers as first shewing itself, by a dropping of the ears, and frequent rubbing of the tail; but not to have any relation or affinity to giddiness, as the sheep do not turn round as in that disease. It appears to have the greatest resemblance to the disorder called the faggots in lambs; but differs from it, as that the faggots lambs display weakness before, and of course fall in that direction, while the gogho sheep show weakness behind, and when forced to run fall backwards. Sheep under this disorder constantly get poorer and poorer, and become more weak, until they are not able to drag their limbs after them, and consequently die. Some have contended that it is a disease of the paralytic kind, and that the seat of the complaint is in the spinal marrow. It was formerly either wholly unknown, or unattended to by sheep-farmers, as it is never mentioned.

Hitherto no satisfactory method of cure has been pointed out for the disease, but warmth and frequent change of pasture have been found beneficial in it.

Goggles, in Surgery, are instruments used for curing squinting, or that distorsion of the eyes which occasions this disorder. They are short conical tubes, composed of ivory flamed black, with a thin plate of the same ivory fixed in the tubes near their anterior extremities. Through the centre of each of these plates is a small circular hole, about the size of the pupil of the eye, for the transmission of the rays of light. These goggles must be continually worn in the day-time, till the muscles of the eye are brought to act regularly and uniformly, so as to direct the pupil straight forwards; and by these means the cure will be sooner or later effected. Warne on the Eye, p. 32.

GOGOMOW, in Geography, a town of Hindoostan, in Ouda; 55 miles N. of Maniapour.

GOGO. See Goga.

GOGODUNGA, a town of Bengal, on a small island formed by a branch of the Hoogly; 45 miles S. of Calcutta.

GOGOROMOW, a town of Guzerat, on the coast; 50 miles W. S. W. of Nonnagur.

GOGRA, also called Dewah and Soorjeaw, a river of Hindoostan, which proceeds from a lake named Lakedehe, having to the E. of it another larger lake, named Manfawar, both situated on the western side of Thibet, and forces its way through the valley called Himimalch, and afterwards joins the Ganges. See Dewah.

GOGUEET, Anthony-Yves, in Biography, was born at Paris in 1716, where his father was an advocate. He himself became a counsellor to the parlement. By close study and by great affability in his manners, he produced in the year 1758, a work that has obtained a high reputation, and which has been translated into the English and other languages. It is entitled "Origine des Loix, des Arts, des Sciences, et de leur Progres chez les anciens Peuples," in three volumes 4to. It was printed in 1778, in six volumes 12mo. This work treats of the origin and progress of human knowledge, from the creation to the age of Cyrus, and displays much erudition in historical discussions, thoroughness of science and philosophy than might have been expected. He died of the small-pox almost immediately after the publication of this valuable work. He was a man of much private worth, modest and unassuming. He had begun another work on the Origin and Progress of the Laws, Arts, Sciences, &c. in France, from the commencement of the monarchy.

GOHANNA, in Geography, a town of Hindoostan, in Ballogiliana; 54 miles W.S.W. of Delhi.

GOHEE, a town of Hindoostan, in Balhar; 35 miles W.N.W. of Safaran.

GOHUB, a city of Hindoostan, in the foubah of Agra, lying on the right side of the river Jumna. It is bounded on the N. by the Chambal, on the E. by Doob and Ouda, on the S. by Bambol, and on the W. by Rantampour and Cottah--Alfoo, a town of this circuit, the revenues of which are estimated at 20 or 30 lacks of rupees per annum; 55 miles S. E. of Agra. N. lat. 26° 24'. E. long. 78° 14'.

GOJAK, a town of Croatia, on the river Mespiltsza; 18 miles S. of Carlstadt.

GOJAM, a province of Abyssinia, about 80 miles in length, and 40 in breadth. It is a very flat country, altogether appropriated to pasture; it has few mountains, but these are very high, and are chiefly on the banks of the Nile, to the south, which river surrounds the province. Gojam is full of great herds of cattle, which are largest in the high parts of Abyssinia. The country is populous, but the men are in the lowest elimination as soldiers. The Jefuits were settled in many convents throughout the province, and are held in the utmost detestation. The monks are those of St. Entitius, which may be called the Low Church of Abyssinia; they are said to be much inclined to turbulence in religious matters, and are, therefore, always made tools by discontented people who have no religion at all. On the S. E. of Gojam is Damot; which see, Bruce.

GOJAS. See Gojas.

GOJAV, a town of Africa, on the Grain coast; 25 miles S. E. of Grand Sello.

GOJEIDA, or Gojida, a town of Algiers; 90 miles S.E. of Oran.

GOING, in the Manges, called in French allaire, is the pace or gait of a horse.

GÖIT, Curt, Garl, Leat, &c. are names for a ditch or trench for conveying water, used by engineers and miners of different districts.

GOITO, in Geography, a part of Italy, in the department of the Mincio, situated on the river Mincio, between the lake of Mantua and that of Garda; 9 miles N. N.W. of Mantua.

GOITRE, or Goutier, in Surgery, names sometimes applied to a morbid enlargement of the thyroid gland. See BRONCHOCELE.

Performs labouring under this complaint are found in various mountainous districts of Europe, in China, in Bootan, and many other regions of the East, in Sumatra, &c. (SeeCREFINS.) Turner, in his "Account of an Embassy to Tibet," says, that in Bengal this unfortunately is known by the name of "Gheig," and "Aubi," and in Bootan is called "Baj," or "Ke Baj," the neck-swelling, and that it forms itself immediately below the chin, extending from ear to ear, and sometimes growing to such an enormous size, as to hang from the throat down upon the breast. It is particularly observable, he says, among the inhabitants of the hills of Bootan, immediately bordering upon Bengal, and in the tract of low country watered by the rivers that flow from them to the south, beyond the space of a degree of latitude. The same malady prevails among the people inhabiting the Morung, Njal, and Almora hills, which, joined to those of Bootan, run in continuation, and bound, to the northward, that extensive tract of low land embraced by the Ganges and the Berhampooter. The same disease is also more particularly met with in the low lands adjoining to these hills. From the frontier of Affnam, N. lat. 27° E. long. 91°, it is to be traced through Bijiee, Goocch Bahar, Rungpare, Dinagopore, Parma, Tircoot, and Betain, along
GOL

along the northern boundary of Oude, in Gooracpor, Barra-
raich, Pillibub, and on the confines of Rohilkund, to Hur-
dewar, situated in N. lat. 30°. E. long. 78° 25'. It has
the effect, he adds, or rather is accompanied with the effect,
 arising from the same cause, of debilitating both the bodies
and the minds of those who are affected with it. Maric, in
his "History of Sumatra," observes, that it has been usual to
attribute this affection to the baddafs, thawed slate, mineral
quality, or other peculiarity of the waters: "My ex-
perience," he adds; "enables me to pronounce without hesi-
tation, that the disorder, for such it is, though it appears
here to mark a distinct race of people, (orang geonong,) is
immediately connected with the hill-sides of the country,
and, of course, if the circumstances of the water they use
contribute thereto, it must be only so far as the nature of
the water is affected by the inequality or height of the land.
But in Sumatra neither snow nor other congelation is ever
produced, which militates against the most plausible conjec-
ture that has been adopted concerning the alpino goitres.
From every research that I have been enabled to make, I
think I have reason to conclude, that the complaint is
owing, among the Sumatrans, to the fogginess of the air
in the vallies, between the high mountains, where, and not
on the summits, the natives of these parts reside. I before
remarked, that between the ranges of the hills, the "ca-
boat," or dense mist, is visible for several hours every
morning; rising in a thick, opaque, and well-defined body,
with the fun, and feldom quite dispersed till afternoon.
This phenomenon, as well as that of the vlogs, being peculi-
ar to the regions of the hills, affords a premonition that
they may be connected; exclusive of the natural probabili-
ty that a cold vapour, clouds, to an uncommon degree, and
continually enveloping the habitations, should affect with
the fumes of the habitants. I cannot pretend to say how far
this solution may apply to the case of the goi-
tres, but I recollect it to have been mentioned, that the
only method of curing these people is by removing them
from the vallies to the clear and pure air on the tops of
the hills; which seems to indicate a fimilar fource of the dif-
temper with what I have pointed out. The Sumatrans do
not appear to attempt any remedy for it, the vlogs being
confident with the highest health in other respects."

GOKAUX, in Geography, a town of Hindooftan, in
Vifapour; 16 miles S.E. of Raiboung.

GOKIA, a town of Turkih Armenia; 30 miles E.S.E.
of Akadizik.

GOLABAD, a town of Persia, in the province of Irak;
45 m. E. of Ifppahan.

GOLAH, a town of Hindooftan, in Bahar; 10 miles
E. of Ramgur.

GOLAN, a town of the duchy of Waffaw; 10 miles
N.E. of Pofen.

GOLAPILLY, a town of Hindooftan, in the eircar of
Gif-toor; 10 miles W. of Lanneouka.

GOLAWARRY, a town of Bengal; 48 miles N.W.
of Midnapour.

GOLCONDA, a province of Hindooftan, part of the
posseffion of the Nizam, or Soubaah of the Deccan, our
from ally, corresponds to the ancient province of Telingana,
Teling, situated between the lower parts of the cour-
tries of the Kilinah and Godavery rivers; and is bounded on
the N. by Berar, on the E. by the Circars, on the S. by the
Myficorn country and the Carnatic, and on the W. by Dow-
kabad and Vifapour. It takes its name from a famous
fortrefs. The kings of this country were, at a former time,
immensely rich and powerful; as they maintained in their
pay 500,000 soldiers, and derived very large revenues from

their lands, customs of merchandizes and provisons, but
chiefly from the diamond mines, for which this country has
been singularly famous. The winter in Golconda begins
in June with rain and thunder; the rain pouring down,
accompanied by violent storms of wind, till the middle of
July, with occasional intervals of fine weather. In Augu-
ust, September, and October, the rains again fall, and very
much swell the rivers. These rains render the land excessively
fertile, particularly in fruits. Vines are plentiful, and of
the grapes, which ripen in January, they make white wine.
Two crops of rice are produced annually, and the country
affords other kinds of grain. The capital of Golconda is
Hyderabad.

GOLCONDA is also the name of a fortresses, surrounded by
stone walls and deep ditches, which was formerly the refe-
dence of the kings of the country. This fortresses, on ac-
count of its extent, might be denominated a city; a hill
rose in the middle of it like a sugar-loaf, and the sides
of it were encompassed by the king's palace, which was
very large and well situated for air, and which had a good
view of Hyderabad. When Aurungzebe conquered the
kingdom of Golconda in 1687, this fortresses was taken by
treachery; the king offered to pay a tribut of 3,700,000
rupees, and become the vallal of the conqueror; but he re-
fused, and entered the palace in triumph.

GOLD. Gold, Gerin.; Gold, Swed. Dan.; Or, Fr.;
Arany, Hung.; Salofo, Ruff.

Mineralogical Description.—This metal never having been
found in a mineralized slate, we are acquainted with one spe-
cies only, namely,

Native gold, which is subdivided by Werner into three sub-
species, viz. gold-yellow, brown-yellow, and greyish-yellow gold.
Though this subdivision may appear arbitrary, and not found-
ed on conflant characters exclusively belonging to each of
the above varieties or sub-species, it is Nevertheless entitled
to attention, since colour, however unimportant it may be in
the clasification of earthy foils, constitutes a character of
considerable value in native metallic subfiances, the range of
whole colours is confined to a narrow compass. But
also their geographic relation appears to culminate a dis-
tinction, at least between the two first of the Wernern
sub-species; for as to the third, or the greyish-yellow gold,
it is not known if it is its being found in small flat parti-
cles, along with that mixture of different metals called pla-
tina in grains, of whose colour it partakes in general, and
with which it is supposed to have occurred also originally
under the same geographic relations.

1. Light or Brown-coloured native Gold. Meetting-yellow ge-
gen gold of Werner. Its colour is pretty well indicated by
its name; but it varies in intensity from what may be called
pale-yellow to yellowish-silver white. It is also some-
times found with deep-yellow, and with pavonine tarnish.

It occurs malleable, disseminated in angular and amorphous
particles, but more frequently in films, membranes, and plates
even and curved or twisted, and with smooth or drused sur-
face; also capillary, tooth and wire-shaped, shrub and fern-
like, and as monoliform rings; often imitating reticulated
and filigree work; all which forms are generally produced
by the aggregation of minute imperfect crystals. Among
these, perfect crystals are not unfrequently seen, sometimes
single, often in groups, on the margin of the plates, &c.
The following secondary forms have been observed: the
cube; the octahedron; the garnet-dodecahedron; the lutei-
ci-dodecahedron with trapezoidal planes. Also modifications
intermediate between the cube and the octahedron occur, but they

3 G 2
are scarce. The minute three-sided pyramids, which are often seen to dropt the membrane, and the simple triangular marks on the plates of the Transylvania native gold, are the results of hurried and disturbed crystallization; the former of them being the solid angles of the cubical, and the latter the rudiments of the octahedral variety.

The crystals are minute (those described by Mr. Eimmart as octahedra and cubes of two lines in diameter, have never before been heard of); their surface is always smooth.

Lustrous metallic; externally brilliant; while that of the grains is sometimes glistening, sometimes approaching to dull; internally it is glimmering and glistening.

The fracture of gold is fine hackly. Its fragments are indeterminate angular.

It is soft, highly flexible, malleable, and ductile.

The specific gravity of pure gold is from 19.353 to 19.640; but that of the brass-yellow variety, owing to a greater proportion of silver with which it is alloyed, is generally considerably less, though always above twelve.

The light, or brass-yellow gold, occurs almost always in veins in greywacke, greywacke slate, and newer porphyry; seldom, as the following sub-species, in primitive rocks, or under other circumstances that bespeak a similar remote antiquity.

It occurs chiefly with quartz and iron pyrites, and not infrequently with grey antimony. Other concomitant substances are, among the earthy fossils, calcareous spar, brown spar, barytes, feldspar, and seldom small quantities of bole, lathmomar, and common garnet; of metallic substances, red and vitreous silver ores; (feldspar native silver,) copper pyrites, grey copper ore, copper green, brown iron stone, galena, green lead ore, blende, with occasional traces of white cobalt, copper nickel, red orpiment, native arsenic, and arsenical pyrites.

2. Deep or Gold-yellow Native Gold.—Gold-gelbes gelegen-gold of Werner.

Its colour is the highest gold-colour, feldspar gathering on brass yellow.

It occurs massive and in small roundish and flattened pieces, as also in grains of various dimensions, detached or disintegrated; feldspar in particular external forms, such as in leaves and lamine, fibrolite and moflikite; scarcely ever crystallized: almost all the crystalline forms described by authors belonging to the light-coloured sub-species.

External luster glistening, sometimes (as in the variety called Spanish infus) divided of all luster. Its specific gravity is rather greater than that of the light or brass-coloured gold, with which it agrees in the remaining characters.

It occurs mostly loose, in alluvial situations; and in the bed of rivers, and as such, appears to have been originally disintegrated in rocks of ancient formation: it is, however, also found in veins in Norway, Siberia, Bohemia, Hungary, in the Earl Indies, &c., almost always disintegrated in quartz, accompanied by iron pyrites; but nothing is as yet known respecting the age of these veins. At Fatzebay it is found in minutely moflikite external forms, often of a dull powdery appearance, on common quartz sometimes mixed with iron pyrites; in this slate it is by the miner called Spanish infus.

Geographical situation.—The following localities comprise head both the sub-species into which native gold is divided by Werner. By far the greater part of that found in Europe belongs to the brass-yellow sub-species, except the gold of rivers and alluvial soil, which is principally deep yellow, and to which the immense quantities of this precious metal, tarnished by the other parts of the world, appear likewise to be referable.

Europe:—Hungary, the Banat, and principally Transylvania. In Upper Hungary it occurs in gneis: at Schen-itz, in Lower Hungary, it is found accompanied with several silver ores, and with galena; at Kemenitz, in and on cellular and flattened quartz, lamellar barytes, with vitreous silver and grey copper ore, copper pyrites, brown spar, &c. at Oravizza, in the Banat, it occurs silifom and diffuminated in pale flecked and greenish-white fom, with white cobalt ore and copper nickel. In Transylvania, the richest country of Europe in this metal, it principally occurs in a kind of clay-porphyry of different degrees of freehense, which is the Saxon metaliferous of Born, in greywacke and greywacke slate: at Kapnik it is sometimes found with red orpiment; at Stanfia in calcar-ous fpar, mixed with arsenical pyrites, &c.: other places of Transylvania aboundling in gold (which is for the greater part brass-yellow), are Verebapatik, Abrabdaya, Boiza, Oblenbaya, Fatzebay, Topilza, Treffyam, &c. Alto the rivers, both of Hungary and Transylvania, are richly auriferous; gold sand is found in the Nera, and underneath a stratum of clay on the plain traversed by this river. The richest river of Transylvania is the Armoni, and the plains bordering on the river Mohor, contains likewise gold in grins, between a stratum of mud, and another of schists, neither of which strata is in the least auriferous. Alto of Olapian, gold is obtained by washing; it is there mixed with magnetic iron stone, titanium, garnet, and cyanite. The gold of the great rivers of Transylvania is generally of 21 carats, that of Olapian and Rohnia is even of 23 carats, fix grans.

In Germany it is found in several places, at Johangeorgenflad in Saxony, in Caritania, where it accompanies copper ores, in Tyrol and Salzburg; but it is only in the half of the districts, or rather in the chain of mountains, separating Tyrol from Caritania, that gold-mines are worked: in the Zillerthal it is found in various external forms, and accompanied with iron pyrites, &c. in the Heine slate. In Bohemia gold occurs in quartz.

Spain is probably very rich in gold; certain it is that considerable gold mines were worked there in former times, and, according to Diodorus Siculus, as far back as the time of the Phocicians, after whom the Romans undertook to work them; and Pliny informs us, that those nations derived their great profit from them. Africa was the province which furnished most of this metal. After the discovery of America these mines were entirely given up and left. The Tagus and some other rivers of Spain are likewise auriferous.

France has no gold mine that is worthy to be worked; the first discovery of gold in that country was made in 1781, at la Gardette, in the valley of Oyon, in the present department of the Iere: the mine was worked for six years, but the produce in gold and accompanying minerals was too small to compensate for the expense of obtaining them, and, indeed, the lots amounted to upwards of 21,000 livres. It occurs there, with rock crystals and iron pyrites, in gneis. The sand of several rivers of France is auriferous, such as that of the Arriane near Mirepoix, the Gardon and Cesse in the Cevennes, the Rhone in the Pays de Gen, the Rhine between Strausburg and Philippsburg, the Salz in the neighbourhood of St. Giron, in the Pyrenees, the Garonne near Toulouse, and the Herault at Montpellier. Also most of the black sand and of the bog-iron found in the neighbourhood of Paris is said to contain a small quantity of gold.

In Piedmont veins of auriferous pyrites and quartz are found near Macugnaga, at the foot of Monte Rosa: which mountain consists of veined granite in horizontal beds. The veins of pyrites and quartz have upon the whole a perpendicular direction, but in some parts they cross each other, and...
G O L D.

and where this takes place, grupp, or reefs, are found which contain the greatest proportion of gold. The proprietor of these mines extracted out of such reefs, in no more than twenty-two days, 189 mares of pure gold, although a hundred weight of the ore yields no more than from 10 to 12 grains of that metal. Formerly upwards of a thousand workmen were employed in these gold-mines; and the proprietors still possess 86 mills, by which from 10 to 12 pounds (of 12 ounces) of mercury impregnated with gold are produced per day. Twelve pounds of mercury contain two mares of gold. There are likewise several auriferous rivers on the S. side of the Andes, in Peru, between mount Rupa and the valley of Aosta, such as the Avenfon, which runs from the valley of Chialant into the Daire, and where some gold-mines were also worked by the Romans; the Ore, &c.

Sweden has a gold mine at Edelfors in Smoland: the gangue, a brownish quartz, is said to be in a kind of hornblende slate, which also contains the metal differentiated.

Gold has also been found in Great Britain: in Cornwall; at Lead-hills, in Scotland, differentiated in quartz; at Wicklow, in Ireland, under the soil, and in a stream which runs over rocks of chaly-flake with veins of quartz. It belongs to the deep yellow variety.

Africa.—The gold-sores of Siberia are partly of the light coloured, but principally of the deep coloured variety: that of Berezof, which occurs in pyrites, or rather brown iron stone, and iron flint quartz, and in the rock which serves as gangue to the red lead ore, belongs to the latter. Patrin mentions a specimen of gold in spangles on hornflcle, found in one of the silver mines of Schlangenberg.

The geognostic relation of the gold found in several parts of India, in Japan, the Philippine and Maldives islands, Sumatra, Borneo, &c. is not known; all the specimens from India, that have come under our inspection, were in the form of small rounded and amorphous particles in quartz, and belonged to the deep yellow variety.

Africa.—Of the occurrence of gold in this part of the world we know so much that the greatest part, at least of that which comes to Europe, is deep yellow and in grains. African travellers have made us acquainted with a few of its localities, but not with any particulars relating to its geognostic habits. Though the commerce of gold-powder extends almost over the whole of Africa, yet, according to Heeren, there is none to be found in its northern parts. Among the principal African gold mines are those of Kordofen, between Darfur and Abyssinia, mentioned by Browne. The ancients, says Brongniart, appear to have been acquainted with these mines: they confedered Ethiopia as a country rich in gold; and we find in Herodotus, that the king of that country exhibited to the ambassadors of Cambyses all the prisoners of war fettered with chains of gold.

A second most considerable district for gathering gold-powder appears to be Southward of the great defart of Zabra, in the well of Africa, at the foot of those lofty ridges of mountains on which originate, among many smaller rivers, the Senegal, the Gambier, and Niger. The country of Bambouk, at the N.E. of those mountains, is, according to Golbery, that which furnishes the greatest quantity of gold which is sold on the west coast of Africa, from the mouth of the Senegal to the Cape Palms. This gold is found in spangles and small lumps, principally near the surface of the earth, in the beds of rivulets, and always in a ferruginous soil. In some parts of the country they find something like shafts, but without giving any support to the sides of the pits: nor are they wont to follow up the vein, if any should appear, or to make galleries. The metal is obtained by repeated washing of the earth that includes it. The same country furnishes likewise the greatest part of the gold carried to Morocco, Fez, and Algiers, by the caravans which, from Tombuctoo, travel through the great defart of Zabra. The gold which is brought to Cairo and Alexandria from Sennaar comes likewise from thence. See Parke's travels, where also an interesting account is to be found of the gold in Manding, and of the process by which the negroes obtain it.

The third principal district of Africa, for collecting gold, is on the S.W. coast between 15° and 22° S. lat. opposite Madagascar. This gold comes principally from the country of Sofala. According to the relation of some travellers in this part of the world, the gold is found there not only in powder, but likewise in veins. Some are of opinion that the country of Ophir, from whence Solomon obtained gold, was situated on this coast.

America.—The gold of this part of the world, as far as we are acquainted with it, is to equally the production of the sand of rivers and of alluvial land; but it is also, though rarely, found in veins. South America, particularly Brazil, Choco, and Chili, are the countries that yield most; but most is found in North America, particularly in Mexico, where it occurs along with silver-ores. The annual produce of these Mexican mines is valued at from 12 to 1500 kilograms. All the rivers of the Caracas, 10° north lat. are auriferous.

The gold of Chili, according to Frezier, is lodged in the alluvial formation.

The Peruvian gold occurs in ferruginous quartz; that of Choco, the richest province in gold in South America, is found as grains in alluvial country, and in rocks belonging to the newest fels-trap formation. Almost all we know respecting the geognostic situation of the gold of Spanish America, we owe to M. de Humboldt.

Brazil furnishes gold in abundance, and it is from thence that the greatest part actually seen in commerce is brought to Europe. There are, however, properly speaking, no gold-mines in that country; the gold is not found there in veins, but differentiated in sand and other alluvial depositions, out of which it is obtained in the usual manner.

The gold that has been furnished by Brazil within 120 years, may be valued (according to Correa) at 2,000,000,000 of French livres; and, according to other authors, the amount is calculated to be 24,000,000 per annum. Brongniart, See Ores.

Observations.—1. It would appear that most writers who adopt Werner's distinction between gold-yellow and brass-yellow gold, have mistakenly described the one sub-species for the other, and some even speak of "gray-yellow gold from Transylvania." The sub-division indium may be deemed inadmissible; but if it be at all adopted, by far the greater part of the native gold of Transylvania and Hungary, and consequently almost all crystallized gold, must necessarily be referred to the indium-club; and that found in the sand of rivers to the peculiarised sub-species; and this not on account of their colour only, but also indicative of the chemical composition of the metal, but principally on account of the geognostic relation under which they respectively occur, and on which it appears to be laid by Werner.

2. Iron pyrites, containing not unfrequently a considerable portion of gold, in most cases invisibly disfigured and disguised, has by some been considered as a species of gold; a distinction to which (though such auriferous pyrites are often subject to mechanical treatment for extracting the metal, as will be seen hereafter) it cannot be considered as entitled. See Parke, Min. Afric.
The brown cubic crystals from Beresof, in Siberia, which contain grains of gold, are considered by some as decomposed, by others as hepatic pyrites, and by some as brown iron in foppollitions crystals. Whatever they may be, they are certainly not what Werner means by hepatic pyrites.

3. The native gold of Transylvania is often accompanied, and sometimes incrusted, by particles of a pale yellow earthy substanee, which was considered by Hacquet as an oxys of gold. Muller and others have described it as iron-ochre, from which, however, it appears to differ both in colour and consistence. It is almost always to be met with in the specimens of native gold from Vereinipatak, but sometimes in such fine particles as to appear merely as a tint upon the metal. It is to this doubt probably that the gold ore, called Spanish snuff, owes its name, yellowish-brown colour. It deserves further examination.

4. The grey metallic substanee occurring as accicular indeterminate crystals, along with the gold of Siberia, in quartz, and which has been described as tellurium, as grey copper ore, &c. appears to be native bismuth.

For the chemical characters of gold, and the siles to which it is applied, see the sequel of this article.

Extraction of Gold.—This metal is obtained separate from foreign substaneees, with which it is mixed by amalgamation with quicksilver. After it has been freed, by pounding and washing, from the flaky matter, it is triturated with about ten times its weight of mercury. The more fluid part of the amalgam is forced through leather, while that which is more confident, and which contains the chief part of the gold, remains. This is subjected to dilution, the quicksilver is separated and evaporated, and the gold remains in a state of fusion. When this metal is found in other ores, they are first roasted, to dilute the volatile principles, and to oxidize the other metals. The gold, which is but little subject to oxidation, is extracted by amalgamation, by cupellation, or other methods adapted to each ore, according to its properties or confidential parts. The metal obtained in these ways is always more or less alloyed, particularly with silver and copper. The first layer in its purification is the process of Cupellation, to which article in our Cyclopaedia the reader is referred for accurate information on this part of the subject.

The gold, after it has been submitted to this process, is often alloyed with silver, which, being nearly as difficult of oxidation, is not removed by the action of lead, and hence the necessity of the operations denominated Parting and Quatation, which may be explained in a few words.

In Parting, the metal is rolled out very thin, and cut into small pieces, which are digested in diluted nitric acid moderately hot. The acid has an action upon, and dissolves the silver, leaving the gold undissolved in a porous mass. When, however, the proportion of silver is very small in comparison of the gold, the latter sometimes protects the former from the action of the acid; in such cases the previous layer of Quatation is employed, which is so named on account of the proportion of materials employed, viz. three parts of silver, with one of gold, and then subjecting the alloy, rolled out, to the operation of the acid. Sometimes they are melted together, and sulphur thrown in, the sulphur combines with the silver, and the gold falls to the bottom. It is observed by Lagrange, that rolling and annealing are operations very necessary to the success of the parting process, and which require some precautions. If the plate must not be too thin, lest it should break in consequence of the motion communicated to it by the action of the acid; if it is too thick the acid could not penetrate to its centre. 2dly. The annealing of the plate, at the same time that it gives pliability, facilitates its being rolled without cracking; it also opens the pores of the metal, which the rolling may have precluded together, and by these means favours the action of the acid.

The process recommended by Bergman is this: first to dissolve it in nitric-acetic acid; the silver is deposited spontaneously in the form of nitrate of silver, which is insoluble; the gold is precipitated in fine powder by the sulphate of iron. Each of the above-mentioned processes is performed in such a manner as to lead to an estimate of the quantity of gold, and also of the different metals with which it is alloyed.

Gold, it is said, by some able French chemists, as Le Sage and Rouelle, exists in the vegetable kingdom, it having, in experiments intimated for the purpose, been extracted from the ashes of certain plants; the quantity, however, being of course, too trifling to be sought after for practical purposes, it is sufficient merely to mention the fact in this place.

GOLD. Chemical Properties of.—Gold melts at the temperature of 32 of the scale of Wedgewood; and what is very remarkable is, that it is more difficult of fusion in the state of filings and grains, than in larger masses; and that the small fragments, even after they are fused, remain in separate globules; and in order to make them run into one mass, a little nitre or borax is thrown into the crucible. Gold, which has only been subjected to a degree of heat barely necessary for its fusion, is brittle after cooling. To preserve its ductility, which, as will be hereafter shown, is one of the more important mechanical properties of gold, the temperature must be raised much higher. It is brittle also when it is too suddenly cooled after fusion. By an increase of temperature, the metal becomes convex on the surface, and when it cools, it sinks, circumstances which are ascribed to the expansion and contraction of the metal. When it is gradually and slowly cooled, it crystallizes in the form of quadrangular pyramids, or regular octahedrons. If the heat be continued while it is in perfect fusion, it seems to undergo a kind of ebullition. This circumstance was noticed by Homberg and Macquer, as well in the application of the burning-glass, as when a small globule of the metal was acted on by the blow-pipe. Macquer asserts that it rote in vapour to the height of five or six inches, and attached itself to the surface of a silver plate, which it completely gilded.

The strongest heat of a furnace, which has been applied to gold in fusion, has been found incapable of producing the smallest change or the least tendency to oxidation; but, by the action of a very powerful burning-glass invented by Tichurtheun, and which has been described under the article Burning-glass, Homberg found that gold, placed in its focus, not only rote in vapour, but that it was covered with a violet-coloured vitreous oxide. The experiment was frequently repeated, so as to ascertain the fact most completely. The same thing has been done by means of the electric discharge, by which gold-leaf, placed between two cards, has been converted into a violet-coloured powder. These instances of real oxidation were, at first, regarded, by some who witnessed the experiment, as merely minute mechanical divisions of the metal, but this apparent objection has been removed by the experiments of Van Marum on the conductibility of gold by means of the large electrical machine at Harkem. A strong electric shock was passed through a gold wire suspended in the air. It kindled, burned with a perceptible green flame, and was reduced to fine powder, which was dissipated in the air. A similar oxidation has been observed to take place on the gilding in the infide of houses,
Gold.

Phosphorus, or on the furniture which has been struck with lightning. The purple oxyd of gold, thus obtained, contains five or six percent of oxygen. By precipitation from some of its saline combinations, a yellow oxyd has been obtained, in which the proportion of oxygen amounts to ten percent. The oxyd in both instances may be decomposed, and the oxygen completely expelled, by an elevation of temperature not much superior to that of ignition.

The attraction of gold to oxygen is too weak, that it is scarcely affected by the greater number of acids. It was formerly supposed to be perfectly insoluble in the nitrous and nitric acids, which in general part with oxygen with so much facility, and when gold leaf is put into the acid cold, it seems to suffer no change, but when nitric or nitrous acid is boiled on gold, it is capable of dissolving a small portion of it. The quantity dissolved is, however, so incomprehensible, and depends on so many conditions, which it is needless to enumerate, that the accuracy of the process of affaying can scarcely be affected by it.

When gold is dissolved in the nitro-muriatic acid, or in a mixture of equal parts of nitric and muriatic acids, an effervescence takes place, and the solution becomes of a yellow colour. In this process the nitric acid is decomposed, its oxygen combines with the gold, and the oxyd, as it is formed, is dissolved in the muriatic acid. By adding lime-water a precipitate is formed, which is the yellow oxyd of gold, confining of from eight to ten parts of oxygen in the hundred. There is no action between gold and azote, hydrogen, carbon, or sulphur: but the oxyds of gold are readily decomposed by hydrogen, as will be soon seen.

Phosphorus combines with gold by heating together in a crucible a mixture of one part of gold in filings, with two parts of phoshroric glafs, and an eighth part of charcoal. Part of the gold of the phosphorus is separated from the acid, and driven off, but there remains a small quantity united with the gold, forming a phosphuret of gold. It may be done also by adding phosphorus to gold in a red heat in a crucible. It is, in this state, pale coloured, granulated, brittle, and a little more fusible. The proportion of phosphorus is not more than one part in twenty-four; and the sublimate may be decomposed by being kept in fussion; the phosphorus is driven off in the state of vapour, and inflamed. Bergman has arranged the affinities of gold and its oxyd in the following order:

Sales of Gold.—These are the nitrate and muriate.

1. Nitrate of Gold. When concentrated nitric acid is several times successively poured upon gold, boiled and diffused to dryness, the gold is dissolved, and the solution attains a yellowish colour. This solution is more readily effected in proportion to the quantity of gas or nitrous gas which the acid contains. Gold-leaf, according to Fourcroy, is dissolved in nitric acid, impregnated with nitrous oxyd, and he supposes that it is owing to the nitrous oxyd that the gold is oxidated, this oxyd being so much more easily decomposed than the nitric acid. The acid which, at first, is deprived of its colour by the oxidation of the gold, as this oxyd is dissolved, affumes an orange-yellow colour, holding in solution the nitrate of gold with an excess of acid. The nitrate cannot be obtained in crystals, and it is decomposed by heat or by being exposed to the light of the sun; it is also decomposed by the alkales, or by introducing a plate of tin or silver into the solution, and the purple oxyd is precipitated in the form of powder, and likewise by muriatic acid, which at the intant of combination converts the orange-colour to a pure yellow.

2. Muriate of Gold.—Muriatic acid of itself has no action on gold, or on its purple oxyd, but gold is immediately oxidated and then diffused in oxymuriatic acid: or if nitric acid be added to the muriatic in certain proportions, the solution of gold in the mixture is readily effected: hence the nitro-muriatic acid was distinguished by the name of "aqua regia," because it dissolved gold, which was regarded by the alchemists as the king of metals. The action of the chemical action is thus explained. Gold is oxidated with great difficulty, but it is effected by oxymuriatic acid, with readily parts with its oxygen, or by the addition of the nitrous to the muriatic, the former of which is decomposed, giving out its oxygen to the gold, which being now oxidated is diffused in the muriatic acid, forming with it a muriate of gold. This solution of the muriate of gold is of a deep yellow colour, extremely acid and caustic; has an astrincent metallic taste, and stains the skin of a deep purple colour, which becomes darker by exposure to the air and light. It produces a similar effect on all vegetable and animal matters, and on marble and silicious stones. By evaporating the solution to one half, nitric acid is diffused, and crystals are obtained. These assume a red colour by the action of strong light. They attract moisture from the air, and spontaneously become liquid. When oxymuriatic acid is used, the oxygen of this acid being retained even by a weaker affinity than the nitric acid, the gold attracts it, and combines with the muriatic acid. In this case the solution is slow, and but a very small quantity of gold can be diffused, partly from the oxymuriatic acid not being in a very concentrated state, and partly, it is supposed, from the quantity of oxygen present not being sufficient to form a sufficient quantity of oxyd to entirely the acid. It ought, however, to be observed, that if the late discoveries of Professor Davy be established, which make the oxymuriatic acid a simple sublimate, and even possessing no oxygen whatever, then a new theory must be introduced to account for the facts above-stated. In oxymuriatic gas, gold-leaf is instantly fused with inflammation, and diffused. Gold cannot be diffused by the other acids when in its metallic state, but its oxyds may be combined with them, and a number of the salts of gold be formed. The sulphate and nitrate also, as we have seen, do not crystallize: the phosphpate of gold may be fused, and in this state it forms a fine red glafs. We shall now briefly notice some of the properties of the muriate of gold. In connection with this subject, we must not omit the experiments of Mrs. Fulhame, which she announced in an "Essay on Combustion," with a view to a new art of dyeing and painting, &c. in the year 1794, and which were, at that period, expected to lead to some important practical results.

The muriate of gold is very soluble in water, and is decomposed in hydrogen gas. If a piece of silk be moistened with.
GOLD.

with a solution of muriate of gold, the salt is decomposed, and the gold, reduced to the metallic state, attaches itself to the silk. It is decomposed also by phosphorus. If a drop of phosphorus be introduced into a saturated solution of muriate of gold, the salt is decomposed, and the gold being reduced to the metallic state, forms a yellow, vitreous layer, which may be separated by dissolving the latter in hot water. A similar effect is produced by burning sulphur, by sulphurated and phosphorated hydrogen gases, and by sulphuric acid. If a solution of muriate of gold be cautiously added to sulphuric acid, a fine pecile of gold appears on the surface, which is instantly precipitated in the form of small grains. These, and many other experiments equally curious and interesting, were first described by the lady above-mentioned, and the rationale of the subject is thus explained. All the substances which have been enumerated have a stronger affinity for oxygen than gold, so that the oxyd of gold, in combination with the acid, is decomposed; the oxygen combining with the hydrogen, and forming water, or with the phosphorus or sulphur, and forming sulphuric or phosphoric acid.

The muriate of gold is soluble in ether, and forms with it a solution of a golden yellow colour, which floats on the top of the fluid. By the addition of ether to a solution of gold, and agitating the mixture, as soon as it is left at rest, the two liquids separate, the ether rises to the top, and assumes a yellow colour, while the nitric-muriatic acid remains below and becomes white. By a process of this kind, a tincture of gold was prepared, called "potable gold." The solution of gold in ether is not permanent; it is quickly reduced to the metallic state, and is sometimes found crystallized on the surface. The etheral solution is used by Mr. Stothart for defending lacets, and other surgical instruments, from injury by a moist atmosphere.

The muriate of gold is decomposed by all the alkalies and earths, and is reduced to the state of yellow oxyd.

Most of the metals decompose the muriate of gold: copper, iron, zinc throw down the gold in its metallic state; other metals, as silver or lead, in the state of purple oxyd. The precipitate obtained by means of tin is valued for the beauty of the colour which it gives to glass or enameled ware. This preparation is known to artists by the name of the "Purple powder of Caucasus," and it may be obtained by various processes. That which is commonly referred to, is to dissolve pure gold in a nitric-muriatic acid, which is composed of three parts of nitric and one of muriatic acid. A solution of tin is to be prepared by dissolving the metal, in small portions at a time, in an acid containing two parts of nitric and one of muriatic acid, previously diluted with an equal weight of water. This solution, after it is saturated, is largely diluted, perhaps with a hundred parts of distilled water; to this the solution of gold equal in quantity to half the quantity of solution of tin, is added, and the precipitate is obtained after it is allowed to subside, which is to be washed and dried. This is the only known preparation capable of giving a red colour to glass; and if the experiment be performed with accuracy and judgment, the glass so treated serves as a capital imitation of the ruby. The process is, however, attended with considerable difficulty, owing to the colour of the precipitate being various, from circumstances not easily discovered. According to Pelletier, it is a compound of oxys of tin and gold; and its formation is owing to the strong attraction of the tin for the oxygen, with which it is disposed to combine in large quantities. When the solutions, above described, are mixed, the oxyd of tin, which is nearly at the minimum of oxydization, attracts part of the oxygen of the oxyd of gold: the two oxys thus brought to states of oxydization, different from those in which they existed in the separate solutions, and probably likewise exerting mutual affinities, are no longer soluble, and are precipitated in the state of a nitre. The muriate of gold is decomposed by some other metallic salts, in consequence of similar actions; the oxygen of the oxyd of gold being attracted by the oxyd of the other metal, which hence passes to a higher state of oxydization. Those which have a strong tendency to exist in such a state, are capable of completely de-oxydizing the oxyd of gold. Example.—If a solution of the green sulphate of iron be added to the solution of muriate of gold, the gold is precipitated in very minute particles in the metallic state, while the iron passes to the state of a red sulphate. A solution of muriate of gold, when heated in a crucible, yields beautiful yellow crystals, not unlike topazes.

Gold, as we have seen, does not combine with sulphur by fusion, and on this is founded a method of freeing it from silver or other metals, the alloy being fused with sulphur, the silver, &c. unite with the sulphur, leaving the gold separate. But gold and sulphur may be united by the medium of an alkali. Example.—Let a phusonc of potash be fused with one-eighth of its weight of gold-leaf, and the combination is even soluble in water, the solution being of a green colour.

Alloy of Gold.—Gold forms alloys with the greater number of the metals, which produce on the metal so alloyed a very particular change in its properties. An extensive and accurate series of experiments on these alloys was made by Mr. Hatchet, with the view of determining some important and interesting facts relating to the use of gold as a coin. Of these we shall give a brief abstract, referring our readers for a more particular account to the Transactions of the Royal Society for the year 1803.

The chief enquiry of Mr. Hatchet, as connected with the alloys of gold, was, whether soft and ductile gold, or gold made as hard as is compatible with the process of coming, fuses more or less by wear. His experiments were intended to examine the effects which various metals produce upon gold, when combined with it in given proportions, beginning with iron, which is the standard proportion of alloy, and gradually decreasing to the state of a mass. The results drawn from the trials were, that fine gold, alloyed with silver, copper, and with tin, did not suffer any loss during the experiment. The gold alloyed with lead only lost three grains, chiefly by vitrification; with iron it lost 12 grains, which formed scoria; with bismuth it lost 12 grains, chiefly by vitrification; with zinc it lost a pennyweight by volatilization; and with arsenic, it not only lost the whole quantity of alloy, but also two grains of the gold which were carried off in consequence of the rapid volatilization of the arsenic. Hence it was inferred that only two metals are proper for the alloy of gold coin, namely, silver and copper; as all the others either considerably alter the colour, or diminish the ductility of gold. In respect to the latter quality, the different alloys employed in this series of experiments appear to affect gold nearly in the following decreasing order: 1. Bismuth. 2. Lead. 3. Antimony. 4. Arsenic. 5. Zinc. 6. Cobalt. 7. Manganeze. 8. Nickel. 9. Tin. 10. Iron. 11. Platin. 12. Copper, and, 13. Silver. The three first have nearly the same effect on gold, and bismuth is found to render gold brittle when the proportion of that metal is to gold only as 1 to 1020; even the vapour arising from bismuth, lead, and antimony in fusion, produces these changes.
The alloy with platina is of a yellowish white colour, very ductile, and of a considerable specific gravity. The alloy with silver in the standard proportion, or 1 to 12, approaches, as we have seen above, the nearest to the ductility of fine gold of any alloy, and its specific gravity differs but little from the mean specific gravity of the two metals. When the silver amounts to 4th, the colour of the alloy approaches to green, and forms the green gold of the goldsmiths. In combination with copper, gold has its colour rather heightened than impaired; its hardness is increased and its ductility very little lessened, when the standard proportion of 1 part in 12 is not exceeded. This alloy of 22 carats fine is generally used, when gold is fabricated into plate or ornaments, and likewise forms the gold coin of the country. With quicksilver, gold unites with great facility, making it an amalgam which will be deferred hereafter. The alloy with iron is much harder than gold, very ductile and malleable; but the colour is debased to a dullish grey, inclining to white. Tin was formerly regarded as the metal which rendered the alloy with gold the most brittle of all the alloys, but the experiments of Mr. Bingley and Mr. Hatchet have shewn that this notion is to a certain extent erroneous, and that the effects produced by the mixture of tin with gold, ought probably to be ascribed to other metals, with which the tin was contaminated, such as bismuth, antimony, lead, and zinc. The alloy, consisting of equal parts of zinc and gold, is very hard and facets easily of a fine polish, and not being subject to much alteration from the air, it is recommended for the fabrication of the mirrors of telescopes. The alloy of gold with silver, in which there is only 1/4 part of silver, changes the colour of the gold very sensibly; and the alloy is employed for fordering gold, being more fusible than this metal.

**Gold. Physical properties of.** Gold, aurum, a yellow metal, heavy, pure, ductile, malleable, and thinning; and on those accounts, the most valuable of all metals. In fusibility it ranks between silver and copper; it is not oxidizable by fusions in atmospheric air; nor is it acted upon by any of the acids, except the oxyymuriatic and nitro-muriatic.

The yellow colour of gold is rendered paler by fusion with borax; but this may be prevented or corrected by fusion with nitre, or sal ammoniac. The colour of gold is heightened by an alloy of copper, and this property of copper has given rise to fummary processes for exalting the colour of this noble metal. Other metals render it paler. The alchemists call gold, φό, the fun; to denote its pre-eminence over the other metals, which are called by the names of the planets. Its symbol, or character, is O; which, in their hieroglyphical way of writing, denotes perfection, simplicity, fulness, &c.

The weight of gold is to that of water, according to some statements, as 19.637 to 1000. Fine gold, immersed in water, weighs nearly one nineteenth part less than in air, and consequently it is upwards of nineteen times heavier than its own volume of water. However, the specific gravity of gold, or its comparative weight with an equal volume of water, has been variously assigned; some have made it 19.637, others 19.643, and in the Swedish Translations it is made no less than 20.000; that of water being 1000.

Others again have made it as low as 18.75. But from the experiments of Mr. Ellicott, it does not appear to have exceeded 19.207; and from those of Dr. Lewis, on the purest gold, well hammered, its gravity is flattened between 19.320 and 19.400. In all experiments of this kind, the result should be specified with an account of the sensibility of the balance, and the quality and warmth of the water. An increase of heat rarefying water more than it does gold, the gold must turn out proportionally heavier than an equal volume of the expanded fluid; and this difference is very considerable than it has generally been found. But this effect from freezing to boiling water, or by an augmentation of heat equivalent to 180° of Fahrenheit's thermometer, Dr. Lewis found that a rod of gold was lengthened about one part in 552, and consequently its volume increased about one part in 233, while the volume of water is increased one twenty-sixth or more; hence it appears, that by an augmentation of 40 of the thermometer, or from a little above freezing to the summer heat, the volume of gold, if its expansion be uniform, is increased one part in 184, and that of water one in 117; and the gravity of gold, weighed in the water, so warmed and expanded, should be greater than when the gold and water are 40 colder, in the proportion of about 19.265 to 19.400: and this calculation gives a difference, in the gravity, of 0.034 for every 10° of the thermometer; but some trials seemed to make it greater. It has been imagined, that the comparative gravity of gold to brass weights, which are more than double in volume to an equal weight of gold, must be far influenced by the variable gravity of the atmosphere, that there must be an advantage in buying gold by weight when the air is lighter. But Dr. Lewis observes, that this difference appears too incensitive to be regarded in a commercial view. For the life of their los in water, as air is lighter than water; and air, if we admit the accuracy of the conclusion deduced from an experiment of Mr. Hawkshoe, being in its lightest state about a 937th, and in its heaviest state about a 848th part of the weight of water; it will be found, on calculation, that the gold preponderates above the brass, in the heaviest state more than in the lightest state, only by one part in 105,000, or one grain in about 300 ounces; which is a difference too minute to be sensible in the nicest balance. If the mean gravity of gold be reckoned 19.359, as a cubic inch of water weighs about 254 grains, a cubic inch of gold will consequently weigh about 4502 grains, or 10 ounces, 152 grains. The pound weight, or twelve ounces Troy, of gold, is divided into twenty-four carats. Dr. Lewis fixes the specific gravity of fine gold at 53 Fahrenheit, to be 19.359. According to Brillon the specific gravity of fine gold in ingot is 19.258, and when hammered 19.361. The specific gravity of gold made standard by British copper, was found by Mr. Hatchet (see Phil. Trans., for 1805) to be 17.281, when cast in an iron mould; but when the same was cast in gold, it was only 16.954. (See Specific Gravity.)

The softness of gold, for it is nearly as soft as tin, and its toughnels, adapt it for receiveing the impressions of dies, and of course to be reduced to the state of coin, and for various other purposes in the arts. It is but slightly electricity and freezable. With regard to tenacity, it is inferior to iron, copper, platin, and silver, and therefore the alterations of former chemists and philosophers have been contradicted by later experiments, for gold has been usually represented as the most tenacious as well as the most ductile of all metals. Its malleability and ductility are sufficiently evinced by the Gold-leaf and Goldwire, which see. See also Ductility.

The value of gold to that of silver, was ancienly only as twelve to one. Indeed, this proportion varies as gold is more or less plentiful: for Systematic relates, that Cæsar brought such a quantity of gold from Italy, that the pound of gold was only worth seven pounds and a half of silver. In our coinage, the value of fine gold to fine silver is nearly as 15 to 1.
GOLD.

in the year 1717, that in the mints of Spain and Portugal the value of gold is sixteen times that of silver; but that in those countries, payments in silver bearing generally a premium of six per cent. fixed by commercial statute, at 15; 1. to 1, that in the other parts of Europe, the value of gold is at most fifteen, and in China and Japan but nine or ten times that of silver; so that gold is rated higher in England than in any other part of Europe, and higher in Europe than in the Eastern countries. Hence, in great measure, arise the profits of exchanging gold for silver in one place, and re-exchanging them in another; and hence the greater disparity between the relative quantities of gold and silver in one commercial nation than in another; this metal being brought in most abundance which is rated highest in proportion to the other, and that which is rated lowest being drained away. There are various ways of determining the fineness of gold; or the proportion of alloy which it contains. Those who are averse to this business can judge nearly the proportion of alloy from the colour of any given mafs, provided that the species of alloy is known. For the method of doing this, see TOUCH-neddle.

The great excess of the weight of gold, above that of the metals used for its alloy, affords another method of determining the Quantity of alloy in any given mafs, where the species of alloy is known. Thus fine gold lofts in water one grain in every 19.3 nearly; and fine silver lofts one grain in about eleven; from whence it is easy to find the mafs of any number of grains of each, and consequently of any assignable mixture of the two metals. Thus, fifty grains of gold will loft above 2 1/2, and fifty grains of silver somewhat more than 4 1/4, so that a mixture of equal parts of the two will loft above seven in a hundred, or one in fourteen. A mixture of gold with half its weight of silver will loft one part in 15. 4; with a third of silver, one in 16. 2; with a fourth, one in 16. 7; and with an eleventh of silver, which is the standard proportion of alloy, one in 18. 1. On this principle, the specific gravity or proportional lofts in water, of gold alloyed with different quantities of silver, copper, and mixtures of both, may be computed and formed into tables for use. The accuracy of this method, it should be observed, depends on the supposition that each of the two metals, that are melted together, retains its own proper gravity, which is the case in mixtures of gold and silver; but gold and copper, melted together, are specifically lighter than if they were weighed separately; or the specific gravity of the alloy is less than that of the mean of its ingredients; the case is the same with the alloys of nickel and gold, of lead and gold, of iron and gold; but the reverse happens in mixtures of gold with zinc, bismuth, and tin. It appears, therefore, that the hydrostatic balance cannot discover, with certainty, the exact fineness of gold, unless when silver is the metal mixed with it.

There are various methods of separating gold from gilt works: It may be separated from the surface of silver, either by spreading over the gilt silver a paste made of powdered ful ammoniac mollified with aquafortis, and heating it till the matter fumes, and is nearly dry; throw it into water; and the gold will easily come off by rubbing it with a ferrath brush; or, by putting the gilt silver into common aqua regia, nearly boiling, and turning the metal frequently, till it becomes all over black; then wash it with water, and rub it with the ferrath brush, which will disengage the gold left by the aqua regia. See Gilding.

Gold may be separated from gilt copper, by applying a solution of borax to the gilt parts with a pencil, and sprinkling over the plate thus moulded a little powdered sulphur; when the piece is made red-hot and quenched in water, the gold may be wiped off with a brush.

Gold may be recovered from wood, gilt on a water size, by steeping it for a quarter of an hour in a quantity of very hot water, sufficient to loosen it; then rub the wood in a little warm water, with short stiff bristle brushes of different sizes: boil the whole mixture of water, size, gold, &c. to dryness; make the dry matter red-hot in a crucible to burn off the size, and grind the remainder with mercury. The gold will be more easily laid hold of by the mercury, by the addition of some clean sand.

GOLD, Alchemical History of. See Philosopher's Stone, and Transmutation.

GOLD, Amalgam of, is a preparation of gold much used by the gilders (see Gilding); and it is made by heating some pure quicksilver in a clean crucible, and adding to it, when it is nearly boiling, about a sixth of its weight of fine gold in thin plates that are hot; after this mixture has kept hot for a few minutes, it becomes an homogeneous substance; and when cold, it is put into a piece of soft leather, and which is gradually pressed till the fluid part of the amalgam, confining almost wholly of mercury, is forced through the pores of the leather; while the gold, combined with about twice its weight of mercury, will remain in the state of a yellow filvery mafs, of the consistence of soft butter; when this mafs has been bruised in a mortar, or shaken in a phial, with repeated portions of salt and water, till the water receives no founfes from it, it is fit for use, and may be preserved for any time in a corked phial. For the purposes of gilding it is of great importance, that this amalgam should be formed of pure materials, as any portion of lead or bismuth would deteriorate the colour of the gold, and tarnish it with black specks. The mercury should therefore be previously distilled from the red precipitate (nitrous red oxyd of mercury), either alone or mixed with a little charcoal powder. See AMALGAM and MERCURY.

GOLD-heating, and GOLD-heater's skin. See GOLD-leaf.

GOLD, Burnished, is that which is polished with a file instrument, called a burnisher, if it be wrought gold, or gilding on metal; or with a wolf's tooth, if it be gilding in water. See Gilding.

GOLD Chain. See CHAIN.

GOLD COIN, or SPECIE of gold. See COIN and COINAGE.

GOLD COLOUR on GLASS and China. See CEMENTS, GLASS, GILDING, and PORCELAIN.

GOLD-coloured Glazing. See GLAZING.

GOLD-coloured Metal is produced by melting zinc with copper. According to the purity of the zinc and copper, the proportions in which they are mixed, and the intimacy of their union, the compound metal proves more or lefs malleable, and approaches more or lefs to the colour of gold. Some direct the zinc to be taken only in a fifth or sixth part of the weight of the copper, and others in an equal weight or more. Dr. Lewis observes, from the result of many experiments, that both with the smallest and largest of these quantities of zinc, the metal proves more like gold than with the intermediate proportions. The colour of the compound is improved by a small mixture of some other metallic bodies. Cramer recommends the addition of a small quantity of pure tin to copper, melted with a fourth or fifth part of zinc, which forms a compound metal, that acquires, on being well cleaned, and laid in the air for some days, a superficial colour of fine gold. Geoffroy says that iron has the best effect: with the proportions of ten parts of zinc, eight of copper, and one of iron-filings, he produced a metal of a fine smooth grain, compact, hard, and bright, and of a beautiful gold colour. By making the copper first into brass, and then melting it with a suitable quantity of zinc, a metal may be obtained of fine period.
GOLD.

perior quality to that produced either by melting the copper end zinc, or by impregnating the copper with zinc, by cementation and fusion with calamine; which is a method sometimes practised. A very ingenious artist, says Dr. Lewis, who now prepares a gold-coloured metal in great perfection, has a fine kind of brass made on purpose for this use. The union of the copper and zinc in fusion, succeeds best with lead lots of the zinc, according to Dr. Lewis, by using a mixture of black flux and borax, or a composition of twelve parts of green glass powdered, six parts of potash, two of borax, and one of powdered charcoal: when this flux is fused in the crucible, the copper and zinc are dropped into it; and when they appear perfectly melted, they are to be well stirred together with an iron rod, and expeditiously poured out. The same flux will serve for melting several fresh quantities of the metal. Dr. Hooke gives the following receipt for making a gold-coloured metal: eight parts of distilled verdigris, i.e. of verdigris purified by solution in distilled vinegar and crystallization, and four parts of Alexandrian tincture, with two of nitre, and one of borax, are directed to be mixed with oil to the consistence of paper, then melted in a crucible, and poured into a flat mould first well warmed. A composition of this kind is called aurum fabuliferum.

The following method is recommended by Homborg for giving a gold colour to copper, without the addition of zinc; make an amalgam of one part pure copper, and three parts quicksilver; boil this in river-water for two hours, then distill off the quicksilver in a retort, and coagulate it once; take out the copper and fuse it, and it will be founded of a beautiful gold colour, more ductile than common copper, and extremely well fitted for watch-work, gilding, and the finer machines and utensils. The celebrated Mr. Pott affirms that a gold-coloured metal may be made from a mixture of copper and tin, and directs it to be compounded in the following manner: Take one half ounce of tin ashes, and four half ounces of copper; melt them well together in a cluse luted crucible, with a strong fire; or take one half ounce of the purest tin cut in pieces, and sixteen half ounces of pure copper beaten into thin plates; lay the tin between the copper-plates, lute the crucible close, and melt with a strong fire. See Prior's Metal and Tommac.

Silver is tarnished superficially, by certain vapours, as that of putrid urine, to a colour so like that of gold, that several edicts have been issued in France to prevent frauds of this kind, with regard to silver and laces.

GOLD-coloured Pigments. See Pigments.

Gold, Dutch, is a kind of leaf used in gilding, &c. which is copper gilt, or brass beaten into leaves like the genuine gold-leaf. It is said to be made from copper-plates, by cementation with calamine, without subsequent fusion. The thickness, compared with that of leaf-gold, is as nineteen to four, and under equal surfaces it is considerably more than twice as heavy as the gold.

Gold, Farring of. See Farring.

Gold, Fine or Pure, is that purged by the fire of all its impurities, and all alloy. The Latins call it aurum purum, aurum primam, aurum obirizum, aurum calidum.

The moderns frequently call it gold of twenty-four carats; but, in reality, there is no such thing as gold so pure; and there is always wanting at least a quarter of a carat. Gold of twenty-two carats has one part of silver, and another of copper: that of twenty-three carats has half a part, i.e. half a twenty-fourth of each.

Bouteron maintains, that the electrum of the ancients was gold of nineteen carats; or four parts gold, and a fifth silver.

From an ordinance of king John of France, it appears that the gold then struck at Paris was of nineteen carats one-fifth; and yet it is added that it was the best and finest gold then known on earth. See Standard.

Gold, Fulminating, aurum fulminans, a precipitate of gold from its nitro-muriatic solution by ammonia, which possesses a most remarkable explosive property. See Ammonia.

It is prepared by diluting a solution of muriated gold with six or eight times its bulk of distilled water, adding drop by drop liquid ammonia, till the precipitation ceases; then let the yellow powder thus obtained be separated by a filter, well washed in hot water, and afterwards dried. The fulminating gold, thus procured, will exceed the weight of the original gold by about 33 parts in 100. If a small quantity, e.g. half a grain of this powder be held over a candle, in a spoon or on the blade of a knife, it presently explodes with a very loud report. This powder should be very cautiously used; the temperature requisite for its explosion is flattened at above 250° of Fahrenheit. Before it explodes, its yellow colour changes to black, and at the moment of its decomposition an inustaneous flash is observed. The principal energy in explosions are directed downwards, insomuch that two or three grains of it exploded on a moderately thick sheet of copper will burn a hole in it. This salt is decomposed by an electrical shock, but it cannot be ignited by a spark from electricity or from flint and steel. It will vehemently explode by sudden friction, and therefore, in order to avoid dangerous accidents of this kind, it should never be kept in a ground-hopper bottle. The facility of its explosion is very much increased by high drying; so that if it be heated till it becomes black, and is immediately removed from the fire, it will frequently go off by a mere touch. If the fulminating gold be mixed with four or five times its weight of chalk, or fulpeat of potash, or with any pulverulent substance neither fusible nor decomposable at a moderate temperature, and exploded gradually to a low heat, it will be quickly decomposed, leaving merely the purple oxyd of gold. The same effect may be produced by very cautiously heating the fulminating gold without any addition, removing it from the fire when it has changed its colour, and when cold heating it again, and proceeding in this way till the powder becomes purple, in which state it will have entirely lost its explosive faculty. A similar change occurs by melting sulphur at the lowest possible heat, and dropping in the fulminating gold by half a grain at a time, well mixing it; the sulphur may then be burnt off without danger, and minute grains of metallic gold will be left behind. The true theory of the decomposition of fulminating gold was partially discovered by Bergman, and has since been fully illustrated by Berthollet. The former of these able chemists showed that this salt when decomposed in close vessels was reduced to gold, partly in the metallic state and partly in that of purple oxyd, and at the same time a gas was extracted in bulk about a thousand times as great as that of the original fulminating salt, and which extinguished flame and animal life, was not absorbed by water, and gave no precipitate with lime-water. Berthollet, by decomposing the same substance in a copper tube, connected with a jar inverted in mercury, obtained azotic gas and a few drops of water, and the gold was reduced to the metallic appearance. Now as ammonia is composed of hydrogen and azot, and as the affinity of gold for oxygen is very slight, it is manifest that the decomposition and explosion, under the circumstances already mentioned, are occasioned by the oxygen of the gold.
Gold, Leaf, or beaten gold, is gold beaten with a hammer into exceedingly thin leaves. It is astonishing to consider the fineness to which a body of gold is thus reduced. In an experiment of Reaumur's, forty-two square inches and three tenths of gold-leaf weighed one grain; and Mr. Boyle found that fifty and seven tenths weighed but a grain. As a cubic inch of gold weighs 4902 grains, the thickness of the gold-leaf examined by the one was the 207555th, and of that by the other only the 24552nd part of an inch. See Ductility of Gold.

This gold is beat on a smooth block of black marble, from two hundred to six hundred pounds in weight, and about nine inches square on the upper surface, fitted into the middle of a wooden frame, about two feet square, so as that the surface of the marble and frame form one even plane. Three of the sides are furnished with a high ledge, and the front, which is open, has a leather flap fastened to it, which the gold beater uses as an apron, for preserving the fragments of gold that fall off. Three hammers are employed in this business, having two round and somewhat convex faces: the first, called the cutch hammer, is about four inches in diameter, and weighs fifteen or sixteen pounds: the second, called the shoddering hammer, weighs about twelve pounds, and is of the same diameter: the third, called the gold or finishing hammer, weighs ten or eleven pounds, and is nearly of the same width. The French use four hammers, differing both in size and shape from those of our workmen.

The gold beaters also use three kinds of animal membranes; some of which are laid between the leaves to prevent their uniting together, and others over them to defend them from injury by the action of the hammer. For the outside cover, they use common parchment made of sheep skin; for interlaying with the gold, first, the smoothest and closest vellum made of calves skin; and afterwards, the much finer skins of ox-gut, flirip off from the large straight gut slit open, prepared on purpose for this use, and hence called gold-beater's skin. The general process of their preparation, is said to consist in applying one upon another, by the smooth sides, in a moist state, in which they readily cohere and unite indissolubly; fetching them on a frame, and carefully cutting off the fat and rough matter, so as to leave only the fine exterior membrane of the gut; beating them between double leaves of paper, to force out the remaining unctuity; mollifying them once or twice with an infusion of warm spices, and lastly, drying and prefling them. It is said, that some calcedine gypsim, or plaster of Paris, is rubbed with a hare's foot. Both on the vellum, and ox-gut skins, which fill up their pores, and prevent the gold-leaf from sticking. These skins, after seventy or eighty repetitions, become unfit for use; but their virtue may be restored by interlaying them with leaves of paper moistened with vinegar or white wine, heating them for a whole day, and afterwards rubbing them over with plaster of Paris; and even holes in them may be repaired by the dextrous application of fresh skins.

Gold, the manner of preparing and beating. They first melt a quantity of the purest gold in a black-lead crucible, with some borax, in a wind furnace, and pour it into an iron ingot mould, six or eight inches long, and 3 of an inch wide, previously greased and heated; the bar of gold is made red-hot and forged on an anvil into a long plate, which is further extended, by being paffed repeatedly between polished steel rollers, till it becomes a ribband, as thin as paper. This ribband is divided by compasses, and cut with shears into equal pieces, which are forged on an anvil till they are an inch square, and afterwards well annealed. Two ounces of gold, which is the quantity melted at a time, make a hundred and fifty of these ribbands; so that each of them weighs six grains and two fifths; and as 4902 grains of gold make a cubic inch, the thickness of the square pieces is about the 760th part of an inch. All these ribbands are interlaid with leaves or vellum, three or four inches square; one leaf being laid between every two of them, and about twenty more of the leaves are laid on the outsides; over these is drawn a parchment cafe open at both ends, and over this another, in a contrary direction, so that the vellum and gold leaves are both tight and entire. The whole is then beaten with the heaviest hammer, till the gold is stretched to the extent of the vellum: the pieces taken out of this cafe or mould, are cut in four with a flid knife; and the five hundred pieces thus produced are interlaid, in the same manner, with pieces of the ox-gut skins, five inches square. The beating is repeated with a lighter hammer, till the golden plates have acquired the extent of the skin; when they are divided into four, by a piece of cane cut to an edge. The whole number of leaves is then divided into four parcels, which are interlaid, as before, and beaten separately, till they are stretched for the third time to the size of the skins. The French repeat the division and beating once more. After the last beating, the leaves are taken up by the end of a cane instrument, and being thrown flat on a leathern cushion, are cut to a size, one by one, with a square frame of cane made of a proper sharpness, or with a frame of wood edged with cane. They are then fitted into books of twenty-five leaves each, the paper of which is well smoothed, and rubbed with red bale to prevent their sticking to it. The size of the French gold leaves is from somewhat less than three inches to ½ square; that of ours from three inches to ½. We shall here observe, that the gold used for the above purpose is never pure, because pure gold is too ductile to be worked between the gold-beater's skins. The newest skins will work the finest gold, and make the thinnest leaf, because they are the smoothest. Old skins, being rough or foul, require coarser gold. The finest gold for this purpose has three grains of alloy in the ounce, and the coarsest 12 grains. In general the alloy is six grains, or one eighth part. The alloy of leaf-gold is silver, or copper, or both, and the colour is produced of various tints accordingly. Two ounces and two pennyweights of gold are delivered by the master to the workman, who, if very skilful, returns 2000 leaves, or 80 books, of gold, together with one ounce and six pennyweights of waste cuttings. Hence one book weighs 4.8 grains; and as the leaves measure 3.3 inches in the side, the thickness of the leaf is one two hundred and eighty-two thousandth part of an inch.

The French prepare what is called green gold-leaf, from a composition of one part of copper and two of silver, with eighty of gold; but Dr. Lewis observes, that such an admixture gives no greenness to gold, and that this kind of leaf is made from the same fine gold as is the highest gold-coloured leaf, the greenish hue being a superficial tinge given to the gold in some part of the process; this leaf is chiefly used for the gilding of books. A kind of leaf, called party-gold, is formed by laying a thick leaf of silver, and a thinner one of gold, flat on one another; they are then heated and pressed together, so as to unite and cohere; and being beaten into line leaves, as in the foregoing process, the gold, though only in quantity a fourth of
of that of the silver, extends over it and every where covers it.

Gold, Million of, a phrase often used to signify a million of crowns.

Gold Money. See Money and Coin.

Gold, Mofane, is gold applied in panels on proper ground, distributed into figures, lozenges, and other compartments; part of which is shadowed to raise or heighten the rest. See Mosaic.

Gold Plates for Enamelling are generally made of ducat gold, whose fineness is from 22½ to 24½ carats; and the finest gold is the best for this purpose, unless where some parts of the gold are left bare and unpolished, as in watch-cases, snuff-boxes, &c. for which purpose a mixture of alloy is necessary, and silver is preferred to copper, because the latter disperses the plates to tarnish, and turn green. See Enamelling.

Gold, Potable, aurum potabile. See Aurum Potabile, and Gold.

Gold Powder, for the purposes of gilding, may be made by grinding gold leaf with honey, or thick gum-water. (See Shell-gold); by distilling to dryness a solution of gold in aqua regia; by evaporating the mercury from an amalgam of gold, taking care well to filter the muds after the end of the process with a glass rod or tobacco pipe; or by precipitating gold from its solution in aqua regia by applying to it a solution of common green vitriol in water, or some copper, &c.

Gold Precipitated with Tin, called also, from its supposed different nature, calx Gafth, is prepared with great care both in dissolving the tin, and diluting the solution. For this purpose, a mixture of two parts of aquafortis, and one of spirit of salt, is supposed to be the best menstruum for the tin. Into this mixture some fine black tin granulated, is to be let fall, grain by grain, waiting till one grain is dissolved before another is dropped in, that the dissolusion may go on slowly, without any heat or discharge of fumes. The gold is dissolved in common aqua regia; and a few drops of this solution being mixed with some ounces of pure water, as many drops of the solution of tin are added. If the mixture changes immediately to a clear bright purplish red colour, the due degree of dilution has been determined; if the colour appears dull, a greater quantity of water must be added for the rest of the solutions. After the mixture has deposited its red matter, and become clear, a little more of the tin solution is to be dropped in, for discovering and precipitating any gold that may still remain in it; the liquor being then poured off, the precipitate is washed and dried. Lewis's Com. Phil. Techn. p. 176. See Ruby Glass.

Gold, Queen. See Queen gold.

Gold, Shell, is that used by the gilders and illuminers, and with which gold letters are written. It is made by grinding gold leaves, or gold baster's fragments, with a little honey, and afterwards separating the honey from the powdered gold by means of water. When the honey is washed away, the gold may be put on paper, or kept in bottles; whence its name. When it is used, it is diluted with gum-water, or spirit finds. The German gold-powder, prepared from the Dutch gold-leaf in the same manner, is generally used, and when it is well covered with varnish, answers the end in splendid gilding, as well as the genuine stuff. See Gilt Rose.

Gold-paper, for bound gold gilding, is prepared of one pound and a half of tobacco-pipe clay, half an ounce of red chalk, a quarter of an ounce of black lead, forty drops of sweet oil, and three drams of pure tallow; grind the clay, chalk, and black-lead f separately very fine in water; then mix them together; add the oil and tallow, and ground the mixture to a due consistence; or it may be more simply prepared by grinding together some finely calcined red ochre with the thickest and oldest drying oil that can be procured; and, previously to use, mixing it with a little oil of turpentine for giving it a proper consistence. See Oil Gilding.

Gold-leaf of Jews, prepared by polishing gum arabic and asphaltum, or, if one ounce of red-lead, litharge of gold, and umbre, of each one ounce and a half, mixing them with a pound of linseed oil, and boiling them, observing to filter them till the whole be incorporated, and appears, on growing cold, of the consistence of talcum, in the mixture through a flannel, and keep it stowed up in a bottle, for use. When it is used, it must be ground with as much varnish as will give it an opaque body, and diluted with oil of turpentine, so that it may be worked freely with the pencil. A simple preparation consists of one pound of linseed oil, and four ounces of gum acacia; powder the gum, and mix it gradually with the boiling oil: let it continue to boil, till it becomes of the consistence of tar; strain it through a coarse cloth, keep and use it as the other.

Goldsmith, or as some choose to express it, floristsmith, the artist who makes vessels, utensils, and ornaments in gold or silver. The goldsmiths work is either performed in the mould, or bent out with the hammer or other engines. All works that have raised figures are call in models, and afterwards polished and finished; plates or dishes of silver or gold are beat out from thin flat plates, and tankards and other vessels of that kind are formed of plates folded together, and their mouldings are bent, not cast. The bolder-worke of the goldsmith formerly required much more labour than it does at present, for they were obliged to hammer the metal from the ingots to the things they wanted; but there are now invented flatting-mills, which reduce metal to the thickness that is required, at a very small expense. The goldsmith is to make his own moulds, and for that reason ought to be a good designer, and have a taste in sculpture: he also ought to know enough of metallurgy to be able to assayed mixed metals, and to mix the alloy.

The goldsmith in London employs several hands under him for the various articles of his trade. In this great city there are always hands that excel in every particular branch of the trade, and there is commonly employment enough for every one in his particular branch. The jeweller, the snuff-box and toy-maker, the silversmith, the goldsmith, the hatter, the tailor, the art of the gold-beater, are all employed by and under the goldsmith.

Gold-Thread, or spun gold, is a flatted gilt wire, wrapped or laid over a thread of yellow silk, by twisting it with a wheel and iron bobbins. By means of a curious but complex machinery, a number of threads is thus twisted at once by the turning of one wheel. The principal art consists in regulating the motion, that the linear circulations of the twisted wire, on each thread, may still touch one another, and form, as it were, one continued covering. At Milan, it is said, they make a fort of flatted wire, gilt only on one side, which is wound upon the thread, so that only the gilt side appears. There is also a gilt copper wire, made in the same manner as the gilt silver, chiefly at Nuremberg: and the ordinances of France
GOLD.

France require it to be spun on flaxen or hempen threads. The Chinese, instead of flatted gilt wire, use slips of gilt paper, which they interweave in their stuffs, and twist upon gilt threads.

GOLD, Tun of, is a kind of money of account, formerly used by the Dutch, and in some other countries, containing a hundred thousand florins.

A hundred pounds of, or in, gold, is found to weigh two pounds ten ounces : the sum in silver weighs twenty-six fix ounces four pounds. Twenty-two pence in copper farthings and half-pence, weigh one pound avoirdupois. A tun of gold, at 41. the ounce, amounts to 96,000. A tun of silver, at 5l. 2d. the ounce, to 6200. A pound flarding of gold to 4 S. An ounce is worth 4l. The penny-weight 4s. One grain, 2d. A pound of flering silver amounts to 3l. 2d. An ounce is worth 5z. 2d. The penny-weight, 3d. and something more; one grain a half-penny. A pound of silver avoirdupois comes to 5l. 5s. 3d. half-penny.

GOLD, Virgin, is pure gold, just as it is taken out of the mines, before it has undergone any action or preparation of fire; whence the Greeks call it αὐτόππος.

Such is ζηθήμενον, or gold-dust, and that got by lotion in the lavaderos in Chili : it is added, that there are maffes or lumps of pure gold found in the mines, particularly those of Hungary. Accordingly, in the emperor's collection, are still preserved several plates of gold, said to have been thus found.

Virgin gold is sometimes very pale, and so foist, that it may be moulded into any figure with the hand; it even takes an impression from a feel, like the softest wax. To harden it, as also to heighten its colour, they mix emery with it.

GOLD, White. See Platina.

GOLD Wire is a cylindrical ingot of silver, above an inch thick, two feet in length, and weighing about twenty pounds, superficially gilt, or covered with gold at the fire, and afterwards drawn successively through a great number of little round holes of a wire-drawing iron, each less than the other, till it be sometimes no bigger than a hair of the head. There is very little wire made entirely of gold, and this chiefly for one particular purpose, that of stiffwire work.

It is amazing to what degree of finesness the gold is here drawn; and yet it still keeps firm together, and never swells the leafy signs of the silver underneath it. The reader may see a computation herof, as also a more particular account of the manner of proceeding, under the article Ductility of gold.

GOLD Wire flattened, is the former wire flattened between two rollers of polished steel, to fit it to be spun in silk, or to be used flat as it is without spinning, in certain stuffs, laces, embroideries, &c.

Manner of forming Gold Wire and Gold thread, both round and flat.—The first object, which is of the utmost consequence, is the choice of the purest gold; for on this chiefly depends the beauty and durability of the colour of the laces, brocades, and other commodities prepared from it. To a difference in this respect, the boasted superiority of the French laces to the generality of those made in England, till of late, has been wholly owing. With regard to the silver that forms the body of the wire, it is said that there is an advantage in its being alloyed. The French silver for gilding is said to be alloyed with five or fix penny-weight, and ours with twelve penny-weight of copper, in the pound Troy. The gold is employed in thick leaves, which are applied all over the silver rod, and pressed down smooth with a steel burnisher. Several of these leaves are laid one another, as the gilding is required to be more or less thick. The smallest proportion allowed by act of parliament, is 100 grains of gold to a pound; or 5760 grains of silver. The largest proportion for the bell double gilt wire was formerly 120 grains to a pound; but the proportion of gold has been of late increased to about 140 grains. The first part of the drawing proceeds, as well as the preparation and gilding of the silver rod, is performed by the refiner, who uses plate of hardened steel, with a piece of tough iron welded on the back, to prevent the feel from breaking. The holes in these plates are conical, being larger in the back part than in the feel, so that the rod may not be scratched against the outer edge, and that they may contain bees-wax, which makes the rod pass more freely, and prefers the gold from being rubbed off. One end of the rod, made smaller than the rest, is pulled through a hole that will admit it, when the plate has been properly secured, and held hold of by strong pincers, called clamps, adapted to the purpose; to these pincers, which are so contrived, that the force which pulls them horizontally, serves at the same time to press them together, a rope is fastened by one end, and the other end goes round a capstan with cross bars, which requires the strength of several men to turn it. The rod, thus drawn through, is well annealed; it is then passed through the next hole; and the annealing and drawing are repeated, till being reduced to about the size of a large quill, it is delivered in coils to the wire-drawers. The remainder of the proceeds requires plates of a different quality, which are brought from Lyons in France, and are formed of metallic mafs, whose prevailing ingredient is iron: the holes are drilled in them here. These plates are of two sorts; some of considerable thickness, for the wire in its larger flate, and others about half as thick, for the finer wire. In the use of these plates, furnished with a variety of holes, the dexterity of the workman principally consists in adapting the hole to the wire for: this purpose he uses a brass plate, called a fine, on which is measured, by means of notches, like steps cut at one end, the measure which a certain length of wire should gain in passing through a fresh hole; and if the wire is found to stretch too much or too little, the hole is widened or contracted. Slots of different widths, in thick polished iron rings, serve also as gages for measuring the degree of finesness of the wire.

The wire-drawer's proceeds begins with annealing the large wire received from the refiner, which he does, by placing it, coiled up, on some lighted charcoal, in a cylindrical cavity, called the pit, under a chimney, and throwing more burning charcoal over it. When it is cooled by being quenched in water, one end is passed through the first hole in the thick plate, and fastened to an upright wooden cylinder fix or eight inches in diameter; in the top of which are two flaps, and through these is passed the long arm of a handle, by which the cylinder is turned on its axis by several men. By this proceeds, called degrossings, the wire is frequently annealed and quenched, after passing through every hole, or every other hole, till it is brought to about the size of the small end of a tobacco pipe, and then cut into portions for the fine wire-drawer. In this last part of the wire-drawing processes, annealing is not necessary, but the wire is waxed at every hole. The contrivance for drawing the wire through the plate in this case, when left force is needful, is a kind of a wooden wheel placed horizontally, having in its upper surface small holes at different distances from the axis, into one or other of which, according to the force required,
G O L D.

Gold of Pleasure, in Botany See Myagrum.

Gold Coast, or, as it is sometimes called, Guinea proper, a country of Guinea, on the S.W. coast of Africa, bordering on that part of the Atlantic which is called the gulf of Guinea, and extending between three and four degrees from the river Ankobar, or, as others say, from the Colla, or the Affilee, to the Volta, and deriving its name from the quantity of gold which it produces. It is bounded on the north by Kongo or Congo, on the east by the Slave coast, on the west by the Ivory coast, and on the south by the gulf of Guinea. It comprehends a number of petty states or kingdoms, viz. Adomur, called likewise Sako and Avena, Axim, Ankobar, Adom, likewise called Little Inkaflan, or Warhebi, Jabi or Jabo, Camomero or Guafio, Petu, Sabo, Fantin, Acoron, Agonna or Anguira, Amra or Aqualoubo, Lableade, and Niago or Lambi. Each of these provinces or kingdoms contains one, two, or more towns or villages on the sea-coast, between, or under the European forts and settlements. Eight of these are real monarchies, having their own proper kings; the rest are republics, governed by magistrates, who are subject to the laws and periodical changes. Upon the river Ankobar, or Cobre, which some reckon the first proper county of the Gold Coast, there is a number of towns, which compose three different provinces of Ankobar or Ancober, Aborrel or Aborco, and Eguira, at which latter place the Dutch had formerly a fort, and carried on a considerable trade in gold. Eight leagues E. of cape Apollonia stands the town of Axim, called by some Achembone. (See Achembone and Axim.)—See Acors, Adum, Aoderm, Anba, Camonero, &c &c. The country throughout the Gold Coast abounds in hills, adorned with high and beautiful trees, among which are the palm, the cocoa-nut, the papaw, and the banana. The valleys between the hills are wide and extensive, and fit for the plantation of all sorts of fruit; and if they were as well cultivated as watered, they would supply half the coast with provisions. The soil produces in great abundance very good rice, the richest sort of millet with red grain, yams, potatoes, and other roots, all good in their kind. The sugar-cane grows here plentifully, and larger than anywhere else on the Coast of Guinea. Palm-wine and oil are very good, and very abundant; the country also has plenty of tame cattle and wild beasts. The domestic animals are bulls, cows, sheep, and goats, the last of which are numerous and their flesh is excellent; neither the mutton nor beef is good; but of all animal food dog's flesh is most preferred by the negroes. The wild animals are elephants, tygers, jackals, boars, deer of various sizes, cats, porcupines, monkeys, rats, mice, &c &c. Among the birds are pheasants, parrots, macaws, turtle-doves, and several others. The reptiles are numerous; such as snakes, lizards, vipers, lizards, scorpions, spiders, &c. The coasts, lakes, and rivers abound with fish, and likewise with alligators and gannans, an amphibious animal, resembling the crocodile, and four feet in length. The climate is very hot, from October to March, but during the other months tolerable. The natives are generally healthy; but to Europeans the climate is infalubrious, and often fatal, especially in the months of July and August.

It is ordered that of all the countries on the coast of Western Africa, the Gold Coast experiences the most intense heat. First, a modern traveller, near Rio Volta, has seen Fahrenheit's thermometer as high as 110° in his chamber, and 154° in the open air, surpassing by 26° the greatest heat observed by Adamson on all the banks of the Senegal. Although this traveller advanced only 10 miles from Chirikumbur on this coast, his journey is curious.
G O L D.

The countries he visited during his short excursion in the interior, are represented as very beautiful, fertile, and populous; they are, in general, woody, but, nevertheless, more healthy than the shores; they areagreeably intersected with mountains, valleys, and hills. Fresh water, which is scarce and bad on the coast, is here excellent and abundant. About five miles from Christianburg he observed a chain of mountains covered with tall trees, and composed of large grained granite, of gneiss, and of quartz.

The native negroes of the Gold Coast are in general tall, straight, and well-proportioned, with oval faces, sparkling eyes, regular, white teeth, mouths of a moderate size, and lips tinged with a better colour and thinner than those of the negroes of Angola. As to the qualities of the mind, they have a quick apprehension and ready memory, accompanied with an astonishing precocity of mind, and equanimity; but they are generally so indolent that mere necessity puts them upon exerting the faculties they possess. In general, they are crafty, fraudulent, and treacherous; thieves, gluttons, and drunkards, and equally incessant and covetous. When they obtain a victory over their enemies, they return home dancing and singing, and when defeated do the same round the graves of their friends and fellow-soldiers. Alike insensible of grief or joy, they sing till they die, and dance into the grave. The women are proportionably handomer than the men, fairer, flender, and well-limbed; their cheeks high, their mouths small, and their eyes indicating vivacity and spirit. They are quick, cheerful, and loquacious; gay in their deportment, and loath in their principles as to galantry, but temperate in their diet. When the men and women overcome their natural indolence, they are industrious, industrious, and ingenious; and apply to agriculture and gardening, far as they are excited by poverty or avarice. Their dress is various according to their rank and circumstances; but the rage of drefs is chiefly prevalent among the women, who are fond of adorning all parts of their bodies with gold, coral, and ivory trinkets; and this rage they derived from the Portuguese and Dutch, as before their arrival men and women went naked to the age of maturity. They are fond of frequent ablutions, and being accustomed to the use of water, they are excellent swimmers and divers from their youth. Besides the natural inhabitants of the Gold Coast, there is a great number of Mulattoes, a mixed-progeny, arising from the commerce of Europeans with the black women. This spurious race forms gangs of thieves and plunderers, void of decency, honour, honesty, or principles in their dealings with each other, with the Negroes, or the Europeans. These call themselves Christians, although they are the groffets of all idolaters, and most of their women prostitute their bodies publicly to Europeans, and privately to the Negroes. The towns and villages of this coast consist of a multitude of little huts or cabins, diffused in groups, without order or design, and communicating with each other by narrow crooked roads, which terminate in the centre of the town or market place. It is observable that the farther you remove from the coast, the more civilized do the natives appear, at least so far as relates to their mode of building and of living. The common food of the Negroes, in this part of Africa, is a pot of millet boiled to the consistency of bread, yams, and potatoes, over which they pour some palm-oil, and garnish the dish with herbs and putrid fish. This is their meat on common days; and on holidays they eat upon beef, mutton, and fowls. They begin the day with drinking brandy, and conclude the evening with palm-wine, mirth, riot, and tobacco, of which they are extravagantly fond. In eating they are temperate, but very profuse in drinking. Their marriages are cumbered with few ceremonies, and without any previous courtship; and they are as readily dissolved as contracted. Polygamy is allowed among them; and the women are generally doomed to the most laborious offices; they are obliged to cultivate the ground, sow millet, plant yams, and provide subsistence for the husband, who is idly spending his time in gorging, drinking, and smoking. The rich, however, have two wives, who are exempted from labour and all servile employments; and to them the management of the house is intrusted, and a sort of authority over all the other women is committed. It is said to be no uncommon expedient among Negroes to marry, in order to obtain a livelihood by the prostitution of their wives. As the wealth of the Negroes consists chiefly in the number of their family, they are anxious for multiplying their children; and a pregnant woman is treated with great tenderness and respect. A child, as soon as it sees the light, is consecrated by the priest, and has three names given to it. Circumcision, it is said, though practiced in other parts of Africa, is hardly known on the Gold Coast, except at Acre, where it is performed at the time of baptism or consecration. Besides their lawful wives, the Negroes often keep concubines, who are preferred to their wives, and more tenderly treated; nevertheless their children are reckoned illegitimate. But legitimate children never inherit any paternal fortune, in any kingdom on the Gold Coast, except at Acre. In the countries of Eguira, Aasia, An- cobar, Atea, and Adam, there are certain women who never marry, but are dedicated by profession to the public and initiated in their vocation in a formal manner. Among the Negroes there is a vast number of various technical arts, in which they are experts; such as the making of wooden and cardboard vessels and plates, chair-mattings, copper, or iron boxes, bracelets, necklaces, rings, and ornaments of gold, silver, or ivory; and all sorts of materials and inlets of war. Their tools, which are rude and simple, consist only of a bone for an ax, a pair of tongs, a pair of hammers, a file, a saw, and a hammer. They can finish with extraordinary exactness. Red-ware, and materials of gold, brass, and copper. In building houses, which are of various sizes, from 80 to 14 feet in length, and three or four feet in breadth, the Negroes are very ingenious, and they are no less dextrous in the use of them. With regard to the husbandry of the Negroes, they live in the rainy season, the soil at other times being unmanageably hard; and they adapt their ground to the nature of the grain; growing maize in elevated and dry situations, and rice or millet in low marshy lands, subject to inundations. The natives of the coast, finding it easy to dispose of all their grain, have established corn markets in every village, and the price of grain, in gold-dust, cowries, &c., is rated by certain officers of police, appointed by the king. Hither the men and women meet from considerable distances, bearing heavy burdens; and the women especially submit to great labour and fatigue in this way, that they may exchange their heavy loads for European commodities, such as looking-glasses, bracelets, ear-rings, glass-bells, and other female trinkets, sold to them for dyes and finery. The markets are exempted from all duties and impojs. Besides these frequent markets, they have also fairs twice a year for European wares. All the diversions among the Negroes consist of dances, to which they are excessively addicted, mufic, and mock combats, which often terminate tragically. The principal musical instruments among the Negroes are horns, made of ivory, trumpets, drums of different sizes, and a kind of harp, with six or eight strings.
The honour of the first discovery of the Gold Coast is contested between the French and Portuguese; the French pretend that they were acquainted with Nigrina and Guinea above 100 years before the Portuguese began their discoveries; and in the year 1546, little credit is attached to these accounts of French writers. The Portuguese, it is said, fitted out a ship at Lisbon, under the protection of Don Henry, for the sole purpose of making discoveries along the coast of Africa. At this time Alphonso I., reigning in Portugal, the navigators, it is further said, were driven on an island in the gulf of Guinea, which they called St. Thomas, and where they made a long stay, laying the first foundation of a colony in this island. Having repaired their vessel, they returned to Lisbon, and arrived there in 1544. The Portuguese soon equipped a fleet, and pushed their discoveries as far as Benin, and in process of time arrived in the road of Acre, on the Gold Coast, where they procured a quantity of gold. A number of adventurers from the island of St. Thomas arrived at Elmina four years after the departure of the French. Purchases relates, that Alphonso, having little leisure for pursuing discoveries towards the latter end of his reign, gave an exclusive privilege for five years to Fernando Gomez, a citizen of Lisbon, to fail to the coast of Africa; and a person, deputed by him, says Purchas discovered Elmina: and during this period, were also discovered the islands of St. Thomas, St. Matthew, Annobon, and del Principe. In 1581 II. encouraged the commercial spirit of his subjects, and projected further discoveries; and it was probably upon this occasion, notwithstanding the affections of French writers, that fort St. George de la Mina, or Elmina, had its first rife. Join, the successor of Alphonso, conferred many privileges on this new colony. A few years after the same prince established a Guinea company, with exclusive privileges. In the reign of Henry III. of France, after the termination of the civil wars, the French began to renew their voyages to the Grain and Gold Coast. From this period the credit of the Portuguese began to decline, and other Europeans began to open a commerce with the Coait of Guinea. Among others the Dutch engaged in the warfare, which had been prosecuted between the Portuguese and other Europeans; and by perseverance they made themselves masters of the forts of Elmina and Axim; obtaining, by their courage, that security, which the Portuguese had lost by their insolvency and cruelty. The first Dutchman who led the way to Guinea, was one Bernard Erick, in 1595. Running along the Gold Coast, he established a correspondence with the natives, treated them with civility, and alienated their affections from the Portuguese. At length, by their intrigues with the king of Sahu, the Dutch obtained permission to build a fort, three leagues E. of Cape Corso, or Cape Coast. This fort was founded in 1624, and the Dutch power founded in Guinea, at the time when the States were engaged in a war with Philip IV. of Spain. In the year 1637 they succeded, after much resistance, in taking the fort of St. George d'Elmina, and in the year 1642 the fort of Axim also fell into their hands. The Dutch, having thus far been successful, proceeded to attack the English settlements. In tracing the first British establishments on the Coast of Guinea, we may begin with observing, that a trade here had been carried on by some private adventurers, without the aid or protection of the government. In 1585 and 1588, queen Elizabeth granted two patents to certain rich merchants of England; one for an exclusive trade to the coast of Barbary, and another for that of Guinea. In 1592 a third patent was obtained by the same body of merchants. In 1651 the republic of England encouraged the African trade; and in 1662 Charles II. granted a charter to a body of merchants, under the name of the Royal Company of England trading to Africa, extending their limits from the mouth of the Straits to the Cape of Good Hope. The affairs of this company falling into disorder, the king erected another corporation, called the Royal African Company," which has subsisted to this day. This charter bears date, Sept. 27, 1663. This company, with a small capital, was diligent and successful; Cape Coast was enlarged and beautified; the forts of Acri, Dixtlove, Winchuck, Sukkonda, Commende, and Amabon, were built or repaired, all of them on the Gold Coast, and several within a little-shot of the Dutch settlements. They bought Fredericksburg of the Danes, and built a new fort in Whidah. See African Company.

GOLD CRONACH, a town of Germany, in the principality of Bayreuth, which had formerly a gold mine; 5 miles N. of Bayreuth.

GOLDAPP, a town of Prussian Lithuania; 63 miles E. S. E. of Konigberg — Alto, a river of Prussia, which runs into the Oonme; 6 miles N. of Goldapp.

GOLDAST, MELCHOR HEIMENSPFELD, in Biography, a learned writer of the 16th century, was a native of Switzerland. He studied the civil law in Altdorf, but he is better known as a man of letters. His works, though not marked for originality, were highly esteemed by the learned of the period in which he flourished: the principal of these are, 1. "Monarchia Sancti Imperii Romanii," in three volumes folio, published in 1561-14. These volumes contain a collection of treaties on the civil and ecclesiastical jurisdiction of the empire. 2. "Alemannia Scriptores," three volumes folio, 1730. 3. "Commentarius de Bohemia Regno," 4to. 4. "Innoturiae de statu Bohemiae," 4to. 5. "Sylvia Francica," being a quarto collection of pieces relative to the maid of Orleans: "Scriptores Rerum Svecorum." 6. "Collectio Consectudinum et Legum Imperii." 7. "Politica Imperialia," and a collection of letters, written to him by several men of learning. This last work was printed at Frankfurt in 1688. Mr. Goldast was of a capricious temper and of changeable habits, which prevented him from rising in the world. He died in 1653, having long struggled with poverty. Moreri. Bayle.

GOLDBERG, in Geography, a town of Silesia, in the principality of Lignitz, deriving its name from a gold-miner in its vicinity, which was formerly very rich. The earth, called filglattel in Saxon, is dug near it; and the inhabitants are employed in the woolen and linen manufactories: 12 miles S.W. of Lignitz. N. lat. 51° 41'. E. lang. 15° 53'. Alto, a town of the duchy of Mecklenburg; 15 miles E. of Wilmar.

GOLDECK, a town of the archbishopric of Salzburg; 28 miles S. of Salzburg.

GOLDEN, something that has a relation to gold, or consists of gold, is valuable like gold, or the like. Golden Bull, Bulla Aurea. See Bull.

Golden Calf was a figure of a calf, which the Israelites cast in that metal, and set up in the wilderness to worship, during Moses's absence in the mount, and which that legislator, at his return, burnt, ground to powder, and mixed with the water the people were to drink of, as related by Exod. xxxii.

The commentators have been greatly divided on this article: the pulverizing of gold, and rendering it potable, is an operation in chemistry of the highest difficulty; and it is hard to conceive how it should be done at that time, before chemistry was ever heard of, and in a wilderness too! Many, therefore, suppose it done by a miracle; and the rest, who allow
allow of nothing supernatural in it, advance nothing but conjectures as to the manner of the process.

Moles could not have done it by a simple calcination, nor amalgamation, nor antimony, nor calcination: nor is there one of those operations that quadrates with the text.

Mr. Stahl has endeavoured to remove this difficulty. The method Moles made use of, in making his aurum potabile, according to this author, was the same with that which now obtains; only, instead of tartrar, he made use of the Egyptian natron, which is common enough throughout the East.

Golden Cape, in Geography, a cape of England, on the W. coast of Dorsetshire. N. lat. 50° 43'. W. long. 2° 52'.

Golden Cape, a name by which some call the racemus, or cow-foot.

Golden Eye, in Ornithology, the Anas Clangula. See Duck.

Golden Eye, a species of fly. See Chrysops.

Golden Fleec, in the Ancient Mythology. See Argonautic.

Golden Fleec, Order of, is a military order, instituted by Philip the Good, duke of Burgundy, in 1429. It took its denomination from a representation of the golden fleece, borne by the knights on their collars, which consisted of flints and feathers. The king of Spain is now grand master of the order, in quality of duke of Burgundy; the number of knights is fixed to thirty-one.

It is usually said to have been instituted on occasion of an immense profit which that prince made by wool; though others will have a chemical mystery couched under it, as under that famous one of the ancients, which the adepti contend to be no other than the secret of the elixir, written on the fleece of a heep.

Golden Flower, in Botany. See Chrysanthemum.

Golden Flower-gentle, a name sometimes given to several species of the amaranth.

Golden Hand, in Ornithology, a water-fowl, otherwise called anas arctica. See Duck.

Golden Island, in Geography, a small island at the entrance of the gulf of Darien, in Terra Firma, S. America. N. lat. 8° 26'. W. long. 72° 32'.

Golden Lake, a lake of the island of Borneo. N. lat. 3° 36'. E. long. 115° 45'.

Golden Maiden-hair. See Adiantum aureum, and Polyticum.

Golden Monf-ear. See Hieracium.

Golden Number, in Chronology. See Cycle of the Moon, and Number.

Golden Precendary of Hertford. See Precendary.

Golden River, in Geography, a river of America, which runs into the Missirips, N. lat. 43° 20'. W. long. 92° 2'.

Golden River, or Rio del Oro, a river of America, which runs into the Spanish Main. N. lat. 14° 44'. W. long. 82° 55'.

Golden Rod, or Sarracen's Wound-curt, virga aurea, in Botany. See Solidago.

Golden Rod Tree. See Bonea.

Golden Rule, in Arithmetic, a rule or praxis of great use and extent in the art of numbers, whereby we have a fourth proportional to three quantities given. The Golden Rule is also called the Rule of Three and Rule of Proportion. See its nature and use under the article Rule of Three.

Golden Sapphire is a species of the inula or clecampane. (See Inula.) It grows naturally on the sea-coasts in many parts of England, and is sometimes sold in the London mar-

ket for the true sapphire, though entirely destitute of its warm aromatic taint. See Saphire.

Golden Sacrifinge. See Chrysophrum.

Golden State, order of the. See Stole.

Golden Sulphur of Antimony. See Antimony.

Golden Thistle, in Botany. See Scorbium.

Goldenstein, in Geography, a town of Moravia, in the circle of Olmutz; 32 miles from Olmutz.

Goldsentetl, a town of Germany, in the country of Diefelholz; 11 miles N. of Diefelholz.

Golendraun, a town of Upper Lusatia; 16 miles S.E. of Goriitz. N. lat. 50° 27'. E. long. 15° 26'.

Goldingen, a town of the duky of Courland, situated near the river Wetsa, defended by an old castle, and containing two churches; 48 miles W.N.W. of Mittau. N. lat. 56° 51'. E. long. 21° 44'.

Goldlaüter, a town of Germany, in the county of Henneberg, 12 miles N.E. of Meinungen.

Goldman, Nicholas, in Biography, a mathematician, was born at Breifaw, in Silezia, in the year 1623, and died at Leyden in 1665. The works by which he is generally known are "Elementa Architerturæ Militaris," 1643. "De Ufo Proportionarii Circuli." "De Stylometricis," 1662, and another treatise "On Architecture," published in 1666, with numerous engravings, and the life of the author. Morte.

Goldoni, Charles, was born at Venice in the year 1707. Almoft from his infancy he gave indication of a humorous character, and a propensity to dramatic performances. Before he could well read he became an author, and wrote the plan of a comedy by the time he was eight years old. This piece pleased so much merit, that it required the testimony of respectable witnesses to verify its being the production of a child. He received the elements of education at Venice from this city he went to the Jesuits' college at Perugia to study rhetoric, and afterwards he studied philosophy at Rimini. His mind was, however, too deeply engaged in theatrical exhibitions to make the system of Arifotle a predominant pursuit. Every leisure moment he spent at the theatre, till at length he passed from the pit to the stage, and joined a company of players. This, by his own account, was an error, which drew after it many serious confequences. He had been intended by his father for the profession of physic, which he was unable to study: he was then solicited to prepare himself for the bar, and was engaged, after many changes, in practice at the courts of Venice. After this he was appointed secretary to the Venetian resident at Milan, where he became acquainted with the manager of the theatre, and wrote a farce for him, entitled "The Venetian Gondolier," which was performed and printed: by degrees he became united to the company, and composed many pieces for them. He now turned his thoughts towards reforming the Italian stage, and so earnest was he in his projects, that it is said in a single year he wrote sixteen new comedies, besides forty-two other pieces for the theatre, and among these are reckoned some of his best productions. The first edition of his works was published in 1753 in 13 vols. 8vo. After this he published many additional pieces under the title of the "New Comic Theatre." He had composed 59 other pieces fo late as the year 1761, and here closes the literary life of Goldoni in Italy. He now repaired to Paris, and was as zealous in his endeavours to reform the Italian theatre there as he had been in his own country. His first attempt was in a piece called the "Father of Love," but the bad success of this comedy was a sufficient warning to him to desist from his undertaking. He continued, during the remainder of his engagement, to produce pieces agreeable to the general taste, and published twenty-
twenty-four comedies. At the end of two years he was preparing to return to Italy, when he was suddenly urged to become Italian walmart to the princes, and to the reigning monarch. During this engagement he lost his sight, which he never after completely recovered, and at the end of three years he received a very inadequate remuneration for his labours and constant attendance at court, namely, 100 louis in a gold box, and the grant of a pension of four thousand livres per annum. This, with what he was enabled to make by his works, was amply sufficient for all his wants. When he had attained his 62d year he began to publish comedies in the French language, which were well received, and some of them became extremely popular. After the death of Lewis XV. Goldoni was appointed Italian teacher to the princes CLOTILDE, the present princes of Piedmont, and after her marriage, he attended the unfortunate princes Elizabeth in the same capacity. His last work was the "Volponi," written after he had retired from court. It was his misfortune to live to see his pension taken away by the revolution, and, like thousands in a similar situation, he was obliged to pass his old age in poverty and distress.

He died in the beginning of the year 1793, at a period when the Brissotines had the sway in the national councils, and when Goldoni would, for a short time at least, have received every attention that a grateful country could have afforded. As a comic poet, Goldoni is reckoned among the best of the age in which he flourished. His works were published at Leghorn in 1788-91, in 31 vols. 8vo. He has been reckoned the Molière of Italy, and he is styled by Voltaire "The painter of Nature." "Goldoni," says his biographer, "is one of those authors whose writings will be relished in the most remote countries, and by the latest posterity. His profound knowledge of the human heart, his extensive description of the vices and virtues of men, in all ages and nations, will justify my concluding this imperfect eulogy with applying to him the following lines of Horace from his first Epistle:"

"Æque pauperibus prodit, locupletibus æque
Æque neglectum pueros, famuli tibi nocentem.

His principal works are comedies in prose, for declamation, of which the exact number is not known; but they at least amounted to 120 before he left Italy at the desire of Louis XV. to write for the "Theatre Italien" at Paris, for which theatre he composed at least 50. This fertile, natural, and pleasing writer, was ambitious at first of treating serious and tragic subjects; but finding, as he tells us himself in his life and preface, that Metastasius was arrived at so high a point of perfection in his serious operas as that species of drama was capable of, he pointed his thoughts wholly to comedy, which had long been treated in such a burlesque and farcical manner, as to stand in great need of reformation.

But though he had determined not to attempt serious pieces for music, yet Galuppi prevailed upon him, much against his inclination, to furnish him with three serious operas for the theatre at Venice; these were, Oronce, King of Scythia; Gustavus Adolphus; and Statira. But though they had great success, Goldoni never thought them worthy of publication. He was not more vain of his comic operas.

However, he produced at different times and places 40 or 50, which, without his consent or knowledge, were collected and published in 6 vols. 12mo.; they are not very edifying works, being on the old burletta model, full of buffoonery, and a brand kind of Italian humour, tailed in no other country, though suited for the sake of the music, which is often ingenious, imitative, and sometimes graceful, but more frequently grotesque.

Goldoni is, perhaps, the only author of comic operas in Italy, who has given them a little common sense, by a natural plot, and natural characters; and his celebrated comic opera of the "Buona Figliuola," set by Pecini, and first performed in London Dec. 9th, 1766, rendered both the poet and composer, whose names had scarcely penetrated into this country before, dear to every lover of the Italian language and music, in the nation. This admirable production, before it was brought hither, had gained the improviso of the opera at Rome from ruins, and been performed in the principal cities of Italy. In the year 1762, Pecini, passing through Rome, in his way to Milan, was entreated to compose a comic opera for the Teatro delle Dame in that city, which had lately become very unfortunate. No libretto was ready, and application having been made to the poet Goldoni, at this time in Rome, he furnished the musical drama of "La Buona Figliuola," from his comedy of "Pamela," in a few days. Several of the original performers were now in London, particularly the first buffo, Lovattini, and the serious man Savoi, with the buffo carativo Morigni.

And though females are not allowed to appear on the stage at Rome, yet signora Guadagni had previously performed the part of Cecchina in several cities of Italy, with great and well-deserved applause before his arrival here.

After the great success of the "Buona Figliuola," the public was disposed to hear with partiality any productions by the same authors; and when the "Buona Figliuola Maritata," (or Pamela in high life), was brought out, the crowd at the opera-house was prodigious; but expectation was, as usual, so unreasonable as to spoil the feast; to gratify it was impossible. Some ascribed their disappointment to the composer, some to the performers, but none to themselves. The music was excellent, full of invention, fire, and new effects; but so difficult, particularly for the orchestra, that the performers forgot it was winter. The principal part of the Marchesa was given to Zamparini, a very pretty woman, but an affected singer. Music so difficult to perform was not easy to hear; and this drama was never sufficiently repeated for the public to be familiarly acquainted with it. They were glad, as well as the performers, to return to the "Buona Figliuola" for their own sake and relief from a too serious attention.

In France, Goldoni wrote several very successful comedies for declamation in the French language, but we are not acquainted with any dramas which he produced for music in that country. Poor Goldoni was in such favour with the royal family of France before the revolution, that he was never allowed to return to his own country; but died at Paris in the year of terror, 1793, at the age of 83.

GOLDSBOROUGH, in Geography, a poilt town of America, in Hancock county and state of Maine, incorporated in 1759, and containing 379 inhabitants; 47 miles E. of Pembroke. N. lat. 44° 19'.

GOLDSINNY, in Ichthyology, a fish discovered on the coast of Cornwall, in the whole form of the body, lips, teeth, and fins, resembling the Brochis, which is said never to exceed a palm in length; near the tail is a remarkable black spot; the first rays of the dorsal fin are tinged with black. See LAMBRO Corallinus.

GOLDSMITH, Oliver, in Biography, was born in the county of Longford, Ireland, in 1731, though, according to other accounts, this event took place at Elphin, in 1730. He was the son of a clergyman, who gave him a literary education, and sent him early to Dublin college. Being designed for the profession of medicine, he was removed to Edinburgh in 1751, where he continued till 1754, when he left that place to avoid a process against him.
for debts incurred, probably to administer to his disposition. He was intercepted at Sunderland, and thrown into confinement, from which he was released by the kindness of two fellow-collegians. After this, he determined to visit the continent, embarked for Holland, travelled through Flanders and part of Germany, passed some time at the universities of Strasbourg and Louvain; at the latter place he took his degree of bachelor of physic, and thence accompanied an English gentleman to Geneva. Here he engaged himself as travelling tutor to a young man who had become possessed of a large fortune, but whose mind was ill adapted to do credit to the gifts of Providence. They disagreed in the south of France, and Goldsmith was left to contend with the hardships of indigence in a foreign country. He returned in 1755, and laboured in most of his peregrinations, trust- ed for his support to his own casual efforts. His learning conferred him a favourable reception at the monasteries, and his German flute feldom failed to procure him a meal and a night's lodging from the pantheries, who were delighted with trains which a potter audience would have treated with disdain. His arrival at London with a few pence in his pocket, was not likely to be the termination of his pecuniary difficulties. He attempted to get into the employ of an apothecary, but his appearance being against him, his application was treated with disdain. He at length was ad- mitted as usher to Dr. Milner, who kept an academy at Pockrwm. Here he remained but a short time, and then refused to follow the profession of an author in London. He obtained some employment in the Monthly Review, and furnished papers for the public Ledger. He published a weekly pamphlet, entitled "The Bee," and "An Enquiry into the State of Polite Learning in Europe." After he had been some time exercising his pen in obscurity, he be- came a pnlular among the literary characters of the age. In the following year was published his novel of "The Vicar of Wakefield," which had been sold to a bookseller some years before, but had been kept back as the work of an unknown writer, and excite no expec- tations of success. It was, however, received with unbounded applause, and has ever since borne a distinguished rank among similar compositions. His next work was a "His- tory of England," in a series of letters from a nobleman to his son, in two volumes 12mo. a work that still continues to be read with great delight. His poetical fame reached its summit in 1770, by the publication of his "Defeated Vil- lage," which was universally admired. For this he obtained of his bookseller 100l. a sum which appeared to the author so exorbitantly great, that he refused to take it; but the sale of the work convinced him that he might fairly ap- propriate the sum out of the profits. As an author of comedy, he produced in 1768 "The Good-natured Man," which was not very successful; and in 1772 another play, entitled "She Stoops to Conquer, or the Mistakes of a Night." From this Goldsmith cleared a large sum, and it is still occasionally represented to applauding audiences. Notwithstanding the successes of his pieces, by some of which it is asserted he cleared 1800l. in a single year, his circumstances were ever very precarious, which was partly owing to the liberality of his disposition, and partly to an unfortunate habit which he had contracted of
gaining; the arts of which he knew very little of, and conse- quently became the prey of those who were bafe enough to take advantage of his simplicity. Besides the works already treated of, Dr. Goldsmith, as he was called, though he had only taken a bachelor's degree, compiled an English history in four volumes, and a Roman and Grecian history in two volumes each; and "A History of the Earth and Animated Nature," in eight volumes 8vo. Such was the confidence which he acquired in his skill at compilation, that he formed a plan for a much greater work, viz. "A Dic- tionary of Arts and Sciences," but this and other schemes which he had planned were cut off by his untimely death.

A dependence of mind, probably occasioned by the con- ditions of his life, and his affairs, had been frequently in his mind. In March 1774, he was attacked with the symptoms of a low fever, under which he lunk on the 4th of April. He was buried in the Temple church- yard without much attendanee, but a monument has since been erected to his memory in Westminster abbey, with a Latin inscription by Dr. Johnson.

Goldsmith, as a man, was rather admired for his genius, and beloved for his benevolence, than solidly esteemed. The best part of his moral character was a warmth of tender- ness, which made him in all fortunes ready to share his purfe with the indigent, and rendered him in his writings the constant advocate of the poor and oppressed. The work feature was a malignant envy and jealousy of successful rivals, which he sometimes displayed in a manner not lefs ridicu- lous than offensive.

As a writer, no one of his time was possessed of more true humour, or was capable of more poignancy in marking the foibles of individuals. This last talent he displayed in a very amusing manner in his poem entitled "Retafimation," written as a retort to the jocular attacks made upon him in a club of which he was a member. His literary fame stands highest as a poet, in which character a place may be given him perhaps at the head of the minor divsrs, the term minor being applied with relation to the quantity, rather than the excellence of composition. "It would not be easy," says his biographer, "to point out in the whole compafs of Eng- lish poetry, pieces that are read with more delight than "The Traveller," and "The Deserted Village." The elegance of the verfification, the force and splendour yet simplicity of the diction; the happy mixture of animal sentiment with glorious deference, are calculated to please equally the refined and the uncultivated taste. The moral and philosophical views of socety they exhibit are, indeed, objectionable; yet upon the whole they exert a favourable influence over the heart. In addition to their capital works, his pleasing ballad of "The Hermit," and some short humorous and miscellaneous pieces, complete the catalogue of his performances in verse. As a profe writer he devotes high praise for lyle, which he adapts with great felicity to his subject, and which, whether elevated or plain, is always clear, pure, and unaffected. Life prefixed to his poems. Europ. Mag. Ann. Regis.

GOLDWIN, John, an ecclefaftical composer, was brought up under Dr. William Child, and, in 1697, suc- ceeded him as organist at the free chapel of St. George at Windor. In 1703 he was appointed master of the choristers there, in both which stations he continued to the time of his death in 1719. Dr. Boyce, out of a great number of anthems by this composer, selected one for four voices, "I have set God always before me," which he has inserted in the second volume of his "Collection of Cathedral Music," and well characterized it with respect to the modulation, by saying that "it is singular and agreeable."
GOLDYLOCKS, in Botany. See Chrysocoma and Gnaphalium.

GOLUMEH, in Geography, a town of Bengal; 18 miles E. of Ramgur. N. lat. 22° 28'. E. long. 85° 51'.

GOLETTA, a fortress of Africa, situated on a canal, in the kingdom of Tunis; 25 miles N. of Tunis.—Alfio, a narrow channel between the lake of Tunis and the sea, defended on each side by a caille.

GOLI, or Gour, the name of a diversion or exercice, much used in Scotland, and played upon the laws or links, as they are there called.

It consists of driving a ball with clubs, between two goals or holes, half a mile or a mile aduant. He who can drive it with the fewest strokes of his club is the conqueror.

GOLFO TRISTE, in Geography, a bay on the coast of South America, in the government of Caracas. N. lat. 12° 31'. W. long. 68° 20'.

GOLGAM, a town of Hindoostan, in Dowlatabad; 15 miles N. of Beder.

GOLGOM, a town of the island of Ceylon; 48 miles N.W. of Candy.

GOLGOTHA. See Calvary.

GOLIATH, in Scripture History, a famous giant of Gath, who defied the armies of Israel, and was slain by David. 1 Sam. xvii. 4, &c.

GOLICH, in Geography, a town of Russia, in the government of Irkutsh, on the Lena; two miles S. of Orelgen.

GOLINDA, a small island near the N. coast of Cuba. N. lat. 23° 20'. W. long. 8° 4'.

GOLISANO, a town of Sicily, in the valley of Demona; 9 miles S. of Cefalu.

GOLITZ, a town of Nubia, on the left side of the Nile; 45 miles W.N.W. of Dongola.

GOLUM, James, in Biography, was born at the Hague in 1596; but he purified his studies at Leyden with the most unremitting diligence and ardour, and became distinguished for his deep knowledge of the learned languages, antiquities, philosophy, and mathematics. In 1622 he accompanied an embassador of the United Provinces to Morocco, where he excited the admiration of the emperor Moulay Zeidan, with whom he had frequent interviews. After his return to his native country he succeeded to the Arabic professorship on the death of Erpenius, under whom he had formerly studied. In 1625 he obtained permission to travel in the Levant, and passed more than a year at Aleppo, whence he made various excursions into Arabia and Mecopotamia. On his return he visited Constantinople, where he obtained very distinguished notice from the learned in that capital, by whose means he had access to the best libraries. During his absence he was appointed professor of mathematics, and returned to Leyden in 1629, and applied himself to the duties of his office. He died in 1667, having occupied with much credit the arduous situation of professor for more than forty years, and passed through all the academical honours. As an author he published the "Saracen History of Elmacin," which had been begun by Erpenius; also a life of the great Tamerlane, written by an eminent Arabian author: "The astronomical Elements of Allergan," with a new version and learned commentaries; "An Arabic Lexicon;" a "Persian Dictionary," which was printed in London. Bayle, Moreri.

GOLLENS, Peter, brother of the preceding, entered when very young among the Carmelites; like his brother he excelled in the knowledge of the Arabic language, and taught it in the seminary belonging to his order at Rome, where those monks were educated who were intended to be sent on missions into the East. Golius was denized to this service, and having visited every part of Syria and Palestine, founded a monastery of his order on mount Lebanon, over which he presided till he was recalled to Rome. Here he was employed as one of the principal assistants of Sergius Renatus, archbishop of Damascis, in preparing his edition of the Arabic Bible, which was published in 1671 by the direction of the college "De Propaganda." After it was completed, Golius was appointed visitor of the missions of the East Indies. He died in this employment at Surat about the year 1673. He was author of translations into Arabic of Thomas' Kopem's imitation of Jefus Christ: of sermons on the Evangelists: an "Historic Discourse of St. Gregory of Dascopolis," several small devotional pieces, and a translation from Arabic into Latin of a "Collection of Parables and Proverbs." Moreri.

GOLDI, or Golli, in Geography, a town of Africa, near the river Grado, the inhabitants of which trade in flaves, ivory, and cotton.

GOLLING, a town of the archbishopric of Salzburg, on the Sulza; 14 miles S.S.E. of Salzburg.

GOLLOSING, a town of Bengal; 70 miles W. of Midnapour.

GOLNITZ, a town of Hungary, on a river of the same name; 14 miles S.E. of Kapidorf.

GOLNOW, a town of Anterior Pomerania, formerly Hanftein, situated on the Ilma; 12 miles N. of Stargard. N. lat. 53° 37'. E. long. 24° 57'.

GOL, a river of Corsica, which rises nearly in the centre of the island, and pursues a N.E. course, runs into the sea; 12 miles S.S.E. of Ballia. It gives name to one of the two departments into which the island is divided; the other being Lianome. Golo comprehends the northern division of Corsica, in N. lat. 42° 30', and containing 156 square leagues, and 163,466 inhabitants, is subdivided into three circles, viz. Ballia, whose inhabitants are 47,842; Calvi, having 20,282 inhabitants; and Corte containing 35,342 inhabitants. There are several lofty mountains near the centre of a chain that traverses the island longitudinally. The most considerable lakes are Ino and Creto, the former of which is of unknown depth. The soil is tolerably fertile, yielding barley, millet, olives, chufutas, wine, fruits, &c. On the hills are forells and excellent pastures. See CORSICA.

GOLOBUNGE, a town of Bengal; 10 miles E. of Silhet.

GOLPHINGTON, the chief town of Washington county and state of Georgis, in America, situated near the head of Ogochee river, about 26 miles E.S.E. of Oconee town.

GOLPS, in Herod. are roundles, or torteaux, of a purple colour.

GOLTBERGENSIS TERRA, in the Materia Medica, is a whith earth, used in the shops of Germany and Italy as an astringent, a cordial, and a sudorific, but little known among the English apothecaries. It is dug in many parts of Germany, as Goldberg and Strigaw, and Ligntz in Silfia; but particularly at this time in the neighbourhood of Haife, in the bishopric of Liege, in the circle of Wellphalia. It is taken up there in considerable quantities, and usually is sealed with the impression of an eagle, and with its old name Goltbergenis terra under it. It was imagined to contain some particles of silver, and thence to derive some of its virtues; on this account Montanus called it aundis lane; but experience shews that it doth not contain a particle of that metal. It is a dense compact
compact earth of a dull greyish white, soft and friable, and adheres firmly to the tongue, and makes no effervescence with acids.

GOLTIAVINA, in Geography, a town of Russia, in the government of Tobolsk; 188 miles E. of Enfick. N. lat. 58° 20'. E. long. 93° 14'.

GOLTPACH, a town of Prussia, in the patinatate of Coln; 8 miles N.E. of Thorn.

GOLIVA, a town of Russia, in the government of Kiev; 112 miles S.E. of Kiev. N. lat. 49° 15'. E. long. 32° 55'.

GOLTZEN, a town of Lower Lusatia; 10 miles W. of Lauen. N. lat. 51° 58'. E. long. 13° 30'.

GOLZIUS, HENRY, in Biography, a painter, who was born at Venlo in 1520, and studied under Lambert Lombard. Becoming enamoured of the antique by having copied several works of that class, he resolved to cultivate his taste by visiting the more important Greek works preserved at Rome; and therefore travelled to that city, where he resided some time, and thence drew an ample flock of materials for his future progres in the art he professed.

He lived principally at Antwerp, where he painted the history of Jafon; but as he was engaged in a variety of studies, his pictures are rare. Among other things he investigated coins and medals, and published a collection of them with critical annotations. He died at the age of 63.

GOLZIUS, HENRY, an artist of considerable talent, who practised both painting and engraving. As a painter, he drew his resources from the study of the antique, of Raphael, Polidoro, and Michael Angelo; the last of whom appears to have been his favoured Apollo in the art, but whose faults he exaggerated in an outrageous manner, deluding attaining any of his beauties. Hence his style of design is inflated and caricature; and his expressions participate of the same tale but his hues of line in colour are rich, vigorous, and transparent. He died in 1617, aged 59.

GOLUS, in Geography, a town of Prussia, in the territory of Coln; 25 miles S.E. of Coln.

GOLUENSKA, a town of Russia, in the country of the Cossacks, on the Don; 200 miles E.N.E. of Azosp.

GOMAHNY, a town of Hindoostan, in the cerc of Moghurunge; 45 miles N.W. of Harripour—also, a town of Bengal; 8 miles S.E. of Goragot.

GOMAR, FRANCE, in Biography, celebrated as the great opponent of Arminius, and from whom the Calvinistic party in Holland received the name of "Gomarists," was born about the year 1563 at Bruges. His parents had been brought up in the Roman Catholic religion, but having embraced the Protestant doctrines, they retired into the patriciate in 1573, for the sake of professing their principles in peace and security. Their son Francis was sent to Strasbourg for his education, and purified his studies there under the celebrated John Sturm, after which he went to New-fildt, whither the professors of Heidelberg had been obliged to retire by the elector Lewis, because they were the opponents of the Lutheran faith. In 1582 he took a journey to England, and attended the divinity lectures at the universities of Oxford and Cambridge. He was admitted to the degree of B.D. in the year 1584. By great affability he became very deeply learned in the Greek and Hebrew languages, and in 1587 he settled with a Dutch congregation at Frankfort, and continued to discharge his ministerial functions until the year 1593, when his flocks was entirely dispersed by persecution. In the following year he was invited to accept the theological professorship at Leyden, and having taken his degree of D.D. he entered upon the duties of his new station. In 1603 Armi-
and at this time composers being scarce, he gained some reputation among those of Flanders, with very little genius. For after performing the tedious task of scoring the music of the nanim on Julqin, we found its chief merit to consist in imitations of his admirable manner. This composition was in the third ecclesiastical mode of E, with a minor second, as well as third; which Mr. Blainville some years ago wished to pass on the public for a third or new key, different from the major and minor, which comprise all familiar music at present. And it is extraordinary, that this pretension should have had any adherents in a Roman Catholic country, where old compositions in this mode are daily performed in cathedrals and collegiate churches. However, it was a matter of wonder and debate, during some time, in France. See Mercure de France, 1751, and Dict. de Mus. par Rouffeau, art. Mode.

GOMBREVILLE, MAIR LE ROI, Seur de, a man of letters, was born at Chevreuse, in the diocese of Paris. He became distinguished at the age of fourteen by a collection of quatrains in honour of old age. In 1635 he was so much distinguished for a literary reputation, that he was of the number assembled by cardinal Richilieu for the purpose of founding the French academy. He had published romances and works of a light nature, of which he afterwards seemed to be ashamed, for at the age of forty-five he formed the resolution of confecting his pen to religion. He even adopted a penitentary course of life, and is mentioned by some of his contemporaries as having joined the Christian virtues to those of morality. He died in 1674, leaving behind him many works, of which perhaps the best is a "Diction sur les Vertus et les Vices de l'Histoire et de la Maniere de bien Ecrire." This is deemed a sensible and very judicious performance. Moreiri.

GOMBEEY, in Geography, a town of Asia, in Botonga, on the Zambere. 8 lat. 18'. E. long. 36'.

GOMBEZCALA, a town of Peru, in the province of Farfifiain; 106 miles N.N.W. of Chirias.

GOMBIN, GAMII., or Gabin, a town of Poland, in the duchy of Warsaw, situated on the river Duna; 34 miles N.N.E. of Warsaw.

GOMERON. See GAMERON.

GOMER, in Scripture History, the son of Japheth (Gen. v. 2.) and, according to Josephus, father to the people of Galata. The ancient inhabitants of that country were called Gomares before the Galatians fessed possession of it. The Chaldees place Gomer in Africa; Boulhart in Phrygia, because Phrygia, in Greek, has the same signification (a coal) as Gomer, in Hebrew and Syriac. Others are of opinion that the ancient Cambi, or Cimmerians, sprung from Gomer, and probably from them the Welsh, called Cymry. It is not improbable, that Gomer, or the Gomerites, his descendants, peopled likewise Germany and Gaul; the name German not differing much from Gomerian. Cluver (Germ. Antiq. l. i. c. 5. 6.) conjecturing that the ancient Celtica comprehended Ilyria, Germany, Gaul, Spain, and the British isles, as all these people an idly spoke the fame language, further supposes, that Gomer, or his family, peopled the countries in Asia, between the Paropamisus and mount Iannus, and between the confines of the Oxus and Oby; whence these people are called Gomares by Ptolomy (l. vi. c. 17.) and Mele (l. i. c. 2.).

GOMER, or Gomer, an Hebrew meteeme. See CORES.

GOMERA, or VELEZ DE PEINX, in Geography, a kalle of Africa, in the country of Fez, built on a rock near the coast of the Mediterranean. Before this fortress there was anctently a city, called "Bedes," imagined to have been founded by the Carthaginians. The Arabs called it Belis and Veles, whence Veles. These two places, surrounded by mountains and forests, were supported by the building of ships for fishing and piracy, before they were taken by the Spaniards. - Alto, a river of Fez, which runs into the hills of Gibraltar, near the above-mentioned fortress.

GOMERA, or Gomera, one of the Canary islands, about 20 miles long and 10 broad, having a capital of the same name, situated on the coast, with a good harbour. The island is fertile and well cultivated, and produces sugar-cane and vines in abundance, as well as figs, together with sufficient corn for the supply of the inhabitants, who amount to about 7000; 18 miles S.W. of Tenerife. N. lat. 28° 6'. W. long. 27° 8'.

GOMETRA, one of the western islands of Scotland. This is a small island at the west end of Ulva, tolerably fertile, but without wood.

GOMEZ DE CIUDAD REAL, ALVAREZ, in Biography, a modern Latin poet, was born in 1488 at Guadalaxara in Spain. He was page of honour to archduke Charles, afterwards emperor. As an author, who entitles him to a place in this work, he possessed a great facility in writing Latin verse, which is seen by his "Thalia Christiana," or the triumph of Jesus Christ, in twenty-five books: "Musa Paulina," or the epistles of St. Paul, in elegiac verse: the Proverbs of Solomon, and other works of a similar kind. His work on the order of the Golden Fleece, entitled "De Principis Burgundiae Militia quae Velletris aurei vocant," is reckoned his master-piece. The subject which he chose in this instance was more favourable to poetry than the others. Moreiri.

GOMEZ DE CASTRO, ALVAREZ, a native of St. Eulalia, near Toledo, was educated at Alcalá, where he obtained a high character for diligence and real learning. He was patronized by Philip II., who engaged him to prepare an edition of the works of Idiades, which death prevented him from completing. He was author of many works; but the chief, and that which is most esteemed, is a "Life of Cardinal Ximenes," inferted in a collection of the writers on Spanish history. Gomez died in 1520, at the age of 65. Moreiri.

GOMEZ, SEBASTIANO, a Mulatto slave of the Spanish painter Murillo, who employed his leisure hours in painting, and obtained considerable success. The city of Seville is, or was, adorned with many of his works: the most conspicuous among them were a "Madonna with the Infant," in the portico of Lof. Mercenarios Descalzos, and the "Flagellation of Christ," at the Capuchins. It is not known at what period he died; but he is said to have survived his matter, whose decease happened in the year 1683.

GOMGAH, in Geography, a town of Hindooistan, in the circuit of Surgooga; 22 miles S.W. of Surgooga.

GOMI, a town of the province of Gurel, on the Black sea.

GOMMERN, a town of Saxony, on the Elbe; 8 miles E. of Magdeburg.

GOMMALPAR, a town of Hindooistan, in the circuit of Guntoor; 15 miles E. of Innaconda.
GOMORA, a small island in the East Indian sea, near the west coast of Oby, S. lat. 1° 52' E. long. 128°.

GOMORRAH, in Ancient Geography, a town of Palestine, and one of the principal cities of the Pentapolis, consumed by fire from heaven. It was probably the most northern of the five cities. Gen. xix. 24.

GOMOZIA, or GOMEZIA, in Botany. See NERTHEA.

Gen. Ch. Cal. Perianth inferior, of five lanceolate, sharpish, ribbed, colored, decussated leaves, two of which have a membranous margin at each side, one on one side only, and two are detached of any. Cor. Petals five, spreading, longer than the calyx, rather unequal; the claws are shorter than the calyx, each gradually widening into a roundish, flat, entire border. Stam. Filaments ten, very short, thick and angular; anthers erect, shorter than the calyx, square, tapering upwards, curving at the top, on the outside, by two pores. Pist. Germs placed on a short flabellate angular receptacle, with five angles and five divisions; style longer than the stamina, marked with five furrows; stigma acute. Peric. Drupas from one to five, mott generally two, ovate, obliquely attenuated at the base, somewhat compressed, obtuse, erect, spreading on a very large globose receptacle, which is undivided, if the berry be solitary, lobed if there be more, one lobe being appropriated to each berry. Seeds solitary, ovate.

Vahl and Swartz describe five species, all trees, natives of tropical climates. The chief and original one is G. Jabotapita, (Ochra Jabotapita; Linn. Sp. Pl. 732. Jabotapita pyramidal flore luteo, fructu rubro; Plum. L. 147. t. 153.) This is a native of South America, flowering in December and January. The wood is soft and tough. Leaves simple, as in the whole genus, alternate, stalked, ovate, acute, serrated. Flowers in terminal clusters, yellow, fragrant, compared by Marsgrave to those of a Wall-flower in figure, or rather colour, but he says their scent is sweeter. The fruit and its receptacle are black, juicy, aromatic.

This genus is certainly very nearly related to Ochra, both in habit and character.

GOMPFIASIS, from γομφος, a nail, a disorder of the teeth, in which they become loose and painful. The connection of the derivative with the Greek is imputable to the circumstance of the teeth being fixed in their sockets, like nails in a piece of wood.

Gen. Ch. Cal. Perianth inferior, small, in five acute, permanent segments. Cor. of one petal, regular, in five deep, reflexed segments, deciduous. Nectary of five hooded-leaves, simple within, furnished with a tooth at each side, placed on the top of the united filaments. Stam. Filaments five, colorless; anthers of two cells, terminated by a membranous, and producing two compressed masses of pollen, which attach themselves by a taper point to the stigma, and remain pendulous there. Pist. Germs two, superior, ovate, fleshy, two very short, standing close together; stigma common to the two, dilated, horizontal, flat, with five angles to receive the masses of pollen. Peric. Foliaces two, inflated, ovate, pointed, clothed with soft trusses. Receptacle membranous, longitudinal, linear, at length separate. Seeds numerous, imbricated, pendulous, crowned with silky down.

This genus is separated from Asclepias by Mr. Brown, (whose effay on the whole order, and whose discovery of the mode in which the pollen is projected by the anthers upon the stigma, do him the highest honours,) on account of the inflated prickly fruit, and the singular horn which in Asclepias grow out from the bottom of the nectaries. It conforms of Asclepias arborensis, Linn. Mant. 216; fruticosa, Linn. Sp. Pl. 315; and sevens, Vahl. Symb. v. 1. t. 8; and, as Mr. Brown supposes, of cribosa, Linn. Mant. 215. Suppl. 170. A. pubescent, Linn. Mant. 215, is, as he justly observes, on the authority of the late excellent Mr. Dryander, borrowed from the Linnaean herbarium, the same plant as arborensis, with a synonym from Plukeet (t. 135. f. 1.) and Morison, which is prefixed to be cribosa.

GOMPHOLOBIUM, so named by the writer of the present article, from γομφος, a knoll, club, or any thing swelling upwards from a narrow base, and γομμος, a pod, or legume, expressive of its tumid fruit. Sm. Tr. of Linn. Soc. v. 4. 220. Ann. of Bot. v. 1. 555.—Clafs and order, Decandria Monogynia. Nat. Or. Papilionaceae. Linn. Legumenosa. Juff.

Gen. Ch. Cal. Perianth inferior, of one leaf, coriaceous, short, bell-shaped, in five deep, oblong, pointed, unequal segments. Cor. papilionaceae. Standard very large, more or less heart-shaped, carinated at the back, recurved, with a short claw. Wings shorter than the style, parallel, horizontal, with a prominent lobe on one side near the base. Keel the length of the wings, of two half-ovate, tumid, clawed petals, with a reversed tooth at the upper edge of each. Stam. Filaments ten, concealed in the keel, awl-shaped, dilated, ascending, rather unequal in length; anthers roundish, two-lobed. Pist. Germs flalked, oblong, somewhat cylindrical; style awl-shaped, ascending, as long as the flaments; stigma fimbriate, acute. Peric. Legume on an ilalk, nearly globular, inflated, of one cell, crowned with the style. Seeds several, roundish, ranged along the upper future on short filaments.

Five species of this genus are defined in the Transactions of the Linnean Society, v. 9. 249, G grandiflorum, Exot. Bot. t. 5.—Latifolium, (fouabriam; Exot. Bot. t. 58.) fuculorum, a species communicated by Mr. Menzies: minuus, very near the last, except in the acute recurved points of the leaves; and pinnatum, a small species from Port Jackson, remarkable for its pinnate leaves, and zigzag herbaeous stem. Probably the sublimate volume of Mr. Brown's Prodromus will add more to this number.

The habit of Gompholobium is marked by the compound (ternate or pinnate) leaves, and a certain aspect of rigidity and smoothness. The stipules are not intradriaceous as in

Potentilla.
GOM

Puttenes, but stand on each side of the base of the common footstalk, being a pair of acute flat clove-prest leaves, extremely minute, and often altogether wanting. The flowers are yellow, generally numerous, large and handsome; in G. sebem, they are purple when dried, but this is suspected to be an alteration of their original hue, and they are judged, from the analogy of Derrifia, to be yellow, with crimson keel and wings, when fresh.

All the species, as far as hitherto known, are natives of New Holland. S.

GOMPSTOPSIS, in Botany, from γόμπτστόπίς, a mail, denotes the manner in which the fangs of the teeth are fixed in their sockets.

Gen. Ch. reformed. Col. Perianth inferior, coloured, membranous, permanent, double; the outer of two large, compressed, keeled leaves, cohering by their inner margins, and one smaller; inner in five deep, awl-shaped, upright, downy segments. Cor. of one petal, tubular, cylindrical, the length of the inner calyx; its margin equally five-leaf, spreading. Stam. Filaments five, very short, inserted into the orifice of the corolla, betwixt its segments; anthers erect, roundish, closing the mouth of the corolla. Pet. Capsule roundish, membranous, of one cell, burrowing all round. Seed solitary, large, roundish, with an oblique point.

Eff. Ch. Calyx coloured, the outer of three unequal leaves; inner in five deep segments. Corolla cylindrical, five-toothed, bearing the filaments at its orifice. Capsule burrowing all round. Seed solitary.

The species of Gomphora come under the denomination of Everlastings, or Aramaria, on account of the permanent nature of their calyx when dried, which retains its original colour and splendour.

G. globosa, Globe Amaranth, a native of India, is commonly raised on a hot-bed, and planted out in our borders, like other tropical annuals. It is also frequently kept in pots to decorate the flower or green-house. The original crimson form is much more handsome than the paler varied variety.

G. perennis, figured in Dill. Hort. Elth. t. 20, a native of Buenos Ayres, is scarcely cultivated but in curious gardens, having heads of yellowish flowers of no remarkable beauty.

There are eight species besides in Wildenow, of which the arborensis, Linn. Suppl. 173, is by far the most remarkable. This was not sent to Linnaeus by Nuttis from New Granada, as erroneously alleged by the younger Linnaeus in the Supplementum, but by Vandelli, who received it from Brazil, and who has designated it under the name of Bragantia, in his Fl. Brazil. p. 6. The stem is woody, round, leafy, clothed with rigid, prominent, brown hairs, as are also the leaves, which are opposite, obovate, obtuse, entire, about three inches long, and half as broad. Heads terminal, solitary, the base of an African Marigold or Tagetes, pale red or whitish, composed of innumerable flowers, the segments of whose calyx are about six to eight long, linear, acute and softly clothed in their lower part, with long dense silky hairs. We know of no figure of this fine plant.

Mr. Brown, Prod. Fl. Nov. Holland. v. i. 416, all new species to Gomphora, while he removes from it the be蜊enifla and terminifera, which, with two new ones from the tropical part of New Holland, he forms into a new genus, Philoxera. He considers what we term corolla in Gomphora, as the tube of the united filaments.

Gomphora, in Gardening, contains a plant of the flowery annual kind, of which the species cultivated is the annual globe amaranth (G. globosa).

It is a fine flowering plant, the heads of which at their first appearance are globular, but as they increase in size become oval, and, according to Martyn, the flowering heads are extremely beautiful, and, if gathered before they are too far advanced, retain their beauty several years.

There are varieties with fine bright purple heads, with white or silvery heads, which never alter from seeds, with mixed colours, with purple and with white heads, which two last are much smaller and rounder than the others; the plants also grow much larger and spread more into branches, and are later before they flower; these are called hatchelor's buttons in America.

Method of Cultivation.—It may be increased by sowing the seeds annually, in pots of light fresh mould, in the early spring months, and plunging them in the dark hot-bed. When the plants are up, they should be watered often with care; and, after they have attained some growth, be removed with their roots into other pots, and replanted in the open ground. When they have some growth in this situation, they should be removed into a deep frame, being placed in a fresh hot-bed, to bring them up tall and handsome. Afterwards they should be often refreshed with water, and have air admitted freely as the farmer advances, till they are capable of bearing it without injury; when about August they may be set out during the daytime, being protected in the night, and from wet weather. At this period they should be watered three or four times a week at least, in a rather sparing manner.

They afford a good effect when set out in the principal situations about the house, in afflumage with other plants of the potted kinds.

GOMRAITENIO, in Geography, a town of Hindoostan, in the Carnatic; 25 miles N. of Madras.

GOMS, one of the seven independent dixains or common-wealths of the Upper Vallais, in Switzerland; called Dixain, because the Upper and Lower Vallais comprehend 11 districts, each being a dixain or tenth of the whole. Goms is situated at the foot of mount Grimsel, and extends along the bank of the Rhone; and is so called from a town, 33 miles E. of Sion. See Vallais.

GOMUT, a river of Bengal, which runs into the Magna near Chandpore.

GOMUT Pepere, a town of Hindoostan, in Dowlatabad; six miles N. of Amedanagur.

GOMUTTRA SELAGUTTA, in Natural History, the name given by the Indians to a kind of fowl, found in great plenty on the mount Vindy in the East Indies, in places, as they observe, where the cows frequently urinate. It is a bituminous fowl, and after calculation the reddish, given in cafes of internal ulcers and in gonorrhoeas. The Indians supposed it formed by the drying up of the cows' urine.

GONACRA, composed of यु, ल्ल, and ई, ब्रह्म, । फ्रीि, in Medicine, the gout in the knee. See Goff.
GONAMBouch, in Ornithology. See Emberiza Grica.

GONANPILLY, in Geography, a town of Hindooftan, in the cirecor of Ellore; 18 miles N. E. of Ellore.

GONAPI, one of the smaller Bandha islands, in the centre of which is a volcano. The only inhabitants are wild hogs, cows and serpents. S. lat. 4° 10'. E. long. 150° 34'.

GONARCHA, a term in the ancient dialling. Mr. Perrault, in his notes on Vitruvius, lib. ix. cap. 9, takes the gonarcha to have been a dial drawn on divers surfaces or planes; some of which being horizontal, others vertical, oblique, &c., formed divers angles.

Whence the appellation, from vert, knee, or vertice, angle.

GONARY, in Geography, a town of Hindooftan, in the Mylore; 12 miles S. of Kydroid.

GONAVE, 1A, an island situated on the west side of St. Domingo, about 14½ leagues in length, and about three in breadth. This is called Grand Gonave by way of distinction from Petit Gonave, another small island about two miles in each direction, separated from the S.E. corner of the former, by a channel three miles wide. Gonave is 13½ leagues W. by N.W. from Port au Prince. N. lat. 18° 54'. W. long. 73° 40'. See St. Domingo.

GONAVES, a fort on the above-mentioned island, at the head of a bay of its own name, on the N. side of a bay of Legone. The harbour is excellent; the town has a medicinal spring, and in 1772 both were erected with lodging-houses for the accommodation of those who refer to it, and an hospital for soldiers and sailors. It lies on the great road from Port de Paix to St. Mark, 16 leagues S.E. of the former. N. lat. 19° 22'; W. long. 73° 20'.

GONCANAAM, a town of S. America, in the audience of Quito; 20 miles S.W. of Loxa.

GONCELIN, a town of France, in the department of the Ifere, and chief place of a canton, in the district of Grenoble; 13 miles N.N.W. of Grenoble. The place contains 1,558, and the canton 10,259 inhabitants, on a territory of 1,671 kilometers, in 13 communes.

GONDAR, the metropolis of Abyftinia, is situated upon a hill, elevated 840 feet above the ocean, and confines of about 10,000 families in times of peace. The houses are chiefly constructed with clay, and the roofs are thatched in a conical form, which is the mode of building within the tropical rains. On the west end of the town is the king's houfe, formerly a structure of considerable importance; it was a square edifice, flanked with square towers; formerly four stories high, and the top of it afforded a magnificent view of the whole country S. of the lake Tzama. Although the greatest part has been burnt at different times, there is ample lodging in the two lowest floors of it; the audience chambers being above 120 feet long. Annexed to this ruined palace are apartments, constructed by preceding kings, also of clay, according to the fashion of their own country; for the palace itself, says Bruce ('Travels, vol. iii.') was built by masons from India in the time of Faedida, and by such Abyftinians as had been instructed in architecture by the Jefuits, without embracing their religion, and afterwards remained in the country, unconnected with the expulsion of the Portugueses, during this prince's reign. The palace and its contiguous buildings are surrounded by a stone wall, 30 feet high, with battlements upon the outer wall, and a parapet roof between the outer and inner, by which you may pass along the whole and have a view of the street. There never appear to have been any embrasures for cannon; the four sides of this wall are above 1½ English mile in length. The mountain, on which the town is situated, is encompassed on every side by a deep valley, which has three outlets; the one to the south, to Dembea, Matthaw, and the Agows, the second to the N.W., towards Senammar over the high mountain Debra Tsai, or the mountain of the Sun, at the foot of which Kofcam, the palace of the Iteghë, is situated; and at the mouth of the Kordhen, the palace of the other Iteghë; the third is to the N. to Woggora, over the high mountain Lumalanon, and on through Tigré to the Red sea. The river Koba, coming from the mountain of the Sun, runs through the valley, and covers all the south of the town; the Angurab, falling from Woggora, surrounds it on the N.N.E.: these rivers join at the bottom of the hill, about a quarter of a mile S. of the town. On an eminence opposite to Gondar, on the other side of the river, is a large town of Mahometans, containing about 10,000 houset. They are all active and laborious, and are employed in taking care of the baggage and field-equipage of the king and nobility, when they take the field and return from it; but they never fight on either side. N. lat. 12° 34' S. 30'. E. long. 37° 33'.

GONDEBAUD, in Biography, third king of the Burgundians, celebrated as a legislator among the barbarians over whom he reigned as sovereign. He obtained the crown in 491, and almost immediately, under pretence of affilling Odace against Theoderic, ent red Italy, carrying fire and sword through Emilia and Liguria, and made a great number of captives, many of whom he liberated without ransom, at the request of Epiphanus bishop of Pavia. He assembled, in 499, a council at Lyons, in order to effect a reconciliation between the Catholics and Arians. He was himself an Arian, from habit and education; but he was unable to effect so laudable a purpose. About this time he was attacked and defeated by Clovis king of the Franks, who made the Burgundian monarch his tributary. Clovis returned to his own country, and Gondebaud revenged himself upon his brother Godegesil, who had joined Clovis, surprised him, and put him to death. From this period he reigned in peace over his people, whom he rendered flourishing by the arts of civilization, and by a regular system of laws. Those, says the historian, were in general founded on equity, and display much sagacity in preventing all causes of dispute; nevertheless, they enjoin the barbarian of judicial combats, which the legislator justified as an inference from the admitted doctrine of the interference of a particular providence in human affairs. The Burgundian code, called La loi Gambrette, has been published in several collections of ancient laws. This prince died in 516, leaving behind him, as memorials, letters upon theological subjects to Avitus, bishop of Vienne. Univer. Hitt.

GONDEGAMA, or GONDELACOMMA, in Geography, a river of Hindooftan, which forms the nominal boundary of the Carnatic, and discharges itself into the sea at Medipelly, Combam, or Commam, is near its source. It is sometimes called Giligama, and Guata-camma.

GONDICOTTA, a town of Hindooftan, in Narawar; 33 miles N. of Trumian.

GONDOLA, a little flat boat, very long and narrow, chiefly used at Venice to row on the canals.

The word is Italian, gonduca. Du Cange derives it from the vulgar Greek saivadca, a bark, or little fish; Lancelot deduces it from sa, a term in Athenæus for a sort of vase.

The middle-sized gondolas are upwards of thirty feet long, and four broad; they always terminate at each end in a very sharp point, which is raised perpendicularly to the full height of a man.
GON

The address of the Venetian gondoliers, in passing along their narrow canals, is very remarkable; there are usually two to each gondola, and they row by pulling before them. The foreman rests his oar on the left side of the gondola; the hind-man is placed on the stern, that he may see the head over the till or covering of the gondola, and rests his oar, which is very long, on the right side of the gondola.

GONDOLA is also the name of a passage-boat of six or eight oars, used in other parts of the coast of Italy.

GONDOLA, in Natural History, a name given by authors to a peculiar kind of concha globosa, supposed, in some degree, to represent the shape of a Venetian boat. It is of the genus of the dolium, and there are seven species of it. See DOLIUM AND CONCHOLGY.

GONDAR, in Geography, a town of Spain, in Galicia; 6 miles E. of Bayona.

GONDRECOURT, a town of France, in the department of the Meuse, and chief place of a canton, in the district of Commercy. The place contains 1113, and the canton 8873 inhabitants, on a territory of 34000 square kilometres, in 24 communes.

GONDUFEL, a town of Africa, in the kingdom of Kong; 100 miles S.E. of Kong.

GONDWARRAH, a town of Bengal; 15 miles S.S.W. of Purnea.

GONESSE, a town of France, in the department of the Seine and Oise, and chief place of a canton, in the district of Pontneuf, nine miles N. of Paris. The place contains 2402, and the canton 14811 inhabitants, on a territory of 1824 square kilometres, in 22 communes.

GONET, John Baptist, in Biography, was born at Beziers in the year 1616. He embraced the ecclesiastical life when he was young, and was admitted to the degree of doctor of divinity by the university of Bordeaux in the year 1640. He was at the same time elected to the professorship of theology in that university, an office which he held with great dignity till the year 1674, when he was appointed provincial among the Dominican friars. In 1675 he refixed his abode as professor, which he continued about two years, and then retired to his native place, where he died in 1681. He was author of a system of divinity, entitled "Clypeus Theologica Thomistic, contra novos ejus impugnatores," first published at Bordeaux in 1666, in eighteen volumes 12mo, but it was afterwards enlarged, and printed in five volumes folio. He was likewise author of a "Mammal Thondilaram, seu brevis Theologia Curus," which has passed through different editions, of which the last was published at Lyons in 1681; and "Differtio Theologiae de Probabilitate." Morell.

GONFALON, or Confax, a kind of round tent, borne as a canopy, at the head of the processions of the principal churches at Rome, in cafe of rain; its verge or banner serving for a shelter, where there is not a great deal of attendance.

GONG, a Chinese metallic musical instrument of percussion, in the form of a flat bason, with a ridge round it, and beaten by a mallet covered with several folds of woolen cloth. It is carried on a pole by two men, and beaten by the hindmost. In the march of an army, it is used as a military instrument to regulate the steps of the soldiers; when struck with great force, it is sufficiently loud to be heard at a mile's distance; but so confused is the sound, that no distinct tone can be ascertained. Yet by reiterated gentle strokes on the same part of the bottom of the bason a musical tone may be produced; but different parts of the circle produce tones of different gravity and acuteness.

GONG, in us used in processions, and at court on days of ceremony and festivals, in concert with other instruments, as a double drum. On the water, in vessels that are rowed, this instrument regulates the strokes of the oars.

It is formed of brass or bronze, and called lu by the Chinese, who, on hearing it only on great occasions, regard it with reverence.

GONGA, in Geography, a town of European Turkey, in Romania, near the sea of Marmora; 36 miles N.E. of Gallipoli.

GONGA, or Bain Gonga, a river of Hindoostan, which falls into the Godavery about 50 miles from the sea. See Bain Gonga, and Godavery.

GONGACA, a town of Bengal; 30 miles S.W. of Calcutta.

GONGADEE, a town of Bengal; 30 miles S.W. of Regonampour.

GONGLARA, in Botany, a name by which Imperata has called a very beautiful sea plant, known among botanical writers by the name of fucus erica folius, or erica marina, the sea holly.

GONGONG, is an instrument used by the Hottentots, and all the negroes on the west coast of Africa. Of this kind there are two sorts, the large gongong and the small. In the supplement to the fifth edition of the French Encyclopédie, a description of this instrument has been attempted, that seems totally unintelligible.

"The small gongong (say the editors) is an iron or holly bow, of which the string is the finew of a sheep dried in the sun, or a bowel string; at the extremity of the bow is placed, on one side, the pipe of a fplit quill, in the hollow of which the string of the bow is lodged. The performer holds this quill in his mouth while he is playing, and the different tones of the gongong proceed from the different modulations of his breath."

"The great gongong only differs from the small by the shell of the cocoa-nut, of which the upper part has been cut off, and the string of the bow, before its tension, passed through it on each side. In touching the instrument the cocoa-shell is moved to and from the quill according to the tone which is to be produced."

We hope our readers will comprehend this description, by which we frankly own ourselves not to be much enlightened; nor can we well conceive how the motion of the split quill, or the fiction of the cocoa-nut, can produce different tones. Nothing that answers to this description is to be found on the plate referred to (fig. 3, Pl. 11.) but in Pl. III. fig. 9. May. Ind. there is, we think, a very unsatisfactory representation of it. And in the rude state in which the European arts in general have been found in such parts of Africa as have already been explored, we have little reason to lament our ignorance of the construction and use of the gongong.

GONGOO, in Geography, an island in the Neel Abud or Guin river of Africa, in its course between Caffina and Kaffina, and Mezkara. N. lat. 16. E. long. 11.

GONGOPOUR, a town of Hindoostan, in Oude, 12 miles S. of Kaibad.

GONORA, Lewis, in Biography, a celebrated Spanish poet, was born at Cordova in 1762. He studied at Salamanca, and being brought up to the church, was made chaplain to the king, from whom he received considerable ecclesiastical preferment. He died at Cordova, of the church of which he was prebend. His reputation is built on a volume of poems, under the title of "Obras de Don Lewis de Gongora y Argones," 4to. The poems consist of a variety of compositions, chiefly of the shorter kind, especially
lysical, in which style he so much excelled, as to be termed
by his countrymen "the prince of lyric poets." Gon-
gora polishes, in the estimation of his countrymen, a very
high rank among the Spanish poets for an artificial elevation
of language, and uncommon turn of thought, which were
formerly the characteristics of the poetry of that nation.
So much, indeed, did he surpass in these qualities, that he
had many enemies in his own country, though he also met
with as many warm defenders. He is said to have enriched
his native language by the introduction of many Latin words
happily employed. Moreri.

GONIARRON, in Surgery, a hard tumour; but espe-
cially a branchocoele, or swelling of the thyroid gland.
The word is said to be derived from 727,727, a round tubercle
on the trunk of a tree.

GONHARY, in Geography, a town of Hindooistan, in
Onoe: 40 miles W. of Lucknow.

GONIA, a town of Attic Turkey, in Natolia; 16
miles W. of Apshian-Karabiar.

GONIAH, or Kono, supposed to be the Contoh of
D'Anville, and the Gorge of Delphos, a kingdom of Africa.
Situatet to the N. of Guinea, between the meridian of
Greenwich, and 5 W. long, and between the 10th and 12th
degrees of N. lat. It is about 870 miles westward from
Cadtha or Kattina, and between 530 and 620 miles from
the Gold Coast. Some say, there is no communication be-
tween this coast and the country of Gonjah; the king of Af-
centoi, who polishes the intervening space, prohibiting his
inland neighbours from passing through his country. Others
report, that other states (e. g. the Fannees, and their confede-
rates) lie between Afcentoi and the sea; and that the Af-
centois have often unsuccessfully attempted to open a com-
munication with the coast.—Alio, the name of a town, which is
the capital of the kingdom of Gonjah or Kong. N. lat.
11° 50'. W. long. 3 30.—Alio, the name of part of a
claim of mountains, extending from almost the mouth of the
river Gambie, in the Atlantic, to Nigria, towards Abyssi-
nia.

GONIAH, a decayed town and large castle of Attic
Turkey, belonging to the province of Guriel, at the mouth
of a river which runs into the Black sea. It is garrisoned
by a few Janissaries, and inhabited chiefly by feamen;
50 miles E.N.E. of Trebisond. N. lat. 41° 9'. E. long.
41° 10'.

GONJENPILLY, a town of Hindooistan, in the Car-
natic; 18 miles N.E. of Nellore.

GONIOCARPUS, in Botany, so called from εγκεις, an
angle, and 327,727, fruit, expressive of one of its efficien-
t characters. The name, originally contrived by Thunberg, was
Goncarpus, which being incorrectly contrived, and too
near Gonocarpus, was judiciously changed by Mr. Konig,
Schreber, Wildenow, and others, have made it Gonocarpus,
for want of attending to its meaning and application, which
has no reference to γα διας, a lance, but to the very pecu-
lar angles of the fruit.—Konig in Ann. of Bot. v. i. 546.
t. 12. f. 3. 6. (Gonocarpus; Thunb. Nov. Gen. 55. F.
Lamarec. Illntr. t. 73. Gonocarpus; Schreb 86.
Willd. Sp. Pl. v. 1. 692. Mart. Mill. Dict. v. 7.)—Clas-
and order, Gonocea Monogynia. Nat. Ord. Ovagras, or
Oongraea, Jull. Konig.

Gen. Ch. Cot. Periun superior, in four deep, acute,
equal, upright segments. Cot. Petals four, equal, oblong,
convex, inserted into the rim of the calyx, and twice as
long as its teeth. Stam. Filaments four or eight, very short,
inserted into the calyx, opposite to the petals if four, to
the petals and calyx-teeth if eight; anthers oblong, large,
shorter than the corolla. Pfl. German inferior, turbinate,
with eight stamens and as many angles, crowned with the
permanent calyx; style extremely short; stamens four, ob-
tuse, downy.

El. Ch. Calyx superior, in four deep equal segments.
Petals four. Drum dry, with eight angles. Nut solitary.

One cell.

Three species of this inconspicuous though curious genus
are at present known.
1. G. micrantho. Thumb. Jap. 69. t. 15.—Leaves ovate,
obtuse, crenate, smooth, as well as the stem.—Gathered by
Thunberg in Japan. Root fibrous, annual. Stem three or
four inches high, ascenditng, quadrangular, smooth, leafy,
fimbly below, panicked above. Leaves opposite, on short
stalks, ovate, rather acute, half an inch long, bluntly crenate
and carinationgs in the margin, smooth on both sides, minutely
dotted, furnished with a rib, but no veins; the upper one
gradually smaller and more entire. Stipiles none. Flowers
very small, purplish, drooping, in several slender, lax, upright,
spikes, forming a fort of panicle. The petals as well as calyx
are sufficiently evident in Thunberg's own specimens before
us. The fruit is no bigger than the smallest pin's head, and
the petals feebly longer.

2. G. rotundifolius. —Leaves rounded, somewhat heart-
shaped, obtuse, crenate, smooth. Angles of the stem
rough. Spikes in a compound panicle.—Gathered near Port
Jackson, New South Wales, by John White, M. D.—We
are by no means certain that this is more than a variety
of the former, but its different country, much more rounded
leaves, heart-shaped at the base, and the slightly angles of the
stem, induce us to propofe it as a species. Possibly the pan-
cled spikes may owe to the greater luxuriance of the spe-
cimens. The fructification appears precisely like that of the
fruits species.

—Leaves elliptic-lanceolate, sharply ferrated, blister as well as
the stem.—Gathered by Mr. David Nielson, in cultivated
ground in the island of China, near Macao. This appears
to differ from the two former very materially, being all over
rough, with deprestted bristles, and having longer and nar-
rower sharply ferrated leaves. The flowers, moreover, have
eight flames, and the angles of the fruit are wavy or crinkled,
not smooth and even.

We have a plant gathered by Dr. White, near Port Jack-
non, which seems to answer in every point to Mr. Konig's
definition and figure of the last, except that its petals have
a brilily keel, and the stamens are singularly branched
and plumose, making a large tuft in the centre of each flower
after the petals are fallen. Perhaps Mr. Konig's specime
has lost all their stamens. We remark, however, a further
difference in the fruit, whose alternate angles are less distinct,
or rather more crinkled and interrupted than the rest.
Not having examined authentic specimens of G. fuscifolius,
we must leave this matter in doubt.—Possibly this may be G. tergo-

GONIOMETER, an instrument used for the purpose of
measuring small angles (particularly of crystals), or the
inclination which one plane surface makes with another. The
smallest goniometers, as usually fold at the shops, are of a
construction so simple, as to require but little description.
They generally consist of a small pair of compasses or nippers, de-
fined to receive the angle of the crystal; and the legs of these
being continued in the opposite direction, beyond the angular
point or joint, the angle is measured by applying them to a
protractor or semicircular scale of degree.

But notwithstanding much sagacity has been bestowed on
instrument described on this principle, none have
Goniometer.

have been found nearly accurate enough for the purposes for which they are required, many interting questions in the
modern science of crystallography requiring a much more
exact determination of the angle than can possibly be obtained
by instruments of this construction.

We are indebted to Dr. Wollaston for having removed all
these difficulties, by the invention of an instrument which
accomplishes all that the most scrupulous naturalist can pos-
dibly desire. The principle of this invention is entirely op-
tical, and (Plate XIX. Mfcedony, fig. 2) represents the in-
strument as made and sold by Mr. Carey, in the Strand; but
the reader, when acquainted with the nature of it, will rea-
dily see that any person possessed of a graduated instrument,
such as a theodolite, transit, &c., may, without great diffi-
culty, apply it to the measurement of angles, though in a
much less commodious manner than on an instrument made
expressly for the purpose.

Dr. Wollaston's method consists in employing a ray of
light reflected from the surface, instead of the surface it-
self; and, for a radius of 1-50th of an inch, we may
substitute either the distance of the eye from the crystal,
which would naturally be twelve or fifteen inches, or for
greater accuracy we may, by a second mode, substitute the
distance of objects seen at a hundred yards or more from
us. The instrument described by Dr. Wollaston, in the
Transactions for 1809, consists of a circle, grad-
ated on its edge, and mounted on an horizontal axle sup-
ported by an upright pillar. This axle, being perforated,
admits the passage of a smaller axle through it, to which
any crystal of moderate size may be attached by a piece of
wax, with its edge, or intersection of the surfaces, hori-
zontal and parallel to the axis of motion. This position of
the circle is first adjusted, so that by turning the smaller
axe, each of the two surfaces, whose inclination is to be
measured, will reflect the same light to the eye. The circle
is then set to zero, or 180°, by an index attached to the
pillar that supports it.

The small axle is then turned till the further surface ref-
lects the light of the candle, or other definite object, to
the eye; and lastly, (the eye being kept steadily in the
same place,) the circle is turned by its larger axle, till
the second surface reflects the same light. This second sur-
f ace is thus ascertained to be in the same position as the former
surface had been: the angle through which the circle has
moved, is, in fact, the supplement to the inclination of the
surfaces; but as the graduations on its margin are numbered
accordingly in the inverted order, the angle is correctly
shown by the index, without requiring any computation.

It may be here observed, that it is by no means necessary
to have a clean uniform fracture for this application of the
instrument to the fracture of laminated substances; for
since all those small portions of a shattered surface that are
parallel to one another, (though not in the same plane),
glisten at once with the same light, the angle of an irregu-
lar surface may be determined nearly as well as when the re-
flected surfaces are actually in the same plane. In this
method of taking the measure of an angle, when the eye
and candle are only ten or twelve inches distant, a small
error may arise from parallax, if the interference of the
planes or edge of the crystal be not accurately in a line
with the axis of motion. But such an error may be re-
dered insensible, even in that mode of using the instrument,
by due care in placing the crystal; and when the surfaces
are sufficiently smooth to reflect a distinct image of objects,
all errors from the same source may be entirely obviated by
another mode of using it.

For this purpose, if the eye be brought within an inch
of the reflecting surface, the reflected image of some dif-
cult chimney may be seen inverted beneath its true place,
and, by turning the small axis, may be brought to corre-
spond apparently with the bottom of the house, or some
other distant horizontal line. In this position the surface
accurately reflects the angle which the height of that house
subtends at the eye, or rather at the reflecting surface:
then, by turning the whole circle and crystal together, the
other surface, however small, may be brought exactly into
the same position; and the angle of the surfaces may thus
be measured, with a degree of precision that has not hitherto
been expected in goniometry.

The accuracy, indeed, of this instrument is such, that a
circle of moderate dimensions, with a vernier adapted to it,
will probably afford corrections to many former observa-
tions. Dr. Wollaston has remarked one instance of a mis-
take that prevails, respecting the common carbonate of lime,
which he mentions, because this substance is very likely to
be employed as an object of the correctors of such a goni-
ometer, by any one who is not convinced of its accuracy,
from a distinct conception of the principles of its construc-
tion.

The inclination of the surfaces of a primitive crystal of
carbonate of lime, is stated with great appearance of pre-
cision to be 105° 28° 46": a result deduced from the sup-
posed position of its axis, at an angle of 45°, with each of
the surfaces; and from other less reducing circumstances of ap-
parent harmony by simple reasons.

But however strong the presumption might be, that this
angle, which by measurement approached to 45°, is actually
so, it must nevertheless be, in fact, about 105° 28°; for the
inclination of the surfaces each other is found to be very
nearly, if not accurately, 105°, as it was formerly deter-
mined to be by Huygens; and since the measure of the
superficial angle, given by Sir Isaac Newton, corresponds
with this determination of Huygens, his evidence may be
considered as a further confirmation of the same result; for
it may be presumed, that he would not adopt the measures
of others without a careful examination.

Exposition of the Figure.

a b, Is the principal circle of the goniometer, graduated
on its edge.

b c d, The axe of the circle.

e, A milked head, by which the circle is turned.

f, A milked head on the small axe.

g, A brass plate supported by the pillar, and gradu-
ated as a vernier to every five minutes.

h, The extremity of a small spring, by which the cir-
acle is stopped at 180°, without the trouble of reading off.
i f, w e, Are two centres of motion, the one hori-
zontal, the other vertical, for adjusting the position of a
single point in the circle, by the handle f, the other by the milked
head m. The crystal being attached to a screw head at the point
n, in the centre of all the motions, with one of its surfaces
as nearly parallel as may be to the milked head m, is next
rendered truly parallel to the axis, by turning the handle i
till the reflected image of a horizontal line is seen to be truly
horizontal. By means of the milked head f, the second sur-
f ace is then brought into the position of the first, and if the
reflected image from this surface is found not to be horizon-
tal, it is rendered so by turning the milked head m, and
since this motion is parallel to the first surface, it does not
derange the preceding adjustment.

Goni-
GONIOMETRICAL LINES, derived from \textit{goniometry}, or determining the quantity of angles. Such are lines, tangents, secants, vertical lines, &c.

We have a paper by Mr. Jones, in the Philosophical Transactions, containing a commodious disposition of equations for exhibiting the relations of goniometrical lines, from whence a multitude of curious theorems may be derived. See Phil. Trans. N. 2. 483. sect. 26.

Gonium, in Zoology, a genus of Vermes, characterized only by their very simple, flat, and angular form, and being invisible to the naked eye. The species at present known are few, amounting to no more than five in number; and for the existence of these we rely chiefly on the microscopic researches of Müller and Schrann, the former of whom describes four of these minute creatures with great accuracy in his "Zoologia Danica." They are mostly inhabitants of fresh or pure water, though some of them occur in stagnant water or in dunnghills.

Species.

\textit{Polysphecium}. Orbicular, pellucid, with innumerable spherical molecules. Schrann.

Found in stagnant water; the colour greenish-yellow, and general appearance that of a thin membrane filled with innumerable lucid globules. Very common in the month of July.

The molecules are oval and nearly of an equal size, their colour greenish, pellucid, and disposed in a quadrangular manner within the membrane, like diamonds in a ring; or rather, as Müller compares them, to the jewels in the breastplate of the high priest among the Jews, and reflecting light on both sides. Its progress is by an advancement alternately towards the right and left, at which time all the molecules are in motion, and assume their oval form, these molecules being round when the animal is in a quiescent state.

\textit{Truncaturn.} Angles obtuse; posterior part arched. Müll.

This occurs in fresh or pure water, and is rarely met with; its size is rather considerable; the fore-part is a straight line, the sides forming therewith obtuse angles, the extremity of the sides being united by a curved line; the internal organs, perceptible to the eye by the assistance of the microscope, consist of a number of molecules of a dark green colour, and two vesicles of peculiar brightness in the middle. Its motion is languid.

The projection at the base of the body in this species is placed in a right angle; the interlines green, with the larger vesicle transparent.

\textit{Pleminatum}. Quadrangular, opaque, with four cylindrical protuberances. Müll.

This species, according to Müller, appears under a slight magnifier like a quadrangular membrane, plain on both sides, but, when a deeper lens is applied, resembles the figure of a bolster, formed of three or four cylindrical pillows, flattened or fink in various places; this was the appearance it assumed when first examined; some days after all the sides were plain without convexity and decurated, or divided into little figures by the intersection of straight lines. It is found in puddles under dunnghills.

GONKOFEN, or Gankofen, a town of Bavaria; 14 miles E. of Landshut.

Gonna, a town of Hindooscan, in Lahore; 12 miles W. of Nangorote.

GONNI, or Gonno, in Ancient Geography, a town of Greece, in the Peribabia, situated near Paeaus, towards the north where the Olympus and Ossa approached each other.

GONNOCONDYMMU, a town of Greece, in Macedonia, in the Peribabia.

GONNOLESSA, a town of Greece, in the Peloponnesus.

In the time of Pananias it belonged to the Sicyniata.

Gen. Ch. Cal. Pieranth inferior, of one leaf, in the deep, acute, spreading segments, permanent. Cor. of one petal, wheel-shaped, in five deep spreading segments. Nectary a leaf-like, crowning the flowers, lobed. Stem. Filaments five, thickish, united into a short tube; anthers bursting transversely, terminated by a membrane, their nectaries of pollen attached to the outer extremity, with respect to the cell, and covered by the stigma. \textit{Pf}. Germens two, ovate-oblung; illes two, very short, close together, stigma common to both, flat, flat or depressed, with five angles. \textit{Peric}. Pouches inflated, more or less angular or ribbed. Seeds numerous, imbricate, oblong, crowned with down.

This appears to be a numerous genus, properly separated from \textit{Cynanchum}, and consisting of climbing shrubs, with opposite broadish leaves, and flowers growing in umbels between the insertion of the foot-flalks. They are natives of America, chiefly within the tropics. Examples of it are \textit{Cynanchum maritimum}. Lim. Mant. 54. Jacq. Amer. 83. t. 56, a hairy plant, with dark-purple blossoms; \textit{faberfolium}. Limn. Sp. Pl. 310, figured in Dell. Hort. Edh. t. 229, f. 296, likewise a downy species, with purplish-green flowers; and \textit{cristiflorum}, Ait. Hort. Kew. v. i. 302. Plum. Edh. t. 216. f. 1: as well as many others presumed to have the same generic characters, but which, according to Mr. Brown, require to be thoroughly examined, as does the whole genus.—Michaux enumerates three species, natives of the warmer parts of North America, and which he calls \textit{G. macrophyllum}, \textit{hirfusis}, and \textit{levis}.

GONON BESAR, in Geography, a mountain on the E. side of the island of Java, famous for the quantity of pepper which its trees produce.

GONONG, or Gana, one of the group of Asiatic ifles, called \textit{Banda}, in which there is a remarkable volcano.

GONOR, a town of Hindoostan, in the cirear of Go- hud.

GONORHYNCHUS, in Ichthyology, a species of \textit{Cypora}, which fec.

GONORRHGEA, in Surgery, a disease in which a kind of matter, which is either actually pus, or a fluid of very similar qualities, is discharged from the urethra of the male subject, and from the surfaces of the labium, nymph, clitoris, and vagina of the female, attended with more or less heat, pain, and difficulty in making water. The disease is infectious, and capable of communicating the complaint from one person to another, whenever it comes into
GONORRHEA.

He remarks, that if a Greek name is to be retained, he would call the complaint "blennorrhagia", from δέλλον, mucous, and φασιν, to flow. Now this last expression is objectionable, on the identical principle which makes Dr. Swedaour with for the relinquishment of gonorrhoea; for it is generally thought by all the most eminent modern surgeons, that the discharge is pus, and not mucous. Besides, we do not see much utility in abandoning the ancient appellatio. The knowledge of surgery is now so highly cultivated, that there is not the least danger of any man imbibing an absurd opinion respecting this common complaint, from the etymological import of its name. Every juvenile apprentice knows that a clap is a running of matter from the urethra. Few common practitioners trouble themselves about Greek derivations; and where is the object of changing the name of one disease, while many hundred other surgical terms stand in equal, and often greater, need of alteration?

The Hunterian doctrines go so far as to assert, on the authority of experiments, that the poison of the lues venereus, and that of gonorrhoea, are in fact the same, though usually productive of opposite effects, by reason of the parts affected, and those concerned in gonorrhea having quite different structures. These things, if true, tend to prove, that the matter of a clap may, under certain circumstances, impart the venereal discharge to the constitution. However, it should be understood, that the statement just now made can only refer to the gonorrhoea virulenta; for it is certain, that a simple discharge from the urethra, and a seething fenstration in making water, which would constitute a gonorrhoea, may be the consequence of any thing which produces irritation in the passage without the possibility of the venereal or common gonorrhoeal virus being at all concerned. Thus, a man may have a lacerity, and begin the employment of boughies for its cure; their irritation may bring on a forehead in the urethra, and excite a discharge. Here we have an instance of the complaint arising from the operation of no virus whatever; but altogether from the unequivocal, mechanical, irritation of the boughies. Doubtless, also, there are sometimes discharges both from the male and female parts of generation, which, when applied to other persons, are capable of bringing on certain kinds of gonorrhoea by the entire effect of their irritation. So were a man, with a gonorrhoea, excited by the irritation of boughies to have connection with a woman, there is no doubt that the latter would be very likely to become troubled with a discharge and seething in making water, merely in consequence of the application of same of the matter from the male urethra to the surfaces of the labes, mons, &c.

The arguments which have been adduced to show the poison of one form of gonorrhoea, and that of the venereal disease, are the same, will presently come under consideration hereafter. In the meanwhile, it is our part to enter a little more particularly into the history of gonorrhoea.

The etymological meaning of gonorrhoea is a running of the fermen, the term being derived from γονος, signifying the seminal fluid, and ρηθος, to flow. The ancients are said to have entertained the very erroneous notion that the disease consisted of an oozing of the fermen in a morbid and altered state. As it is long since so absurd a supposition has had any partisans, a refutation becomes superfluous and every one now knows, that in the present, as in many other examples, truth and etymology are not coupled together. Dr. Swedaour, who has found fault with the term gonorrhoea, as conveying an untrue idea, has not been happy in a substitute.

When the inflammatory symptoms have come on, the penis seems swollen, and as if it were in a state of half-erection. The glass appears red, smooth, and enlarged, with a kind of transparency about it. Sometimes it is affected with a slight excoriolation, which makes it exceedingly tender, and is the source of some trivial quantity of matter. The canal of the urethra becomes narrower than natural, if we may form a judgment from the diminution which takes place in the stream of urine. Indeed, very frequently, this fluid can only be discharged in a broken furred current, or by drops. We have often seen severe retentions of urine attendant on the inflammatory stage of a gonorrhoea.

Small tumours may frequently be noticed along the internal surface of the penis, in the course of the urethra. These swellings have been considered as the mucus gland of that canal in a furred state. Sometimes they acquire a very large size, and ultimately suppurate and form abscesses, which, in some instances, burst externally, while in others they break into the urethra itself. In the latter event, the swelling all on a sudden subsides, as soon as the contained matter has escaped. Sometimes, after a certain interval, the tumour is seen to re-appear, which circumstance is said to be owing to a premature closure of the opening. Abscesses of the preceding kind are often met with in the situation of Cowper's glands. Here they also sometimes burst outwardly, sometimes inwardly, sometimes in both ways in the same patient. In this last case a new passage is made for the urine, termed a fistula in primis. See Fistula.

A painful fenstration is frequently felt by the patient along the lower surface of the penis, extending as far as the anns, and depending on the inflamed state of the urethra. In most cases the erections are frequent, and generally productive of infinite pain, particularly when a foreboding exists along the track of the urethra towards the anns, or when the complaint is complicated with chordee. See Chordee.

The vicifous transparent fluid which is naturally secreted by the glands of the urethra changes into a thick aqueous liquid,
lilory, and the secretion which takes place from the lining of this canal, and is intended for its lubrication, also becomes less transparent. At length both these fluids, becoming thicker and thicker, gradually assume more and more the qualities of pus. The discharge often undergoes an alteration in its colour and consistence, a circumstance which Mr. Hunter imputed to the dilution of the parts by which the matter is formed. Sometimes it is white, sometimes yellow, sometimes of a greenish colour. Such varieties depend upon the diminution, or increase of the inflammation, and not upon the poisonous quality of the matter; for the same appearances happen whenever the parts are irritated in a certain degree by any cause whatsoever, as several facts confirm.

Dr. Svedius injected into his urethra some caustic volatile alkali mixed with water, by way of experiment. The usual symptoms of a gonorrhoea ensued, together with a discharge which had the same appearances and alterations of colour, as the matter of the gonorrhoea virulent. We have already stated that the same circumstances most frequently attend the employment of bougies.

In the generality of inflations, the discharge does not proceed from any great extent of the urethra, not from more than an inch, or an inch and a half of that part of the passage, which is nearest the orifice in the glans penis. This distance was what Mr. Hunter used to name the specific extent of the inflammation. Before this celebrated surgeon flourished, it was commonly supposed, that the matter came from the whole of the urethra, and even from Cowper's glands, the prostate, and the vesicles feminines. Due attention to the symptoms, however, makes this idea seem quite improbable. If, for example, every part of the urethra, beyond the bulb, or if the bulb itself contributed to the discharge, the matter would be propelled out of the passage in the same manner as the semen, that is to say, by a sudden convulsive kind of action. It is well known that nothing can lodge in the bulb of the urethra, without immediately putting that part of the canal into action, particularly when in a state of irritation and inflammation. A drop of urine is not allowed to remain there, and if simple warm water be injected thus far, it is instantly forced out by the action of the accelerators or urine muscles. Therefore it seems rational to conclude, that if the membranous and bulbous parts of the urethra, Cowper's glands, the prostate, and the vesicles feminines, all had a share in forming the matter, no sooner would a certain quantity have collected in the bulb, than an immediate expulsion would be occasioned by the muscles of the part. No symptom of this kind, however, is usually observed, although it occasionally happens, that the accelerators urine are affected with spasmotic contractions, which are particularly dispoled to occur just after the patient has been making water, and do not seem to have any dependence on the discharge.

Mr. Hunter has taken notice that when the inflammation is violent, some of the vesicles of the urethra often give way. Hence a hemorrhage arises, which is most profuse, just after the patient makes water, though it also continues at other times. Sometimes the blood is inconsiderable in quantity, and only just sufficient to give a red colour to the matter. The erections, which are so frequent in this complaint, are apt to occasion an extravasation of blood, a symptom which is always attended with an increase of the pain felt at the time of making water; but the bleeding always in the end lessens the inflammation, and tends to the relief of the patient. The inflammation, accompanying a gonorrhoea, is attended with several of the characters of common inflammation; but yet it differs also from the latter affection in many respects. It does not excite any pulmonary sensation; it causes little pain, except what arises from the irritation of the urine and the tension of the parts; and the inflammatory irritation seldom extends beyond the affected surfaces. The reason of so large a quantity of pus being secreted, in consequence of so moderate an inflammation, has been attributed to the parts being such as naturally secrete, so that they readily alter the natural into a morbid secretion.

Although the inflammation of a gonorrhoea is commonly moderate, there are inflations in which it is exceedingly severe, and extends into the reticule texture of the surrounding corpus spongiosum urethra, particularly of that which is near the glans penis. Sometimes the inflammation advances further along the corpus spongiosum, and occasions a swelling, or extravasation of coagulating lymph, which is the cause of chordee. We have already stated that the inflammation occasionally gives rise to abscesses of the glands of the urethra, particularly of those in the perineum.

It is not decidedly known in what manner the disease communicates itself to the urethra. Some suppose that the inflammation creeps from the glans penis to the edges of the orifice of the urethra, and thence further into the passage. These reasoners will not allow the probability of a common opinion, that some of the infectious matter gets into the urethra at the time of coition. At all events it seems clear, that none of the contaminating fluid can get as far as the disease extends in ordinary inflations, much less in others, where the affection reaches a great way towards the bladder. There are some facts which tend to prove that the simple application of the infectious matter to the end of the penis may give rise to a gonorrhoea. A case related by Mr. Hunter in his treatise on the venereal disease, seems to confirm the truth of what we have mentioned.

As we have already observed, the complaint seldom extends further along the urethra, than about an inch and a half, or two inches. Mr. Hunter thought, that this part of the canal appeared to be most susceptible of the particular kind of inflammation brought on by the infection, and it constituted, what he used to term, the specific distance of the disorder. However, neither the fact of this case, nor which the patient complains, nor the irritation of the parts, corresponded to the real seat of the disease. The neighbouring parts are often affected with a variety of symptoms, of a nature more or less feverish, such as uneasiness, and even pains every where about the pubes, scrotum, perineum, anus, and hips. It is often necessary to suspend the teffules, which become so irritable, that the leaf accident, or exertion, which, in other circumstances, would have no effect, makes them swell. It frequently happens that the glands in the groin are sympathetically affected; they swell and inflame, though they do not commonly suppurate. Cakes also occur in which the irritation extends to the buttocks, thighs, and abdominal muscles, occasioning acute pain, swelling, and extreme forceps of the parts, and putting the patient under the necessity of always continuing in an horizontal posture. These symptoms, however, are not strictly inflammatory; if the patient be bleed, his blood does not exhibit the inflammatory crust, and the constitution is little or not at all affected.

When the case, independently of the affections arising from sympathy, is not more violent than what has been described, it is called a common gonorrhoea; but the violence of the essentia] symptoms of the disease will be more or less considerable, according as the patient is more or less susceptible of such complaints as depend upon irritation. Thus, in particular habits, the inflammation does not continue.
fine itself to the specific disease, but reaches all along the urethra. Severe pain is also frequently experienced in the perineum. Sometimes the acceleratores urinæ muscles are affected with the spasmoidal contractions, of which some mention has already been made. Such spasm is particularly apt to come on when the patient has just finished making water; it flows itself by the manner in which the last drops of urine are expelled; and it is generally attended with contractions of the erecære muscles. Sometimes the inflammation is so great as to occasion a swelling, and even an abscès in the cellular membrane. It has already been observed, that the most common situation of such suppuration is in Cowper's glands; but the small glands of the bulb may also be affected in a similar manner, and the irritation, in certain infirmities, is found to extend even to the bladder itself.

When the latter organ is once affected, it becomes more susceptible of every kind of irritation, so that very distressing complaints are apt to be produced. It is no longer capable of bearing the degree of dilatation of which it is capable in the healthy state. Hence the patient cannot hold his water in the usual way; but no sooner does the inclination to discharge it arise, than he is immediately compelled to make the evacuation, notwithstanding the severe pain, which, while the urine is escaping, is felt in the bladder, and especially about the glans penis. This pain has been compared with what is experienced in a fit of the stone, and it lasts for some time after the evacuation is completed.

The ureters, and even the kidneys, are sometimes sympathetically affected, when the bladder is considerably inflamed or irritated. Such an occurrence, however, is exceedingly uncommon. Mr. Hunter mentions his having seen an inflammation of the peritoneum brought on by a severe affection of the bladder in gonorrhœa; and others have observed a violent inflammation of the kidneys from the same cause. (See Encyclopædia Méthodique partie chirurgicale, tom. i. p. 584.) It has already been mentioned that a chorea is one of the occasional effects of a gonorrhœa. It arises in general from inflammation, but in some cases it appears to be entirely of a spasmoidal nature.

When the inflammation is not confined to the urethra and its glands, but spreads further, it attacks the sub stance of the corpus spongiosum, where it occasions an extravasation of coagulating lymph, which, unifying the cells together, makes the urethra incapable of yielding and being stretched in the same degree as the urethral caverns. Hence during an erection, the penis becomes bent forward. The adhesion of the cells of the corpus spongiosum urethrae together, which is the cause of chorea, in general, comes on in consequence of mere inflammation of the canal; but occasionally it is the effect of a species of inflammation, which is seen accompanying certain ill-conditioned chanteres. A chorea often continues after all the other symptoms of a gonorrhœa have quite ceased.

A chorea is sometimes altogether spasmoidal, in which case it is seen to disappear and re-appear alternately, at indeterminate intervals. At one time the erections, which are so common in cases of gonorrhœa, happen without being attended with any curvature of the part; while at other periods the chorea takes place in a great degree; the intervals of time between these changes being sometimes remarkably short.

A swelling of the testicles is a frequent consequence of a gonorrhœa. It may happen in any stage of the disease; but, perhaps, it takes place most frequently when the complaint is on the decline. It was considered by Mr. Hunter as an affection arising from sympathy. It is seen attending any kind of irritation in the urethra, whether occasioned by injections, bougies, or any other circumstance. In many cases, the swelling comes on and disappears very suddenly, or seems to leave one testicle to attack the other.

The swelling of the testicle generally begins with a soft, pulpy tumefaction of its glandular part, which becomes rather painful when handled. The tumour afterwards increases in size and firmness, and produces considerable pain. The inflammation seldom ends in suppuration, though some infirmities of this kind are met with. The epididymis (especially its lower end) is usually the hardest part; but, frequently, the induration and swelling attack the whole of the epididymis, and form a sort of knot at its upper part. The spermatic chord also is often affected, especially the vas deferens, which is thickened, and exceedingly tender. Sometimes the veins of the testicles are varicose.

The inflammation of the testicle, as well as that of the urethra, is frequently attended with sympathetic symptoms of irritation in other parts; for instance, pain at the lower end of the spine, a sense of weakness in the loin, colic pains, nausea, flatulence, disorders of the digestive organs, &c.

The swelling of the testicle is noticed to take place remarkably often just when the pain in the urethra hassubsided, and the discharges has stopped; or else the truth is, that on the testicle becoming affected, the symptoms of irritation in the urethra immediately cease. Here it is somewhat difficult to determine which is the cause, and which the effect. However, it is worthy of remark, that it is not uncommon for the testicle to begin to swell at the very moment when the inflammation of the urethra, and the discharges, are becoming worse. Sometimes the epididymis alone is affected; sometimes only the vas deferens; and, on other occasions, only the spermatic chord. No reason can be assigned, why one of these parts should be affected rather than the rest. The inflammation of these organs is frequently attended with a strangury, especially when the discharge is suppressed; and, indeed, it is remarked, that the stoppage of the running generally brings on a tendency of that distressing complaint.

Another occasional effect of a gonorrhœa is a swelling of the lymphatic glands in the groin, a symptom, which is of the same nature as the inflammation of the testicle, but much more common. It has been supposed that the tumefaction of the glands depends on the absorption of some part of the matter from the urethra; but Mr. Hunter contended against this opinion. He thought that, in gonorrhœa, the matter was seldom absorbed, and he derived this sentiment partly from seeing that a haus veneris was seldom the consequence of this difease. However, this argument will have no weight with those practitioners, who disbelieve in the doctrine that the poisons of gonorrhœa and the venereal disease are of the same nature. Another consideration, which influnced Mr. Hunter, will meet with more general approbation.

It was the fact, that any simple mechanical irritation of irritable organs is capable of exciting an inflammation of their absorbents, and of the glands to which such vessels run. Now, since the lymphatics and their glands usually inflame before suppuration has taken place in the part originally affected, and their inflammation often subsides as soon as this late occurrence begins, we must conclude, that the swelling of the inguinal glands, in gonorrhœa, arises altogether from the irritation in the urethra. It is observed also, that such swellings almost always admit of resolution; while those which originate from the absorption of venereal matter from chanteres very frequently suppurate, burst, and turn into supplicative ulcers. It is true, however, that swellings of the inguinal glands, induced by the irritation of gonorrhœa,
do sometimes end in abscesses and frost; but no lues venereal follows, nor is mercury requisite for the cure.

Another sympathetic affection, sometimes attending on a clap, is a swelling of the absorbent vessels themselves. In some instances, this symptom accompanies the swelling of the glands. It makes its appearance in the form of a hard, painful cord, which, proceeding from the prepuse, extends along the dorium of the penis, sometimes as far as the groins. This effect is not the consequence of the absorption of matter; for it is seen attending other irritations in the urethra, where no suspicion of any irritating or poisonous matter being taken up by the lymphatics can be entertained by any kind of reasoning whatsoever. The symptom is sometimes brought on by the employment of bougies, in the treatment of strictures. It was for a long while supposed, that the matter which is discharged from the urethra, in cases of gonorrhoea, was furnished from ulcers in this canal; but observation at length detected, that the opinion was delusive of all foundation. Dr. William Hunter is reputed to have been the first who ascertained, that in gonorrhoea no ulcers existed in the urethra, and he is said to have begun to inculcate the fact in his lectures about the year 1750. This celebrated physician had derived his sentiment from some particular cases, in which he had seen, where a large quantity of pus had been formed upon the surface of the visera, without any ulceration of these parts whatsoever. In 1753, his brother, Mr. John Hunter, had an opportunity of dissecting the bodies of two male infants, who were executed, while it was known that they were affected with a fever gonorrhoea. After a most careful examination, no ulceration could be discovered in the urethra of each was merely found to be rather redder than natural, particularly near the glans penis. Mr. Hunter afterwards opened the urethra of many patients who had died with gonorrhoea upon them, and he never could find any vestiges of ulceration. It constantly appeared, that the membranous lining of the canal, near the glans penis, was redder than usual, and that the lumen were frequently filled with pus. Morgagni is said to have remarked the same fact. (De Sedibus et Causis Morborum. Epit. 44. &c.)

As an attempt has been made by a late writer, Dr. Svediaur, to transfer the honour of the discovery from the Hunter to Morgagni, we deem it our duty to observe, that we cannot discover any accuracy, or justice, in the doctor's statement, since Morgagni's work was not published till 1761.

Although there can now remain no doubt, that in gonorrhoea there are no ulcers essentially, or commonly present in the urethra, to furnish the matter which is discharged, yet Mr. Hunter himself has explained, that a fore, occasioned by the bursting of an abscess in one of the glands of this passage, is sometimes produced. This kind of ulceration, however, never takes place till long after the commencement of the running; and it is quite of a different nature from such fores as were fancied to be the cause of gonorrhoea.

We shall now consider the identity of the gonorrhoea and venereal poisons. It has been represented by some surgical authors, that the essential difference between gonorrhoea and the venereal disease depends upon the circumstance of the first complaint being an affection of a secreting surface. Many other writers, and we may add, the generaliism enlightened practitioners in this country, contend, that the two diseases originate from different poisons, a sentiment which is supported by the striking dissimilarity of the two affections, and the wide difference of their modes of cure.

Such authors, as maintain the doctrine of the two complaints being the consequence of different distinct poisons, found their arguments upon various circumstances. First, the history of these diseases, and of their progress in different countries. Secondly, the phenomena peculiar to each disorder. Thirdly, the remedies necessary for the cure.

It is asserted, that the venereal disease and gonorrhoea did not make their appearance in Europe at the same period; but that the former was many years antecedent to the latter. The same thing is stated to have happened in other parts of the world, whether Europeans have conveyed the venereal virus. For instance, the venereal disease was known in China almost immediately after it had made its appearance in Europe; yet it is remarked by Alfrue, that at the time when he wrote, gonorrhoea was a malady which had only been very recently observed among the Chinese. Also, in the South-sea islands, discovered in modern times, where both the venereal disease and gonorrhoea were unknown before the landing of European navigators, but where these maladies were afterwards difubstanced, gonorrhoea was not noticed till several years after syphilitic disorders had begun to flow themselves. Claps are said to be have been yet unknown to the natives of the South-sea islands, at the period when captain Cook was performing his second voyage. (Duncan's Medical Cases and Observations.) All these circumstances have been adduced to prove the difference between that virus which gives rise to the venereal diseases, and that from which gonorrhoea has its origin.

On the other hand, the circumstances attending the commencement of the venereal disease in these remote countries, led Mr. Hunter to draw a conclusion diametrically opposite to the one deduced by the foregoing class of reasoners; for, he observes, that it is almost impossible for a man to have a chance during a voyage of several months, without the whole of the penis being destroyed, while it is well known, that a gonorrhoea may last an immense time, without losing the character of being virulent. It is related in the account of captain Cook's voyage, that the inhabitants of Otaheite, who were infected with the gonorrhoea, went up the country and got well; but that when the consequences of the malady was the venereal disease, the latter was incurable. Hence it is inferred, that the complaint which the Otaheites contracted was the gonorrhoea, since chancres and venereal affections would never have yielded to the simple means which were adopted. Besides, if the disorder had consisted of chancres, and the natives of Otaheite had been acquainted with the mode of curing such fores, it is contended, that they would likewise have understood how to cure other venereal symptoms. We find, also, from the perusal of captain Cook's third voyage, that the venereal disease afterwards raging in all its forms in the island of Otaheite. Now, since there is no document to show, that the gonorrhoea was again introduced into that country, subsequently to Cook's second visit, it is concluded, that every form of the venereal disease which has been observed there has been derived from one source, which, in all probability, was a gonorrhoea.

Mr. Hunter mentions a gentleman who had a gonorrhoea thrice, of which he was cured without mercury. About two months after each infection, he had symptoms of lues venereal. The slight were ulcers in the throat; the second, were blemishes on the face; both which forms of the disease yielded to mercury. Thirdly, two punctures were made on the penis, with a lancet dipped in the matter of a gonorrhoea. One of these produced, on the part of the prepuse where it was made, a red, thickened speck, which increased and discharged some matter. This suppurated chancres healed on having its surface repeatedly destroyed by caustic. The other puncture was made on the glans, where it was followed by...
GONORRHEA.

by a pimple, full of yellowish matter. This pimple was touched with cautery, and healed in the same way as the fore
on the prepuce. Four months afterwards the chancre on the
prepuce broke out again; then it healed, and returned. This it did several times; but always healed without any
application to it. While the fores remained on the prepuce and
clitoris, a bubo formed in the groin. A sufficient quan-
tity of mercury was given to cure the gland locally, but not
to prevent the constitution from being affected. Two months
after the cure of the bubo, a venereal ulcer, according to
Mr. Hunter, formed on one of the tonsils. This was cured
by mercury; but the medicine was purposely left off so soon
as the fore was trimmed over, in order to see what parts
would next be affected.

About three months afterwards, copper-coloured blotsches
made their appearance in the arm, and the ulcer on the
tonsil recurred. This disease was again only palliated by
mercury; but the complaints returned in the same situation
as before; and were ultimately cured by a proper quantity
of mercury.

On the other hand, doubts must exist, concerning this ac-
count of the matter of gonorrhoea, when the following cir-
cumstances are taken into consideration:

II. It is impossible to say what time may elapse between
the application of venereal poison to the penis, and the com-
menecement of ulceration. Therefore, Bougainville’s sailors,
alluded to by Mr. Hunter, might have contracted the infec-
tion at Rio de la Plata; but actual ulcers on the penis
might not have formed till about five months afterwards,
when the ship arrived at Otaheite. 2dly. The second argu-
ment adduced by Mr. Hunter is certainly inconclusive.
Every ulcer in the throat is not regularly venereal. A
common ulcer may heal while the patient is using mercury.
Hence the cure, apparently accomplished by this medicine,
is no proof that the complaint was syphilitic. 3dly. The
last fact of inoculation is undoubtedly very strong. But,
though the infection of gonorrhoeal matter, or any other
moral or matter, beneath the euticle, will undoubtedly pro-
duce troublesome local complaints, may we not doubt that
the fores, in the above case, were actually venereal ones?
Can we not equally depend on the continence of the subject
of the above remarkable experiments, during the long space
of four months, between the healing of the fore on the prepuce,
and its recurrence? If we cannot, the inference, in regard
to the power of gonorrhoeal matter to communicate the venereal
disease remains unsatisfied. How much more conclusive
in this respect, the experiments would have been, had the
inoculation been practised on any other part but the penis.
If the matter of gonorrhoea be capable of communicating
the venereal disease, why does not the discharge commonly
produce chancres on the glands and prepuce, with which
parts it must lie in contact a very considerable time in every
case? Why also does not the presence of a chancre fre-
quently cause a gonorrhoea? If the infection of gonorrhoea,
and the venereal disease, be really of the same identical
nature, certainly, it seems very extraordinary, that the
former complaint should receive no benefit from mercury,
and the latter disease invariably require this specific re-
medy.

With respect to the venereal disease and gonorrhoea having
arisen in Europe and elsewhere at different periods, it has
been observed by such writers, as incline to the belief in
the identity of the virus of the two affections, that every kind
of contagious disease appears with greater violence in new-
infected countries, than in other situations where it has been
a considerable time establish. In this manner, an endeavour,
which, in our opinion, is quite unsuccessful, is made to ex-
plain the cause why the gonorrhoea generally did not make
its appearance till a long while after the venereal disease had
flown itself in much worse shapes. The same class of
reasoners also affect, that, notwithstanding the diligent en-
quiries of many able men, there is still a degree of doubt
concerning the exact time when these diseases originated,
and, of course, regarding the point, whether one of them
actually existed a long while before the other. As we shall
have occasion to treat of the origin of the venereal disease
henceforward (see Louis Venereus), we shall not enter into
this disquisition in the present article. We may, however,
express our opinion, that discharges from the urethra must have been occasioned from time immemorial. Whether there be a species of gonorrhoea
truly venereal, that is to say, one which depends upon the
same virus, as syphilis, there may for certain remain doubts;
but, that there are ulcers or discharges which arise from
no poisonous or infectious matter whatsoever, but altogether
from mere irritation in the urethra, as, in certain cases of
strictures, is certain and undisputed. These gonorrhoeas
must have prevailed as long as that could have been liable to
various kinds of irritation.

One argument adduced against the identity of the virus,
is derived from the striking difference observable in the
progress and symptoms of the two diseases. When the
venereal disease is neglected, it always grows worse and
worse, and sooner or later brings on the patient’s dissolution.
On the contrary, a gonorrhoea tends to a natural cure, and,
though left to itself, commonly ends in a favourable way.

The advocates for the identity of the poison, however,
contend, that, in order to account for this last fact (which
they state is not without exceptions), it is by no means
necessary to suppose a different virus. They bring into
consideration the circumstance of gonorrhoea depending upon
an inflammation of the surface of the urethra, and not ulcer-
ation; and they maintain, that the abscess of the
venereal poison generally happens much more easily from
ulcerated surfaces, than from such as are simply inflamed.
This mode of reasoning is brought forward as explanatory
of the cause why, in the majority of cases, a gonorrhoea
remains entirely a local complaint, and admits of a spontaneous
cure, while the venereal disease is always prone to extend
itself, and spread from one part of the body to another.

An argument against the identity of the virus is also
founded on the reflection, that the venereal disease is only
capable of communicating the venereal disease, and genera-
ing impurity in gonorrhoea. The partizans of the decti-
time which imputes this latter infection to the venereal
virus, acknowledge, that things do usually correspond with
the statement just now given: but they affirm that the
contrary case is also frequently observed. They remark,
that we may easily convince ourselves of this circumstance,
by a fact which is well known to practitioners, namely,
that when persons, who have a gonorrhoea, are not particu-
larly careful to keep the glans and prepuce clean, chan-
cres are very apt to form upon these parts, and by one chan-
cre the whole system may become infected. It is also
asserted, that, independently of the formation of any chan-
cres, there are cases proving, that the venereal disease may be
the consequence of a gonorrhoea, and that every inci-
dent practice must meet with influence of this kind. Ob-
tensive practice must meet with influence of this kind. Ob-
tensive practice must meet with influence of this kind. Ob-
tensive practice must meet with influence of this kind. Ob-
tensive practice must meet with influence of this kind.

With respect to chancres arising from the matter of
gonorrhoea being in contact with the glans and prepuce,
we do, undoubtedly, for men and women who have
claps and chancres together; but, in our opinion, it is more rational to impute the fore to the application of venereal pus from chancres, together with the gonorrhœal matter, at the time of coition. We have no doubt that this act is often performed, when, between the two parties, both kinds of infection are present.

Certainly it seems extraordinary, that if the virus be of the same nature in both cases, the two effects should not always occur in the same patient. We ought naturally to expect, that when a gonorrhœa makes its appearance first, it would always be the cause of a chancre; and that when a chancre is the first symptom, it would invariably be the occasion of gonorrhœa. We diffimit from present consideration the affection of such writers as defend the identity of the virus, that, in some few instances, one malady does become the cause of the other. Mr. Hunter suspected, that the irritation of one of the parts, forming the seats of the two diseases, became the precursor of the other. He thought, that when the urethra inflames and discharges matter, the adjacent external parts might, on that account, be exempt from a disease which they would otherwise necessarily contract, by reason of the effect of the virus which gave rise to the gonorrhœa. The same celebrated writer also entertained a suspicion, that when a chancre attacks the glans, or prepuce, the urethra might become incapable of the irritation, which, without the external disease, would certainly lead to a discharge from that canal. This mode of explanation appears to us somewhat theoretical. We are of opinion, also, that in arguing in this way, the advocates for the identity of the virus only bring forward the shadow, instead of the substance of reason. In fact, they lay nothing more than that supposed venereal matter cannot make the external parts of the penis ulcerate, because there is an irritation in the urethra; and that the urethra cannot be affected with gonorrhœa, because a chancre already occupies the external parts. If this reasoning be not hypothetical and fanciful, we cannot conceive what arguments can ever be confidered so. They who talk in this manner, inadvertently fall into difficulties, and make one opinion inconsistent with another. Thus, they have already told us, that, occasionally, a chancre is apt to occur, when patients with gonorrhœa neglect to keep the glans and prepuce clean; yet, according to their principles, a clad renders the external parts incapable of infection, and, of course, there would be no need of cleanliness as a preventative. We think that the weakness of the argument must be obvious to the youngest reader, who, on his entrance into any venereal ward of an hospital, is almost sure of immediately finding a patient who has at the same time both chancres and gonorrhœa.

The different treatment required by gonorrhœa and the venereal disease, is another argument against the identity of the virus, mercury being unnecessary in claps, and the pole specific in the other complaint. The partisans of the opposite opinion endeavour to diminish the force of this fact, by advertizing to the different ways in which the two diseases affect the parts which are attacked, and by maintaining that no just inference can be drawn from the difference of treatment, while the particular action of mercury, on various parts affected with the venereal poison, is not understood. They also contend that, though mercury may have no effect in gonorrhœa, when used in the same way as for other venereal affections, yet, when applied to the female sex, serves to moderate the symptoms, and accelerate the cure.

Having seen the calomel injection employed in some hundreds of cases, with less benefit than the common viridical one, we cannot assert to the last observation. The other remarks, being bare opinions, may be received or not, as the judgment of the reader may incline him; but, for our own part, we have no hesitation in refusing them a place among such information as is founded on rational evidence. We shall now say a few words, respecting the time, between the application of the infection and the beginning of its effects.

In the greater number of diseases, a certain space of time always elapses between the application of the cause and the first appearance of the effect. The time when a gonorrhœa begins, after contamination, varies considerably in different cases. In some examples, the poison takes effect in a few hours, as Mr. Hunter has seen two or three times; while, in other instances, the complaint does not shew itself till the end of five or six weeks. There are also cafes to be met with, in which the disordor begins at all the intermediate periods. It is calculated, that the most common time of its origin is in the space between the sixtieth and twelfth day. In one instance, in which the malady did not commence till the end of six weeks, it was noticed by Mr. Hunter, that the affection was preceded by various symptoms of irritation, and uncommon sensation, in the parts. Hence, this celebrated author concluded, that the virus feldom, or never, remains so long inactive; but that the inflammatory state may exist a good while before suppuration takes place. The delay in the commencement of the discharge, however, may be owing to causes which are not understood, and this is very likely to be true, if we consider that some cases of gonorrhœa do not begin for five or six weeks after infection, and yet are not preceded by any remarkable symptom whatever.

The observations already made in a preceding part of this article, must have apprized the reader, that discharges from the urethra may originate from more causes than one, and from more irritations than that which is produced by one particular kind of virus. There are sometimes spontaneous discharges from this passage, while no immediate cause whatever is assignable. Such infames as occur independently of a specific gonorrhœal, or, according to the Hunterian doctrine, the venereal virus, have been termed simple or benign. Some affect, that these cases may be known by their coming on immediately after coition, and it is violent from the very beginning; while the virulent gonorrhœa does not commence till after some days, and grows gradually worse. However, this criterion is insufficient: simple gonorrhœas are not always owing to coition, nor are they always sudden in their appearance.

Mr. Hunter has seen the urethra sympathize with the gums in dentition, and all the symptoms of gonorrhœa affect the same infant several times. The author of the article Gonorrhœa, in the Encyclopédie Methodique, also mentions his having seen two female children, who were affected during dentition with a discharge from the pudenda, attended by a certain degree of inflammation, and pain in making water.

We shall now introduce a few remarks on the effect of the discharge on the parts producing it.

It was formerly not an uncommon opinion, that the discharge was a means employed by nature for carrying off the virus occasioning the complaint, and thus bringing about a cure. However, it is impossible for this to be true, with respect to inflammations, which arise from a specific virus; for to make the suppuration could wash away all the poison, causing the original irritation, yet, as all the matter afterwards secreted is equally virulent, no good would be done; the irritation, according to the preceding idea, would be perpetuated, and, of course, the discharge. This
GONORRHEA.

The foregoing opinions do not rest altogether upon theory; they are also founded on experience and observation. Men, who have just had a gonorrhoea, have frequently been known to expose themselves to be infected again without any recurrence of the complaint taking place, while other healthy persons, who had connection with the same woman, have immediately caught the malady. Perhaps, it is on the same principle, that the first gonorrhoea is generally the most violent, and that such persons as are often affected with claps have them more and more mildly, particularly when the intervals are short.

In corrobororation of these sentiments, Mr. Hunter relates several cases, among which is the following: a married man, who, for several years, had had no connection with any woman except his own wife, happened to meet with an old acquaintance, who gave him a severe gonorrhoea, though he declared her belief that she was quite well. Both adopted some means of cure; but continued to cohabit together during the treatment. The man got well, and it was presumed that the woman was also cured. They continued to live together several months, without the former experiencing any inconvenience, or having any reason to suppose that there was still any thing the matter with the latter. At length they parted, and the woman formed a new attachment. She had no sooner made this last connection, than she gave the new lover a gonorrhoea. She again consulted Mr. Hunter, whom she assured, that she had never cohabited with any others, except the preceding; and consequently, if this be true, the infection of her last lover must have arisen from the very same gonorrhoea, of which she supposed that she had been formerly cured. However, she now used no remedies, and the man, after he was well, continued to cohabit with her for several months without receiving any new infection. But her old lover now returning, after a year's absence, and thinking that, as she was living regularly with the second, there could be no danger, ventured to have connection with her; the consequence was, that he caught another gonorrhoea.

Before describing the treatment, it is proper to say a few words of the disease in women.

The gonorrhoea in females is not so complicated as in men, the parts affected being more simple and fewer in number. In women the disease is not so easy to be afforded, because they are also liable to a complaint, called the flor albus, which has some resemblance. A mere running from the parts is not so much a proof of the existence of an infectious gonorrhoea in a woman, as a discharge without pain in a man; and in the former the disease will often exist, while there is no increase whatever in the natural secretion from the parts. Nor can any criterion be deduced from the kind of matter, since the discharge of the flor albus frequently puts on all the appearances of gonorrhoeal matter. Neither is pain, nor any peculiarity in the sensations of the parts, necessarily attendant upon the complaint in women. Mr. Hunter also remarks, that the appearance of the parts often gives us but little information; for he frequently examined them in patients, who complained of all the usual symptoms, such as an increased discharge, pain in making water, foemen, &c. and yet he could perceive no difference in the look of the parts and of such as are quite healthy. When the patient was not conscious of any particular symptoms, or was disposed to conceal her knowledge of them, Mr. Hunter thought that some judgment might be formed from her having had connection with men supposed to be unfaithful, and from her power of communicating the disease to others. However, it is acknowledged,
GONORRHŒA.

Acknowledged, that as this last circumstance is derived from the testimony of another person, there are obvious reasons why it should not always be trusted.

When a woman contracts a gonorrhœa, the vagina must be first attacked, a part which is not endowed with considerable sensibility. Frequently, however, the complaint extends much further, producing disagreeable sensations and forms of the inside of the labia, nympha, clitoris, carunculae myrtiformes, and meatus urinaris. The parts are sometimes so sore that the patient cannot bear them to be touched; she can hardly walk; and a great deal of pain is experienced when the urine comes into contact with the fore surfaces, as it must unavoidably do as often as the bladder is emptied.

When the disease extends to parts which are more sensible than the vagina, and more susceptible of inflammation, women have nearly the same symptoms as men; a fulness about the parts, a discharge from the urethra, violent pain in making water, and great uneasiness from the pressure on the parts in sitting. Sometimes the bladder is also affected.

The inflammation frequently extends to some depth, running along the ducts of the glands, and affecting the glands themselves, so as to occasion hard swellings under the surface of the inside of the labia. These tumours often suppurate, and burst near the orifice of the vagina. They resemble the abscesses in the glands of the urethra in men.

The time in which a gonorrhœa may be cured is exceedingly variable, some cases terminating in a week, while others continue for months under the same treatment.

According to Mr. Hunter, the object in the cure is to destroy the disposition and specific mode of action in the fluids of the parts, and, as soon as that change is accomplished, the poisonous quality of the matter produced will also be destroyed. Thus the disease may be cured though not always in its consequences.

A gonorrhœa is not capable of being continued beyond a certain time in any constitution, and when the complaint is violent and lasts a long while, it is owing to the parts being very susceptible of such irritation, and readily retaining it.

Since there is no specific medicine for the gonorrhœa, it is very fortunate, as Mr. Hunter observes, that time alone will effect a cure. This celebrated surgeon was inclined to think, that, in cases of gonorrhœa, medicines were seldom of service, perhaps not more frequently than once in ten instances. With the idea, that every gonorrhœa cures itself, he gave certain patients pills of bread, which were taken with great regularity. These persons all got well; but Mr. Hunter thought that some of them were not cured quite so soon as they would have been, had artificial means been employed.

The surgical methods of cure consist of internal remedies and local applications; but in putting any plan of treatment in execution, more attention should always be paid to the nature of the constitution, or to any attending disease in the parts themselves, or parts connected with them, than to the running itself.

The nature of the constitution is principally to be judged of from the local effects of the disease. These are so different in different people as to require a great variety of treatment, a circumstance, says Mr. Hunter, which has been too little attended to, every one endeavouring to attack the immediate symptoms, as if he had a specific for a gonorrhœa.

We are first to consider, whether the inflammation is violent or mild, common or irritable. When the symptoms are violent, but of the common inflammatory kind, which is to be judged of from the attending circumstances, and particularly from the extent of the inflammation not exceeding the specific distance, the local applications may be either of the irritating or soothing kind. In this example, irritating applications may be less dangerous, than when the inflammation is of the irritable sort, and may have the effect of altering the specific action, the parts afterwards recovering of themselves, as from any other common inflammation. Mr. Hunter, however, expresses his belief, that the soothing plan is the best at the beginning.

When the inflammation is great, and of the irritable kind, no violence is to be used in the treatment, as the symptoms would thus only be increased. Mr. Hunter thought, indeed, that there were some cases, which are exceptions to the latter remark, the great degree of inflammation arising entirely from a susceptibility of this irritation, and not from any general irritability in the constitution. He confesses, however, that such examples can seldom be discriminated.

When the symptoms run very high, nothing should be done to stop the discharge, as, were it to be checked, the inflammation would still continue, and no good be effected.

Mr. Hunter recommends us to alter the constitution, if possible, by remedies adapted to each disposition, with a view to alter the actions of the parts arising from such dispositions, and reduce the disease to its simple form. If the constitution cannot be altered, we can only allow the action to wear itself out.

When the inflammation has considerably abated, and the disease only remains in a mild form, its cure may be attempted either by internal remedies, or local applications. If local means are used, violence is still to be avoided, because it may bring back the irritation. At this period (continues Mr. Hunter), gentle astringents may be applied with a prospect of success; or, if the disease has begun mildly, and there are no signs of an inflammatory disposition, either of the common, or irritable kind, an irritating injection may be used, in order to get rid of the specific mode of action quickly. Such application will therefore the symptoms for a time; but, when it is left off, they will frequently abate, or wholly disappear. In such a state of parts, astringents may be used; for the only thing to be done, is to procure a cessation of the discharge, which is now the principal symptom.

When the itching, pain, &c., are felt for some time before the discharge appears, Mr. Hunter rather prefers the soothing to the irritating plan of treatment. He suspected, that thus the coming out of the discharge would be promoted, which occurrence he conceived was the first step towards a resolution of the irritation. He believed that, at all events, in this case, the employment of astringents would be bad practice, as, by preventing the discharge from taking place, they might prolong the inflammation, and protract the cure. Also, in cases of fœtures, and of discharged fetidness, he is adverse to the use of astringents; for, says he, while the discharge lasts, both the other complaints are relieved.

The internal remedies commonly recommended in a gonorrhœa, may be divided into evacuants and astringents. The evacuants (says Mr. Hunter), are principally of the purgative, or diuretic kind, and these are not confined to any particular medicines, every practitioner supposing that he is in possession of the bell. Some use mercurial evacuants; whilst others carefully avoid mercury in every form. The neutral
neural falls have been given from the idea of their being cooling. Some of the profession have chiefly kept to diuretics, perhaps with two views; first, as evacuants acting mechanically upon the urinary passages, so as to wash away the matter; secondly, as specifics. For this purpose, nitre has been given, a medicine which has always been thought to have great effect in lefTing inflammation, though Mr. Hunter had doubts concerning the truth of the opinion. Under every mode of treatment the patients always get well, and the cures are ascribed by each practitioner to his own favourite method.

Mr. Hunter remarks, that "to keep the body open in most cases, even when the patient is in other respects in health, must, no doubt, be proper; but what idea can we form of an irritation, produced all along the intestinal canal, curing a specific inflammation in the urethra? Yet there are cures where a brisk purgation has been of service, and even in some has performed a cure. But I suspect, that, in such cases, the disease had been continued by habit only, and that this practice would not have succeeded in the beginning. A gentleman had a gonorrhœa, all the symptoms of which continued for two months, and by taking at once ten grains of calomel, which purged him most violently, he was almost immediately cured. The calomel could not have acted specifically, but by a kind of derivation, that is, an irritation produced in one part, cured one that subsisted in another; but even if it should be granted, that in some circumstances purges have the power of making the solids less susceptible of this irritation, it cannot be supposed they will have this effect in every case; in some constitutions, they might debilitate, increase irritability, and of course increase the symptoms. The contrary effects must take place in different constitutions, in which a medicine has no specific action. On the supposition of the cure being promoted by an evacuation from the blood, what service can purging out some of the blood, in form of a secretion from one part, do to an inflammation of another part? On such a supposition would not a sweat, or an increase of saliva, by chewing tobacco, or stimulating the nose by snuff, all tend equally to cure a gonorrhœa? But humours having been considered as the universal cause of every disease, especially those in which pus is formed, or a discharge produced, and purging having been supposed to be the cure for humours, purgatives were of course made use of in this disease; and as the patients have always been cured, the practice became generally established.

"Those who recommended mercury in this form of the disease, did it most probably from the opinion, that this medicine was a specific for the venereal disease in all its forms. On this supposition, we can see some reason for their practice, as it would be absorbed from the intestines, circulate through the inflamed vessels of the urethra, and thereby destroy the venereal irritation. Here we can only suppose it to act by its specific virtue; but I doubt very much of mercury having any specific virtue in this species of disease; for I find, that it is as soon cured without mercury as with it; and where this medicine is only used as a purge, or purged off the next day, and therefore allowed to act merely upon the bowels, I cannot conceive that it could have any more effect upon the venereal inflammation in the urethra, than an irritation in the bowels arising from any other purgative. So little effect, indeed, has this medicine upon a gonorrhœa, that I have knew a gonorrhœa take place while under a course of mercury insufficient for the cure of a chancre. Whether the gonorrhœa arose from the same infection that produced the chancre, I cannot say; nor can it be easily determined in such cases. Men have also been known to contract a go-

GONORRHŒA.

norrhœa when loaded with mercury for the cure of a lues venerea; the gonorrhœa, nevertheless, has been as difficult of cure as in ordinary cases," P. 72, &c.

With respect to diuretics, considered as evacuants, Mr. Hunter observes, that they may have the same general remarks made on them as have been offered in regard to purgatives. It is possible, says he, that specific medicines, taken into the composition (if we had such), and passing off by the urine, might act upon the urethra in their passage through it. The ballasts and turpentine past off in this way, and become specifics for many irritations in the urinary passages; but how far medicines which have the power of affecting particular parts when found, or when under diseases peculiar to those parts, have also the powers of affecting a specific irritation in them, Mr. Hunter was uncertain. He conceived, however, that they might be capable of removing any attendant irritation, though not the specific one. He thought, that diuretics did good inasmuch as they increased the quantity of urine; but he believed simple water would for this purpose, or water joined with such things as encourage the patient to drink a good deal, as with tea, capillaries, or gripes, &c.

Allringuts have frequently been prescribed, though without the approbation of the generality of regular practitioners. It was Mr. Hunter's opinion, that such medicines did not lessen the inflammation, but that they often lessened the discharge.

With regard to local applications, they may be either internal to the urethra, or external to the penis. In many cases both kinds are proper. One would suppose, that what is applied to the urethra, must be the most likely to effect a cure, by coming immediately into contact with the diseased parts.

Local applications to the urethra may be either in a solid or fluid form, each of which has its advantages and disadvantages. A fluid, (says Mr. Hunter) is only a temporary application, and that of very short duration.

The solid applications may remain a long time, and, in this respect, would seem to be better than liquid ones; but in general they create irritation. They must be used in the form of a bougie, which Mr. Hunter imagined was commonly injurious, when the parts were in an inflamed state, though he confesses, that he never saw any harm from it in any case, when employed with caution.

Fluid applications to the inside of the urethra are usually called injections, and, like the internal remedies, are without number. However, as the inflammation is frequently removed under the use of injections of various kinds, have we not, (as Mr. Hunter notices) a strong corroborative circumstance in favour of an opinion, that every such complaint will in time cure itself? This eminent surgeon thought, however, that practice evinced, that an injection often has almost an immediate effect upon the symptoms, and, therefore, that it must have some powers, though the injection, which would have the greatest specific effect, he believed, was not yet known. If an injection has no specific powers, it must be very uncertain in its effects, and can only be of service as far as it may be adapted to a peculiarity of constitution, or parts. As injections are only temporary applications, it becomes necessary to use them often, especially in cases where they are found to be of service. They should therefore be applied as often as convenient, perhaps every hour, or even oftener; but Mr. Hunter adds, that this must be regulated in some measure by the kind of injection; for, if it be irritating, it will not be proper to use it too often, as it may be productive of bad consequences.

The same author observes, that many injections remove the
the symptoms immediately, or soon after the application, and prevent the formation of matter, which has given rise to the notion of their shutting up the diæse and driving it into the constitution; but this supposition cannot be true, since the matter is the only subsistance in which the poison is contained, and the formation of the poison is inseparable from the formation of matter. Therefore, if we can prevent the one, the other cannot take place, and, of course, there can be no room for aborption; so that there can neither be any power of infecting the constitution in the same person, nor of communicating the infection to others.

Mr. Hunter divided injections into four kinds, namely, the irritating, sedative, emollient, and astringent. He believed that we are not acquainted with any specific one, although a mercurial injection, of some fort or another, is frequently fancied to have such a quality.

All irritating injections act upon the principle of producing an irritation of another kind, which ought to be greater than that of the gonorrhœa, by which means the halt is destroyed and the diæse cured, although the pain and discharge may still be kept up by the application. These symptoms will soon go off, as soon as the injection is laid aside, because they only arise from its irritating qualities. In this way bougies, as well as many injections, may be supposed to perform a cure; and although they increase the symptoms for a time, they never can increase the diæse itself, any more (says Mr. Hunter) than the same injection, which would produce the same symptoms, if applied to the urethra of a found man, can communicate the diæse. Most of the irritating injections have an astringent effect, and, when mild, prove simply astringents; their irritating quality depending chiefly upon their strength.

Mr. Hunter was not able to determine absolutely the kind of cases in which irritating injections might be used with advantage. He thought, however, that such applications should never be used when there is already much inflammation, especially in constitutions which cannot bear a great deal of irritation, as a previous knowledge of the diæse in the same person sometime teaches us. Neither should these injections be used when the irritation has spread beyond the specific distance; when the tefficles are tender, or when they have become more upon a sudden diminution of the discharge; when the perineum is very injuriable of inflammation, and particularly if it should have formerly suppurred. Irritating injections also ought not to be employed when there is a tendency in the bladder to irritation, which is known from the patient having had, for some time, a frequency in making water. In all the preceding cases they do no good, and often do mischief: Mr. Hunter thought he had seen abces in the perineum brought on by their employment.

In mild cases, and in constitutions which are not irritable, such injections often succeed, and remove the diæse almost immediately. The practice, however, as the foregoing writer remarks, ought to be attempted with caution, and not, perhaps, till milder methods have failed. Two grains of corrosive sublimate (hydrargyrum muriatus), dissolved in eight ounces of distilled water, are an eligible injection of this kind; but an injection of only half this strength may be used, when it is not the design to attempt a very sudden cure. If, however, the injection thus weakened should give considerable pain, or occasion a great increase of foremen in making water, it must be still more diluted.

Sedative injections, according to Mr. Hunter, will always be of service in cases where the inflammation is considerable, not by lessening the diæse itself, but by lessening the diæse action, which always allows the natural actions of the part more readily to take place. They are likewise very useful in relieving the painful feelings of the patient. Perhaps, says this celebrated surgeon, the best sedative which we have is opium, as when given by the mouth or anus, as when applied to the part affected in the form of an injection. But even opium will not agree, nor act as a sedative in all constitutions or parts. On the contrary, it has often opposite effects, producing great irritability. Lead may be reckoned a sedative, so far as it abates inflammation, while, at the same time, it may act as a gentle astringent. Fourteen grains of faccharum saturni (acetate of lead), dissolved in eight ounces of distilled water, make a good sedative astringent injection.

Mr. Hunter next remarks, that the drinking freely of diluting liquors may, perhaps, be considered as having a sedative effect, as it in part removes some of the causes of irritation, rendering the urine less stimulating, either to the bladder, when the irritation is there, or to the urethra in its passage through it; and the plan may possibly lessen the susceptibility of irritation. The vegetable mucilages of certain seeds and plants, and the emollient genus, are recommended for impregnating the patient's drink. Such infusions pass off with the urine, and render the evacuation of that fluid less painful. It is proper to notice, however, that Mr. Hunter does not appear to have a high opinion of the utility of this practice.

When the inflammation is very great, Mr. Hunter believed, that emollient injections are the most proper applications. It seems probable, that they act first by simply washing away the matter, and then leaving a soft application to the part, in which way, says this eminent writer, they can be of singular service by lessening the irritating effects of the urine. A solution of gum arabic, milk and water, or sweet oil, will frequently lessen the pain and other symptoms, when the more active injections have done nothing, or seemed to do harm.

When great irritation and foremen prevail at the mouth of the urethra, the point of the syringe cannot be introduced, and no attempt to use an injection ought to be made before the inflammation abates. Emollients may be used externally in the form of fomentation.

The astringent injections, observs Mr. Hunter, can only act by lessening the discharge. They can have no specific effect upon the inflammation. They should only be used towards the latter end of the diæse, when it has become mild and the parts begin to itch. However, if the diæse should begin mildly, they may be used at the very beginning; for, by gradually lessening the discharge, without increasing the inflammation, we complete the cure, and prevent a continuation of the discharge called gleet. If the astringent injections be strong, they will be irritating, and frequently increase the discharge, instead of diminishing it. When weaker, they often stop the running, without lessening, however, the cure in all cases; for the inflammation may still continue even longer than it would have done, had the tendency to secretion not been removed. But sometimes an astringent injection will cure a slight irritation in a very few days. Mr. Hunter never found one astringent more efficacious than another. The astringent genus, as dragon's blood, the balsams, and the turpentine, dissolved in water; the juices of many vegetables, as oak bark, Peruwyn bark, tormentil root, and, perhaps, all the metallic salts, as green, blue, and white vitriols; the salts of mercury, and also alum; probably all act much in the same way. Mr. Hunter, however, owns that they do not act equally well in every gonorrhœa.
GONORRHEA.

Gonorrhea, and that changing the injection will often succeed, when a long perseverance in a previous one would not.

We have to observe, that the astringent injection, which is most generally approved of by practitioners, is that containing white vitriol (zincum vitriolatum), about half a scruple of which, dissolved in eight ounces of water, is a very good application to begin with. The strength may be increased or diminished, however, as the patient's feelings may require.

Poultices and fomentations have been used as external applications in cases of gonorrhea; but, says Mr. Hunter, they can be of little service, except when the prepuce, glans, and orifice of the urethra are inflamed. It is now more common, in the inflammatory stage of the complaint, to surround the penis with linen kept continually wet with the turpentine lotion.

When any of the glands of the urethra remain in an indurated state, after the subsidence of the inflammation, the hardness may be removed by frictions with camphorated mercurial ointment.

It is remarked by Mr. Hunter, that in women, the mode of curing the gonorrhea is nearly the same as in men; but the disease itself is milder, and the secondary symptoms less numerous in females. Hence the cure is more simple.

When the disease is confined to the vagina, it may be easily cured by means of injections, taking care also to wash the external parts with the application. The patient cannot, however, apply an injection to the meatus urinarius, when that passage is affected.

The same kinds of injections are proper for women as are prescribed for men; but they may be made doubly strong, as the parts in women are not nearly so irritable as the common feat of this disease in the other sex.

When the inflammation runs along the ducts of the glands, either of the mouth of the vagina, or of the urethra, or where it affects the glands themselves, the caufe claims the same treatment as in men. The mercurial ointment should be freely applied to the indurated parts. When the ducts and glands suppurate and form abscesses, these should be opened and dried like a sore. The ulcer, however, is not regarded as venerial. Though Mr. Hunter entertained such a sentiment, and directed a corresponding treatment.

In pellitory constitutions, the symptoms are frequently violent, attended with a strong propensity to the inflammatory fever. The inflammation, however, does not extend beyond the specific distance. Many medicines, which might be of service in another constitution, here do harm, and increase the symptoms which they were intended to relieve. Mr. Hunter has seen opaque gyotiers, after a short doing good, bring on fever and an exacerbation of all the symptoms. He has seen the balsam capivi render the inflammation worse. The treatment of such a constitution, when affected with this disease, should chiefly consist in bleeding and gentle purging. It is proper also for the patient to live sparingly, and use little exercise.

In the weak and irritable constitution, as Mr. Hunter observes, the symptoms are frequently very violent, and often extend beyond the specific distance, the inflammation running along the urethra, and even affecting the bladder. In this instance the foregoing author was of opinion, that a strengthening plan should be adopted.

Sometimes a gonorrhea is so capricious in its cure, that the accesion of an accidental fever stops the discharge, removes the pain in making water, and the disorder is permanently cured. Sometimes the symptoms cease on the commencement of the fever, and return when the latter complaint is well. In other examples a gonorrhea may begin mildly; but a severe fever coming on and continuing for several days, the symptoms of the first disorder are rendered much worse, and, on the fever going off, the gonorrhea likewise disappears. Mr. Hunter remarks, that although a fever does not always cure a gonorrhea, yet, as it possibly may, nothing should be done while the fever lasts; and if the local complaint should continue after the fever is gone, it is then to be treated according to the symptoms.

The same writer represents, that, unfortunately, there are cases in which no known method lessens the symptoms; evacuations, a strengthening plan, sedatives and emollients, all prove ineffectual, and time alone seems to bring about the cure. In these instances, Mr. Hunter thought the soothing plan of treatment the most advisable, and was against the employment of astringents. Neither had he much opinion of the capivi and Canada balsams, nor of turpentine in general, though they might diminish the discharge.

A gonorrhea is also considerably affected by the patient's way of life, during the inflammatory state. Most things which hurry or increase the circulation, aggravate the symptoms, such as violent exercise, drinking strong liquors, eating strong indigestible food, taking peppers, pipes, spirits, &c.

When the complaint begins mildly, or after the violent symptoms have subsided, we may prescribe medicines which will afflict the above local remedies, in checking the discharge. Mr. Hunter thought the turpentine the most efficacious. Cantharides, cuprum vitriolatum, acetic acid, and galum, have also been recommended.

The reader is already aware, that Mr. Hunter regarded gonorrhea as a disease arising from the venereal poison, and believed that the matter from the urethra, if introduced into the circulation, would occasion a flux venerea. In order to guard against the effects of absorption, he was an advocate for exhibiting small doses of mercury at an early period of the malady, and for continuing them even for some time after the formation of matter is at an end. He advised a grain of the hydrargyrum caelestum to be taken every night, or every evening and morning; but frictions, with the mercurial ointment, when mercury disagreed with the stomac.

Many practitioners at this day are strongly attached to the sylen of prescribing a grain or two of calomel every day during the treatment of a gonorrhea, and deem it unsafe to abstain altogether from the use of mercury, in some form or another. Others give calomel with a view of its acting as an alternative and purgative. We never have seen any reason, however, for exhibiting either the hydrargyrum caelestum, or calomel, or for employing mercury in any mode whatsoever.

Before closing the present article, it only remains for us to say a few words respecting some complaints, which are occasionally attendant on gonorrhea.

When the inflammation is violent, or spreads along the urethra, there is frequently a discharge of blood from the vesicles of that part. Mr. Hunter states, that in such cases the balsam capivi has been found serviceable; but that he did not observe any good result from the use of astringent injections.

Opium alone, or joined with camphor, is the best medicine for the prevention of painful eruptions. Cistota is also said to prove useful for the same purpose.

With regard to the treatment of chordee, Mr. Hunter remarks, that in the beginning of this complaint, lodging from the arm is often of service, but that it is more immediately useful to take away blood from the part itself by beeches. Great benefit often follows the accidental burning of a vesel, and a profuse hemorrhage. Relief is often ob-

Vol. XVI.
tained from expelling the penis to the stream of warm water. Poultices and fomentations, especially those containing camphor, are frequently productive of benefit by removing the inflammation. Opium given internally is of singular service, and is still more beneficial when joined with camphor. It relieves the pain and prevents erctions, which are the immediate cause of the complaint.

When the chordee continues after all the other symptoms are gone, the only remaining object is to promote the absorption of the extravasated coagulable lymph, by friction with mercurial ointment on the parts. Mr. Hunter informs us, that if in one case considerable benefit seemed to result from giving canta, after the common methods had failed. Electricity, he says, may also be of service. A chordae is often longer in disappearing than either the running or pain; but, like most of the consequences of inflammation, its declension is gradual and uniform.

Mr. Hunter has been the kind of chordae, which seems to depend on spasm, relieved by bark.

When the glands of the urethra suppurate, Mr. Hunter advises the use of mercury, just as if the case were a cleaner; but this practice is not deemed necessary by the most judicious surgeons of the present day. It is proper to make an early opening into the abcess, when Cowper's glands suppurate, in order to prevent the matter from making its way into the urethra or ferotum.

When the bladder is affected with irritation, in consequence of gonorrhea, opiate clysters, the warm bath, and copious bleeding, are the chief means of relief. Leeches applied to the perineum have also good effects. Bleeding, however, in certain constitutions, is hurtful, and should always be referred to with caution. When the complaint lasts very long, restifing ordinary methods, Mr. Hunter suggests the trial of an opiate plaster on the pubes, or small of the back; or a small blister on the perineum.

The mode of treating a swelling of the testicle, we shall consider under the head, Hernia Homerals.

The decline of a gonorrhoea is generally known by the pain becoming less, or changing into an itching, similar to what is often felt in the beginning of the complaint, and which at length goes away altogether. The tense of weariess about the loins, hips, testicles, and ferotum is no longer felt; and the cherry-like appearance of the glans penis gradually subsides. The running diminishes, or at all events becomes whiter, then paler, and by degrees assumes a more flimy consistence, in proportion as it becomes more like the natural secretion, which is designed to lubricate the urethra.

Recurrences of the discharge every now and then are met with, after the pain, discharge, &c. have quite ceased. Such relapses, however, are more common in women than men, and the complaint is usually in a milder form than before.

GONRA, in Geography, a town of Hindoostan, in Bundeloud; 20 miles N. of Callissing. GONS, a town of Hungary; 22 miles S.S.W. of Zatmar.

GONSAVO, Hernandez DE CORDOVA, in Biography, an eminent Spanish commander, was born in 1443, and brought up from a very early age to the profession of arms. He signalized himself in a war against Portugal, and under the reign of the celebrated Ferdinand and Isabella he served in the conquest of Granada. He was afterwards employed to succor Ferdinand king of Naples against Charles VIII. of France, and by his assistance the whole of that kingdom was recovered from the French. Kings, however, are not always consistent in their projects, and the monarch of Spain who had defended and saved one king of Naples, formed a project of supplanting his successor, and making a partition of the country with Lewis XII. of France, and Gonvaldo was employed to execute the attempt. The warrior was completely successful, and made Alphonso, son of the king of Naples, his captive. Elated with his successes, and wishing to swell his moderation, Gonvaldo swore upon the holy sacrament, a wretched abuse of a religious rite, that the young prince should enjoy his liberty; but after the surrender was complete, and the time was come when he could execute his promise, he pretended that he had received new orders from his own sovereign, which obliged him to send Alphonso a priour into Spain. The partitioning powers soon disagreed among themselves, and the French, being in a greater state of preparation, attacked, defeated, and expelled the Spaniards from most of the places which they possessed. Gonvaldo was now compelled to retire with his army, delitate of money, provisions, and ammunition. He retired, however, only to recruit himself, which he had an opportunity of doing among the Venetians, when he rallied, drove the French before him, and entered Naples in triumph. Ferdinand, in the mean time, doubtful of the event, had negotiated a treaty with Lewis, confirming their former partition; but upon the intelligence of the great successes of Gonvaldo, such was "Spanish honour," that he refused to sign it, and the French were, by the efforts of Gonvaldo, obliged entirely to evacuate the kingdom of Naples. For these and other eminent services, he not only obtained the title of the "Great Captain," but was rewarded by his sovereign with many valuable as well as honourable gifts of honour. He was made confable of the kingdom of Naples, raised to the dukedoms of Terranova, St. Angelo, and other estates. He at length fell under the suspicion of his sovereign, who sent letters to recall him, which the general repeatedly eluded upon different pretenses. The king determined to go to Naples, and was met at Genoa by Gonvaldo. They entered Naples together in apparent harmony, and the king conferred an additional dukedom on his "Great Captain," but Ferdinand thought it prudent, in the following year, when he left Naples, to take his general with him. At Savona they had an interview with Lewis XII. when he bowed his obeisance for Gonvaldo, by decorating him with a gold chain taken from his own neck, and causing him to sup at the same table with himself. At Venice also he received some magnificent presents. On his arrival in Spain, he was commanded to retire to his own estate at Grenada, where he died in 1515, at the age of seventy-two. Gonvaldo is distinguished as a firm disciplinarian, a great master of the art of war, but as one who was never distinguished for generosity of sentiment. Univer. Hist. Moretii.

GONSAVO, St., in Geography, a town of Brazil, in the government of St. Salvador; 40 miles W. of Sergipe.

GONTAPILLY, a town of Hindoostan, in the circuit of Ciacile; 25 miles S. of Cossimotta.

By Loweree's description of his own species, G. amariflora, a shrub with pinnated hairy leaves, and by his reference to Rumph. Amboin. Append. t. 15, it should seem to be allied to Epigera, and the description of the pill and fruit does not exactly answer. It agrees perhaps better with Brasenia. Juss. 373, both in botanical characters and medical properties; see that article. Loweree says his plant is found in the woods of China and Cochinchina, and that
the virtues of the root and fruit are diaphoretic, alexiteric, antifebric, and anthemimtic. He adds, that "it seems to be the same drug which the Portuguese call radice de Solor, because it grows in the isle of Solora, as well as in Timor, and which is in great use in India." Is the Branca, after all, an Indian plant?

GONWA, in Geography, a town of Hindooftan, in Guzerat; it is 20 miles N.W. of Amoog.

GONYALGIA, of 500, lives, or 5/6\% pain, a term used by some authors to express a violent pain in the knee.

GONZALES, Bartolome, in Biography, a painter, born at Valladolid in the year 1564. He frequented the school of Patricio Caxes at Madrid; in the sequel painted much for Philip III. at Burgos, Valladolid, Lema, in the Paro and Efearial, till 1617, when he was made painter to the court, in the place of Fabricon Cellado. His portraits are admirable, especially the six whole lengths with the date 1621, possessed by the baron of Cana Davallino. In history, his style was ornamental; his drapery, a varied imitation of life, by its illusion captivated the vulgar, whilst it destroyed the dignity, simplicity, and generally the costume of the subject. He died in 1627, not, as Palamino states, in 1611. Fufeli's Pilkington.

GOOBER, in Geography, a country of Africa, S. of Wanga, between 10° and 12° N. lat. and 15° and 20° E. long. The mountains of Komri, so called by Abulfeda, commence in this territory.

GOOCHLAND, a county of Virginia, in America, surrounded by Louisa, Flavanna, Henrico, Hanover, and Powhatan counties; about 40 miles long and 14 broad, and containing 4803 free inhabitants, and 4803 slaves.

GOOD, or GOODNESS, denotes whatever tends or conduces to preserve or improve human nature or society; in opposition to evil, which tends to destroy, injure, or impair the fame.

Hence good is divided by the philosophers into 1. Bonum fis, private good; which is that whereby a thing tends to preserve, &c. itself, under which comes that popular division of goods of body, mind, and fortune.

2. Bonum communis, whatever promotes the interest and welfare of society; as all the civil offices, &c.

GOOD, in Metaphysics, or Metaphysical Good, called also absolute or real good, and good per se, is the essential perfection or integrity of a thing whereby it has every thing that belongs to its nature.

In this sense, all things are good, inasmuch as they have the perfections naturally belonging to things of their kind. Thus, a thinking substance is good, or perfect, as it has all the essiential attributes of thought; if an extended substance is good, as it possesses all the parts necessary to constitute it such.

In effect, as it is absurd to imagine a being without its essence, fo is it to imagine a being without the requisites of its essence: so that it appears an error in some philosophers, who divided beings into good or perfect, and evil or imperfect.

See Essence.

Others define metaphysical, or transcendent natural goodnes, by congruency with the divine will, which, they say, constitutes the measure of all real goodnes.

Good, Physical or Natural, is that whereby a thing possesses all things necessary to its Gute effe, i. e. its well being, or second perfection, and to the performance of its functions and uses.

In this sense, physical goodnes coincides with physical perfection.

To this are required the several powers and faculties, in their proper degree; a due situation, figure, and proportion of parts, &c.

Note, beside absolute physical goodnes, there may be a relative one; as in foods, which to one, are salutary, to another poison, &c. To this head also belong the things good pro tempore, or according to circumstances; as the amputation of a mortified limb, &c.

3 M 2 Natural.
Natural good may be otherwise defined to be that which makes or denunciates a being happy, or prepares him for happiness; or, at least, prevents or removes his misery: accordingly, good is either objective or formal; objective good is that which makes us happy; formal good, or the pleasure resulting from the application of the faculty to the object, is that which denominates us happy.

Good, Moral or Ethical, is the agreement of a thinking, reasonable being, and of the habits, acts, and inclinations of such a being with the dictates of right reason, and the will of the Creator, as discovered by natural light. See Virtue.

In order to this, it is not enough that a thing done, said, thought, defined, be just and good; but it must be done, thought, &c. well, i.e. from good principles, and to good ends.

Others define moral good more largely. Moral, which they also call relative good, according to them, is something that is good to another, or that tends some way to the perfection thereof. In this sense they divide it into three kinds, benevolent, juridical, and utilitarian.

The first, bonum benevolentium, is what agrees with right reason, and is desirable for itself, as all things virtuous; e.g. to love God, respect our parents, &c. It is considered without any regard to pleasure; not but there is sincere pleasure annexed to it. Zeno and the Stoics allow of no other goods; those of the body, &c. they call commodas, convenientias, not goods.

Bonom juventatis is that which is good, as it tends to give us pleasure, and is defined on that account; but without any repugnancy to virtue or right reason; as music to the ears, painting to the eyes, &c.

Bonom utilitarum, or commodarum, is that which is good on account of something else for which it is defined; as money, riches, &c.

Good, chief, supreme, or suprema, summun bonum, is that, the enjoyment of which renders men truly and completely happy. The schools distinguish this chief good of man into that which is simply and adequately so, and beyond which there can be no other; and an inferior, subordinated kind, which is, in some measure, attainable in this imperfect state. This last they call felicitas viarum, and the former felicitas comprehendens.

The chief or sovereign good, according to the idea collected of it from the original, natural, and universal preconceptions of all mankind, is something agreeable to our nature, conducive to well-being, accommodative to all places and times, durable, self-derived, and indestructible; and this confides in the sentence of Harris, in respect of conduct, or in living perpetually feelling, as far as possible, what is congruous to nature, and rejecting what is contrary, making our end that feeling and rejecting only. Three Treatises, Sc. 1765, p. 121, &c. 265, &c.

Philosophers are divided as to what the chief good of man consists in; whether in the goods of fortune, of body, or of mind. Some hold riches and honours the supreme good; others, as Aristotle and the Cynic school, bodily pleasures; and others, as Zeno and the Stoics, virtue, or living according to nature. The Peripatetics agreed with the Stoics in maintaining that virtue is the sumnum bonum: but the Stoics ascribed farther, that virtue was the only good; whilst the Peripatetics denied, with reaon, that virtue was self-sufficient, and therefore required several other things as auxiliaries, such as health, prosperity, friends, &c. which are to the virtuous man in the nature of instruments or ornaments to his felicity. An excellent writer lays down the following criteria or characteristics of the sumnum bonum, or chief good, which reaon can demonstrate to be actually designed for man: it is something which all men, if not wanting to themselves, may be possessed of; it is one and the same to all mankind; and while in itself fitted to make the possessor happy, is not prevented in its operation by some other thing which keeps him from reifying it; and as to the highest good which it is possible for man to enjoy, it must be referred to no other, but all others must be embraced for the fake of this; and it must be sufficient to furnish a happiness adequate to the capacities of human nature, and of equal duration; i.e. it must be not only perfect whilst it lasts, but everlasting. According to these characters we may infer, that neither the goods of fortune, nor those of the body, nor even virtue itself, constitute the chief good. Virtue, rightly understood, is the perfection of human nature; it is the instrument of obtaining happiness: but this alone will not make a man happy; it is farther necessary that he be perfect as to life, or happy in the circumstances of his being: and, therefore, natural reason demonstrates, that the favour of God, secured by virtue, is properly man's supreme good. Grove's System of Moral Philosophy, vol. i. part. i. paffim. See Epicureans, Peripatetics, and Stoics.

Good-will, See Benevolence. Good Works. See Merit and Supercerogation. Good Steering, bona gestia, in a Late Style, is particularly used for an exact carriage or behaviour of a subject towards the king and his liege people; to which some men, upon such instances, are bound. The juries are empowered by 34 Edw. III. cap. 1. to bind in this manner all them that be not of good fame; under which general expression, it is held that a man may be bound to his good behaviour for causes of scandal, contra bonos mores, as well as contra pecunias; as, for haunting base-dungeons; for keeping bad women in his own house; or for words tending to scandalize the government; or in abuse of the officers of justice, especially in the execution of their office: a justice may also bind over all night-walkers, eavesdroppers, such as keep infamous company, or are reported to be piphers or robbers, common drunkards, whores-mothers, the putative fathers of bastards, cheats, idle vagabonds, and any other persons, whose misbehaviour may reasonably bring them within the general words of the statute. Persons of this description may be bound, with one or more forfeitures, in a recognizance or obligation to the king, entered on record, and taken in some court, or by some judicial officer, whereby the parties acknowledge themselves to be indebted to the crown in the sum required, e. g. 100l. with condition to be void of none effect, provided that they behave themselves well, either generally or specially, for the time therein limited; as for one or more years, or for life. This recognizance, if taken by a justice of the peace, must be certified to the next sessions, by 3 Hen. VII. cap. 1. and if the condition of it be broken, the recognizance becomes forfeited or absolete; and being effaced or extracted, (i.e. taken out from among the other records) and sent up to the exchequer, the party and his forfeitures are become the king's debts, and are fixed for the several sums in which they are bound. All persons under the king's protection may obtain such security, upon due cause shown; and the justice may be compelled to grant it by a mandatory writ, called suppliatio: but this writ is seldom used, for, when application is made to the superior courts, they usually take the recognizances there, under the direction of the statute 21 Jac. I. cap. 8. A recognizance may be discharged, either by the demise of the king, or by the death of the principal party bound thereby, or by order of the court to which it is certified by the juries. He that is bound to this, Lambard says, is more strictly bound than to the peace;
GOODENOVA, or Goodenovia, like, not named by the writer of the present article in honour of the Right Rev. Samuel Goodenough, lord bishop of Carlisle, F.R.S. and a vice-president of the Linnean Society, a most valuable paper on British Corices, in the second volume of the Linn. Society's Transactions, and of one on British Fuci, in conjunction with Mr. Woodward, in the third. The name was constructed after the example of Tournedort, who, as he tells us, not without much consideration, contrived to form *Genula* out of *Gundelfsheimer.* It did not occur to us at the time that *Goodenovia* might have come nearer to the original, and have been equally unexceptionable. It is now too late to make any such alteration. Linnaeus named Richardia after Dr. Richardson, Stilligia after Mr. Stillingfleet, and these are sufficient precedents. Sm. Tr. of Linn. Soc. v. 2, 346. Brown. Prodr. Nov. Holl. v. 1, 574. Willd. Sp. Pl. v. 1, 954. Mart. Mill. Dict. v. 2. Clas and order, *Pennantia Monogynia.* Nat. Ord. Compances, Linn. Compances. Jull. Goodenovia, Brown.

Gen. Ch. Cal. Perianth superior, of five, nearly equal, linear leaves, permanent. Cor. of one petal, much longer than the calyx, irregular; tube flat from top to bottom at the back; limb of five deep, firm, lanceolate segments, with thin dilated longitudinal borders, turned moist to one side, forming one lip, or generally two. Stam. Filaments five, shorter than the tube, often projecting through its slit, capillary, equal; anthers vertical, oblong; of two lobes. Pijf. Germin inferior, oblong, crowned with the calyx-leaves, which run down its sides and form ribs; stile taper at the base, swelling upwards, undivided, nearly as long as the tube; stigma large, firm, obtuse, enveloped with a cup-shaped cover, more or less two-lipped, its margin fringed with dense upright hairs. *Peric.* Capsule oblong or elliptical, of two valves separating at the top, and two (rarely four) cells, the partition flat, parallel to the valves. *Seeds* numerous, imbricated, compressed.

Eff. Ch. Corolla of one petal, flat longitudinally at the back; limb in five deep segments turned one way. Anthers separate, beardless. Stigma with a cup-shaped fringed intragum. Capsule inferior, of two or four cells, with a parallel partition. *Seeds* numerous, imbricated. Obf. Mr. Brown has remarked, in some species, a small bag of honey attached to the germen, opposite to the slit in the corolla.

Eight species of this very curious genus were originally defined in the Linnean Society's Transactions, three of which, having been described without a knowledge of their fruit, are now, on more full examination, removed by Cavanilles and Brown to other genera. These are the *albida,* *fritha,* and *ramosiflora,* the latter, which, like the *albida,* is a *Scevola,* may be seen in Sm. Bot. of N. Holl. t. 5. The *fritha* belongs to Mr. Brown's *Dampiera.* But on the other hand the discoveries of this indefatigable collector and accurate botanist have increased Goodenia to 32 species, all natives of New Holland or of Van Diemen's land. Of these the first 28 have a two-lipped corolla, and the first four of them have yellow flowers, the rest blue or purple. Of the remaining four, two have a single-lipped corolla, and the others are doubtful in this respect, it being doubtful whether these last properly belong to the genus. One of them is *Sellbrera radicans.* Cavan. 1. t. 474. f. 2. *Goodenia repens,* Billard. Nov. Holl. t. 76.

Satisfactory examples of the genus are, *G. paniculata.* Sm. n. 2. Cavan. 1. t. 507. This has yellow flowers in terminal panicles. Leaves mostly radical, strongly toothed. *Herbage* hairy. *G. stellata.* Sm. n. 1. Cav. 1. t. 506. Andr. Repol. t. 68. The perianth in five flowers that flowered in England, and from which the genus was described. This has rather a thorny *flame,* ovate nearly serrated smooth leaves, and axillary forked flasks, bearing elegant yellow flowers. It is a desirable ornament for a greenhouse, and not difficult of culture.

*G. grandisflora.* Sims in Curt. Mag. t. 890. Differs from the last in being downy, with lyrate leaves and larger flowers. Whole tube is split into four segments, and singularly rough or bearded within.

*G. elongata.* Billard. Nov. Holl. t. 75. Is a very slender species, with long simple flower-flanks definite of bracteas.

GOODENOVIÆ, a natural order of plants recently established by Mr. Brown, Prodr. Nov. Holl. v. 1, 573, being separated by him from the *Campanulaceae* of Jullien, and essentially distinguished by a peculiar cup-shaped intragum, either undivided or two-lobed, which contains the stigma, and has hitherto been described by botanists as the stigma itself. See *Campanulaceae.*

Mr. Brown describes his new order as follows:

_Calyx_ superior or half superior, rarely inferior, five-cleft, sometimes five or six deep divisions, sometimes short, undivided, and occasionally obsolete; its segments equal, rarely unequal, permanent.

_Corolla_ of one petal, more or less irregular, deciduous or withering. Tube split longitudinally, sometimes separable into five portions, while the calyx is merely attached to the base of the germen. Limb in five deep segments, compounding one lip or two, their disk lanceolate, flat, their sides, or wings, of a thinner texture, elevated, folded inwards when young, rarely obsolete or deficient.

_ Stamina_ five, unconnected with either corolla or stile, and alternate with the divisions of the former. Filaments distinct. Anthers either separate or cohering, linear, vertical, attached by their base, undivided, two-celled, the cells opening lengthwise. Pollen simple, rarely compound.

_Germen_ of two or four cells, rarely of one only; the rudiments of the seeds either indefinite or definite, erect; sometimes bearing a gland between the two anterior filaments. Style one, simple, very rarely divided. Stigma fleshy, obtuse, either undivided or two-lobed. Encompassed from beneath with a somewhat membranous, cup-shaped, entire or two-lobed intragum, the great peculiarity of the order.

_Pericarp_, when the number of the seeds is indefinite, a capsule of two cells, rarely four, or sometimes, from the shortness of the partition, of scarcely more than one. Partition mostly parallel, rarely contrary, to the valve, which are either undivided or cloven, bearing the seeds on its middle. When the number of the seeds is definite, one being in each cell, the pericarp is a drupa or a nut, rarely an *arillicula* (or membranous undividing capsule), bearing the seed from its base.

*Seeds* often with a thickish coat, sometimes with a hard
shell. Albinous fleshly, shaped like the seed, seldom wanting.

Embryo straight, about as long as the albumen. Cotyledons of a middling size, often leafy. *Plumula inconstipacious.*

These plants are either herbaceous or shrubby, not milky, chiefly found in the southern hemisphere, rarely within the northern tropic. Their pubescence when present is generally simple, sometimes glandular, rarely fimbriated. Leaves scattered, without stipules, simple, mostly undivided, sometimes lobed, often toothed. Inflorescence terminal or axillary, various. Flowers distinctly, very rarely aggregate, yellow, blue or purplish, seldom reddish.

The first section, with indefinite seeds, contains six genera; *Goodenia, Calegania, Euthalia, Villa* of Smith, *Lathanuilla* and *Authroianus*; the second, with definite seeds, three genera; *Sparoa* of Linnecus, much augmented, *Diaphora* and *Damiera*; the third section, with a fingle-seeded *urticales*, is contrived to admit the *Buuunia* named after the worthy and intelligent author, by Dr. Smith in the twelfth volume of the Linnean Society's Transactions not yet published. The place of this genus in a natural order is extremely difficult to determine. It agrees with the *Goodewia* chiefly in having an integument to the stigma, but in habit, aggregate flowers, four distinct bracteas, and some other marks, agrees with the *Dipsacea* of Jussieu, to which it is referred, not without doubt, in the Linnean Transactions. It consists of two species, *Buuunia fricera* and *aunulata*, herbaceous plants, with the aspect of single-leaved *Scaequalia*.

**GOODEROE, in Geography, a town of Abyflinia; 94 miles S.S.E. of Minic.**

**GOOD HOPE, or Hope Island, an island in the S. Pacific ocean, discovered by Le Maire and Schouten in 1616. The land is mountainous, not very high, and abundes with cocko-nut trees; the coast affords no anchorage. S. lat. 16. E. long. 174° 15'.—Also, the name of a Danish colony in Wett Greenland. N. lat. 64°.**

**GOOD Hope, Cape of. See Cape.**

**GODIA, in Botany, in memory of Dr. Peter Good, an industrious gardener, employed in collecting seeds in New South Wales for the Kew garden. He died, some years since, in that remote country, and Mr. Brown has always been so fatigued with his merits, that he has long defined a genus to his honour.**—Salif. Parad. Lond. t. 41. Sims. in Curt. *Mag.* t. 938.—Clais and order, *Diasphea Decandria*. Nat. Ord. *Papilionaceae*, Linn. *Leguminoses*, Jaff.

Eff. Ch. Calyx two-lipped; the upper cloven, broadest and shortest. Legume filated, compressed, flat at the upper edge, of one cell. Seeds two.

Obf. This genus, as Dr. Sims observes, ought to be placed next to *Bussus*, Tr. of *Linn. Soc.* v. 9. 502, from which it differs essentially in its legume, which has no dilated thickened borders, nor is it internally spongy nor many-celled. The stamens are truly diaphibous, in which it differs from *Catralaria*, as also in not having an inflated legume, though its habit comes nearest to that genus.

Two species are known.

1. G. *latifolia*. Curt. *Mag.* t. 958.—Leaflets smooth, as well as the branches and flower-tilts.—Native of Van Diemen's land. One of the first New Holland plants raised in this country, and very hardy in the greenhouse, possibly able to bear our climate. Mr. Atten we favored us with specimens from Kew in 1796. It is a delicate smooth *frub*, with ternate somewhat glaucous leaves, and terminal clusters of numerous yellow flowers, the base of which is white; and part of the wings, are flayed with crimson, as in many New Holland flowers of this family. The legume is somewhat ovate, with a taper base, smooth, but marked with numerous, transverse, parallel, reticulate veins. One fed only is usually perfected.

2. G. *pubescens*. Curt. *Mag.* t. 1310.—Leaflets downy, as well as the branches and flower-tilts.—Very like the former, and brought from the same country. It flowered at Mr. Lodige's at Hackney. We think with Dr. Sims it has sufficiently the aspect of a distinct species, though its downiers, often a variable circumstance, affords the only specific character. The leaflets in the plate do not answer to his definition of obcordate, and we believe they vary in shape, as in many leguminous plants.

**GOODIANELLI, in Geography, a town of Hindoostan, in Myore; 19 miles N. of Seringapatam.**

**GOODIMANELLE, a town of Hindoostan, in Myore; 20 miles W. of Bagalore.**

**GOODINGAR, a town of Hindoostan, in Tinewely, near the coast; 50 miles S. of Panemtotta.**

**GOODLUCK BAY, a small bay in the strait of Mageland, entirely surrounded by rocks. This bay supplies a little wood, and plenty of good water, but it is very difficult of access. S. lat. 53° 23'. W. long. 74° 33'. Variation two points easterly.**

**GOODNESS, in Theology, expresses one of the attributes of the Deity, sometimes denominated *Benevolence.* (See Attributes and Benevolence.) Dr. Paley, in his "Natural Theology," illustrates and proves the divine goodneces by two propositions, which may be evinced by observations drawn from the appearances of nature. The first of these propositions is that in a vast plurality of instances in which contrivance is perceived the design of the contrivance is beneficial. No productions of nature display contrivance fo manifestly as the parts of animals, and all these parts have a real, and, with very few exceptions, a known and intelligible, subserviency to the use of the animal. Nor is the benevolent design of the creator abortive. The world, made with this design, is a happy world. The air, the earth, the water, teem with delighted existence. This argument is flated by the author in his "Moral Philosophy" in the following manner; "Contrivance proves design; and the predominant tendency of the contrivance indicates the disposition of the designer. The world abounds with contrivances, and all the contrivances which we are acquainted with are directed to beneficial purposes. Evil do not exist; but is never, that we can perceive, the object of contrivance. Teeth are contrived to eat, not to ache; their aching now and then is incidental to the contrivance, perhaps inseparable from it; or even, if you will, let it be called a defect in the contrivance; but it is not the object of it. This is a distinction which well deserves to be attended to. In describing implements of husbandry, you would hardly lay of the sickle, that it is made to cut the reaper's hand, though, from the construction of the instrument, and the manner of using it, this mischief often follows. But if you had occasion to describe
describe the instruments of torture or execution, this
engine, you would say, is to extend the fines; this to
dislocate the joints; this to break the bones; this to sear
the sores of the feet. Here pain and misery are the very
objects of the contrivance. Now, nothing of this fort is to
be found in the books of nature. We never discover a train
of contrivance to bring about an evil purpose. No anatomist
ever discovered a system of organization, calculated to pro-
duce pain and disease; or in explaining the parts of the
human body, ever said, this is to irritate; this to inflame;
this duct is to convey the gravel to the kidneys; this gland
to secrete the humour which forms the coat; if by chance
he come at a part of which he knows not the use, the most
he can say is, that it is useless; no one ever suspects that it
is put there to incommode, to annoy, or to torment."

Our author’s second proposition is, “that the Deity has added
pleasure to animal sensations, beyond what was nec-
"essary for any other purpose, or when the purpose, so far as it
was necessary, might have been effected by the operation of
down.” There is a class of properties, pertaining to animals,
which may be said to be superadded from an intention ex-
pressly directed to happiness; an intention to give a happy
existence distinct from the general intention of providing the
means of existence, with which other capacities are con-
tracted; and that is, of capacities for pleasure, in cafes,
wherein, so far as the conservation of the individual, or of
the species, is concerned, they were not wanted, or wherein
the purpose might have been secured by the operation of
pleasure. The provision which is made of a variety of objects,
not necessary to life, and administering only to our pleasures;
and the properties given to the necessities of life themselves,
by which they contribute to pleasure as well as to preservation;
drew a farther design than that of giving existence. This
observation is illustrated by our ingenious author in a variety
of familiar instances, deduced from the senses of taste,
hearing, smell, and sight. The senses appear to be specific
graces, ministering not only to preservation, but to pleasure.
But the senses, as they are usually called, are far from being
the only vehicle of enjoyment, or the whole of our condition,
which is calculated for the purpose. We have many internal
sensations of the most agreeable kind, hardly referable to any
of the five senses. Besides these there are exercises of the
understanding in volition, &e. of the imagination, and of
other faculties of the mind, which furnish unmixed gratifica-
tions, without any counterbalancing pains. Whilst the
above-mentioned propositions can be maintained, we are au-
thorized to ascribe to the Deity the character of benevolence
and what is benevolence at all, must in him be infinite bene-
volence, by reason of the infinite, that is to say, the inca-
"tably great, number of objects, upon which it is exercised.
But besides the evidences of divine goodness that are fur-

Hindooeflan, in the circum of Adoni; 15 miles N.N.E. of
Condore.

GOODS, in Mining, signify, in Derbyshire, the large
and massive lumps of lead ore, otherwise called bing or potter’s ore.

Goons, among public brewers, denote the malt or grains
and liquor in their matthum.

Goods, bona, in Law, and particularly the Civil Law,
include all kinds of effects, riches, lands, possessions, &c.
There are two kinds of goods; movables, res moventia, or
mellibius; and immovables, called res non moventia, or immo-

It is a maxim in the civil jurisprudence, that he who con-

-Goods, again, are divided into real and personal. (See
 Chattels and Estate.) And, lastly, into noble or free,
and servile or slave.

Goods belonging to the domain of the crown, ad jure
applicata, cannot be alienated for ever, unless it be done by
way of exchange; they may be sold under the faculty of
perpetual redemption.

Goods, Adventitious, adventitia, are those which arise ot-
other than by succession from father or mother, or from
direct ascendant to descendant. See ADVENTITIOUS.

Goods, Dotal, dotalia, those accruing from a dowry, and
which the husband is not allowed to alienate. See Dowry.

Goods, Fugitives. See FUGITIVE.

Goods, Paraphetamine. See Parapharmaceutical.

Goods, Prohibited. See PROHIBITED.

Goods, Proscriptions, procriptions, are those arising by direct
succession.

Goods, Receptual, were those which the wife might re-
serve the full property of to herself, and enjoy them inde-
dependently of her husband; so called, in distinction from
dotal and parapharmaceutical goods.

Goods, Vacant, vacantia, are those abandoned, or left
at large, either because the heir renounces them, or that
the distinct has no heir. See Bona.

Goods, Allotting of. See ALLOTTING.

Goods, Confinnement of. See CONFINEMENT.

Goods, Running of. See RUNNING.

GOODWIN, John, in Biography, a learned divine in the
fifteenth century, who is said to have made more noise
in the world than any other perfon of his age, rank,
and profession. He was born in 1593, and received his academical
education at Queen’s college, Cambridge; and, immediately
after he was admitted to orders, he was much admired for
the erudition and elegance which distinguished his pulpit com-
positions. In 1635 he was induced to the living of St.
Stephen, Coleman street, London, from which he was ejected in
1645, because he refused to baptize the children of his
parishioners prominently, and to administer the sacrament
"to his whole parish. He embraced the Arminian doctrines,
and eagerly pleaded their cause in his sermons and writings;
he adopted and maintained the independent form of church
government,
government, and he was reckoned to be exceedingly skilful and courageous in attacking or repelling those who opposed him. His tenets were not those generally embraced, and at one period he is characterized as a man by himself; as being against every man, and having almost every man against him. He had a clear head, a fluent tongue, a penetrating spirit, and a marvellous faculty in debating on scripture. In politics he was a decided and furious Republican, and, being eager in whatever he engaged, distinguished himself by his discourses and writings to promote, and afterwards to justify, the condemnation of the king. He lived, however, long enough to feel the weight of Government directed against himself and his writings. He was obliged to abdique for a faction, and one of his pieces was burnt by the common hangman, and in the fame fire which executed its commission on the "Defenso pro populo Anglicano," by John Milton of immortal memory. The friends which his Arminian principles had procured him, found means to pacify the people in power, and to assure themselves that Goodwin should not be prosecuted for the part which he had taken in the late reign. He returned from solitude, and became minister of a private congregation in the neighbourhood of Coleman street, and, disapproving of the act of uniformity afterwards passed, continued a dissentient from the established church of the Independent denomination, till his death in 1665, in the seventy-second year of his age. His works, which are chiefly theological, are very numerous, among which the following may be mentioned; "Redemption Redeemed," in folio. "The divine Authority of the Scriptures," 4to. "An Exposition of the ninth Chapter of the Epistle of St. Paul to the Romans," 4to. Neal's Hill of Puritans, &c.

Goodwin, Thomas, who is styled by Anthony Wood "One of the Atlases and patriarchs of independency," was born in the year 1600 at Roleby in Norfolk. Having received the elements of a grammatical learning, he was sent, when he was thirteen years old, to Christ-church college, Cambridge, where he applied himself with so much diligence to his studies, as to secure the esteem of his tutors, and to attract much notice in the university. In 1619 he was removed to Catherine Hall, of which he became a fellow. He soon showed a decided inclination to the views and sentiments of those who were denominated Puritans, and taking them as his models, he prepared himself for the office of a Chartist minister. It is not known when he took orders, but he was elected lecturer of Trinity church, in Cambridge, in the year 1628, and in 1632 he was presented by the king to the vicarage of the same church. In these employments he was greatly admired and followed by the Puritans, who began to look up to him as a leader, but becoming disaffected with the terms of conformity, he relinquished his preferments, and quitted the university in the year 1634. In 1639 he was selected as an object of persecution by the episcopal consistory, and to enjoy liberty of conscience he fled to Holland, where he was chosen pastor to an independent congregation at Arnhem. During the fittings of the Long Parliament he returned to London and became pastor of a church there, and also a member of the assembly of divines. In his conduct in their various meetings, and his zealous support of the Presbyterians, contributed to render him a favourite with Cromwell, through whose influence he was, in 1649, made one of the commissioners for the approbation of public preachers, and also appointed president of Magdalen college, Oxford. Here he formed a church upon the independent plan, and was exceedingly diligent in promoting the interests of learning and piety. His public duties as a preacher did not prevent him from those studies which enabled him to become distinguished as a writer. He attended Cromwell upon his death-bed, and was overheard to express himself boldly and enthusiastically confident of the protector's recovery; and it is affirmed that when the event proved him mistaken, he exclaimed in a subsequent address to God "thou hast deceived us, and we are deceived." After the restoration he was dismissed from his presidency, when he retired to London, where, however, he was permitted to continue in the exercise of the ministry till his death in 1679, when he had attained to his eightieth year. He was a considerate scholar, and a learned and eminent divine. In common register at Oxford he is described "in scriptis in re theologica qua plurimis Orbi notus." He was a high Calvinist, but while he zealously enforced what he conceived to be the doctrines of Christianity, he did not forget to enforce by every incitement in his power the necessity of pure moral conduct. He was author of numerous pious and controversial pieces, sermons, expostulations, &c., some of which were printed during his life time, and inserted, after his death, in a collection of his works published in five volumes folio, which continue to be read and quoted by Calvinists of the present day. Neal's Hill of Puritans, by Toulmin.

Goodwin, in Geography. See Goodwin Sand.

Gooings, in Sea Language, are clamps of iron bolted on the stern-post of a ship, whereon to hang the rudder and keep it steady; for which purpose there is a hole in each of them, to receive a corresponding spindle bolted on the back of the rudder, which turns thereby as upon hinges.

Goodgors, in Geography, inhabitants of the inland territory of the island of Sumatra, covered with long hair, and little superior to the orang outangs of Borneo. See Sumatra.

Gojindergur, a town of Hindoostan, in Sanore; 25 miles N. N.W. of Sanore.

Gool, a river of Hindoostan, which rises near Burraway, and runs into the Tapt, 8 miles S. of Chuprah.

Gool signifies a ditch or trench for water; called also a goit, gurt, leat, &c.

Gool, a breach in a sea-bank or wall; or a passageworn by the fluid and reflux of the sea. Vide 16 and 17 Car. II. cap. 11.

The word comes from the French, goulet, the gullet or neck.

Goolungee, in Geography, a town of Hindoostan, in the circar of Chandore; 25 miles E. of Chanderee.

Gooli, a small circar or province of Bengal, situated E. of Coos-Beyhar.

Goomah, a town of Bengal, 45 miles N. of Rampur. N. lat. 24° 23'; E. long. 85° 34'. - Also, a town of Hindoostan, in Bahar; 40 miles N. E. of Chittor.

Gombo, a town of Africa, in Bambara. N. lat. 15° 3'. W. long. 5° 10'.

Gombo, a town of Africa, in Kassan. N. lat. 14° 23'; W. long. 8 50'.

Gomong, a town of Hindoostan, in Derar; 12 miles S. of Nagpore.

Gomerpunk, a town of Hindoostan, in Oude; 16 miles S.W. of Azimgur.

Goopina, a town of Hindoostan, in Golconda; 20 miles N. E. of Culloor.

Goomepour, a town of Hindoostan, in Allahabad; 20 miles E. N. E. of Jompor.

Goomity, a river of Afa, which rises in the mountains.
GOO

GOOO, the island of Komonoon, and crossing the country of Oude, joins the Ganges, about 15 miles from Benares.

GONGAYAP, a small island in the East Indian sea, near the N.E. coast of Cumbhawa. S. lat. 8° 10'. E. long. 155° 24'.

GOONDHANAH, the ancient name of the province of Kajpur, which see.—Also, mountains of Hindustan, called "Konannah," situated in the E. part of the country of Malwa, extending from Huddinghah to Mundelly, about 150 miles long. N. lat. 22° 40', to 23° E. long. 75° 10'.

GOOPAMOW, a town of Hindustan, in Oude; 29 miles W. of Kairabad.

GOOPINGUNGE, a town of Hindostan; 32 miles W. of Benares.—Also, a town of Hindustan, in the bush of Agra. N. lat. 26° 24'. E. long. 79° 18'.

GOORACKPOOR, a province of Oude, bounded on the N. by the Tihbett, on the E. by Bittiah and Sarum, on the S. by Gazypour, and on the W. by the Oude proper and Bahratigh, about 60 miles long and 50 broad. The capital of the same name is situated 65 miles E. of Fyzabad.

GOOREH, the name of two towns of Hindustan; one in Oude and another in Allahabad.

GOORENTY, a town of Hindostan, in the circar of Chandos; 17 miles S.W. of Ganjam.

GOOS, a town of Nubia. N. lat. 18°. E. long. 34° 18'.

GOOSANDER, in Ornithology. See Mergus Mercator.

GOOSE, Anser, forms an order of birds in the Linnean system. (See Anseres.) The several species of geese belong to the genus of anas or duck under this order. See Duck.

Goose, a well-known bird, which, in many situations, may be highly beneficial to the farmer, as, where there are large waters and commons, and where the flusses are abundant. It is valuable both for its flesh, fat, and feathers.

The varieties of geese are numerous, but the large common kinds are probably the best for the use of the farmer.

Goose, Ember. See Columba Inser.

Goose, Solan or Solax, sometimes called gaumet. The English name of a large water-fowl, called by authors Anser Baffanicus, and by Linnaeus Pelecanus Baffanicus, which see.

Goose Creek, in Geography, a river of New Jersey, which runs into the Atlantic, N. lat. 39° 53'. W. long. 74° 16'.—Also, a river of Kentucky, which runs into the Ohio, N. lat. 38° 10'. W. long. 86° 3'.—Also, a river of North Carolina, which runs into the Atlantic, N. lat. 34° 40'. W. long. 77° 21'.—Also, a river which falls into the Potomac, about a mile S.E. of Thorpe, in Fairfax County, Virginia.

Goose-dung, in Agriculture and Medicine. See Dung and Cinnepopulis.

Goose-foot, or Wild Oat, or Good Henry, in Botany. See Cnicopodum.

Goose-grass, or Wild Orchid, or Goose Grass, in Botany. See Cnicopodum.

Goose-grass, the common name of a troublesome weed that is frequently met with on chalky soils. It is best destroyed by cutting it in the summer, and keeping the land under the plough in good condition. See Galium Aperine.

Goose-grass, Great. See Asperugo.

Goose Island, in Geography, a small island in the gulf of St. Lawrence, near the coast of Labrador. N. lat. 50° 52'. Vol. XVI.

W. long. 59° 15'.—Also, a small island in Christmas Sound, on the coast of Terra del Fuego.

Goose Lake, a lake of North America. N. lat. 52° 55'. W. long. 94° 45'.—Also, a lake of North America. N. lat. 54° 30'. W. long. 101° 21'.

Goose-neck, in Sea Language, is a kind of iron hook fitted on the inner end of a boom, and introduced into a clamp of iron or eye-bolt, which encircles the mast, or is fitted to some other place on the ship, so that it may be unhooked at pleasure.

Goose River, in Geography, a river of America, which runs into the Mississippi. N. lat. 43° 14'. W. long. 93° 56'.—Also, a river of South Carolina, which runs into Cooper's river. N. lat. 33° 2'. W. long. 79° 57'.

Goose-wing, in Sea Language, denote the claws or other corners of a ship's main-fall, or fore-fall, when the middle part is furled or tied up to the yard.

Goose-wing, at Sea, a certain manner of fitting a fall, which is thus performed: when a fall falls before a wind, or with a quarter-wind, and in a fresh gale, the foremen sometimes, to make the more halyards, unpar the mizen-yard, and then they launch out both fall and yard over the quarter on the lee-side, fitting guys at the farther end, to keep the yard steady with the boom, and this booms out the mizen-fleet. This they do to give the ship the more way, which otherwise, with these winds, the mizen-fall could not do; and this fall, so fitted, is called a goose-wing, and sometimes a fludding-fall.

Gooseberry Bush, Grosflabula, in Botany, is a species of the Ribes in the Linnean system. See Ribes.

The gooseberry-bush is propagated either by suckers or cuttings, but the latter way is preferable, as the roots are less subject to shoot out suckers afterwards.

The best season for planting the cuttings is in autumn, just before the leaves begin to fall; observing always to take the handiornent shoots, and to pick them from such branches as produce the greatest quantity of fruit. The cuttings should be about six or eight inches long, and should be planted in a bed of light earth exposed to the morning sun; they must be planted about three inches deep, and watered to help their taking root. The shoots should be rubbed off from their plants as they put out, except those at the top, that may be a regular stem. In the October following, they should be removed to a bed of fine light earth, and planted in rows at three feet distant; and one foot under in the rows. They should remain here one year, and the crofs branches at times be cut off, as also the lower ones, so as to keep a clean item about a foot above the ground. They will be then fit to plant out where they are to stand, which should be in a light sandy loam. They should be kept from the shade of other trees; and have the fruit in its utmost perfection, should be set in an exposed place in rows of eight feet asunder, and each of the shrubs fix feet from the others in the rows. The best time for transplanting them is in October, when the leaves begin to decay.

Gooseberry, in Agriculture, is a plant that may sometimes be employed in the forming of hedge-fences, especially that found in the North by the name of Ironmonger.

Gooseberry Caterpillar, in Gardening, the common name of a very destructive insect to the gooseberry and some other plants. Many different methods of destroying it have been proposed, but with little success.

Gooseberry, in America, is a plant that may sometimes be employed in the forming of hedge-fences, especially that found in the North by the name of Ironmonger.

Gooseberry, in Cactus. See Cactus.

Gooseberry, in Malaysia. See Melastrum.

Gooseberry, in Natural History, the name given by author.
authors to a species of protruberances of the gall kind, found very frequently on the oak. They are of a roundish figure, and sometimes adhere to the tree by a short pedicle, but more frequently by a part of their spheric surface. They are usually found on the under side of the leaves of the oak, but sometimes on the young shoots, and sometimes on the pedicles of the leaves.

They are most frequent in spring, but they are found at all times when the leaves are upon the trees. Thee galls are greenish at first, and afterwards become yellowish, and finally red; in which last state they very much resemble the small red gooseberry. They are very soft to the touch, and when opened are found to contain a juicy substance, with a cavity in the middle, in which there is lodged a single insect. This, according to the time in which the gall is opened, is found in the form of a white worm, or else of a white chrysalis, or finally of a small short-bodied four-winged fly of a black colour; for the creature does not leave the gall to go through any of its changes, but paffes all its states in it. The gall, in all these cases, is found whole and unmarred; but if one is opened in which there is a hole pierced, this is sure to be found empty, that being the pantage by which the fly has made its way out. Reaum. Hill. Inf. vol. vi. p. 214.

Gooseberry Islands, in Geography, small islands near the E. coast of Newfoundland; 24 miles N.W. of Cape Bonavista.

Gooseberry Rocks, dangerous rocks lying on the coast of Effex county, in the state of Massachusetts.

GOOTA, a town of Hindooftan, in Gooondwaah; 10 miles S. of Nagpaur.

Gootoka, a town of Hindooftan, in the cirec of Ruttpunpaur; 5 miles S. of Ruttpunpaur.

Gooty, or Gotti, a town and fortrefs of Hindooftan, the capital of a diiftict in Mylore; 170 miles N. of Serinagapam. It is situated on a hill beyond the river Pen-mar, or Pen-auur, and towards Adoni; and was formerly the seat of government of a Maltratta prince; but at the death of Tippeo, the town and district were assigned to the Nizam. N. lat. 15° 15'. E. long. 77° 48'.

Go-out, in Mining, is sometimes used to express the appearance of the edge of a stratum at the surface; otherwise called the baffle, crop, out-going, or out-bur of that stratum; and each stratum is said to go out, buried-out, run-out, lead-out, want-cover, &c.

When the ore in a vein is suddenly ended in the leads or gages, it is said to go out; also when a stratum of coal's ends abruptly against a fault, or wall of gravel filling a fault, or baffle under a heap of gravel, as is not uncommon in the south of Derbyshire, it is said to go out, and so of the irregular or feather-edge masses which are sometimes met with in the strata accidentally, or without being continuous like all the regular strata, however thin.

Gopachitty, in Geography, a town of Hindooftan, in Coimbose; 18 miles N.W. of Errond.

Gopachun, a town of Bootan; 58 miles N. of Dinagepaur.

Gopaldroog, a forte of Mysore; 36 miles E. of Seringapatam.

Gopaulgunge, a town of Bengal. N. lat. 23° 2'. E. long. 89° 56'.

Gopaulnagur, a town of Bengal, 42 miles S. of Bardwan. N. lat. 22° 31'. E. long. 88°.

Gopeer, a town of Bengal; 15 miles E.E. of Ramgur.

Goperaillery, a town of Golconda; 20 miles E.S.E. of Hyderabad.

Gophina, Gopunthi, or Gapohn, in Ancient Geography, a town of Palestine, and chief place of one of the ten patriarchs of Judah. Eufebius places it fifteen miles from Jerusalem, towards Sichem.

Goplo, in Geography, a lake of Poland, in the palatinate of Brafzef, 16 miles long, and four wide.

Goppingen, a town of the kingdom of Wurttemberg, situated on the Vils, in a fertile country, having considerable woollen manufactures, and near it a medicinal spring; 20 miles N.N.W. of Ulm. N. lat. 48° 47'. E. long. 9° 41'.

Gor, a town of Peria, in the province of Fariflan; 57 miles N.N.W. of Schira. —Also, a town of Italy, in the department of the Meta; 8 miles S. of Brefcin.

Gor, a name given by some writers to a very lofty tree, which bears a fruit like the cfeufun; it grows principally on the banks of the river Niger, and that not near the sea, but far up the country.

Gor-cock, in Ornithology, the name of a bird of the gallinaceous kind, called by authors the lagopus altera, and by many the moor-cock, or red game; it is of the shape of the partridge, but is half as large again. See Gruse and Tetrao Lagopus.

Gora, in Geography, a town of Hindeoostan, in the cirec of Chandali; 20 miles W. of Saipour.

Goracally, a town of Bengal; 12 miles S.S.W. of Mahmulbour.

Goragot, a province of Bengal, bounded on the N. by Rungpour, on the E. by Radjoow, Patладah, and Isma-bad, on the S. by Bettoorish and Pargunnah, and on the W. by Dinagepaur; about 55 miles long, and from 12 to 50 broad. Its capital, Goragot, is distant 80 miles N.N.E. from Moorheadabad. N. lat. 25° 14'. E. long. 89° 22'.

Goral, a town of Poland, in Galicia.

Goram, a small islend, being one of the Moluccas, in the East Indian sea, S.E. of Ceram; reputed the most easterly boundary of Mahometanism. It has thirteen mountains. S. lat. 3° 42'. E. long. 121° 36'.

Goranto, a town of Asiatic Turkey, in Caramania; 80 miles S.W. of Sattah.

Gorapari, a town of Brazil, at the mouth of a river of the same name, which runs into the Atlantic. S. lat. 20° 40'.

Gorbara, a town of Coreica; 8 miles N.E. of Cabii.

Gorbata, a town of Africa, in Bikeludergeri, anciently "Orbita"; 12 miles S.W. of Gafia.

Gorbatov, a town of Rouflia, in the government of Nizoe Novogorod. N. lat. 56° 51'. E. long. 43° 14'.

Gorca. See Gorkah.

Gorce, or Gourte, denotes a weir. By lat. 25 Edw. III. cap. 4. it is ordained, that all gorges, mills, weirs, &c. leived or fet up, whereby the king's ships and boats are disturbed, and cannot pass in any river, shall be utterly pulled down, without being renewed. Sir Edward Coke derives this word from gurge, a deep pit of water, and calls
GOR

it a gers, or gulf; but this seems to be a mistake, for in
Doomfiday it is called gour and gart, the old French word
for a twist.

GORCHWICH, in Geography, a town of Saxony, in
the Vogtland, 18 miles S.S.W. of Gera. N. lat. 50° 22'.
E. long. 11° 53'.

GORMUM, probably a corruption of Gorcum, a
town of Holland, situated on the river Linge, at its union
with the Waal. From the riecke of the principal church
may be seen 22 walled cities, besides a great number of
towns and villages; before the revolution it had one parish-
church, and three religious houses; 12 miles E. of Dort.
N. lat. 51° 52'. E. long. 4° 50'.

GORDENE', in Ancient Geography, a country of the
Greater Armenia, according to Ptolemy; which country is
called "Gordyene" by Strabo and by Plutarch in his life
of Lucullus.

GORDIES, in Geography, a town of France, in the de-
partment of Vaucluse, and chief place of a canton in the
district of Apt; 9 miles W. of Apt. The place contains
1813, and the canton 4453 inhabitants, on a territory of
1674 kilometres, in 8 communes.

Gордеворр Point, a cape of Hindooftan, on the
coast of Rajamundry, at the mouth of the Godavery.
N. lat. 16° 42'. E. long. 82° 20'.

GORDIEUS MUS, in Ancient Geography, a mountain of
the Greater Armenia. Ptol.

GORDIAN I, Roman emperor, grandchild of the older
Gordian, was but thirteen years old when he was chosen
emperor, in connection with Maximus and Balbinus. He
was created Cæsar, and assumed the family name. His two
colleagues were in a few months murdered by the Pretorian
bands, and the youthful Gordian remained sole emperor.
His person and manners excited universal favour, and the
metropolis, people, and army united in giving him the enduring
appellation of their son. In the commencement of his reign he was governed by his mother's uncles, who abused his authority, and fet the honours and offices of the empire up to sale.
He was, however, happily rescued from this disgraceful condition by Mithusus, a man of learning, to whom he was also indebted for literary instruction and advice. In the year 241 he married the daughter of Mithusus; and raising his father-in-law to the post of praetorian prefect, committed to him the principal direction of public affairs. He proved himself worthy of the important trust confided in him, and discharged the duties of a triumvir and general, as well as he had maintained those of a more private station. By his persuasion, the young emperor accompanied him in 242, in an expedition to the Euxine, for the purpose of repelling an invasion from Sapor king of Persia. Under his guidance, Gordian relieved Antioc, crossed the Euphrates, defeated Sapor, and recovered the whole of Mesopotamia. The young emperor did not assume the glory of the deeds, but, in a letter to the senate, announcing the success, he modestly ascribes them to the conduct, the experience, and wisdom of Mithusus, who shortly after died. During the whole expedition Mithusus had watched over the safety and discipline of the army, while he prevented their murmurs by maintaining a regular plenty in the camp, and by establishing ample magazines of vinegar, bacon, flour, barley and wheat, in all the cities of the frontier. The prosperity of the emperors expired with Mithusus; he was succeeded in the office of prefect by Philip, an Arab by birth, and consequently, says Gibbon, in the earlier part of his history, a robber by profession. He was a man of considerable military talents, but obsti-
lacious, and delinquent of true moral principle. His energy
and boldness prompted him to aspire to the throne, and his abilities were employed to supplant, not to improve, an indul-
gent power. By his arts discontents were fomented among
the

N 2
the troops, which induced them to demand that his invincible
Philip should be associated with Gordian as partner in the
empire. This was not sufficient to satisfy his ambitious
views; the young emperor was sacrificed at his inclination;
he was put to death near the banks of the Euphrates, in
March 244, after a reign of five years and eight months.
A sepulchral monument was erected to his memory on the
spot where he was killed. Gibbon.

GORDIAN, a term in History. Gordian knot was a
knot made in the leathers or harness of the chariot of Gor-
dian, king of Phrygia, and father of Mithras; so very
intricate, that there was no finding where it began or
ended.

The inhabitants had a tradition, that the oracle had de-
declared, that he should be master of Asia who could untie
this knot. Alexander having undertaken it, and fearing
that, if he should not be able to effect it, it would be
deemed an ill augury, and prove a check in the way of
his conquests, cut it asunder with his sword; and thus,
lay Quintus Curtius, either accomplished the oracle, or
eluded it. But Arillobulus gives a different account of
this matter. See Arrian, lib. iii, cap. 20, and Plut. in
Vit. Alex.

Some will have the phrase derived from Gordius who tied
thefatal knot; others from Gordium, a city in Phrygia,
where the knot was made.

GORDIUM, in Geography, a town of Asia, in Phrygia,
situated on the river Sangar; afterwards called Juliodis.

GORDIUS, in Zoology, a genus of Vermes, the essen-
tial character of which consists in the body being round,
filiform, naked or smooth, and of equal thicknesses through-
out.

Linnæus, and after his example the French naturalists
Bruguier, has placed the animals of this genus among the
intestinal vermes, an order of beings to which, from their
general structure, they seem to bear no very remote alliance:
and this similarity is still more strongly evinced in the habits
of those species which occasionally penetrate into the flesh
of men and animals, and wherein for a while derive their
sustenance from the blood and other fluids. Notwithstanding
this analogy, under such circumstances we cannot but
agree with Linnæus that it is impossible to consider them as
internal vermes with propriety; since they only occasionally
reside in the bodies of animals as before mentioned, and in
their habits and manners of life at other periods differ more
effentially: they are literally aquatic animals, with carno-
vorous appetites; though for a certain length of time they
may subsist like the true intestinal vermes, when by any acci-
dental circumstance they happen to infest themselves
into the flesh of a living animal.

At the head of this tribe we may justly place the species
meridana, or hair worm of the Indies, a pernicious creature,
referred to the genus Gordius by Linnæus in the latest edition
of his Syll. Nat., but from which it was afterwards removed
by his editor Gmelin to that of Filaria. This removal we
deem unnecessary, and under this prescription wish to restore
the species to its former situation in the genus Gordius.

Species.

MEDENAEIS. Body entirely pale. Linn. Sloane, Jam. &c.

This very remarkable creature is often from ten to twelve
or even fifteen feet in length, and in thickness not exceed-
ing a horse-hair. It is well known by its disfluous effects
as an inhabitant of both the Indies, where it lives in marshy
places, and is frequently observed on the ground in the
morning dew. In this situation it easily creeps up, and en-
twists itself round the naked legs of the negro slaves, or
animals, and penetrating the skin, buries itself greedily in
the flesh, where it causes the most violent pains, accompanied
with troublesome itchings, and sometimes inflammation and
fever. The most certain means of extirpating the worm is
to make an incision in the part of the flesh at which its
entrance was effected, so as to obtain secure hold of either
of the extremities, or the head if possible, and this being made
fail to a small flick by means of a piece of silk, the animal
may be gradually drawn out of the wound by turning the
flick round a little each day. The utmost circumcision is
required in performing this operation, for if by being too
much strained the worm should break, the part remaining
within the flesh grows with increased vigour, gangrene
appears almost immediately, and death itself ensues very
shortly.

AQUATICUS. Pale brown, with blackish extremities.
Linn. Gordius feta, Müll. Vitulus aquaticus, Geln.
Moerovium, Jon. Chretin, Hill. &c.

This fo entirely resembles a hair of from four to six
inches in length, that except by its motions it could be in no
manner distinguished from a substance of that kind by the
casual observer; its internal structure is equally remarkable
also for its simplicity, confining merely, as it appears, of a
causal extending from one end to the other, and both the
mouth and vent over the most simple, without, since a small
vent communicates the first, and a groove or hollow the latter.
Its ordinary places of residence are stagnant waters, in pools
and ditches, or in very tranquil rivers, as the agitation of
turbulent waters would destroy its tender frame. During
winter it remains buried deep in the clay, from whence it
emerges in spring, and is found in the water during the sum-
mer months, where it is frequently observed, and from its ap-
pearance is vulgarly imagined to be the offspring of horse-hair
dropped by accident into the water. It twists itself into
various contortions, and it is affirmed that its bite will oc-
casion the complaint called a whitlow. A fact still more ex-
tordinary, and which appears in some measure to be au-
thenticated with tolerable accuracy, is the retentive power of
animation, which this creature poiffesses in a very superior de-
gree, though not by any means to the extent that certain
naturalists conceive. Some writers affirm, indeed, that it has
been known to recover the free exercise of its vital functions
upon being steeped for a short space of time in water, after
having remained in a dried state for weeks, months, and even
years, and when of course it might be naturally conceived
the moll latent spark of life must be extinct. If these latter
affirmations have not arisen from the result of some very
superficial experiments, they are at least to be received with
cautions, since their observers seem to believe that these animals
partook also in some measure of the reproductive properties
of the polype, and which more recent observations prove
to be erroneous; we cannot, therefore, upon the whole,
avoid concluding that although the animals of this kind are
extremely tenacious of life, there is no foundation in truth
for the very extraordinary assertions above related.

ARGILLACUS. Body uniformly yellowish. Linn.

Very much resembles the last, and like that species is
found in the clay at the bottom of stagnant waters.

FILUM. Body uniform and whitish. Müll.

Extremely slender, tapering at one end, and hyaline.

Found in the bark of old wooden pipes which had been
placed in the ground for the conveyance of water.

LACTEUS. Body uniformly white and opaque. Müll.

Occurs in myriads in stagnant water from the month of
July till September. When touched, this species contracts
itself in a moment, and then again expands immediately.

ARNARIES. Pulious and obtuse. Müll.
Inhabitsthe bottom of Christians bay, in Norway.

GORDON, BERNARD, in *Biography*, a French physi-
cian of the thirteenth century, is said to have conferred
honour on the medical faculty of Montpellier, where he be-
gan to teach in the year 1275. As was the custom of
the time, he took his surname from the place of his birth, (Gor-
don in Rouergue) and called himself Bernardus de Gor-
donio, and not Gordonus, as it is commonly written.
According to the accounts of some writers, who place
the death of this physician in 1305, he taught at Montpellier
only twenty years; but Renchins affirms, that he was living
in 1318. He left a considerable number of treatises, which
were published together at Ferrara in 1487, at Venice in
1494, at Paris in 1542, and at Lyons in 1550. Eloy.
Dict. Hill.

Gordon, Mr., in the year 1744 played the first violin in
Drury-lane play-house. He was a young man, born in Nor-
folk, who had travelled to Italy for improvement. He was
very war-fightened, and always played in spectacles. He su-
ceeded Charke, had a strong hand, good tone, and was well
fitted to his situation. He generally played a concerto in
the second muse, as was then the practice, which was very
attractive. He was brother to the full title of the following
article.

Gordon, ——, an eminent performer on the vio-
loncello, the son of a clergyman in Norfolk, and many years
the first violoncello at the opera. He was remarkable for
the fulness of his tone, and perfect execution of whatever he
undertook, though far surpassed by sub-frequent players in
the use of the bow, and knowledge of the finger-board.
He lived reputedly, had many powerful friends, and rea-
lised a competence by his profession.

In 1756, Mellers, Gordon, Vincent, and Crawford, under-
took the opera regency in the Haymarket. The two first
were experienced professors, and the third had been many
years treasurer under different managers. Gordon, an ex-
ceptional performer on the violoncello; and Vincent, a schoal
of the celebrated Martini, long a favourite on the lantbois.
His father was a bassoon player in the Guards, and his bro-
ther, James Vincent, who died young, was joint organist of
the Temple with Stanley, and a brilliant performer. Mr.
T. Vincent, the impresario, had in great favour with the
late prince of Wales, father to his present majesty; had
acquired a considerable sum of money in his profession, which
he augmented by marriage. However, the ambition of com-
mand, though of so forward a family as an opera, vocal, and
instrumental band, turned his head and his purse inside out;
in short, he soon became a bankrupt, feuded in indigence
during the rest of his life; and his colleagues, though they
escaped utter ruin, were not enriched by the connivance.

Gordon, Alexander, a learned writer of the eighteenth
century, was a native of Scotland. He was well acquaint-
ed with the Greek and Latin languages, and being a good
draughtsmen, he was enabled to derive peculiar advantages
from a long residence in Italy, and from his travels in other
parts of Europe. He was engaged as secretary to the so-
ciety for the encouragement of learning; and to the Egy-
pitian club, and to the Antiquarian society. He afterwards
accompanied governor Glen to Carolina, where he occupied
various posts in the province, and received a handsome grant
of land. Here he died, leaving a good estate to his family.
He was author of "Itinerarium Septentrionale, or a jour-
ney through most parts of Scotland, illustrated with copper
plates. This was published in 1726, and in 1732 he gave
additions and corrections to it, containing an account of
Roman antiquities in Scotland, and ancient monuments in
the north of England. He wrote likewise "The Lives of
Pope Alexander VI., and his Son Caroli Leprena."
"A
complete History of ancient Amphitheatres, translated from
the Italian."
"An Essay towards explaining the hiero-
lyphical Figures on the Coffin of a Mummy."
"Twenty-five
Plates of all the Egyptian Mummies in England, and other
Egyptian Antiquities."

Gordon, Andrew, was born in 1712 near Aberdeen.
He was sent to Ratibon, where he applied himself to poeti-
literature. In 1731 he made a tour through Austria, Italy,
and France, and on his return in the following year entered
into the order of the Benedictines in the Scots monastery,
where he applied to philosophy, and was ordained priest.
In 1735, he went to Salzburg to study the law, and he at-
tended the theological lectures till he was invited, in 1737,
to be professor of philosophy at Erfurt. His discoveries in
electricity made his name known to the philosophers in
Holland, France, Italy, and England, and he is mentioned by Dr.
Priestley as the first person who used a cylinder instead of a
globe in electric experiments. His first work on this sub-
ject was entitled "Phenomena Electricitatis Expound,"
1743; and in the following year he published in 3 vols.
Svo. "Philosophia utilis et jucunda." He was author of an
"Impartial Account of the Origin of the present War in
Great Britain," and of "Physica Experimentalis Ele-
ments."

Gordon, James, a Scotch Jesuit, was born in the year
1743. He left his native country, and went to Rome,
where he entered the society of Jesus, in 1753. He became
distinguished for deep and extensive learning, and was sent
on religious missions into Germany, Denmark, and the Bri-
tish isles, where he is said to have founded much on account
of his attachment to the Catholic faith. He died at Paris
in 1762, leaving behind him a work in two volumes Svo.
titled "Controversiarum Christianae Fidei Epitome."

There was another Scotch Jesuit of the same name, and
contemporary with the above, who wrote a commentary on
the whole Bible, which he published at Paris, in three vol-
umes folio, under the title of "Biblia sacra, cum Commen-
taria ad fumum Literae, et explications Temporum, Locali-
rum, Rerumque omnium, quae in sacris Codicibus habent ob-
seuratam: una cum Textu Biblico." This work is well
spoken of by Dupin. He was author likewise of a work on
Chronology: and of "A System of moral Theology." &c.
Roreri.

Gordon, Thomas, a native of Kirkcudbright, in Scot-
land, after having received an academical education in his
own country, came to London, and maintained himself by
teaching the learned languages. His talents were made
known to people of confection, and he was employed by
the earl of Oxford in queen Anne's reign as a political
writer. He wrote in defence of bishop Bradshile in the
Bangan controversy, and became the agent and partner of
Mr. Trenchard, in his literary undertakings. They pub-
lished, in conjunction, a series of papers, entitled "Cato's
Letters;" and the "Independent Whig," which M. Gor-
don continued alone after the death of Trenchard. When
this event took place, sir Robert Walpole engaged Gordon
as one of the writers in defence of his measures, and pre-
cured him a place, which he held as long as he lived. Mr.
Gordon made himself known by translations of Tacitus and
Sallust, as well as by his political pieces. To these trans-
lations he prefixed discourses relative to subjects of each or-
iginal author. He died in 1759, at the age of sixty-five.
Some of his posthumous tracts appeared in two works,
titled "A Cordial for Low Spirits," and "The Pillars of
Priestcraft and Orthodoxy shaken." He was a distinguished
writer in favour of civil and religious liberty, and is highly
esteemed.
GOR

eoine by the friends of freedom for the manly spirit with which he supported its cause against tyranny of every kind.

Gen. Bract.

GORDONA, in Geography, a town of Naples, in the county of Milef; six miles S.W. of Milef.

Gen. Ch. Cal. Persian, simple, inferior, of five roundish, concave leaves. Gor. Petals five, large, obsolete, or obcordate, concave, cobering at their base, somewhat unequal. Stam. Filaments very numerous, thread-shaped, united at their base into a thick cup-shaped body; authors oval, erect. Pet. German superior, ovate or nearly globose; style short, columnar, obtusely five-fused, sometimes five-cleft; stigma five, acute, horizontal; Peric. Capsule ovato or globular, of five cells and five valves, the partitions from the middle of the valves, which are deeply cleft at their base. Seed in two rows in each cell, angular, winged, inserted into a five-clefted angular column.

Native of swamps in South Carolina, where it forms a very handsome tree, but is with great difficulty cultivated in England. It blooms in August and September. We have seen this plant flowering in great perfection at Kew 25 years ago. The leaves are scattered, on short flalks, elliptic-lanceolate, three to five inches long, bluish, with numerous shallow furrows, veiny, smooth on both sides, of a thin shining green, like those of Prunus Laurocerasus above, paler beneath. Stipulas none. Flowers solitary or simple axillary flalks, thrice as long as the footflalks, as large as a moderate rose, white with yellow stamens, very handome but indorosum. A pair of deciduous fringed bracteas, a little below the flower, are called by Cavanilles an outer calyx. Authors have differed about the clafs of this plant in the Linnaean system, the flalks cohering imperfectly and irregularly together in parcels, besides being connected by one common flaky base. If this base be called a notary, for which there is no good reason, then the flower is polydelphous, but we think, with Dr. Sims, and most others, that it is monodelphous.

2. G. Hematophyllum. Swartz. Ind. Oct. 1199.—Blood-red Wood Tree.—Flower-flalks very short. Leaves elliptic-lanceolate, pointed, serrated, smooth. Petals inveredly heart-shaped. Style deeply five-cleft.—Native of dry woody places on lofty mountains, in the west side of Jamaica; Dr. Swartz, from whom we have specimens. A tree, whose stem is from twelve to sixteen feet high, with a smooth greyish bark, and round slender straight compound leafy branches, Leaves two or three inches long, foliiferous, elliptic-lanceolate, tapering at both ends, with a blintith recurved point, smooth on both sides, little coriaceous than in the former, their margin somewhat revolute, with numerous shallow ferratures. Flowers from the bosoms of the upper leaves, solitary, on very short flalks, not so long as the footflalks, bearing one or two unequal brackeas; their petals pale flesh-coloured, unequal, deeply lobed, feecly so large as those of G. Lafianthus, but flatter and more spreading. Germes silky, ferrowed. Style, according to Dr. Swartz, divided into five. Capsule oblong, rather pointed. Seeds two in each cell, with an abrupt wing.—This tree was omitted by Dr. Swartz in his Prodromus, and is little known to botanists, having never yet been brought to Europe. It flowers in February and March. The wood is hard and of a blood-red, valued in Jamaica for making ornamental furniture, but as yet no known, or not distinguished, by European workmen. The peculiar structure of the style does not constitute any generic distinction here, any more than in the neighbouring genus Stauraitis. See Sm. Exot. Bot. v. 2. 101.

3. G. pubescens. L'Herit. Stirp. Nov. 156. Cavan. Diff. t. 162. Vent. Jard. de la Malmaison, t. 1. —Flowers nearly sessile. Leaves downy beneath. Capsule globose.—Native of South Carolina, now not uncommon in green-houses, flowering in August. A handsome fern, whole branches, calyx, and the backs of its leaves, are clothed with fine white pubescent down. The flowers most a flable to the fruit in the first, but it is not a herbaceous plant that can anywhere be seen, except that the French mode of printing in colours gives indifferently an idea of a downy surface, so that in this case both sides of the leaves look alike.

4. G. Franklinii. L'Herit. Stirp. Nov. 156. (Franklinia Alatamaha; Marshall. Arb. 49.)—Flowers sessile. Leaves smooth. Capsule globose.—Native of South Carolina. Flowers sessile, solitary, large, white, very much admired in their native country, but we have not heard of their being produced in Europe, nor have we seen a dried specimen. The capsule, according to L'Heritier, is "globose and umbilicated. Seeds numerous in each cell, imbricated in two rows, slightly angular, much like those of the Cypres, the angles somewhat bordered. Leaves alternate, on short foot-flalks, oblong, toothed, attenuated at the base, and smooth."—Marshall and Bartram say the flowers smell like a china orange, and are often five inches in diameter, the lower petal hollow, enfising the roll till they expand, as in G. pubescens. It was first observed by Mr. John Bartram in 1760, on the borders of the Alatamaha river, in Georgia.

GORDYGONG, in Geography, a town of Hindooflan, in Vifapur ; 22 miles N.E. of Poonnah.

GORE, in Heraldry, deserves one of the regular abate- ment. It is used, according to Guillim, to denote a coward. It consists of two seven-rays on both sides, drawn from the outer chief, the other from the outer bow, and meeting in an acute angle in the middle of the sable point.

GOREE, or GOFRE, in Geography, an island in the German ocean, near the mouth of the Mask to 15 miles in circuit; two miles N. of Schouwen. Nat. lat. 51° 49°

E. long.
GOR

E. long. 3° 50'.—Algo, a sea-port town of this island, near
the E. coast, on a canal communicating with the Meuf; for-
merly carrying on a considerable trade, but the harbour
is now choked with sand ; 6 miles W. of Helvoëtsluys.

GORE, a small island in the Atlantic, within camou-
flage of the coast of Africa, about two miles in circum-
ference. The air is cool and temperate, being refreshed by
alternate breezes from the land and sea. It is almost inaccessible
on account of its surrounding rocks; but it has two bays, and
a fort with several new buildings constructed by a late director
M. de St. Jean, who has also rendered it a very strong place.

By his perceiving the fertility of the soil, the springs of fresh water
have been discovered, and a variety of vegetables and fruit trees have
been planted; so that the island, once barren and despicable,
now makes the most fertile, pleasant, and important settle-
ings in Africa. Gore was ceded to the Dutch in 1617
by a king of Cape Verd, and by them fortified. The Dutch
were driven out by admiral Holmes in 1663, and the island
was garrisoned by the English. It was two years after taken
by De Ruyter, and its fortifications augmented by the
Dutch; but in 1667 a French squadron compelled the Dutch
to abandon Orange fort, and retire to fort Nafjau; but
here, incapable of defending themselves, they were obliged
to surrender at discretion. Upon the arrival of M. du
Caffes, the island was formally taken possession of in the name
of the Senegal company, and a treaty was concluded with the
king and negroes of the neighbouring country on the same
conditions with those by which the Dutch had possessed the
island. The conquest was secured to the company by the
league of Nimeguen. The French immediately repaired
the forts, and changed their names, calling the lower fort
"Vermandaine," and the higher "St. Michael." In 1759
Gore was taken by the English. By the treaty of 1753
Gore and its dependencies were left to the French. In
1778 it was taken by the English. N. lat. 14° 40'. W. long.
17° 30'.

GOREG, a small island on the coast of Brazil, at the
mouth of the Rio dos Reyes Mago. S. lat. 10° 10'.

GOREING, or Goreg, is said of a fall when cut flan-
ing, so that it is broader at the close than at the earing, as
all top-fails and top-gallant-fails are.

GOREL, a name or title given to the prince of Georgia.
The gorel is always a Mahometan. The sphyra of Persia
obliges him to observe the religion of the Alcoran, in order
to preserve the dignity of gorel in his family.

GORE's BAY, in Geography, a bay on the S.W. coast
of the island of Tavai-Pennamooz. S. lat. 43° 12'. W. long.
186° 36'.

Gore's Island, an island in the N. Pacific ocean, so named
by captain Cook in the year 1778. This is a narrow island,
particularly at the low necks of lands which form a junction
between the islands; it is about 50 miles long from N.W. to
S.E.; and it appeared barren and uninhabited. Some sea-
otters were seen. N. lat. 60° 40'. W. long. 172° 30'.

GORESBRIDGE, a small port town of the county of
Kilkenny, Ireland; 51 miles S.W. from Dublin, on the road
to Waterford.

GOREY, a port town of the county of Wexford, Ireland,
also called Newborough, which, before the Union, was re-
membered in parliament. It is 45½ miles S. from Dublin, and
21 N. from Wexford.

GOREY-MOUNTAINS of Ireland, in the county of Donegal,
near Raphoe.

GORGES, a town of Mingrelia, on the Black sea; 50
miles S. of Anargria.—Algo, a river of Naples, which
runs into the Liban, in Calabria Citera.

GORGE, in Falconry, is the uppermost bag or stomach
of a hawk or falcon, being that which receives the food the
bird.

The gorge, ingluvies, is the same, in birds of prey, with
what we call the crop or crop. When the bird is fed, it is
said to be gorged.

GORGE, in Architecture, denotes a sort of concave mod-
elling, wider but not so deep as a festoon; used chiefly in stanes,
chimneys, &c.

Gorge of a Chimney, is that part between the chambranle
and the crowning of the mantle. Of this there are divers
forms; straight, perpendicular, in form of a half, &c.

Gor od sometimes also used for a moulding that is con-
cave in the upper part, and convex at bottom; more pro-
perly called guila and cymatium.

Gorge is also used for the neck of a column; more pro-
perly called colonum and gorrerin.

Gorong, in Fortification, the entrance of a Bastion, or of a
Ravelin, or other Outwork. See each article.

The Gorge of a Bastion is what remains of the sides of the
polygon of a place, after retrenching the curtains; in which
case it makes an angle in the centre of the bastion.

In flat bastions, the gorge is a right line on the curtain,
reaching between the two flanks.

Gorong of a Half moon, or Ravelin, is the space between
the two ends of their faces next the place.

Gorge of the other outworks is the interval between their
sides next the ditch.

All the gorges are to be made sufficient of parapets;
otherwise the besiegers, having taken possession of a work,
might make use thereof to defend themselves from the foot
of the place: so that they are only fortified with palisades,
to prevent a surprise.

GORON, Half the Gorge, demi-gorge, that part of the poly-
gon between the flank and the centre of the bastion.

GORGED, in Heraldry, is when a crown, coronet, or the
like thing, is borne about the neck of a lion, a swan, &c.
In that case they say, the lion or cygnet is gorged with a
ducal coronet, &c.

Gorong is also used when the gorge or neck of a peacock,
swan, or the like bird, is of a different colour or metal
from the rest.

Gorong, among Fortresses, &c., signifies as much as swell-
d. In which sense they say, "the legs of an horse are
gorged;" the pattern joint is gorged; you must work him out,
to disgorge his shoulder.

Gorong, in Rural Economy, a term which is sometimes
applied to signify being laden by fresh luxuriant green food,
and relates to cattle, &c.

GORGEM, a part of the ancient armour, being that
which covered the throat or neck of a person armed at all
points.

GORGEM, or Gorge, in Architecture, the little freeze in
the Doric capital, between the astragal, at the top of the
shaft of the column, and the annulet.

Some call it collars. Vitruvius gives it the name hypa-
trachelion.

GORGE, in Military Affairs, a piece of brass or filter,
borne by the officers of foot on their breasts when on duty.
The gorge hanges round the neck by a riband; they are
sometimes gilted, and have commonly some device engraved
on them, as the sovereign's, or even the colonel's coat of
arms, crest, or cypher.

Gorong, an instrument used in Surgery, for the purpose
of cutting an opening into the bladder, so as to enable the
operator to introduce the pair of forceps and extract the
stone.
GOR

It is impossible to give the reader a proper notion of the form and manner of using the gorget, without presenting him with engravings of the instrument, and entering into a description of the operation of lithotomy. Hence, we must at present content ourselves with referring to the surgical plates, and the article Lithotomy.

Besides cutting gorgets, contrived for the above design, there are also blunt ones, intended to be introduced into the wound, when their concavity serves as a guide for the forceps into the bladder.

The employment of gorgets for the performance of lithotomy has been objected to by several eminent surgeons of the present day, particularly by Mr. John Bell of Edinburgh. (See his Principles of Surgery, vol. 2.) We have seen the operation most easily executed by means of a common scalpel. Mr. Ayley Cooper uses, instead of a gorget, a common scalpel with a beak, which glides along the groove of the staff into the bladder. Several other knives and instruments have been at different times invented to supersede the gorget. The principal ones will be represented in the surgical plates, and due notice will be taken of them in the article Lithotomy.

GORGIA, surnamed Leontius, in Biography, born at Leontium in Sicily, from whence he derived his second name, was a celebrated orator and learned sophist, who flourished in the fifth century before the Christian era. He was a disciple of Empedocles, and is reckoned one of the earliest writers on the art of rhetoric. He is thought to have introduced numbers into prose, treated of common places, and shewed the use of them for the invention of arguments. Hence Plato gave the name of Gorgias to his elegant dialogue on this subject, which is still extant. He was so great an orator, that in public assemblies he would undertake to declaim extempore upon any subject proposed to him. In the war between Syracuse and Leontium, the citizens of the latter applied to the Athenians for succour, and employed Gorgias and Thras as their ambassadors, the former of whom was peculiarly qualified to influence popular assemblies by his bold and persuasive eloquence. On their arrival at Athens about the year 427 B.C., Gorgias made an oration to the people on the grievances which their countrymen suffered from the people of Syracuse, and the advantages which would accrue to them from sending a powerful army into Sicily, by which he persuaded them to rush headlong into a war, that proved in the end more fatal to them than any in which they had engaged. Afterwards he made a display of his eloquence at the Olympic and Pythian games, on account of which a golden statue was erected to his honour at Delphi. He is said to have lived to the great age of 107 or 108.

GORGONIA, in Geography, a town of Naples, in the Basilliaca; 15 miles E. of Venusia.

GORGONIA, an island of small extent and of a circular form, in the Mediterranean, about 16 miles from the coast of Etruria. The mountains, say Sommii, seem to be of the same nature with those of the continent. This island is famous for the anchovy fishery on its coasts. N. lat. 43° 22'. E. long. 9° 56'.—Alto, an island in the Pacific ocean, about 18 miles from the coast of Peru, about 16 miles in circumference. N. lat. 3° 36'. W. long. 77° 52'.

GORGONIA, in Zoology, a genus of Zoophytes, the stem of which is coraceous, woody, corky, horny, or somewhat bony, and in general flexible; the texture glaffy, fibrous, or like bone, frilled, tapering, fixed at the base, which is dilated, and covered with valvular or cellular flesh, or bark of a spongy and friable nature in a dried state; the mouths or cells covering the surface of the stem and bearing polypies.

These marine productions were regarded by the ancients as a class of plants, and described as such by their hotanists; nor was this idea, however remote from truth, exploded till fo late a period as the eighteenth century, when the discoveries of Peyssonel upon the nature of coral, published in 1772, and those of Trembley on the hydras (or polyps) about fourteen years after, contributed to demonstrate, in a very explicit manner, that the gorgonia in common with other zoophytes (as these particular bodies are now denominated), do not appertain to the vegetable, but animal kingdom, or are at least the fabrication and genuine habitations of animals.

Among the various observers of this curious order of animal productions, few, if any, have pursued their investigations with greater discrimination and success than professor Pallus, or our own countryman Ellis, and his friend Dr. Solander; nor indeed can we hesitate to confess, that our knowledge of the gorgonia tribe has been enlarged only in a very inconsiderable degree by any of the fabricant authors on this subject. The latest observations tend principally to confirm the accuracy of those writers who had before affurred us the gorgonia are the habitations of various kinds of polyziferous animals, each of which resides in a distinct cell; that they lie in general dormant or contracted during winter, and, like the blossoms of plants, push forth buds, and expand in their proper season, which is constantly in summer. The stem and branches of the gorgonia, which are most commonly of a somewhat horny and flexible nature, may be confidered as the true skeleton of the cells of habitations, being covered with a fleathy or pulpous fulfulness, the exterior surface of which is porous. These pores are the mouths or openings of the cells in which the polypes are lodged, and it is the number, disposition, and varied stricture of these, in addition to the general aspect of the plant-like neat of habitations, that constitute the most material differences by which the various species are distinguished; the figure of the animal, when it can be ascertained, the secondary or least important character. It may be lusily observed, that the gorgonia differ exceedingly in size, being from one to two, or perhaps three feet in height, while other species in deep bays, and similar situations of the sea, no less favourable to their growth and increase, attain to the gigantic height of ten or twelve feet, and from their number as well as magnitude; their remarkable ramose, and foliated or flabelliform appearance; interwoven structure, and corallike texture, form a conspicuous portion of those vast submarine “groves of coral” that are sometimes seen by navigators in the hotter regions of the globe.

Species.

Native of the Norway seas, from eighteen inches to two feet high; flesh pale, with whitish skin or scales; stem white, with a brown bark and cartilaginous branches.

VERTICILLARIS. Ramose, ramose, with alternate parallel subdivisions, covered with verticillated incurved florets. Müll Pallas, &c. Sea-earther, Ellis.

From two to three feet high; stem brittle and white, with flexible branches. Native of the Mediterranean and North seas.
GORGONIA.

Placomen. Branching both ways, with flexuous, and rarely uniting or anastomosing branches, covered with conic florets. Linn. Warted-fan, Ellis. Lithosyphon, &c. Brey. Height two feet; item ereth, woody, and yellow, scarlet or reddish cinnereous. Inhabits the Indian and European seas. Mollis. Coriaceous, dichotomous, with perpendicular tubular florets. Pallas. Native of the Mediterranean, and about eighteen inches in height, the colour brown violet; item brown; branches long and slender. Succinea. Round, amber-colour, dichotomous, rigid, the item covered with tubercular gaping florets. Pallas. A very rare species, the native place of which is unknown; it is only six inches high, the item teltaceous. Americana. Branched and sub-divided, the sub-divisions nearly opposite, compressed, with rows of polysperous cells on each margin; flesh yellowish, within pale purple; bone hornly. Gmel. Gorgonia pinnata, Soland. and Ellis. Native of the West Indies; flesh purplish or yellowish. Exserta. Round, with a few alternate branches; florets alternate, eight-valved; flesh covered with minute white scales; bone brownish, hornly. Soland. Height two feet; branches long, slender, and white; polypes with eight feelers and exerted. Inhabits the West Indies. Patula. Compressed, with flexuous sub-pinnate branches, crinmon, with two rows of florets each side, each surrounded with a whitish ring; bone brownish, hornly. Soland. Native of the Mediterranean. Ceratophyta. Branched, with divaricate erect sub-divisions, each marked with two furrows; florets white, in irregular rows; flesh purple; bone black and hornly. Gorgonia ceratophyta, Soland. Corallina fruticosa purpurea, C. B. H. Lithophyton, &c. Gecn. Corallina fruticosa erecta, Catenby. Found in the Mediterranean, Atlantic, and South American seas; height twelve inches; flesh bright purple. Juncea. Stem simple, round, and tapering both ways; bone dusky, hornly; flesh orange-colour, with two furrows; florets longish. Soland. &c. Junca lapidei, Phin. Palmjuneae albus, Rumpf. Inhabits the flores of the American islands adhering to stones; height about three feet, and very flexible when alive. Flammea. Compressed, branched, and sub-pinnated; bone flat and hornly; flesh bright red, with minute florets. Soland. and Ellis. A beautiful species, of a fiery red or flame-colour when recent; this kind inhabits the African coast, and appears to be found in molten abundance near the Cape of Good Hope. Unbractrum. Fan-shaped, and somewhat reticulated; branches numerous, divergent and round; flesh reddish, warted or covered with florets. Soland. and Ellis. Native of the Indian sea; item short, rising from a broad base, divided into about two or three branches, the smaller ones rising from which are numerous, and so intimately connected as to form a kind of net-work. Purpurea. Somewhat dichotomous, with divaricated slender branches; flesh violet and sub-veruculous. Pallas. Round, smooth and blackish, with the extremities of the branches yellow. A South American species.

Sasappo. Sub-dichotomous, round, with divaricated slender branches; flesh red, with numerous hairy florets. Pallas. Aescularis sasappo, virga fangium, Rumpf. About twelve inches in length, the texture hornly, and colour black. The bennace is frequently observed adhering to this species. Palma. Flat, with numerous very long and simple divisions; flesh smooth, sprinkled with simple pores. Pallas. Chamerophyla perigrina, Claffus. Grows to the height of six feet, though more commonly not exceeding two or three feet; the substance hornly, covered with a calcareous coating, and flexible. Inhabits the Indian ocean. Radicata. Very much branched, and corycx; with minute scattered pores, and many-feet at the base. Pallas. Seba, &c. Native of the African seas; sub-dichotomous, grey, with branched trunk, and in substance resembling cork. Suberosa. Woody, very much branched, diffuse, the branches compressed and grooved, and covered with sub-fililated scattered pores. Pallas. Height three feet; flesh red, spongy; bone pale red and corycx; branches long, round and erect. Found in the Indian and African seas. Coralloides. Woody, ereth, sub-dichotomous, and variably formed; flesh tuberosus, with filulated tuberculated florets. Pallas. Corallina lignum incrustans, Bosc. Native of the Mediterranean; length one foot, very tough, pale grey, with yellow florets. Elongata. Dichotomous, divaricated, with the flesh red, and covered with papillosus scattered sub-imbricated pores. Gmel. &c. Pale and brittle, with square branches with pores at the angles; grows to the height of four feet, and inhabits the Atlantic. Scirpea. Very simple, straw color, with a decomposite leafy base, and felt tuberculated flesh. Pallas. Fuscous, tapering towards the tip; the flesh cinnereous when dry; inhabits the Indian seas. Setaceae. Simple, rigid, with calcareous white sub-tuberculated flesh. Pallas. Iclis plecanum. Mercat. Native of the American ocean. Viminalis. Very long, depressed, branched, with erect sub-divisions; flesh yellow; florets seated along each margin of the branches, and rather prominent. Pallas. Iclis placentum. &c. Mercat. Height eight inches; branches long and slender; bone blackish and hornly; florets white; the polype furnished with eight feelers or claws. Native of the Atlantic and Mediterranean. Muricata. Round, with depressed sub-divided branches; flesh thick; pores cylindrical and spinous. Pallas, Ellis, &c. Epiceratium, &c. Petiv. Lithophyton, Tourret. Native of the American islands; height from two to three feet; coriaceous, hornly, with a whitish medullary nerve. Verrucosa. Bifarious, with round, sub-dichotomous flexuous branches; flesh calcareous, pores whitish and prominent. Pallas, Ellis, &c. Lithophyton marinus, Gecn. Corallina alba marina, C. B. H. Frutus marinus flabelliformis, &c. Ray. Frutus marina, &c. Petiv. Inhabits the West Indian, Mediterranean, and rarely the British seas, adhering by the broad base of the principal trunk to the rocks, and rising to the height of twelve or fifteen
fifteen inches, and sometimes rather more, in a fan-like form; colour when dry greyish-white; bone of a texture between horn and wood.

Grows to the height of two feet, and inhabits the Indian and Mediterranean seas. This is the black coral of the shops.

**Nobilis.** Dichotomous, the branches somewhat tapering; flesh red, flabby, and felt; the surface speckled with numerous eight-angled, conic, and rather elevated, irregularly disposed pores; bone bright red, frutted, and slightly punctured externally. Soland, and Ellis, &c. *Plagophyllum,* Linn. Nat. XII. *Medieus maris,* Linn. Nat. Nat. X. *Ipsi Pallas.* Corallium sagrum, Donn. Red coral, Ellis.

The bone of this species constitutes that beautiful and much esteemed marine production, the red, or true coral of the jewellers. The coral is a general inhabitant of the Mediterranean, Adriatic, and Red seas, and appears to be no where more abundant than in the seas about Madeiras, Corse, Sicily, and the coast of Africa, in the vicinity of Barbary, the coral fisheries in these parts being carried on with great spirit, and proving highly lucrative. From the observations of Donini, an author who has devoted much attention to this curious subject of enquiry, we understand that the flesh or exterior coating of the coral is of a red colour, varying from bright to paler hues, the tint of which is uniformly less brilliant than that of the bone or coral itself. The most prevalent colour of the bone is red, exhibiting all the transitions from a pale rose colour to fine scarlet; and sometimes inclining to yellowish or fine saffron. The coral grows in a shrubby form, and not unfrequently in an inverted form, to the height of a foot or eighteen inches, which latter it rarely exceeds; nor is the circumference of the largest branches more than one inch.Externally the surface is frutted, more or less nodulous or warted, and the substance when broken appearing composed of a number of concentric layers. The coral of this species is equal in hardness and durability to the most compact marble, and the material qualities; in addition to its beautiful texture or grain, and colour, have contributed to render it valuable in the estimation of the world from the earlier ages, as we learn from Pliny, and other writers of remote antiquity. At this day the true coral bears a considerable price throughout the East as well as in Europe; its supposed medicinal virtues have, however, fewer votaries at present than formerly. The polypes, by which the cells are occupied, are furnished each with eight arms or tentacula, in the centre of which the mouth is situated; these arms are retractile, contract immediately on being touched; the cells or pores are filled with a white liquor, and the polypes are likewise white.

Inhabits the American, and some of the European seas; height nearly two feet; bone roundish, tapering to the ends, and violet when recent.

**Crassa.** Round, dichotomous, with long, thick, divaricated, erect branches; flesh thick, violet, with small prominent, approximate, equidistant pores; bone dark brown and horny. Soland, and Ellis.

Native of the American seas.

**Pinnata.** Rather compressed and pinnated, with very simple compressed branches; flesh red with oblong pores. Linn. *Palma sagita,* Theophr. *Lithoscylen, Brow.

Grows to the height of one to four feet; the texture horny and brown, the branches yellowish. Native of the African and North seas.

**Sanguinolenta.** Depressed, very ramose, and pinnated; flesh yellow, with purple pores in double rows. Pallas. *Lithophyton flavum pallidum, Tournef.

Native of the Atlantic and Mediterranean seas; height one foot.

**Violacea.** Rather depressed, with pinnated branches; flesh violet; nearly square, with somewhat prominent pores. Pallas. *Quercus marina, Theophr.

Inhabits the American seas, above a foot long, and horry.

**Setosa.** Round and pinnated, with diffuse branches; flesh purplish. *Antipathis hirsutum, Bon. Lithophyton, Tournef.

Grows to the height of two feet; very upright, and inhabits the Mediterranean and American seas.

**Petechizans.** Sub-dichotomous, very much branched, with a yellow hirsute flesh covered with red pores. Pallas. Gmel. &c.

Native place unknown; bone hornv, black, with amber-coloured ramifications.

**Pectinata.** Round, with parallel ascending simple branches; flesh red, with gibbous scattered pores; bone white, hard, and brittle. Gmel.

Very rare, white, with red flesh; found in the Indian ocean.

**Austera.** Ramose pinnated; flesh yellow, with rows of purple florets each side; bone horny and yellowish. Soland, and Ellis.

Native of the African shores, and seldom exceeds a foot in height.

**Calycifera.** Dichotomous and subdivided, with erect thick ramifications covered with truncated papillae; flesh cinereous, within purplish; cells large and cup-shaped; bone dark brown and horry. Ellis.

Inhabits the American seas.

**Briareus.** Subramose, round, thick; flesh pale or whitish within, externally cinereous; bone composed of small purple glairy needles, irregularly and closely disposed longitudinally. Soland, and Ellis.

Cells large, prominent, numerous, and irregularly disposed; the species inhabits the West Indies.

Black or brown; the species inhabits the Indian ocean.

**Reticulatum.** Reticulated, branches with very close and round ramifications, and red tuberculated bark.

Very ponderous, of a grey colour, and inhabits the Indian ocean.

**Clathratus.** Reticulated, wobby; with round ramifications; flesh smooth with simple pores. Pallas.

Native place unknown; about eight or ten inches in height, pale, with a thin reddish-grey flesh.

The bone is black, horry, and slightly frutated on the larger branches.

Found adhering to various substanccs, and varying in colour
colour from yellow to purple: this species inhabits most
feas.

GORGONIUM, in Botany, a name given by some authors to the common crypgium or crynugo, the roots of which we use candidly.

GORGONS, in Antiquity and Mythology. Authors are not agreed in the account they give of the Gorgons. The poets represent them as three sisters, whose names were Stheno, Euryale, and Medusa, the daughters of Phorcus by Ceto; the latter of whom was mortal; and having been delivered by Neptune, was killed by Perseus; the two former were subjected neither to age nor death. They are described with wings on their shoulders, with serpent round their heads, whose heads were of brazen, and their teeth of a prodigious size; so that they were objects of terror to mankind. Echyleus, in his Pindar, adds, that they had but one eye and one tooth among all the three, which they made use of one after the other, and that they killed men with a single glance of the eye.

Pindar (Pyth. 12.) improves upon Echyleus, and heightens the fable by these circumstances, unknown to his predecessors. The first is, that the Gorgons turned those into serpents whom they looked upon, and that it was by this kind of death that Perseus, in preparing Medusa's head, destroyed the island of Seriphus, whose inhabitants he perpetrated, together with their king. The second is, that Minerva, who aided Perseus while he was struggling with Medusa, being surprised with the melody of the Gorgons' sighs, intermingled with the hislings of their serpents, felt certain charms on that mixed composition of dolorous accents; and to renew the idea of the harmony, she invented a flute in imitation of it, which she imparted to men; and in allusion to its first model she called the various sounds it produced "a Harmony with many heads." The third is, that Pegasus, whom Hesiod represents as having taken flight to the mansion of the gods, was afterwards broken by Minerva, and given to Bellerophon, who mounted him to combat the Chimæra; but that he having attempted to ascend to heaven on the wings of that horse, was thrown down to the earth, and Pegasus placed among the stars. (Pindar's OI. III. Pyth. VII.) The Latin poets, though faithful copiers of the Greek ones, have yet loaded the fable of the Gorgons with new circumstances. Homer had said, that the Gorgon's head was engraved upon the tremendous Eglys of Minerva; Virgil adds, and upon her cuirsia too, in the place which covered the goddess's breast:

"— Ipsanque in pelfore Divi
Gorgonae deicta vertem lumina colla." Æn. I. viii.

After the death of Medusa, her sisters, according to Virgil, were appointed to keep the gate of the palace of Pluto:

"Multae praeter caue variauis monitra ferarum —
Gorgones, Harpapheae——" Æn. I. vi.

Ovid of all the poets has more enlarged upon the fable of the Gorgons, and added several particulars which are only found in his Metamorphoses, I. iv. and v.

Diodorus Siculus will have the Gorgons and Amazons to have been two warlike nations of women, who inhabited that part of Lybia which lay on the lake Tritonis. The extermination of these female nations was not effected till Hercules undertook and performed it.

Paulusinus says, the Gorgons were the daughters of Phorcus, probably by mistake for Phorcus; after whose death, Medusa his daughter reigned over the people dwelling near the lake Tritonis. The queen was passionately fond of hunting and war, so that she laid the neighbouring countries quite waste. At last, Perseus having made war on them, and killed the queen herself, when he came to take a view of the field of battle, found the queen's corpse so extremely beautiful, that he ordered her head to be cut off, which he carried with him to show his countrymen, the Greeks, who could not behold it without being struck with astonishment.

Others represent them as a kind of wonderful women, covered with hair, who lived in woods and forests. Others, again, make them animals, refreshing wild sheep, whose eyes had a poisonous and fatal influence.

Xenophon of Lampactus, who is followed by Pliny and Solinus, was of opinion, that the Gorgons were female faeries, who inhabited the islands Gorgades. Hanno, the Carthaginian general, penetrated as far as those islands, where he found women, who, in swindles, turned the flight of birds. Gerard Vossius, in his "Origin and Progress of Idolatry," is persuaded, that the fable of the Gorgons took its rise from the relation of Hanno the Carthaginian general, above cited, from Xenophon of Lampactus. Le Clerc, on the contrary, in his notes upon Hesiod, takes them for the mares of Libya, which the Phœnicians in a voyage to Africa had taken away. Banier (Mythol. vol. iii.) is of opinion, that the Gorgons dwelt in that part of Libya, which was afterwards called Cyrenaicum; and that Phorcys, their father, had conquered Ithaca, which was not far from the coast of Africa, where he resided. It is not incredible that this prince would employ his fleet in carrying on an advantageous trade, and that Polydeuces, king of Seriphus, in order to get rid of Perseus, gave him some ships for the purpose of pirating on the coasts of Africa. Perseus accordingly, thus equipped, sailed from the isle of Seriphus for the coast of Libya, and having fallen in with the fleet of Phorcys, made himself master of some of his ships and a part of his riches. These ships, it is said, bore the names of Medusa, Stheno, and Euryale. They were loaded with the teeth of elephants, the horns of stags, and the eyes of hyenas, which Phorcys bartered for other goods. This, it is said, is the mystery of the tooth, horn, and eye, which the Gorgons bartered by turns; that is, the ships, when arrived in the port, took each of them goods proper for the place where they were bound. The other fiction, that accompanies this history, says the author now cited, will explain themselves.

For a farther account of them, see Mem. Acad. Inscript. vol. iv. p. 72. seq. See Musaena caput.

GORGONZUOLO, in Geography, a town of Italy, in the department of the Oltro; 10 miles N.E. of Milan.

GORGORA, an isle of Abyfes, in the lake Dombes (which see), where a palace was built, which is the usual residence of the emperor in winter.

GORHAM, a post town of America, in Cumberland county and state of Maine, on the N.E. side of Saco river, 130 miles N.E. from Boston; incorporated in 1764, and containing 2053 inhabitants.

GORITZ, or Gonn, in Geography, a country of Germany, in the circle of Augsburg; bounded to the N.E. and S. by the duchy of Carinthia, and on the W. by the Venetian states. The chief produce of the country consists in wine and fruit, with some corn and silk; the horses and oxen are
few, but the goats are numerous. The language of the country is Scavonian, and the religion Roman Catholic.

Goritz, or Goritz, a town of Germany, situated in the above-mentioned country, and divided into Upper and Lower towns; the former is ancient, seated on a mountain, and defended by a castle; the latter is situated on a plain on the river Lisono. Besides the church, since the year 1784, not metropolitain, it has seven convents, nine chapels, and a college. In 1797 it was taken by the French: 20 miles N.N.W. of Trier. N. lat. 46° 5'. E. long. 13° 33'.

Goritz, a town of Brandenburg in the New Mark, seated on the Oder, formerly the metropolis of the circle of Lobs.

Gorka, a town of Hindostan, in Mewat; 12 miles S.S.W. of Cottibah.

Gorkah, a town of Afn, situated in the N.E. part of the small state so called, on the borders of Napaul; 35 miles N.W. of Catmandu. N. lat. 28° 25'. E. long. 84° 36'. The country lies between the provinces of Oude and Thibet, and is governed by a raja dependent of Thibet.—Alto, a town of the duchy of Warsaw; 40 miles S. of Posen.

Gorleus, Abraham, in Biography, a celebrated medallist, was born at Antwerp in 1549. He devoted himself entirely to the collection of ancient medals, seals, rings, and other curiosities. He died at Delft, where he spent his greatest part of his life, in the year 1609. His works are entitled "Dactylythone Teum Annumorum Sigillorumque e Ferro, Aut Argento, atque Auro Promptuarium"; "Theaurorum Numismatum familium Roman." "Paralipomena Numismatum." His works are highly valued by those who are addicted to these studies. Moreri.

Gorlitz, in Geography, a town of Upper Lusatia, seated on the river Neisse, and the first town in the country with regard to fire, population, and wealth. Within the walls it has three churches, and as many without. The principal trade is brewing, with woollen and linen manufactures. 50 miles E. of Dresden. N. lat. 51° 9'. E. long. 15° 32'.

Gorochovetz, a town of Russia, in the government of Vladimir; 32 miles E. of Vladimir. N. lat. 56° 10'. E. long. 42° 32'.

Goroditsch, a town of Russia, in the government of Penza; 32 miles S.E. of Penza. N. lat. 53° 20'. E. long. 45° 30'.—Alto, a town in the government of Kiev, 312 miles S.E. of Kiev. N. lat. 49° 3'. E. long. 32° 54'.—Alto, a town in the government of Tobolsk, 20 miles E.S.E. of Enieffik.

Gorodnia, a town of Russia, in the government of Tver, on the Volga, 23 miles E. of Tver.

Gorodntsew, a town of Russia, in the government of Tchernigof, on the Snov; 32 miles N.E. of Tchernigof.

Gorodok, a town of Russia, in the government of Polotsk; 36 miles E. of Polotsk. N. lat. 55° 36'. E. long. 29° 54'.

Gorod, a town of France, in the department of Mayenne, and chief place of a canton, in the district of Mayenne; 9 miles N.W. of Mayenne. The place contains 1800, and the canton 12,723 inhabitants, on a territory of 200 kilometres, in 11 communes.

Gorce, a small island in the East Indian sea; 20 miles S. of Gollbi. S. lat. 1° 8'. E. long. 128° 33'.

Gornouale, or Gorontano, a town on the E. coast of the island of Celebes.

Gorreta, a town of Hindostan, in Berar; 24 miles W. of Chandon.

Gorris, John, in Biography, was born at Paris in the year 1535. He took the degree of doctor of physic in that city about 1540, and was appointed dean of the faculty in 1548. He is said to have polished both the learning and pedantry requisite to form an accomplished physician, and to have practised with great humanity and success. His works contributed to support this reputation. The greater part of them consists of commentaries on different portions of the writings of Hippocrates, Galen, and Nicander. During the civil war, which was fatal to numerous men of letters, John de Gorris was stopped by a party of soldiers, when on his journey to Melun to visit the bishop of Paris, and the fright which he sustained is said to have deprived him of his reason. This occurred in 1561, and he lived many years in this deplorable condition, having died at Paris in 1577, at the age of 72.

His father, also John de Gorris, was a physician at Bourges, attained considerable eminence, and left two works, one on the general "practise of medicine," dated 1555; the other, a "collection of formularies," 1562, both in Latin. Eloy Diet. Hill.

Gorriti, in Geography, a small island in the river La Plata.

Gorsa, a small island near the S. coast of Cuba. N. lat. 21° 45'. W. long. 81° 25'.

Gorse. See Purze and Ulex.

Gorsiho, in Geography, a town of Sweden, in Helsingland; 30 miles W. of Hudikswall.

Gort, a small town of Ireland, in the county of Galway. It stands on an eminence, and is a dirty straggling town, but can boast of a few good houses. Adjoining to it are the ruins of a castle, and near it is Kilmacough, the site of a bishop. Gort is 68 miles W. from Dublin.

Gorter, John, in Biography, a physician, who, after having been a disciple of the celebrated Boerhaave, became a distinguished teacher of medicine at Harderwick, his native place; in consequence of which he was elected a member of the academies of Petersburg, Rome, and Haerlen, and obtained the title of physician to Elizabeth, empress of all the Russias. He was the author of several works, which are written with excellent method, and contain many interesting and original observations. He died on the 11th of September, 1762, at the age of 74.—His works, the titles of which are enumerated by Eloy, relate to physiological and practical subjects, as well as to the practice of the ancients. Eloy. Diet. Hill.

Gen. Ch. Common calyx of one leaf, inbricated with spinous flakes, the innermost gradually longer, straight, bristle-shaped, rigid. Cor. compound, radiated. Florets of the common species, pericarp, with a funnel-shaped five-lobed corolla; that of the radius fewer, female, with a flagellum lanceolate one. Stam. (in the perfect florets only) Filaments five, short; anthers united into a cylindrical tube. Piff. (of the perfect florets) German hairy; style thread-shaped, the length of its own little corolla; stigma cloven. In the female florets the german is obsolete and abortive; style none; stigma none. Petio. none, except the calyx, falling off.

All the plants ranged under this genus are natives of the Cape of Good Hope. In the 2d edition of Linnaeus’s Species Plantarum, where it first appears, are five; *pennisetum*, *jacq.*. *Plantarum* v. 4. t. 21. f. 1; *rigens*, Curt. Mag. t. 92; *squarrosa*, *ciliata*, and *fruticosa*. The latter is the same plant as *G. affinis*, Linn. Suppl. 381, but different from *Atriplex hoffmanniana*, under which it is quoted in Syll. Veg. ed. 14. 730.

The genus thus understood undoubtedly forms a very unnatural arrangement, Linnaeus having chiefly considered the simple-leaved calyx, as Gortyn long ago remarked. Willd.-now accordingly has but seven *Gorteria*, *pennisetum*, *rigens*, and *ciliata* of Linnaeus, with *diffusa*, *gracilis*, *pelatina*, and *helia* of Thouars. Others are feit to his genera of *Myrtus*, whose receptacle is villous, and feed-down formed of simple hairs; and *Berkheya*, whose receptacle and feed-down are chaffy. Among the latter are the beautiful and truly wonderful *G. ciliata*, and the *spinosus*; the latter figured in Jacq. Hort. Schonbr. t. 372. This doubtleas a great improvement, but it seems to us that the genus mull, after all, chiefly depend on *G. pennisetum*, which is an annual plant, of no beauty, with many spreading *flos*, about a foot high. Leaves alternate, spatulate, revolute, pinnatifid or undivided; very white and cottony beneath, and green and brightly, like the *flos*, above. Flowers solitary, terminal, small, yellow, with numerous prominent spines to the calyx. The *flos* are crowned with wool, but have no proper *pappus* or seed-down. The leaves of *G. rigens* bear some analogy with this, but the large orange blossoms, unarmed calyx, and long simple seed-down, urge the propriety of separating it. The latter is Lamarr’s *Gaertneria*, above quoted.

**GORTYNA**, or GORTYN, in Ancient Geography, an inland city of Crete, being, according to Strabo, near 90 furlongs distant from the city of Phaestus, or that part of the Mediterranean which lay the southern part of the island. Its origin is obscure, some ascribing it to Gortyn, the son of Rhamanidus, and others to Taurus, who carried off Europa. In process of time, however, it eclipsed all the other cities of Crete, especially after the island was reduced by the Romans. Of its ancient splendour and magnificence we may form some judgment from its ruins, which are still visible about six miles from mount Ida; though many of them have been carried away by the Turks. In ancient times it was famous for the temples of Apollo, Diana, and Jupiter Hecatombus, so called because Menelas there sacrificed to Jupiter 100 oxen, when he received information of Helena’s flight. Its walls were walled by the river Lethia. Theophrastus, Varro, and Pliny speak of a plane tree near Gortyn, which never shed its old leaves till new ones sprouted forth.

**GORTYNA**, a town of Greece, in the northern part of Macedonia.

**GORUH**, in Geography, a town of Hindooistan, in Bahar; 62 miles W.S.W. of Bahar.

**GORY**, a town of Georgia, in the province of Cardedel, on the Kurr; 45 miles W. of Telhis. N. lat. 41° 55'. E. long. 44° 30'.

**GORZ**, a town of France, in the department of the Meurthe; and chief place of a canton, in the district of Metz; 7 miles S.W. of Metz. N. lat. 49° 3'. E. long. 6° 4'. The place contains 1535, and the canton 14,258 inhabitants, on a territory of 220 kilometres, in 31 parishes.

**GORMEGNO**, a town of France, in the department of the Stura, on the Bormida; 13 miles S.E. of Alba. N. lat. 44° 58'. E. long. 8° 17'.

**GORSKE**, a town of the principality of Magdeburg; 34 miles E. of Magdeburg.

**GOSAYPOUR**, a town of Hindooistan, in Allahabad; 13 miles N.W. of Jumnapur.

**GOSCHGOSCHEN**, a town of America, in the Delaware, confining of three villages situated on the banks of the Ohio. Its name signifies "the habitation of owls," from the number of those birds that resort thereto.

**GOSCHUTZ**, a town of Silesia, in the principality of Oels; 25 miles N.E. of Breslau. N. lat. 51° 23'. E. long. 17° 30'.

**GOSELINI, JULIAN**, in Biography, an Italian writer, was born at Rome in 1525, where he pursued his mature studies in the house of the cardinal de Santa Flora. When he was seventeen years of age he was taken into the service of Ferdinand Gonzaga, then vicerey of Sicily. He accompanied that nobleman to Milan in 1546, and became his secretary, and was afterwards taken to the court of Spain, where he obtained the esteem and favour of Philip II. Under the duke of Albuquerque he was imprisoned on a charge of conspiracy against the life of Giambatista Monti. He vindicated his own cause, was released, and admitted to public employment. He died in 1547, leaving behind him several works, that obtained for him high reputation; of these the principal are, "The Life of Ferdinand Gonzaga," "Three Conspiracies," &c.; "Rime," or a collection of poems, several times reprinted. "Dilecours," "Letters," &c. Bayle.

**GOSFIELD**, in Geography, a township of Essex county, in Upper Canada, situated upon lake Erie.

**GOSHAWK**, in Ornithology, the English name of the *Falco columbarius*; which see.

**GOSHEN**, in Ancient Geography, a territory of Egypt, situated between the Red sea and the Nile, upon the borders of Canaan, not far from On or Hierapolis, which Joseph purchased of Pharaoh for the residence of his father Jacob and family. This was a fertile spot of ground, and fit for cattle; and, therefore, as Josephus tells us, Pharaoh kept his own in that district. It was also separate from Egypt, and therefore fitted for Jacob and his family, which would be out of all danger of interfering with the Egyptians.

**GOSHEN**, in Geography, a township of America, in the county of Hampshire, and state of Massachusetts, between Cummington and Conway; 14 miles N of Northampton; incorporated in 1781, and containing 724 inhabitants.

—as Allo, a township in Vermont, lying partly in Addison county, and partly in Caledonia, adjoining to Salisbury on the west.—Allo, a township in Cheshire county, Pennsylvania, containing 866 inhabitants.—Allo, a town in Litchfield county, Connecticut, famous for the production of excellent chestnuts, containing 1493 inhabitants: 7 miles N.W. of Litchfield.—Allo, the most considerable town in Orange county, New York; about 53 miles N. of New York city; its situation is pleasant, and it contains about 30 or 70 compact houses, an academy, court-house, jail, and Presbyterian church. The township contains 2576 inhabitants.—Allo, a place in London county, Virginia, where is a post-office; 57 miles from Washington.—Allo, a town in Kennebec county, Maine, containing 570 inhabitants.

**GOSVIN CRK.**, a river of New Jersey, which runs into Delaware bay; 17. N. lat. 31° 18'. W. long. 74° 54'.

**GOSCHGOS-**
The world is Saxon, and of the same import with the Latin term evangelum, or the Greek εὐαγγέλιον, which signifies glad tidings, or good news; the history of our Saviour being the best history ever published to mankind. This history is contained in the writings of St. Matthew, St. Mark, St. Luke, and St. John, who, from thence, are called Evangelists. (See each of these articles.) The Christian church never acknowledged any more of these four gospels as canonical; notwithstanding which, several apocryphal gospels are handed down to us, and others are entirely lost.

We shall here subjoin the titles of some of the principal of these apocryphal gospels, as we find them in Jones's Canon, and Lardner's Works, with remarks that will serve to enable us to distinguish them from our four gospels, the authenticity of which is evinced under other articles in this work. (See Bible, Canon, and Testament.) Several of these apocryphal gospels are mentioned in the decree, ascribed to pope Gelasius, in the council of Rome, A. D. 494, which pronounced them to be apocryphal. The gospel of "Andrew the Apostle" is only mentioned in this decree. No fragments of it are extant, nor are there any testimonies concerning it. The gospel of "Apella" is not mentioned by any writer before Jerome, who places it among the apocryphal pieces of the New Testament. Apella was a disciple of Marcion, flourished about the year of Christ 136, and is supposed to have formed this gospel out of the true and genuine gospels for the use of his followers at the close of the second century. The gospel, "according to the twelve apostles," is mentioned by Origen, Ambrose, and Jerome, but they unanimously concur in rejecting it, and in expressly affirming that the church receives only four gospels. Jerome supposes this to have been the same with the gospel according to the Nazarenes. The gospel, "according to St. Barnabas," is not noticed by any of the Christian writers of the first four centuries; nor do there seem to be any fragments extant, that unquestionably belong to it. Mr. Jones apprehends that this was merely some interpolated corrupted gospel of St. Matthew. The gospel of "Bartolomew" is mentioned by Jerome as apocryphal, and Jones, for reasons which he alleges, inclines to think, that it was the same with the gospel of St. Matthew, used by the Hebrews or Nazarenes. M. Daille is of opinion that it was forged but a very little time before Gelasius. The gospel of "Basileides" is named by Origen, Ambrose, and Jerome, among the apocryphal books of the New Testament; but no fragments of it remain. The gospel of "Cerinthus" is mentioned only by Epiphanius in connection with an exposition of the first words of St. Luke's gospel, as many other Christian writers notice the apocryphal books; and it seems probable, from the similarity of the order adopted by Cerinthus and the Ebionites, that the gospel of Cerinthus and his followers were no other than the Ebionite or Nazarene gospel, &c., the gospel of St. Matthew corrupted and interpolated, in Hebrew. The gospel "according to the Egyptians," was one of the most celebrated apocryphal books, and supposed even by several modern critics to have been a faithful compendium of some Catholic Christians in Egypt, before either of the four canonical gospels was received. The first Christian writer who cites it is Clemens Alexandrinus, who, however, rejects it, though some have supposed, that it is a fragment of the second epistle of Clement to the Corinthians, taken from this gospel. It is mentioned by Origen, Jerome, and Epiphanius among apocryphal books. Many modern writers, as Erasimus, Gratian, Crispius, Miles, suppose, that it is referred to in the introduction to St. Luke's gospel, and therefore that it was prior to his; and Dupin and F. Simon think, that though it is not of the same authority with the four canonical gospels, it ought not to be rejected. Mr. Jones is of opinion, that it was composed by some very early heretics to support their doctrines of celibacy and abstinence, and very probably by those of Egypt; and Dr. Lardner thinks that it was not written before the third century. The gospel of the "Ebionites" was either altogether, or very nearly, the gospel of the Nazarenes. The gospel of the "Encratites" has been mentioned by Fabrius and some others, but there is reason for doubting whether any gospel was ever called by this name. The gospel of "Eve" has been mentioned by several modern writers, but only by Epiphanius among the ancients; it was, without doubt, a forgery of the Gnostics. The gospel of the "Hebrews" was the same with that of the Nazarenes. The gospels of "Hebraicus," were some interpolated copies of our received gospels. The gospel of "Iudas Icarnos" is mentioned by Irenæus and Epiphanius as peculiar to one of the most monitory and unconfident sects that ever assailed the Christian name. The false gospels of "Lucian," who was a famous critic and martyr under Diocletian, were, like those just mentioned, corrupted, interpolated copies of our genuine gospels. The gospel of "Matthias," of which there are now no remains, is mentioned by several of the most celebrated writers among the ancients, viz. Origen, Eusebius, Ambrose, and Jerome; but they all represent it as apocryphal. The gospel of "Marcion" is taken notice of by Tertullian and Epiphanius; but it appears to have been one of our own gospels, mutilated and altered; probably that of St. Luke, from which he took away entirely the two first chapters, and many other parts, inflicting many things of his own, with a view to favour the opinions he had adopted. The gospel of the "Nazarenes" or "Hebrews" is the most famous of all the ancient gospels. Some have supposed that St. Paul refers to this gospel, Gal. i. 6. It is cited by Igrarius, as some have supposed, by Clemens Alexandrinus, by Origen, by Eusebius, by Epiphanius, by Jerome; and it is mentioned by Bede, Sixtus Sevinius, Bar- numis, Caufabon, Grotius, F. Simon, Dupin, Grabe, Toland, Nye, Richard Mill, Fabricius, Mangely, and other modern writers. However it is alleged, that this gospel was never received by any primitive writer as canonical, nor was it cited or appealed to, as of any authority, by any one writer of the first four centuries; and moreover that it was composed out of St. Matthew's and the other authentic gospels, with additions of some other things received by oral tradition. It is allowed, that it was an early compendium, and Mr. Jones says, that it was undoubtedly extant in the beginning of the second century, and seems to have been made by some converted Jews, to favour their notion of blending Judaism and Christianity together. "As many mistakes," says Dr. Lardner, "have been entertained about the gospel according to the Hebrews," it may not be unfeasible to observe here, that probably it was an Hebrew translation of St. Matthew's original Greek gospel, with additions from the other gospels; to which possibly might be added some few particulars received by tradition from the early Jewish believers."
believers." (See ENRONITES and NAZARENES.) This excellent writer elsewhere observes, it is not necessary for us to suppose, that the ancient fathers who mention other gospels, thought, "that all, if any of those gospels, were written before St. Luke's, or that he spoke of them; for Balaam and Apelles could not write gospels before the second century; and they might suppose, that several, if not all the others, mentioned by them, were written after St. Luke's. The meaning of what these ancient writers say is, that the church receives four gospels only. There were many others. But to them may be applied the words of St. Luke; they only took in hand, or attempted. They did not perform, as Matthew, and Mark, and Luke, and John did. And they might express themselves in that manner concerning gospels written after St. Luke's, as well as before it."

The gospel of "Peter" has been taken notice of by many of the ancient writers, as Serapion, Tertullian, Origen, Eusebius, and Jerome. Some have supposed, that this was the gospel of St. Mark, who was the companion of Peter, and wrote the gospel now extant under his name. But there is reason for believing that the gospel of Peter was different from that of St. Mark. It is not very certain by whom it was forged. Dr. Grabe, and after him, Dr. Mill, suppose it to have been made by Lecessis, whom they reckon to have been a heretic of the second century; but Lecessis did not live till the latter end of the third, or the beginning of the fourth century; whereas this gospel appears to have been extant in the second century, as we may infer from the account of it by Serapion, who was bishop of Antioch in the 11th year of the emperor Commodus, i.e. A.D. 190. Mr. Jones apprehends, that this gospel was composed by those ancient heretics in the second century, called DOetez (see that article); and he conjectures that the gospel of Balaams above-mentioned, was either wholly, or in a great measure, the same with this apocryphal gospel under the name of Peter. The gospel of "Perfection" was one of the numerous forgeries of the Gnostics, who pretended to a greater perfection in knowledge and virtue than all others, and hence took their name. (See Gnostics.) The gospel of "Philip" was another forgery of the same province. The gospel of "Sebastianus" was composed by him who was the source and author of the Manichæan heresy. The gospel of "Tatian" was no other but a harmony of four gospels, or a fort of epitomes of the whole history contained in our four gospels. The gospel of "Thaddæus" is merely mentioned in the decree of poès Cæcilian. The gospel of "Thomas," or the gospel of the "Infancy of our Saviour," is mentioned by Origen, Eusebius, Cyril, Ambrose, Athanasius, and Jerome, and is unquestionably apocryphal; though this is different from the gospel of Thomas, one of the followers of Manes, the head of the Manichæans, for Origen, who mentions the former, lived a confidantable time before the Manichæan heresy was divulged. The gospel of "Truth" was a forgery of the Valentinians in the second century. This is supposed by some to be the same with the gospel of "Valentinus," but others are of opinion that he had a gospel of his own, different from that called the gospel of Truth used by his followers. For further particulars we refer to Jones's Canon and Lardner's Works.

GOSPAN, in Geography, a town of the island of Sardinia; 24 miles S. of Oristani.

GOSPORT, a sea-port town of Hampshire, England. In the time of king Henry VIII., when Leland visited this part of the island, Gosport was only a poor village inhabited by fishermen, but it has gradually become a town of considerable extent and importance; and of late years has been regularly fortified on the land side by a line of bastions, redoubts, counterartes, &c. that extends from Weovil to Stoke, or more properly, Alverstoke lake. Within the works on the Weovil side, are the king's brewery and cooperage, with an immense range of breweries for wine, malt, hops, &c. This place communicates with the sea by means of a large basin and canal, with extensive quays, where vessels of considerable burthen can take in their stores. Many small sloops, belonging to Weovil are employed in the conveyance of wine, beer, and water, to the ships in the harbour. On the Weovil side are also the new barracks, an extensive range of buildings, with every convenience for a great number of soldiers. Gosport, considered as a sea-port, is handsomely built, and the police well regulated. The town is a chapelry to the neighbouring village of Alverstoke; the chapel is a spacious edifice, standing in a large well-planted cemetery, to the south of the town; the interior is neat, and disposed into a middle and two side aisles. The work-house for the poor is a large, airy, and commodious building. Here are also several charity-schools; and some almshouses for destitute widows. The markets are held three days weekly, and are much frequented; fish and vegetables are sold in great abundance; the latter being brought, not only from a considerable distance inland, but 21 miles from the Isle of Wight. Two fairs are held annually. Several breweries are established; and a very extensive iron foundry, where numerous articles are manufactured for government. Gosport is 78 miles distant from London; the population of the parish of Alverstoke, including the inhabitants of this town, was returned, under the act of 1821, at 11,295; the number of houses being 1966. The connection between Gosport and Portsmouth is preferred by numerous ferry-boats that ply across the harbour, which is in this place about three quarters of a mile in width.

At a small distance south of Gosport, is the Royal Hospital of Hasler, built between the years 1746 and 1762, for the reception of sick and wounded seamen, on the earnest recommendation of the late earl of Sandwich. It is situated within 500 yards of the extremity of the point of land which bounds the west side of the entrance to Portsmouth harbour; and consists of an extensive front, and two wings, each comprising two distinct ranges of buildings. In this hospital upwards of 2000 patients can be accommodated; the regular expense of the establishment in wages, &c. is above 5000l. annually.

Nearly a mile south-west from Hasler hospital is Fort Mounton, in modern and regular fortification, exceedingly strong, and defended by thirty-two pieces of heavy ordnance; to the westward, ranges a strong redoubt; and this, together with the fort, effectually secures this part of the coast. On the shore, to the westward, a high and massive stone wall has been erected, to preserve the land from the ravages of the sea.

Near the extremity of the neck of land which terminates the entrance of the harbour on the east side, is the Black house, a very strong fort, defended by a formidable battery. Beauties of England and Wales, vol. vii.

GOSPORT, formerly called APPLEDORE, a fishing town of America, on Star island, belonging to Rockingham county, New Hampshire, containing 35 inhabitants; about 12 miles E. S. E. of Piscataqua harbour.

GOSS, in Rural Economy, a term occasionally applied to the common wheat in different places, and which is sometimes written getz. See FEYZ.

GOSSINGUNGE, in Geography, a town of Hindoostan in Oudes; 15 miles S. E. of Lucknow.

GOSSAMER is the name of a fine filmy substance, like cobwebs,
cobwebs, which is seen to float in the air, in clear days in
autumn, and is more observable in stubble-fields, and upon
farms and other low bushes. This is probably formed by the
flying spider, which, in traversing the air for food, shoots
out these threads from its anus, which are borne down by the
dew, &c.

GOSSEMPINUS, a name given by Pliny and the an-
cients to a tree growing in the East Indies, which produced
a fort of cotton, the threads of which were too short to be
spun or carded; so that it served only for the stuffings of
beds and the like, for which it was very proper, being very
light and soft. It was in some esteem in medicine also, to
recal the heat and spirits into parts to which it was applied.
It is called by Piso *arbor langera,* the wool-tree, and had
its ancient name from the words *gossypium* cotton, and *pinus,*
the pine-tree, being somewhat like the pine in external ap-
pearance, yet bearing a fort of cotton.

GOSSE-ABDIAH, in Geography, a town of Nubia, on
the Tacezé; 90 miles S. of Jalaac.

GOSSEC, M. in Biography, a voluminous French mu-
cical composer of the old school, almost the only lineal
defendant of Lulli and Rameau. He had force, fire, and
knowledge; but his style was not that of the present day,
either in Italy or Germany, nor could his friend, M. La-
bordes, persuade us, that "true genius is in need of no school
or model." In whatever nation a man of genius may be
born, he will make himself known, and not march with less
firmness, though without a guide, in the road to glory.
Celebrated schools cannot give genius, that is the boon of
nature, and nature wants no school." Elysia fer la Mus.

Unluckily, nature alone has never made an artist. A good
painter, poet, or musician, cannot be made without edu-
cation, study, and models. Ingenious works have been pro-
duced by dint of genius, but never faultless. The awk-
wardness of self teaching will always appear; and taste, ele-
gance, facility, grace, and often learning, will be wanting to
render them perfect.

GOSSEINS, in Geography, a town of Thibet, on the
Dewah. N. lat. 30° 30'. E. long. 81° 24'.

GOSSELIES, a town of France, in the department of
Jemnappe, and chief place of a canton, in the district of
Charleroy. The place contains 2872, and the canton 12,894
inhabitants, on a territory of 100 kilometres, in 17
communes.

GOSPIUM. See Gossypium.

GOSSLAR, in Geography, a town of the kingdom of
Weilphalia, on the Gose, which runs near this place into the
Ocker. It was a free and imperial town, having on one side
the bishopric of Hildesheim, and on the other the principa-
lity of Wolfenbuttel. It was founded in the year 922, by
Henry the Fowler, and part of it re-built after being de-
stroyed by fire in 1728. It has four parish churches, two
chapels, and two Lutherian convents. Its principal trade
arises from the mines of iron and lead in the Rammel moun-
tain near it; 30 miles S. of Brunswick. N. lat. 51° 55'.
E. long. 10° 26'.

GOSSUM, a dwelling of the thyroid gland. See Brion-
ciocele.

GOSSWEINSTEIN, or Gossmanstein, in Geography,
a town of the bishopric of Bamberg, on the Putlach, 20
miles E. S. E. of Bamberg. N. lat. 49° 45'. E. long.
11° 10'.

GOSSYPIUM, in Botany, the Cotton plant. The
name is supposed to the learned by the he of Egyptian origin,
and if so, is akin to *Cotynus,* or *Cotynus,* the evi-
dent source of our word Cotton, which is given as the
Egyptian appellation of the plant in Alpinus, de Plantis
*Egypti,* 71. Pliny makes it a Latin word, though the
more common name he says is Xylus; the Greek *goss-

Gen. nat. t. 134. (Xylon; Tourn. t. 27.) Clafs and order,
Malvacea, Julf.

Gen. Cal. Ch. Periarth double; the outer of one leaf,
three-cleft, flat-lined, larger; inner of one leaf, cup-shaped,
with five blunt notches. *Cor.* Petals five, irregularly heart-
shaped, flat, spreading, attached to the tube of the flumens
by their base. *Stam.* Filaments numerous, connected in
their lower part into a tube, separate and lax above, inserted
into the corolla; anthers kidney-shaped. *Pfyl.* German su-
perior, round-lined; *style* columnar, as long as the flaments;
flagmas three or four, oblong, thickish. *Peric.* Capsule
round-lined, pointed, with three or four cells and as many
valves, with contrary partitions. *Sedus* numerous, oval,
fringed and enveloped with long wool.

Eff. Ch. Calyx double; the outer three-cleft. Capsule
with three or four cells. Seeds enveloped in wool.

The species of Cotton, like those of all plants cultivated
from the most remote antiquity, in various countries, for
economical purposes, are extremely difficult to define and
obscured by various names. Linnæus in Sp. Pl. ed. 1, defines three species only,
2. f. 2, supposed to be a native of the Levant, East Indies, and
Africa, and generally cultivated in those countries for its
produce.—Leaves five-lobed, pointed, with one gland be-
neath. Stem herbageous, nearly smooth.—This is annual,
with a single, bracted, often zig-zag *flamen,* smooth or only
slightly downy. *Leaves* cut half-way down into three prin-
cipal, and two smaller lateral, pointed rounded lobes. The
mid-rib bears one gland at its back, about half an inch from
the stalk. *Flowers* yellow, purple at the base. *Capsule* the
size of a walnut, enveloped in the calyx like a linden.
2. G. barbadense, taken up from Pluncken, t. 188. f. 1.
Leaves three-lobed, entire, with three glands beneath.—
Supposed to be a native of Barbadoes. It is at least one of
those cultivated in the West Indies. The plant is in all its
parts larger than the foregoing; lobes of the *leaves* not near so deep.
3. G. arboreum. Cavan. t. 165. Pluk. t. 188. f. 3.
(Cutiam-paria; Rheede Hort. Mal. v. 1. 55. t. 31.)—
Leaves palmate, five-lobed; lobes lanceolate. Stem shrubby.
—Native of the East Indies in a sandy soil. The woody
pennular flamen, and deep-cut long-lobed *leaves,* whose
mid-rib bears one gland, distinguishes this. The *flowers* are
dehiscent. The cotton is used in manufactures. Willdenow er-
roneously quotes Alpinus here.

His *Cotynus* is in the Plant. *Egypti.* 71, not his
Exot. t. 38, and does not agree with the East Indian
plant.

To these is added in Sp. Pl. ed. 2. 275;
4. G. birsutum. Cavan. t. 167. Leaves with three or
five acute lobes. Stem branched, hairy.—The synonym of
Tournéfort is wrong.—This is said to come from America.
It appears to us a hairy variety of the first, for the gland on
the mid-rib, which Linnæus thought an exclusive mark of
*birsum*, is found in both.

What Linnæus intended by G. religiosum, Syll. Nat.
ed. 12. v. 2. 462, is rather doubtful. He defines it
"Leaves three-lobed, acute, with one gland beneath,
branches dotted with black."—We have an East Indian
plant which answers to this definition, but it does not exactly
agree
agree with what he has marked *religiosum* in his own herbarium, which appears to us *barbarous*; though it may be what he had in his garden.

With the *herbarium* of Murray, Comm. Gott. for 1776, t. 1, we are unacquainted.—Cavanilles figures and describes several more species, especially *G. albofimbra*, t. 166, a noble plant, from Commeron's herbarium, gathered in the Manilus.—Willdenow, adopting these, reckons ten species in all, but the fynonyms of the whole genus require revision.

GOSTADT, JOTSTAD, or *Josipstado*, in Geography, a town of Saxony, in the circle of Erzgebirch; 23 miles S. of Chemnitz. N. lat. 56° 26'. E. long. 13° 2'.

GOSTIN, a town of the duchy of Warsaw; 48 miles N.N.W. of Rawa.

GOSTULLA, a town of Bengal; 22 miles E. of Kithenagur.

GOTARA, a town of Hindoostan, in Bahar; 57 miles S.S.W. of Patna.

GOTERON, a valley of Switzerland, in the canton of Fribourgh, on the N.W. of the town of Fribourgh, near the bridge leading to Bern, takes its name from the Goteron, a small rivulet; it is extremely narrow, and above two miles in length, and is bounded on each side by overhanging rocks of sandstone. Vernet, the celebrated landscape painter, studied these rocks with great attention, and frequently declared that, excepting those of Tivoli, he never saw any where varying tints had a more pleasing and harmonious effect. This valley contains several mills, an iron foundery, where the ore brought from Franche Comté is forged, and a manufacture of linen and cotton, established by some merchants of Neuchâtel, under the protection and encouragement of government.

GOTH, Steph., in Biography, archbishop of Upsal, in Sweden, in the 16th century, concurred in the measures adopted by king John, to restore and re-establish popery in that kingdom. With this view he functioned a new liturgy, which, under the pretence of bringing the Lutheran church nearer to the simplicity of the earlier ages of the gospel, artfully alluded to the doctrines and ceremonies of worship to those of Rome, with the omission of some particular forms and expressions which would have too plainly disclosed the object in view. This liturgy was ordered to be used in all the churches. The king's brother Charles, and the clergy within his jurisdiction, were alarmed at this attempt, and they so effectually roused the jealousy and excited the fears of the people, and of the states, that after repeated efforts to carry his point, which introduced great confusion into the kingdom, and had nearly produced a civil war, the king was obliged to relinquish his scheme, and the liturgy was suppressed. It has long since become an object of curiosity among collectors, and is entitled *Liturgia Suecana Ecclesiæ cum praefatione et notis Laurentii Upaliensis Episcopi*, 1576. Univer. Hitt.

GOTHA, in Geography, a principality of Germany, in the circle of Upper Saxony, bounded on the N. by the electorate of Saxony, on the E. by the duchy of Weimar, on the S. by the county of Henneberg, and on the W. by the principality of Eisenach. The duchy contains 12 towns, and more than 200 churches: it abounds in grain and fruit, and the southern division contains part of the forest of Thuringia, and some mine works. The state consists of three dukes, with councils, nobility, and some barons; convoked by the prince. The reigning duke maintains a guard of 60 men, two regiments, each of which is composed of 800 men, and a corps of artillery. The chief rivers are the Leine and the Nelle.

The capital of the principality of the same name is seated on an eminence near the Leine, which supplies the town with water, conveyed by stone-canals, and is among the belt and hamlet-like towns in Thüringen. It has an hospital for the soldiers, two schools for their children, and barracks, in which the military art is taught; it has likewise a foundery for cannon, balls, &c. two churches, a good academy, a house of correction, an hospital for widows, and asylum for orphans. The inhabitants carry on a considerable trade in wood and wooden manufactures, and beer; and they derive benefit, not only from the agriculture of the vicinity, but from the paper-mills which are carried through it from Leipzig to Upper Germany. The residence of the duke, called Friedenstein, stands on a hill above the town, and contains an armoury, a valuable library, a museum of natural curiosities, and an excellent cabinet of medals; 13 miles S.W. of Erfurt. N. lat. 56° 17'; E. long. 10° 40'.

GOTH, a river of Sweden, which issues from the southern extremity of the lake Wener, near Weinersburg, and after a course of 70 miles, falls into the sea near Gothorp. It flows low along this river flows with a gentle current and in a narrow channel, and is navigable only in some parts of its course for small craft of 20 tons burden. If it could be rendered navigable through its whole course, the Wener lake might be joined with the German ocean; but as numerous shoals and cataracts intervene, the communication has been attempted by the Carlgraf canal, the canal of Troad, and the stream of the capital are to the edent, and the stream formed by the union of the two branches is called the Northern river, and falls into the sea after a course of 10 miles. The third branch retains the original name of Goth; and the space included between the Northern river and the Goth is named the island of Hisingen.

GOTHARD, Sr., a town of Hungary, near which the Turks were defeated by the Hungarians, in the year 1564; 21 miles W. of St. Crec.

GOTHARD, Sr., a chain of mountains of Switzerland, in the canton of Uri, the summit of which rises above the sea 9075 feet, though some have estimated its height to be much greater. The particular parts of this chain are called by different names: of which the principal are the Silla, Fondo, and Suringa, to the east; the Fondo, the Patina, and the Lucendro, to the west; to the north, the Urfingen; and to the south, the ridge of naked and piked rocks of the Val-Maggia. Of these, the Fondo is the highest. There are five passes on the neighbouring heights, on which are fed 200 cows, 150 goats, and 30 horses. The river Doldan has three principal sources in the chain of St. Gothard: the first is springing near the foot of the Fondo, and flowing into the Lake of La Silla, in another part of the eastern chain, and the third is furnished by the streams of mount Fondo. These three sources unite with another branch, that flows from the Fondo, through the valley of Bedneto, form one great torrent, which takes its course towards the south, enters the lake of Lucerna, and traversing part of the Maggia, falls into the Po. The source of the Rhine is also in the lake of Lucerna, an oblong piece of water, about three miles in circumference, stretching between the mountains of Patina and Lucerna, and almost entirely supplied by the numerous glaciers which crown the summit of the Lucerna. The stream issuing from this lake runs down the valley of St. Gothard, and joining in the vale of Urfingen, the two branches which come from the Fondo on one side, and from the Grison mountains on the other, flow towards the north into the lake of Lucern.
cern, and from thence throws itself into the Aar. The valley of St. Gothard is exceedingly dry. It does not contain a single tree, nor produce a single tree; and the sides of the mountains are barely sprinkled with short herbage.

Mount St. Gothard affords one of the best Alpine passages from Germany and Switzerland to Italy. The Romans were acquainted only with that over the Great Bernhard and Septimer. The Gothard was called by them sometimes Adula, sometimes the High and Lepontine Alps. The present road over this mountain begins at the village Hospitall, in the Uriera valley, and terminates on the south side, at Airolo; its breadth is from ten to twelve feet, and it is covered with large pieces of granite.

The first attempt of passing over the Gothard in a traveling carriage, was successfully made in the month of July, 1775, by the late Mr. Grevel, the gentleman to whose early exertion in collecting and in employing persons well qualified to assist him, we owe the extensive alluviation of minerals lately purchased by government for the British museum.

Though, in the high Gothard valley, the temperature is far below that of Romanum; yet, on the N. side of the mountain, the climate is sufficiently rough to make the growth of trees cease at the height of 4566 feet. Among a vast number of plants common to the Alps in general, we find here, as peculiar to mount Gothard, the Viola minima, and Campanula patula.

But most interesting is this mountain in regard to its mineral substances, and its geognostic structure in general: for, respecting the former, it may be said, that there is feared any where a tract of country known, that, within the same extent of space, affords so considerable a variety of them. This is not the place for enumerating all these fossils; we should, however, not omit mentioning, that the tremolite, which has received its name from the valley of Tremola, is, according to Ebel, not found there, but deeper down the mountain, in the Leventine valley. See Tremolite.

The St. Gothard confits entirely of primitive rocks, which, however, display great variety in their mixture. On the N. side veined granite, gneifis, mica-date; in the plain of the rocky valley, where the Hospitall stands, granite of large grain, traversed by beds of veined granite and mica-date; from the summit downwards, on the S. side, massive granite of large and small grain alternately, veined granite, mica-date; in the Tremola valley, on the Fiida and Sorefin, hornblende-date commences, mixed in some places with fine granular quartz, in others with feldspar, and lower down with fine reddish-brown, deodechedal garnets; over which beautiful rock the road winds, through the Pffeelel forest, down to Airolo. On the N. side, in the Uriera valley, among the left mentioned rocks, una pot-tone on the S.E.-part of the valley, and on the N. N.W. primitive limestone and clay-date; while the S. side in the Leventine, Canaria, and Piora valleys, exhibits primitive lime-date and gypseum.

All rocks of the Gothard are dipposed in slits, having a direction from E.N.E. to W.S.W., and from N.E. to S.W., which is best observed between Hospitall and Airolo, where the road makes a transversal fiction, almost through the whole of the central chain. The regularity of the stratification of the granite is most striking in the neighbourhood of the Rundu bridge; the slits are from three to four inches thick, and have their direction from N.E. to S.W. Likewise, on the Profa and Fiida, and southward from Hospitall down the valley of Tremola, the primitive lime-tone and gypseum, which pass on the S. side of the mountain through the Leventine, Canaria, and Piora valleys, and the lime-date, clay-date, and pot-tone, seen on its N. side, in the Uriera valley, are the continuations of the same formations that range through the whole of the Pays de Vaud.

The ridges of mountains constituting the Gothard are exceedingly broken, and bear the marks of caustic the most destructive; nor is it improbable that they were infinitely higher in ancient times, and that, at the period of the Romans, they were not unaptly called the High Alps. The upper rocky valley, where the Hospitall is situated, is covered with numberless pieces of rocks, which are all precipitated from the surrounding peaks. The great proportion of a small grained granite, among the rocks of the Gothard, are the probable causes of this extraordinary devastation. The upper, nearly circular, rocky valley, was in former times completely shut on all sides; the remains of the rocks that formerly filled the chasms are still distinctly seen on the N. side, near the bridge over the Rundu, where the Reufs forms a beautiful fall; and on the S. side, below the Hospitall, the rocks approach each other so closely, that the violent action which produced the present chasms is sufficiently evident. Before that revolution happened, it is highly probable that this considerable valley was filled deep below; and now it lies so, that the Urner-valley, before the Devil's mountain was broken through, and the upper Leventine valley, before the Platier, near Daaco Grande, was rent asunder, represented deep feas of considerable extent.

GOTEBURG, a town of Sweden, is Well Gothland, distinguished by a commodious port, and landing near the seat of Lodoe, a town built by Gustavus Vasa, which being endowed with singular privileges, soon became the great emporium for the trade of the western provinces. Charles IX., when duke of Gotland, having, in 1604, laid the foundations of a new town in the island of Hisingen, not far from Lodoe, called it Goteborg, in honour of his dukedom. On his accession to the throne, he erected in his new town a trading company; drew thither many foreigners, particularly the Dutch, to whom he allowed an exemption from all duties of export and import during twenty years; established a corps of English and Scots troops, and granted to the Calvinists the free exercise of their religion, the first place in Sweden where this toleration was permitted. By these means Gothberg soon became a flourishing port, and, next to Stockholm, the most commercial town in Sweden. In 1611 it was reduced to ashes by the Danes, and afterwards rebuilt in the reign of Gustavus Adolphus on the present site, and obtained a confirmation of its ancient rights, with a grant of several new privileges.

Goteborg is built in a singular situation. At a small distance from the sea is a marshy plain, not more than half a mile in breadth, watered by the river Gotha and Moldal, and almost inclosed with high ridges of bare and rugged rocks. Goteborg stands partly on the ridges, and partly in the plain, and is divided into the upper and lower town. The latter is entirely level, intersected by several canals, and the houses are conducted on piles: the upper part hangs on the declivities, and rows of buildings rise one above the other like the steps of an amphitheatre. The whole is regularly fortified; and the circumference is near three miles, exclusive of the suburbs, called "Haga," which lie towards the harbour. The streets are uniformly straight; some few of the houses are of brick, but most of them are constructed of wood, painted red. The harbour, formed by two chains of rocks, is about a quarter of a mile in breadth; and the entrance is defended by the fort of New Elishborg, which stands on a small rocky island, and contains a garrison of 250 men.

A royal society of sciences and literature has been lately established.
established in this town, on the plan of that of Upfal. The
acts, written in the Swedish tongue, and printed in 8vo.
contain disquisitions on various subjects, in the several
branches of science, moral history, antiquities, history,
and polite letters. This population amounts to 20,000
persons, in consequence of an increase, occasioned by
the extension of its commerce, particularly on account of the
East India company, and the success of the herring fishery.
The East India company was established in 1731, and
on account of the ice, which closes the port of Stockholm,
in the gulf of Botnia, at the proper season of the departure
of ships for the East Indies, the company carries on its
commerce from Gothborg, whose harbour, lying in the
German ocean, is more open. In 1740, the herring, which
had not heretofore unusually approached the western shore
of Sweden, flocking to Gothborg, the inhabitants of Gothborg
established a fishery, which has been very lucrative. The
fishery begins in November, and though it continues scarcely
three weeks, it supplies the fishermen of Gothborg with
not less than 600,000 barrels. Of these, 200,000 are salted,
and train oil is drawn from them; fifteen barrels of herrings yielding one of oil, which is principally exported
to Holland and Spain. One barrel of salt, procured
from Spain, cures three barrels of herrings: the average
exportation of salted herrings may be estimated at 150,000
barrels, and the annual consumption of Sweden at 50,000.
An English confidant factory reside at Gothborg; and a
chapel, with a regular chaplain, is appropriated for their
use. The fortifications of Gothborg are so weak, that in the
year 1788 it must have fallen into the hands of the
Danes, if foreign powers had not interfered. N. lat. 57° 40'.
E. long. 17° 44'. Coxel's Travels in Sweden.

GOTHIC, or Gorman, something that has a relation
to the Goths, an ancient people, originally inhabiting that
country which we called Gothland; whence they spread them-
Selves over Greece, Dalmatia, Bulgaria, Italy, Spain, &c.
See GOTHIS.

Gothic Architeclure, a term of reproach to denote one
or more kinds of architecture which prevailed during the
middle ages. It seems to have been invented by the reformers
of the Grecian orders in Italy, about the middle of the 16th
century, to signify every preceding species of European
architecture not conformable to them, and it was imported
in the same sense into England by Mr. Evelyn and Sir
Christopher Wren, though the latter appears sometimes to
confine the term to the pointed style, in which particular he
is followed by the greater part of late writers. Mr. Evelyn,
quoted by Sir Christopher Wren, in his "Parentalia," says:
"Gothic architecture is a conglomeration of heavy, dark, mel-
ancholy, monstrosity. In the same sense, Sir Christopher
himself, speaking generally of what he terms Gothic archi-
tecture, calls it "Mountains of stone; vast, gigantic build-
ings, but not worthy the name of architecture. This we
now call the Gothic manner; so the Italians called what
was not after the Roman style." In opposition to the idea
which this eminent architect here gives of the architecture
in question, he, in another part of his Parentalia, describes
the inventors of it as "setting up slender and misshapen
pillars, or rather bundles of flues and other incongruous
props, to support ponderous arched roofs without entabla-
ture." In conformity with this latter notion of Sir Chris-
topher, Mr. Kious, a professional writer, says: "Modern
Gothic is distinguished by the lightness of its work, the
excessive boldness of its elevations and of its feutures, by
the delicacy, profusion, and extravagant fancy of its ornaments."
The same confusion of language, if not of ideas, prevails
amongst the admirers of the Gothic style, so called, as
amongst the declared foes of it. The late poet laureate,
Thomas Warton, who has written a great deal on the sub-
ject, and who had planned a "History of Gothic Archi-
tecture," speaking of Salisbury cathedral, expressly denies
that it is in the "Gothic style, while two other celebrated
writers in the same line, the Rev. James Beatson and Capt.
Grofts, as positively affirm that this cathedral is "entirely
in the Gothic style." The perplexity and uncertainty of
an ordinary reader must necessarily be increased by the dif-
terent fenses in which the terms, ancient architecture, mo-
dern architecture, Saxon architecture, Norman architecture,
and English architecture, are now used by different writers.
To clear up this confusion, and to present distinct and clear
ideas on these much agitated subjects, it seems best to treat
them in an historical manner.

It is demonstrable that the regular orders of Grecian
architecture were upon the decline throughout the Roman
empire after the reign of the Caxars, and still more so after
that of Constantine the Great. A century later the Ostro-
goths over-run and subdued Italy, the Vifigoths, Spain,
the Franks, Germany, the Vandals, the Roman provinces of
Africa, the Franks, France, and the Saxons, Britain.
These few barbarians destroyed innumerable monu-
ments of architecture as well as of the other arts, but
they none of them introduced a style of building different
from that which they found in the conquered countries.
They did not imprint the ancient inhabitants to
build in a new manner; on the contrary, they learnt of them
so much of the art as they actually acquired. But the art
itself being vastly degraded in the fifth and sixth centuries,
and those warlike hordes not being very apt scholars, we
wonder their first structures were executed in a rude and
heavy style. Still nothing is more groundless than to speak
of Gothic architecture in the manner of Mr. Evelyn and
Sir Christopher Wren, as of a style of building invented
or introduced by the Goths. The fact is, the heavy cir-
cular manner of building which prevailed throughout Christ-
tendom, from the fall of the Roman empire, in the fifth
century, down to the twelfth century, was the Roman, or, what
is the same thing, the Grecian style, incorrectly and rudely
executed. Amongst us it is called the Roman style, because
it prevailed during what is called the Saxon period or dynasty
in South Britain; but the first teachers and the models of
it were both of them strictly Roman.

On the first introduction of Christianity amongst our
Saxon ancestors, at the conclusion of the sixth century, they
consecrated many of the existing Pagan temples to the
Christian worship, according to the instructions which
they received to this effect from pope Gregory the
Great, and they ran up other temporary oratories of wood
or wattles, as we learn from Bede, and other original his-
torians. Very soon, however, the same Roman millionaires,
who converted them, taught them to build churches of
stone after the Roman manner; for this denomination of it,
the Roman manner, (more Romano,) is always mentioned
by the aforesaid historians. The first archbishop of the
Northumbrians, Paulinus, who was a Roman monk, appears
in the chronicles to have been the chief architect amongst the English Saxon
architects at the beginning of the seventh century, He built churches of
stone at York, Lincoln, and other places. His next
successor but one, Wilfrid, was an Englishman, who not
only equalled but greatly surpassed his master in architecture.
For the churches which he built at Rippon and at Hexham
were long celebrated for being the finest buildings of their
kind north of the Alps; but then it is expressly recorded,
both of him, and his rival in architecture, Benedict Biscop,
abbot and founder of the church and monastery of Wear-
mouth;
mouth, that they made different journeys to Rome, and studied the architecture of the church of St. Peter’s and other churches there, and that they even hired workmen from thence to execute their works in England. Thus it evidently appears, that the style of architecture, which is called the Saxon style, was not the invention of our ancestors, but was imported from Italy in the seventh century; and it is equally evident, from various monuments, that the Italians in this and the subsequent ages built in the same heavy manner, and made use of the same members and ornaments, that the English Saxons did. Still the architecture of our ancestors, previously to the conquest, though very heavy and rude, has been too much depreciated by many English writers. The Rev. Mr. Bentham, in his “History of the Church of Ely,” or rather the poet Gray, who drew up the architectural part of that work, refutes Sonner, Stewley, and other authors, who deny that the Saxon builders made use of stone for their buildings, or knew how to turn an arch; but then this very writer fails to do them the justice due to them, where he signifies that they were unacquainted with the use of towers, bells, and transepts, previously to the tenth century. If we have been strange if they had not imported these amongst other ecclesiastical inventions from Italy during the preceding centuries; but we have otherwise sufficient proofs that they had adopted each of them long before the tenth century.

During a great part of the ninth and tenth centuries, England and France were as much harassed by invasions of the Northern barbarians, as their former inhabitants, the Gauls and Britons, had been in the fifth century, by the ancestors of the now civilized Saxons and French. These turbulent invaders, who were indifferently called Danes or Normans, were guilty of much greater devastation upon the existing religious monuments, at least, than the Goths and Vandals had committed; because the latter were Christians, though Arians, when they over-ran the civilized world; whereas the Danes and Normans, when they invaded England and France, were persecuting Pagans. So great was the dread of their violence throughout the last mentioned country, that the following petition was there added to the litany: “From the fury of the Normans, O. Lord deliver us.” In fact, the Almighty was pleased to deliver first France and then England, from the scourge which had so long and so sorely afflicted them; but in a very different manner from what the Christian inhabitants expected. Instead of witnessing the extermination or subjugation of their barbarous enemies, they saw them bend their necks to the yoke of Christ, and become models of piety and morality, to themselves and the other Christian nations.

Such at least was the case with the Northern men, who settled in that part of France, which from them has since been called Normandy. A lasting peace and tranquillity being, through this happy event, restored to the French provinces, its princes and nobles began to rebuild their demolished churches, and to erect others with incredible diligence. But no people moved so much zeal in this undertaking as the newly converted Normans. The reader will be convinced of this, when he is given to understand that William the Conqueror, during the few years that he reigned in Normandy, previously to his invasion of England, built two noble churches and abbeys, and his nobles, not fewer than thirty-eight, each of them building with the zeal to make his building the most magnificent and splendid. Such were the Normans, the bravest, most industrious, and most religious people, and the most elevated, in particular, to ecclesiastical architecture of all Christian people, when William, their prince, with the power of his nobles, his army, and his ecclesiastics, came to settle in England soon after the middle of the eleventh century. It is to be observed, that the most celebrated schools of literature and the arts, and more particularly of architecture in Europe, at this period, were the abbeys of Bec and Caen in Normandy, the former of which produced those three great architects, Lanfranc and Anselm, successively archbishops of Canterbury, and Gundulphe, bishop of Rochester. But indeed all the Norman prelates and abbots appear to have been able architects; for there was hardly a cathedral or abbey church in England which was not rebuilt by one or other of them, in the course of thirty or forty years after the conquest. The characters which they aimed at in these structures were evidently the fabuline and beautiful. To produce the former effect, they built their churches along and as lofty as possible; to produce the latter effect, they not only built in a much more neat and perfect manner than the Saxons had done, but also they made use of certain new invented ornaments in their structures. Of these the most objectionable and ordinary was the arcade or series of arches which, in one or other of its various forms, is to be met with in all the existing Norman churches. From the continued efforts of these indefatigable and ingenious architects, to mould these churches as awful and as beautiful as possible, before the middle of the twelfth century, a new style of building was produced, called “the Pointed Style.” It certainly appeared, for the first time, either in England or in France; nevertheless, the first ascertained influence of it which has hitherto been produced, claims the honour of the invention for this country. But before we proceed to give a more particular account of the rise and progress of this singular style of building, it will be proper to detail the various systems which have been published respecting it.

It has been seen above, that Mr. Evelyn and Sir Christopher Wren describe the architecture of the middle ages, in general, whether circular or pointed, under the opprobrious term of Gothic, as being the real invention of the Goths and other barbarians. The former of these writers, as quoted with applause by the latter, says, in his “Parentalia:” “The Goths and Vandals having demolished the Greek and Roman architecture, introduced, in its stead, a certain fantatical and licentious manner of building, which we have since called modern Gothic, of the greatest industry and expensive carving, full of fret and lamentable imagery,sparing neither pains nor cost.” We fee that the writer here speaks of the light pointed ornamental style of our ancestors no less clearly than he does in another passage, quoted above, of the plain heavy circular style, called the Saxon; and that he supposes the former so less than the latter to have been really introduced into the countries, which had formed the Roman empire, by the Goths and Vandals, who subdued them. How little reason there is for attributing the Saxon style to these barbarians has been shown above; and, with respect to the pointed style, it is sufficient to observe that this appeared in no part of Christendom before the twelfth century; whereas the Goths and Vandals committed whatever depredations on the monuments of Roman art, which they did commit, in the fifth century, and that their power was every where crushed, and their very name extinguished in the course of the sixth century, except, indeed, in Spain, where the name of Gothic remained attached to the reigning family, till the beginning of the eighth century and no longer. So groundless and absurd, in every respect, is the term Gothic, as applied to pointed architecture!

At the same time that sir Christopher commands the stylem of his friend Mr. Evelyn, he himself departs from it, since he prefers the word Saracenic to denote the pointed style.

“What we now vulgarly call the Gothic,” he says, “ought properly and truly to be named Saracenic architecture, refined by the Christians, which first of all began in the East, after the
the fall of the Greek empire. The holy war gave the Christians who had been there an idea of the Saracen works, which were afterwards imitated by them in the West.

This system concerning the pointed style, namely, that it originated with the Saracens, has, out of mere respect to the name of its author, Sir Christopher Wren, been followed by bishop Lowth, in his life of Wykeham, by Rionus, by Warton, by Grofe, and, in short, by the generality of modern writers who have had occasion to enter upon the subject. In refutation, however, of this system, we have to remark that the first, or Grand Crusade, in which the conqueror's son, Robert, and many other Normans and Englishmen embarked, making part of above a million of persons, who were engaged in it, began in 1096, and terminated by the capture of Jerufalem in 1099. Now it is certain from history that the cathedrals of Exeter, Rochester, and Chichefter, with many abbey churches, were built wholly in the circular style after the last-mentioned year. Amongst these the influence which is most to the present purpose is that of Rochester cathedral, which was built by that greatest architect of his age, Gundulp, formerly a monk of Bec abbey, then bishop of Rochester, as well as the castle of that city, the chapel in the white tower of London, &c. without the leaf mixture of the pointed style. The reason of this is, because Gundulp had travelled through the East on a pilgrimage to Jerusalem, a little before the crusade took place, when he had an opportunity of surveying the churches and other buildings of those countries at his leisure. Again, it has been remarked by Grofe, Bentham, and other writers on the subject, that in all the descriptions and drawings of buildings in the Holy Land and other parts of the East, given us by Pocock, Norden, Shaw, Le Bruyn, &c., there is but one church, namely, that of St. John d'Acro, in the proper pointed style (which church the writer of this article has discovered to have been built by William, an Englishman, at the time when our Richard I. made himself master of that city); and that very rarely such a thing as a pointed arch is represented as existing in those countries. It is true a late writer, the Rev. Mr. Whittington, in his "Survey of the Ecclesiastical Antiquities of France," has proposed to discover from these and other drawings pointed architecture in every part of the East, from the Euxine sea to Egypt; but then it appears that he calls the mis-shapen obelisks and minarets of the Mahomedan mosques pointed architecture. He has another argument for his assertion, namely, that "it is improbable the dark ages of the West should have given a model of architecture to the East." If there is any force in this argument, it would follow that the musical scale of bells, optical glaftes, the mariner's compass, gun-powder, and printing were discovered in the East instead of the West, contrary to the known fact.

Mr. Murphy, to whom the admirers of pointed architecture are indebted for his elegant views of the church of Brothla in Portugal, conjectures that this style was borrowed from the pyramids, and that of course Egypt was its native soil. But in almost every country and age men have built their habitations with sloping roofs to carry off the falling rain; hence they must have seen the figure of a triangle at the gable ends of them, no less than the Egyptians did in their pyramids. Denon's, Meyer's, and other views of ancient buildings in Egypt, are by no means favourable to Mr. Murphy's system. There is indeed an ancient hall in the caftle of Cairo, called Joseph's Hall, which is a great deal in the pointed manner, and which is supposes by the vulgar to have been built by the patriarch of that name; but Nebular and lord Valentia give sufficient reason to believe that it was built by Saladin, the enemy of our Richard I., whose true name was Joseph. In fact, it is in the style of that period. According to this supposition, we are warranted in believing that this hall was the workmanship of Christian prisone,: after the third crusade. Mr. Murphy's theory is equally destitute of historical grounds and moral probability.

Bishop Warburton, in his "Notes on Pope's Epitaph," endeavours to unite together two of the above-mentioned reputed systems, which derive pointed architecture from the Northern Gofs, and that which brings it from the Eastern Saracens, at the same time that he aligns the western peninsula of Europe for the real place of its birth. The following is an abridgment of his account: "When the Gofts had conquered Spain, and the religion of the old (Christian) inhabitants had inflamed their piety, they struck out a new species of architecture unknown to Greece and Rome. For this northern people having been accustomed, during the gloom of Paganism, to worship the Deity in groves, when their new religion required covered edifices, they ingeniously projected to make them refemblable groves; at once indulging their old prejudices, and providing for their present convenience by a cool receptacle in a sultry climate, with the assistance of Saracen architects, whole exotic style of building suited their purpose." All this is a mere revery. The Gofs and Vandals entered Spain in the year 409. They did not, however, acquire there a new religion from the old inhabitants, for they were already Christian, and habituated to the use of churches. On the other hand, the Moorish Saracens did not enter Spain till three hundred years afterwards, namely, till the year 712, when having cooped up the Christians in the mountain of Atarjas, there continued ever afterwards the most relentless warfare between the two people. It is impossible to conceive more monstrous ideas than that the Christian Gofs should have brought with them into Spain a partiality for the Pagan worship which they had practised in the forests of Germany, and that they should have retained it for the space of three hundred years afterwards, till they had the means of employing their implacable enemies, the Mahomedan Moors, to build Christian churches for their use; and that when this was effected, they should have kept the secret of pointed architecture to themselves for the space of 300 years longer! Were all this possible, or were it a fact that this style had been imported into our country from any other, where it had been practiced for a considerable time before, it would have made its appearance amongst us at once, with its several striking characters; contrary to what we actually see was the fact. After all, if the style of an ancient cathedral resembles an avenue of trees in some respects, it differs from it in many others, which are obvious to the sight.

Having followed different guides, north, east, and west, in search of the original pointed architecture, we have latterly been invited by an ingenious artist to a company last to the fourth, namely, into Italy, the cradle of modern art, with a promise that he will there point out to us much earlier specimens of this style than are to be met with in the northern climate. In the year 1829, Mr. Smirke, F.S.A., returned from Italy, laid before the Society of Antiquaries a certain drawing, since engraved in the "Architectural," vol. xiv., of the drawings of a window belonging to the cathedral of Meffina, in the richest style of the third pointed order, being such as we have no example of in this country before the middle of the 13th century. These drawings he would have us believe are equal with the cathedral spirit, which was built by the Norman chief, Roger, earl of Sicily.
ly, in the eleventh century. He presented another drawing, published by the society as aforesaid, which appeared to be much more for his purpose, because of the known dates of the original. This drawing represents a portion of the outside of the baptistery of the cathedral church at Pisa, which baptistery was certainly built by Diotti Salvi in 1132. The drawing exhibits what we should call Roman and Saxon work, with interiorized crocketted pediments and pinacles, such as we were unacquainted with for more than a hundred years afterwards. Lollly, this gentleman flew a view to the cloister of Campo Santo, adjoining the last mentioned cathedral, built in 1254. Here we see the richest tracery milliions under semi-circular arches, the whole of which he considered as being the same original work. These specimens gained many converts to his syllem, that of Italy being the parent country of pointed architecture.

But there is no error which we have so much to guard against in studying architectural antiquity as the confounding of sublateral alterations with the original work. There are few adepts in this science who would not start at the first sight of Mr. Smirke’s drawings, and who would not pronounce the works they represent as an incongruous mixture of the architecture of different ages; but it was reserved for Sir Henry Englefield’s profound knowledge of the subject and critical acumen to detect and exhibit in detail the pointed enrichment with which later architects had decorated the plain circular works of their predecessors. To the justice of this learned antiquary’s remarks the accurate history of the cathedral of Pisa, written by Martini a canon of that church, bears ample testimony. In a word, the very specimens which Mr. Smirke has produced in favour of Italy’s claim to the invention of pointed architecture, as well as all the other buildings, tombs, and altars at Rome, and in every other part of Italy, demonstrate its great inferiority both in date and in execution, to England, France, and Germany, with respect to this particular style.

Allied, in one respect to the syllem of bishop Warburton, is that of Sir James Hall, bart., who, in “An Effay on Gothic Architecture,” now published, endeavours to flew that the pointed style was borrowed from the idea of upright palls surrounded with offer, the heads of which are to meet like those of trees in an avenue. But the utmost that the ingenious baronet proves is that basilica-work may be made to resemble pointed architecture, not that pointed architecture was borrowed from existing models of basilica-work. Lord Orford, heretofore for Horace Walpole, in his “Observations on English Architecture,” says, that the architecture in question was copied from shrine-work; just as if the making of boxes preceded the building of houses! After all, this is only placing the tortoise under the elephant; for where did artiffs learn to fashion their shrines in the pointed style? Lally, Mr. Payne Knight derives this style from all the three parts of the world, heretofore known, Europe, Asia and Africa, where he decides, in his “Principles of Taste,” that “the style of architecture which we call cathedral or monastic, is manifestly a corruption of the sacred architecture of the Greeks or Romans, by a mixture of the Moorish or Saracenic, which is formed out of a combination of the Egyptian, Persian, and Hindoo.”

But why should we wander into every remote corner of the world, and even into the regions of fancy in search of an invention which belongs to our own climate? And for what purpose should we take so much pains to prove a plant to be an imported exotic which we have seen sprouting up, and attaining its full growth in our own garden? Let us now go back to the point from which we started in pursuit of various falle syllems. We have been above that the greatest people, without dispute, of the eleventh and twelfth centuries, namely, the Normans, the conquerors of England, France, Italy, Sicily, and various regions in the East, were at the same time a most industrious and ingenious people, and possessed of the most ardent passion for ecclesiastical architecture of any people we read of; and that they vied with each other in the grandeur and beauty of their respective structures. To produce the effect of grandeur, as it has been before observed, they gave the greatest possible length and height to their churches; for that of beauty they devised several architectural ornaments; the most common of which was the arcade or series of small round arches, which appear on some part or other of all their churches built in this country subsequeint to their construction, and which sometimes cover the whole of them over; as we see on the outside of St. Botolph’s priory, and St. Olivy’s abbey in Effex, and in the basement story of the inside of Durham cathedral. These arcades the architects diversified in a great variety of ways, as may be seen upon the tower of St. Angeline’s monastery in Canterbury, built by the Norman abbot Scauldoun in 1280. One of the varieties consisted in making the circular arches intersect each other. The portion thus intersected formed a new kind of arch, more graceful in its appearance, and far better calculated to give an idea of height than the round one, which, however, had hitherto been adopted by all nations, whether Egyptians, Greeks, Romans, or Saxons. In fact, every one must be sensible that a pyramid or obelisk, from its aspiring form, appears to be taller than a semi-circular arch, the diameter of which is equal in height to it. These plain and intersecting arcades were sometimes irregularly intersected, as in Carlepho’s and Flamard’s work on the north side of Durham cathedral; and sometimes placed in alternate rows, as in that of Remigius on the facade of his church at Lincoln. The pointed arch thus formed appeared first in mere batts reliefe, as in the above mentioned instances, amongst several others; but soon it was likewise seen in alto relievo over niches and recesses, in the walls of churches, as in the remains of archbishop Lanfranc’s work in Canterbury cathedral, and in the abbey churches of Glastonbury and Runneby. It is probable that some of the first, if not quite the first open arches in the pointed style now existing, are the twenty windows in the intersected portions of such croffing arches in the choir of St. Crofs near Winchelsea, made by that great encourager of the arts, and particularly of architecture, bishop Henry de Blois, king Stephen’s brother. The date of this work is 1132, according to Godwin, Crofe, and others, or else 1130, according to bishop Lowth, who had examined the records of this foundation, and Rudborne, the monk of Winchelsea, in his “Historia Major Wintoniensis.” Most probably the choir was begun in the former year, and finished in the latter. As the prelate proceeded in his work, from the choir to the transept and tower of his church, he made several other pointed arches without any intersecting circles over them, notwithstanding the greater part of his work, as still appears, was the circular Saxon. In 1138, as we are assured by the above-mentioned monk of Winchelsea, and another monk who wrote the “Annales Wintoniensis,” bishop De Blois rebuilt his episcopal mansion of Farnham in Surrey, where his succellers still ordinarily reside. Now in the ancient part of this building, we see at the present day pointed arches reposing upon circular Saxon columns, just as we do at St. Croe; and no architectural critic, with these documents before him, will hesitate...
state a moment in pronouncing them part of the work in question, executed by De Blois in 1138. As the fame pro-
late restored the abbatial church at Rumsey, where his
niece Mary was a nun, and as he himself had been abbot
of Glastonbury, before he was bishop of Winchester, we
may safely attribute the pointed arches, intermixed with
the circular ones in these two structures, to his direction,
some time in the latter end of the reign of his cousin
Henry I.

After all, it would be rash to pronounce absolutely that
bishop De Blois of Winchester was the author of pointed
architecture, since we have convincing evidence, that churches
were built by other architects about this period, in the fame
mixed style of pointed and circular work. We must, however,
incidentally observe, that before the conclusion of this twelfth
century, the circular style was entirely laid aside, as well
with respect to columns as to arches. We have evidence for
example, in the amals both of St. Wurzburg's abbey
Cheller, and of Peterborough abbey, quoted by Dugdale,
that Biddwas abbey in Shropshire, where the seven pointed
arches of the nave, surmounted by small circular arches, in
the upper story, are still seen, was founded either in 1135
or 1139; it probably was begun in the former year, and
finished in the latter. We might argue in the same manner
from the dates and actual state of Kirkstall abbey, Lanctony
abbey, and several other ancient structures. If we may give
implict credit to the testimony and the plates of captain
Gros, the Scotch architects were not long in adopting the
style of their English neighbours. It is remarkable that the
ecclesiastical buildings erected by David king of Scotland,
and his nobles, before he came into England in order to com-
mand the armies of his niece, the empress Maud, were
purely in the Saxon style; whereas those founded there,
after that event, present the same mixture of circular and
pointed architecture which prevailed at that period in
England.

A late writer, the Rev. Mr. Whittington, whose pro-
selled object it was to transfer the credit of the discovery
in question from the Norman English and English to the
French, which credit the latter seem disposed, from tradi-
tionary accounts, to attribute to our countrymen, has af-
firmed that examples of pointed arches, of a more ancient
date than any existing in England, are to be met with at
the abbey church of St. Denis near Paris, which church
was finished in 1144. It appears, however, that this
writer was unacquainted with the historical evidence on
which the above-mentioned early instances of the pointed
arch in England rest, and that he was even at a loss to de-
termine which of the works at St. Denis really belonged
to the period he has alluded. If we examine the pointed
windows of this abbey, exhibiting different transissions of
the first crucifix in Montfaucon's "Monarchie Françoise,"
which windows are said by this great antiquary to have been
executed by abbot Sugar in 1140, we shall not find the
appearance of a pointed arch in any one of them. It may
be added, that in the famous tapestry of Bayeux, represen-
ting the conquest of England, and said to have been wrought
by the conqueror's mother, there is no appearance either
of a pointed, or so much as of an intersected arch, in the
several churches, fibries, and other architectural works there
displayed. In a word, throughout the whole of Montfaucon's
places, we every where find the French pointed architecture
much inferior to that of a corresponding date in our own
country.

To return to the subject of intersecting arches: we ob-
serves these sometimes to consist of plain semicircles crossing
each other, as on the outside of the south transept of Wal-
krelyn's work at Winchester, and on the north transept of
Warwell's work at Exeter, forming in the latter case simple
pointed arches; and for instances we may name that an
intersecting roll upon pillars, each of them being intersec-
ted by a capital, or at least with an abacus, as on the
north transept of Durham, and the west front of Lichfield
cathedrals. In the latter case, we have the appearance of
pointed arches with lateral points, or cusps upon the heads
of them, as Sir James Hall has very aptly observed. This
addition to the pointed arch was occidentally made in the
first period or order of pointed architecture, but afterwards
it became universal. The addition of another cuspid or ex-
sive of the pointed arch turned its trifoliate head into a
foil. In like manner, four of these cusps being placed on
equal dailances within that circle or "L'Œil du Bœuf,"
which the Roman and Saxons architects had been in the
habit of placing in the tympanum of their pylons, transof-
med it into an elegant quatrefoil or crofs. By means of
additional cusps, and circles within circles, the cathedral of
the Wheel, or Marygold window, as it is called in England,
"La Roche du Pontus," as the French term it, was easily
produced. In all the works executed during the middle
and latter part of the twelfth century, a confused and in
trigent mixture of styles is every where discernible, as
might be expected where circular fashion began to be left
off, and the pointed one to be used instead of it.

In a general way, the arches were altered before the
columns. Hence nothing is so common as to find in the
structures erected between 1140 and 1180, arches of the
sharp point, rolling on circular Saxon pillars of the greatest circumference. It could not, however, long
escape the observation of our indefatigable architects, that
such heavy supporters ill accorded with the lightness of
the aspiring arch. Accordingly, towards the latter end of
this twelfth century, in some instances the circular Saxon
column began to be shaped like the Arabic numerical
figure 8, so as to retain its former strength, and to appear
gracefully slender; and where columns were made use of
more for decoration than for strength, as for example to
support ornamental arcades, or the corners of windows
or doors, very thin detached columns were employed,
and those for the most part made of Purbeck or Pentworth
marble. We have a striking and most interesting example of
these and other improvements which took place in the point-
ed style, towards the latter part of the twelfth century,
in the east end of Canterbury cathedral. Persons who
cannot see the original, will find it accurately represented
in Mr. Carter's treasury of original specimens, called "The
Ancient Architecture of England." This portion of our
Metropolitan church was rebuilt, after an accidental fire had
destroyed the upper part, and weakened the remainder of
it, between the years 1175 and 1180. As we have the
most incomparable advantage of perceiving a circumstantial
account of this rebuilding, and of the differences between it
and the former structure, raised a hundred years before by
archibishop Lanfranck, which account is drawn up by the
intelligent monk Gervase of Canterbury, who was an eye-
witnenss of what he relates, we shall submit some of the
most material parts of it; he tells us that, the pillars of
the new choir were of the same form and the same width
those of the old choir, but that they were twelve feet
longer; that the former capitals were plain, while the
latter were delicately carved; that there were no marble
columns in Lanfranck's work, but that there was an
incredible number of them in the work of the two
Williams; that therones which he raised the ancient
arches were cut with a axe, but these of new arches with
a chisel.
GOTHIC ARCHITECTURE.

a châtel; that the vaulting of the side aisles of the choir was plain, whilst that of the new choir was groined and fixed with key-stones; that the former choir had a flat ceiling ornamentally pointed; but that the succeeding choir was elegantly vaulted with hard stone for its ribs, and light toph stone for the interfaces; finally, that there was only one triforium, or gallerie, round the ancient choir, whilst there were two such in the modern choir. The east end of this venerable cathedral, as it is seen at the present day, and as it is represented by Mr. Carter, exactly corresponds in these and in other particulars with this description of it, given 500 years ago. It is all in the first order of the pointed style, except the main pillars, which are (to the eye) round, with a sort of Corinthian capital, and except the arches springing from these pillars, which are also circular as far as the console abside or altar end, these being pointed, as likewise with the exception of certain blockings and mouldings, where the Saxon billet ornament is still seen.

The improved architecture of this, the most dignified church in the island, could not fail of being adopted in our other churches, when there was occasion for rebuilding or repairing them. Lincoln cathedral seems to have led the way in this particular about the year 1192, under the direction of its bishop St. Hugh, who was not less renowned for his skill in architecture than for the sanctity of his life. This prelate undertook to rebuild the whole of his vast cathedral, and he was so intent upon the work, that, as Matthew Paris tells us, he carried mortar and stones on his own shoulders for the sake of the masons. The building was so far advanced at the time of his death, which happened in the year 1200, that he is considered and called its founder, though his work was not finished till about fifty years afterwards, in the episcopacy of Robert Grosetete. Excepting the west front, which is almost all the work of the Normans, prelate Remigius, and the towers, the groining, the screens, and certain other decorations added in the fourteenth century, the whole vault pile of St. Mary's church and Chapter-house at Lincoln is in the simple style of the first or lancet order of pointed architecture; but awful and beautiful beyond the conception of those who have not seen it, and greatly superior to any church of the same order and period to be found in France. In 1222, the rich and powerful bishop Godfrey de Lucy, amongst his other great works, began to rebuild the eastern part of his cathedral at Winchester, which he executed in the style of the Metropolitical choir, but without the vault mixture of the Saxon. His extensive work is still to be seen there, confounding of long narrow sharp-pointed windows and other arches, detached pillars of Purbeck marble, quatrefoil mouldings, and light groining of simple intersecting ribs. And, whereas, it became very usual, for the sake of the gracefulness and utility of such windows, to place two of these narrow arches close together under another pointed arch of greater width, in consequence of which a vacant space occurred between their heads; a trefoil, quatrefoil, or cinquefoil was frequently introduced, with the happiest effect, to fill up this space. In 1227 archbishop Walter de Grey began to rebuild the northern Metropolitical church of York in the prevailing style, and he actually finished the south crofs aisle as it is now seen. The same kind of work was going on at this time at Worcester, Salisbury, and other cathedral and abbey churches. The last-mentioned church, which was an entire new foundation, begun by bishop De Poore in 1220, and finished by bishop Bridport in 1258, exhibits, in its front and other parts, the double lancet arch, with the intermediate quatrefoil rofe, and all the other cha-

rafters described above. There being occasion, however, to place three lancet arches together in the windows of the upper story, the head of the middle one was gracefully raised above the other two, an improvement which was soon adopted in many other churches. A still more striking improvement which took place, if not at Salisbury for the first time, at least about the time of its completion, was the elevation of the cornice, pediment, or canopy which had hitherto adhered, or at least had been very near to the architrave of the arch. This was now raised, like the two sides of a triangle, to a considerable height above it. The jambs of the pediment were at first rather short, not reaching, by any means, to the springing of the arch, and generally resting on some small flower or other light ornament. The point of the canopy always terminated in a trefoil or other graceful ornament, but was not, as yet, adorned with crockets or foliage down the jambs. Bishop De Poore, being translated to Durham, began to ornament the east end of his present cathedral in the style which he had introduced into the one he had left. Whilmt the work at Salisbury was drawing towards a conclusion, that at Westminster abbey was beginning, namely, in the year 1245. The north transept, and part of the adjoining nave of the church, remain in almost the same state they were left in by their founder Henry III. The windows of the last-mentioned portion of the abbey, together with the corresponding aisle, are larger and better proportioned than any which had hitherto been seen in this island. Here also we meet with the cinque-foil rofe between the heads of the two lights; while the exterior windows of the triforium or gallery consist entirely of a triple cinquefoil under a pointed arch. These two models for the upper part of church windows were long followed. On the other hand, the arches and windows of the transept, being placed in a regular order, and very near to each other, presented an appearance of those large mullioned windows which, in the succeeding period of this style, came into fashion. In this part also of the abbey church, namely, the inside of the transept, we begin to meet with good statuary.

During the reign of Henry's son, Edward I., which began in 1272, the architecture of this country, through the ingenuity and industry of its artists, acquired a new character, and may be said to have grown into a new order of the pointed style. The first and distinguishing feature of this was the general adoption of the well proportioned and well turned alpining arch. The arches which had hitherto been constructed, though sometimes accidentally perfect, were, for the most part, too acute. But the arches built at the latter end of the thirteenth century generally approached to the perfect proportion. This proportion, according to the able judges, is when an equilateral triangle can be inscribed within the crown and imposts of the arch. The arches also were gracefully turned. Besides all this, they were now invariably ornamented in their heads with cusps, fo as to form trefoils, cinquefoils, or sepfoils. In like manner the pediments or canopies over the arches were universally purfled, that is to say, adorned with the representation of foliage called crockets, from the corbel on which they rested up to the rich flower or other elaborate finial in which they terminated. These corbels or brackets now corresponded in height with the springing of the arch, and mostly exhibited buls of the founders or other benefactors of the establishment. Pinnacle, which hitherto had been both very simple and very rare, were, in this improved order, placed at the sides of almost every arch, and on the top of almost every buttress, being invariably purfled and surrounded with rich finials. A pinnacle of a proportionable fl-
GOTHIC ARCHITECTURE.

the nave being placed on a tower, instead of a buttress, became a broach or spire. Accordingly the use of spires became almost general in the fourteenth century. We even read of a new built tower being pulled down, because it was unequal to bear the weight of this grand ornament, when a new one was built, which, with its spire, was as high as the church was long. In the same spirit of ornamental grandeur, the buttresses, supporting the upper part of the nave, instead of being concealed in the roofs of the side aisles, were brought into view with suitable decorations, and made to stretch over the tops of these aisles, in what are called flying buttresses. The window no longer composed of an arch divided by a simple mullion, and surmounted with a single or a triple rote, but was henceforward, in all grand churches, portioned out by mullions into three, four, five, six, and sometimes into nine different bays or days, as the separate lights in a window were then called; and these again were frequently subdivided by one or more transoms running across them. Their heads also were varied by tracery work into a variety of architectural designs, and sometimes, as at the west end of York, into the form of a beautiful flower. The plain niches of the thirteenth century, in the fourteenth, groined, large and beautiful, in which much architectural skill was often displayed as in the whole church of which they belonged. These tabernacles, as well as various other parts of the sacred edifice, were filled with statues, which frequently showed equal spirit in the design and art in the execution. Finally, the ribs supporting the groined ceiling were no longer simple intersecting arches; but they branched out into tracery work, still richer and more elegant than that in the grand windows of this period; and wherever the ribs met, they were tied together by an architectural knot or boss, which generally exhibited some instructive device. It must not be forgotten, that during the latter part of this period, the pediments which before had been straight, began to humour the sweep of the arch, by which means they became less high and more graceful.

We have instances of these improvements, or rather of this new order of the pointed style, in the three remaining architectural crofts, erected by Edward I. the elder of Northampton, Geddington, and Waltham, to the memory of his queen Eleanor, who died in 1290; likewise in the magnificent tomb of his brother Edmund Crouchback in Weftminster abbey, who departed this life in 1296. But the most complete specimen of the whole detail of these improvements is York Minster, the nave of which, as it stands, was built between the years 1290 and 1355, and the choir some thirty years after the latter period. If any similar structure in the same style, but upon a smaller scale, could, in its time, have vied with this in beauty and grandeur, it was St. Stephen's chapel, Weftminster, now the house of commons, which Edward III. began to erect in 1348. Of the inimitable beauties of the latter erection, only a few scattered vestiges remain, to shew the architectural antiquity which it was in its glory. There are few, if any, of our cathedrals and remaining abbey churches which were not rebuilt or restored in some considerate part or other of them, according to this improved order. Before 1221, bishop Langton had added the Lady chapel to his cathedral of Litchfield, and groined the nave and choir, and had erected the magnificent western façade. About the same time the greater part of the nave of Weftminster abbey church was rebuilt. Between the years 1327 and 1349, Exeter cathedral was groined, and its heavy Norman arches and pillars were changed into light and graceful pointed arches and clustered columns, by its ministerial prelate Grandison. During the pontificate of archbishop Courtenay, which began in 1351, and that of his successor Arundel, the nave of Canterbury was rebuilt. During the same period, that elegant prelate and architect, William of Wykeham, was employed in performing the same difficult transmutation of the same nave of Winchester cathedral, which had been performed in that of Exeter. The circular columns and arches were not taken down, as has been generally supposed, but the former were cased and the latter reduced to a point. This may be ascertained by an attentive examination of the work within the roofs of these structures; and without this trouble, by simply looking at the nave of Gloucester, St. Albans, or Romsey great church, where the operation here described will appear to have been performed, on two or three of the circular pillars and arches at the west end, and to have been left off with respect to the other pillars and arches. The tale for these improvements is described even to country parish churches, few of which did not lower or later exchange their ancient windows, at least, for those of the pointed style.

But human arts, like the human body, when they have attained the perfection of their race, tend towards their decline. This was the case with that singular invention, pointed architecture. Its rise, progress, and decline, occupy little more in the chronology of the world than four centuries. As its characteristic perfection consisted in the due elevation of the arch, so its decline commenced by an undue depression of it. This new style, or third order of pointed architecture, took place in the latter part of the fourteenth century, and is to be seen in the royal chapels of St. George, Windsor, of King's college, Cambridge, and of Henry VII., Weftminster. It cannot be denied, that the builders of these splendid and justly admired structures displayed more art and more professional science than even their predecessors had done; but then they displayed this at the expense of the style itself, which they cultivated, and of the awful and devout impressions which this style was invented to excite. The spectator was now amazed to see huge masses of stone, called pendent capitals, each one of more than ten weight, hanging in the air, which, instead of supporting the vast groins they were fixed in, were supported by them; the consequence of this, however, was to bring the flat arches of the ceiling still nearer to the eye, so that their curvature was henceforward discernible at their springing rather than at their point. Finally, ingenuity was at this period much more pointed than awkward; hence those royal chapels, and several mortuary ones built in Winchester, Peterborough, and our other grand churches, during the time of the two last Henrys, are seen covered over with tracery, and loaded in their groins and friezes with buds, armorial bearings, and retables, beyond all due proportion, so that, however elegant the design, and exquisite the execution of them generally is, a judicious spectator, after admiring them, falls not to prefer to them the chaste grandeur of York Minster, or even the unadorned majesty of Salisbury cathedral. The church-windows of this period were so multiplied and enlarged, as to become what a late writer, Mr. Whittington, professes to admire as all windows, but which they certainly could not become without great detriment to the character of awfulness in the church itself. The same depression of the pointed arch took place on the outside as in the inside of the buildings of this period. Instead of the tapering pinnacles and lofty spires which had hitherto adorned the towers of churches, these structures were now generally covered with round cupolas, and the portals, instead of being surmounted with crowned pediments and graceful pinnacles,
were generally enclosed within square architraves, the chief
ornaments of which were seen in the spandrels. All this,
however, is to be understood with some exceptions. For
example, bishop Oliver King erected his church at Bath,
about the year 1502, in a very simple fashion of pointed
architecture, and bishop Fox repaired the prebbytery and chan-
cel of Winchester cathedral with a chaste and tasteful
elegance.

But the downfall of pointed architecture in this kingdom
became inevitable from various causes; chiefly, however,
from the loss of its characters of majesty and awfulness,
the necessary consequence of the depreciation of its sublime
and graceful arch. The deflection of it was complete
at the beginning of the reign of Edward VI., from which
period, till the introduction of the pure Greek style in
the reign of Charles I., a real Gothic, or at least a truly barbaric
style took place, consisting of a confused medley of all
the known styles and orders of styles, intersected with globes,
triangles, pyramids, obelisks, friezes, and other whimsical
and ugly devices, as may still be seen in the sepulchral and other
monuments of the period in question.

From what has been said, it appears that the term
Gothic architecture is an improper one, as applied to any
species of architecture whatsoever; that the mode of building
which prevailed amongst our ancestors before the con-
quest, called the Saxon style, consisting of round pillars
with rude capitals and bases, and of circular arches, was strictly
Roman, being copied, even to its minute ornaments, from
coeval originals at Rome, and having been first taught and
practised in this island by Roman masters; that this style
was succeeded, before the middle of the twelfth century, by
a style of architecture perfectly new, the essential character
of which is the pointed arch, from which, by a natural
process, the slender cluster columns, the aspiring cornice or pedi-
ment, the crocketed pinnacle and lofty spire, with the other
ornaments mentioned above, actually grew; that this style
was not borrowed from Northern Goths, nor Eastern Saracens,
nor Western Moors, nor Southern Italians (for in this style the Italians themselves were but novices, and not very
apt ones), but that it was discovered in this climate, most
probably by the English Normans, the greatest people of the
12th age, and the fonder of ecclesiastical architecture
that ever existed; that the style was improved by the joint
efforts of the Normans, English, and French, at a time when
our kings were masters of the fairest provinces of France,
and brought to its perfection, chiefly by the ingenuity and
industry of the English, during a period in which England
was in prosperity by her conquests, and France in depo-
sition from her defeats; that there are three distinct orders in
this style, the members and proportions of which can be dif-
tinctly pointed out by professional men, (such as the author
of the "Ancient Architecture of England") with almost as
much accuracy as those of the five Greek orders; on which
subject it may be observed, that these Greek orders were
practised long before their members and proportions were
accurately laid down, that the characteristic of the first order
is the acute arch, and that the period of its duration may, in
a general way, be said to have lasted from the middle of the
twelfth to the end of the thirteenth century: of this order,
Lincoln, Beverley, and Salisbury churches are examples;
that the chief characteristic of the second order, is the per-
fect or equilaterial arch, the reign of which was from the
end of the thirteenth, till after the middle of the fifteenth
century, to which order York Minster, and the naves of
Winchester and Canterbury cathedrals belong; and that
finally, the characteristic of the third order is the obtuse
arch, which grew into fashion about the first-mentioned pe-
riod, and lasted to the downfall of pointed architecture itself
in the middle of the sixteenth century. The finest specimens
of this, doubtless, are the above-mentioned royal chapels.

With respect to the proper denomination of this style,
none of the learned, as well as the vulgar in general, still call it
the Gothic, others the Saracen, a third class, the Norman,
a fourth, the English, and a fifth, the pointed. From the
whole of what has been said above, it will be readily con-
cluded, that the present writer conceives the last of these
terms to be the best adapted to the style, as being the most
strictly descriptive of its characteristic quality.

This article is the abridgment of a much longer treatise
on pointed architecture, which is shortly expected to appear
from the press of Mr. Taylor's Architectural Library; in
which treatise many historical documents in support of the
present system, and certain plates to illustrate it, will be
seen.

Gothic Bible. See Bible, and Argenteum Codex.

Gothic Character, or Writing, is a character or manner
of writing, which, in the main, is the same with the Roman,
only that it is very full of angles, turns, and bends, espe-
cially at the beginning and ending of each letter.

The manuscripts in Gothic characters are not very ancient.
Ulphilas, bishop of the Goths, was the first inventor of the
Gothic characters, or the first who composed the Gothic
alphabet, in imitation of the Greek, and the first that trans-
lated the bible into the Gothic tongue.

The letters used in the Gothic gospels are twenty-five in
number, and formed, with slight variations, from the cap-
tals of the Greek and Latin alphabet.

As these characters, in which the Codex Argenteus, or
Gothic version of the bible, was written by Ulphilas, their
inventor, were derived partly from the Greek and partly
from the Latin, Michellus (Intro. to the N. T.) thinks it
natural to ascribe the said version not to the Franks or Ger-
mans, but to the Goths, who lived on the borders of the
Danube; or in Wallachia, where they at that time resided,
the Latin was spoken, and their nearest neighbours were the
Greeks. A mixed alphabet, such as that which is found in the
Codex Argenteus, is such as might reasonably be ex-
pected. Some of the words in this version are still used in the
Lettich Tartary, the ancient seat of the Goths; e.g. "facilis,
" to do;" from "facio, "to do," a word that is quoted by
Bobeck, from the language of the Crim Tartars. In this
version, many words are adopted immediately from the
Greek; e.g. ort, orta, orter, father; ann, am, the shoulder,
where even the s is retained from the Greek termination, &c.
Hence it is inferred, that the dialect, in which such words
occur, was that of a nation that lived in the neighbourhood
of the Greeks. This version has also Salazarian words, such as
"fam, "a matter, which prove it to have been written in the
dialect of a nation that bordered on Sarmatia. The same
may be said of many Latin words: such as "amabilis, accu-
cumere, to sit at table, "militantes, "militantes, soldiers, ohyse,
water, &c. This argument is the more decisive, when we
consider, that the Goths, in the time of Ulphilas (see his
biographical article,) lived in Wallachia, a country in which
Roman colonies had been planted, and where a corrupt Latin
language was current at this very day. Ulphilas himself lived in
Wallachia, and had in his power at least to make use of Latin
letters, as well as those of the Greeks, with whom he had
continued intercourse. See Gothic Language.

The Runic characters are also frequently called Gothic
characters. See Mabillon, De Re Diplomat. lib. i. cap. 2.

But
GOTHIC LANGUAGE.

But they who take the Gothic characters to be the same with the Runic, are mistaken; as is shown by Ol. Wormius, Junius in his preface to the Gospels written in Gothic letters, and Dr. Hicks on the Runic Tongue.

Gothic Column is any round pillar in a Gothic building, either too thick or too small for its height.

There are some found even twenty diameters high, without either diminution or swelling.

Gothic Language, the language of the Goths. This language, as the acknowledged parent of the English, is of considerable importance; while its remote antiquity, the fancies of its records, and the circumstance of its having been utilized only by few among the learned, have rendered it a matter of great uncertainty as to its character and origin. The questions respecting its antiquity and genius are resolvable in those in regard to the people who used it. Mon. Mallet, in his "Northern Antiquities," supposes that the ancient Gauls and Germans, the Britons and the Saxons, were all originally one and the same people; and thus he makes the Gothic the same with the Celtic tongue. This opinion, which was first taken up by Cluverius in his "German Antiquities," has been since adopted by KEYFIER in his "Northern and Celtic Antiquities," and PELLONIER in his "History of the Celts," and maintained by them with uncommon regard. According to these writers, the ancient and original inhabitants of Europe consisted only of two distinct races of men, viz. the Celts and Sarmatians; and from one or other of these, but chiefly from the former, all the ancient nations of Europe are descended. The Sarmatians, or Sauromates, were the ancestors of all the Scythian tribes, viz. the Poleis, Ruffians, Bohemians, Wallachians, &c. who continued to this day a distinct and separate people, extremely different in their character, manners, laws, and language from the other race, which was that of the Celts; from whom, as they suppose, were descended the old inhabitants of Gaul, Germany, Scandinavia, Britain, and Spain, who were all included by the ancients under the general name of Hyperboreans, Scythians, and Celts, being all originally of one race and nation, and having all the same common language, religion, laws, customs, and manners.

This opinion, though supported with an uncommon display of deep erudition and a great variety of specious arguments, is controverted by the late learned and ingenious Dr. Percy, in a preface to Mon. Mallet's Northern Antiquities, which he has translated and enriched with notes. This profound antiquarian, in opposition to the French writers, states that ancient Germany, Scandinavia, Gaul, and Britain, were not inhabited by the descendants of one single race; but on the contrary, divided between two very different people; the one of whom he calls with most of the Roman authors Celtic, who were the ancestors of the Gauls, Britons, and Irish; the other Gothic or Teutonic, from whom the Germans, Belgians, Saxons, and Scythesians derived their origin; and that there were ab origine two distinct people, very unlike in their manners, customs, religion, and laws.

The Gothic, then, is radically different from the Celtic according to Dr. Percy, who, on the authority of Hicks, as quoted in the preface to his "Institutiones Grammaticae Anglo-Saxonicae," gives the following genealogy of the two languages. Gothic is the parent of 1. Old Saxon, or Anglo-Saxon; 2. Frisian or Franco-Theotis; 3. Cimbri, or Old Icelandic. From the first, viz. the Anglo-Saxon are again derived English, Broad Scotch, Belte, Low Dutch, and Frisian. From the Frisian, are derived German, or High Dutch, German of Swabia, and Swedes; while the Cimbri, in its turn, gave birth to the Icelandic, Norwegian or Norse, Danish, and Swedish. On the other hand, the Celtic is represented by the same writer as the parent of the ancient Gaulish, the ancient Irish, (ramified into the Cornish, Armonian, or Brit-Breton, and Welsh,) and the ancient Irish, which was subdivided into Manx, or language of the Isle of Man, into Erse, or Highland Scotch, and Irish. To the old mother tongue of all the Gothic dialects, it has been usual to give the name of Teutonic, not as such, Dr. Percy affords from its being the language of Teuton, the great father and deity of the German tribes, as from the Teutones, the people who used it in the name probably with the Cimbri, or as the Greeks called them, Teutoni, who inhabited the northern regions, and more particularly, the Danubian hills. Now, in opposition to this writer, we are free to affirm, there is no ground for believing that this mother tongue, whether called Gothic or Teutonic, was in its primeval form different from the Celtic. And this proposition we shall endeavour to make manifest from the very specimens by which Dr. Percy has attempted to show their essential difference. But before we enter on this question, it is necessary to remark, that learned men, in their enquiries concerning the origin of nations, have not sufficiently attended to the consideration which we learn from the Mosaic history, that all nations originated in a common family, and at first spoke a common language. Let us suppose that some members or descendants of this family, (as we read of Gomer,) emigrated from Asia to Europe. If they settled in Greece, they introduced with them the primeval customs, and language, though somewhat corrupted no doubt from its original purity. Others, actuated by the same spirit of emigration, would soon follow; and, if more powerful, would disseminate their predecessors, who had no other resource but to seek new habitation in remote regions. As the wanderers multiplied, they advanced, till, in the course of years, all the countries on the north and west, as well as on the east of Europe, were completely peopled. But this population of course could not take place before they had been divided into independent tribes, and distinguished by correspondent difference in dialects and manners. But still a very great resemblance must have as yet been visible among them in both their respects, however separated from each other; for in the earlier periods of society, language, though widely used, must long have continued the same, with little variations, it being corrupted and diversified into distinct tongues only by the progress of civilization, by the refinements of literature, by improvements in art and in government, and by those political convulsions which the love of conquest, inspired by conscious superiority in those arts, produces. All the nations of Europe, therefore, in the ruder and more early ages, may be considered as using only the same great primordial speech, grown indeed into distinct branches, and affixed in one country the appearance of being independent of, and unconnected with those used in other countries. Now, if we suppose that the Celts were the first emigrants from Asia, who, prevailing Europe, settled in Gaul, Old Spain, Britain and Ireland; while their brethren, under the name of Celti (Goths), Storians, Cimbri, &c. directing their course to the North, occupied Thrace, Scandinavia, and other northern territories; it would follow, that these tribes, however remote, used at first either the same language, or languages which had a close affinity to the common primeval tongue. Nor would there be material difference in this condition, though we should suppose, with many learned men, that the inhabitants of the North of Europe came, not from the East, but from
the North of Asia, as they must still have been descendants of the same primitive family, which, according to Moses, peopled the world. Thus the Celtic and the Gothic or Teutonic must have been, in their origin, the same oriller tongues.

But further, while the ancient Celts and Goths continued in the darkness for which they became proverbial, the inhabitants of Greece rapidly improved in laws and the arts of life. In this improved state, Greece became, in regard to the left favoured inhabitants of the North and West, what Asia had hitherto been in respect to Greece, a fresh source of civilization and letters. Its language, growing more copious and refined with the people, diffused itself with the blessings of knowledge and society, which their example or influence imparted to the Northern and Western inhabitants of Europe. Thus Greek, with the arts of Greece imported into Italy, gave birth to the Latin tongue; and this at a later period necessarily affected the Celtic language, in consequence of the victories which the Roman arms attained in Gaul and in Britain. This revolution greatly widened the line of distinction which for ages had been extending between the Celtic and the Gothic tongues; the former being assimilated to the Latin, the latter to the Greek, by a copious influx of new terms. It was indeed matter of great curiosity if some records of the Celtic and Gothic tongues had been preferred before they were yet modified by the attendant languages of Greece and Rome; but no such records unfortunately have survived the wrecks of time. And we can judge of the ancient Celtic only from the Welsh, its acknowledged daughter; while we are left to form our judgment of the primitive Gothic from the remnants of a version of the New Testament, effected by Ulphilas, into the dialect used by the Goths in Moesia, and hence called Mero-Gothic.

Having made this preface to shew that the Celtic and Gothic had one common basis, viz. the primordial tongue imported from Asia, we proceed to prove, as far as we are able from their respective offshoots, that they had in common many Asiatic words, and were modified by a great portion of Latin and Greek terms; and that from these two causes they effectively resembled each other. The Lord’s prayer is thus rendered in the ancient Gothic of Ulphilas.

1 Atta unfar thi in himin 1 Father our thou in heaven
2 Veilmai name their 2 Be sanctified thy name
3 Quinmai thildmaius theins 3 Come thy kingdom
4 Vairthai Vilga theins fuc in himina, gah ana airthai 4 Be done thy will be done in heaven, also on earth
5 Hialf unferana thana feintian gaf uns himinadiga 5 Give us this day the bread of Paris
6 Gah afet uns thari feulan figanian, fua fe gah vevs alisiam than feulum unferan 6 And forgive us that we are debtors, as also we forgive those our debtors
7 Gah ni bringais uns in fratstubgai 7 And bring us not into temptation
8 Ak laudt uns aithanna 8 But deliver us from evil, ubelin, Amen.

The following is a specimen of the Celtic, as existing in the Welsh tongue:

1 Ein Taad, yr hwm wyth 1 Ourfather, the one who
yn y Neboth 2 Our art in heaven
2 Statheidler dy enw 2 The halbed thy name
3 A bryster dy deuranns 3 Our Thy Kingdom
4 Bydded dy Euyllys ar 4 Be thy will on the earth
y ddaiar meigis y mae 5 As it is in the heaven
yn y nevyth 6 Give us this day our daily bread
5 Dyro i ni heiddyw en 6 And remit to us our
barn barwyddiel debts as we remit to our
6 A madde ni ein Dy- debtors
ledion fel y maddeuwn 7 And lead us not into
6 ni ein dyledwywr trial
7 Ag nae arwain ni i 8 But deliver us from evil,
brofodigath 9 Amen.

We propose next to lay before our readers a brief analysis of the two specimens, which it is premised will shew that the two languages in question have much nearer resemblance to each other, than Dr. Percy, or any person who has not a thorough knowledge of both, could possibly imagine. The Hebrew בֵּית, pronounced with an initial and closing vowel, is adda, and signifies beer or wine, and this is the source of the Gothic atta, and the Greek αὕτη, with the usual propriety applied to a parent as the dearest object of love. The fame word in Hebrew is written יָמָן, doom, and is no other than the Celtic tand, under a difference of character. In the Cornish it is tam, in the Irish fettia, in the English other, and the old Cantabrian or Basquean atta, father. Unfar is the Greek προφετής, thus strangely corrupted, but, unser, unser; and hence the English our. In the same manner, tym, has degenerated into wuns, won, us. The Celtic ni is the Hebrew and Arabic pronoun יָנָה, and, which, founded with only the closing vowel, is 31 us, and with only the initial ein, our. The Gothic in and the Welsh yu have originated in the Greek εῦ, or the Latin in; but it is observably that these languages use this preposition as it is used in Latin, when followed by an accusive noun in the sense of into, unto, or to: thus in fremðbygnæ, into temptation; inni, or i ni, to us. The Welsh language is remarkable for the attention paid to harmony in the arrangement of its terms. To produce this effect the termination of a preceding word, in order to coalesce with the succeeding one, is sometimes changed, and thus made to unite both into one. Thus tym, which is yw hwn, the one, where r or rh (aspirated after the manner of the Greek χ) is prefixed to yw, the Latin unus, or the Anglo-Saxon an. Why, moreover, is a coalition of any fy art ibus, or thou art; any being the substantive Gothic verb to or won, whence the Goths derived their in, and the English our an. The Greek προφέτης, tempeli, or cloud, by softening the guttural into an aspirate, of which we shall presently give some more examples, has in the Gothic degenerated into browning, the place where the tempests or clouds reside, namely, the fly or heaven. In the Franco-Thorifte the same word is browning, and in the Cumbric browning. It exists also in the Celtic; but there it has retained its original sound and sense, under the form of ratum, a cloud. It is singular that the same association of ideas, founded on the nature of things, has transferred the Greek εὐ, or the Latin nubes, to signify in Welsh heaven, under the shape of nef or nefaid.

2. Veilmai is the verb of veil or veils, kilt, which is but the Greek προφέτης, with the ablative a substantiated for the aspirate, as the old Latins have done in numerous inclusions, some of which we shall presently produce. On the other hand, samtindier is familiar, converted by the Welsh into a verb; while dy
The Gothic language.

d is the same with the Gothic the, and no other than the Latin in, or the Anglo-Saxon ige, or the English thing. The Gothic thein, it is obvious, has given birth to the English form of thing. Name, whence our name, retains the Persian character of ige, though perhaps it is more immediately derived from *manan, and is a kindred noun with the Welsh an, which probably degenerated from *mōn, by dropping the last syllable.

3. The Arabic ʾydyn, queen, legs, has given birth to the Greek γυναῖκα, to use the legs, i.e. to come, and to the Anglo-Saxon ige, and our come. The same word has been imported into the Celtic in the shape of *commun, signifying to hop or leap. The same word exists in the Shanfer, unmum, to go. The corresponding Welsh dened or dywad, is the Greek γυναῖκα, τήν, or τίνι, to stretch to an object, which last depended from the Arabic ʾydyn, at, by dropping the initial vowel. The same verb exists in Welsh, under the different figure of thowyn or thoryn, and is no other than the English to, to conduct. The Gothic thiudan, a kingdom, seems originally to have meant the emperor of a divided nation, from the Greek *thiwos, and *ihos, or *ihos, as the offspring of the former exists in this tongue: thiud, gent, nation. On the other hand, the Welsh dywys is the Greek ἤπως, corrupted, by the transposition of r, into thos, or dyros. Our English thorn conforms to the original in sound and sense. In the Anglo-Saxon the corresponding word is yrce, which still exists in such English compositions, as hophen, i.e. the dominion of a bishop. In the Great Indian language abovementioned, this term figures under the character of yrph, meaning earth, and which is nearly the same in sound and sense with the Anglo-Saxon yrce, or our rice, and the Latin rēs, property.

4. As light or air is the chief medium of existence, the Hebrew term נֶפֶשׁ, otsias, gave birth to the Latin eram, erat, and the Gothic wair or verthorm, to be, to become. The Welsh yrdded, which exists also in the form of leu, and which is the same with the Greek δύναμις, and the Latin virtus, descended from the Persian bodan, to be. Wilka is ʾbāša, or ʾbēa, with ga annexed, by an analogy common in the Gothic tongue. The Welsh yrddw, or yrdd, prefixed, yrddlys, has flowed from the same source; and under the former of these forms is nearly allied to the English will. Sue is our se, or the Greek ἥσσος, or σέ, and in the name of Salei, a reverend, a fete very common with monosyllables in the ancient languages. Gab came from *ūl, and *ūl, which, in composition, means up, and has given birth to the Gothic geno of upon. Airghai is the Arabic arid, from the Hebrew יָרָץ, ares; while the Welsh arfer, or it as otherwise written, ʿer, originated in terra. The Hebrew יִבְרָץ, aber, the parent of ʾbrz in Greek, of *ber in German, ofer in Gothic, and over in English, has contrived in Celtic into ar, in the sense of upon.

5. The Arabic ʾydīn, dīb, fūd, is the origin of the Greek ὑδάς, and the English bath. Than, or than, is the accretive article τὸν. Sinim is formed from the noun ʿayn, scissurae, change, which is no other than the Hebrew יָמָע, or יָמַע, ʿayn, and ʿayn, that change or period of time called a year; hence ʿayn came to signify continued, or perpetual. Our Lord, we believe, by the clause ʿayn ʿayn ʿayn ʿayn ʿayn, meant not, as it is generally rendered, daily bread; but the bread belonging to us, and essential to us as immortal beings, namely, the bread of the soul. (See "Mr. Jones's Illustrations of the four Gospels," p. 123.) In this sense the clause was understood by the early commentators, and by the Greek translator, who has rendered it ὑδάς sinim, the eternal bread. In Hebrew, Arabic, and Persian, ḫēb, ḫēb, denotes the palm of the hand; hence it came to signify the action of the hand, which consists either in imparting or receiving. In the former sense it gave birth to the Gothic gíz, and in the latter to the Latin capio. Hirminige means this day; hūma, or as we write it, him, being the personal pronoun used derivatively, and dies, or dāg, according to the Anglo-Saxon, being the Latin dies; his day for this day, which is more common in the plural form among the vulgar than days.

The Welsh yrde, in the same veric, is the Greek ὑρδα, a gift, converted into a verb. Heldydyn is a dissociated form of huley, which last is only a contraction of brei dīe, this day. Buru is a word which exists in all languages. Its origin is the Hebrew יָבָע, pluralus, fruits: and hence, יָבָע in Greek, farr, and parso in Latin, handeth in Cimbrice, beast in Francize, breadth in German, braudo in Norse, bred in English, bred in Danis, and breu in Frisie. Brongydyn, rendered daily, appears to be composed of breu, a top or formns, and yddel, the Latin dixs adjectived, and means a top of each day, or a head of each day, i.e. daily. This word is also used beynydel, beyn being a corruption of pen, a head. The Welsh are fond of this expression, and have a phrase, poch dyrb ar y pen, each day on his head, meaning every day in succession.

6. Aftar, i.e. of after, or 1s. dū, distant to 2s. Thatis is a corruption of the Greek τοιαύτης, but or that thing, and is thus the parent of the English that; hence the realambence of the explanation which the celebrated Mr. Tooke has given of such phrases—remit us to that thing, τοιαύτης, festeus sines, we are debtors, s Delaws were peroni under command, under obligation or debt, from the Greek ἰδεπτοι is labouer: hence appears to have been derived our fudgement, a mean domestical servant. In ancient times labourers usually paid their rents in kind from the products of their fields; hence, in Greek, the tenant was called ἱδεπτος, in the same principle, in Gothic, the word signifying to labour, came to signify to owe, or to be in debt. Signina is only the Latin sūna corrupted by the infection of ga, a particle of frequent ufe in Gothic. The Welsh a math, or as it may be written, ammaddus, is a compoite of ag addde, and remit, the first being the Latin conjunction ar, the second the Greek μετα, the fame with μετα, to disjunt or remit. Dyedlen, the plural of dykel, is the Latin delites, things to be eradred, or to be cancelled by being paid, i.e. debts. The noun u, or the plural u, which in this tongue is to often added to the name of a thing, is but the Latin vir—dyldwyern, dedum or delverns.

7. The Goths and Anglo-Saxons corrupted ʿayn into ieran and bringan, and hence our to bear, and to bring—in bringan, do not bring us. The Latin in Gothic is mi, in Anglo-Saxon and English is, in Welsh na or nge. Frafitben is the corresponding noun of freifan, to tempt, and appears to have been borrowed from the Latin perfite, and therefore primarily meant perfite, starlhtvs. The Welsh arman is the French rien: with the vowel a prefixed, and is the same with our rites: its proper sense is to lead a horse with a bridle. The French, in deriving words from the Latin, generally reject the guttural in the middle or at the end; and on this principle the root of rent is regna, to rule, direct. Prefixedh th affection denotes experience, and its origin is the Latin præfite, which last is derived from the Greek προσφέρω, προσφέρα, or the corresponding verb προσφέρω, to take or offer.

8. The Gothic ʿak is the Latin aca, though used by the latter in a conjunctive, by the former in a disjunctive sense— but. The root is ʿak, or the thence derived ange, whence the Gothic anag: and at, conformably to the form of this last
left verb, is also written ane in the sense of name, same. The corresponding Welsh word is eithe, derived from *epeis, another. The explanation of it is this—lead us not into trial; another thing, i.e., do another thing, namely, deliver us from evil: on this principle: the conjunction allea, but, originated in alloa. Laufen, which has given birth to various words in Anglo-Saxon and in English, and among the number to loafe, leafe, relafe, let, is apparently the offspring of the Hebrew י֛וָנ, bus, deedo, receed: to deliver from evil is but to cause to receed from evil, and thus laufen corresponds in sense as well as in found to the original. A boole character is a character freed or loosened from the rules of sobriety and justice, and this deviation from rectitude is implied in the original י֛וָנ; while the compound relafoe comes close to the Gothic signification of laufen, to deliver. The Welsh which answers to this is gwared, and is no other than the Latin gerae, (properly pronounced guero,) to manage, to carry. The Arabic يُحَرَد, phard, is the origin of our word free, its primary sense. Being thence applied to men, it came to signify those who were the heads of families, or who went before them; hence it was used to convey the more general and abstract ideas of precedence or beginning; in this sense it is the origin of θυρις in Greek, peæ in Latin, free or from in Gothic, sfeda in Cimbric. In the Anglo-Saxon m is annexed, and hence our word from through the Scotch ufe it in the original purity of sfeda. The corresponding Welsh rhads, which means far distance, has retained with great exactness the found and fene of يُحَرَد, phads, its Hebrew original. The Gothic uhol, German uhol, Anglo-Saxon iffe, and English evil, is the Persian and Arabic يُحَرَد, bus, with a vowel prefixed. The Persian tarik, is the parent of the English dark; and as darkness was the symbol of evil, or of the suppolled demon which created it, the Celts received it to express evil under the form of dręs: and it is remarkable that the same word with alpha privative is used by the Greeks to denote a contrary fene, δραστης, not dark, ingenious, sincere, true. In the same language ἐρασης means an import, which the lexicographers, misled by mere similarity of sound, have erroneously referred to ἐρέσης, to eat.

From this analysis, which we hope is worthy the attention of the learned, we shall draw a few conclusions respecting the Gothic tongue. First, it appears to resemble the Celtic, in having a common Aftatic basis, and in containing a copious influx of Greek and Latin words. As the two languages were not essentially different, there is no foundation for supposing, with Dr. Percy, that the Celts and the Goths were originally distinct races of men. And here we cannot help speculating a feature in these tongues, which, in a remarkable manner, befits their original identity, or their immediate descent from a common parent. The Gothic, with its offspring the Anglo-Saxon and the German, uses the particle ge or ge prefixed to words, and especially to verbs. The Gothic sometimes infers g in the middle of words, and frequently before the infinitive termination of verbs: see, or auger, is weifgen, and *weifgen, to decide, blaghen, to laugh. In consequence of this analogy, words borrowed from Greek and Latin are remarkably disguised, and they must be stripped of this peculiarity before they can be traced to their true origin. The Celtic, if we may judge from the Welsh, was distinguished by the same characteristic feature: thus, the Latin vis is gaor; vinum, γυριν; vagus, gwaer, &c. On this principle is, like, as, in Welsh is wngis, which bears the sense of the original. The identity or similitude of the two languages will account for the Goths and Celts being called by the common name of Cimmerians or Cimbri, which the true Britons, the un­doubted descendants of the Celts, still inherit under the name of Cymri.

Sir W. Jones, in his sixth discourse delivered to the society at Calcutta on the antiquities of Asia, has the following passage well worthy of our attention, as tending to confirm, in a remarkable manner, the result of the preceding inquiry. The passage is this: "It has been proved by clear evidence and plain reasoning, that a powerful monarchy was established in Iran long before the Aryan government; that it was in truth a Hindoo monarchy, though, if any chue to call it Cufcan, Caffean, or Scythian, we shall not enter into a debate on mere names; that it subsisted many centuries, and that its history has been ingrained on that of the Hindoos, who founded the monarchies of Ayodhya and Indraprokha; that the language of the first Persian empire was the mother of the Sanskrit, and, consequently, of the Zend and Parth, as well as of Greek, Latin, and Gothic; that the language of the Aryan was the parent of Chaldäic and Pahlavi, and that the primary Tartarian language also had been current in the same empire; although, as the Tartars had no books, or even letters, we cannot, with certainty, trace their unpolished and variable idioms. We discover, therefore, in Persia, at the earliest dawn of history, the three distinct races of men, whom we described on former occasions as poïcflors of India, Arabia, and Tartary; and whether they were collected in Iran from distant regions, or diverged from it, as from a common centre, we shall easily determine from the following considerations. Let us observe, in the first place, the central position of Iran, which is bounded by Arabia, by Tartary, and by India; whilst Arabia lies contiguous to Iran only, but is remote from Tartary, and divided even from the skirts of India by a considerable gulph. No country, therefore, but Persia seems likely to have sent forth its colonies to all the kingdoms of Asia: the Brahmans could never have migrated from India to Iran, because they are expressly forbidden by their oldest existing laws to leave the region, which they inhabit at this day; the Arabs have not even a tradition of an emigration into Persia before Mohammed; nor had they, indeed, any inducement to quit their beautiful and extensive domains; and as to the Tartars, we have no trace in history of their departure from their plains and forests till the invasion of the Medes, who, according to cymnologists, were the sons of Madai, and even they were conducted by princes of an Aryan family. The three races, therefore, whom we have already mentioned, (and more than three we have not yet found,) migrated from Iran, as from their common country: and thus the Saxon Chronicle, I presume on good authority, brings the first inhabitants of Britain from Armenia; while a late very learned writer concludes, after all his laborious researches, that the Goths or Scythians came from Persia; and another contends, with great force, that both the Irish and Old Britons proceeded severally from the borders of the Caspian; a coincidence of conclusions from different media, by persons wholly unconnected, which could scarce have happened, if they were not grounded on solid principles. We may, therefore, hold this proposition firmly established, that Iran or Persia, in its largest sense, was the centre of population, of knowledge, of languages, and of arts; which, instead of travelling westward only, as it has been fancifully supposed, or eastward, as with equal reason might have been ascertained, expanded in all directions to all the regions of the world." Here we see it stated, as the result of Sir William Jones's inquiry, that the Goths, the Irish, and the Old Britons, or the Celts, were originally the same people, and
GOTHIC LANGUAGE.

and of Asiatic origin; that they used the same language derived from the primordial language of Asia: and this he gives not merely as the consequence of his own investigation, but as a coincidence of conclusions, through different media, by persons wholly unconnected. We know not whether this great man was aware of the great similarity subsisting between the Gothic and the Celtic tongues. From his silence we may conclude that he was not: and if he had seen specimens of them, analyzed similar to that above, he would have deemed the resemblance a surprising confirmation of his theory.

We conclude, in the second place, from the above analysis, that the Gothic had a close affinity to the Greek and Latin. And Sir William Jones gives it as his opinion, that the Greek, Latin, and Gothic originated in one and the same language; namely, the ancient language of Persia. The three languages, therefore, originally resembled each other, not merely because they borrowed some words one from the other, but because they had the same words, phrases, and even conjunctions, in so far as any of the distinct languages had derived them from a common tongue. And here we cannot help mentioning one feature in which the ancient Gothic bore a very singular resemblance to the Greek in the time of Homer, or that dialect of the Greek, namely, the Æolic, from which the Latin was principally derived: we mean the much disputed Æolic digamma. In the Oriental languages gutturals abound: these, by degrees, fastened into a mere aspirate; and this aspirate was, in very numerous instances, substituted a labial letter wo, or ω, or f. Thus ανδα, a ling, degenerated into bain; and being introduced into Greek in the form of ψανή, or ψαντο, was pronounced ψανές, ψαντο. While the oral Greek was thus corrupted, the written retained the aspirate; and as the works of Homer became the subject of universal study, the true orthography triumphed over the caprice of oral sounds. But the Latins had no such monument of genius as the Æsop to study: the corruptions of pronunciation, therefore, prevailed, and the digamma was universally substituted for the aspirate. Thus λεγον, φύλο, επιστολον, κτυπωμον. The digamma was also prefixed to a broader open vowel, and always interposed between a diphthong, as ων, pronounced ωνι, ωνι; ωνινονο, ωνινονο, ωνινινι; ωνινινι, ωνινινι, ωνινινι. Now, this same digamma runs through the Gothic language, which shews that a great part of it, though from some channel or other, was derived from the Greek, about the early age in which the Latin separated into a distinct dialect. We shall give a few examples of this fact. The Greek ψανές, in Gothic, is written conformably to the corrupt pronunciation of ψανές, φανές, ψανές, ψανές, ψανές, (which is equivalent to ψανές) is goth. digamma, digamma, digamma; hence the English, to work.

But though the Greek may have the same form and basis with the Gothic; and though by some communications, now unknown, it may have enriched the Gothic with its own early improvements, yet the dialect dignified with this name is only the remains of the Gothic tongue, debased by a strong mixture of Greek and Latin terms, a century or two after the commencement of the Christian era. The Goths who used it lived in Wallachia, a country in which Roman colonies had been planted, and which was contiguous to the provinces of Greece. As the version of Ulphilas, contained in the "Codex Argenteus," is the only repository of this dialect, it is worth while to hear what Michaelis says of it in his "Remarks on the Ancient Versions," Marth's translation, vol. ii. p. 142. "In the "Codex Argenteus," many words are adopted immediately from the Greek. Here I understand, not such as have been common to the German and the Greeks from the earliest ages of antiquity, and shew either an original relation, or original connection between the two nations, but such Greek words as are found in no other German dialect than that of the "Codex Argenteus," and have been transferred from the Greek, after the complete formation of both languages: for instance, ψανε, father, am, the shoulder, a... where even the ψ is retained from the Greek termination. This betrays not a dialect that was used in Germany, or in the North, but that of a nation that lived in the neighbourhood of the Greeks. Even the mode of expressing the sound of 9g, in the "Codex Argenteus," is purely Greek, and never used in Germany, where the Latin orthography has been received; for fager is written in that manuscript fager, as the Greeks would have expressed it by a double gamma." Ulphilas is said to have invented the characters of this dialect; which are evidently a mixture of the Greek and Latin, alphabet. The use of such characters was natural, if the dialect which they expressed contained a great mixture of the languages to which they properly belonged.

This representation must greatly diminish our veneration for the Gothic, as far as it can be known by us; yet, in this light, it demands our attention and respect as the undoubted parent of the English tongue. Nevertheless, we are hence compelled to regard the Gothic and the Anglo-Saxon as hot corrupt channels by which the terms of Greece and Rome have been imported into our own language. There are, indeed, those who consider them in this humble and degraded state, as claiming the dignity of original, ancient, and independent languages. And Mr. Horne Tooke, in particular, in his celebrated work on grammar, has attempted to induce the public to receive corruptions from Greek and Latin in the dark ages, as the original words of a Northern language: whereas Greek and Latin have, according to him, themselves been derived. The merits of this question will more properly be discussed under the articles Grammar and Greek. But if the account we have given of the Gothic be just, we shall want no other evidence to convince us that the theory of Mr. Tooke, as far as this question is concerned, (and it forms a very leading feature of his system,) is not only erroneous, but ridiculous and absurd.

Goticke Metals. See METAL.

Goticke Music. When fig, Eximeno calls fugues and canons Gothic compositions, he does not disguise their structure any more than he would our cathedrals, by calling them Gothic buildings. Let fugues be banished from the theatre and private concerts, if he pleases, but let him remain in the church as a distinct species of composition, where they were first generated, and where they can never become vulgar or obnoxious. The style is naturally grave, requires musical learning, and will, by the solemnity of the words and place of performance, continue to be reverenced and respected. It is allowed that variety is more wanted in music than in any other art, and by totally excommunicating canons and fugues from the church, the art would lose one capital source of variety, as well as ingenuity; and intelligent hearers be bereaved of a solemn style of music, to be heard no where else.

Gothinli, or Gothein, in Ancient Geography, a name given to the Goths. They were called Getones by Tacitus and Julius, and Gutones by Pliny. Claudian calls them Gothani.

Gothland,
GOTHLAND, a country of Sweden, bounded on the
N. by Sweden Proper, on the E. and S. by the Baltic,
and on the W. by the Sound, the German ocean, and Nor-
way. This country is inhabited by a people, who derived
their origin from the Gete, or Tartars of the Crimea. The
Goths had kings of their own, till the year 1132, when
they were united to Sweden. The country is pleasant and
fertile, confining of pasture and arable land; and abounding
in lakes and rivers plentifully floored with fish, and also with
forests and mines. It contains 48 towns, and is divided into
East, West, and South Gothland.

East Gothland is bounded on the N. by the provinces of
Norcia or Nereke, and Sudermanland, on the E. by the
Baltic, on the S. by Smaland or Smålend, and on the W.
by the Wetter lake, which separates it from West Gothland.
It is about 80 miles long, and 70 broad. It produces wheat,
yre, barley, oats, peas, &c. in such abundance as to supply
the neighboring provinces. It has likewise many fine
orchards, with meadows, pastures, lakes, and rivers abounding
with fish, extensive forests, iron-mines and founderies,
and quarries of stone and marble. The inhabitants are occu-
pied in husbandry, hunting, and fishing, and also in some
places in the mines. The chief towns of this province are
Nordköping, Söderköping, Linköping, and Vadstena;
which see respectively.

South Gothland is divided into three provinces, viz.
Schenen or Skone, Halland, and Blekingen, which have at
fundenry times changed their masters, till at length Charles
Gustavus annexed them for perpetuity to the Swedish domi-
nions, by the treaty of Rödhold, in the year 1658.

West Gothland is bounded on the N. by Warmeland, on
the E. by Nerica, the Wetter lake, and Smaland, on the S.
by Smaland and Halland, and on the W. by the Scan-
garac. It is about 115 miles long, and 15 broad; like East
Gothland it was under the administration of its own kings
and laws. The soil produces corn, vegetables, and fruit;
and affords excellent pastures, which enable the occupiers
to supply other provinces with butter and cheese. The
rivers, lakes, and sea-coast abound with fish; and in several
places are erected iron-forges, alum-works, paper mills.
The inhabitants are chiefly employed in agriculture and
fishing. The chief towns are Göteborg, Vemdonborg,
Linköping, and Falköping; which see respectively.

Gothland, or Gotland, an island belonging to Sweden,
situated in the Baltic, between N. lat. 56° 54' and 57° 50',
and E. long. 18° 6', and 19° 6'; about 70 miles long and
25 in its greatest breadth. It was formerly an independent
kingdom, but is now subject to the supreme court of justice
at Stockholm. Its situation has gained for it the appropriate
denomination of the “Eye of the Baltic.” The soil is
fertile, and affords fine woods of oak and pine, and good
pastures; and its breed of sheep is accounted excellent.
It has large quarries of stone, which is exported to Stock-
holm and other places, and some curious species of stone
marbles, carnelians, agates, and beautiful petrifications.
It furnishes likewise good lime-stones, tar, and deal-boards.
Although it is not infested with bears or wolves, it abounds
with foxes, deer, and hares. The inhabitants gain their
subsistence by tilling the ground, grazing, fishing, working
in the quarries, burning lime, and other arts of mechanic
trades, and navigation. The peasants are in a state of ab-
solute dependence on the burghers, who supply them with
necessaries, and with money for paying their taxes, and to
whom they surrender the whole produce of their industry,
without fluctuating any price. This island was at first sub-
ject to the crown of Sweden, and afterwards to the Danes
for near two centuries, till the year 1645, when by the
treaty of Brömberg, it was referred to Sweden. The
capital of the island is Visby, on the western coast.

GOTHS, a people, who came originally, according to
Jornandes (Rec. Get.) who abridges the Gothic history of
the learned Caesiodorus, comprised in 12 books, from the
vast island, or rather peninsula, called Scandinavia, and
including the present Sweden, Norway, Lapland, and Fin-
mark. The learned Grothus, and after him Shrapshingam,
and most of the northern writers, maintain by arguments,
which, as many conceive, have not been refuted, but which
are not convincing to others, that the Cimbrians (see Cim-
bita, Getes (see Geth), and Goths, were the fame
nation; that Scandinavia was first peopled by them; and
that from thence they detached colonies into the islands
in the Baltic, the Chenesius, and the adjacent places, yet
deficient of inhabitants. Many velliges, which cannot be
attributed to the arts of popular vanity, attest the ancient
residence of the Goths in the countries beyond the Baltic.
From the time of the geographer Ptolemey, the southern
part of Sweden seems to have continued in the posession of
the less enterprising remnant of the nation, and a large
territory even at present divided into East and West Gothland.
(See Gothland.) The time when the Goths first settled
in Scandinavia, and the period at which they first peopled
with their colonies the islands, the Chenesius, and the
neighboring places, have not been ascertained. Some have said,
that their first settlement was conducted by Eric, contempo-
rary with Sarach, grandfather of Abraham. However this
be, the peopling of the islands in the Baltic sea, of the Chenesius,
and of the adjacent places on the continent, is called by
the Northern writers, the first emigration of the Goths or Getes.
The attempt to cross the Baltic was natural and easy. The
inhabitants of Sweden (as we learn from Tactitus) were masters
of a sufficient number of large vessels with oars; and the
distance is little more than 100 miles from Carlseron to the
nearest ports of Pomeria and Prussia. At least as early as the Christian
era, and at least as the age of the Anto-
nines, the Goths were established towards the mouth of
the V的心ba, and in that fertile province, where the commercial
centers of Thorn, Elbing, Koningenberg, and Dantzig
were long afterwards founded. Westward of the Goths, the nu-
erous tribes of the Vandals were spread along the banks of
the Oder, and the sea-coast of Pomeria and Mecklenburg.
A striking resemblance of manners, complexion, religion,
and language, seemed to indicate that the Vandals and Goths
were originally one great people. (See Vandals.) In the age of
the Antonines the Goths were still feated in Prussia. About the reign of Alexander Severus, they made
frequent and destructive inroads into the Roman province of
Dacia. In this interval, therefore, of about seventy years,
we must place the second emigration of the Goths, from the
Baltic to the Euxine. To what cause this was owing is
matter of more conjecture. Perhaps a pestilence or a famine,
a victory or a defeat, an oracle of the gods, or the eloquence
of a daring leader, were sufficient to impel the Gothic arms
on the milder climates of the south. Besides the influence
of a martial religion, the number and spirit of the Goths
were equal to the most hazardous adventures. The use of
round bucklers and short swords rendered them formidable
in a close engagement; the manly obedience which they yielded
to hereditary kings gave uncommon union and Ribility to
their councils; and the renowned Amala, the hero of that
age, and the tenth anecelor of Theodore, king of Italy,
ensured, by the descendent of personal merit, the prerogative
of his birth, which he derived from the 
anes, or demigods of the Gothic nation.

Whatever was the motive of their migration, they took
their route eastward, entered Scythia, advanced to the
Cimmerian Bosporus, and, driving out the Cimmerians, set-
tled in the neighbourhood of the Mazotic lake. Thence, in
proceeds of time, they sent out numerous colonies into Thrace,
Dacia, Media, or Italy, and laterly into the countries bor-
dering on the Euxine Sea, forcing every where the ancient
inhabitants to abandon their native abodes. Such is the
account given by Jornandes, and Abalvius, a celebrated writer
among the Goths, who lived long before him. In the vic-
nity of the Mazotic lake, they had, it is said, Filimir for
their king, who was a warlike prince; in Thrace, Media, and
Dacia, Xanokhis, a great philosopher; and in the coun-
tries on the Euxine Sea, princes of the illustrious families of
the Balbut and the Amal, the Vifigots being subject to the
former, and the Ostrogoths to the latter. In all these coun-
tries they were the same people, though subject to different
princes, and known by various appellations. As for the
denominations of Wolfergoths, fastened by the Latins into
that of Vifigots, and Oltroggoths, they were distinguished
by those names before they left Scandinavia, being called
Wolfergoths and Oltroggoths, or western and eastern Goths,
from their situation to the west and east, the former inhab-
iting that part of Scandinavia which borders on Denmark,
and the latter the more easterly parts, near the Baltic. The
information we derive from Jornandes concerning the various
migrations and settlements of the Goths is conformable to the
accounts that are given by the ancient Greek and Latin
writers with respect to the different colonies and settlements of
the Goths. That the Goths and Getes were the same
people, is supposed by all the writers who flourished in or
near the times in which both empires were overrun by them.
Those authors, without doubt well acquainted with their
origin, call them sometimes Goths, sometimes Getes, and
sometimes Scythians; and several authors tell us, that
the Getes and Goths had been long known to the Romans,
and also to the Greeks by the former names, but not by the
latter, till their incursions into the empire.

When the Goths greatly increased in Scythia, they re-
solved to seek new settlements; and accordingly, pursuing
their route eastward, and travelling through several coun-
tries, they returned at length to Germany. Their
leader in this migration was the celebrated Woden or Odin, to whom many strange things are related. It is said
by the northern writers, that he was king of the Afgar-
gians, supposing to be the same people with the Afgarians
mentioned by Ptolomy and Strabo. Afgardia and Afgar-
gia are said to be a common name of their city, situated,
according to Strabo, near the Bosporus Cimmerian; and Afgar-
gia was the metropolis of a country which Strabo calls Asia;
hence Woden and his followers are styled by the ancient
Gothic writers Afafs, Afasian, and Afate. The kings of
Afgarzia are represented as being masters of all that part of
Scythia that lay west of mount Imanas, and which the
Latins called "Scythia intra Imaum," or Scythia within
mount Imana. Of this Afgardia or Afgorgia, Woden is
said to have been king; and hence he emigrated with a great
multitude of his followers in quest of new settlements; or,
as some say, with the great design of forming in Sweden,
considered as the inaccessible retreat of freedom, a religion
and a people, which, in some remote ages, might be subdi-
vient to his purposes; when his invincible Goths, armed
with martial fanatical, should issue in numerous swarms from
the vicinity of the Polar Circle to chastise the oppressors of
man-kind. Having passed through different countries, and perform-
ed a variety of exploits, he at length arrived in Sweden, where
he was allowed to settle, and where he reigned till his death.
His name became so famous that the northern nations ranked
him among the gods, and worshipped him with divine ho-
nours. He is supposed to have brought with him out of
Aasia the Runic characters (see Runes), and to have taught
the northern nations the art of poetry; whence he is styled
the father of the Scalds or Sechiirs. See Scalds.

That the Goths, under the conduct of Woden, came from
Scythia into the northern parts of Germany, is a received
opinion among the northern writers, and, as they allege,
confirmed by an immemorial tradition, by the ancient chron-
icles of those countries, and by many monuments and in-
scriptions in Runic characters, some of which are still to
be seen in Sweden, Denmark, and the neighbouring islands.
That there were such migrations can hardly be questioned,
since we find the same names common to the inhabitants of
Scandia and Asiatic Scythia, and likewise the same language,
as Grotius, and after him Sheringham, have shown. The
ancient language of the Goths is now spoken by the Tartars
of Precop, whence, and from other collateral circum-
stances, it has been concluded that the Scandinavian and Asiatic
Scythians had one and the same original. As to the time of
this migration of Scythians under Woden into the northern
parts of Germany, those who maintain it have not been able
to determine. Some refer it to a period about 25 years B. C.;
for at that time, they say, Pompy laid waste Syria, and
great part of Asia, and menace the north with ferocity.
After all, this wonderful expedition of Woden or Odin is
admitted with great hesitation, or indeed scarcely admitted
at all by many, into authentic history. According to the
obvious sense of the Edda (see Edna), and the interpre-
tation of the most skilful critics, Afgard, instead of de-
noting a real city of the Asiatic Sarmatia, is the fictitious
appellation of the mythical abode of the gods, the Olympus
of Scandinavia; from whence the prophet was supposed to
defend, when he announced his new religion to the Gothic
nations, who were already settled in the southern parts of
Sweden.

Before we proceed with our brief abstract of the history
of the Goths, we shall give an account of their civiliza-
tions, laws, and religion, before they embraced Christianity.
With regard to their general disposition and character, they
were celebrated for their hospitality and kindness to strangers;
and it is said that they derived their name from their being
enemies to goads; the time of Goths being derived, accord-
ing to Grotius and other writers, from the German word
goten, signifying good. They encouraged, says Dio, the study
of philosophy more than any other barbarous or foreign
nation, and often selected their kings from among their philos-
ophers. Polygamy was not only allowed, but encouraged,
and every one was respected according to the number of his
wives, and of course his children. Adultery with them was
a capital crime, and invariably punished with death.

The severity, and likewise polygamy, prevailed among them,
when they were known to the Greeks and Romans only by
the name of Geats, as appears from the poet Memnon,
who was himself a Geat, and from Homer (Iliiad, 24) who
blesses great eunuchians on the virtue and chaste-
ity of their women. Of their laws we shall have occasion to
speak in the sequel of this article. Their government was mon-
cracy. Their religion seems to have been the same with
that of the ancient inhabitants of Scandia and Saxony;
which see respectively. Till the end of the eleventh century,
a celebrated temple laboured at Upsal, the most consid-
erable town of the Swedes and Goths. This temple was en-
riched with the gold which the Scandinavers had acquired
in their piratical adventures, and sanctified by the uncounted representations of the three principal deities, the god of war, the goddess of generation, and the god of thunder. In the general festival that was solemnized every ninth year, nine animals of every species (without excepting the human) were sacrificed, and their bleeding bodies suspended in the sacred grove adjacent to the temple. The only traces that now subsist of this barbaric superstition are contained in the Edda; which see. See also Osir.

Concalla was the first Roman emperor who quarrelled with the Goths, and marched against them into that part of Duænis, north of the Danube, of which they had taken possession; but the advantages which he seems to have gained over them in a few skirmishes were very incon siderable. It appears, that the Romans were alarmed at an early period by the progress of this warlike nation; for in the reign of Alexander, which began in 222, considerable sums of money were lent to them from Rome, in order to prevent their disturbing the peace of the empire. Notwithstanding these tributes, as soon as they heard of the assistance given to the emperor Maximin, who was of Gothic extraction, they resolved to revenge it, and accordingly entered Moesia, they totally laid waste that province. Not long after they made themselves masters of Thrace, from which they were driven by Gordian. Under Philip, his successor, they committed dreadful ravages both in Thrace and Moesia. Soon after their retreat from the siege of Marcianopolis, the capital of the second Moesia, and after having compelled the inhabitants to ransom their lives and property, they passed the Danube a second time, under the command of their king, Chiva, with a more considerable force; and having obliged Darius, the son of the Roman emperor, to fly himself by flight, they were opposed by the emperor himself. Darius, having compelled them to raise the siege of Nicopolis, they retired towards Philoppolis, took it by storm, and massacred, as it is said, 100,000 persons in the face of that city. The time, however, which was consumed in this tedious siege, enabled Darius to revive the courage, restore the discipline, and recruit the number of his troops, after the defeat they had sustained in their pursuit of the Goths. Thus recruited, the emperor exerted his utmost vigilance to oppose either the progress or the retreat of the barbarians. The Goths were now, on every side, surrounded and pursued by the Roman armies; and exhausted by the long siege of Philoppolis, they could gladly have purchased, by the surrender of all their beasts of burden and prisoners, the permission of an undisturbed retreat. The emperor, confident of victory, refused to listen to any terms of accommodation; and the high-spirited barbarians preferred death to slavery. The two armies, therefore, prepared for an engagement. The conflict was severe; two lines of the Gothic army were thrown into disorder; and the third only remained entire, prepared to dispute the passage of a morass, which was imprudently attempted by the Roman troops. Here the fortune of the day assumed a new aspect. In this morass the Roman army, borne down by the weight of their armour, after an intellectual struggle, was irrecoverably loit; nor could the body of the emperor ever be found. Upon the election of Gallus A. D. 251, the first object of his attention was to deliver the Illyrian provinces from the intolerable weight of the victorious Goths. He offered them every inducement in his power to withdraw their forces; and he even promised to pay them annually a large sum of gold, on condition they should never afterwards infest the Roman territories by their incursions. This tribute, however, though granted at the expense of the honour of the Romans, was insufficient to secure their permanent peace.

New swarms of barbarians, encouraged by the successes, and conceiving themselves not bound by the obligation of their brethren, spread devastation through the Illyrian provinces, and terror as far as the gates of Rome. In this period of alarm and distress, Emilianus, governor of Pannonia and Moesia, rallied the scattered forces of the empire; and the barbarians were unexpectedly attacked, routed, chased, and pursued beyond the Danube. Under the reigns of Valerian and Gallienus, the frontiers of the ill-mentioned river was perpetually infested by the inroads of the Germans and Sarmatians; but it was defended by the Romans with more than usual firmness and success. Nevertheless, the great stores of the Gothic hostilities were diverted into a very different channel. The Goths, in their new settlement of the Ukraine, soon became masters of the northern coast of the Euxine; to the fourth of that inland sea were situated the wealthy provinces of Asia Minor, which possessed all that could attract, and nothing that could resist, a barbarian conqueror. The little kingdom of Bosphorus, whose capital was situated on the shores, through which the Maeotis communicates itself to the Euxine, was composed of degenerate Greeks, and half-civilized barbarians. In this small kingdom, domestic factions, and the fears, or interest, of obtuse usurpers, who feized on the vacant throne, admitted the Goths into the heart of Bosphorus.

Here they acquired a naval force sufficient to transport their troops to the coast of Asia. For this purpose, they constructed a fort of flat-bottomed boats, called "Camaras," framed of timber only, without any iron, and occasionally covered with a shields roof, on the appearance of a tempell. With this kind of fleet, they first appeared before Pityus, at the utmost limit of the Roman provinces, with a convenient port, and fortified with a strong wall. Their first attack was repulsed; but, renewing their attempts, they destroyed this city. Then circling round the eastern extremity of the Euxine sea, their navigation from Pityus to Trebizond was a course of about 350 miles. This city was large and populous, defended by a double inclosure of walls, and had its usual garrison strengthened by a reinforcement of 105,000 men. But this numerous garrison was disdained in riot and luxury, and thus rendered cardeles in guarding their impregnable fortifications. The Goths, availing themselves of the feeble negligence of the besieged, erected a lofty pile of fagaces, ascended the walls in the silence of the night, entered the defended city, sowed in hand, massacred the inhabitants, destroyed the temples and splendid edifices, and gained an immense booty. With the rich spoils of the city they filled a great fleet of ships, which they found in the port, and, satisfied with the success of their first naval expedition, returned in triumph to their new establishments in the kingdom of the Bosphorus. In their second naval expedition, possessed of greater powers both of men and ships, they took a new course, followed the western coast of the Euxine, passed before the wide mouths of the Bosphorus, the Nicker, and the Danube; and increasing their fleet by a great number of fishing harks, they approached the narrow outlet through which the Euxine sea pours its waters into the Mediterranean. In this expedition they plundered the cities of Bithynia, Chalcedon, Nice, Prusa, Apamea, Cius, and Nicomedea. From the recent attack of Prusa, the Goths advanced within 18 miles of Cyzicus; but their progress was stopped by the small river Rhynacetus, which issues from the lake Apollinates, and which was then swelled into a broad and rapid stream. Their retreat to the maritime city of Heraclea, where their fleet was probably stationed, was attended by a long train of wagons, laden with the spoils of Bithynia, and
G O T H S.

and was marked by the flames of Nice and Nicomedia, which they wantonly burnt. The third naval expedition of the Goths consisted of 5000 sail of transports, containing about 15,000 warriors. They now cleared their destructive course from the Chimerian to the Thracian Bosphorus; and were carried to the lake of the Propontis. Their landing on the little island of Cyzicus was followed by the ruin of that ancient and noble city. They thence passed through the narrow passage of the Hellespont, and purloined their winding navigation amidst the numerous islands scattered over the Archipelago, or Euphrus fa. At length the Gothic fleet anchored in the port of Pireus, five miles from Athens, ravaged Greece, and caused the ravages of war, both by land and sea, to spread from the calumny point of Sunium, to the western coast of Epirus, advancing within sight of Italy. The indolent Gall emus was routed; the emperor appeared in arms; and his presence contributed to check the ardour of the enemy. Some of the numerous Gothic host broke into Macedonia, for the purpose of forcing their way over the Danube to their settlements in the Ukraine. Others returned on board their vessels, and re-tracing their course through the Hellespont and the Bosphorus, and finding themselves secure within the bason of the Euxine, landed at Anchialus, in Thrace, near the foot of Mount Hermon, and refurnished themselves by the use of those pleasant and salutary hot-baths. Amidst their devastations, we may select the destruction of the famous temple of Diana at Ephesus, which they burnt in their third naval invasion. It is also said, that they threatened to destroy all the libraries of Athens, but were prevented from executing their menace by the profound observation of one of their chiefs, that as long as the Greeks were addicted to the study of books, they would never apply themselves to the exercise of arms. Under the reign of Claudius A.D. 269, the Goths collected an armament more formidable than any that had yet issued from the Euxine. On the banks of the Niell they constructed a fleet of 2000, or even of 6000 vessels, which, in their passage through the Bosphorus, encountered various difaters. However, they made several conquests on the coasts, both of Europe and Asia. But discontent and division arose in the fleet, and some of their chiefs deserted them, and failed away towards Cretce and Cyprus: the main body, nevertheless, purloined their course, anchored at the foot of Mount Athos, and assaulted the city of Thessalonica. Their attacks were soon interrupted by the rapid approach of Claudius. The Goths, eager for a general engagement, relinquished the siege of Thessalonica; and with this view, leaving their navy at the foot of Mount Athos, traversed the hills of Macedonia. Claudius was diffraited, but at the same time firm and determined. The event exceeded even his own expectations, as well as those of the world; and having gained signal victories, and delivered the empire from this host of barbarians, he was distinguished by posterity under the glorious appellation of the Gothic Claudius. The decisive battle was fought near Naelius, a city of Dardania. The war was afterwards diffused over the provinces of Macedonia, Thrace, and Macedonia, and the superior talents of the emperor generally ensured the success of his arms. The Goths suffered to such a degree, that a select body of their youth was received among the Imperial troops, the remainder was fold into servitude, and the female captives were so numerous, that every soldier appropriated to himself two or three women. To complete the disasters of the Goths, their fleet was either taken or sunk, so that their rear was thus intercepted. Aurelian, the successor of Claudius, distinguished himself during the Gothic war, and, at last, put an end to it by a lasting and beneficial treaty. The Goths were engaged to supply the armies of Rome with a body of 2000 auxiliaries, confining entirely of cavalry, and, in return, permitted an undisturbed retreat, with a regular market as far as the Danube, provided by the emperor's care, but at their own expense. But the most important condition of peace was understood rather than expressed in the treaty. Aurelian withdrew the Roman forces from Dacia, and tacitly relinquished that great province to the Goths and Vandals. This proved, in the event, a wise measure; for, after Dacia became an independent state, it seemed as the foremost barrier of the empire against the invasions of the foes from the North.

About the year 273, the second of the reign of Procopius, the Goths entered Thrace, and advanced as far as Illyricum, laying waste the country with fire and sword; but as soon as they heard that the emperor was marching against them, they retreated and left their booty behind them. In Illyricum, Procopius was met by deputies from the Gothic nations, suing for peace, and submitting to his power. No further mention is made of the Goths till the year 289, at which time Diocletian is said to have gained a complete victory over them. From this victory Diocletian assumed the name of "Sarminianus," as appears from several ancient coins and inscriptions. From this year to the 15th of Constantine, the Goths gave no disturbance to the empire, being engaged in wars with the neighboring nations. As soon as the Goths were disengaged from other wars, they invaded the Roman empire; but they were overcome by Constantine in several battles, fought at Campana, in Pannonia, and at Margus and Borea, in Upper Media. The emperor determined to chastise as well as to repulse the indolent barbarians who had dared to attack the territories of Rome, pulled the Danube, and penetrated into the inmost recesses of Dacia; and when he had inflicted a few reverses, condescended to give peace to the suppliant Goths, on condition that as often as they were required, they should supply his army with a body of 40,000 soldiers. In the year 331, a war broke out between the Goths and Sarmatians; on which occasion the latter had recourse to Constatine, who was glad to embrace an opportunity of humbling that ferocious nation. In the first act the barbarians gained the advantage; but the event of a second and more successful action, in April 332, retrieved the honour of the Roman name. Near 100,000 of the enemy were either put to the sword, or perished after the battle with hunger and cold; and this defeat was so great, as to oblige Alaric, king of the Goths, to sue for peace, and to deliver hostages to the emperor, one of whom was his own son. The Goths not only continued quiet, but served the Romans with great fidelity, during the remaining part of Constantine's reign: and in the reigns of Constahtine, Julian, Trajan, and Valentinian I. But in the first of Valens, they made inroads into Thrace, and laid waste that province. The emperor purchased their retreat for a sum of money. In the following year news was brought him to Bithynia, that the Goths were again ready to break into Thrace. When Procopius revolted, and assumed the title of emperor, the Goths deplored his cause, and sent a body of troops to his assistance; but before their arrival, he was defeated and put to death. They, however, continued in the territories of the empire, committing great ravages in Thrace and Media. Valens sent a strong detachment against them, and their retreat being cut off, they were obliged to lay down their arms, and yield themselves prisoners. After hostilities which lasted three years from 366 to 369, the barbarians submitted, and thus appeared the redemtment of Valens. After the ratification of the treaty, Valens returned in triumph to Constatine, and offered the empire in return for his services.
flamnplex, and the Goths remained in a state of tranquillity about six years; till they were violently impelled against the Roman empire by an innumerable host of Scythians, who appeared to issue from the frozen regions of the North. In the year 373, the Huns invaded the territories of the Goths, and spread among them such a general consternation, that they fled for refuge to the Roman dominions. Valens listened to their supplications, and granted them protection. The liberty of the emperor, however, was accompanied with too hard and rigorous conditions. Before they passed the Danube, they were required to deliver their arms; and it was intimated that their children should be taken from them, and dispersed through the provinces of Asia; where they might be civilized by the arts of education, and force as hostages to secure the fidelity of their parents. A probably true statement has fixed the number of the Gothic warriors at 200,000 men; and if we can venture to add the full proportion of women, of children, and of slaves, the whole sum of people which composed this formidable emigration must have amounted to near a million of persons, of both sexes and of all ages. The Goths, joyfully availed at the cruel treatment they met with from the Roman officers, who were to supply them with provisions, had fearely entered Thrace, under the conditions imposed upon them, when they began to mutiny and plunder the country. This occasioned a long and bloody war between them and the Romans. They were joined by the Huns, Alani, Thaffara, and other saxons of their countrymen. In the battle of Hadrianople, A.D. 378, the Roman cavalry fled; and the infantry was abandoned, surrounded, and cut in pieces; and though the Goths were obliged to raise the siege of Hadrianople, the tide of the Gothic invasion rolled from the walls of this city to the coasts of Constanctinople; and the Roman provinces were ravaged by the barbarians. At this time a suspicion prevailed, that the Goths of Asia had formed a secret and dangerous conspiracy against the public safety. An order was promulgated that, on a flated day, the Gothic youth should assemble in the capital cities of their respective provinces; and as a report was industriously circulated, that they were summoned to receive a liberal gift of land and money, the pleasing hope allayed the fury of their resentment, and perhaps fulfilled the motions of the conspiracy. On the appointed day, the unarmed crowd of the Gothic youth assembled in the square, or forum; the streets and avenues were occupied by the Roman troops; and the roofs of the houses were covered with archers and slingers. At the same time in all the cities of the East, the signal was given of indiscriminate slaughter; and the provinces of Asia were delivered by the cruel prudence of Julius, who was master-general of the troops, from a domestic enemy, who, in a few months, might have carried fire and sword from the Hellespont to the Euphrates. At length the Goths submitted to Theodosius I., and were allowed by him to settle in Thrace and Moesia, which two provinces had been almost depopulated by the frequent incursions of the neighbouring barbarians, and the late destructive war. A numerous colony of the Visigoths was settled in Thrace; the remains of the Ostrogoths were planted in Phrygia and Lydia; their immediate wants were supplied by a distribution of corn and cattle; and their future industry was encouraged by an exemption from tribute for a certain number of years. Hopes were entertained that the manners of the barbarians would in time be polished, and that their politeness would be infinitely blended with the body of the Roman people. Notwithstanding these flattering expectations, it was apparent to every discerning eye, that the Goths would long remain the enemies, and might soon become the conquerors of the Roman empire. As the impatient Goths could only be restrained by the firm and temperate character of Theodosius, the public safety seemed to depend on the life and abilities of a single man. He died in the month of January A.D. 395, and before the end of the winter of the same year, the Gothic nation was in arms. The interruption, or at least the diminution, of the fidelity to which the Goths had received from the prudent liberality of Theodosius, was the natural result of their recent defeat. Instead of being impelled by the blind and headstrong passions of their chiefs, they were now directed by the bold and ardent genius of Alaric. In the year 396 Alaric marches into Greece; and he halted to occupy the city of Athens, and the important harbour of the Piraeus. Corinth, Argos, and Sparta yielded without resistance to the arms of the Goths. From Thermopylae to Sparta, the leader of the Goths pursued his victorious march, without encountering any mortal antagonists; and the Christian faith, which he had devoutly embraced, taught him to despise the imaginary delights of Rome and Athens. In 397 Stilicho, the general of the West, advanced to chastise the invaders of Greece. The skill and perseverance of the Roman at length prevailed; and the Goths, after fulfilling a considerable loss by defection and desertion, gradually retreated to the lofty mountains of Phocas, near the fources of the Peneus, and on the frontiers of Elis; a sacred country, which had formerly been exempted from the calamities of war. Their camp was immediately besieged; and reduced to great distress by thirst and hunger. A strong line of circumvallation was formed to prevent their escape. Alaric was secret, prudent, and rapid in his operations; he immediately negotiated a treaty with the magnates of Constantinople; and Stilicho was compelled to retire from the dominions of Arcadius; and he respected, in the enemy of Rome, the honourable character of the ally and servant of the emperor of the East. Alaric is declared master-general of the Eastern Illyrians; and the chief among them, and his new command distinguishes the firm and judicious character of his policy. He issues his orders to the four magazines of offensive and defensive arms, Margus, Ratiaria, Maifus, and Thefalonica, to provide his troops with an extraordinary supply of shields, helmets, swords, and spears. With the unanimous consent of the barbarian chieftains, the master-general of Illyricum was elevated, according to ancient custom, on a shield, and solemnly proclaimed king of the Visigoths. Thus armed with all his power, and seated on the verge of the two empires, he annexed the two emperors Arcadius and Honorius, till he declared and executed his resolution of invading the dominions of the West. He was tempted by the fame, the beauty, and the wealth of Italy, which he had twice visited; and he secretly aspired to plant the Gothic standard on the walls of Rome, and to enrich his army with the accumulated spoils of three hundred triumphs. Alaric loses no time in executing his purpose of invading Italy; and advances, against much opposition, towards the capital of the empire. It was in the year 400 that he first entered Italy, making dreadful ravages in his progress. His march, probably from Thefalonica, through the warlike and hostile country of Pamnonia, as far as the foot of the Julian Alps; his passage of those mountains, which were strongly guarded by troops and entrenchedments; the siege of Aquila, and the conquest of the provinces of Illyria and Veneti, appear to have employed a considerable time. In the year 402, Alaric, to prevent his army from encamped at Placentia, on the Tanaro, in Piedmont. While the
Goths.

Christian Goths were devoutly celebrating Easter, they were attacked by Silicho, and after a very severe engagement, they retreated from the field of battle, after the total defeat of the infantry, with their cavalry entire, under the command of Alaric, who possessed a mind, that was invincible and superior to misfortune, and that derived new resources from adversity. The Gothic sovereign, willing to distinguish his retreat by some illustrious exploit, attacked Venetum, but the battle that ensued he suffered a defeat, and he retired. In the year 408, Alaric marched again towards Rome; with bold and rapid marches he passed the Alps and the Po; hastily pillaged the cities of Aquila, Altinum, Concordia, and Cremona; increased his forces by the accession of 50,000 auxiliaries; and, without meeting a single enemy in the field, advanced as far as the edge of the mora, which protected the impenetrable residence of the emperor of the West. He soon, after pitched his camp under the walls of Rome. A renown having been offered and accepted, he raised the siege. A.D. 409. Alaric's next attack was directed against the part of Olla, one of the boldest and most stupendous works of Roman magnificence; and as soon as he was in possession of this important place, he summoned the city to surrender at discretion; but he contented himself with supererogating Honorius, and lowering the purple on Ataullus, prefect of the city. Ataullus was soon after degraded, and his degradation was followed by the third siege and sack of Rome, Aug. 24, A.D. 410. At the hour of midnight the Salarian gate was silently opened, and the inhabitants were awakened by the tremendous sound of the Gothic trumpet. Eleven hundred and sixty-three years after the foundation of Rome, the imperial city, which had faltered and civilized to considerable a part of mankind, was delivered to the licentious fury of the tribes of Germany and Scythia. After six days' pillage and devastation, the victorious Goths evacuated Rome, and their intrepid leader advanced into Campania, and having ravaged that and the neighbouring provinces of Lucania, Samnium, Apulia, and Calabria, he approached the Infantry of Italy, with a design to pass over into that island, and thence into Africa; but he was seized in the neighbourhood of Rhegium with a fit of illness, of which he died in a few days. (See Alaric.) He was succeeded in the Gothic throne by his brother-in-law Atanplius, or Adolphus, who concluded a peace with the empire, and marched into Gaul A.D. 412. Being driven out of Gaul A.D. 415, he retired to Spain, where he was soon after assassinated. Jingeric, his successor on the Gothic throne, shared the same fate. After his death the free choice of the nation bestowed the Gothic sceptre on Valia or Wallia, who concluded a peace with the Romans, and commenced a formidable, but successful war with the barbarians, who had settled in Spain. His victorious Goths, A.D. 419, forty-three years after they had passed the Danube, were enfranchised, according to the law of treaties, in the possession of the Second Aquitania, a maritime province between the Garonne and the Loire, under the civil and ecclesiastical jurisdiction of Bourdeaux. The Gothic limits were afterwards enlarged by the additional grant of some neighbouring dioceses; and the successors of Alaric fixed their royal residence at Thoulou. Thus, about the same time, in the left year of the reign of Honorius, the Goths, the Burgundians, and the Franks, obtained a permanent seat and dominion in the provinces of Gaul. Vaila was likewise by Theodoric, who first made war with the Romans, and gained several places in Gaul belonging to them, and afterwards concluded a peace with them. The Goths continued quiet in the countries that had been allotted them in Gaul for the space of ten years, or till the year 456, when, the Romans being engaged at a war with the Burgundians, Theodoric availed himself of that opportunity to enlarge his dominions. At length the Gothic king made peace with the Romans; and in the year 453 engaged by an alliance with them to afford them against the Huns, who had entered Gaul. Thorifumund, his son and successor, breaks with the Romans; but his brother Theodor, who next occupied the Gothic throne, and who was incessantly distinguished by his talents and attainments, cultivated the friendship of the Romans, and contributed by his martial exploits to the support of the Roman empire. Theodoric entered Spain with a large army of Goths and Burgundians; and having almost reduced the Suevians in Galicia, A.D. 457, he passed from thence into Lusitania, and reduced several places. Upon his return to Gaul, he took several cities belonging to the Romans, but was at length checked in his career and defeated by Rigild, commander in chief of the Roman forces in that country. In Spain the Goths were more successful than they were in Gaul, and became masters of the greater part of the country. Under Ermig, who attended the throne A.D. 460, the Goths drove the Romans out of Spain; and all the provinces, except Galicia, and part of Lusitania, which were subject to the Suevians, acknowledged him for their king. His son, theodoric, governed them by his lieutenants. Ermig, having also made himself master of the best part of Gaul, comprising the whole tract between the Rhone and the Loire, and of the greater part of Spain, was still desirous of reducing the remaining parts of both countries, when his death at Aries, A.D. 484, put an end to his great designs. Ermig is said to have been the first who gave written laws to the Goths, for till his reign they had been governed by custom only; and for this purpose he employed Leo, his prime minister, one of the most learned men, and best counsellors of that period. These laws were called the "Theodoric's laws"; and were obtained by Ermig upon the people of Gaul and Spain, who had long accustomed to the Roman laws; but Alaric, his son and successor, restored the Roman laws to their former authority, and caused them to be observed throughout his dominions. About this period the kingdom of the Vifgots in Gaul terminated; and they, being driven from thence, fixed their royal seat at Toledo, in Spain. (See VIFGOTS.) For the history of the Ostrogoths; see OSTROGOCTS. Under Theodoric, who A.D. 484, caused himself to be proclaimed by his Goths king of Italy, he was acknowledged as such by the emperor Zeno, and Theodoric secured his new kingdom by alliances with neighbouring powers; he quartered all his Goths in the civitates and strong holds, with their officers who were to command them in time of war, and govern them in time of peace; he retained the Roman laws, the same form of government, the same distribution of provinces, the same magistrates and dignities; and, besides, according to the custom of the Goths, he appointed for each city inferior judges, distinguished by the title of counts, who were to administer justice, and decide all disputes; and in this respect the polity of the Goths, as Goths observes, far excelled that of the Romans. Thus Italy, from the dominion of the Romans, fell under that of the Goths, almost without any perceptible change. See TURONS.
Goths, who besieged it A.D. 537, and continued it above a year till their final departure. During this siege, which was carried on in March, A.D. 538, one-third of their enormous host was destroyed in frequent and bloody combats under the walls of the city, and the evils of famine and pestilence were aggravated by their own licentiousness, and the unfriendly disposition of the country. Wittigis, their king, retired for shelter within the walls and morasses of Ravenna. At length Belisarius besieged the city, and took it in the latter end of the year 539. The submision of the capital was capitulated in the towns and villages of Italy; and the independent Goths who remained in arms at Pavia and Verona, were ambitious only to become the subjects of Belisarius. But his inflexible loyalty rejected, except as the subfittute of Julianus, their oath of allegiance. In the year 540, the Goths revolted, and Totila, the nephew of their late king, undertook the restoration of the kingdom of Italy. His first movements were rapid and successful; and after reducing by force, or treaty, the towns of inferior note in the midland provinces of Italy, Totila proceeded, A.D. 546, to encompass Rome, and to harve its inhabitants. Famine had relaxed the strength and discipline of the garrison, and Rome was taken by the Goths in December, A.D. 546. After the departure of Totila, it was recovered by Belisarius in February, A.D. 547. (See BELISARIUS.) When Totila returned to avenge the injury and disgrace, the Goths were thrice repulsed; they lost the flower of their troops, and the royal standard was almost fallen into the hands of the enemy, and the face of Totila sunk, as it had risen, with the fortune of his arms. Rome was again taken by the Goths, A.D. 549. Julianus made great preparations for the Gothic war, the conduct of which was committed to Narsetes, who defeated Totila in a bloody engagement, July, A.D. 552, and Totila himself was struck through the body with a lance. Narsetes then proceeded to the conquest of Rome; and Julianus once more received the keys of the imperial city, which, under his reign, had been five times taken and recovered. The last king of the Goths was Teias, who was unanimously chosen to succeed and revenge their departed hero, March, A.D. 553. Sixty days were consumed in diligent and fruitless combats, between the Gothic and Roman armies, but at length, after an engagement of many hours, Teias fell, and his head, exalted on a spear, proclaimed to the nations, that the Gothic kingdom was no more. After a reign of 60 years, the throne of the Gothic kings was filled by the exarchs of Ravenna (see EXARCH); and the remains of the Gothic nation evacuated the country or mingled with the people. (Ancl. Un. Hist. vol. xvii. Gibbon's Hist. vol. viii. palfim.)

The Goths spread themselves very widely in their various associations, and formed part of the population of the several nations of Europe. In England the Celtic population was succeeded by the Goths, and about two-thirds of England were peopled by the Belgic Goths. (See BELGIAC and ENGLAND.) About the time that the Belge feized on the fourh of England, it appears that a hundred Gothic tribes passed to the south of Ireland. (See IRELAND.) In France, or Gaul, the Goths, or warlike German tribes, under the denomination of Belge, feized on a third part of the country into which they introduced the Gothic language and manners. (See BELGIAC and GAUL.) The original population of the Netherlands was Celtic; but it was afterwards supplantated by the Belge. (See BELGIAC and NETHERLANDS.) In Germany, the Scythians or Goths, proceeding either from Scandinavia, or, as others say, from their original seat on the Oxus, expelled the Cimbri and Fins, and the, intermixed with the German nations, destroyed the Roman empire in the west. (See Germany, and the preceding part of this article.) Prussia appears to have been peopled by the Pucini and Adili, Gothic tribes bordering on the Venedi, who were Slavonians. (See PRUSSIA.) The Vandals, who conquered Spain in the fifth century, were fabulated by the Visigoths under Euric, who founded the modern kingdom of Spain. (See Spain.) The original population of Turkey in Europe chiefly sprung from the ancient Scythians on the Enixine, the progenitors of the Dacians, Thracians, &c. and even of the Greeks. The regions of Turkey in Asia were peopled by Scythic nations, intermixed with a few Alcyrians from the south. (See Turkey.) The Batavi of Holland were the most northern people of Belgic Gaul, and without doubt a German or Gothic progeny. (See BATAVI, GAUL and HOLLAND.) The Cimbri or northern Celts, who originally peopled Denmark, were expelled by the Goths, if they were not, as some conceive, tribes of the same nation; and the Fins or Laps of Norway, which, with Sweden, constitutes the ancient Scandinavia, were driven to the northern extremities by the Gothic invasion. (See DENMARK, NORWAY, SCANDINAVIA, AND SWEDEN.) The Helveticans, or original Swiss, are supposed by some writers to have been Celts; but others, with greater probability, consider them as a Gothic race, or very ancient colony of Germans.

It has been a general opinion, firmly maintained by Claudian and Polland, and adopted by Mallet in his "Northern Antiquities," that the Gothic and Celtic nations were the same; but the ingenious English translator of M. Mallet's "Northern Antiquities" has produced a variety of testimonies from ancient authors, to prove that the Celtic and Teutonic or Gothic nations were, ab origine, distinct, and that they differed considerably in persons, manners, laws, religion, and language. The former were the ancestors of the Gauls, Britons, and Irish; and the Germans, Saxons, and Scandinavians derived their origin from the latter. The Celtic tribes were probably the first that travelled westward; and the Goths, or Goths of the ancients, who emigrated at different times from the eastern countries after them, might borrow some of their opinions and practices, which will account for the resemblance that has been observed between them, without admitting that they were descended from them, or that they should be considered as the same people. In the same way we may account for those relics both of Celtic and Gothic superstitions, which are discernible in Gaul and Britain, and many other countries, the inhabitants of which derive their descent equally from the Celts and Goths, who were at different times mailers of these kingdoms, and whose descendants are now blended together; thus, the first inhabitants of Gaul and Britain being of Celtic race, followed the Druidical superstition. The ancient Germans, Scandinavians, &c. being of Gothic race, professed that polycem of polytheism which was afterwards delivered in the Eda; and the Franks and Saxons, who afterwards settled in Gaul and Britain, being of Gothic race, introduced the polytheism of their own nation, which was in general the same that prevailed among all the other Gothic or Teutonic people. See, however, the article Gothic language, where the original identity of the Celts and Goths is maintained partly by general reasoning, and partly by etymological investigation.

GOTLANDA, in Geography, a town of Sweden, in Norcia; nine miles N. E. of Orebro.

GOTOMB, a town of Poland, in the province of Lublin; 28 miles N.W. of Lublin.

GOTON, a town of Gbisa, in the province of Soesthauen; 48 miles N. W. of Osnam.
GOTSEELA, a town of Bengal; 48 miles W. of Midnapour.

GOTTA, or Gotto Islands, a cluster of small Japanese islands. N. lat. 30° 40'. E. long. 131° 40'.

GOTTAUL, a town of Bengal; 33 miles S. of Burdwan. N. lat. 22° 44'. E. long. 88° 5'.

GOTTESBERG, a town of Slesvig, in the principality of Schleswig-Holstein, near which are two rivers, one of gold, not now worked, and another of coal. The manufacture of this town consists of knit worsted stockings. It contains two churches; 12 miles S. W. of Schleswig. N. lat. 50° 35'. E. long. 15° 54'.

GOTTESGAB, a town of Bohemia, in the circle of Saaz. N. lat. 50° 22'. E. long. 12° 54'.

GOTTI, Vincent-Lewis, in Biography, was born at Bologna in the year 1664. At nineteen years of age he embraced the clerical life among the Dominican monks, and when he had completed his course of philosophy at Bologna, he was sent to study theology for four years at Salamanca in Spain. Upon his return to Italy in 1689, he was appointed professor of philosophy in the university of Bologna; and soon recommended himself by his talents and virtues to the pupils of prior and provincial of his order. In 1728, pope Benedict XIII. raised him to the dignity of the purple; and three years afterwards appointed him member of the congregation for examining bishops. So highly was he esteemed, that in the last conclave, which was held during his time, he had the suffrages of a great number of the college for his being raised to the papal throne. He died at Rome in 1742, in his 70th year. His works, which are much valued by the Catholics, particularly by those in Italy, display considerable erudition and abilities. Of these the principal are "De vera Chrilli Ecclasia," in three volumes; "Theologia Scholastico-dogmatica, quae Mentem div. Thomae Aquinatis, &c." in six volumes. 4to.; "Colloquium Theologicae-polemicae, in tres clades distribuito, &c." 4to.; "De Eligenda inter Diffidentes Christiano Sententia," written in answer to a piece with the same title, by the celebrated John le Clerc; and an elaborate work in defence of the truth of the Christian religion against Atheists, Idolaters, Mahometans, Jews, &c. in 12 volumes. He was employed at the time of his death in writing "A Commentary on the book of Genesis." Moreri.

GOTTIGNIES, Giles-Francis, was born at Brussels in the year 1630, and entered into the order of the Jésuites at Mechlin in 1655, whence he was sent to Rome, to pursue his theological studies; here he spent the rest of his life employed in teaching the mathematics, and writing different works in that science. He died in 1689, when he was about sixty years of age. He was a considerate mathematician: a great lover of pure geometry, and had a dislike to the algebraic method of resolving problems; his works are very numerous, and have been highly recommended for perspicuity and precision. They relate to arithmetic and geometry; to the various parts of astronomy, and other branches of speculative and practical mathematics. Moreri.

GOTTINGEN, or Göttingen, in Geography, a town of the kingdom of Westphalia, and principal place of a district, named from it, is situated in a spacious, pleasant, fertile valley, on a canal, branching from the river Leine, and dividing the town into the New town and Marisch. The number of houses is about 1000, containing about 8000 persons; the streets are large and paved; it has five parish churches, and one for Calvinites; the Roman Catholics perform their religious service in a private house. The town is governed by a provost, named by the sovereign, burgomasters, and a fynod chosen by the regency, assisted by a council. The university of Göttingen claims peculiar notice; it was founded in 1734, by George II., king of England, and consecrated on the 17th of September 1737, and by the visitation of its first curator, Baron Munchhausen, it has risen to distinguished reputation. It has a splendid church, with its own pastor; and it is accommodated with a lately edifice of stone, the ground-floor of which serves as a hall for public lectures, and the upper apartments are appropriated to the library, council-chamber, and other necessary purposes. Its library is very large and valuable, and it is called the "Bibliothek," from a collection of about 100,000 volumes, with which it originated, bequeathed by Baron Bubow for public use, and granted by his heirs to the university. A royal society of sciences, founded in 1751, and a royal German society, form part of the university. It has likewise a fine observatory, erected on a tower on the ramparts, with a physical garden, anatomical theatre, &c. The territory belonging to the town is very considerable; 22 miles N. E. of Celle. N. lat. 51° 51'. E. long. 9° 52'.

GOTTO, a country of Africa, situated to the south of Juba and Tombutteo, and the river Niger or Joliha, about 15° N. lat., and from 0 to 2° E. long. It was formerly divided into several petty states, under their own chiefs, but it is now under the government of a king. Its chief town is called Moufleidou, from the name of its first monarch.

GOTTOLENGO, a town of Italy, in the department of the Moda; 15 miles S. of Brescia.

GOTTORP. See Sleswig.

GOTTSCHIE, a town of Middle Carniola; 20 miles S.S.E. of Ljubljana. N. lat. 45° 53'. E. long. 14° 48'.

GOTZEL, a town of Bavaria; 36 miles E. of Ratiboh.

GOVAN, a town of Scotland, in Lanarkshire; the population of which, in 1801, was 6701, of which 1314 were employed in trade and manufactures; four miles W. of Glasgow.

GOUANDORE, a bay on the coast of Chili.

GOUANIA, in Botany, was named by Jacquin in honour of Anthony Gouan, a physician and celebrated botanist of Montpellier, where he has long filled the botanical chair, and, as far as we know, is still living, though at a very advanced age. He was the friend and correspondent of Linnaeus, and is the author of a Flora Montpeliensis, arranged according to what he himself calls a hybrid syllabus, the outlines being on the principles of Tournefort, the subordinate sections taken from the Linnaean system. The work appeared in 1765. He had previously, in 1762, published a Hortus Montpeliensis according to the last-mentioned syllabus. Each work forms an octavo volume. They are chiefly remarkable for the secondary generic characters, taken from the habit, subjoined to the collateral ones which are founded on the fructification. Professor Gouan published also a folio volume of Observations Botaniques, with plates, illustrative of the plants of his neighbourhood; as well as a quarto in Latin and French on the methodical arrangement, and generic characters at length of flowers.—Ibid. Amer. 263. Linn. Gen. 545. Schreb. 33. Mart. Mill. Ditt. 2. Jull. 381. Linn. Rhamni, Nov. 845.—Chief of order, Polyantha Moutzela, or rather Pterostylis Moutzela, Nov. Ord. Dainii, Linn. Rhamni, Nov.

Gen. Ch. Cal. Perianth of one leaf, superior, 5-angled, setaceous, obtuse at the summit, spreading, deciduous. Cor. Petal 5, 5-foil to the filaments, hood-shaped, clavate. Stam. Filaments 5, awl-shaped, the length of the stigmas, a little, and alternate with them, inserted into the tube; anthers roundish, incumbent, sheltered by the petals. Pyl. Ger- men inferior, roundish; style awl-shaped, divided half-way down.
down into three segments; stigmas obtuse. *Peris.* Capsule with three angles, separable into three parts, of one cell each, not burbling. *Seco* solitary, ovate, compressed, polished.—There are some male flowers, furnished with a style, but destitute of germen and stigma.

Jacquin originally described two species, of which Linnaeus adopted but one. Lamarrack has added three more, all in our possession, to which we are enabled to furnish three non-descript species, making eight in all.

1. *G. dominifera.* Lam. Sp. Pl. 1653. Lamarck Dict. v. 3, 4. (G. glabra; Jacq. Amer. 264. t. 158. f. 49. Lupinus fyllodis americana, &c. Pluk. t. 207. f. 4.)—Leaves ovate, pointed, serrated, nearly smooth. Wings of the fruit dilated, kidney-shaped.—Native of woods in Hispaniola and the Bahama islands. A climbing much branched shrub, the young branches downy, ending in long simple spiral tendrils. Leaves alternate, on short hairy stalks, ovate, a little unequal, an inch and half long, bluntly serrated, furnished with a blunt entire point, and with several straight parallel veins directed forward. The young leaves are rather downy, old ones nearly smooth. *Stipulas* small, half arrow-shaped. Flowers in long terminal clusters, small, greenish and unornamental. *Capsules* of a light spongy texture, their central part as big as a small pen, the wings three to six, long, spreading, pale brown, smooth and somewhat polished. *Seco* hard, of a brownish brown.

2. *G. tomentosa.* Jacq. Amer. 253. Lam. Sp. Pl. (G. crenata; Lamarck Dict. v. 3, 5) "—Leaves ovate, crenate, downy."—Native of woods in Hispaniola, climbing to the tops of lofty trees. Jacquin of this we have seen no specimen. Jacquin says the leaves are four inches long. *Seco* black and shining. Lamarrack supposes his plant to be the fame on account of the great size of its leaves, and he says it is distinguished from all others by its crenature. Jacquin describes his as slightly crenate.

3. *G. cylindrica.*—Leaves elliptic-oblong, pointed, obtusely serrated, roughly, naked on both sides. Wings of the fruit brown, orbicular.—Native, we believe, of the West Indies. The very young shoots and leaves only are silky and serrigenous. The full-grown leaves are near three inches long and one broad, somewhat ovate, either almost entire, or furnished with shallow distant serratures, and a short entire blunt point; they are green and quite naked on both sides, but hairy to the touch on the upper surface. Veins distinct. Faworks, flower-skulls, and *Stipulas* hairy. *Flowers* somewhat silky. Fruit orbicular at each side, each wing forming a hemisphere, and not being much dilated.

4. *G. denticulata.*—Leaves ovate, pale and downy beneath, entire, with a finely-toothed point.—Gathered by the late Mr. Christopher Smith in the island of Hominois, East Indies. The leaves are about an inch and half long, with straight veins, connected by numerous minute rectifications, and are remarkable for the numerous little sharp teeth which border their upper part and terminal point, while the rest of their margin is entire. Their upper side is rough to the touch, but green and naked; while the lower is hoary with very dense short fly, the veins only being naked. *Stipulas* small and deciduous. A simple curled *tendril* terminates each lateral branch, as in all the foregoing. *Flowers* in axillary downy clusters, with lanceolate deciduous bracteas. The fruit we have not seen.

5. *G. murrayana.* Lamarck Dict. v. 35.—Leaves ovate, pointed, variously serrated, downy on both sides.—Native of the heights called the Goi, in the desert, of the isle de Bourbon, where it was gathered by Commerfon, and sent to the botanic garden at Paris. The leaves are the size of the last, but green and clothed with silky down on both sides. Their figure is ovate, rarely somewhat cordate, often unequal, sharp-pointed, their marginingularly variable, being sometimes nearly entire, having only feinted shallow serratures, sometimes very deeply and doubly serrated, not unlike the Roman nettle, *Urtica pilulifera.* *Stipulas* ovate, acute, clothed with shining reddish silky hairs, as well as the young twigs and tendrils. The fruitification is wanting in our species. Lamarrack says the *Capsules* have rounded thin and membranous wings.

6. *G. filifolia.* Lamarck Dict. v. 3, 5. (G. Stadtmannii; Willem. Herb. Maurit. 83.)—Leaves heart-shaped, bluntly pointed, smooth on both sides, bluntly and slightly serrated. Native of the ile de Bourbon, near la Pliibagne. Commerfon. The stem is much branched and diversified, smooth, except the very young shoots. Leaves an inch or inch and half long, and nearly as broad, heart-shaped, with shallow serratures and a short blunt point. They are light green and naked on both sides; the young leaves very minutely chagrined beneath. *Stipulas* glandular. Flower-skulls rusty and downy. The tendrils become very thick and strong by age.

7. *G. integrifolia.* Lamarck Dict. v. 3, 5. —Leaves ovate, bluntly, entire, smooth on both sides. *Stipulas* awl-shaped. Long cultivated in the Paris garden, but its native country is not reknown. We have a specimen from thence, definite of flowers and fruit, yet we readily agree with Lamarrack that there can be no doubt respecting its genus. The habit, stem, tendrils, folded young leaves, and their pale parallel veins, all indicate a *Goua*, for no genus can be more natural than this. The leaves are usually about an inch long, exactly ovate, (not oval) without any elongated point, though tipped with a gland; their margin quite entire, their midrib sometimes slightly hairy at the back. *Stipulas* awl-shaped, deciduous. Flower-skulls hairy only while young.

8. *G. finifolins.—Leaves heart-shaped, minutely serrated, acute, somewhat hairy. *Stipulas* awl-shaped. Flower-skulls umbellated, scarcely so long as the leaves. Brought by the late Sir G. L. Staunton, Bart. we believe from the Draufs. The zig-zag branches, with small heart-shaped leaves, and numerous axillary umbels of flowers, give it the aspect of a *Smilax*. The tendrils grow from the first joint of each branch, and are elegantly spiral; rusty and hairy, like the flower-skulls and calyx. The principal leaves are usually about an inch long, green on both sides, their ribs and veins always very hairy, their surface more or less so. *Stipulas* awl-shaped, hairy. 8.

GOUAREC, in Geography, a town of France, in the department of the North Coasts, and chief place of a canton, in the district of Louvain; 24 miles S.W. of St. Brieuc. The place contains 678, and the canton 6,293 inhabitants, on a territory of 203½ Kilometres, in 5 communes.

GOUD, or GAUD. See WELD.

GOUDA, or THE KOELW, in Geography, a city of Holland, seated on a branch of the Rhine, called IJssel, where it receives the Gouw, from which it derives its name. The great church of this town is one of the largest and handsomest in the country, and is particularly famous for its painted glas windows, which were executed principally by Theodore and Walter Crabeth of this town, and which are carefully preserved. The town is advantageous situated, on account of the sluices and canals, which are running screaming, and its convenient port on the IJssel. It has five gates, and is so circumstanced by reason of the sluices, which may imitate the current of the adjacent country, the breadth and depth of its ditches, and
and the strong fortifications on the banks of the Iffel, that it cannot easily be besieged. Its chief trade consists in cordage, cheese, and tobacco-pipes; and it has a regular communication by boats with Amsterdam, the Hague, Rotterdam, Utrecht, &c; 22 miles S. of Amsterdam. N. lat. 52° 8'. E. long. 4° 36'.

GOUDHURST, a post-town of England, in the county of Kent, containing 1752 inhabitants; 11 miles S. of Maidstone, and 44 S.E. of London.

GOUDOZ, a town of Afiatic Turkey, in Natolia; 72 miles E.N.E. of Kuitaja.

GOUDIMEL, CLAUDE, in Biography, one of the early and most celebrated composers of music to the metrical French translations of the psalms for the use of the Calvinists. He was a native of Franche-Comté, who seems to have left his life at Lyons, on the day of the massacre of Paris, for having met to music the psalms of Clement Marot. Goudimel has been much celebrated by the Calvinists in France for this music, which was never used in the church of Genoa, and by the Catholics in Italy for introducing Palestrina in the art of composition, though it is doubtful whether this great harmonist and Goudimel had ever the least acquaintance or intercourse together. He set the "Chansons Spirituelles" of the celebrated Marc-Ant. de Muret, in four parts, which were printed at Paris, 1555. We may suppose Goudimel, at this time, to have been a Catholic, as the learned Muret is never ranked among heretics by French biographers.

Ten years after, when he set the psalms of Clement Marot, this version was still regarded with fear by the Catholics than in later times; for the music which Goudimel had set to it was printed at Paris by Adrian Le Roy, and Robert Ballard, with a privilege, 1565. It was reprinted in Holland, in 1567, for the use of the Calvinists, but seems to have been too difficult; for we are told by the editor of the psalms of Claude le Jeune, which were printed at Leyden, 1633, and dedicated to the States-General, that, "in publishing the psalms in parts, he had preferred the music of Claude le Jeune to that of Goudimel; for as the counterpoint was simply not for note, the most ignorant in music, if pleased of a voice, and acquainted with the psalm-tone, might join in the performance of any one of them; which is impracticable in the compositions of Goudimel, many of whose psalms being composed in fugue, can only be performed by persons well skilled in music."

The works of Goudimel, who was certainly the greatest musician in France, during the reign of Charles IX., are become scarce, that his name and reputation are preferred by Protestant historians, more in pity of his misfortunes, than by any knowledge of their excellence. With respect to his having been the master of Palestrina, that point will be discussed elsewhere.

The earliest mention of Goudimel, as a composer, that we have been able to discover, is in a work entitled "Liber quartus Ecclesiastico-Romanum quater quattuor vocab vocum Motetx vocant," printed at Antwerp, by Sufato, 1554, eighteen years before his death. On forswearing several of these motets, we found the harmony pure and correct, but constructed entirely on the principles of the ecclesiastical tones: probably before he became a disciple of Calvin. The title of all his compositions may be seen in Draudus, Bibl. Class. et Bibl. Exot. (See FANCI, CLAUDE LE JEUNE, and PALESTRINA.) The motets of Goudimel, in four parts, remind us of gravity of style, simplicity in the subjects of fugue, and purity of harmony, the ecclesiastical compositions of our venerable countryman Bird.

GOODSWAARTE, in Geography, a small island at the mouth of the Meuse, S. of the island of Putten.

GOUEGA, a town of Africa, in Whidah; 10 miles W.S.W. of Sabi.

GOVENDING, a town of Bengal; 32 miles E. of Calcutta.

GOVERDAN, a town of Hindostan, in Masulipatam; 10 miles E. S. E. of Dig.-Also, a town in Oude, near the De- wash; 20 miles N. of Azimugur.

GOVERDUNPOUR, a town of Hindostan; 44 miles N. of Allahabad.

GOVERNMENT, a town or place which has no man power or right to command or rule over a place, city, county, or kingdom, or the like, either supreme or by deputation.

Government is either general and supreme, as that of a whole kingdom, empire, sovereign state, &c of particular and subordinate; which, again, is subdivided into civil, military, and ecclesiastical.

Our cities, corporations, and boroughs, are usually governed by mayors, with aldermen and common-councilmen.

Government is also used for the country, city, or place to which the power of governing or commanding is extended.

Government, again, is used for the manner or form of governing, i.e. for the police of a country, state, &c.

In this sense the various forms of government have generally received their denominations from the number of persons to whom the supreme power has been entrusted. If it be in one person, it is called a monarchy, especially if the chief magistrate lies under considerable restraints, or governs by fixed and established laws; whereas, if this single person lie under fewer restraints, or directs everything by his own will and caprice, the government is called despotic. If the supreme power be lodged in a limited number of persons, the government is called an oligarchy, or aristocracy; and if all the citizens have an equal voice in making laws, and appointing magistrates, or the supreme power be lodged in the whole body of the people, it is called a democracy or republic. See the several articles.

Civil government and society originate in the wants and fears of individuals, who, being naturally free, equal, and independent, associate together, either by express or tacit consent, for the mutual preservation of their lives, liberties, and estates, on this fundamental principle, that the whole should protect all its parts, and that every part should pay obedience to the will of the whole. However the several forms of government, that now subsist, actually begun, there is and must be in all of them a supreme, irremovable, absolute, uncontroverted government, in which the jura summi imperii, or the rights of sovereignty, reside; and this authority is placed in those hands, wherein, according to the opinion of the founders of such respective states, either expressly given, or collected from their tacit approbation, the qualities requisite for supremacy, viz. wisdom, goodness, and power, are the most likely to be found.

Individuals unite for mutual protection and benefit; and, therefore, the legislative and executive authority of government, originally derived from themselves, should be invariably directed to no other end but their safety and welfare; and that form of government is most eligible, which is best adapted to these purposes. Cicero declares himself of opinion, in his fragments De Rep. lib. iv. ... optimam con-

GOV
The subject of the patriarchical chief, or favorer by any previous division of ancestry, would enable the person who posseffed it to acquire the almost absolute division of the affairs of the community; more especially if he took care to associate to himself proper auxiliaries, and to gratify or remove those who opposed his pretensions.

The causes which have contributed to introduce hereditary dominion, are principally the influence of association, which communicates to the son a portion of the respect that was paid to the virtues or station of the father, the mutual jealousy of other competitors, the greater envy with which all behold the exaltation of an equal, than the continuance of an acknowledged superiority, and the number of adherents left by a reigning prince, who preserve their own importance, merely by supporting the succession of his children, and the apprehension of calamities that are incidental to contested elections. The ancient state of society in most countries, fays our author, and the modern condition of some uncivilized parts of the world, exhibit that appearance, which this account of the original of civil government would lead us to expect. The earliest histories of Palestine, Greece, Italy, Gaul, and Britain, inform us that these countries were occupied by many small independent nations, resembling those which are now found among the savage inhabitants of North America, and beyond the coast of Africa. This theory, it is added, affords a presumption, that the earliest governments were monarchies, because the government of families, and of armies, from which, according to the preceding statement, civil government derived its institution, and probably its form, is universally monarchal.

Our readers will observe that this theory is very different from Sir Robert Filmer's patriarchal scheme, now, indeed, almost forgotten and fearfully deserving to be recorded, the refutation of which constitutes the first part of the admirable Locke's Treatise on Government. According to this scheme, all government is absolute monarchy, which the author founds on this previous principle, that no man is born free. The absolute sovereignty of Adam was the result of a divine appointment and donation, and this sovereignty has been regularly conveyed by a divine hereditary right to all succeeding monarchs. The notion, that kings reign by a divine right, independently of the designation of the people, and not accountable to them for the exercice of their power, absurd as it will now very generally be thought, was, however, for a long time not only admitted, but prevalent even in this country. It is strongly inculcated in the Homilies of our established church, and was strenuously maintained by several of its respectable divines. Dr. Tillotson, enlightened and excellent as he was in other respects, could not, in the middle part of his life, emancipate himself from the idea, that it was fitful to refild government, as is evident from his letter to lord Ruffell. That power originates with the people was condemned as an abominable tenet by the famous Oxford decree of 1683; but this is a topic on which it is needless to enlarge.

In the most popular forms of government, says Dr. Pakey, the physical strength resides in the governed; and it therefore becomes an inquiry of considerable importance, among politicians, what motives induce the many to submit to the few. In the discussion of this question our author distributes the subjects of a state into three different classes, viz. 1. Those who obey from prejudice, or who are determined by an opinion of right in their governors, which opinion is founded upon prescription: this prescriptive title, in hereditary monarchies, is corrodorated, and its influence considerably augmented, by an acception of religious sentiments, and by that

Another source of personal authority, which might extend, or supercede, the patriarchal, is that which results from military arrangement. A popular and successful leader, in every action of aggression or defence, would gain a powerful and permanent influence among his followers. This advantage, added to the authority of the patriarchal chief, or favored by any previous division of ancestry, would enable the person who possessed it to acquire the almost absolute division of the affairs of the community; more especially if he took care to associate to himself proper auxiliaries, and to gratify or remove those who opposed his pretensions.
GOVERNMENT.

Sacredness which men are apt to ascribe to the persons of princes. 2. Those who obey from reason, by a consideration of the necessity of some government or other, and of the certain mischief of civil commotions. 3. Those who obey from self-interest, and who are kept in order by a variety of considerations that immediately affect themselves.

Concerning the moral obligation of submission to civil government, those who adopt the principles of Mr. Locke, and many other political writers, allege a compact between the citizen and the state, as the ground of the relation between them; and this compact binding the parties, like private contracts, resolves the duty of submission into the universal obligation of fidelity in the performance of promises. This compact is either, 1. Express, on the part of the primitive founders of the state, who are supposed to have met together for the declared purpose of settling the terms of their political union, and a future constitution of government. The whole body is supposed to have unanimously consented to be bound by the resolutions of the majority; and that majority is supposed to have fixed certain fundamental regulations, and thus to have constituted, either in one person, or in an assembly, a standing legislature, to which, under these pre-established restrictions, the government of the state was thenceforward committed, and whose laws, the several members of the convention were, by their first undertaking, thus personally engaged to obey.—This transaction is sometimes called the "Social compact," and these sup- posed original regulations compose what are meant by the "constitution," the "fundamental laws of the constitution," and form, on one side, the "inherent indefeasible prerogative of the crown," and, on the other, the unalienable "birthright" of the subject; i.e. a tacit or implied compact by all succeeding members of the state, who, by accepting its protection, consent to be bound by its laws. "This account of the subject," says Dr. Paley, "although specious, and patronized by names the most respectable, appears to labour under the following objections; that it is founded upon a supposition false in fact; and leading to dangerous consequences." No such social compact was ever really made, nor any such original convention of the people ever actually held, or could be held in any country, antecedent to the existence of civil government in that country. It is to suppose it possible to call savages out of caves and deserts, to deliberate and vote upon topics, which the experience, and studious arrangements of civil life alone suggest; therefore no government in the universe began from this original. At a Revolution some imitation of a social compact may have taken place. The establishment of the United States of North America bears the nearest resemblance of it. Should it be said, that the original compact is not proposed as a fact, but as a fiction, for the commodious explication of the mutual rights and duties of sovereigns and subjects; to this representation it may be replied, that the original compact, if it be not a fact, is nothing; it can confer no actual authority upon laws or magistrates, nor afford any foundation to rights, which are supposed to be real and existing. But in the books, and also in the apprehension of those who deduce our civil rights and obligations à patris, the original convention is appealed to, and treated of, as a reality.

Moreover, it is alleged, that the theory of government, which affirms the existence and the obligation of a social compact, leads to conclusions unfavourable to the improvement, and to the peace, of human society. Upon this theory it may be presumed that many points, called "fundamentals" of the constitution, were settled by a convention of the people, anterior to the establishment of the fulfilling legislature, and which the legislature has no right to alter, or interfere with. This circumstance affords a dangerous pretence for disputing the authority of the laws. Hence arose the doubt, which so much agitated the minds of men in the reign of Charles II, whether an act of parliament could of right alter or limit the succession of the crown. Besides, if it be by virtue of a compact that the subject owes obedience to civil government, he ought to abide by the power of government which he finds established, however absurd or inconvenient it may be. Moreover, every violation of the compact on the part of the governor releases the subject from his allegiance, and dissolves the government.

Dr. Paley, rejecting the intervention of a compact, as unfounded in its principle, and dangerous in the application, assigns for the only ground of the subject's obligation, "the will of God as collected from expediency." Accordingly the author reasons in the following manner. It is the will of God that the happiness of human life be promoted; civil society conduces to that end; civil societies cannot be upheld, unless in each, the interest of the whole society be binding upon every part and member of it; and this step of the argument conducts us to the conclusion, namely, that so long as the interest of the whole society requires it, that is, so long as the established government cannot be refilled or changed without public inconvenience, it is the will of God (which will universally determines our duty) that the established government be obeyed; and no longer. This principle being admitted, the justice of every particular case of resistance is reduced to a computation of the quantity of the danger and grievance on the one side, and of the probability and expense of redressing it on the other. If it be asked, who shall judge of this? the answer is, "Every man for himself." In contentions between the sovereign and the subject, the parties acknowledge no common arbitrator; and it would be absurd to refer the decision to those whose conduct has provoked the question, and whole own interest, authority, and fate, are immediately concerned in it. From the substitution of "public expediency" into the place of all implied compacts, promises, or conventions whatsoever, our author infers, 1. That it may be as much a duty at one time to resist government as to obey it. 2. That the lawfulness of resistance, or the lawfulness of a revolt, does not depend alone upon the grievance which is sustained or found, but also upon the probable expense and event of the contest. Hence those who concerted the revolution in England were justifiable in their counsels. 3. That irregularity in the first foundation of a state, or subsequent violence, fraud, or injustice in getting possession of the supreme power, are not sufficient reasons for resistance, after the government is once peaceably settled. 4. That resistance is not justified by every invasion of the subject's rights, or liberty, or of the constitution; by every breach of promise, or of oath; by every stroke of prerogative, abuse of power, or neglect of duty on the part of the chief magistrate; unless these crimes draw after them public conceptions of sufficient magnitude to outweigh the evils of civil disturbance. 5. That no usage, law, or authority whatever, is so binding, that it need or ought to be continued, when it may be changed with advantage to the community. 6. As all civil obligation is resolved into expediency, what, it may be asked, is the difference between the obligation of an Englishman and a Frenchman, or why is a Frenchman bound in conscience to bear any thing from his king, which an Englishman would... 582
not be bound to bear, since the obligation of both is founded in the same reason? Although their conditions may differ, their rights should seem to be equal; and yet we are accustomed to speak of the rights as well as the happiness of a free people, compared with what belong to the subjects of absolute monarchies; and how, it may be reasonably inquired, can this comparision be explained, unless we refer to a difference in the compacts by which they are respectively bound? In order to obviate this difficulty, it is allowed that a Frenchman is in conscience bound to endure many things from his prince, to which an Englishman would not be bound to submit for the following reasons; vis. because the same act of the prince is not the same grievance where it is agreeable to the constitution, and where it infringes it; and because redress in the two cases is not equally attainable. The duty of obedience is defined by different boundaries, and the point of justifiable resistance is placed at different parts of the scale of suffering—all which is sufficiently intelligible without a facial compact. 7. The interest of the whole society is binding upon every part of it. If we appeal to the Christian scriptures with regard to the duty of civil obedience, it extends to our civil rights and obligations, Christianity hath left us where the found us: she has neither altered, nor ascertained it. The two passages to which writers have generally referred in their investigation of this subject are Romans xiii. 1–7, and 1 Peter ii. 13–18. In order to comprehend the proper import of the instructions contained in these passages, there are two questions relating to the subject of civil obedience, which should be considered, viz. whether to obey government be a moral duty and obligation upon the conscience at all, and how far, and to what caffes, that obedience ought to extend? These passages, it may be observed, inculcate the duty; but they do not describe the extent of it. The due consideration of this distinction is sufficient to vindicate these passages of scripture from any explanation of them that shall favour an unlimited passive obedience. But admitting what many commentators have stated, that an opinion was privately cherished by the first Christians, which led them to conceive, that their conversion to Christianity entitled them to new immunities, to an exemption as of right (however they might give way to necessity) from the authority of the Roman sovereign, we are furnished with a still more apt and satisfactory interpretation of the Apostle’s words. The two passages apply with great propriety to the refutation of this error. Little need be added in explanation of particular clauses. St. Paul has said, “whosoever refuseth the power, refuseth the ordinance of God.” This phrase, “the ordinance of God,” is by many so interpreted as to authorize the most exalted and superstitious ideas of the regal character. But surely such interpreters have facriYiced truth to adulation. For, in the first place, the expression, as used by St. Paul, is just as applicable to one kind of government, and to one kind of succession, as to another, to the elective magistrates of a pure republic, as to an absolute hereditary monarch. In the next place, it is not affirmed of the supreme magistrate exclusively, that he is the ordinance of God; the title, whatever it imports, belongs to every inferior officer of the state as much as to the highest. The divine right of kings is, like the divine right of constituencies, in the law of the land, or even actual and quiet possession of their office; a right ratified, we humbly presume, by the divine approbation, so long as obedience to their authority appears to be necessary or conducive to the common welfare. Princes are ordained of God by virtue only of that general decree, by which he afflicts, and adds the function of his will, to every law of society, which promotes his own purpose, the communication of human happiness; according to which idea of their origin and constitution, and without any repugnancy to the words of St. Paul, they are by St. Peter denominated the “ordination of men.” Paley, ubi supra. See King, Law, Liberty, Monarchy, Parliament, Passive obedience, &c.

Government, in Grammar, is understood of that con- struction of nouns and verbs, wherein they require some alteration to be made in others joined or constructed with them.

Construction is divided into two parts; that of concord, and that of government, called also regimen. See Concord and Regimen.

GOVERNOLO, in Geography, a town of Italy, in the department of the Mincio; 12 miles S. E. of Mantua.

GOVERNOR, an officer vested by a king, or sovereign prince, with the command and administration of a province, place, &c.

A governor represents the king; and not only commands the garrison, troops, &c. but the citizens, &c. A governor of a fortified place was anciently required to hold out three attacks, before he surrendered.

GOVERNOR is also frequently used for a president or superintendent.

Thus we say, the governor of the bank; the governor and directors of the South Sea company; the governor of an hospital, &c.

GOVERY, in Geography, a town of Hindooalan, in the circar of Rajamundry; 10 miles W. N. W. of Rajamundry.

GOUF. See Golf.

GOUFRE, in Geography, a town of Canada, in the river St. Lawrence; 50 miles E. of Quebec.

GOUGAN-BANIA, a lake of Ireland, in the county of Cork, not far from Inchigeele. The river Lee rises in a mountain above this lake, through which it flows. It was formerly the residence of St. Fin-Bar, and is visited by great numbers of pilgrims, whilst its romantic beauties attract a few travellers, notwithstanding the ruggedness of the road.

GOUGE, William, in Biography, who flourished in the former part of the seventeenth century, was born in the parish of Baw, in the year 1575. He was educated partly at St. Paul’s school, and partly at Eton, and, in 1595, he was elected to King’s college, Cambridge. Here, in due time, he performed with much applause all the exercises required by the statutes, and took his degrees. In 1607, he was admitted into orders, and in the following year obtained the rectory of Blackfriars, London. In this situation he continued during the remainder of his life, discharging the pastoral functions with great diligence and fidelity, and setting before his parishioners an example worthy of imitation. The zeal with which he performed the duties of his office, led him to establish a weekly lecture, which was frequented not only by his own people but by many of the London clergy, the members of the Inns of Court, and the more respectable and serious citizens. In 1628, he was admitted to the degree of doctor of divinity, and about the same period he became one of the trustees of the society that had united for the purpose of buying up appropriations, to bestow them on such unpatronized clergymen as were distinguished for piety and other ministerial qualifications, which occasioned his being prosecuted in the Star-Chamber. In 1653, he was nominated one of the assembly of divines, and was held in such reputation by that body, that he was often called to fill the moderator’s chair during
GOU

during his absence. He was selected as a proper person to write notes on the bible, and took, for his share of the work, from the beginning of the first book of Kings to that of Job. He died in the year 1653, soon after he had completed his 78th year. He had, for several years, been esteemed the father of the London ministers. In his department, he was modest, humble, and affable; he had a pious and benevolent spirit, and continued to preach as long as he had strength to walk into the pulpit. Besides the "Annotations," already referred to, Dr. Gouge published many other theological pieces, as "A Commentary on the Epistle to the Hebrews"; "An Exposition of the Lord's Prayer;" "The Whole Armour of God," &c.

GOUGE, Thomas, son of the preceding, was born at Baw, in the year 1655; and having, in his academical course, followed the steps of his father, he was first chosen fellow of his college, and afterwards presented with a living at Colden, near Croydon, in Surrey, where he continued but a short time; and, in 1658, he undertook the more important charge of St. Sepulchre's parish, London. During a period of twenty-four years he discharged the duties of his station with much merit, and was frequently invited to preach twice every Sunday, and often on week days, he visited his flock, catechized their children, enquired into and relieved the wants of the poor, and devised plans for their employment. He is said to have given the hint which produced the humane and benevolent institutions of Mr. Firmin, which have been referred to in the memoir of that excellent citizen. When the act of Uniformity took place, he was too conscientious to sacrifice his principles on the shrine of power, and was ejected from his living. His time was now zealously devoted to acts of beneficence and charity. He employed his own fortune, which was considerable, in relieving the wants of his poorer brethren, who, on account of their non-conformity, were deprived of their means of subsistence; and he was a successful applicant to the rich, from whom he received large sums, which were applied to that humane purpose. In the year 1671, he set about a plan for introducing knowledge and religion into the different parts of Wales, which at that period were in the most deplorable darkness. He established schools in different towns where the poor were willing that their children should be taught the elements of learning, and he undertook to pay all the expenses which were incurred in the outlay of the buildings. By degrees these schools amounted to between three and four hundred, and they were all annually visited by Mr. Gouge, who hospitably escorted into the progress made by the young people, before whom he occasionally preached in a style adapted to their age and circumstances in life, until he was obliged to desist by professions carried on against him in the ecclesiastical courts. With the assistance of his friends, whose parishes were ever open at his command, he printed eight thousand copies of the bible in the Welsh language, a thousand of these were distributed freely among those who could not afford to purchase them, and the rest were sent to the cities and chief towns in the principality, to be sold at reasonable rates. He procured likewise the church catechism, and other practical pieces, to be printed in the Welsh language, and distributed among the poor. To these and such like charitable undertakings did Mr. Gouge devote his time, his talents, and his fortune, when precluded by the intolerance of the laws from officiating in the capacity of a preacher. He was accustomed to pay with pleasure, "that he had two livings which he would not exchange for two of the greatest in England." These were Wales, where he travelled every year to diffuse the principles of knowledge, piety, and charity; and Christ's Hospital, where he catechized and instructed the children in the fundamental principles of religion. He died suddenly in 1691, in the seventy-seventh year of his age. His death was regarded as a public loss. A funeral sermon was preached on the occasion by Dr. Tillotson, afterwards archbishop of Canterbury; who, at the conclusion of an animated eulogy on his piety and virtue, observes, that "all things considered, there have not, since the primitive times of Christianitv, been many among the sons of men, to whom that glorious character of the son of God might be better applied, that "he went about doing good." And Mr. Baxter, in his Narrative of his own Life and Times, says of Mr. Gouge, "I never heard any one person, of whatever rank, fort, or sect forever, speak one word to his honour, or name any fault that they charged on his life or doctrine; no, not the partizans themselves, save only that he conformed not to their impositions; and that he did so much good with so much industry." This eminent Christian divine published a few practical pieces, of which the following are mentioned; "The Principles of Religion Explained;" "A Word to Sinners;" "Christian Directions to walk with God;" "The framed and jafele Way of Thriving, &c. by Charity to the Poor;" "The Young Man's Guide through the Wilderness of this World." Gen. Binq. Neal's Hist. of the Puritans.

GOUGEON, John, in Biography, a French sculptor and architect in the reigns of Francis I. and his successors, is reckoned the first who introduced a true taste for sculpture in France, and freed it from the barbarism of former times. He was employed in many of the public works with which Paris began to be decorated in the reign of Francis I. Of these the most considerable is the fountain of the Nymphs, called the Innocents, finished in the year 1550. Among the other remains of his workmanship is a statue of the bailiff des Cent-Suifles, at the Louvre, enriched with sculptures, and supported by four gigantic Caryatides. He was an able medalist, and struck several pieces for Catharine de Medicis, which are sought by the curious. He generally worked in small, and there are no detached figures or groups by his hand. His reliefs are executed with taste, his drapery is light and elegant, his figures graceful and flexible, but their attitudes somewhat forced. He was a Huguenot, and was shot as he was working on a scaffold, on the infamous St. Bartholomew's day, 1572. Gen. Binq.

GOUGH'S ISLAND, in Geography, a small island in the Southern Atlantic ocean, discovered by captain Gough in 1715. It is very high land, in S. lat. 40° 15'. W. long. 81° 57'. Some doubt being entertained with respect to its true longitude, it was recommended to M. de la Perouse to ascertain its true position, as it lies in the way of ships going directly to India, or China, early in the leasom, without touching at the Cape.

GOUJET, Claude Peter, in Biography, was born at Paris in 1607. His father, a tailor by trade, in vain opposed his inclination for a ludicrous life. He was educated among the Jesuits, and, having taken orders, became a canon of the church of St. Jacques de l'Hôpital in Paris. He was an associate of several academies in France, and was generally esteemed for his learning, and also on account of the mildness of his temper and the purity of his morals. He died in 1757, and had collected a library of ten thousand well chosen volumes, which was the basis of his numerous works. Of these, the following may be mentioned, "Vies des
two volumes. 4to. "Supplement to Morey's Dictionary," two vols. folio. "Bibliotheca des Ecrivains Ecclésiastiques," three vols. 8vo. "Difcours sur le Renouvellement des Études depuis le xiv siècle." "De l'État des Sciences en France depuis la Mort de Charlemagne jusqu'à celle du Roi Robert." This disfertation obtained for the author the prize of the Academy of Belles Lettres, and he was complimented by a deputation from that body, defering permission to nominate him to the vacant place of the deceased abbé Vertot. Goujet was likewise author of "Bibliothèque Française, ou Histoire de la Littérature Française," 18 volumes 12mo. which is reckoned his most valuable work. Moreri.

GOUVIN, in Geography, a town of Portugal, in the province of Beira; 12 miles S.W. of St. João de Pefquera.

GOVINPOUR, a town of Hindooftan, in Balcar; 26 miles S. of Balcar.—Allo, a town of Bengol; 10 miles W. of Nudinga.

GOULAMCONDRA, a town of Hindooftan, in the Myr-fore, 9 miles S. of Gooty.

GOULART, Simon, in Biography, a French Protestant divine, was born at Senlis in 1542. He began his studies late in life, but by persevering industry, he made a great proficiency in the learned languages, and was chosen pastor of the church of which Calvin had been minister. Here he discharged the duties of his office with much diligence and success, till within a few years of his death, which took place in 1628, when he was about 85 years of age. He edited many works, performing at the same time the busines of a commentator. Among these were the "Works of Plutarch;" "St. Cyprian's Works;" "Seneca's Works," &c. He made a collection of "Remarkable Histories" in 2 vols. 8vo., and wrote several pieces relating to the history of his own times. The most interesting and curious of the latter description is his "Collection of the most memorable events which occurred during the League, with notes and original documents," in fix vols. 4to. Many of his pieces were anonymous, but to these he usually affixed the initials S. G. S. signifying "Simon Goulart Senlifien." He had such an extensive acquaintance with the literature of his time, and knew so well to whom different publications, that were printed without the writer's name, were to be attributed, that Henry II. of France, being desirous of knowing who was the author of a piece published under the affixed initials of Stephanus Junius Brutus, and intended to propagate republican doctrines, sent a perfon to Geneva to inquire into the matter of Goulart, but the latter refused to communicate the fact, for fear of exposing the author to ferous injury. Moreri. Bayle.

GOULDSBOROUGH HARBOUR, in Geography, a harbour of the United States of America, in the district of Main. N. lat. 44° 25'. W. long. 67° 53'.

GOULERGAUFT, a town of Thibet; 28 miles S. of Deprag.

GOULOUR, a town of Hindooftan, in the circuit of Sanore; 18 miles N. of Sanore.

GOULSTON, Theodore, in Biography, was the father of William, rector of Wymondham, and was born in Northamptonshire. He became probationer fellow of Merton college, Oxford, in 1556; and, after applying himself to the study of physic in this university, he practiced for a time with considerable reputation at Wymondham and its neighborhood. At length, after taking his doctor's degree in 1610, he removed to London, and became a fellow of the College of Physicians, and afterwards censor. He resided in the parih of St. Martin's, near Ludgate, and was in great esteem, as well for classical learning and theology, as for the practice of his profession. He died in the year 1632; and by an article in his will testified such regard to the interests of medicine, as entitled him to grateful commemoration. This was a bequest of 200 pounds, to purchase a rent charge for the maintenance of an annual pathological lecture within the College of Physicians, to be read by one of the four youngest doctors of the College. The public has been indebted on several occasions to this institution for ingenious disfertations, delivered as Gulianian Lectures; as those of Dr. Mufgrave; Dr. Fordyce's Treatise on Digestion; &c.

GOUMEL, in Geography, a town of Africa, and capital of the country of the Foulahs, and residence of the Saratik. N. lat. 16° 16'. W. long. 11° 52'.

GOUNDA, a town of Hindooftan, in Oude; 32 miles E.N.E. of Manickpaur.

GOUPIA, in Botany. See Glossoptalum.

GOUPIL, James, in Biography, a physician of the sixteenth century, was born in the province of Poitou. He acquired a considerable knowledge of the ancient languages, and afterwards directed his studies to medicine, in the schools of Paris, where he graduated in 1547. His talents attracted the attention of the court, and he was appointed by Henry II. to the professorhip of medicine in the royal college, in 1555, a vacancy being occasioned by the death of Sylvius. He is principally known as an editor and annotator of the writings of Dioscorides, Alexander Trallian, Acurius, and some other Greek writers: and he was engaged in the same labour, in respect to some of the writings of Hippocrates, when his studies were terminated by death, in 1568. Eloy.

GOUR, called allo Lucknowi, in Geography, the ancient capital of Bengal, supposed to be the "Gangia Regia" of Ptolemy, which float on the left bank of the Ganges, about 25 miles below Rajennal. N. lat. 24° 53'. E. long. 88° 14'. It was the capital of Bengal 730 years B.C. and was repaired and beautified by Aschur, A. D. 1575, who gave it the name of "Lemmteabad," which name part of the circur in which it was situated fell bears. It was defeoted, as it is said, on account of the infulature of its air. Taking the extent of the ruins of Gour at the most reasonable calculation, it is not less than 15 miles in length, along the old bank of the Ganges, and from two to three in breadth. Several villages stand on part of its site; the remainder is either covered with thick forests, the habitation of tygers and other beats of prey, or become arable land, whose foil is chiefly compos'd of brick-dust. The principal ruins are a moque lined with black marble, elaborately wrought; and two gates of the citadel, which are grand and lofty. The bricks, which continue to be an article of merchandize, are of a peculiarly solid and durable texture.

GOURA, or GURA, a town of the dychy of Warfaw, on the Wullala: 12 miles from Warfaw.

GOVRA, a town of Persia, in the province of Irak; 35 miles E. of Iphahan.

GOURAY, a cape on the E. coast of the island of Jersey; 4 miles E. of St. Heller.—Allo, a town of France, in
GOURGON, a town of Hindooftan, in Allahabad; 10 miles N. of Corah.

GOURGOUTY, a town of Hindooftan, in Goconda; 36 miles W. S. W. of Rochore.

GOURIN, a town of France, in the department of the Morbilian, and chief place of a canton, in the district of Pontivy; 26 miles W. N. W. of Pontivy. The place contains 3,754, and the canton 11,819 inhabitants, on a territory of 242.5 kilometres, in five communes.

GOURMA, a town of Abyflinia, on the coast of the Red Sea. N. lat. 14° 52'.

GOURMUNGUL, a town of Hindooftan, in Goconda; 12 miles S. W. of Malar.

GOURMELEN, Etienne, in Biography, was a native of Brittany, and was sent at an early age to Paris, where he studied surgery, and afterwards medicine; in the latter of which he took the degree of doctor in the year 1559, and was elected dean of the faculty in November, 1574. Surgery, however, continued to be the favourite object of his attention, and he was appointed by Henry III. professor of surgery in the Royal College in the year 1588. But he did not long fill his chair, for he died in 1594. His writings, which were valuable in their day, have now lost their interest, in consequence of the great improvements of modern surgery: they consist of a "Synopsis Chirurgiae," printed in 1566, and afterwards translated into French; a Latin translation of Hippocrates' "De Alimento," with a commentary; and a treatise, entitled "Chirurgia Artis ex Hippocrate, et Veterrn decreatis ad rationes normam redacta, Libri tres," 1580. Elyo. Dict. Hist.

GOURNAIL, le Jars de, Mary, was born at Paris in 1596. She was, while very young, deprived of her father, and acquired an adoptive one in the celebrated Michael Montagne, who became the object of her enthusiastic admiration. After the death of Montagne she became heiress of his writings, and published an edition of his "Effays," dedicated to cardinal Richelieu. She had well improved the lessons of youth, and was intimately acquainted with the learned languages. She maintained a correspondance with many of the most eminent literary characters of the age, by some of whom she was honoured with the title of the "Tenth Muse," by others she was denominated the "French Siren:" it is not, however, improbable, that the uncommonness of female learning at that time in France, rather than the intrinsic merit of her writings, excited admiration. In her own language she wrote a fluff and awkward style, and her talent in reading was usually turned to the compilations and commentaries of past ages. She passed her life in celibacy, contented with a small pension from the court, and much esteemed by her particular friends, some of whom were persons of high rank. She died at Paris in 1645, in her 79th year, and was honoured with many epitaphs from literary characters. Her works were collected in a quarto volume, under the title of "Les Avis ou les preludes. M. Demoiselle de Gournall." Her temper was apt to be violent, and she was very reffentful of real or supposed injuries; by these means she made herself many enemies, who attacked her in their writings, in which neither her person, nor the defects in her character were spared. Bayle. Moreri.

GOURNAY, in Geography, a town of France, in the department of the Lower Seine, and chief place of a canton, in the district of Neuachalet, 24 miles E. of Roven. N. lat. 49° 27'. E. long. 4° 47'. The place contains 3,543, and the canton 11,301 inhabitants, on a territory of 185.5 kilometres, in 19 communes.

GOURNEI, a town of Egypt, on the site of the ancient Thebes.

GOUROCH, See Greenock.

GOURRI, a town of Abyflinia; 35 miles S. W. of Affab.

GOURVILLE, John Herauld de, in Biography, born at Rochefoucauld in 1625, was taken by the celebrated duke of that title into his service as valet de chambre, but in a short time he became his confidential friend. He was patronized by the great Comte, and was employed by the superintendant Fouquet, in public business. So well did he approve himself to his employers for political talents and integrity that he was proposed to the king as successor to Colbert in the ministry. He died in 1705, leaving behind him "Memoirs of his Life from 1642 to 1692," in two volumes 12mo. These memoirs are written with frankness and simplicity, in a lively, though incorrect style, and they contain many curious and well authenticated anecdotes of the ministers and principal persons of his time, of which, it is said, Voltaire made much use. Moreri.

GOURY PASINIUS, in Natural History, a name given by the people of the East Indies to a kind of orpiment of a deep yellow colour, veined with red in several places, and in some with white. It is found principally at the bottoms of mountains. They calcine it several times, and afterwards give it internally after intermitting fevers, and use it externally inointments for the taches.

GOUSET, James, in Biography, was born at Blois in the year 1635. He was educated for the ministry, and was chosen pastor of the Protestant church at Poitiers in the year 1662. He was thrice invited to undertake the professorship of divinity at Saumur, but refused to quit his flock till compelled to become a fugitive from the kingdom, in consequence of the revocation of the edict of Nantes. On this occasion he took refuge in Holland, and afterwards was settled, as French minister, at Groningen, where he likewise exercised the offices of professor of divinity, and of the Hebrew language in the university of that city. He died there in 1704, in his sixty-ninth year. His principal works were "Dissertationes in Controversy with the Jews," 1699. "Commentari Linguae Hebraicae," 1712, which form a valuable Hebrew dictionary, of which the best edition was published at Leipsic in 1743. "Dissertationes in Epistolam Pauli ad Hebreos," &c. 1712. At his death he left behind him numerous MSS., among which are commentaries upon the whole of the sacred Scriptures. Moreri.

GOUST, Gour, a French term, for what the Italians call gufso, and we taffo.

GOUT, in Medicine, a disease principally characterized by inflammatory attacks of the joints, more especially of the
foot, which return at intervals, and are connected with derangement of the digestive organs. The term, however, includes such a variety of morbid affections, in its extended sense, that it is not easy to give a concise definition of it; and we must have recourse to a more ample description of those affections, in order to convey a just notion of its signification.

The ancient physicians included all the varieties of inflammation, that are liable to occur in the joints, under the general term, Arthritis, (from ἄρθρον, a joint, with the termination ἱτις, denoting inflammation,) for the distinctions, made by modern physicians, between the two modifications of inflammation in the joints, now denominated gout and rheumatism, had not then been attended to. The term Arthritis, however, was used both as a generic and specific term, and signified, not only inflammation of the joints generally, but the ordinary form of gout by way of excellence. But the Greeks also gave specific names to the varieties of arthritis, according to the particular joints which the disease occupied: thus, for the ordinary form of gout in the foot, the term ὑατηξής, podagra, was employed; which, to become a generic title; for gout in the hand, the word πέρναξ, chiraqs; and for gout in the knee, ώατηξής, γωνιράς; and so on. Among the species of arthritis was also included the ἱέβιατα, ἱέβιατικα, or ἱεβ-γούς, which is now deemed a species of rheumatism. These terms the Romans adopted; and they are still retained in medical language. Our vernacular term gout, which came to us probably through the French, la goutte, originated in the dark ages among the humoral pathologists, who considered the disease as arising from the flow deposition of a morbid humour, goutain, as it were, upon the joints; hence, the name gouti, or drop, was applied to the disease. This term, according to Du Cange, was used by Radulphus, a Dominiean of the 13th century, who writes, "cum gutti, quam podagrum vel arthriticum vocant, frequenter vexaretur." Mulgrave de Arthritide.

In consequence of the various forms which gout assumes, physicians have divided it under two heads, regular and irregular gout, or, as some have termed it, tonic and atomic gout; the former occurring in the earlier periods of life, while the strength or tone of the system remains unbroken; the latter, after a certain degree of weakness, or atony of the constitution, has been produced by the frequent attacks of the disease, advanced age, or other causes. We shall first describe the symptoms by which these forms of the disease are characterized, and afterwards flate the causes and method of treatment, together with the speculations of pathologists, respecting the nature of the disease, beginning with an account of the paroxysm of Gout.

Regular Gout.—It is an inflammatory affection of the joints of the foot, which constitutes what is called a fit or paroxysm of the regular gout. This sometimes comes on suddenly without any warning of its approach; but it is generally preceded by several symptoms, especially by those of indigestion, as heart-burn, flatulence, and heaviness after meals, with eruptions of acid or bitter matters, and some degree of languor and torpor of the body; but immediately before the fit the appetite is sometimes unusually sharp. There is also often an unusual coldness of the feet and legs for a few days preceding the fit, with the cessation of the perurbation about the former; a frequent numbness, alternating with a tinge of prickling, along the whole of the lower extremities; occasional cramps of the muscles of the legs; and an unusual turgescence of the veins, are occasionally observed.

The attack is sometimes felt in the evening, but more commonly about two or three o'clock in the morning; when the patient is awakened from a quiet sleep by a pain affecting one foot, generally the ball or first joint of the great toe, but sometimes the other parts of the foot, or the ankle. This pain is accompanied with more or less of chilliness and shivering, which, as the pain increases, gradually ceases, and are succeeded by a hot flag of pyrexia, or symptomatic fever, which continues during the same time as the pain. The pain becomes by degrees more and more violent: at first it is attended with a sensation, as if warm water were poured upon the membranes affected, and is fad to resemble the pain of a dislocated joint; as it becomes severer it is sometimes described as resembling the pain of a tension, or laceration of the ligaments, sometimes as like that from the gnawing of a dog, and sometimes as a feeling of weight and concretion of the membranes of the part, which becomes so exquisitely tender, as not to endure the weight of the bed clothes, nor even the flashing of the room from a person walking briskly in it. Hence, great reliefs of the whole body, and especially of the part affected, always accompanies this patient, constantly changing his posture, with a view to ease the pain, which, whenever it subsides, continues severe all the following day, until mid-night, after which it gradually remits; and about two or three in the morning, that is, after twenty-four hours from the first attack, it commonly ceases almost entirely; and this freedom, with the breaking out of a free perspiration, allows the patient to fall asleep. On waking, he finds the pain slight, and the part affected with some redness and swelling.

When a paroxysm has thus come on, although the violent pain, after the period of twenty-four hours, is considerably diminished, yet the patient is not entirely without pain. For some days he has a return every evening of pain and fever, which continue, with more or less violence, till morning. After continuing in this manner for several days, the disease sometimes goes off entirely, not to return till after a long interval; and in such cases it generally leaves the person in very perfect health, enjoying greater ease and alacrity in the functions both of body and mind, than he had for a long time before experienced.

It often happens, however, that the disease does not thus speedily quit the patient, especially when he has previously suffered considerably from its attacks. For, instead of ceasing altogether after a few days, itizes the other foot in the same manner as it did the former, both in respect to the vehement and duration of the pain. Most commonly the foot first affected becomes quite easy, in such a case, and even as strong and healthy as if it had not been affected; but sometimes both feet are affected together, and with equal violence. When this happens, the succeeding exacerbations, as Sydenham remarks, are less regular both as to the time of coming on, and as to their continuance; but the pain always increases in the evening and remits in the morning; and what is called a fit of the gout, which goes off sooner or later, according to the age and constitution of the patient, is made up of a number of these little fits. For when this disease lasts two or three months, it is not to be esteemed one continued fit, but rather a series or alternation of small fits, the last of which proves milder and shorter, until the whole is terminated. In strong constitutions, and such as have the gout seldom, the attack is commonly finished in fourteen days; but in those of advanced life, or who have frequent returns of the disease, these series of fits will continue for two months; and in such persons are more debilitated, either by age or the long continuance of the disorder, it will not
go off till the summer advances, (beginning, as is most
common, in January, or early in February,) which seems to
drive it away.
When the fit is going off, a violent itching seizes the
foot, especially between the toes, and the cuticle peels off.
The appetite and strength return sooner or later, according
to the greater or less severity of the preceding fit, and the
interval of health between the paroxysms is generally nearly
in the same ratio; i.e. longer in proportion to the greater
violence of the last fit. At the beginning of the disease,
Dr. Cullen observes, the returns of it are sometimes only
once in three or four years; but after some time the inter-
vals become shorter, and the attacks become annual; after-
wards they come twice each year, and at length recur
several times during the whole course of autumn, winter,
and spring; and as it happens that, when the fits are
frequent, the paroxysms become also longer, so, in the
advanced stage of the disease, the patient is hardly ever
tolerably free from it, except, perhaps, for two or three
months in summer.
Before the disease becomes thus inveterate, however, it
has gradually assumed other appearances, and attacked
other parts of the body. At first it commonly affects one
foot only; but afterwards every paroxysm affects both
feet, the one after the other, and then both together; and
its changes of place, as it continues to recur, are not only
from one foot to the other, but also from the feet into other
joints, as the hands, wrists, elbows, knees, &c.; so that
there is scarcely a joint in the body that is not, on one
occasion or other, affected. It sometimes feizes on two
different joints at the same time; but more commonly it is
severed in a single joint only, and passes successively from
one joint to another; so that the patient’s affliction is often
protracted for a long time. The pains, indeed, are com-
nonly less violent, in this state of the disease, than they
were at first; but, in addition to them, loss of appetite,
sicknes, and other symptoms of the atomic gout, now
affect him. Besides, in the intervals between the first
paroxysms of the disorder, the joints which had been affected
were entirely restored to their former suppleness and strength,
and were free from pain or uneasiness, and all the functions
of life were well performed. But in this protracted con-
dition of the disease, the joints remain not only weak and flabby,
after the termination of the fit, but they become at length so
contracted and disfigured, that although the patient can
stand, and perhaps walk a little, yet it is very slowly, and
with great lamens and difficulty, so that he is fearfully able
to move from room to room; and sometimes the joints
lose their motion altogether.
In many persons, though not in all, when the disease has
readily recurred, this immobility of the joints is farther
increased by the formation of concretions, of a chalky ap-
pearance, upon the outside of them, and for the most part
immediately under the skin. The secretion or deposition of
this matter is characteristic of the disease, being the conse-
quence of gouty inflammation alone. It seems to be de-
posited at first in a fluid form, but afterwards becomes dry
and firm; in which state the concretions have the appear-
ce of a friable earthy substance, and have been called
Cauliflower (which see). From the investigations of Dr.
Wollaston, however, and other modern chemists, it has been
ascertained that they contain no calcareous or earthy matter,
but consist of a neutral fluid, formed by the combination of
the lithic or uric acid, with the fixed alkali, soda,—consti-
uting a lithate or urate of soda. These concretions form pri-
cipally about the joints of the toes and fingers, in little no-
dules, which Sydenham compares to crab’s eyes; but some-
times they appear about the larger joints, as the elbow and
knee, occasioning a whitish swelling about as large as an
egg, which becomes gradually inflamed and red. Mr. Wat-
ford has described an example of a very extensive deposition
of urate of soda, in a greater man, who was a martyr to the
disease. Chalk-flours do not generally envelop the joints of
great toes, formed tumours upon his leg, and, being mixed
with the synovia of the large joints, rendered this fluid as
thick as cream; but “the joints of the fingers were puffed
and knotty, every knot being a lump of chalk,” and it was
told,” he adds, “that when he played at cards, he used
frequently to score up the game with his knuckles.” (See
Medical Communications, vol. i. p. 3.—See also Parkin-
son’s Obs. on the Nature and Cure of Gout, p. 5.)
Such is the progress of gout, as it affects the joints, and
while it may, therefore, be called regular gout. Syden-
ham, indeed, and some other writers, confine the appellation
of regular to gout in the feet only; and consider it as irregu-
lar, when it attacks the hands or other joints. But Dr. Cul-
len, Warner, and the physicians of the present day, in gen-
eral, agree in calling the disease, when it consists only of an
inflammatory affection of the joints, the regular gout; “and,”
Dr. Cullen observed, “whatever symptoms we can per-
cieve to be connected with, or to depend upon, the dispo-
fition which produces that inflammatory affection, but with-
out its taking place, or being present at the same time, we
name the irregular gout.” First Lines, § 578.
Irregular gout, anomalous, internal or atomic gout, as it
has been also called, consists of various symptoms of disor-
der in the internal organs of the body, which do not differ
from the symptoms affecting the same organs under other
circumstances; it is, therefore, inferred that these symp-
toms are of gouty origin, when they occur in persons bear-
ing the marks of a gouty diathesis or disposition; and espe-
cially when, in such habits, either a manifest tendency to
the inflammatory affection of the joints has formerly appeared,
or when the symptoms alluded to are intermixed with, and
are relieved by, some degree of the inflammatory affection.
The morbid symptoms which appear, in such cases, and are
considered as signs of atomic gout, are principally affec-
tions of the stomach; such as loss of appetite, indigestion,
and its various concomitants of sickness, nausea, vomiting,
flatulency, acid eructations, and pains in the region of the
stomach. These symptoms are frequently accompanied
with pains and cramps in the upper extremities of the body,
which are relieved by the discharge of wind from the
stomach. Together with these affections of the stomach,
collines also commonly occur; but sometimes a loose-
ness with colic pains. These affections of the alimentary
canal are often attended with all the symptoms of hypochon-
drisia; as dejection of mind, a constant and anxious atten-
tion to the slightest feelings, an imaginary aggravation of
these, and an apprehension of danger from them.” In the fame
atomic gout, the viscus of the thorax are also sometimes affect-
ed, and palpitations, faintings, and allhem occur. And the
head also is often disordered, with pains, giddiness, somno-
lessness, and even apoplectic and paralytic affections. (Cul-
len. See also Mulgrave “De Arbireide Acromas.” where
these various modifications of irregular gout are described at
length; and Warner’s “Full and Plain Account of the
Gout,” where his observations are translated, pp. 72—96,
second edit.)
We may here remark, in passing, that many errors have
probably been committed, in considering almost every spe-
cies of indisposition, that occurs in gouty habits, as arising
from
from the gouty diathesis. We remember to have heard this
point frequently infallibly upon by the able professor of physic,
in the university of Edinburgh, Dr. Gregory. Many of
the symptoms above enumerated are obviously connected with
the impaired functions of the stomach, and occur in dyspep-
sia, or indigestion, in habits not gouty; such are the various
hypochondriac sensations; the palpitations of the heart, often
arising from over-diffusion of the stomach with flatus, by
which the heart is mechanically pressed upwards; the cramps
in different parts of the body, which are often relieved by a
discharge of wind from the stomach; the difficulty of breathing,
often occasioned by great diffusion of the stomach, which
impedes the descent of the diaphragm; and the head-ache, giddines, &c. which are daily observed to be
connected with impaired digestion. On the other hand, in-
flammatory disorders of the lungs and other visceræ, con-
gelations in the head, inducing head-ache, somnolency, verti-
igo, &c., and ultimately various degrees of paralytic and apoplectick disfaee, not essentially different, in any respect,
from the same affections in habits not tainted with gout, have
probably been suffered to go on, and to prove fatal, under a
notion that they were gouty, and the proper remedies have
been therefore neglected.

The irregular gout occurs in a less equivocal form, when the
inflammatory state of the joints has come on in the usual
manner, but when, without arising to the ordinary degree,
or at all without continuing for the usual time, and receding
gradually, as is common, the pain and inflammation sudden-
y and entirely cease, while some internal part becomes dis-
ordered. This has been called the retrocedent or rejected gout.
When the gout is thus retrocedent, the same internal parts are
attacked, and the same disorders produced, as in the irregular
or atomic gout, where no previous imperfect attack upon
the joints had existed itself. The stomach is for the most
part commonly affected, whence violent pain, listlessness, vo-
miting, anxiety, &c: the heart and lungs are also occasion-
ally attacked; and sometimes the occurrence of apoplexy,
palsy, or delirium, mark the head as the seat of the retro-
cedent disfaee.

Another variety of irregular gout has been denominated
misplaced gout; namely, when, instead of the joints of the
extremities, the stomach, brain, lungs, intestines, kidneys,
or bladder, become affected with symptoms of inflammation,
which give way upon the appearance of the inflammation in
the extremities, when that takes place. This inflammation
of the internal organs, however, is indicated by the same
symptoms which accompany inflammation of the same parts,
arising under other circumstances, and in conjunctions not
gouty: and it has probably been sometimes supppered to be
of gouty origin, when it arose from the ordinary causes.

Dr. Cullen affirms, that he never met with any instances of
misplaced gout in his practice, and that no case has been dif-
tinctly made out by medical writers, except that of pulmo-
nary inflammation. But he had known two varieties of in-
ternal disfaee alternate with external gouty inflammation;
avs. the one an affection of the neck of the bladder, pro-
ducing pain, stricture, and cariesus vesicæ: the other an
affection of the rectum, sometimes marked by pain alone in
that part, and sometimes by hemorrhoidal swelling.
Such are the phenomena, by which the various forms of
regular and irregular gout are chiefly characterized. The
next object of our inquiry will be the

Causes of Gout.—Among the predisposing causes of gout,
an original peculiarity of constitution, often transmitted from
the parent to the offspring, appears to be the most common;
in other words, the disfaee is said to be hereditary. This
passion, indeed, has been controverted, especially by Dr.
Caddogan (see his Diff. on the Gout, and all Chronic Dis-
cases, p. 7;) but the disfaee has turned upon a mere dif-
pate about words. For it is admitted, on all hands, that the
predisposition of the constitution to be affected by gout is
transmitted from father to son, like other peculiarities of
habit; like the family-likeesses, for instance, in features, in
voice, complexion, &c. It is true, indeed, as Dr. Caddogan
contends, that some persons acquire this gouty disposition, who
have it not by hereditary transmission; and, on the other hand,
that the hereditary disposition may be counteracted by
various causes, but particularly by certain modes of life, so
that the disfaee itself shall never appear. Yet it is equally
tru, that the same occasional causes, which will excite the
disfaee in those who are hereditarily predisposed to it, will
not produce it in others, otherwise applied in greater force;
and, therefore, the existence of an original constitutional
predisposition must necessarily be inferred. The middle and
advanced periods of life are also more disposed to gout,
than the early periods; thus it does not commonly attack
men until after the age of thirty-five, and generally not till a
full later period. When the gout does appear, in more
early life, of which there are instances, it seems to be in
those in whom the hereditary disposition is very strong, and
to whom the exciting causes have been applied in a con-
 siderable degree. Hippocrates remarks, that eunuchs are
not liable to be affected by gout, nor boys previous to vene-
ry; but the latter remark included in the remark is probably
unfounded; since, with respect to the latter, the disfaee,
as we have already stated, is almost peculiar to an advanced
period of life; and the eunuchs, who, in the time of Hip-
ocrates, were chiefly Persian slaves, were doubtless confined
to the strict discipline and the frugal and temperate life,
which the rigorous laws enjoined to all, and therefore not
exposed to the most active causes of gout. For Galen, in
his commentary upon this observation of Hippocrates, ob-
erves that, in his time, the remark was no longer true,
"owing to too much indulgence on their part in an indolent,
as well as intemperate mode of life;" and the remark is
confirmed by modern experience. (Van Swieten, loc. cit.)
It has been fully ascertained, indeed, that the principal
source of the gouty habit consists of high feeding and in-
dolence conjoined. Sydenham (who, upon the subject of gout,
stands unrivalled in accuracy of observation, and the model
of all succeeding writers, many of whom have done little
more than copy his history of it) begins his account of the
disfaee with these remarks. "The gout generally attacks
the elder persons who have spent the greater part of
their lives in cafe and indulgence, both in the use of
high feeding and of wine, or other spirituous and fermented
liquors; and who, in conformance of the figurines of ad-
anced life, have ceased from all those exercises to which
they were accustomed in their youth. The gout, however,"
he adds, "does not always wait till an advanced age; it
sometimes attacks those who are in the prime of life. But
these persons have unfortunately received the seeds of the
disfaee from their parents; or, if not, they indulged in
precipitate and excessive venery, or left off entirely those ex-
ercises which they had previously used with great activity,
and have been besides most indulgent to the appetite, and
drank to excess of vinous and spirituous liquors, afterwards
suddenly turning to those that are thin and cold." (Syden-
ham, Tractatus de Podagra.) Thefe facts have been long
known. There is a Greek epigram literalliy signifying
"of limb-relaxing Bacchus and limb-relaxing Venus is born
a daughter, the limb-relaxing Gout." And a similar ob-
ervation is contained in the adage, "Bacchus pater, Venus
mater, et Ira obstetric Arthritis." While this fact is
confirmed,
confirmed, on the one hand, by the testimony of ages in the affirmative, it is corroborated also, on the other hand, by observation in the negative. Dr. Cullen remarks that gout seldom attacks those who are employed in bodily labour, or who live much upon vegetable aliment, or those who make no use of wine or other fermented liquors. Indeed, the gout is said to be altogether unknown where these liquors are not used, as among the common people of Turkey. Among the lower orders of people, even in this country, the disease is very rare, and still more rare in Scotland and Ireland, where animal food and strong ale and beer are less used. Van Swieten observes, that some people who, from comfortable circumstances, have been reduced to labour for their livelihood, and to exchange a luxurious table and indolence for a spare diet and activity, have left their gout. He mentions particularly the influence of a certain person, who enjoyed a rich living, and had been an old and constant sufferer from the gout; but having been taken by the pirates of Barbary, he was kept constantly at work in the galleys for the space of two years: "which had this good effect, that afterwards, when he was ransomed from captivity, having lost all his troublesome and moral fatness, he never once had a fit, though he lived several years after the event." (Van Swieten, Comment ad Aph. 1555.) Several anecdotes of a similar nature are related by the indubitable Schenckius, (Obv. Med. Rariora, lib. v. p. 657, edit. 1644.) In a word, much exercise, which will often counteract the influence of intemperance, will, when combined with temperance, counteract even the hereditary disposition to the disease.

The effect of full living and indulgence, in producing the gouty diathesis, is also manifest from the form and temperament of the persons in whom it occurs. There are especially men of robust and large bodies with large heads, and of full and corpulent habits. They have commonly also a coarser skin; and if, with the ancients, we might denote the temperaments of men by certain terms, we should say that the gout especially affails men of a choleric-fangwine temperament, and seldom affails the purely fanguine or melancholic.

Women are not very liable to the gout, probably from their less temperate mode of life, in general, than that of men: but those females whom it affails are generally of robust and full habits. It is said not to occur in them commonly till after the cessation of menstruation; which perhaps only implies that it is a disease of advanced life. For as Dr. Cullen justly remarks, "it often happens to such (the robust) long before the menstrual evacuation has ceased;" and he had found it occurring in several females, whose menstrual evacuations were more abundant than usual. (First Lines, § 494.) A fact, which we may explain, with Dr. Gregory, by observing, that those women who indulge much in vinous and fermented liquors, are more liable to menorrhagia than others.

It is obvious, then, that the experience of all ages consents in allowing intemperance and indulgence as the principal causes of that habit of body, in which the gout is liable to occur. This habit, or predisposition, seems to be sufficient, in many cases, to produce the disease itself, or at least to require the application of slight and imperceptible exciting causes to bring it forth. The disease, indeed, depends so much upon predisposition, that it is difficult to allude the occasional causes; the same agents appear to be sometimes the generators of a predisposition to it only, and at other times actually to excite the disease.

The exciting causes which often suddenly bring on a fit of the gout, in those who are predisposed to it, are, in the first place, those circumstances which induce a sudden debility, especially of the stomach. The concurrence of indigestion, and the local inflammation in gout, is one of the characteristics of the disease; and, as we have already stated, the latter is usually preceded for some time by the former. Hence whatever suddenly depresses the digestive power, is liable to induce the local and constitutional disease. Thus a paroxysm of gout has frequently been excited by an occasional excess in the use of wine or spirits; by overloading the stomach with food, or by eating such as is not easily digestible in its nature; by the copious use of vegetable seeds or aseptic matter, especially by weak aseptic wines, punch, &c.; all of which tend to debilitate the digestive organs either directly or indirectly. In the same way, excess of venery, which powerfully influences the stomach, (Van Swieten, Aph. 556, and 1555,) has often brought on a fit. This seems to have been universally understood by the ancients. We have already noticed the observation of Hippocrates, and Aetius, in recounting the general causes of gout, says, there are, "abounding diseases, frequent drunkenness, and, above all, an immediate use of venery." (Sermon xii. Cap. 6.) Sydneyham and Van Swieten add their testimony to the fact. Intemperate living, night-watching, excessive anxiety and attention to business, all of which greatly deprees the power of the body in general, and of the stomach in particular, depressing the appetite, and producing a feverish uneasiness, finding, or weight about the region of the stomach, are likewise enumerated among the accidental causes of the gouty paroxysm. The same is true with respect to the violent emotions and passions of the mind, more particularly of anger. "In obliteris arthritis" is part of the adage above quoted; and the three causes of gout, intimated on by Dr. Cadogan, are intemperance, indulgence, and vexation. The influence of violent mental emotions on the functions of the body is, indeed, very manifest, and more especially on the function of digestion; the disturbance of which, we have already observed, is exceedingly instrumental in the production of gout. "The first immediate effect of violent grief or vexation," says Dr. Cadogan, "is to take off the action of the stomach entirely. Let us suppose a man in the best health, the highest good humour and spirits, as well as good stomach, sitting down to dinner with his friends, receives suddenly some very alluring news. Instantly his appetite is gone, and he can neither eat nor swallow a morsel. Let the same thing happen after he has made a hearty cheerful meal, as suddenly the action of his stomach, the whole power of digestion is cut off totally, as if it were become paralytic, and what he has eaten lies a mellow oppressive load. Perhaps as the excess of weakness is often conunined, it may be rejected by a violent vomit, or do greater mischief: for which reason such stokes of diffords are less hurtful received upon an empty than a full stomach." &c. (Loc. cit. p. 55.) The gouty habit, indeed, is often an irritable habit; and Sydneyham observes, that a fit of gout may be called a fit of anger. (See also Van Swieten, § 1578.)

Among other exciting causes of gout, the sudden ceasing from the customary exercises or labour is commonly mentioned, and its principal effect is probably upon the function of digestion, which is so much under the influence of exercise. Indolence, in general, as contributing to induce the gouty disposition, is well understood; and the sudden cessation of activity, like all other sudden changes, is apt to produce a sudden accession of the paroxysm, in those who are predisposed to the disease. In a similar manner, a sudden change in the mode of living, the opposite to excess, namely, from high feeding to a very spare and ablemious diet, is liable to induce the paroxysm of gout. That such a sudden abstinence of the powerful stimulus of a copious supply of food and strong liquors, must necessarily induce a considerable direct
direct debility in the organs of digestion, is well understood by those who are acquainted with the laws of stimulants on the animal body. (See Debility and Excitability.) This fact, however, although sometimes added as an argument against the advantages of an abstinence regimen, in preventing the gout, affords no such legitimate inference. It is too obvious, indeed, to require an elaborate discussion, that all extremes, hitherto adopted, are liable to derange the animal economy; and that habit alone can render extreme moderation invariably beneficial, on the one hand, and enable us to bear excess with a considerable degree of impunity on the other. Another mode of debilitating the system, which sometimes brings the paroxysm of gout, is excessive evacuation of any kind; such as by hemorrhages, brisk purging, vomiting, &c.; especially as aged persons, whose constitutions are already much broken down by the disease.

Sudden vicissitudes of weather, especially when connected with moisture, as from mild to cold, or from severe cold to damp and mild weather, often excite the gout; hence, Sydenham remarked, that the most frequent occurrence of the gouty paroxysm takes place in the latter end of January, or the beginning of February. The fit may be produced either by the local application of cold and moisture to the foot, or by a general exposure to it; for such exposure, which in most people will occasion rheumatism, a catarrh, or a sore throat, will, in a gouty subject, excite a fit of the gout. In like manner, bruises or sprains of the leg or foot, or mere over-exercise of the muscles and ligaments of those parts, as in long walking, will sometimes bring on a paroxysm.

There is another alleged cause of the gout, which it would not now be necessary to mention, were it not noticed by Boerhaave, Van Swieten, and others, viz. contusion. Van Swieten considers the disease as analogous to dysentery and other maladies, which, although originating from very obvious causes, nevertheless propagate themselves afterwards by contagion. But the stories, by which this doctrine is supported, are somewhat ridiculous; such as this, that a dog lying at his master's feet during a paroxysm of the gout, suddenly ran howling and barking round the room, expressing the pain which he had caught from his master, whose throat at the same time became greatly alleviated, &c. (Swieten Com. ad § 1255.)

Of the Diggenss. — The attack of the regular gout is readily distinguishable from the only disease which resembles it, viz. acute rheumatism, if all the symptoms are taken into consideration. In the first place, gout is commonly a disease of advanced life; acute rheumatism is most frequent from the age of 18 to 30. Nor does rheumatism, like the gout, seize the feet in preference to the other joints, or remain for a considerable time in the same joint; but at the first attack it often attacks every joint of the body in succession, and sometimes continues for several months. The colour of the skin of the part affected in rheumatism, if it be changed, is only slightly red, whereas it becomes of a deep bright red in the gout. The pain in the rheumatism is not extremely acute, while the part is at rest, but becomes violent when it is moved only; which is not the case in the gout. And the symptoms of indigestion and disordered stomach, which precede the paroxysm of the gout, together with the marks of distemper just mentioned, will serve particularly to determine the nature of the paroxysm. It must be admitted, however, there are infinities of the combination of the symptoms of the two diseases, which renders it difficult to decide to which of them the individual examples belong. (Heberden, Comment. de Morb. p. 58.)

Again, the symptoms which the irregular gout presents, are extremely numerous and proteiform. appearing frequently as dyspepsia, hysteria, hypochondriasis, althma, palpitation, syncope, vertigo, apoplexy, paralysis, &c. according to the original or acquired tendency of the constitution to those diseases. Hence the discrimination between these modifications of gout, and the disease which it mimics, is occasionally very difficult.

Of the nature or proximate cause of Gout. — This is a part of the subject upon which, if we were to confine ourselves to the communication of actual and useful knowledge, we should be altogether silent, or say but a few words. The observation, indeed, will apply to many other diseases, as well as to gout; but as gout is an affection almost exclusively occurring in the higher classes of society, among the wealthy and intelligent, it has claimed a more general attention, and become the object of more general discussion. It is greatly to be lamented, however, that the most mistaken notions have prevailed, from the earliest times, in regard to the nature and extent of the malady, which we are capable of obtaining, into the operations of the animal economy, and to the means by which we can obtain efficacious of confirming themselves to the observation of the phenomena of health and disease, faithfully recording their phenomena, and arranging them according to their most obvious analogies; physicians have been busy in searching after their hidden causes; and, fancying a resemblance between the most dissimilar things, have successively called to aid the analogies of every human science, as it advanced in cultivation, to explain the phenomena of animal life. The ancient doctrines of numbers and elements, and their qualities, and the modern discoveries and suppositions of the chemical, mathematical, and mechanical philosophers, have in turn been assumed as affording the most perfect elucidation of the operations of the living body; and, as they have, of course, been in turn exploded, we need not recur to any other argument in proof of their want of foundation. By these remarks we wish only to shew the futility of reasoning on the subject of proximate causes of disease, which, as we are and must remain entirely ignorant of the proximate cause of health and life, must be equally inerustable. "Nam quae denunm causa," as Celsus justly observes, "vel secundum valetudinem præcedent, vel morbos excitat, &c. ne superficiem quidem proficillores scientiam comprehendant, sed confidentia proficuum." (De Med. Phys. lib. 1.) The inquiry respecting the proximate cause of diseases is as futile as the speculations of the Curtissians to explain the essence of gravitation, and have as little to do with the advance of true medical science, as the hypotheses of an other affifled Newton in his observations and calculations respecting the phenomena of that agent.

If these observations should not be sufficiently intelligible to the general reader, a brief enumeration of the hypotheses, which have been invented by medical writers, in order to explain the essential nature of gout, will probably be sufficient to prove the absurdity of such attempts. Most of the Greek and Roman physicians, with the exception of the methodists, considered the prevalence of a corrupted humour in the small vessels as the essential cause of gout. Hippocrates believed this humour to conffit of bile and phlegm, which flowed upon the joints. Galen followed him in supposing the defluxion upon the joints to be chiefly pithious or phlegm, or bile mixed with phlegm. Paulus Regius attributed the disease to a redundancy of blood, black bile, and phlegm. Trallian and Celsus imagined, that it arose from the blood itself being force into the joints; and Oppenhtius affirmed that the blood in gouty people was viscid, resembling...
resembling melted glass, which remaining in the joints, produced the cretaceous matter. Arctaeus, one of the most able of the Greek writers, is the only one who passes over the essential cause of the disease, a knowledge of which he assigns to the gods alone; the evident cauæs, he says, are apparent to man. Themison, Cælius Aurelianus, and the methodist sect, attributed goüt to relaxation or vitriication of the parts; hence, however, it imputed it to the one cause, and others to the opposite. The Arabians followed closely in the path of their masters, and taught that one or other of the humours was predominant, or that they were variously combined, in cases of goüt. So luminous and instructive were the doctrines of the ancients!

In the dawn of modern science, the humours were almost banished by the hypotheses of the chemists; but although we hear little more of bile, phlegm, and melancholy, or black bile, all diseæse was nevertheless attributed to a morbid or peccant matter, and fists, earth, or tartar, were deemed the immediate cause of goüt and other maladies; and Paracelsus, Van Helmont, and others, are very abusive of the ancients for promulgating so many absurd doctrines. When the mathematical and mechanical philosophers arose, they took up the hypothetical doctrines of their predecessors, and reasoned concerning the action of these supposititious humours, fists, &c, upon mechanical principles; the chemical doctrines predominated, however, over the ancient humours. Thus, to use the words of Dr. Warner, "according to Sydenham the morbid matter consists of the putrefying heat and acrimony of indigested juices: Boerhaave gives it the appellation of an acrimony or over-toughness of the liquid which waters the nervous parts: Liller makes it to be a crude and vifcid forum become ichorous and corrosive: Bennet defines it an acrimony that is invariably of the putrid, volatile alkaline nature: Quincy says that it consists of rigid particles, such as approach near to the saline, of the nature of tartar, and not much unlike that which forms itself into concretions in the urinary passages: Cheyne in one place calls it tartarous, urinous, or other fists: Ingram will have it to be a conglomeration made by a mixture of saline particles with the oil of the adipose membrane. As every one of these writers makes the gouty matter to be an acrimony taken in with our aliment, which they call either putrid, vifcid, corrosive, saline, urinous, or tartarous, fo Dr. James, whose name needs no addition, differing with them all, hath judged this acrimony to be earthly." (See Warner on the Gout, p. 91.—See also a sensible and learned disquisition on this topic, in an Historical, Critical, and Practical Treatise of the Gout, by Thomas Thomson, M.D. London, 1742.) But such hypotheses did not die with Dr. James; for in a treatise on the gout, published in 1853, we find the following statement: "The prevalent cause of gout appears to be, a peculiar saline acrimony existing in the blood, in such a proportion, as to irritate and excite to morbid action, the minute terminations of the arteries, in certain parts of the body." (See Observations on the Nature and Cure of Gout, &c. by James Parkinson, a statement, which is equally indeinite, hypothetical, and practically useless, with those that have preceded it.

On reviewing these opinions of men, who have been deservedly esteemed the ornament of their profession, some readers may express their surprize that such an extraordinary difference should be found among them; and that so much error (for at opposite opinions one half at least must be wrong) should exist in the science. But the only rational ground for wonder is, that so many men of sound understanding should have employed themselves in inquiries beyond the reach of their faculties, and should have imagined that, in framing hypothetical suppositions, they had acquired any actual knowledge, or had advanced one step in the practical improvement of their art. If a number of philosophers were engaged in investigating the nature of light and heat, and should not only execute a series of experiments upon the reflection, refraction, and divisibility of the one, and on the properties of expansion, inflammation, vaporization, &c. of bodies, which belong to the other; but should likewise think it necessary to form conjectures relative to the nature and qualities of the sun, which is the source or proximate cause of both; these conjectures, like the medical hypotheses just quoted, however they might amuse us, would add not a little to our knowledge, nor would the want of them be any diminution of our information, or of our practical powers.

The great source of these hypotheses, reflecting the existence of a morbid humour in the gouty habit, is, no doubt, the appearance of a palpable matter, of a peculiar nature, in the joints diseæsed. This chalk-like matter, however, will be found to afford no ground for such a conclusion, if the circumstances are duly examined. In the first place, the production of this morbid matter may be the effect of the disease; and that it is for is apparent from its not occurring in all cases of gout, and from its action or never accompanying the first attacks of the disease, but only appearing after repeated paroxysms. Nor have we any direct evidence, from experiment or observation, of the smallest difference in the blood or other humours of gouty people, from those of other persons. On the other hand, we know that the vesicles in particular parts acquire the power of secreting or otherwise producing new fluids, when inflammation is induced. Thus a blow in a flthy or membranous part shall occasion inflammation, and a considerable quantity of pus shall afterwards be accumulated or discharged, as in a common abscess; yet no one supposes that this pus was contained in the mafs of the circulating blood, any more than he supposes that urine and bile are contained in that mafs, and not elaborated by the kidneys and liver. The appearance of the chalky matter, or urate of soda, in the parts attacked by gouty inflammation, is therefore to be considered as the result of that inflammation, and not as its cause. If the general mafs of blood were contaminated with this morbid matter, or any peculiar acrimony tending to produce it, why is it never deposited on the vessels and other internal parts? yet no such deposition was ever observed; those parts remain invariably free from it in the most acute forms of the gout, and the appearance of chalk-dust is confined exclusively to the membranous and ligamentous parts which exhibit inflammation externally. In the next place, the frequent and sudden translation of the diseæses from one part to another is not consistent with the supposition of its dependence on the presence of a morbid matter; but analogous changes or manifestations of other inflammations, in which no peculiar matter is produced, are exceedingly common. Besides, up in the supposition of such a translation of morbid matter, its operation should be similar on every part; whereas it seems to be very different, being insulant and exciting inflammation in the joints, but sedative and destroying the tone or energy of the stomach. Further, as Dr. Cullen judiciously observes, "the supposition of a morbid matter is quite superfluous; for it explains nothing, without supposing that matter to produce a change in the state of the moving powers; and a change in the state of the moving powers, produced by other causes, explains every circumstance, without the supposition of a morbid matter; and to this purpose it may be observed, that many of the causes exciting goüt do not operate upon the state
of the fluids, but directly and solely upon that of the moving powers." Dr. Cullen likewise remarks, that the supposition of a morbid humour being the cause of gout has been hitherto useless, since it has not suggested any successful method of cure; but, on the contrary, that particular suppositions have often corrupted the practice, and have frequently led from those views, which might be useful, and from that practice which experience had approved. (First Lines, pt. 530.)

Having failed to explain the phenomena of the disease, on the supposition of a morbid condition of the fluids of the body; we might take up the doctrine of the nervous philosophers, and attempt an explanation of the symptoms, upon the notion of a derangement of the living fluid, or moving fibre, as Dr. Cullen has done. (Loc. cit. §. 735—6.) But it is sufficient to persuade the account given by that celebrated physician, to be convinced that it is a mere repetition of the phenomena of the different varieties of the disease, couched in a new phræalogie; and therefore that it is practically as useless as that which he contovers. It cannot be questioned, we apprehend, in the present state of our physiological knowledge, that the prime agents in the operations of the living body, whether in health or disease, are the solid, irritable, and moving parts; and that by these the fluids or humours are chiefly elaborated and modified: but it is likewise obvious, that the solids derive their powers from certain conditions of the circulating fluids, which are varied by respiration, nutrition, &c. Therefore the disputes between those, who confine the origin of gout to the one or other part of the fibres exclusively, must be deemed frivolous. Our knowledge is necessarily limited to the phenomena of the disease, and the order in which they occur, and to the effects of physical agents upon them, as taught us by observation and experiment. *Nulla tamen adhuc obscurior quæstio clt.* says Dr. Heberden, *quam que veratür de hujus morbi causis, effectibusque, et remediosis.* (Comment. de Morb. Cap. 9.) But we cannot doubt that these numerous hypotheses, which have at once diverted the minds of physicians from the labour of observation, and have perverted their views of facts, have rendered the subject more obscure than it would otherwise probably have been.

Before we come to the method of treatment, there is another question to be noticed, upon which much confusion has taken place, and which has perhaps been popularly solved with considerable incorrectness: we mean the question, whether regular fits of the gout are fatal; i.e. whether they altogether remove or prevent other complaints. The affirmative is generally maintained; and this opinion has arisen partly from observation, and partly from the hypothesis, that a paroxysm of gout consists in an effort of the constitution, by which the morbid matter is thrown off through the part affected. In a number of infinances, beyond a doubt, the various symptoms of indigestion, whether affecting the stomach and bowels only, or the lungs and heart by vicinage, and the head by sympathy, are relieved or altogether carried off by the complete fit. Perhaps Dr. Heberden is fearfully correct, when he considers this relief as either, in a great measure imaginary, like that which many invalids invariably obtain from a change of their physician, or from a new medicine; or as not more frequent than similar relief from flight indiposition after other violent diseases; he appeals, however, to an ample experience in support of his opinion. He thus writes: (we tranflate from the Latin edition) *There are some countries in which the itch is a very frequent disease, and there this eruption is deemed fatal. Even an ague was formerly considered by the majority of physicians as a wholesome affection, and is still so considered by some persons; its occurrence was therefore a subject of congratulation both with the patients and their friends, and every precaution was taken not to get rid of it too soon. But these notions are almost exploded in this country; and if we shall discover a remedy equally effectual for the gout, as those with which we cure the diseases just mentioned, we shall at length learn with what perfect safety and advantage the gout may likewise be eradicated.*—*1 confes,* he adds, *that I have seen some persons who rejoiced on the first attack of the gout, as if it afforded to them all future happiness, and who, dreaming only of the most perfect health to come, easily persuaded themselves that this first fit had been wonderfully beneficial. This is a common disposition with mankind, as often as they have recourse to new physicians, or to remedies not before tried. But, passing by such persons, let us inquire the opinion of those, who have suffered under long and frequent paroxysms, and who are better acquainted with the disease. Of a very great number of patients whom I have seen, and whose cases I have committed to writing, more than twice as many, to say the least, have found no relief whatever from their previous complaints, in consequence of the regular fit, or have even suffered an increase of them, as have seemed to derive any benefit; and, in my opinion, the evils which were attributed to the diseasc, more certainly originated from that care, than the supposed advantages. Occasionally, indeed, we find that other complaints have ceased on the suppression of the gout; but the same thing also happens after acute fevers, after pally, althma, small-pox, and infancy, of all which I have witnessed many examples; yet no one will call those diseases fatal. On the other hand, gout frequently occurs to persons afflicted with vertigo, althma, indigention, and melancholy, where, so far from alleviating these disorders, it produces a considerable aggravation of their symptoms. Besides, in some patients, all these complaints concomitantly accompany the paroxysm of gout, and continue during the whole of its course.* (Loc. cit. p. 36.)

At all events, if we look at the life of the gouty in general, we find ultimately but little ground for congratulation. In some, it is true, the disease occurs at distant intervals, and soon goes off, and therefore occasions very little, if any, obvious injury. Even epilepsy itself, when its attacks are rare, does not prevent the patient from reaching old age. But this is far from being the case frequently with either disease. In many persons whom the gout attacks, the health suffers from the time of the first fit, and gradually grows worse, until it is greatly broken, or fails altogether. It may possibly be doubted, in such cases, whether the gout caused these evils; but we are very certain that it has not been the remedy for them, nor in any way fatal. We may judiciously wonder, therefore, with Dr. Heberden, how it has come to pass, that the gout is held in so much honour in England, unless it be that it is a disease, which several great men have suffered, and which chiefly attacks those happy perfomances who enjoy leisure and affluence, and all the good things of life. Louis XIV. of France happened to labour under a fitulna in the anus, and the surgeons of that time were constantly called in by his fashionable subjects to administer relief to imaginary fulneas; which royal disease they persuaded themselves had attacked them: and it is probable, as Dr. Heberden lugggests, that had there existed any medicated waters in France, capable of producing fulnea, they would have been visited with the fame anxiety with which our countrymen haffen to those of Bath, in the hope of returning with the gout.
GOUT.

Of the Cure.—Perhaps this may be deemed an improper term for the treatment of a disease, which, on the one hand, has been affirmed to be incurable by medicine, and called the opprobrium of physicians; and, on the other, has been considered so salutary, that it ought not to be cured, and could not be cured without the most imminent danger to the patient. Nay, further, as much trouble has been taken to produce and excite the gout, as to relieve or cure it; and all the evils which arthritis suffers, are not supposed to arise from a superabundance of gout, but because they have not had enough. It would be only justice, however, as the intelligent writer just quoted remarks, to the art of phyic, no longer to call the disease its opprobrium, until the patients lay aside its prejudices and fears, and have a disposition to be cured. “Utinam,” he adds, “tan in promptu ellet in venire, quum tatum adhibebere, podagre remedium.” (Comment. p. 43.)

The treatment, it is obvious, must be necessarvly very different according to the different forms of the disease, the different periods of life, and the state of strength of the patient, &c. We shall first speak of the practice necessary to be pursued in the regular gout; which will resolve itself into the treatment requisite during the fit, and which is proper during the interval.

Treatment of the Regular Fit.—All active measures, during the occurrence of a regular paroxysm of gout, have been prescribed by writers in general since the days of Sydenham. This physician remarked, that the more violent the pain and inflammation, the shorter in general will be the fit, the recovery most perfect, and the interval between this and the succeeding paroxysm the longer. If this opinion were admitted as just, it would suggest the prohibition of any remedies which might moderate the inflammation. But against this doctrine another hypothesis has been advanced by Dr. Cullen, which is at least equally plausible, and better supported by analogy, if not by fact: namely, that the violence of the inflammation may weaken the tone of the parts, and while it renders them liable to similar violent attacks, and the consequent more perfect recovery, may, by that very debility, invite a return of the disease. On the whole, the indications of practice generally pursued at present, are to moderate the violence of the inflammation, and febrile action, when it is severe, without applying any active remedies to the foot itself. After enumerating the various external applications, such as poultices, fomentations, blisters, liniments, and illuminating substances, which have been occasionally recommended, Dr. Cullen concludes, that from any of them there is danger of rendering the gout retrocessed; and that therefore the common practice of committing the person to patience and flannel alone, is established upon the bell foundation.” As there is no danger from the fit of gout, when regular, in a constitution not much broken, this method may be pursued with a certain degree of impunity; but it cannot be questioned, that the loads of flannel, which are sometimes used, often augment the necessity for a supply of patience, by increasing the inflammation and pain in the foot. It is true, that the parts thus swollen and painful, are more acutely sensible to cold, as well as to other impositions, than in health; but no covering beyond what is sufficient to prevent a troublesome sensation of cold, if that should occur, can be necessary. (Hepburn.) All poultices, fomentations, and warm bathing during the inflammatory stage are pernicious.

It is more than probable, that considerable errors have been committed, upon the hypothetical notion of keeping the gout in the extremities, at least in the younger subjects of gout, by deviations from the antiphlogistic regimen. In such subjects vinous and fermented liquors should be altogether abstained from during the fit; and the diet should consist of light aqueous and vegetable matters, or that animal matter, the bowel should be kept open by laxatives administered, and the skin moist by diaphoretics of the neutral sort. This is at least a palliative system, and the prejudices of men in general are averse to any more active interference with the disease.

But in cases the inflammation is extremely violent, in young and healthy men, Sydenham, Cullen, Huxham, and other able authors, concur in recommending the employment of blood-letting from the arm. This, however, they do not recommend to be often repeated, or in any case, it may prove dangerous. Local blood-letting, by means of lancets, applied to the foot itself, promises more advantage, and experience itself has proved the efficacy and safety of the practice. (See Cullen, Firil Lines, par. 563 — Muigrafe de Archite, regulari, cap. 8. § 4.) Cupping and scarifying the neighbouring parts have also been found beneficial. (Muigrafe.)

We are persuaded that this hypothesis has had much more influence than observation and experience, in exciting the general fears about interfering with the progress of the gout, inflammation, and of the danger of its being driven to some interval by such interference. When it was believed, that a quantity of morbid matter exsulted in the inflamed part, it was inferred, of course, that it could only be removed by expulsion or by purgation, in which last case it must fall upon some other organ. We know very well, that the same hypothesis, and the same fears prevailed no long time ago with respect to cooling the skin in fevers, and especially in eruptive fevers, such as scarlet fever and small-pox. The hemorrhage will be checked,” said the theorist, “if you allow the skin to be cooled, and the putrid matter must therefore be blown back upon the bowels, or the lungs, or the brain, and the effect may be fatal.” But ample, and unvarying experience has now demonstrated, not only that such danger was altogether imaginary, but that washing the skin with cold water, even under the full eruption of fevers, and in the eruptive fever of small-pox, affords the most grateful relief to the patient, and is the most effectual moderator of his disease. (See Comm. effects of a removal.) Nor is a considerable experience of the safety and efficacy of a similar practice, in fulminating the inflammation of gout, wanting. The great Dr. Harvey himself, whose name is immortalised by the discovery of the circulation of the blood, was in the habit of immersing his foot in cold water, as soon as he perceived the approach of the gout, and thus removed the disorder: he lived to the age of eighty. Van Swieten mentions an officer of infantry, who was induced to rub his gouty feet with snow, and afterwards, emboldened by success, walked a little way barefoot upon the snow, and returned quite free from pain: the interval before another fit was also lengthened by this practice. Similar observations were likewise made by the ancients. Aetius informs us, that he had seen a patient labouring under what he called a bilious gout, “who obtained extraordinary relief from immersing and keeping his feet some time in cold water.” And it is an aphorism of Hippocrates, that “cold water, copiously poured upon swellings of the joints, painful ulcers, gouty diarrhoea, and convulsed limbs, keels and removes the pain.” (Aph. 25. sec. 5.—See also Hepburn Comment, p. 43. — Van Swieten, Com. ad Aph. 1273.) But the most extensive evidence...
of the efficacy of this practice, in curing the paroxysm of
gout, has been adduced by Dr. Kinglake, (see a Dittera-
tion on Gout, &c. Lond. 1804.) who brought forward about
thirty cases, in which the application of cold water to the
inflamed part, during the gouty paroxysm, was invariably
and speedily successful in relieving the pain and removing the
disease, without any untoward circumstance ensuing. Dr.
Kinglake maintains, that the inflammation of gout is to be
treated upon the same principles as other local inflammations,
and yields to the same treatment. That this proposition is
correct, while the constitution remains unbroken, we fully
believe; but to what extent the principle will hold, in those
whofe fevem is greatly debilitated and decayed, as well by
age as by frequent and protracted disease, remains as yet
undetermined by experience. With the diminished strength of
the patient, the paroxysms become diminished in intensity,
and active remedies are, therefore, the less required; but
from what we have detailed above, it appears at feaft highly
probable that, in the reftr attacks of gout, the application of
cold, judiciously employed, fo as to remove the morbid
heat and no longer, would always be safe, and would con-
tribute as well to shorten the paroxysm, as to diminish the
fevering of the patient, and to prevent the junctions from
the injury, which protracted inflammation and morbid effusions
necedarily occasion.

The operation of purgatives, which is known to be effen-
tially useful in other inflammations, has been confidered as
beneficial in the gout by fome physicians, but has more
commonly been altogether forbidden. Sydenham expresses
himself very strongly in prohibition of purging, at any
period of the fit, or even in the interval of health. Had
he expressed his conviction upon this point simply as the re-
ftult of experience, we should have been disposed to bow to
his authority; but his theory appears to have had at
leat an equal share in producing this conviction; and
unfortunately this theory involves the most gross contradic-
tion. In the beginning of the paroxysm, we are told that there
is great danger left purgatives should inflame the inflammation
of the foot, "by throwing back into the mafs of blood that
pecant matter, which nature was protruding to the extreme
parts." (Tract. de Podagra.) But after the termination of
the fit, there is extreme danger, "left a new paroxysm in
the foot, equally severe with the former, should be
produced by a purgative." (Ibid.) So that this theory
blows hot and cold, like the fayir in the fable; and
defere dangerous purgatives draw the pecant matter out of the foot,
when it happens to be in, and are the most effeclual means
of throwing it into the foot after it has been driven out not
only from the foot, but from the whole body (according to
the hypothesis) by nature!

Sydenham, however, lived long enough to retract, in part,
his opinion respecting the injurious influence of purgatives in
the gout, especially if the milder ones are used, and an
anaodyne given after the operation. (Differt. de Micta San-
guinico, &c. 1686.) Van Swieten observes, "many phy-
cicians are of opinion, that part of the gouty matter may
be carried off by purgatives, and the fit rendered much
more mild, especially if it be occasioned from errors in
diet," and he quotes Hoffmann, who recommends gentle
purgatives in all cases of local pain, and has mentioned an
influence in his own person of the most striking benefit deriv-
ed from a purgative taken immediately before the fit of
gout. An influence has been related to us, in which the
gout was completely banished, during a space of nearly
twenty years, by the use of a brisk purgative, taken when
the initial symptoms of the fit began to appear; the medicine
employed in this influence consisted principally of feverfew,
in the dose of about fifteen grains. We have been
this medicine used in a few cases, with some relief, in smaller
doses, and without any untoward consequences. That pur-
gatives, as well as cold applications, may be referred to
with advantage in the beginning of the paroxysm of gout
wherever the constitution is unimpaired, we confider as te-
lerably well established on the grounds of observation; al-
though we do not doubt that many of the cases of repeated
gout, which have been attributed to such caufes, may have
really occurred, under circumstances of broken and foible
constitution, or of peculiar idioftarcy. But the accidents
arising from a careless or injudicious abuse of any practice,
afford no just argument against the rational and cautious use
of it.

We apprehend, however, that many disorders have been
very erroneously attributed to repulition of the gout, which
might be more correctly explained upon other grounds.
For every inflammatory disease that occurred, even at the
distance of several months from the effusion of the fit, has
been confidered as the refult of the premature cure of the
gout; whereas, it is next to impossible that fo long an inter-
val could have taken place between the eame and its effect;
and, on the other hand, as gout is most frequent in pletioric
habits, which are also most liable to inflammatory dif-
ces, the occurrence of pleurisy or apoplexy, in fuch caufes,
is doubtlefs to be attributed to the pletorina, and not to
the previous gout. Dr. Cullen mentioned that he had
known about twenty persons die suddenly, more than half
of whom were of gouty habits.

The violence of the pain, in the paroxysm of gout,
would naturally suggest the ufe of opiates: but experience
has shown that opium, in any form, when administered in
the beginning of any inflammatory disease, with which
much heat of skin and great febile excitement are connected,
generally fails to give relief; on the contrary, that it tends
to increafe the heat, fever, and refleffines, and, with them,
the pain likewise. When, however, the violence of the
paroxysm is somewhat abated, yet continues to return, fo
as to occasion painful and reflieffed nights, opiates may then
be given with safety and with advantage, efirecially in the
case of persons advanced in life, and who have been often
affected with the disease. The hypothetical objection to the
ufe of opiates, that they tend "to lock up the morbid
matter," is altogether groundlefs. Dr. Warner speaks with
delight of the soothing influence of opium in the fits of
gout, which he suffered in the latter periods of his life.

(P. 133-156.)

Hitherto we have seen that the practice, generally pur-
fiued in the paroxysm of gout, is merely palliative; an actual
cure being deemed a deludement by most perfons, and a
thing improper to be attempted by others. Of late, howev-
er, a medicine has been introduced into this country from
France, which is made to possefs a specific power over the
gouty paroxysm, which it removes "cito, tut si, et jucundum."" The
composition of this medicine is at present unknown,
but it has been aecertained that it is a vegetable matter, and
it is sold by the inventor to be a plant heretofore not ufed in
medicine. It is called eau medicinale d Haffen. It
has appeared, in many infances in which it has been employed in
this country, and that in perons of the high rank and char-
acter, to possefs the power of removing the paroxysm of
gout in the course of twenty-four hours, leaving the patient
in a state of good health, and in possession of the fame
tue of his limbs which he enjoyed before the fit. It is said
that, in general, it increases the various exercitions considerably,
if taken in the full dose, producing several loose motions
from the bowels, a free perspiration, and an increased di-

charge
charge of urins. But the influence of the medicine on the gouty paroxysms is not attributed to these evacuations; since, in some instances, in which a smaller dose was taken, a similar relief to the gout was procured, without any increase of the evacuations. No untoward circumstance whatever has yet occurred, in consequence of the speedy removal of the paroxysm; but farther experience will be requisite to enable us to form a satisfactory estimate of its properties. (See G. Jones. M. D. Loud. 1810.)

Treatment in the Interval.—Whatever method is adopted in the treatment of the fit of gout, whether it be merely palliative, or so active as to shorten the attack, the constitution retains its predisposition, and is equally liable to suffer a return of the disease. It is not yet ascertained, we believe, whether the fits, when warded off by the cure medica, do not recur more frequently. It is the treatment of the patient in the interval of health, by which alone the disease can be cured, i.e. the paroxysms prevented from returning, and the gouty diathesis eradicated. How this is to be effected, we cannot learn from a view of the proximate causes, or partial nature of the disease; for upon this point we have no actual knowledge: but, as we possess some knowledge of the exciting causes of the disease, or of the circumstances which generate or foster the predisposition to its attacks; so, by removing these, we may hope to prevent the production of that predisposition, or to diminish it, if not to remove it altogether. Now, we have seen that temperance and indolence are the parents of the gouty diathesis, where it is not hereditary, and are the chief agents in exciting it to activity, where it is. The inference, then, is obvious: by temperance and activity, not by medicine, the return of the gouty paroxysms is principally to be prevented.

There is, perhaps, no subject, on which Englishmen in general entertain so many unfounded prejudices, or listen to argument with so little attention or conviction, as that of temperance. It is conceived that physicians, in inculcating the advantages of it, only talk idly about it, in the way of their profession; and that what is called good living, when not carried to actual debauch, is favourable to the support and health of the body. It is, indeed, so universally the practice, in this country, to indulge an artificial appetite, beyond the actual wants of nature, that temperance is a thing, as Dr. Cadogan observes, of which an Englishman can acquire no idea at home. It is, however, altogether comparative with respect to individual constitution; for some persons will become phlegoric to a morbid degree, upon diet which is barely sufficient to support life in others. Perhaps Dr. Cadogan's toot is correct. "As long as a man eats and drinks no more than his stomach calls for," (i.e. when unexcited by variety of dishes, by fancies and condiments, or by interposing liquor of any kind) "and will bear without the least pain, dilution, excitation, or uneasiness of any kind, &c. he may be said to live in a very prudent well-regulated state of temperance, that will probably prefer him in health and spirits to great old age."

(On the Gout, p. 31.)

We know too well, however, the general want of power or inclination to relish the pleasures of the table, with that degree of perseverance and to the requisite extent, to expect that many cures of the gout will be effected in this way; but this we may assert, that the only influences of the eradication of the disease, which are known, have been accomplished by rigid and persevering temperance. Dr. James Gregory, the present professor of medicine in the university of Edinburgh, is a remarkable example of the perfect cure of the gout by such means. Born of gouty parents, he was attacked severely when young, and suffered several paroxysms, which, after being banished by abstemious living, recurred on a short indulgence on revisiting Oxford; but he has since that time entirely kept the foe at a distance for about thirty years, by extreme temperance and much exercise, and is now hale and strong, though advanced several years beyond the age at which his father died, broken down by the gout. This he repeats annually to his pupils with no small exultation. His diet has been chiefly broth, or a sparing quantity of plain animal food, with little or no wine. Dr. Cadogan affords another instance of the benefit of rigid temperance in his own person, "having not only got rid of the gout," he says, "of which I had four severe fits in my younger days, but also emerged from the lowest ebbs of life, that a man could possibly be reduced to by colic, jaundice, and a complication of complaints, and recovered to perfect health, which I have now uninterruptedly enjoyed above ten years." (Lec. cit. p. 83.) Dr. Heberden likewise observes, that although complete cures of the gout are extremely rare, yet he has seen more than one instance in which, by a total abstinence from animal food and wine, the patients were restored from a state of extreme debility and misery, to such a degree of health and strength, as rendered their life no longer unprofitable to others, nor painful to themselves. Comm. p. 44.

It can scarcely be doubted, indeed, that a complete cure of the disease might, by a rigid plan of life, be accomplished in most cases, when the patients are not above the age of 30 or 35 years, even if they should already have experienced two or three paroxysms. In older habits, where the disease is of longer standing, a complete cure cannot be so confidently anticipated; but experience has shown that the severity and the consequent evils of the disease may be effectually mitigated by temperance, even under such circumstances. It is a most dangerous and mistaken notion that the gout is to be encouraged; for its tendency is to increase in frequency, and in duration, to cripple the limbs, and to render the body liable to a variety of disorders, which tend to render life both shorter and more miserable than it would otherwise be.

The fear of the pernicious consequences of rigid temperance is an unfounded prejudice, very prevalent in this country; but if there be any danger, it can only originate in general from the fulness with which an extreme change is made. We have seen, in the case of the miller of Hereford, however, what a small quantity of nutriment absolutely requisite for the wants of the constitution, and how beneficial even an extreme change of diet sometimes proves. (See Convulsion.)

The next point of management in the interval, which, together with temperance, conduces to the prevention of the recurrence of gout, is exercise. This tends to obviate palsy, on the one hand, by promoting the circulation and all the secretions, and to strengthen the body, on the other hand, and promote the function of digestion; and plethoric and indigestion, as we have already stated, commonly preclude the gouty paroxysm, and are connected with the gouty diathesis. By those who cannot walk, which is the best mode of exercise for the gouty, riding on horseback, or even in a carriage, should be substituted. Even fencing, where these modes of exercise cannot be resorted to, may be an useful succedaneum. Dr. Cadogan's directions on this head are worthy of attention. If the patient "can neither walk nor ride at all, he must by degrees be brought to do both."
both by the assiduous of others, which may be given him in the following manner: let a handy active servant or two be employed to rub him all over, as he lies in bed, with flannels, or flannel gloves, fumigated with gums and spices, which will contribute greatly to brace and strengthen his nerves and fibres, and move his blood without any fatigue to himself. This may take up from five to ten minutes at first, but must be repeated five or six times a day, supposing him totally unable to help himself. But if he can walk a hundred yards only, it will forward him greatly to walk that hundred yards every two hours; and if he can bear a carriage, let him go out in it every day, till he begins to be tired. The first day or two this may disturb and fatigue him a little; but if he has patience to persevere to the fourth, I dare promise him some amendment and increase of strength; which he must employ, as young merchants do a little money, to get a little more. Thus he must go on rubbing, walking, and riding a little more and more every day, supposing always on the first fumination of weariness to rest a little, till he be able to walk two or three miles at a stretch, or ride ten without any weariness at all.

He must ever remember, however, that the habit of body is only to be corrected by habitual maturations; and perseverance, therefore, must be his motto in regard to exercise, not less than with respect to temperance. But it must be observed, in general, that the exercise should not be violent; for if violent, it cannot be long continued, and must always endanger the production of atony and debility in proportion to the degree of violence. "It must be moderate," to use the words of Dr. Cullen, "but at the same time constant, and continued through life."

It has been fupposed by some persons, that an ablemious and active mode of life for a limited time, as for instance, an abstinence from animal food and fermented liquors, and a diet of milk and farinaceous matters alone, for the space of one year, might be sufficient for a radical cure of the gout. Such an opinion was expressed by Cullen, who says that "some, by cleaning themselves thoroughly by drinking aies' milk, have for ever banished the disease; and others, by abstaining, during a whole year, from wine, mufle, and veal, have obtained a security for it from the remainder of their lives." (De Medicea, lib. iv. cap. 22.) In a few cafes, this plan may possibly have succeeded; but it is well known that many persons, who, by entering on an ablemious course, had been delivered from the gout, have, on returning to their former mode of living, had the disease return with at least equal violence.

While an ablemious regimen, combined with exercise, will tend to correct the gouty habit, if steadily pursued; it will be at the same time advisable to avoid as much as possible some of those circumstances, which we have mentioned above as among the frequent exciting causes of the disease; more especially when the gouty habit has become established by a repetition of the fits, or is hereditary in its origin. In such cases, the maturations, which we have proposed, are not easily pursued to the requisite extent, and are commonly attempted even with reluctance; men, therefore, have been very disinclined to find a medicine which might answer the purpose, without requiring a restraint on their manner of living. Of this desire numerous empires and self-interested pretenders have taken advantage, and have been induced either to mock the gouty with inert medicines, or have falsely employed those of the most pernicious tendency. It is unnecessary for us to inquire into the nature of those alleged poisons, which, after being for some time in vogue, were neglected or exploded, as their injurious or injurious qualities were thus acknowledged. But after pronouncing that we are much disposed, with Dr. Cullen and others, to believe the impossibility of curing the gouty habit by medicines, we shall notice one or two known medicines, which have been in vogue no long time ago. If the gouty constitution is created by a series of high-feeding and indolence, how is it to be expected that medicine can change that constitution, especially while the cause continues to operate?

The Portland powder is a medicine which obtained considerable reputation, as a cure for the gout, about the middle of the last century. This powder derived its name from the duke of Portland, who received much relief from it, that he ordered the formula to be printed, and delivered to all who should ask for it. It was brought from Switzerland by a friend of the duke's. The powder consists of the roots of arnica montana and gentian, and of the tops and leaves of germander, ground-pine, and centuary, well dried and powdered, equal weights. This powder was ordered to be taken for a year or two, at first in the dose of a dram daily, but afterwards in smaller quantities. (See Medical Off. and Inquir. vol. i. art. 14.) In the work just referred to, Dr. Chalmers has shown that a similar competition was used by the ancients for the same disorder. Such a formula is given by Galen, in his treatise De Antidotis, lib. ii. cap. 17., which he says he had used himself. Chalmers Aurelianus speaks of similar medicines, under the denomination of anemia medicamenta, from their being taken for the space of a year. Allius gives, among other gouty medicines, an "antidotus podagricus et duobus centuriae generibus," which differs from the Portland powder in one ingredient only. But several of the ancients considered the long uninterrupted use of these medicines as dangerous; and affirms that they are extremely hurtful in the hot and bilious, and are only proper in cold and phlegmatic constitutions. The Portland powder has fallen into neglect, under a notion that it was ultimately prejudicial. "In every instance," says Dr. Cullen, "which I have known of its exhibition for the length of time prescribed, the persons who had taken it were indeed afterwards free from any inflammatory affection of the joints: but they were affected with many symptoms of the atomic gout; and all, soon after finishing their course of medicine, have been attacked with apoplexy, asthma, or dropsy, which proved fatal." (Firth Lines, par. 557.) Dr. Hibernian, however, is of opinion, that the popular prejudices against this medicine at present are as far beyond the truth, as they formerly were in its favour. (Comment. p. 48.) He attributed to it considerable powers of alleviating the disease, by strengthening the remach and supporting the function of digestion; and believes that many of the evils (which, because they followed its exhibition, were imputed to its operation) were in reality the consequences of the disease, and not of the remedy. That those cafes, however, of apoplexy, &c., which, it is admitted, occur in gouty habits, would be probably accelerated, if not occasioned, by the use of a remunctive powder, while the full diet was continued, appears to be extremely probable: for the plethoric must have been increased in proportion to the artificial increase of the digestive powers. We should, therefore, be disposed to conclude, that the confiant use of such a medicine must be pernicious, unless it was combined with temperance in eating and drinking; and that, with such a regimen, it would in all probability be highly beneficial, if taken whenever the symptoms of indigestion should appear.

Another class of remedies has been employed in the intervals between the paroxysms of gout, and in many instances with considerable alleviation to the disease, rendering the
GOUT.

the fifth milder, and the intervals between them longer: we allude to the urate of ammonia; such as the alkalis, and absorbent earths. The nature of the chalky matter, produced in invertebrate gout, which is an acid, and denominated lithic or uric acid, (being the same which is found in the urine and urinatory concretions,) has led to the theory, that this acid, or its elements, is the morbid humour of the gouty; and therefore naturally suggested the idea of using alkaline medicines as remedies for the disease. And as secoent drinks are found to increase the gouty diathesis, and to increase the disordered state of the digestive organs; alkaline medicines have been found to relieve the symptoms of indigestion, and at the same time to lessen the disposition to gout. Thus the caustic alkalis have been found beneficial; but not more so, we believe, than the mild or carbonated alkalis, especially potash; and the absorbent or alkaline earths have likewise afforded relief, and sometimes speedily removed some of the urgent symptoms of disordered stomach; especially the preparations of chalk, lime-water, and magnesia. Magnesia is perhaps one of the best medicines of this sort for the gouty, as it not only corrects the acidity of the stomach, but at the same time is laxative to the bowels, and thus contributes to obviate phlethora. When these acetids do not sufficiently open the bowels, or do not prevent colic, a little rhubarb, aloes, or some other aromatic purgative should be conjoined with them. It appears, from some experiments made by Mr. Home and Mr. Brando, and recently published in the Philosophical Transactions, (Part I. for 1810) that magnesia has a much more powerful influence in preventing the formation of the uric acid, in the urine, than any of the alkalis; it is probable, therefore, that it may be more beneficial in the gout. As a warm laxative the tincture of gum Arabic was much recommended, and as it combines a stimulant with an evacuant property, it may be serviceable in some constitutions.

Cure of the irritable Gout.—We have already remarked, that false theory has led to much false alarm, and doubled as to many mistakes in practice, especially relative to the atomic gout; all the various symptoms of dyspepsia, and hypo-chloridrias being often supposd to be gouty, when no natural gout had ever appeared. Hence fomentations, blisters, rubefacients, and other local stimulants to the extremities, the Bath waters, hot pediluvia, &c. have been employed to bring on the gout in the feet, instead of relying on the remedies which might restore the functions of the digestive organs. The Bath waters are certainly to be recommended in those cases, as they are powerful as considerables powers in restoring the healthful condition of the stomach, especially when it has been disordered by irregular and intertemperate living; and of relieving those wandering pains, which are deemed gouty, but which, as Dr. Heberden observes, are the common accompaniments of declining years and a broken constitution.

In these cases of atomic or wandering gout, as it is called, all the means usually employed to strengthen the habit in general, and the stomach in particular, are to be resorted to. Moderate, but frequent and regular exercise on horseback, or walking, must be pursued; the diet should be a little more generous, and some wine may be necessary; but both food and drink of the acceent kind must be shunned, and if wine, of whatever sort, should be found to increase the acidity of the stomach, spirits much diluted with water should be substituted. At the same time, for the purpose of supporting the tone of the stomach, preparations of iron, the Peruvian bark, blisters, and aromatics in moderation may be resorted to; and laxatives, employed only so as to prevent consticence, must be taken. The propriety of frequent gentle vomiting, which the indigestion is troublesome, is more than problematical; for, while they give a temporary relief, by removing a load of undigested food, they tend to delabiate the organ, and thus to increase the evil which they were intended to remove. At the same time, all the caufes of debility formerly mentioned, must be shunned, and exposure to cold especially must be carefully avoided: the most certain means of doing this is by repairing to a warm climate during the winter season.

Cure of misplaced or retrocedent Gout.—These, like the atomic gout, are in a considerable degree the humours of medical speculation, more especially the misplacd gout; they do, we believe, occasionally occur in cases of old and inactive gout, but certainly much more rarely, than is generally believed. This opinion Dr. Heberden flates from his own experience—(Comment. p. 41.—See also "Letters on the Cause and Treatment of Gout," by Dr. Robert Hamilton, Lynn, 1829.) The last mentioned physician, who had employed bleeding and other antiphlogistic remedies, both upon himself and several of his friends for eighteen years, never saw any thing like a retrocedent gout; and Dr. Cullen now saw an instance of misplaced gout.

When the gout has disappeared in the extremities, the stomach and bowels are sometimes attacked with most acute pain, which is of a phlogistic nature, and to be relieved only by strong diaphoretic stimulants, and opium in full doses. Opiates are doubtless the most effectual antiphlogistics; but their operation will be aided by combining with them the others, volatile alkali, the free use of strong wines, and aromatics, given warm, or ardent spirits, if these are not effectual. Camphor, masts, affaifattias, and other strong fueling substances, may be employed as adjuvants, especially in violent cases. External heat to the region of the stomach, hot pediluvia, or the warm bath, will contribute by their stimulant powers to overcome the pains and pain. If the stomach is known to be loaded, as by a previous repast, its contents may be evacuated upwards, by draughts of warm water, with wine, or of chamomile tea, or downwards by means of some of the cathartic tinctures, or opium, or rhubarb.

As these persons, who are subject to paroxysms of the gout, are generally phlegmics in their habit, so they are liable to inflammatory diseases, and it cannot be doubted, that ordinary attacks of inflammation of the head, of belly, and apoplexy, have been deemed gouty, and have proved fatal from the omission of blood-letting. When the symptoms are pleurisy, or peripneumonic, or the acuate pain of head, vertigo, faintness, threatening apoplexy, or the actual symptoms of apoplexy and palsy occur; we ought not to delay the exhibition of the usal remedies for those diseases, or be inclined to sparing in the use of the lancet, because we apprehend a gouty diathesis for death may be produced in a few minutes. And, as Dr. Heberden judiciously observes, "where the danger is imminent, from the violence of the symptoms, and we are doubtful whether they be gouty or inflammatory, we incur much greater risk by omitting blood-letting in a disease arising from inflammation, than by drawing blood in a disease arising from gout." Indeed there are very physicians, who condemn bleeding and other evacuations in gout, in the extremities, gravely prescribe the prompt administration of their remedies, when the lungs, head, or other viscera are attacked with it. In a word, when the internal visera are affected with unequivocal symptoms of inflammation, the same treatment by local and general evacuation, blisters, &c. must be resorted to, as in all other cases of inflammation, regard being had at the same time (an observance, indeed, which applies to the practice of medicine.
universal to the peculiar circumstances of the patient's age, strength, and constitution.

Gout-court, in Botany. See Angelica.

Goutier, Gothe, or Goffre, terms in Surgery, applied to a chronic enlargement of the thyroid gland. See Bronchocele and Goitre.

Gouty-land, in Agriculture, a term used by the farmers to denote a hollow, fuggy black earth, with little springs, that have no free outlet, and therefore swell and elevate the surface in many places.

Goujea, in Geography, a town of Portugal, in Estremadura; 20 miles S.E. of Vilafranca.

Goux de la Boulaye, Francis J., in Biography, a celebrated traveller, was born in the province of Anjou about the year 1610. Little is known of his early life, but that he felt a strong propensity for rambling into foreign countries; he employed ten years successively in traversing various parts of the globe. He seems to have been willing to become all things to all men, in order to obtain his wishes in safety. In Asia and many parts of Africa he passed for a Mahometan, and in Europe he was a good Catholic. On his return, he published an account of his travels, under the title of "Les Voyages des Observations de Francois de la Boulaye le Goux, en divers Pays, d'Europe, d'Afrique et d'Amérique, jusqu'à l'Année 1650." This work was published in 4to. and illustrated and adorned with engravings. The style is incorrect, but the facts, as far as they are borne out with truth, are said to be very curious. He was so much altered in his person during his absence from France, that his mother even, either could not, or would not recognize him, and he was obliged to institute a law-suit to establish his rights as heir in the family. In 1668 he was appointed ambassador to the Porte and the great Mogul, by Lewis XIV. who was very desirous of renewing his commerce with the East. Le Boulaye died in Peru a few before he had executed this mission. Moreri.

Gouye, Thomas, was born at Dieppe in the year 1639. He was brought up among the Jesuits, and was at an early period distinguished by an ardent love for mathematical and scientific pursuits. In 1659 he was elected a member of the Royal Academy of Sciences at Paris, of which body he became an affluence attendant, and was highly esteemed for the useful contributions which he made to their memoirs. He died at Paris in 1725, leaving behind him, as memorials of his learning and industry, "Physical and Mathematical Observations tending to the Improvement of Astronomy and Geography," from Siam to the Academy of Sciences at Paris, by the Jesuit Missionaries, with Reflections and Notes, in two volumes. The first volume was published in 1688, the second in 1692, and both have been reprinted in the seventh volume of the collections of the Academy. Moreri.

Gow, in Geography, a town of Hindoostan, in Bahar; 40 miles S.S.W. of Bahar. N. lat. 25° 39'.

Gower, John, in Biography, an ancient English poet of the fourteenth century, is said to have been descended from a family at Stittenham in Yorkshire. He had the best education which the times afforded, and at a proper age became a member of the Society of the Inner Temples, where he attained to a high degree of respectability in the profession of the law, and where he became acquainted with Chaucer. Some writers affirm that, in the course of his professional duties he was appointed chief justice of the court of Common Pleas, though others think the judge was another person of the same name who was a contemporary with the poet. Gower attached himself to the duke of Gloucester, uncle to Richard II., and was much noticed by the king himself, at whose desire he wrote his principal work. He had, however, a pliable mind, and could turn his pen to different interests; for on the accession of Henry IV. he not only wrote in satirical terms to the new king, but even reflected on the mis-government of the one who had been deposed, and whose was his patron. His circumstances were such as to put him beyond the fear of want, for he appears to have been a liberal contributor to the rebuilding of the church of St. Mary Overie in Southwark. During the first year of Henry's reign, our poet had the misfortune to deprived of his sight, an affliction which he did not long survive. He died in the year 1402, at a very advanced age. Gower, says his biographer, is entitled to a place among English writers only relatively to the time in which he flourished; for though well furnished with learning, and a successful cultivator of his native language, he has not the least pretensions to genius or invention. He is characterized by his friend Chaucer, as the "moral Gower;" he was uniformly grave, even upon topics that might inspire vivacity. He was author of three volumes, entitled "Speculum Meditantis;" "Vox Clamantis;" and "Confessio Amantis." Of these, the first is a moral tract, and relates to conjugal duties; the second is a metrical chronicle concerning the inflection of the people under Richard II., in Latin elegiac verse; the third, or "Lover's Confessions," relates to the morals and metaphysics of love. This is the only one that has been printed, and it was among the earliest products of the English press, by Caxton in 1483. It seems, says Mr. Warton, to have been his object to crowd all his erudition into this elaborate performance. The most interesting part of the work is a variety of stories adduced as moral examples, and taken from authors most in vogue, ancient and modern. The language is periphrastic, and the versification frequently harmonious. Biog. Brit. Warton.

Gower, in Geography, a district of Wales, in the south-western extremity of Glamorganshire, below the town of Swansea, and bounded by the Irish sea and the Bristol channel.

Gower's Cape, a cape on the E. coast of China, lying in the track from the southward to the gulf of Peking. A reef of rocks runs out from a neck of land near this cape, which appeared to have a compact harbour. The entrance to it was between the cape and the reef just mentioned. When the perfons concerned in the embassy to China passed this cape, a considerable number of vessels were deferred in the harbour, and a pretty large town behind it. N. lat. 36° 57'. E. long. 122° 15'.

Gower's Island, a small, flat, low island, in the Pacific ocean, so called by captain Carteret, who passed it in August 157; he found no anchorage, and could only obtain a few cocoa-nuts in exchange for naiis; the inhabitants resembled those of Elgnor isle. S. lat. 7° 56'. E. long. 150° 56'.

Gower's Harbour, a bay on the S. W. coast of New Ireland; 5 miles N. of cape St. George. M. Bougainville calls this "Praseline Bay," and by Dampier it is called "St. George's bay." S. lat. 4° 50'. E. long. 150° 48'.

Gowgat, a town of Hindoostan; 12 miles W. of Agra.

Gowgathy, a town of Bengal; 12 miles N. of Calcutta.

Gown, Rome, a long upper garment, worn by lawyers, divines, and other graduates, who are hence called gentlemen of the gown, or gown-men.

The gown is an ample sort of garment, worn over the ordinary
ordinary clothes, hanging down to the feet. It is fashioned differently for ecclesiastics, and for laymen.

At Rome, they give the name virile gown, togas viriles, to a plain kind of gown, which their youth assumed when arrived at puberty. This they particularly denominated præstites.

In some universities, physicians wear the scarlet gown. In the Sorbonne, the doctors are always in gowns and caps. Beadles, &c. wear gowns of two colours.

Among the French officers, &c. they distinguish those of the short gown, or robe; which are such as have not been regularly examined. They have also barbers of the short gown, who are such as are obliged to practice in an inferior way to surgeons, or those of the long robe.

Gown is also taken, in the general, for the civil magistrature, or the profession opposite to that of arms.

In this sense it was that Cicero said, "Cedunt arma toges."

GOWRAH, in Geography, a town of Bengal; 27 miles S. S. E. of Dacca.— Also, a town of Hindoostan; 5 miles N. E. of Dacca.

GOWRAN, a post town of Ireland, in the county of Kilkenny. It is a place at present of no importance, but was a borough before the Union, and there are some ruins which seem to intimate its former importance. It is 52 miles S. from Dublin.

GOWREY, a town of Hindoostan, in Oudh; 53 miles W. of Kairabad.

GOWRY-BIRD, in Ornithology, a name given by Edwards to the Loxia pulchella.

GOWRYPOUR, in Geography, a town of Bengal; 26 miles S. E. of Dacca.

GOWT, in Engineering, or go-out, is a name applied to the sea sluice, or valves used in embankments next the sea or tidal rivers, for letting out the land-waters when the tide is out, and preventing the ingress of salt-water. Some of the groves in the fens of Lincolnshire and Cambridgeshire are very large works, and cost immense sums of money.

GÔY, in Geography. See ANCE.

GOYANES, a town of Spain, in Gallicia, on the seacoast; 25 miles S. W. of Santiago. N. lat. 42° 32'. W. long. 8° 50'

GOYAS, GOYAN, or Goyza, a town and government of Brazil, extending from 43° to 54° W. long., and from 6° 30' to 19° S. lat. the inhabitants of which are estimated at 8930 whites, 29,650 Indians, and 34,100 negroes, who are employed in searching for gold in the mines, which were discovered in the year 1726.

GOYAVA, a town on the W. coast of the island of Grenada. N. lat. 12° 13'. W. long. 61° 31'

GOYAVES, a town of the island of Guadaloupe, giving name to a bay in which it is situated.

GOYEN, John VAN, in Biography, a painter, born at Leyden in 1596, who studied successfully the practice of landscape-painting under several masters, and having an uncommon readiness and skilfulness of hand, he produced a great many works of a light agreeable kind; with much character of nature, but no great relish of art; which, in their time, however, were very highly esteemed and widely spread over Europe.

Views of the scenes on the banks of the canals and rivers of the Low Countries were his favourite studies. Sometimes he emerged to the sea shore, or sunk into the interior of the country, and sketched the villages that presented themselves to his taste in the one, or the harbours, &c. of the other; but all are touched by the same kind of pencilling, and generally in the same hue of colour, when he came to work them up into pictures. Certainly, they have much merit of a peculiar kind, such as lightness in the handling, and freedom in their effect; but frequently they are vivid and lively, and by no means justify the high value and reputation affixed to them. It is said that the grey tone, too frequently found in his pictures, arose from the use he made of Haerlem blue, which is apt to fade into that tint, and therefore no longer in use. It may be so; but that grey is not the predominant defect in his pictures: it is the evident fault with which they are wrought, and their consequent imperfection of imitation, that induces us thus to condemn what the world have too long esteemed in a high ratio, which ought only to be given to works completed with the skill and purity of taste of a Caracci or a Claude. He died in 1655, aged 60.

GOZ, or GÖZEN, in Geography, a seaport town of Morocco, on the coast of the Atlantic, in the vicinity of Mogodor.

GOZO, an island of the Mediterranean, situated N.W. of Malta, and at a little distance from it. This island is about 25 miles in circumference, rather fertile, and containing about 3000 inhabitants.

Gozo, or Gofli, a small island in the Mediterranean, about 27 miles from the S. W. coast of Cardia; anciently "Clauda," near which St. Paul failed in his voyage to Rome. Some biblical writers suppose that the Gozo near the isle of Malta is the Claudia of the Book of Acts. It is occupied by about 30 families; who have a Greek church, and is occasionally visited by vessels for a supply of water and provisions. At a small distance to the west is a very little island called "Pulo Gozo," or Little Goz. N. lat. 34° 48'. E. long. 23° 46'. See CLAUDA.

GOZZANO, a town of Italy, in the department of the Gorgo; 18 miles N. of Novara.

GOZZOLI, Benozzo, in Biography, one of the early practitioners of the art of painting on its revival. He was a Florentine, and disciple of Fra Angelico; but subsequently initiated with very great success the style of Maffei, his contemporary. Valari speaks of him with great esteem under the name of Benozzo, and relates histories of his many productions at Florence, Volterra, Rome, and Pisa; at which latter place he is most conspicuous in his labours, both in history and portraits, which indeed at that time were usually introduced in historical pictures. At Pisa he died in 1478, aged 78, and a monument, with a Latin epitaph, is placed near his principal work in the Campo-Santo; a monument of his powers, and the efface in which they were held.

GRAAF, Reinier DE, an excellent physician, was born at Schoonhoven, a town in Holland, where his father was an eminently architect, on the 30th of July, 1641. He studied physic at Leyden, where he made great progress, and at the age of 22, published his treatise De Succo Pancreatico, which gained him considerable reputation. In 1665, he went to France, and received the degree of M. D. at Angers: but he returned to Holland in the following year, and settled at Delft, where his great success in practice excited the envy of his professional brethren. He married in 1672, and died in August, 1673, when he was only 32 years of age. He published three dissertations relative to the anomaly of generation in both sexes, upon which he had a controversy with Swammerdam. His works were published in 8vo. at Leyden, in 1672 and 1703; they were also translated into Flemish, and published at Amsterdam in 1688. Hutchin, Biog. Med. Ely.

GRAAF RYNET, in Geography, a district of southern Africa,
Africa, in the colony of the Cape of Good Hope, extending to the eastern extremity of the colony. On the E. it is divided from the Kaffers by the Great Fish river, the Turkia, the Bambaria, and the Zuurber; on the W. from the districts of Zwelendam and Stellenbosh by the Camtoos river, the Cranka or Lion's river, and Nieuwveld mountains; on the N. from the Bosjesman Hottonetos by Delberg Landmark, the great Table mountain, and the Karroeburg; and on the S. it is terminated by the sea-coast; the whole length and breadth of this district may be about 250 by 160 miles, making an area of 40,000 square miles, which is populated by about 700 families, each family commanding about 57 square miles of territory. Great part of it has been occasionally abandoned on account of the incursions of the Kaffers and Boersmen. The inhabitants are a sort of Nomades, who would long ago have penetrated with their flocks and herds far beyond the present boundaries of the colony, if they had not been repulsed by the Kaffers. The boors of this district are graziers; and it is entirely composed of loan-farms, which are grants made to the original settlers of certain portions of land to be held on reasonable yearly leases, on condition of paying to government an annual rent of 24 rix-dollars.

Barrow’s Travels in Africa, vol. ii.

GRAAT, or GRAY BARTON, in Biography, an historical painter, whose name is remembered principally upon account of his close imitation of the works of Bamboccio, and of his having founded an academy at Amsterdum, where he was born, to which the best artists of his time retired to study after living models; by which means much improvement was obtained, and spread among those who cultivated taste and science in the arts. He died in 1709, aged 81.

GRAY, in Geography, a town of Bohemia, in the circle of Leitmeritz; 17 miles N. N. W. of Leitmeritz.

GRABATARI, or GRABATARI, in Church Antiquity, such person as deferred the receiving of baptism till the hour of death; or who did not receive it till they were dangerously ill, and out of hopes of life: from an opinion, that baptism absolutely washed away all former sins.

The word is formed of grææanem, bed; and that from the Greek λυγυρέα, a hanging bed, of ἵππον, I suspend: such as was the bed of slaves, poor people, Cynic philosophers, &c. who were enemies of luxury and cafe.

GRABAU, in Geography, a town of the duchy of Warfaw, 12 miles S. of Kalit.

GRABAU, a town of Austrian Poland, in the palatinate of Belz; 28 miles N. N. W. of Belz.

GRAFE, John Ernest, in Biography, a learned divine, and editor of the Alexandrian manuscript, in the Royal Library at London, was born at Koningberg, in Prussia, in the year 1666. Here he received his education, and in due time took his degree of M.A. applying himself with all diligence to the study of divinity, and the perusal of the fathers. He had been brought up in the Lutheran principles, but having imbibed some notions inconsistent with the commonly received faith, respecting the uninterrupted succession of bishops being essential to the existence of the true church, he was summoned before his superiors and imprisoned. Upon his release, after a few months, he chose rather to quit the church than abandon his opinion, and determined to become a member of the Catholic religion. He delivered, in a memorial to the elec- toral college at Sambia, in Prussia, in 1693, containing the reasons for his change, and then left Koningberg, that he might be at liberty to carry his plan into execution, in some place where he should be beyond the reach of the Prussian jurisdiction. While he was on the road to Erfurt, through which he went to pay to a Catholic country, the elector of Brandenburg sent three treaties to him in answer to his memorial, by three Prussian divines, written by order of the elector. This great attention of his sovereign claimed the respect of Grafe, who not only read them with care, but felt disposed of discussing the question more clearly before he formed his ultimate determination of abandoning the religion in which he had been educated. He accordingly wrote to one of the persons that had answered his memorial, intimating a strong wish to return to Berlin, that he might enjoy the benefit of a conference with him. This privilege was obtained for him; M. Grafe returned and was soon prevailed on to relinquish his purpose of joining the papal communion, but still he maintained the obstinate tenet for which he had suffered imprisonment.

Finding him immovable on this point, his friend advised him to remove to England, where, said he, "you will find the outward and uninterupted success which you want: take then your route thither: this step will cause less uneasiness to your friends, and, at the same time, equally satisfy your curiosities." He gladly complied with the advice, and was strongly recommended to King William, who immediately granted him a pension of 100l. per annum, to enable him to pursue his studies. From this time he confided England as his country, because he conceived that its ecclesiastical constitution approached nearer on the whole, than that of any other, to the primitive pattern.

He shewed his gratitude for the liberal patronage which he received by the publication of several learned works. Having formed a design of printing some curious and scarce pieces of the fathers, in defence of his own opinions, he obtained access to the university of Oxford, to examine the treasures of the Bodleian library, and, in 1698, he published "Spicilegium S. S. Patrum, &c." vol. I. 8vo.; and in the following year, the second volume of the same work appeared. Shortly after this, he was ordained a deacon of the church of England, and was appointed chaplain of Christ-church, Oxford. This promotion he accepted, in order that he might be entitled to the emoluments without being required to discharge the duties of the appointment, for he had refused, on his ordination, to receive the sacrament, on account of the omission of the prayer in the communion service, mentioning the sacrificer, before the elements were distributed, which had been inserted in the first common-prayer book of King Edward VI., and he ever afterwards continued a non-conformist in this particular. In the same year in which he took orders, Mr. Grafe published "S. Justini Philosophi et Martyris Apologia Prima pro Christianis, &c." illustrated with the notes of several learned men, and additional remarks of his own; and in 1702 he published "S. Irenæi Episcopi Lugudunensis contra omnes Hæreticos Libri quinque, &c." with prolegomena and notes. On the accession of Queen Anne to the throne, Mr. Grafe's pension was continued, and her majesty was advised to employ him in printing the Alexandrian MS. in the royal library, of the Septuagint translation of the Old Testament. The queen took the opportunity of informing him of the appointment herself, and at the same time made him a handsome present as an encouragement to his exertions. In 1705, he published proposals for printing that work by subscription, setting forth the superior value of this copy to the Vatican MS.; he also gave three specimens, containing so many different methods for the projected edition, in the final choice of which he was to be determined by the learned world. As a testimony of their approbation of the design, the university of Oxford presented.
fected him with the degree of doctor of divinity. His proposals met with a very favourable reception on the continent as well as in England, and he received a handsome present from his own sovereign, the king of Prussia, and liberal subscriptions from the principal nobility, clergy, and gentry of all parts. In 1707, he gave to the public his first volume, under the title of "Vetus Testamentum juncta Septuaginta Interpretis; tom. i contineat Octateuchum." This volume contains the Pentateuch, and the three following books. In the expectation of an accession of additional MSS. he deferred the second and third volumes, and published the fourth volume in the year 1750. This contained the book of Psalms, of Job, of the three books of Solomon, &c; and in the following year he published a Latin dissertation, giving a particular account of the reasons why he had departed from his usual order of publication, and of the helps which he expected to receive in order to perfect his plan. These were, a Syriac MS. of the historical books of the Old Testament, with Origen's remarks upon them, and two MSS. one belonging to cardinal Cigoli, and the other to the college of Louis XIV. When he had received these MSS. and had collated them, he prepared a volume of annotations on the whole work, and collected materials for the Prolegomena. The time which these objects took, caused a material delay in the publication of the second and third volumes, which did not, in fact, appear till after the author's death. This event took place in 1712, when he was only in the forty-fifth year of his age. He had previously to this published "An Essay upon the Arabic MSS. in the Bodleian library, and that ancient book, called the Doctrine of the Apostles, which is said to be extant in them, wherein Mr. Whiston's mistakes about both are plainly proved." The third volume of his great work was published in 1719, and the fourth in 1720. On his death-bed he was attended by Dr. Smallridge, by whose means he declared that the public might be informed that he died in the faith and communion of the church of England, though he considered its constitution to be defective in some points, in which he thought the nonjurant clergy adhered more closely to the apostolical doctrine and discipline. Of his talents there were different opinions, but of his industry and learning no one could harbour a doubt. Dr. Thirlby says, in the dedication of his edition of Justin's Apology, "He was a good man, and not unlearned, and well versed in the writings of the fathers. But he was no critic, nor could be one, since he was not furnished with genius or judgment, or, to speak the truth, with learning sufficient for the purpose." In this opinion Le Clerc coincides, and adds, that his books gained him the character of a laborious person rather than that of a great critic. He was the author of many other works besides those which have been mentioned, and was editor of an elegant edition of bishop Ball's works; he likewise assisted in preparing for the press Archdeacon Gregory's edition of the New Testament in Greek; and he left behind him many MSS. some of which have been published. Big. Brit.

GRAFEN, in Geography, a town of Croatia; 15 miles S. of Varadina.

GRABO, a town of Sweden, in East Gothland; 11 miles S.E. Linkoping.

GRABON, a town of the duchy of Mecklenburg, on the Elbe; 80 miles N.W. of Berlin. N. lat. 53° 23'. E. long. 11° 44'.

GRABUSA, an island of the Mediterranean, near the N.W. coast of the island of Candy, confirmed to the Turks by the peace of Carlowitz, and generally garrisoned with 1000 men. N. lat. 35° 40'. E. long. 23° 53'.

GRABUT, in Biography, an obscure French musical composer, whose name is not to be found in the annals of the art. He was brought into England to flatter the partiality of Charles II. for the music of France; and employed by Dryden to fit his political opera of "Allbon and Albanus," though Purcell had already given indisputable proofs of his superior genius, and was rapidly rising into fame and national favour.

This drama, written under the auspices of king Charles II., was rehearsed several times, as the author informs us in his preface, before his majesty, "who had publicly declared, more than once, that the compositions and choruses were more just and more beautiful than any he had heard in England." We believe this prince was not very skillful in music, nor very sensible to the charms of any species of it but that of France, of the gayest kind; however, royal approbation is flattering and extensive in its influence. Unfortunately for the poet and musician, his majesty died before it was brought before the public, and when it did appear, the public seems not to have been very considerable. Upon a perusal of this drama, it seems hardly possible, so near a revolution, that it should have escaped condemnation upon party principles; as, under obvious allusions, Dryden has laathed the city of London, democracy, fanaticism, and whatever he thought obnoxious to the spirit of the government at that period. Had Orpheus himself not only composed the poem and the music, but performed the principal part, his powers would have been too feeble to charm such unwilling hearers.

GRAFAY, in Geography, a town of France, in the department of the Cher, and chief place of a canton, in the district of Bourges; 9 miles S.W. of Vierzon. The place contains 2203, and the canton 5459 inhabitants, on a territory of 145 kilometres, in 9 communes.

GRACHURIS, an ancient town of Hispania Tarraconensis, mentioned by Livy, Antonine, and Polyainy, and said to be built by the proconsul Titus Gacchen Sempronius, after having conquered the Celiberians. Others suppose that it existed before Sempronius, under the name of "Iluricius," and that he only repaired it. It is now called Arreda.

GRACHUS, Tiberius Sempronius, in Biography, a person very memorable in the history of Rome, was the son of a father of the same name, a distinguished commander, and excellent citizen, who, from the Plebeian ranks, arrived at distinguished honours, and the highest offices in the state, having been master of the horse to the dictator, Junius, after the celebrated battle of Cannae, afterwards consul, and, at length, to complete his glory, he was slain while fighting for his country. The mother of the subject of this article was Cornelia, daughter of Scipio Africanus, whose character has been illustrated in the proper place. Tiberius received every advantage of education that the pious affection of a wise parent could bestow, and his natural disposition succeeded the efforts of his instructors. He was modest, and remarkably mild in his temper; and became, at a very early age, distinguished for eloquence, solicitude, and political knowledge; and his reputation was fostered by an admission into the venerable college of augurs. It is mentioned, as a proof of the high character which he sustained, that Claudius Appius, one of the most illustrious orators in Rome, and president of the senate, offered him, spontaneously, his daughter in marriage, which he thankfully accepted. When Appius informed his wife what he had done, the replied, "Why to suddenly, you might have taken
GRACCHUS.

taken time, even if Tiberius Gracchus were the man." In conformity with the Roman custom, Tiberius passed his youth in military service; first in Africa, under his brother-in-law, the younger Scipio, where he obtained great credit in the army, being equally beloved by those above and those below him. He was made questor, in the Numantine war, to the consul C. Hothius Mancinus. This was in the year B. C. 137: the campaign was unfortunate, and the Roman general was under the necessity of negotiating a treaty of peace with the enemy. The Numantines, who had been betrayed in a former treaty by the Romans, refused to negotiate, unless it were with Tiberius Gracchus, with whose character for probity and strict honour they were well acquainted. This being admitted, a peace was immediately concluded. The treaty, though as favourable as, from circumstances, could be expected, was received by the Romans with great indignation; they determined to annul it, and to deliver those, who had been instrumental in making it, into the hands of the Numantines. The consul was accordingly given up to them, naked and in chains, and it is probable that Tiberius Gracchus would have shared the same fate had not a powerful interest been exerted in his favour. A fan of the injustice of the senate on this occasion, and resentment of the dishonour they had thrown upon his treaty, was supposed to be a principal cause of the subsequent hostilities in which he engaged against that body. The condition of the Romans, at this period, afforded a good opportunity for the exertions of patriotism; for the great mass of the lower classes of citizens were in a state of abject poverty. Lælius the Wife, the friend of Scipio, had attempted to introduce some remedy for this evil, but the serious opposition of men in power had deterred him from the execution of his plan. Tiberius Gracchus resolved to take up the cause. He was accordingly elected a tribune of the people, and proposed a revival of the Licinian law, with certain modifications, which greatly softened its operations. (See Agrarian Law.) It offered a full compensation out of the treasury for all the land above the 500 acres allowed, which any one might be obliged to resign to the public, and permitted every child of a family to hold 250 acres above the 500 held in the father's name. This proposal was received, as it might be expected, by the superior orders, whose rights and properties were to be affected by it; they were determined to stand by one another in refiling the innovation. On the other hand, Gracchus lost no time in rousing the people to a knowledge and affection of their claims as men and members of society. His speeches were addressed to their interests and their feelings: his arguments were stipidious and highly dangerous to the peace of those whole wealth was become the object of popular discussion. In one of his harangues, he exclaimed, "The wild beasts have their caves and dens, but the brave men who shed their blood in the cause of their country have nothing free but the air and the light. It is a mere mockery when their generals exhort them to fight for their spoilulces and household gods, when, perhaps, not a man among them ispossessed of a domestic altar, or spolburch, of his ancestors. The private men bleed and die to secure the luxuries of the great; and, by new laws which he got enacted, he rendered the property of all the old families infecure. The difficulties which occurred in carrying the new law into effect were increased by the death of Attalus, king of Pergamus, who made the Roman people his heirs. Gracchus procured a law for the distribution of his treasures among the poorer citizens, and for the disposal of the revenues of Pergamus, not by the senate, but by the assembly of the people. These measures gave him a great degree of influence among the citizens, and he conceived the design of securing the powers of which he felt himself possessed, by raising his father-in-law to the consulate, his brother to the tribunehip, and continuing to himself the same office another year. He also planned other regulations for abridging the authority of the patricians, and throwing more weight into the popular scale. The day of election was approaching, and the senators resolved to make a stand against the innovations which he proposed, and a conspiracy was openly formed to take away the life of Tiberius Gracchus. Of this he was informed by a friendly senator, as he was proceeding to the capital. He, nevertheless, advanced, and his party prepared to repel force by force. In the uproar, he attempted to speak, but his voice could not be heard. He made signs to his friends, by raising his hand to his head, to shew that his life was in danger. This signal was instantly interpreted by his enemies as a demand of the regal crown, and Scipio Nacica, the inveterate enemy of Gracchus, cried out "Since we are betrayed by our conful, let those who love the republic follow me." A general contest now commenced. The adherents of Gracchus were quickly dispersed, and himself was dispatched with a thousand blows. Not less than 300 persons were slain in this commotion, and the bodies of the dead, even that of Gracchus himself, were ignominiously thrown into the river. Several of his friends were afterwards banished, and not a few put to death, without the form even of trial, and the senate passed an act of indemnity for all those who were concerned in the massacre. The people, however, indignant against his enemies, drove Nacica from Italy, and would never permit him to return. With respect to Tiberius Gracchus, his character has been celebrated either as that of a martyr to liberty, or as a victim to hasty ambition, according to the different principles of those who have commented on his actions. Many have thrown on his memory reflections as unfavourable as any the are severe. It seems to be acknowledged on all hands that he possessed great talents, and was esteemed for his private worth. That he was a man of ambition none will deny, and it may be that a love of popularity suggested the great measures which he proposed; nevertheless, the historian may be fairly followed, who says, that he was actuated by the best intentions, but that he professed his design with too much violence.

Gracchus Caius, brother to Tiberius, but his junior by nine years, enjoyed the same advantages of education with his brother, which he so well improved as to become one of the ablest orators of his time. Cicero says of him, that he knew not if he had his equal in eloquence, and recommends his compositions, though unfitted, to the study of youth. After the tragic end of his brother, Caius passed some time in retirement, cultivating his rhetorical talents, and secretly preparing to act his part on the theatre of the public. In the year 126 B. C. he accompanied the consul Aurelius Orles to Sardinia as his queller, and obtained great applause, as well for his humanity and temperance, as for a strict attention to the duties of his office. The senate shewed evident signs of jealousy on account of the
the popularity which he acquired, and retained him as pro-
queillor in Sardinia in order to keep him at a distance from
the Roman forum. Perceiving their intentions, he ventured,
in defiance of their orders, to quit the island without leave
of his commander, and suddenly made his appearance at
Rome. He was called to account for this breach of military
discipline, but was readily acquitted. Soon after he became
a candidate for the tribuneship, and such was the zeal of
the people in his favour, that the Campus Martius was not able
to contain the multitude which flocked from the Italian towns
to support his election, and many gave their votes from the
tops of the adjacent houses. Caius had not forgotten the
enemies of Tiberius, and would have punished them to their
destruction, but was probably diffused from it by his mother.
His speeches were calculated to revive the indignation of the
people against the senators for their conduct towards Tibe-
rius, and he proposed and carried motions for confirming his
brother's laws, and the pawning of others still more obnoxious
to the patricians. He was appointed commissioner for the
division of lands among the poor citizens and allies, and in
his progress through Italy he employed his talents and
wealth in repairing roads, building bridges, and in other
works equally useful and important. He established public
granaries in Rome, from which the citizens were to have
their monthly distributions of corn at a low price, the
expenditures of which were to be defrayed by duties laid on
goods imported into the dominions of the late king Attalus.
By these, and other acts of a like kind, he so ingratiated him-
self with the people, that he was chosen a second time
tribune. Triumphing in his success, he proposed a law for
transferring from the senators to the knights the cognizance
of all private causes. When he had obtained his purpose he
exclaimed, "at length I have humbled the senate." He
now felt himself the arbiter of the republic, and treated the
patricians with contempt. This behaviour hardened his
ruin. There is a point, beyond which the most successful
man, whatever be his pretensions, cannot go with safety.
Caius had transfixed this boundary, and his enemies were
perpetually on the watch for opportunities to check his
power, and to introduce rivals who might, by the appear-
ance of more liberality, depreciate his reputation and influence
in the state. During his absence in Africa his enemies
were ever on the alert to injure his fair fame, and to ascribe
unworthy and base motives to all that he did or proposed to
do; and in the tumult which accompanied the discussion
of some of his laws after his return, he fled to the temple
of Diana, and, unwilling to sacrifice either himself or his
adherents to popular fury, he proposed terms of accommo-
dation. These were rejected by the agents of Optimus the
confidant, and a price was instantly set upon the heads of
Gracchus and his friend Fulvius. A formal battle ensued,
in which multitudes were slain on both sides, and the popu-
lace without hesitation deflected their friends: Fulvius con-
ceived himself, but, being discovered, was instantly killed.
Gracchus, having feloniously imprecated upon the heads of the
Roman people perpetual slavery for the base defection of the
cause, left the city and sailed across the bridge named Sub-
licus. His retreat was favoured by two faithful friends, who
defended the bridge till they fell covered with wounds. In
the mean time Gracchus reached a grove sacred to thefuries,
where it is said a slave, by his order, first dispatched him, and
then put an end to his own life. Others have, however,
given a different account of the matter; they say that he was
overthrown by his enemies, and by them slain. His
head was cut off and fold to the confidant for its weight in gold.
The body was thrown into the Tyber, but afterwards being
taken from the water it was delivered to his afflicted mother
for burial. This catastrophe, in which three thousand per-
sons perished, happened in the year 121 B.C., and the senate
immediately proceeded to abolish all the laws of the Gracchi.
Their names, however, were still fondly cherished by the
people, statues were erected to their memory, and the places
in which they were killed were consecrated, by religious
rites, to their names. Caius has been generally considered
as less pure in his intentions, and less moderate in his plans, than
Tiberius. From the evidence of history it should seem, that
the disturbance of the public tranquillity was rather owing to
his opponents than to him;" so that," says the historian,
"instead of calling the tumults of that period the "sedition
of the Gracchi," we should rather call them the sedition
of the senate against the Gracchi, since the efforts of the
latter were made in vindication of a law, to which the
senate had assented, and as the designs of the former were sup-
ported by an armed power from the country that had never
before interfered in the business of legislation, and the intro-
duction of which gave a most irrecoverable blow to the
constitution. Caius in his person was graceful, his action
was strong and impressive, his voice of great compass and
melodious; when the vehemence of his pleading did not raise
it to too high a key; to correct this defect he was accustomed
to place a judicious person behind him with a pitch-pipe, by
which he was enabled to regulate his tone. In a temper he was
warmer than Tiberius, nor was he distinguished by sobriety of
manners, though in this respect he might be advantageously
compared to the Roman youth in general. Philarch.
Univ. Hill.

GRACE, Gratia, in Theology, denotes in general
any gift or favour, which God freely bestows upon mankind;
whether such gift pertains to the present or future life: but
as those which relate to the improvement of their temper,
and their fitnes for final happiness, were favours of the
greatest importance, this term is by way of eminence
applied to them. The proper signification of the word grace
is favour: favour in such a sense as denotes mercy and
goodness in a superior, either remitting somewhat of his own
right, or conferring somewhat beneficial upon others, freely
and without any obligation of debt. And because this may
be done in various modes and in a great diversity of inci-
ences, hence the word grace in Scripture is accordingly applied in
a corresponding diversity of significations. Sometimes it
signifies those extraordinary gifts and favours of the Holy
Ghost, by which the apostles were enabled to demonstrate
the truth of their communion, to preach their doctrines with
authority, to convince gainers with evidence, and to go-
vern the churches by a proper distribution of different
trials and offices. The gifts or powers, by which the apostles
were enabled to do all these things with extraordinary effica-
cy and success, are therefore called grace, because they
are not at all natural acquisitions but free gifts of God;
distributed to every one, not according to the will of man,
but at such times, and in such proportions, and to such per-
sons, and for such purposes as God himself pleased. See
Rom. i. 9. Ephes. iv. 7, 11.

In other passages, the same word is used to signify that
extraordinary affluence and support which God has been
deprived sometimes to afford to his servants under extra-
ordinary difficulties and trials; and this is called grace, because
it is considered as given particularly and gratuitously upon ex-
traordinary occasions over and above the general supports
arising from the considerations of reason, and from the promis-
ces and motives of the gospel in general. See 2 Cor. xii. 9.

A third sense, in which the word grace sometimes occurs
in the New Testament, is to express such moral virtues as
are the effects of men's being influenced by the spiritual
motive...
GRACE.

Grace is also a term in the formula of all patents, &c. which begin, George, by the grace of God, king of Great Britain, &c. The Roman bishops frequently began their mandates in the like manner: such a one, by the grace of God, and the holy see, bishop of, &c.

The English archbishops are, by divine grace, or divine providence. See Archbishop.

All forefathers use the phrase grace of God; as emperors, kings, princes, &c. Anciently dukes, counts, and even lords, talked in the same style. In the new collection of Father Martene we meet with a mere signifier, or lord, qualified by the grace of God signifer de Comborn. Louis XI. forbade the duke of Brittany to style himself by the grace of God.

Grace is also a title of dignity, attributed to princes of inferior rank, and who are not qualified for that of highness.

In former times the kings of England were addressed under the title of grace, as they are now under that of majesty. See King.

Our English dukes and archbishops are full addressed under the title of grace. But that title is most frequent in Upper Germany, and particularly Austria, where it is borne by the barons, as being inferior to that of excellence.

Grace is also applied to persons, and various kinds of performances, to denote a quality, or rather the result of a combination of qualities, which attracts peculiar notice, and affords peculiar pleasure.

Grace is also used for a short prayer offered before and after meat. This practice is very ancient, and has very generally obtained both in the heathen and Christian world; and hence grace-cup is used by some of our poets for the cup or health drank after grace.

Grace, in the arts of Painting and Sculpture, is used to signify a peculiar quality which heightens the effect that beauty of form is calculated to produce, and renders it still more engaging.

We have already, in the article Beauty, slightly touched upon this subject, and there mentioned the origin of the term among the Greeks; who gave to the Charites or Graces, whom they defined, the presidency over whatever was amiable and engaging in the actions or sentiments of mankind. By the undisguised goddesses, to whom they gave the names of Aglaia, Thalia, and Euphrosyne: they allegorized the pure sincerity and simplicity in which acts of kindliness should always be wrought. By the union of these persons, which are gently holding each other by the hands, or with their arms round each other's necks, they marked the union of spirit which dictates acts of benevolence and social intercourse; and by devoting them to the service of Venus, exemplified the necessity of uniting the virtues of humanity to the beauties of perfon, in order to become truly engaging.

This allegory of the ancient Greeks leads us to the just conception of the meaning of the word grace when applied to the arts. Whatever can lend to beauty, increase of interest upon the beholder, is entitled to be called graceful, or at least elegant. (See Elegance, in Painting.) As the heart of man, when inclined to good, is to his mental, fo is grace to his personal accomplishments; that, which gives the most delightful gratification to those with whom he associates. Without it, art is nothing, compared with the values it acquires by its presence. Independent of all which constitutes mere beauty of form, it is absolutely necessary to give it its full force, its greatest effect; viz., that which

motives of the gospel, and the practice of which prefers men in the favour of God, and recommends them to his gracious acceptance. (See Ephes. iv. 29. 2 Pet. iii. 18. 2 Cor. vii. 6.) Moral virtues are plainly for this reason distinguished by the denomination of grace, because they proceed from and are founded on a regard to God in general, and in particular to his will revealed under the gracious dispensation of the gospel of Christ.

Another signification of the word grace in Scripture is to express the merciful acceptance of repentance and amendment, by which God is pleased, not out of any obligation of justice, but in gracious goodness, to receive men to favour in this sense Paul says (1 Cor. xv. 9.) " By the grace of God I am what I am:" and he, in the same context, declares, "The grace of God which is given unto us." (Rom. ii. 12.) The grace of God is signified by the phrase grace and truth. The Apostles' preaching is by St. Luke (Acts xix. 3.) called "the word," or declaration. "Of God's grace:" and when St. Paul declares, "I am not ashamed of the gospel," that repenting sinners are "justified freely by grace," and blames those "who continue in sin, that grace may abound." The word grace in all these passages signifies that merciful and connnionate distribution of the divine nature, by which God freely remits of his right of punishment, and receives repentant sinners, upon more gracious terms, and to greater degree of his favour, than he was bound to do by any obligations of justice.

Hence it is, that the gospel itself, as being the great and standing declaration of God's mercy and goodness towards men, shewn forth in the free pardon and forgiveness of sin upon the gracious terms of repentance and amendment, is in the New Testament very frequently meant by the phrase grace of God, and the grace of God, (Clarke's Com. vol. ii. p. 265—275. 8vo. fol. ed. vol. i. p. 180, &c.) Bishop Pearce (Comm. vol. ii. p. 293.) renders Xprstv in 1 Cor. x. 30. thanksgiving, and not grace, as it is in our version; and he observes that this sense of the word Xprstv is too frequent in St. Paul's writings to require a proof of it. He adds that Xprstv in the latter part of the verse confirms this sense.

Some divines define grace to be any degree of divine influence on the mind, inclining it to believe in Christ, and to practise virtue; and those divine influences, which are not effectual in producing saving faith and sincere obedience, they call common grace, in contradistinction to special grace, the operation of which is completely efficient and saving; and those influences which introduce special grace, though they do not actually amount to it, are with respect to that introduction sometimes called preparatory. It is disputed among theologians whether special grace, which they suppose is never on the whole finally rejected, so as to fail of working faith in those who are the happy objects of it, be in the nature of its operations upon the human mind irreducible or not; and it is also questioned, whether common grace is sufficient. Whether the mind be entirely passive, in the first moment of its conversion, or whether there be any cooperation of our own together with the influences of divine grace upon the heart, is a question, which has been also very much disputed amongst divines of a particular description; and another question, no less the subject of controversy, is similar to the former, and that is, whether the work of regeneration and conversion be accomplished in an infant. But we should far exceed our prescribed limits if we were to state the arguments pro and con on questions of this nature.

Grace, in Law, is sometimes used for a faculty, licence, or dispensation; but this seemeth to be only in a case where the matter proceedeth, as it were, ex gratia, of grace and favour; and not where the licence or dispensation is granted of course or of necessity.
GRACE.

beauty acquires by motion, wherein alone grace is visible.

Poets as well as painters and sculptors acknowledge the value of this quality; and the best have constantly applied it to the objects of their adulation when speaking. Milton says of Eve, "Grace was in all her steps." Ariosto adds it to the beauties of her Alvina; when he says,

"Avea in ogni parte un lascio tefte
O parli, o ridi, o canti, o paffo nova."

The graces, lurking about the mouth and the eyes of a beautiful person when in motion, are the most constant theme of poets, and as constantly the source of emulation to the painter and sculptor to imitate; and when the artist has by his ingenuity discovered and represented truly those minute variations of form which take place both in figure and features, when the mind is excited by some amiable emotion; he has obtained the ultimatum of his art; no power can go beyond it. Apelles, the ancient Greek artist of most repute, declared of his contemporaries, that their several works poffessed every beauty but the perfection which grace alone can give; in this he found himself unrivalled. Ancient sculpture is fraught with it; their figures, whether in action or repose, poißef it; and when we lay that it may be found in figures repose, we do not militate against the sentiment that action is the basis of grace; a previous motion being supposed to have taken place, to produce the graceful position. No figure, standing, fitting, or lying down, can be graceful, however beautiful it may be, while parts or members are presented altogether straight and flat to the eye. Without some varying turn being given to the head, the body, the arms, or the legs, it will be in vain to look for grace; and it is their being arrested in the action they may assume, at the most agreeable and expressive point of view, which gives the conformation of this invaluable quality to them. Then, if fixed for ever, they will be for ever graceful; and the delight which the contemplation of their mere beauty of form and proportion conveyed, will be heightened to the summit of that gratification which art is enabled to afford.

Wherein then lies this source of perfection? How, with certainty, may we express it in our works? is the hitherto unanswered query of the artist; or answered but in part and unsatisfactorily. All writers on painting have touched upon grace, and some have attempted to give information of the principles whereon it rests. Lazzaro, in his Trattato della Pittura says, that Michael Angelo gave the following precept to Marcus de Sirena, his pupil. "That he should always make a figure pyramidal, serpent-like, and multiplied by one, two, three!" In which precept (Lazzaro continues) in mine opinion the whole mystery of the art confiheth. For the greatest grace and life a picture can have, is, that it express motion. Now there is no form so fit to express motion as that of flame or fire." This text is again repeated by Du Fresnoy, and thus has Dryden translated the passage: "Large flowing gliding out-lines, which are in waves, give not only a grace to the part, but to the whole body, as we see in the Antinous, and in many other of the antique figures. A fine figure, and its parts, ought always to have a serpent-like and flaming form; naturally, those forms of lines have I know not what of life and seeming motion in them; which very much resembles the activity of the flame and of the serpent.

On these two remarks our own invidious and skilful Hogarth has built a fylem, which, if it be not altogether complete, has yet much fagacity and utility in it, and which he has given to the world in his Analysis of Beauty. He therein adopts the serpentine line, (which he illustrates by supposing a wire drawn spirally round a cone from its base to its apex), as the basis of grace, with much apparent truth: and he is most certainly supported by all those fine works wherein gracefulness is acknowledged to reside. The Torso of the Belvidere, the Venus de Medicis, the Apollo Belvidere, the Laocoon, who, in the midst of the violent anguish he suffers, still poßesses grace. All these, and indeed all others, which have any pretensions of the like kind, have the serpentine line for the base of their composition, in a greater or less degree. Where shall laugh at a tydlen upheld by such authority! Walpole attempts to ridicule it, as well as others, because Hogarth was not equal to put it in practice. The futility of such an argument need no illustration. To conceive a thing in the imagination, and not to be able to exemplify it by practice, is by no means an uncommon occurrence among artists, or among men; yet the propriety of the conception may be unquestionable, taken on general grounds. Hogarth's mistake appears to have been, having fixed the boundary of grace; having given what he calls the precise line of it; whereas, all the antique figures mentioned above are graceful, while each varies from the other in the quantum of curve which its action consists of. Hence arises, that he narrowed the sphere wherein grace was observable, which in nature is found to be so widely extended, that, without just consideration, his inaccuracy was regarded as the raving of excentricity; whilst, a few good arguments were adduced to disprove the general principle, which appears to us to be just. How to employ it, is another question. And here we fear no rules will suffice to guide the practitioner in art. As we feid of elegance, we repeat of grace; he that is endowed by nature with a power to feel its beauties, and display its effects, may, by cultivation, improve his original flow; but he that requires to be taught what grace is, will, in vain, set about to obtain the power of painting it; if he ever arrives at the knowledge of it, or the power of feeling it, in nature or in art. A confiant observation upon the actions, in figure and feature, of those who are by nature graceful, is the best school in which to study it, and the realest mode to discover wherein it lies.

Grace is not, or rather ought not, to be confined to the figures in a composition. Every part of the picture should have a conjunctive effect to produce grace in the whole. Contrail of form will aid the beauty of the principal parts, but that contrail should never force itself into notice, the artificer would then become a parasite, and the eye would not be led to the beautiful parts, but, on the contrary, be detained from them. The painter therefore who has conceived a graceful figure, should either paint it singly, or be careful to support it, by proper accompanying lines and objects, that its beauty be not lost in the mass, and its effect overpowering by other forms of less value becoming obtrusive to the observer. And great care should be taken to prevent every attempt to produce grace in the action of figures, from degenerating into affectation. Where that begins, grace ends; and delusion or ridicule, instead of admiration, becomes the need of the artist! No vice in art is so odious as affectation! If the best executed work imaginable be unhappily tinged with it, few minds of an elegant or graceful turn of feeling will bear to dwell upon it. Those artists who allow their minds to be impressed with the passion or sentation they wish to convey in their figures, and thence conceive the action of them, are not so liable to fall into this error, as those who have had ideas more intent on making an agreeable picture, and think of the actions, before they have considered the passions of their figures. Raphael is an imitation of the former; Correggio and Parmigianino,
The best examples of grace are to be found in ancient sculpture and paintings, and in the works of Raphael. Some few of the works of Correggio, of Parmigniano, and of Guido Reni, possess it, perhaps, more refined than Raphael's; but they are far on the extreme boundary where real unaffected grace resides, that they are dangerous exemplars to a student. A confirmed artifex may observe them to advantage.

Sir Joshua Reynolds possessed it largely, and perhaps we ought to have added his name to Raphael's. But yet he is not always pure: a little too much of the Correggian is admitted in some of his fancy pictures; and particularly in the expressions of the features.

Gracie, Art of, properly denotes an act of amity, or oblivion, for the pardon of all offenders who are qualified, or come within the conditions of it. The term is also sometimes extended to an act made for relief of insolvent debtors in the several prisons; for setting those who are qualified, at liberty from their debts and confinement.

Gracie, Covenant of. See Covenant.

Gracie Cup, so called because the beverage contained in it was circulated amongst the community, or other company, at a particular time, and by a special favour. It was also called Peculum Charitatis, or the Cup of Charity, as being intended to indicate and promote brotherly love. At other times it was termed the Wafer Cup or Bowl, because each one of the company, in drinking out of it, drank health to his next neighbour in the old terms, Wai beil. William of Malmsbury, describing the customs of Glastonbury abbey soon after the conquest, says, that on such and such particular days, the monks had "Medonem in juitls et viunm in charitatem;" Mead in their cans, and wine in the grace cup. A large cup or bowl of this nature was always heretofore placed on the table of princes, &c. as well as of abbots. In the eleventh volume of the Archæologia there is an engraving of a grace cup, which formerly belonged to Glastonbury abbey, and a description upon it by Dr. Milner. The inside of this cup, which holds two quarts, is furnished with eight pegs, at equal distances, one below the other, in conformity with Edgar's law, to prevent excels in drinking. This measure allowed of half a pint to each person.

Gracie, Days of. See Day, in Law and Commerce.

Gracie, Herb of. See Rue.

Graces, Gratia, in the Canon Law, are the same with what we otherwise call provident; which see.

Graces, Expectativa, Gratia Expectativa. See Expectativa.

Gracies, Gratiae, Charites, in the Heathen Theology, were fabulous deities, three in number, who attended on Venus. Their names are Aglaia or Egle, Thalia, and Euphrosyne; i.e. shining, florishing, and gay; and they were supposed to be the daughters of Jupiter and Eury-name, the daughter of Oceanus, and by others to be the daughters of Bacchus and Venus. Volusius de Idoli lib. xiii. cap. 15. Homer (Hind, lib. xiv.) changes the name of one of the graces, and calls her Paltëhce, and he is followed by Statius. (Theb. lib. ii.)

Some will have the graces to have been four, and make them the same with the Hours, Hours, or rather with the four seaons of the year. See Hours.

The Lacedemonians admitted only two of them, whom they worshipped under the names of Clio and Phaenax. The Athenians allowed the same number, but denominated them Auxo and Hegemone. A marble in the king of Prussia's cabinet represents the three graces in the usual manner, with a fourth, seated, and covered with a large veil, with the words underneath, AD sorites III. Yet Mons. Beger will by no means allow the graces to have been four; the company there present, he undertakes to be the three graces, and Venus, who was their sister, as being daughter of Jupiter and Dione.

They are always supposed to have held of each other's hands, and never parted. Thus Horace, (lib. iii. od. 21.) describes them:

"Segnique nodum folvere gratie."

They were also represented in the attitude of persons dancing; whence Horace says (lib. i. od. 4.):

"Alterno terram quattuor pede."

They were commonly thought to be young virgins. In the earlier ages they were represented only by mere images, that were not cut; but they afterwards were represented under human figures, at first clad in gauze. But the custom of giving them drapery was laid aside; and they were painted naked to shew that the Graces borrow nothing from art, and that they have no other beauties than what are natural.

Yet, in the first ages, they were not represented naked, as appears from Paulanias, lib. vi. and lib. ix. who describes their temple and statues. They were of wood, all but their head, feet, and hands, which were white marble. Their robe or gown was gilt; one of them held in her hand a rofe, another a die, and the third a sprig of myrtle.

They had temples, as we learn from Paulanias, at Elis, Delphos, Perga, Perinthus, Byzantium, and in several other places of Greece and Thrace. The temples consecrated to Cupid were also consecrated to the Graces; and it was also customary to give them a place in those of Mercury, in order to teach men, that even the god of eloquence needed their assistance. Indeed some authors reckoned the goddes of perfusion in the number of the Graces, thus intimating, that the great secret of perfusion is to please. The Muses and the Graces had commonly but one temple; and Pindar invokes the Graces almost as often as he does the Muses. Festivals were appropriated to their honour through the whole course of the year, but the spring was chiefly consecrated to them as well as to Venus. Greece abounded with monuments facred to these goddeses; and their figures were to be seen in most cities, done by the greatest masters. They were also represented on many medals. The fowrs which these goddeses were thought to dispense to mankind, were not only a good grace, gaiety, and equality of temper, but also liberality, eloquence, and wisdom, as Pindar informs us; but the most noble of all the prerogatives of the Graces was, that they prefided over all kindneses and gratitude; infomuch that, in almost all languages, their names are used to express both gratitude and favours.

Graces. There is a good article for Fr. musie, by M. Frumery, under the term Agrément, New Encyc. Meth. p. 54: in this he candidly acknowledges all the defects ascribed to Fr. singing by Rouleau and Burney. See Agrément, Riformament, Shake, Beat, Trill, and Musical Characters.

GRACIAN, BALTHASAR, in Biography, an eminent Spænish writer, was born in 1603. He entered among the Jefuits at the age of sixteen, and became a teacher in their society,
society, of the belles-lettres, of philosophy, and of theology. He likewise exercised the duties of a preacher, and was at length rector of the Jesuits' college of Tarragona, where he died in the year 1658. He was a much esteemed author, and most of his works have been translated into French and other foreign languages. The principal of these are "The Hero?" "Reflections on the political Conduct of Ferdinand the Catholic"; "A Treatise on the Different Kinds of Witty Conceptions." A work treating of the errors to which man is liable, and a collection of meditations on taking the holy communion. Morei.

GRAÇIAS A' DIOS, in Geography, a town of Mexico, in the province of Honduras, and audience of Guatemala, situated at the mouth of a river, which communicates with the bay of Honduras. It has some gold mines in its neighbourhood. N. lat. 14° 30'. W. long. 96° 6'.-Alfo, a cape on the N. coast discovered by Columbus. N. lat. 15° E. long. 132° 50'.-Alfo, a cape, called "Falfe Cape Gracias a' Dios," on the coast of Nicaragua, 63 miles from the other. N. lat. 13° 36'.

GRACILIS, in Anatomy, a muscle of the leg, thus called from its slender shape. It arises partly tendinous, and partly fleshly, from the os pubis internally, between the first and second heads of the triceps; and in its descent on the infe of the thigh, grows narrow, and becomes tendinous, a little below the farius, and is thus inserted into the tibia. It afflits in bringing the thigh and leg inwards.

GRACILIS Rectus, a name given by Riolan to one of the muscles of the leg, called by Winford the rectus cruris anterior, and by Cowper the rectus femoris. Albinus calls it the rectus cruris.

GRACULÀ, in Ornithology, a genus of the order Picæ, having the bill convex and acute at the edges, the bafe rather naked: tongue entire, sharpish, and fleshly; and the feet formed for walking. The genus graculà corresponds with the mainate of Brifton, from whom it appears to have been adopted by Linneus under the former term. Some of the species of this natural tribe were known to Ray, who refers them to the crowes; and also to Willugby, who considers them as of the fare or flaring kind. The species of graculà, described in the Gmelian Systema Naturae, amount to twelve; and this number is increased to fourteen in the work entitled "Index Ornithologicus" of Dr. Latham, by the addition of the new species leopus, and the introduction of the Linnaean Paradisæa trypis, which latter the last mentioned writer has deemed it requisite to remove to this place. As a secondary to the essential or generic character above described, it may be proper to observe that the birds of this kind have the bill thick, and comprefled at the fides; the noftrils small, at the bafe of the bill and sometimes situated near the edge; the toes three forward and one behind, the middle toe connected at the bafe to the outer one, and the claws hooked and fharp. Their principal food consists of fruits and insects.

Species.

The length of this bird is ten inches and a half, its bulk equal to that of the black-bird: the bill an inch and a half long, of an orange colour tipped with yellow; the legs tawny or orange; feathers of the head, except the middle ones, very short and fharp; and the naked band reaching nearly to the nape. This species is found in many parts of India, and not unfrequently in a tame or domesticated state, being naturally of a familiar disposition, and capable of being taught to whistle, sing, and imitate the articulations of the human voice with greater precision than any of the parrot tribe. In the islands of Sumatra and Java it is called by the natives bill-mayang, and in China, whether it is imported from the latter place, its common name is Teaong. Several supposed varieties of this bird are described by writers, the most remarkable of which is that called the greater muncle, le grand moution; this entirely corresponds with the ordinary kind, except in size, when it materially exceeds, being in this respect not inferior to the jackdaw; it inhabits the island of Hainan, in Aafe.

Size of the black-bird, with the head and cheeks bare of feathers and flesh-coloured, except a narrow lift of short brown feathers, extending from the bafe of the bill to the back of the head; the naked part becoming of a deep red when the bird is irritated: the general colour above is silver-afi, beneath grey-brown, bill and legs brown. The birds build their nest in the hollows of trees, especially preferring those of the cocoa-nut: it is represented as a noisy chattering bird, of voracious appetite, and as living principally on fruit. Found in the Philippine islands.

FUTIDA. Black; external part of the quill-feathers blueish; band round the neck naked. Linn. Native of America, in the first ranked the magpie: the head with erect, short, silky feathers; noftrils oval and naked; tongue sharp; and tail even at the tip.

BAKITA. Somewhat grey; shoulders blue; quill-feathers at the outer edge green. Linn. Monedula teta nigra, Ray. Bunt-tailed grackle, Lath.

Size of the cuckow: the bill short, rather black, paler beneath and naked at the bafe; the plumage black, inclining to grey, and glossed with purple; tail rounded, concave when folded, and becoming flat on being expanded: legs and claws black. The species inhabits the Antilly islands and North America. It feeds on insects and fruits.

CRITATELLA. Black, the first quill-feathers at the bafe, and tail-feathers at the tip white, bill yellow. Gmel. Merulà fuscus grislata, Briff. Merle boppé de la Chine, Buff. Chinese flaring or black-bird, Edwards.

A species rather larger than the black-bird; the plumage inclining to blue, with a crest of feathers on the head which it can raise and depref at pleasure; greater quill-feathers from the bafe to the middle white, the remaining part deep blue; tail-feathers, except the two in the middle, tipped with white; legs dull yellow. The crested grackle sings and talks like the species religiosa, but with inferior distinctness; and is frequently kept in cages in China, which country it inhabits in a wild state; its principal food is rice, worms, and insects.

Native of Bengal. Size of the Miffel thrush, with the head, neck, breast, back, rump and upper tail-coverts black; belly, sides, thighs, and under tail-coverts white; tail even at the end, black above, and white beneath. The female differs in being black instead of brown on the fore-
part of the neck and breast, and in the white being more obscure.

Native of Mexico, and the warmer parts of America; the Wilt Indies; rangers finely, builds on trees, is destructive to plantations, but useful in destroying the noxious insects that infest them. The fleth is black and unavailing. Its size is about that of the black-bird, the male a little exceeding the female in bulk; the bill and legs are black; tail long and uncinated, and with the wings purple; the female entirely dully.

Size of a lark; and is supphed by Hallefquisit to feed on insects, the remains of centipedes and scorpions being found in the stomach. The bill is black; neck with a longitudinul rufy line each side, and the claws black.

**Longirostra.** Brown, beneath ochre-yellow; head and neck black; band round the neck naked and wrinkled; area of the wings white; tail uncinated, black, and at the tip white. *Pallas, &c.*

Native of South America; length eight inches. This appears to be the same species as that described by Soumill under the name of merle des Savyes.

**Sturnina.** Hoary; spot on the crown and back between the wings violet-black; tail and wings with a tinge of green, the latter with a double white fringe. *Pallas.*

Inhabits the Oizer banks of Dauria; the nest and eggs resemble those of the thrush; the plumage of the female is dirty ash, with the back brown; and the wings and tail deep black.

**Leucos.** Black; band on the wings and body beneath white; the region of the eyes naked and wrinkled. *Lath.* Le mainite a fite jaune, Vieill. *Yellow faced grackle.*

Length seven inches and a half; bill compressed; nostrils oval; legs yellow and wrinkled. Native of New Holland.

**Cyaneus.** Striated; above tawny, beneath yellowish; head and chin varied with tawny and white; tail wedged, sharp and with the wings tawny. *Gmel. Chinkin grackle.*

Inhabits the interior parts of Guiana; is about ten inches in length, and remarkable for chinkinng trees; the bill is black, about two inches long, and a little curved; the legs are also black.

**Caruncula.** Cinereous; tail and quill-feathers black; crown and chin with warty excrescences. *Gmel.*

Length six inches; and supphed to inhabit the Cape of Good Hope.

**Melanocephala.** Head black, front white; back, tail, and wing-coverts blue-ash, the tail with a transverse white streak near the extremity. *Don. Gracula melanoccephala, Lath.* Le mainite a Lete noir, Vieill. *Black-headed grackle.*

A species recently discovered in New South Wales; its height is about eight inches; the bill yellow, a little bent, and formed at the base like that of the *Turdus*, or thrush tribe; the tail three inches long; the legs very long in proportion, of a pale yellow ochre-colour, and armed with strong blackish claws.

**Viridis.** Dull green; throat above brown and blackish varied; under parts of the plumage white, with some blackish streaks; wings blackish, edged with white; tail blackish, with white tip. *Don. Gracula viridis, Lath.* Le mainite vert, Vieill. *Green grackle.*

Lately found; the species inhabits New Holland, and appears to be very rare; the bill is strong, somewhat inclining at the base, and the colour of horn; the legs blackish.

**Cyanotis.** Space about the eyes bare of feathers and bright blue; head black, with a white cres of the hind part; upper part of the neck, body, capillaries, wing-coverts, and tail yellowish-green; breal lead-colour; plumage beneath white. *Don. Gracula cyanotis, Lath.* Le mainite a orelles bleus, Vieill. *Blue eared grackle.*

Length twelve inches and a half; bill black; legs blue black, with very hooked black claws. Native of New South Wales.

**Picata.** Greater part of the head, the neck; transverse band on the breast, back, border of the wings, and tail above nearly to the tip black; throat, breast, wing-coverts, body beneath, and under surface of the tail-feathers white. *Don. Gracula picata, Lath.* Le mainite pic, Vieill. *Pie grackle.*

Rather larger than the black-headed grackle, and like that species inhabits the regions of Australia; the general colour black and white, the former partially glazed with purple; bill yellow, and corresponding in form with that of the black-headed grackle; and the legs lead colour.

**GRACULUS, the Shagge, a species of Pelecanus; which see. — Alfo, a species of *Corvus*; which see.*

**GRADATION, the act of ascending, rep by rep, to any pitch or eminence; from the Latin gradus, degree, step.**

**GRADATION, in Architecture, signifies an artful disposition of parts, rising, as it were, by steps or degrees, after the manner of an amphitheatres: so that those placed before do no difcourage, but rather service, to those behind.**

The painters alfo ufe the word gradation for an infinible change of colour, by the diminution of the tints and shades. See below.

**GRADATION, in Chemiftry, is a kind of procés belonging to metals. It confits in gradually raising, or exalting them to a higher degree of purity and goodness, fo as to increase their weight, colour, confluence, &c.**

**GRADATION, in Logic; is an argumentation, consisting of four or more propositions, so disposed that the attribute of the first is the subject of the second; and the attribute of the second is the subject of the third, and fo on, till the last attribute come to be predicated of the subject of the first proposition. As in Porphyry's tree; man is an animal; an animal is a living thing; a living thing is a body; a body is a substance: therefore man is a substance.**

An argument of this kind is liable to many fallacies; both from the ambiguity of words and things; e. g. Peter is a man; man is an animal; animal is a genus; genus is an universal; therefore Peter is an universal.

**GRADATION, in Painting, relates both to chiaro-feuro and to colour: that is, all the different degrees in which light and dark, and colour may be modified, are comprehended in it.**

An object receding from the light, and gradually losing it, becomes at its farthest extremity obscurely defined. A coloured body, pure or bright in tint, under the same circumstances, gradually diminishes in clearness of hue through out its receding parts, and becomes dull and dark. By fixing the scale of gradation in both these particulars, effects of great force or great simplicity may be produced. The scale of descent being made rapid, great force will ensue, from the strong oppositions it promotes; and the reverse will take place when the degrees of descent are prolonged, and less contrast thereby effected. The nature of the subjec,
GRA

jeft, and the situation of the figures with regard to light, must's be the artist's guide in this matter.

The gradation of colour includes not only what is mentioned above, viz., the different degrees of purity, or brilliancy of the same colour, but also the approximations of each colour to its neighbour, necessary to produce harmony; and also the art of gradually losing the local colour in obscurity, and yet maintaining the character of it in the object: which is extremely difficult and of great importance in the art of painting.

Gradation, in Rhetoric, is when a series of considerations or proofs is brought riling by degrees, and improving each on the other. See Climax.

Such is that in Cicero to Herennius: "Africanus induftria virtutem, virtus gloriam, gloria memulos comparavit."

GRADI, Italian, degrees. Every ecclesiastical mode, and every key in secular music, has its gradus, its scale; no note of which can be changed by an accidental, flat, sharp, or natural, without changing the key. As in the key of F major with one flat at the clef, annual that flat by a natural, and the key is changed to C, add another flat and it modulates into B♭. GRADISCA, or GRADISCH, in Geography, a town of Germany, and capital of a small county, annexed with Goritz to the dominions of Austria, seated on the Lizonza, built in the year 1473 to flep the incursions of the Turks, additionally fortified in 1764, and erected into a bishopric in 1784; taken by the French in 1797; 35 miles S. of Goritz. N. lat. 46° 21'. E. long. 13° 27'. - Also, a town of Schla- vonia, on the river Sava, near the borders of Croatia, well peopled and fortified; 132 miles W. of Belgrade. N. lat. 45° 10'. E. long. 17° 50'.

GRADISello, a town of Italy, in the department of the Adda and Oglio; 8 miles S. of Brescia.

GRADISta, a town of European Turkey, in Bulgaria, on the borders of Servia; 40 miles S. of Viddin.

GRADISZE, a town of Walachia; 48 miles N. E. of Galac. N. lat. 45° 23'. E. long. 27° 19'.

GRADITz, a town of Bohemia, in the circle of Konigingsratz; burnt by Ziffa; 12 miles N. of Konig- ingratz.

GRADO, a small island in the gulf of Venice, near the coast of Friuli, with a town which was the first see of the Venetian patriarch. N. lat. 45°. E. long. 13° 17'.

GRADUAL, GRADUATE, was anciently a church-book, containing divers prayers, rehearsed, or sung, after the epistle; called in some of our ancient writers gradale, gradamente, graille, &c.

After reading the epistle, the chantor ascended the ambo with his gradual, and rehearsed the prayers, &c. therein; being answered by the choir; whence the name gradual, on account of the steps or degrees of the ambo.

The gradual or graille, which the provincial constitutions of archbishop Winchelsea, made at Merton, A. D. 1305, required to be in every church, was a book containing all that was to be sung by the choir at high masses; the tracts, sequences, balaheums; the credo, officitory; triffigium, and also the office for sprinkling the holy water.

"Gradale fíc dictum, a gradulibus in tabe libro conten- tis."

It is sometimes taken for a mafs-book, or part of it, instituted by pope Celelino, anno 430. See flat. 37 Hen. VI, cap. 32.

In the Roman church, gradual is an appellation still given to a verse which they sing after an epistle, and which was anciently rehearsed on the steps of the altar: though Ugolino gives us another account, and says it took its denomination gradual because sung in the gradual aecent from note to note. Magri speaks differently still, and will have it to have taken its name because sung while the deacon went up the stairs to the pulpit, to sing the Gospel.

GRADUAL, Gradualiis, is also applied to the fifteen psalms, sung among the Hebrews, on the fifteen steps of the temple. Others are rather of opinion that they were thus denounced because the fingers raised their voice by degrees, from the first to the last.

Cardinal Bona, in his treatise of Divine Psalmody, says, the fifteen gradual psalms are intended to represent to the mind, that we only arrive at the perfection of good-sts, or holiness, by degrees. He goes on to lay down the fifteen degrees of virtue, corresponding to the fifteen psalms; five of them are for beginners; five for proficients; and the rest for the perfect.

GRADUATE, a person who has the degrees of any faculty: a graduate in phyllic, in divinity, in music, &c. See Degree, Doctor, &c.

This privilege of graduates is no older than the fifteenth century; it being observed, that men of learning were much neglected by the collators, and patrons of churches; complaint, therefore, was made to the council of Baif, where this decree was made; which was afterwards confirmed by the Pragmatic Sanction, and again by the Concordat.

GRADUATION of Astronomical Instruments, is the dividing of a circle, or of some aliquot part thereof, into degrees and its sub-divisions, on the limb of any instrument that is used for measuring angles with a great degree of accuracy. (See the article Degree.) When the instrument to be graduated is of a portable size, admitting of only a small radius of curvature for the limb that is to be divided, the operation is very readily as well as accurately performed by an engine, such as Ramdhen's or Troughton's, the former of which we have described under the article Engine for divid- ing Circles, &c. but when the radius of the instrument is too large to admit of division by an engine, the task of graduat- ing, by the determination and adoption of original dividing points or lines, requires no ordinary portion of skill, manual dexterity, and perseverance to be united. Before the estab- lishment of the Royal Observatory at Greenwich, the art of graduating was in a rude state, but a desire to have this institution furnished with superior instruments of observation has stimulated the different astronomers royal, successively, to encourage the talents of inferior arts from time to time, till at length such perfection is attained, that little more can now be hoped for in the improvement of our bell English instruments. The history of the art of graduating astronomical instruments, and the gradual development of the most convenient and most accurate modes of proceeding, together with the difficulties to be surmounted in the various stages of progress towards perfection, will be best explained by a concise detail of each successive method of dividing, that has been practiced, agreeably to the order of time; and by remarks arising out of each detail, as they most naturally occur.

We know not sufficient of the altrolahs of Hipparchus and Ptolemy to enable us to give any satisfactory account of the nature and accuracy of their divisions and sub-divisions, though it is probable that the graduated circles on them contained each 360°, agreeably to the Egyptian mode of dividing the circle. Neither can we give a very perfect de-
scription of the manner in which Copernicus, long afterwards, had his artificial and meridian quadrant graduated, though we have shown under our article Circle that his parallactic instrument, with which his altitudes were chiefly taken, had its limb divided by equal divisions that were the subfences of \(3^49^1\) each.

Tycho Brahe's instruments had the advantage of a long radius, which rendered any inequalities that might occur in his divisions of less value than they would have been in instruments of short radii; the finest sub-divisions into which he professed to mark his spaces were \(10^\circ\) each, and the single minutes and portions of a minute, even to \(15^\prime\) and \(10^\prime\), were indicated by triangular diagonals; but with what degree of precision the sub-divisions were effected, and what dependence could be placed on his diagonals, as to accuracy, at this distance of time, it is not an easy matter to ascertain: it is recorded, however, that the operation of graduating his instruments was performed by his own manual labour.

And what we have here said of the instruments of Tycho Brahe, is equally true of the maquinca celeste of Hevelius; whatever accuracy his apparatus possessed, was the result of his own persevering industry, but we are not aware that his methods of proceeding have been particularly detailed.

In Dr. Hook's Animadversions on the Machina Celestis of Hevelius, 1674, this very ingenious mechanick has published an account of his method of racking the external edge of the limb of his quadrant, as performed by Tompion, which method, he says, "does not at all depend upon the care and diligence of the instrument-maker, in dividing, graving, or numbering the divisions, for the same screew makes it from end to end." But, as Smeaton has very properly observed, this inventive contriver has not given his reader any precautions or particular directions how the perfection of the screw is to be ensured, or how the notches of the rack work are to be rendered perfectly equal among themselves, notwithstanding the unequal densities, and hardnesses of different portions of the metal on racked. The difficulties alluded to here, were acknowledged by the duce de Chaulnes, in a memoir of the Royal Academy of Sciences at Paris, published in the year 1765. The doctor calls the account of his method, "an explication of the new way of dividing," and as an original invention, it may probably be called his own, though the want of a perfect screw, with intervals exactly proportioned to the effective radius of his quadrant, was a source of error, that posterior contrivances were required to remedy. See Engine (by Ramden) for cutting the screws of the circular dividing engine.

The use of Dr. Hook's screw for racking the limb of an almanac instrument was not, however, abandoned, without a fair trial of its accuracy in reading the quantity of the angles so measured; for Flamhead, (or Flamhead,) on his appointment to the Royal Observatory in 1676, employed Tompion to construct him a sextant of fix feet nine and a quarter inches radius, at the expense of Jonas Moore, with an endless screw of fourteen threads per inch, acting on the racked edge of the limb, and with telescopic fights, which had not been before used; the result of this trial was, that some shake took place in the notches, that were worn by the screw, and frequently an error of a whole minute in reading an observation was unavoidably produced thereby. To remedy this evil, in the following year degree spaces, with diagonal divisors to read to the accuracy of \(10^\circ\), were added as a check on the measures of the screw, and a column, to contain the check angle by diagonal lines, was filled up from the 1th of September of the year 1677. These additions, it appears, from the Prolegomena of the Historia Celestis, were inserted by Flamhead himself, and a comparison of the screw with the diagonals proved that an error of as much as one minute was frequently the result of the reading by the screw. In an observation of the moon, taken on the 9th of June 1687, Smeaton says, that on looking over the observations, he detected an error of \(55^\prime\), which, upon a radius of six feet nine inches, he calculates amounts to more than \(\frac{1}{36}\) part of an inch. The screw, however, was useful for giving a regular flow motion to the telescopic fights, and though its use, as an accurate measure of a large arc, was soon abandoned in almanacal instruments, it has been retained as an excellent mode of producing a flow motion, by the aid of a tapped clamping piece, and has been applied with great success to the limb of a dividing engine, which, being a complete circle, admits of equalization of the contiguous notches, by a long continued simultaneous action of several threads of a very perfect screw, carried many times all round the circle, when the exact situations of distant notches have been ensured by the checks afforded by accurate divisors, previously made on its plane.

Notwithstanding what we have above said of the imperfect measuremen of an angle by the screw, it was not relinquished without another trial in Flamhead's time, by Abraham Sharp, his eminence in, whose skill and dexterity in manual operations of a mechanical nature both Flamhead and Smeaton have borne ample testimony; the latter of whom says, "I look upon Mr. Sharp to have been the first person that could accurate and delicate divisions upon instruments." The instrument at which Sharp laboured, and to which he applied the screw in conjunction with the diagonals of the divided spaces, in 1689, was the mural arc at Greenwich, of which the radius is fix feet seven inches and a half. "But yet," says Smeaton, in his paper on this subject, read November 17, 1785, at the Royal Society's room, "whoever compares the different parts of the table for conversion of the revolutions, and parts of the screw belonging to the mural arc into degrees, minutes, and seconds, with each other, at the same distance from the zenith on different sides, and with their halves, quarters, &c. will find as notable a disarrangement of the screw-work from the hand-divisions, as had appeared before in the work of Mr. Tompion; and hence we may conclude, that the method of Dr. Hook, being executed by two such masterly hands as Tompion and Sharp, and found defective, is in reality not to be depended on in nice matters."

This inference of Smeaton obviously implies, that what he calls the hand-divisions of the mural arc, are more accurate than the readings by the screw alone; but, as he has given no other test of the accuracy of these hand-divisions, nor has explained by what process they were infurited, the more legitimate inference would have been, that either the screw, or the hand-divisions may be faulty, or both may be so in their respective degrees. It is to be regretted that Sharp, who was a mathematician as well as a mechanick, has not published the method he adopted of marking out and cutting his dividing lines, which is more immediately the subject of our present article. Had he made his hand-divisions still, and checked his notches, made by the screw, thereby, as Ramden did with his engine afterwards, his measures by the screw would have been more perfect, though the centre-work might have been liable to be galled by too much preasure of the screw against the notched edge of the instrument, when frequently used.

Nearly about the time that the mural arc was fixed at Greenwich, Olaus Roemer, the Danish astronomer, supplied his domestic observatory with an instrument that had divisions and telescopic fights moving in the meridian, by means of a long axis, common to both the divided arc and telescope, which
GRADUATION.

which therefore admitted of better adjustment for the vertical motion than the mural arc was capable of; and which may be considered as the first transit instrument that properly deferves such a name. In dividing his arc, Mr. Roemer disregarded the total length, with respect to an exact number of degrees, and looked more particularly to the equality of the divisions, which were convertible into degrees and minutes, by a table calculated for this purpose. The method he made choice of, for rendering his divisions equal, was to begin at one end of his arc, and to proceed by stepping, and by marking the dividing points with a proper prefix at each step, till the whole arc was finished: for this purpose he did not depend on a pair of dividers, however straight their legs, but two fine pointed pieces of strong tempered steel were tied, or otherwise fixed together in such a way, that the distance between the two points was 1/4th of an inch, and the radius of the arc to be divided was so proportioned, from 2 1/4 to 3 feet, that this distance made a space very nearly equal to 10'; whether exactly so, or not, did not signify, as the difference was allowed for by the calculated table, when an angle had been read by the divided spaces as numbered. It is easy to conceive that this mode of measuring an angle would be as accurate as any other, after the due allowance was made, provided the spaces were perfectly equal to each other; but the theory of this method is more perfect than the practice; for none of the mixed metals is so perfectly uniform in its density, and so free from hard particles, occasionally met with, by the fumbling points, as to ensure the perfect equality of the divided spaces, however carefully the fumbling points are pressed in a vertical direction; the smallest deviation on making the first impression becomes greater by preface, and an attempt to rectify any erroneous points can never be depended upon: but, what is worse, every individual deviation from perfect equality is charged on the whole arc, which therefore will be either longer or shorter than the true length, by the aggregate of all the positive, or negative quantities, that predominate in the inequalities of the individual spaces thus divided; and the longer the arc is from the first point, when any angle is measured, the greater is the error of the measurement in all probability, because the greater is the probable aggregate of the deviations from perfect equality in the spaces. The total arc thus divided was about 75'; but as Roemer applied no correction to the errors of the distant divisions of this arc, no dependence could be placed on the result of the readings, even when converted into degrees and minutes by his table, which supposed the arc perfectly divided.

The next ingenious artist who distinguished himself in the art of graduating astronomical instruments, was the celebrated Graham. At the appointment of Dr. Halley to the Royal Observatory of Greenwich, Flamsteed's instruments were removed by his executors, and in the year 1725, Graham undertook the construction of a new mural quadrant, which remains as a standing proof of his skill, to this day, in the said observatory. This artist availed himself of every contrivance that had been practised by his predecessors, and invented such a strong, and, at the same time, light method of constructing the frame-work of the iron quadrant, contrived by Jonathan Sisson, as evinced his superior knowledge of mechanics, as well as Sisson's precision in the workmanship. The diagonals were now rejected, as being incapable of being read by a fiduciary edge with requisite exactness, and the vernier scale was fubstituted as much preferable in this respect, and the beam-compass, with equal advantage, was fubstituted for the ruler and dividing knife, which were liable to considerable parallax, notwithstanding the greatest precaution taken in drawing the dividing lines, or in marking the dividing points. The screw for flow motion was also used for dividing the vernier scale in a proper way, after its value was ascertained; and its perfection was ensured, with respect to the due inclination of its threads all round, as well as to the equality of their spaces: and haftly, in order that the advantage of continual bisecton might be introduced as a check on the degree spaces, the quadrant was divided in 96 spaces, with sub-divisions, in a separate arc: and the readings from the 96th arc were a confant tell of the readings by the 90°, when converted into degrees and minutes by calculation, or by a table used for that purpose.

As it is not our intention to describe here the structure of Graham's quadrant, but merely to describe his method of graduating the limb of brares, which was laid over the iron frame, we shall satisfy ourselves by stating that two separate arches were ftruck by a beam-compass, painted from bending by several bracing pieces; the respective radii of which were 60 85, and 95 8 inches. The inner arch was divided into exact degrees, and twelfth parts of a degree, or 8 spaces; but the outer one was divided, as we have said, into 96 equal parts, and each of these again bisected into 16 equal parts, so that the sub-divisions were 10 each other as 188° : 139°, or in smaller number, as 25 : 12. To convey to the reader an idea how the arcs were divided, suppose the quadrant to be represented by fig. 1. of Plate XVIII. of Astronomical Instruments, and that the occult line a b d be required to be divided into degrees by points inserted therein, as centres for cutting the dividing lines from; the known property of the circle, that the chord of sixty degrees is always equal to the radius, afforded the means of laying down the total arc of 90° in the first place; thus, from the point a, or zero of the arc, the point b was marked by measurement of the same points of the beam-compass united, that struck the occult line; and this arc of 60° was bisected at c by an extent nearly equal to the chord of 30° from the points a and b respectively; the extent, however, being a trifle less than the chord of 30°, the two sweeps did not intersect each other, but approached to nearly together, that is, where the sweeping lines was bisected by a point put in by hand, by the aid of a magnifying eye-glasf: the distance of this point c from a or b was laid along the limb from b to c, the extreme point of the whole arc of 90°, and when this operation was so carefully performed, that the arcs a c, c b, and b d were precisely of the same length, when compared with each other, the total arc might safely be depended on, as being of its true dimensions. During this nice operation, it was performed, that the length of the dividing beam had not altered by any variation of temperature. The next step was to bisect each of those three arcs of 30° into fix of 15° each, in the same manner as a b, the arc of 60°, was bisected into a c and c d; but the arcs of 15° were not divisible into a lower number than three parts of each 5°; in order to tripartite each arc of 15°, a separate arc was used, as an arc of trial, described by the original radius united, and 1/4° was transferred to it, and divided by trial till one-third of it was ascertained to measure exactly the distance between the two points of the compass; this distance was then laid off from both ways from the aforesaid points of the arcs of 15°, and the second space of each being found equal to their contiguous first and third spaces thus measured, the whole arc was sub-divided into 18 equal arcs of 5° each; in the same manner, a fifth part of one of the arcs of 5°, first transferred upon another part of the arc of trial, was ascertained by repeated adjustments and examinations, and then inserted within the divisions of the
divided arc, by turning the points over twice each way, from every point already laid down, and then the middle space of each five being found equal to the extreme as well as contiguous spaces respectively, the whole arc was subdivided into points of one degree of distance from each other. But to ensure a perfect equality among these spaces required great readiness of hand, as well as observation of the eye, and caution, to preserve the regulated distances of the points, unaltered during the operation. Of course, the marking point was required to be line, and at the same time well tempered, as well as strong enough to bear pressure, which pressure was at first necessary to make it in a perpendicular direction on the face of the limb. The sub-divisions of the degree spaces into 12 parts of 5° each, were done first by trisection, and then by bisection, or vice versa, in the manner we have already described; and the delicacy of these operations, on so small a scale, required extraordinary attention and care to ensure perfect equality among the smallest sub-divisions, which were now in a file to be transferred by lines tending to the centre of the arc to be graduated. This was an operation that could not be done well by the straight edge of a rule, and a marking point, or dividing knife that would be liable to deviate a little, notwithstanding the greatest care; here another, but smaller beam-compas was sublitted for the ruler, probably for the first time, for the purpose of transferring the graduated points from the occult arc into the arc to be graduated, in the following manner; suppose the points g and e to be intended to be transferred; because the lines to be cut, as the dividing lines, are required to be in a direction tending directly towards the centre o of the concentric arcs, described on the limb; the distance of the cutting point, from the stationary point of the compasses, was taken of such a length, that the cutting point croffed the arc to be cut at right angles, or, in other words, the beam was so situated, as to become a tangent to the arc to be cut; therefore the distance of the two points of the beam was regulated by the distance of the occult line of dots q, b, d, from the arc to be graduated by the straight lines, or rather by the curved lines, which in fact were substituted, and which passed without sensible error for straight lines, when the tangent line in question was long. From the point or dot p, the curve b k was drawn, and from the dot e the curve f i; but in such a way that a small portion only of each, that lies between the circular lines, was cut on the face of the instrument. In the same manner all the other dots were successively transferred, while each representative of the numerals 5, 10, 15, &c. were made longer than their intermediate lines of division, and the sub-dividing lines were again filled shorter. The vernier carried by the telescope, when nicely and accurately divided, would detect any inaccuracy in the sub-divisions thus transferred, by the aid of a magnifier properly adjusted.

The arc of 96 divisions, with their sub-divisions, was not, properly speaking, graduated, but divided and subdivided into portions of smaller value than degrees, and 5° spaces; but as the number chosen is divisible continually by the number two, it was completed by continual bisectsions, which method therefore requires no further explanation. We are told by Dr. Smith (in his Optics) that these two arcs were never found to differ from each other more than 5' or 6' on any part of the limb, but that when there is such difference, the preference ought to be given to the bisection of the arc of 96 divisions.

To prove that the spaces obtained by the lines of transfer are equal to those between the corresponding dots on the points, let e f and g h be joined, also of, o b, o r, and o g; and the triangles o e f, g o h, will be very nearly equal, and equal to each other; therefore, if the common angle e o f be taken away from the equal angles e o f, g o h, the angles e o g and f o h, that remain, will also be equal to each other.

It does not appear that Graham took any measures to guard against, or even to detect the errors that his method of dividing is liable to, from variations of temperature in his quadrant and beam, during the time that the operation is going on, and from the corresponding variations of length in the metals, according to their respective expansibilities; nor is it quite certain that he was aware of the probable extent of such errors, seeing he constructed the frame-work of his instruments of iron, and had his circle to be divided of brafs. In Dr. Bradley's zenith sector made by Graham, Dr. Maldeyne has caufed an iron limb to be sublitted for the original brafs one, and has had the points of division invested on fluid of gold, to avoid the errors that arose from the unequal expansibility of the different metals.

We might here mention Mr. H. Hindley's plan of dividing a circle by a toothed circular plate and endless screw in form of an engine, about the year 1750, but that we think his method of dividing and drilling the holes of his plate, by bending a straight slender bar of brafs into a circle, and transferring the holes therefrom, cannot be depended on where much accuracy is required in the divisions of a circle. It was originally intended, and is much better calculated, for dividing and cutting the notches between the teeth of a wheel; but the reader may see the plan described, and some improvements on it proposed by Smeaton, in his paper already mentioned, as contained in the Philosophical Transactions of London, in the year 1785.

Jeremiah, the son of Jonathan Sifton, was of Graham's school of dividing, and did nearly as much justice to the method he adopted, as Graham himself, probably; and his nice care, and perceiving the adum, have claffed him among the first dividers of his time; but we are not aware that he was the inventor of any original contrivance, except, perhaps, that he applied a triple index to some of his instruments, one of which had the vernier, and each of the others had a single line or stroke drawn at one-third of a circle from each other, and from zero of the vernier, which might act as a check on the eccentricity of the circle, as well as on the inequality of its divisions; though it does not appear certain that this was the original intention, as the three props of his vernier-bar in his theodolites required it to be triple; but in his circular indexes one stroke only was made, and that opposite the vernier: the importance of a triple vernier has not been noticed particularly by any one, previously to the time of Mr. Ed. Troughton's introduction of the triple vernier into his circular instruments. Mr. Ludlam, however, says, that Sifton very early rejected the method of trisecting, and that of flitting too. Having (by means of the radius and bisects only) divided his quadrant into three arcs of 30° each, he set off in each of these arcs the chord of 21 20', or 256 times five minutes. This chord was taken off a scale of equal parts, and was checked by the chord of 8 40', both chords together filling up the arc of 30°. The arc of 21 20' was divided by continual bisections into arcs of five minutes each. This description, says Mr. Ludlam, in a note to page 4, of his Introduction and Notes on Mr. Bird's method of dividing, was given by Jeremiah Sifton, in a private letter dated May 20, 1766; and according to the same letter to the premises also, that Sifton placed the fixed or central point of his compasses in a blank tangent line, as hereafter described by Bird, during the operation of transferring the divided points into linear divisions; but as Bird has in the year 1767 published these processes as originally his own, and as he worked for the Sifions previously to 1766, we are disposed to consider Bird, and not
either of the Siflons, as the real conqueror of the methods here advertised to. Sillon (the younger) rejected the arc of 96', as being only a help to a bad divider; but Bird used to retort on him, by saying, that good dividing was not afraid of such a test of its accuracy.

It is the characteristic of a great genius in mechanics, not to tread too closely in the steps of his predecessors, but, availing himself of any hints that may have been presented to him, to mark out a more direct and even path for himself, that shall throw in his way fewer obstacles to impede his progress. This was the case with Mr. Bird, who, having been brought up a cloth-weaver in the county of Durham, and having noticed some very coarse divisions on the face of a clock that fell in his way, immediately set about dividing one himself, in a much neater manner, and was so pleased with his successes, that in the year 1740 he came to London, and was in high favor as an instrument-maker, only five years afterwards. After having made himself acquainted with the methods at that time in use of dividing a circle, he saw that no one had guarded against the errors produced by the effects of variable temperature on the beam of the compasses, as well as on the marks of the scales and circles to be divided; he also saw that bisection of an arc had so much advantage over trisection, or quinquesection, that he abandoned the latter modes of dividing altogether, and was the first probably to compute chords, to be taken from a good vernier (what he calls nonius) scale, by the beam-compasses, in order to determine such points in an arc of 90°, as may enable a division by continual bisection to be adopted, and at the same time such as may be laid down without loss of time, or, in other words, without sensible change of atmospheric temperature.

We cannot better describe Mr. Bird's method of dividing astronomical instruments than by using his own words. "The requisites," says he, "for the performance of this work are as follows: A scale of equal parts, by which the radius may be measured to 0.001 of an inch must be provided. My scale is 90 inches long, each inch divided into 10, continuous to which are nonius (vernier) divisions, viz. 10 inches divided into 100 equal parts, shewing 0.001 of an inch, and by the assistance of a magnifying glass, of one inch focal length, a third of 0.001 may be taken off by estimation."

"Provide fine beam-compasses, to which magnifying glasses of not more than one inch focal length should be applied. Let the longest beam be sufficient to draw the arcs, and measure the radius; the 2d to measure the chord of 42° 40'; the 3d to measure the chord of 30°; the 4th, 20°; the 5th, 40°; and if a 6th, to measure 15°, be made use of, so much the better."

"The radius of the arc of 90° at the points is equal to 95°-98 inches, from which the following numbers were computed. viz. 46.6615 inches = chord of 20°; 25.0448 inches = chord of 15°; 17.270247 inches = chord of 10°-20'; 8.8186 inches = chord of 4°-40'; and 69.80318 inches = chord of 42° 40'. Having drawn the several arcs, between which the divisions were to be cut, the radius and the lengths of the above chords were taken by the beam-compasses, which, together with the scale, were laid upon the quadrant, where they remained till the next morning; during which time, the door of the room was kept locked. Before sun-rise I re-measured the radius, which required some correction; the beam being of white fir, and the scale of brass, which probably contracted, while the beam remained unaltered; the other beam-compasses also required correction. Now the quadrants and scale being of the same temperature, the faint arc of 6 degrees was bisected in a."

Plate XVIII. of "Astronomical Instruments," (1) is [blank] and with a very fine prick-punch (pointtil) the point a was made; with the same beam-compass I laid off from a to e the chord of 60°, making also a fine point: with the chord of 30° a e was bisected in e. Now one point of the beam-compasses containing 60° was fixed in e, and with the other was marked: the point r or 90°: next, with the beam-compasses containing 15°, was bisected r r in n or 75°; from a was laid off the chord of 10°-20'; and from r, 4°-40'; which two last chords joined exactly in g, being the point of 85°-20': now each degree being to be divided into 12 parts, or every 5', therefore, 85 x 12 + 4 = 1024, a number divisible by continual bisections. The half chord computed was 42° 40', with which a g was bisected in e; a o and e g were bisected by trials: but, whoever undertakes to divide a large quadrant, will do well to compute also the chord of 21° 20'; but for this chord any of the beam-compasses already provided, which will take in the length, may be used. The point g, being formed as above, I proceeded, by continual bisections, till I had the number required, viz. 1024. To fill up the space between g and r, containing 56 divisions, the chord of 6a divisions was laid off from g towards d, and divided like the rest by continual bisections; as was also from a towards b. The points 30°, 60°, 75°, and 90°, fell in without any sensible inequality."

"So much will suffice for giving a general idea of Bird's proceeding in dividing his astronomical instruments; but his method of transferring the divided points into dividing lines was equally original, and guarded also against errors that might arise from the handling of the beam during the operation, by variable temperature; before, however, we proceed to detail this process, it may be proper to observe, that the points made on the faint circle were inferred by a pointtil, or piece of steel-wire, with a conical point made fall into a piece of cylindrical brasses rounded at the upper end: the steel part was 5/16 of an inch thick, and 3/16 of an inch long, and the brasses part 2 1/2 long, and 1/16 of an inch in diameter. The angle of the steel conical point was from 25° to 25°, and the point somewhat above a spring temper, so that the point made in the circle did not exceed 0.001 of an inch; as it was sharpened on an oilstone while turning round, and while drawn in a direction outwards from the point itself, the surface partook of the nature of a counter-link, and, as it were, drilled a diminutive hole of a conical shape when gently prefixed on, as it revolved in the point of bisection, which point, by reason of the four angular bars made by the interfacing lines, could be felt as well as seen. The points of the beam-compasses were never made to approach nearer to each other than two or three inches, but at the ends of the arcs springdividers, conical points, were substituted to measure small arcs. Another precaution was, that in all bisections, the place to be pointed was laid off from left to right, and then from right to left, from the respective central points.

"As the maxim, "That an arc may be bisected, but not practically trisected or quinquisection with certainty," was the maxim adopted by Bird, when he introduced the use of his scale for measuring the chords, so the maxim, "that a right line cannot be cut on brass, so as accurately to pass through two given points, but that a circle may be described from any centre, to pass accurately through a given point," was taken up by him when he adopted the beam-compasses, as Graham and Sillon had done, for cutting the small portions of a circle, instead of perfectly straight lines, as boundaries of the divisions. His plan of doing this, however, was new, as may be seen from his own words."

"The next step," says he, "is to cut the linear divisions

\[ \frac{3 \sqrt{2}}{2} \]

from...
from the points: the best instrument for this purpose is the beam-compasses, having both its points conical and very sharp. 

Draw a tangent to the arc $b$, suppose at $c$, it will intersect the arc $x y$ in $g$, this will be the distance between the points of the beam-compasses to cut the divisions (nearly) at right angles to the arc $b$. Lodge that point of the beam-compasses next your right hand, in the point $r$, let the other fall freely into the arc $x y$; press gently with your finger upon the screw-head that fastens the socket (and that is convex), and with the point towards the right hand cut the divisions. In this manner you must proceed with the rule.

The intention of transferring the central or reeding point of the compasses into a blank tangential line, instead of filling the said point to reed in the respective points made in the faint arc, is, that in the former case should any alteration take place in the length of the beam, during the operation of cutting, no error is charged on the divisions cut, but the alteration is compensated by the distance of the newly made point in the tangential line from the cutting point; that is, each division is charged only with such a minute error, if any, as arises from temperature during the act of cutting a single stroke, and if one of the points should break, another may be replaced without inconvenience; whereas, by the method of Graham, a broken point produces considerable difficulty; and the whole error arising from temperature, during the whole process of cutting all the divisions, is charged not only on the total arc, but likewise in a certain undefined degree on each of the whole divisions. This idea of getting quit of the effects of temperature is ingenious, but has been objected to as liable to the ill effects of slipping in a certain degree, insomuch as that a hard particle, lying under the point of reed, may cause a little deviation in the distance, before the stroke is cut. This objection, however, was not allowed to be realized by Bird, who no doubt must have obviated it by some other plan, had he found any real inconvenience arising from it. Great care, notwithstanding, must have been taken in setting down, and pressing on the point at reed, in a perpendicular direction. Another objection applied to Mr. Bird's scale, from which the chord-lines were measured, insomuch as the scale itself might be erroneous in some places, and would impart its errors to the arcs measured from the computed chords taken therefrom.

Besides the arc of 95°, the mural arc by Bird had an arc of 95 divisions, like Graham's, divided by continual bisections, till each of the 95 divisions had 16 sub-divisions, as a check on the accuracy of the arc of degrees; but sub-

The vernier was retained by Bird as the best method he knew of sub-dividing the 5 spaces into quantities of 30 each, which was the smallest angle he professed to measure; and to effect his purpose he made ten divisions on his vernier equal to eleven on the limb of the instrument, first by computing the chord of thirty-two parts, and then by taking ten out of those parts, when bisection, as the proper divisions for the vernier; these, being made in points, were also transferred by a tangential line into linear divisions by the beam-compasses, as before described; but great care was taken, that the stroke zero on the vernier was drawn from the quadrant's centre, precisely parallel to the line of collimation of the telescope. Mr. Ludham says, that the cutting-point which Sisson used was flat in the knife-edge form, but that Bird's was a triangular prism, with a slope ground down to a point at one of the angles, which formed the cutting-point.

At the request of the commissioners of the Board of Longitude, Mr. Bird, in the year 1767, published his method of dividing in a quarto pamphlet, for which they rewarded him with 500l. besides 60l. for his plates, after having bound him to instruct an apprentice of seven years in the art of contracting and dividing astronomical instruments.

Mr. Smeton is of opinion that Bird's method of dividing may be improved in one respect, and expresses himself on the subject thus:

"I must here observe that I apprehend no quadrant, that has ever undergone a severe examination, has been found to form a perfect arch of 95°, nor is it at all necessary it should; the perfect equality of the divisions throughout the whole is the first and primary consideration; as the proportion of error, when ascertained by proper observations, can be as easily and readily applied when the whole error of the rectangle is fifteen seconds, as when it is five. In this view, from the radius taken, I would compute the chord of 16° only. If I had an excellent plain scale, I would use it, because I should expect the deviation from the right angle to be less than if taken from a scale of moderate accuracy; but if not, the equality of the divisions would not be affected, though taken from any common diagonal scale. This chord, so prepared, I would lay off five times in succession, from the primary point of given, which would complete 80°; I would then bisection each of those arches of 16°, as prescribed by Mr. Bird, and laying off one of them beyond the 80th, would give the 88th degree, proceeding then by bisection, till I came to an arch of 2°; laying that off from the 88th degree, would give the point of 95°. Proceeding still by bisection, till I had reduced the degrees into quarters of each, I would there stop, as from experience I know that when divisions are over close, the accuracy of them, even by bisections, cannot be so well attained, as where they are moderately large. If a space of 5ths of an inch, which is a quarter of a degree, upon an eight feet radius, is thought too large an interval to draw the index over by the micrometer screw, this may be shortened by placing another line, at the distance of one-third of a division on each side of the index-line, in which case the screw will never have to move the index plate more than one-third of a division, or 5', and the perfect equality of those fine lines from the index line may be obtained, and adjusted to 5 precisely, by putting each of the fine lines upon a little plate, capable of adjustment to its true distance from the middle one, by an adjoining screw. The above hint is not confined to the chord of 16°, which prohibits the sub-division going lower than 1 5'; for if it be required to have divisions equivalent to 5 upon the limb itself, then I would compute the chord of 21° 20' only; and laying it off four times from the primary point, the lead would mark out the division 85° 20', pointed out by Mr. Bird, supplying the remainder to a quadrant from the bisected divisions as they arise, and not by the application of other computed chords." Mr. Smeton, sensible, however, that this method of laying 16 five times over, or 21° 20' four times over, may be objected to, as liable to the errors of bisection, arising from Roemer's method, afterwards proposed to lay down the chord of 64', or of 85° 20', from computation all at once, and then to bisect, and complete the quadrant from the bisected divisions, which Mr. Bird himself preferred as a good method for Hadley's sextants and octants. But these plans are now superceded for instruments of small radius by the dividing engine, which performs the work with great expedition, as well as accuracy, and the original methods of dividing the circle are only useful for the larger
larger instruments, and for the finifhing of the dividing engines themselves.

In the year after Mr. Bird had published an account of his method of dividing astronomical instruments, the duc de Chaulnes printed in French a folio work, entitled " Nouvelle methode pour diviser les Instruments de Mathematique et d'Astronomie," and also a work proper to be bound with the former, called "Description d'un Microfcope et de differens Micrometres destines a mefurer des parties circulaires ou droites avec la plus grand precision." The former of these pamphlets contains 15 plates, and the latter fix, which exhibit plans and drawings in different points of view, of all the apparatus, both in pieces and together; these are not necessary to be copied by us, but we will describe them as far as they fall within our present purpose. This new method of dividing is performed by the affilience of compound microscopes, with cross hairs in the focus of the eyeglafs of each, to be fixed to the circle to be divided in any given situation, and of moveable pieces of brass with fine dividing lines marked thereon, which may be so fixed with wax, as to be adjustable to the point of intersection in the circle of any of the microscopes, and when duly adjusted, a sliding pointer, moving in a complex frame of brass, cuts the line, on the circle to be divided, that shall correspond to the point of the circle where the adjustable division is fixed; though the line cut is not in the fame part of the circle.

As this method may be considered as the ground-work of Ramsden's method of dividing a large circle, and has not, that we know of, been translated into our language, we will give the substance of that part of the work which more immediately relates to our present subject, without following the author through all his minute details. The circle, which the duc de Chaulnes proposes to divide by his original method, is the table of his dividing engine, but as it is equally applicable to any circle that may be fixed concentrically on it, we will suppose it an astronomical circle for altitudes or azimuths that is to be divided by his method. In the first place, he proposes to have from 30 to 40 thin pieces of smooth brass about one-third of an inch long, and one-sixth broad, having each a fine stroke drawn across, perpendicular to the long sides and just deep enough to be seen; and secondly, three compound microscopes are to be provided, one to be fixed diametrically opposite the pointer, or cutting point, that is carried in and out, i.e. towards and from the centre of the circle by an adjustable frame, and the other two are adjustable to any given points along the plane of the circle to be divided. When the circular lines are struck on, the adjustable microscopes, which we will call A and B, are placed as opposite to each other, in a diametrical line, as can be guèfled, or roughly measured by any of the ordinary means, and a moveable division on a piece of brass already described, is put by means of wax under each of the two microscopes, and moved by hand, till the lines, which must be in a radial direction, fall respectively under the centres or intersecting points of the fields of view; these microscopes, it must be understood, are fixed, not on the table which bears the circle, and which is made so as to revolve on a long vertical axis, but on a fixed or stationary surrounding frame, that is connected with the table itself, when the table is at liberty to revolve; suppose now the table and circle on it to be carried half round, while the microscopes remain fixed, in such a way that the moveable division which was under the microscope A, falls under the centre of microscope B; in this situation, if the opposite division falls under the centre of A, the circle is truly bisected; but as this is not likely to be the case at the first trial, the quantity that is over or short must be adjusted, one half by the moveable division, and the other by the microscope, and the operation of reversing must be repeated, and the rectifications made, till the circle is found to be truly bisected, both backwards and forwards, by the coincidence of the divisions with the intersected points in each focus of the microscopes. The two microscopes A and B may now be removed, and the third or fixed microscope must be made fast over one of these two dividing strokes, after the pointer has been brought precisely to occupy the place of the other, in which situation the pointer and the fixed microscope will stand so diametrically opposite each other, that whenever an adjustable line is brought to bisect the field of view of this microscope, the pointer will be ready to cut a line on the opposite side of the circle, and whenever a set of adjustable divisions are properly placed, by the wax, on one semi-circle, the lines in the other semi-circle, directly opposite these respectively, can be permanently cut, before the moveable pieces are taken off, and afterwards the said lines so cut may be brought successively under the fixed microscope, in order that their opposites, where the moveable pieces were stuck on, may, in like manner, be cut; so that one-half of the circle will be sufficient to be divided and sub-divided by the adjustable pieces, seeing that each of its divisions and sub-divisions, brought in succession under the fixed microscope, may be instantly transferred by the pointer, into the opposite semi-circle, and also those in their turn transferred back again. Let us now see how the semi-circle is divided and sub-divided by means of the two microscopes A and the fixed one, B being no longer wanted; the first operation is the trisection of it into arcs of each 60°; for this purpose, while the pointer remains at T3 (fig. 3 of Plan XVIII), one of the points of the circle, the fixed microscope cuts at Z, or zero, i.e. the first point of the circle, to be figured 0 or 360; two moveable pieces are stuck on at C and D respectively, so as to trisect the semi-circle ZBT very nearly, and the microscope A is placed directly over C, so as to view its stroke or line at the point of intersection in the focus of the eyeglass; there it is made fast for the present; the line C is now brought under the fixed microscope at zero, by making the circle revolve, and suffered to remain; the piece D has its stroke cut under the microscope A, as before was the case with piece C, now at zero; the circle is again made to revolve till the stroke of D is under the fixed microscope at zero; in this situation the point T, or 180°, will have been brought forward 120°, or 60° twice over, provided the pieces C and D were truly placed, and in this case an eye, looking into the microscope A, will see this dividing line bisect the field of view; but as this is not likely to happen at the first trial, the microscope must be moved one third of the error now shown, and each of the pieces C and D another third, accordingly as the portions of the semi-circles ZC, CD, and DT taken together, are found to be more or less than an exact semi-circle. The operation we have here described is repeated again and again, till the three equivalent arcs amount to an exact semi-circle; after which they are rendered permanent, by strokes made successively, on the opposite semi-circle, at the points Z and A, which trisect the semi-circle T A Z, when the adjustable strokes C and D are in succession exactly fixed in the centre of the fid view of the fixed microscope. The distance between the two microscopes, which is here 60°, is called the opening of the microscopes, which are considered as the two points of a pair of dividers, and the arc between them is therefore denominated accordingly.

The next step is to bisect the arcs of 60° each, into two of 30°, by an opening of 30°: to do this one moveable piece, stuck at the middle of each arc of 60°, will be requisite, and the
the two halves, to the right and left of each piece, may be examined and adjusted till the bisections are complete, and in a state to be transferred into the opposite semi-circle; for instance, suppose the arc of 60° from Z to C to be biseected, put a moveable stroke at 30°, more or less, and place the micrometer A over it; make the table and circle revolve till this stroke 30° falls under the fixed microscope; in that situation, the stroke 60° ought to biseect the field of view of the microscope A, and whatever the deviation may be, plus or minus, it must be adjusted by trial, partly by moving the microscope A, and partly by moving the piece with the stroke on at 30°, when brought back again under the microscope A.

In the same way, any other bisection may be made within the possible opening of the microscopes. Again, the arcs of 30° are biseected, as before described, into arcs of 10°, which are all transferred into the opposite semi-circle in succession.

With respect to the division of the arcs into smaller quantities than those of 10°, where the microscopes approach too near together to admit of the necessary adjustments, an ingenious mode of subdividing is adopted by a property of the number 9, thus; having all the arcs of 10° round the semi-circle laid down, the points 90° and 180° are of course among them, and as these are divisible by 9, an opening of nine degrees is taken by trial, which repeated ten times, by means of the moveable strokes, will reach from 0 to 90°, when properly adjusted; besides the 10°, 20°, 30°, &c., there will now be 9°, 18°, 27°, &c., up to 90°, and also 99°, 108°, 117°, &c., up to 180°, and the differences or spaces left between the divisions obtained from 10°, and those from 9° repeated, will be respectively 1°, 2°, 3°, &c., up to 9°; now, if the points 9°, 18°, 27°, &c., which numbers decrease by unity in the units place, be made in succession points of commencement, for the arc of 10° to be repeated from them, they will from 9° produce 19°, 29°, 39°, &c.; from 18° they will give 28°, 38°, 48°, &c.; and from 27° they will give 37°, 47°, 57°, &c., and so of the rest, till all the single degrees are put on by the arc of 10° thus applied from the points derived from 9° and its multiples.

The work is performed thus: make the opening of the microscopes again 10°, by fixing the one called A at the tenth degree when zero is at the fixed one, then turn the table and superincumbent circle to be divided till the stroke 9° comes to zero, then a moveable piece fitted properly under A will be 19°; bring this to the fixed microscope, and the place for 29° will be had for the next stroke, under A again; and in like manner every individual degree may be marked in succession, by taking those ending with 8, after those ending with 9 have been gone through; and after that, those ending with 7, with 6, with 5, &c., till all the numerals are included. If the circle is large enough to admit of division to 5° by the opening of the microscopes, the numbers 4 and 5 may be subdivided with advantage for 9° and 10°, and then the opening may be 20° for inserting them, instead of 10°, as in the mode we have described. When half degrees are required to be inserted into the opening of 15°, all the other half degrees may be marked as before, by the aid of the adjustable marks to be transferred afterwards into the opposite semi-circle, and all the strokes in that semi-circle may then be transferred back again permanently, so as to complete the circle.

The use of the numerals nine and ten, or of the fourth and five, is evidently borrowed from Clavius the Jefuit, whose problem for this dividing a right line, or arc of a circle, was published in 1611.

Another method of subdividing the circle, when marked into degrees, as above described, is also proposed as being less tedious, and capable of carrying the sub-divisions to a lower denomination; thus, a pocket is made to fit the arrow of the revolving table that carries the circle to be divided, so tight, that it will revolve with the divided arrow, or without it, as the case may be: to this pocket a telecope is fixed with a vertical hair in the focus of its eye-glafs, that may biseect any distant mark to which it may be directed, then a long ruler, of fix or seven feet in length, is divided, for instance, into twelve equal parts, so that it may be read distinctly; the distance of this ruler is so adjusted from the telecope, that when placed at right angles to the line of collimation, it may just subtend one degree, which may be first calculated nearly, and then adjusted by trial, till the run of the telecope over the twelve marks of the ruler be exactly corresponding to the run of one degree of the circle under one of the microscopes. In this situation of things, the divisions of the ruler, as seen through the telecope, are, with great care and readiness, transferred in succession, not to one of the degree spaces itself on the circle, but to a pattern-piece of brafs, which may be afterwards fixed with screws under the object lens of the fixed microscope, so as to be applied in succession to each separate degree, as the circle is made to revolve, during the operation of transferring these five minute spaces, to the opposite parts of the circle, by means of the pointill. In this case, the ruler, viewed through the telecope, ought to be a portion of a circle; but the arc and the chord of one degree are fairly alike, that one may be substituted for the other, without sensible error. When small circles, or parts of a circle, were propounded by the due de Chaulnes to be divided, they were fixed on the revolving arrow of the table, and the microscopes and cutting point were so arranged, that the divisions of a large divided circle were transferred to the small one in succession, and the whole apparatus, so arranged, constituted an engine for dividing; but the work could not be performed with such expedition as with our modern engines, where the spaces are subdivided for the microscopes, and where the touch has greatly the advantage over the figbt. With respect to the accuracy of the work performed by the due de Chaulnes, we are greatly inclined to believe, that the sliding mechanism of the cutting-point would not secure the strokes from having a deviating direction sometimes, arising from the necessary liberty that the sliding parts must have had to admit of free motion, unless, indeed, the parts of action were fitted with extreme nicety.

Lastly, the vernier scale was retained by the author before us, as the best sub-divider of the 9° spaces, or other small divisions; but he has not conceived it necessary to describe, in detail, how he proportioned it to the divisions of his circle, though it is easy to conceive how this may be done by the help of microscopes and the cutting-point. Our remark on this original method of dividing is, that it shows great ingenuity; but we conceive, that making an equality in the divided and sub-divided arcs will not always ensure perfection in the angular measure, because the axis of motion may be out of the centre of the divided circle, and the eccentricity will neither be detected by this method, nor allowed for in the divisions and sub-divisions, unless, indeed, two or three equidistant verniers were used for taking an average of the readings from different sides of the circle. It is somewhat remarkable that the same thought that introduced the microscopes for measuring the arcs to be divided, did not sublitate them for the vernier, in reading off small quantities of a sub-division when an instrument was finished; which practice was left for Mr. Ramden afterwards to adopt. The second semi-circle, being only the copy of a
copy, renders this method of dividing less worthy of imitation, as an original method, than it would have been if the imperfections of the former portion of the circle had not been necessarily transferred to the other, and from that back again. In short, we think the wax-work might have been better employed.

The elder Troughton (John) whose dividing was acknowledged to be equal to that of any of his predecessors, or contemporaries, used the beam-compasses, like Bird, but rejected the computation of chords, and the measures taken from circles, as being liable to uncertainty in determining the primary points from which the bifectons were to proceed. Having described his circle, or rather quadrantal arc to be divided, he determined the point 60° with the radius, as Graham and Bird had previously done, and, having bifected it at 30°, set off 30° in addition to the 60° to complete the arc of 90°; he then bifected till he had arcs of 15°, and again till he had 7° 30' in each division: the two marks nearest to 90° were now 82° 30', and 86° 15'; but the point 85° 20', or limit of the largest bifectonal arc, lay between these two, and could not be obtained by further bifectons; the space between the two marks in question was therefore trifected, and the more forward of the two new points was 85°: again, the space between this mark of 85°, and that of 86° 15', was trifected; from which came 85° 25', as denoted by the more backward of the two new marks; and, finally, a fifth part of one of the sub-divided arcs was set forwards from 85° 25', to 85° 20', the point from which the 1024 divisions were inflicted from 0 entirely by bifectons. The quadrantal arc was then completed from the sub-divisions thus obtained. It may be necessary, however, to observe, that the marks at first made by the radius, bifectons, trifectons, &c. were none of them permitted to be permanent, being of no further use than to ascertain the individual point 85° 20', from which the subsequent bifectons were to commence. This method is considered as being preferable to Bird's method of computing the chords and using the scale, insomuch as it does not depend on secondary or auxiliary means of ascertaining the primary point in the bifectonal arc. It has uniformity of means to recommend it in preference to those mixed methods that depend partly on computation, and partly on the extended radius.

The method of dividing a large circle, commonly known by the appellation of Ramdjin's method, or the method of coining, consists of Bird's method, and of that proposed by the de Chaulnes united: the circle is first divided by the beam-compasses into primary points; and the true situation of each of these points is ascertained by opposite microscopes, as the work proceeds, and is rectified accordingly, by pulling the points forward or backward a trifle, till they are in their true places. This method, now generally practised by all the best dividers, except the present Mr. Troughton, has not, that we know of, been very particularly described, with references to drawings, &c. though it is capable of considerable accuracy in the hands of a good workman, who has perseverance enough to do justice to it. The great number of points that will require to be rectified, will, notwithstanding the utmost precaution, render the work irregular in its appearance, and a circular line must necessarily pass through the centre of all the points or conical holes, to render them concentric; besides, the bifectonal arcs deform the conical shape of the points, by palling through them, and the subsequent trifectors must leave an unevenness in the metal that cannot but offend a nice eye.

Sir George Shackburgh, in his paper on the equatorial, calls the points that have been enlarged by rectification, and burnished level again, "doubtful or bad points;" and these bear a considerable proportion to the whole. "It would," says Mr. Troughton, "be a great improvement of this method to divide the whole by hand at once, and afterwards to correct the whole; for a dot, forced to its place, as above, will seldom allow the compass-point to rest in the centre of its apparent area; therefore, other dots made from those will fearfully ever be found in their true places. This improvement also prevents the corrected dots from being injured or moved by the future application of the compasses, no such application being necessary."

The circle that is divided by this method is placed horizontally to have its first points made, after it has had its circle descried from a revolution on its own axis, and then it is placed vertically in a frame, in which it revolves, and which carries the microscopes with micrometers, that sub-divides, and read to the accuracy of one second, in order that the semi-circles, taken from any given opposite points, may have their equality ascertained, or their deviation therefrom determined previously to final rectification. In these operations great attention is paid to the temperature of all the metallic parts employed in the work.

Mr. Ed. Troughton has deviated from the beaten track of his predecessors, and made a road for himself, (probably before Ramdjin's plan was adopted,) that he has trodden with great success, and which he has fully described in a paper of the Philosophical Transactions of the year 1809, which gained him Copley's medal. The reason that caused him to think for himself on this subject, as he has done successfully on many others, seems to have been this: "With as ready a hand, and as good an eye," says he, "as young men generally have, I was much disappointed at finding, that after having made two points, neat and small to my liking, I could not bifeect the distance between them without enlarging, displacing, or deforming them with the points of the compasses."

This discovery led to the abandonment of the beam-compasses and spring-dividers, and the art of turning appearing to have approached the nearest to perfection of any of the mechanical arts, a roller was thought of, which by its revolutions might sub-divide the circumference of a circle rolled over, after the ratio of their respective diameters was ascertained and properly adjusted. When this speculation was first attempted to be realized, some circumstances occurred which could not be certainly inferred from reasoning, a priori, from known data, but of which a perfect knowledge was necessary for the consummation of the project; in the first place, it was found on trial, that however smooth the surfaces of the circle and roller were made, there was no slippery action, as might have been expected, but the points of contact acted with each other in an apparatus like that hereafter to be described, as the teeth of wheel-work of indefinitely small dimensions; the certainty of this kind of action was an indispensable condition; secondly, notwithstanding this flankheft in the motion of the roller, it was found to measure different portions of the metallic circle with different degrees of accuracy, some of the measures being a trifle plus, and others minus, with respect to the truth: this want of accuracy, which, as we have said, did not depend on any sliding of the roller, was expected to take place previously, in a certain undefined degree, by reason of the unequal density of hardened materials, and of their consequent unequal porosity; but thirdly, though there was found to be a deviation from true measurement in individual
dual portions of the circle, yet, when the roller was properly adjusted to measure the whole circle without a remainder, it was found to possess the desirable property of accommodating itself to the same track again, as often as the circuit was repeated, and consequent on arriving at the point zero again without the least sensible deviation. This circumstance, which may be considered as a phenomenon in mechanics, reproduced the hope of success, which the want of perfect regularity in measuring the intermediate portions of the circle was calculated to discourage: and a remedy, heretofore deferred, was successfully employed to equalize the measurements, say, so exactly was the course of the roller found to be identical in every part of its circuit. Thus, when duly adjusted for diameter, the deviation at any individual point, from the first measure, would not exceed a second. This uniformity in the mode of the roller’s movement furnished the means of correcting its own inaccuracies of measurement, seeing that these inaccuracies, once ascertained, always remained the same at the same points on the circle, provided that zero of the roller started from zero of the circle, at the commencement of its first circuit.

We cannot convey an adequate conception of the mechanical application of a roller to the division and sub-division of a circular instrument, without a reference to drawings of the apparatus actually used; nor can we describe that apparatus better than in the words of the author himself. In the instrument, of which he has described the graduation, is a four feet meridian circle, at present the property of Stephen Groombridge, esq. of Blackheath.

"The surface of the circle, which is to receive the divisions," says Mr. Troughton, "as well as its inner and outer edges, but especially the latter, should be turned in the most exact and careful manner; the reason for which will be better understood when we come to describe the mode of applying the roller; and as no projection can be admitted beyond the limb, if the telescope, as is generally the case, be longer than the diameter, those parts which extend further must be so applied, that they may be removed during the operation of dividing." Pages XIX. and XX. of Astronomical Instruments exhibit the principal parts of the apparatus; fig. 1. shows the plan, and fig. 4. the elevation of the revolving parts of the mechanism, in both of which the same letters of reference are affixed to corresponding parts, and both are drawn to a scale of half dimensions. A is a part of the circle, the surface of which is seen in the plan, and the edge in the elevation. B B is the main plate of the apparatus, rolling with its four feet, a, a, a, a, upon the surface of the arc; these feet, being screws, may be adjusted so as to take equal shares of the weight, and then are fastened by nuts below the plates, as shown in fig. 4. C C and D D are two similar plates, each attached to the main plate, one above, and the other below, by four pillars; and in them are centered the ends of the axis of the roller E E. F F and G G are two friction wheels, the latter firmly fastened to B B, but the former is fixed in an adjustable frame, by means of which adjustment these wheels and the roller E E may be made to press, the former on the interior, and the latter on the exterior edge of the circle, with an equal and convenient force; namely, by the bending of the pillars of the secondary frame, and of the axis of the roller. At the extremities of the axis of the roller, and attached to the middle of the plates C and D D are two bridges, having a screw in each, by means of which an adjustment is procured for raising or lowering the roller reflecting the edge of the circle, whereby the former having its diameter at the upper edge about .001 of an inch greater than at the lower edge, on account of its being a little conical, may easily be brought to the position where it will measure the proper portion of the circle.

Much experience and thought upon the subject have taught me, that the roller should be equal to one-sixteenth part of the circle to be divided, or that it should revolve once in 22° 20', and that the roller itself should be divided into sixteen parts, no matter whether with absolute truth, for accuracy is not at all essential here. Each of such divisions of the roller will correspond with an angle of 1° 24' 22''. 55', or 4th part of the circle. This number of principal divisions was chosen, on account of its being capable of continual bifurcation, but they do not fall in with the ultimate divisions of the circle, which are intended to be equal to 5° each.

The next thing to be considered is, how to make the roller measure the circle. As two microscopes are here necessary, and those which I use are very simple, I will in this place give a description of them. Fig. 5. is a section of the full size, and sufficiently explains their construction, and the position of the glaesses; but the micrometer part, and manner of working it, are better shewn in figs. 1 and 4. The micrometer part consists of an oblong square frame, which is folded into a flat, cut at right angles in the main tube; another similar piece, nicely fitted into the former, and having a small motion at right angles to the axis of the microscope, has at one end a cylindrical guide-pin, and at the other a micrometer screw; a spring of filed wire is also applied, as seen in the section, to prevent play, by keeping the head of the micrometer in close contact with the fixed frame. This head is divided into one hundred parts, which are numbered each way to fifty; the uae of which will be shewn hereafter. A fine wire is stretched across the movable frame, for the purpose of bifurcating fine dots. Two of these microscopes are necessary; also a third, which needs not have the divided head, and which must have in the movable frame two wires crossing each other at an angle of about 30°; this microscope is shewn at I, fig. 1. In the two first micrometers a division of the head is of the value of about 0.2, and the power of diminishing such, that when great care is taken, a much greater error than to the amount of one of these divisions cannot well be committed in setting the wire across the image of a well-made dot. The double eye-glass has a motion by hand, for producing distinct vision of the wire; and subject to the very great, as is procured by a similar adjustment of the whole microscope. The first step towards fixing the roller is to compute its diameter according to the measurement of the circle, and to reduce it agreeably thereto, care being taken to leave it a small quantity too large. The second step is, after having brought the roller into its place in the plate B B, to make a mark upon the surface of the circle, near the edge, and a similar one upon the roller, exactly opposite each other; then carry the apparatus forward with a steady hand, until the roller has made sixteen revolutions; if now the mark upon the roller, by having over-reached the one upon the circle, shews it to be much too large, take it out of the frame, and reduce it by turning accordingly: when, by repeating this, it is found to be very near, it may be turned about .001 of an inch smaller on the lower edge, and so far its preparation is completed. The third and last step is the use and adaptation of the two microscopes; one of these must take its position at H in fig. 1, viewing a small well-defined dot made for the purpose on the circle; the other, not represented in the figure, must also be fixed to the main plate of fig. 1, as near to the former as possible, but viewing one of the divisions on the roller with a due attention to each microscope, it will now be seen to be
the greatest exactness, when, by raising or depressing the roller, its concentricate diameter is found.

Fig. 5. is a representation of the apparatus for transferring the divisions of the roller to the circle. It consists of two slender bars, which, being fixed on the figure, have only the appearance of narrow lines; but looked at from above, they resemble the letter A. They are fasened to the main frame, as at W and Z, by short pillars, having also the other end of the angle secured in the same manner; Y is a fine conical steel point for marking the dots, and X is a feeler, whereby the point Y may be pressed down with an uniform force, which force may be adjusted, by bending the end of the bar just above the point, so as to make the dots of the proper size. The point Y yields most readily to a perpendicular action, but is amply secured against any eccentric or lateral deviation.

The apparatus so far described, is complete for laying the foundation, i.e. for making 256 primary dots; no manner whether with perfect truth or not, as was laid respecting the divisions of the roller; precision in either is not to be expected, nor wished; but it is of some importance that they should all be of the same size, concentric, small, and round. They should occupy a position very near the extreme border of the circle, as well to give the greatest radius possible, as that there should be room for the stationary microscope, and other mechanism to be described hereafter.

It must be noticed that there is a clamp and adjusting screw attached to the main plate of Fig. 1, but as it differs in no respect from the usual contrivances for quick and slow motion (see Circle), it has been judged unnecessary to incumber the drawing with it.

Now the roller having been adjusted, with one microscope upon its proper dot on the circle, and the other microscope at the first division on the roller, place the apparatus of Fig. 5, so that the dotting point Y may stand directly over the place which is designated for the beginning of the divisions. In this position of things, let the feeler X be pressed down, until its lower end comes in contact with the circle; this will carry down the point, and make the first impreffion, or primary dot, upon the circle; unclasp the apparatus, and carry it forwards by hand, until another division of the roller comes near the wire of the microscope; then clamp it, and with the screw-motion make the coincidence complete; where again press upon the feeler for the second dot; proceed in this manner until the whole round is completed.

From these 256 erroneous divisions, by a certain course of examination, and by computation, to ascertain their absolute and individual errors, and to form these errors into convenient tables, is the next part of the process, and makes a very important branch of my method of dividing.

The apparatus must now be taken off, and the circle mounted in the same manner, that it will be in the observatory. The two microscopes, which have divided heads, must also be firmly fixed to the support of the instrument, on opposite sides, and then wires brought to bifife the first dot, and the one which should be 180° distant. Now the microscopes remaining fixed, turn the circle half round, or until the first microscope coincides with the opposite dot; and if the other microscope be exactly at the other dot, it is obvious that these dots are 180° apart, or in the true diameter of the circle; and, if they disagree, it is obvious that half the quantity by which they disagree, as measured by the divisions of the micrometer head, is the error of the opposite division; for the quantity measured is that by which the greater portion of the circle exceeds the less. It is convenient to note these errors + or −, as the dots are found too forward or too backward, according to the number of the degrees; and for the purpose of distinguishing the + and − errors, the heads, as mentioned before, are numbered backwards and forwards to fifty. One of the microscopes remaining as before, remove the other to a position at right angles; and, considering for the present both the former dots to be true, examine the others by them; i.e. as before, try by the micrometer how many divisions of the head the greater half of the semi-circle exceeds the less, and note half the quantity + or − as before, and do the same for the other semi-circle. One of the micrometers must now be set at an angle of 45° with the other, and half the differences of the two parts of each of the four quadrants registered with their respective signs. When the circle is a vertical one, as in the present instance, it is much the best to proceed so far in the examination with it in that position, for fear of any general bending or spring of the figure; but for the examination of smaller arcs than 45°, it will be perfectly safe and more convenient to have it horizontal; because the dividing apparatus will then carry the micrometers, several perforations being made in the plate, B, for the limb to be seen through at proper intervals. The micrometers must now be placed at a distance of 22.5°, and the half differences of the parts of all the area of 45° measured and noted as before; thus descending by divisions to 11° 15', 5° 37', and 2° 48'. Half this last quantity is 1.5° small to allow the micrometers to be brought near enough; but let all have the desired effect if they are placed at that quantity and its half, i.e. 4° 45 15', in which case the examination, instead of being made at the next, will take place at the next division but one, to which is the subject of trial. During the whole of the time that the examination is made, all the dots, except the one under examination, are for the present supposed to be in their true places; and the only thing in this most important part of the business, from first to last, is to ascertain with the utmost care, in divisions of the micrometer head, how much one of the parts of the interval under examination exceeds the other, and carefully to tabulate the half of their difference.

I will suppose that every one who attempts to divide a large astronomical instrument, will have it engraved first. Dividing is a most delicate operation, and every coarser one should precede it. Besides it being numbered is particularly useful to distinguish one dot from another; thus in the two annexed tables of errors, the side columns give significant names to every dot in terms of its value to the nearest tenth of a degree, and the mistaking of one for another is rendered nearly impossible.

The foregoing examination furnishes materials for the construction of the table of half differences, or apparent errors. The first line of this table consists of two varieties; i.e. the micrometers were at 180° distant for obtaining the numbers which fill the columns of the first and third quadrants, and at 90° for those of the second and fourth quadrants. The third variety makes one line, and was obtained with a distance of 45°; the fourth consists of two lines, with a distance of 22.5°; the fifth of four lines, with a distance of 11° 15'; the sixth of eight lines, with a distance of 5° 37'; the seventh of sixteen lines, with a distance of 2° 48' 45"; and the eighth and last variety, being the remainder of the table, consists of thirty-two lines, and was obtained with a distance of 4° 13' 7".

The table of apparent errors or half differences, just explained, furnishes data for computing the table of real errors. The rule is this; let a be the real error of the preceding dot, and b that of the following one, and c the apparent error.
error, taken from the table of half differences, of the dot under investigation; then is \( \frac{a + b}{2} + c \) = its real error.

But as this simple expression may not be so generally understood by working as I would wish, it may be necessary to say the same thing less concisely. If the real errors of the preceding and following dots are both + or both −, take half their sum, and prefix thereto their common sign; but if one of them is + and the other −, take half their difference, prefixing the sign of the greater quantity; again, if the apparent error of the dot under investigation has the same sign of the quantity found above, give to their sum the common sign for the real error; but if their signs are contrary, give to their difference the sign of the greater for the real error. I add a few examples.

**Example 1.**

For the first point of the second quadrant.

Real error of the first point of the second quadrant 0.0
Real error of the first point of the third quadrant 6.9
Half sum or difference 3.4
Apparent error of the dot under trial + 12.2
Real error 8.8

**Example 2.**

For the point 45° of the second quadrant.

Real error of the first point of the quadrant 8.8
Real error of the last point of the quadrant 6.9
Half difference 0.9
Apparent error of the dot under trial 8.9
Real error 8.9

**Example 3.**

Point 88°.6, or half point of the third quadrant.

Real error of the point 84°.4 of the third quadrant 21.0
Real error of the point 2°.8 of the fourth quadrant 2.9
Half sum 11.9
Apparent error of the dot under trial 4.0
Real error 15.9

**Example 4.**

Point 88°.6, or half of the fourth quadrant.

Real error of the point 84°.4 of the fourth quadrant 21.6
Real error of the point 2°.8 of the first quadrant 10.2
Half sum 15.9
Apparent error of the dot under trial 9.5
Real error 6.4

It is convenient, in the formation of the table of real errors, that they should be inserted in the order of the numbering of the degrees on their respective quadrants; although their computation necessarily took place in the order in which the examination was carried on, or according to the arrangement in the table of apparent errors. The first dot of the first quadrant having been assumed to be in its true place, the first of the third quadrant will err by just half the difference found by the examination; therefore these are alike in both tables. The real error of the first dot of the second quadrant comes out in the first example; that of the fourth was found in like manner, and completes the first line. It is convenient to put the error of the division 90° of each quadrant at the bottom of each column, although it is the same as the point 0° on the following quadrant. The line of 45° is next filled up; the second example shows this; but there is no occasion to dwell longer upon this explanation, for every one, who is at all fit for such pursuits, will think what has already been said fully sufficient for his purpose. However, I will just mention that there can be no danger in the formation of this table, of taking from a wrong line the real errors which are to be the criterion for finding that of the one under trial; because they are in the line next to it; the others which intervene in the full table not being yet inserted. The last course of all is, however, an exception; for, as the examining microscopes could not be brought near enough to bifection the angle 2° 48′ 45″, recourse was had to that quantity and its half; on which account the examination is prosecuted by using errors at two lines distance, as is shown in the two last examples.

When the table of real errors is constructed, the other table, although it is of no further use, should not be thrown away; for, if any material mistake has been committed, it will be discovered as the operation of dividing is carried on; and in that case the table of apparent errors must be had recourse to, indeed not a figure should be destroyed until the work is done. Reflecting the angular value of the numbers in these tables, it may be worth mentioning, that it is not of the least importance; 100 of them being comprised in one revolution of the micrometer screw; and in the instance before me, 5 of them made no more than a second, it is not pretended that one of these parts was seen beyond a doubt being scarcely 1/55 of an inch, much less the tenths, as exhibited in the table; but as they were visible upon the micrometer heads, it was judged best to take them into the account.

Having now completed the two first sections of my method of dividing; namely, the first which consists of making 250 small round dots; and the second in finding the errors of those dots, and forming them into a table; I come now to the third and last part, which consists in using the erroneous dots in comparison with the calculated errors, to as ultimately to make from them the true divisions.

It will here be necessary to complete the description of the remaining part of the apparatus. And first a little instrument which I denominate a sub-dividing sector presents itself to notice. From all that has hitherto been said, it must have been supposed that the roller itself will point out, upon the limb of the instrument to be divided, spaces corresponding to others previously divided upon itself, as was done in setting off the 256 points; but, to obviate the difficulty of dividing the roller with sufficient exactness, recourse was had to this sector; which also serves the equally important purpose of reducing the biforced points to the usual division of the circle. This sector is represented in full dimensions by fig. 2; it is formed of thin brads, and centered upon the axis at A, in contact with the upper surface of the roller; it is capable of being moved round by hand; but by its friction upon the axis, and its pressure upon the roller, it is sufficiently prevented from being disturbed by accident. An internal frame B B, to which the arc C C is attached, moves freely in the outer one, and by a spring D is pushed outwards, while the færem E, whose point touches the frame B, confines the arc to its proper radius. The arc of this sector is of about four times greater radius than the roller, and upon it are divided the spaces, which must be transferred to the instrument, as represented on a magnified scale by fig. 6. Now the angle of one of the spaces of the circle will be measured by sixteen times its angular value upon the sector; while, or 22° 30′; but this does not repre-
fent any number of equal parts upon the instrument, whose
sub-divisions are to be 5' each; for \( \frac{2}{3}124'22\text{''}5 \) is exactly
16', therefore so many divisions are exactly equal to a mean
space between the dots, whose errors have been tabulated.
Let therefore the arc of the sector be divided into 16 spaces,
of 1' 20' each, and let a similar space at each end be sub-
divided into eight parts of 10' each, as in fig. 6; we shall
then have a scale, which furnishes the means for making the
tru divisions, and an intermediate examination at every
bifectral point.

I have always divided the sector from the engine, because
that is the readiest method, and inferior to none in point of
accuracy, where the radius is very short; but as it is more
liable than any other to centrical error, the adjustment of
the arc by the screw E becomes necessary; by that adjust-
ment also any undue run in the action of the roller may be
reduced to an insensible quantity.

When the utmost degree of accuracy is required, I give
the preference to dividing by lines, because they are made
with a left forcible effort than dots are, and also, because if
any small defect in the contexture of the metal causes the
cutter to deviate, it will, after passing the defective part,
proceed again in its proper course, and a partial crookedned's
in the line will be the only consequence: whereas a dot,
under similar circumstances, would be altogether displaced.
But, on the contrary, where accuracy has been out of the
question, and only neatness required, I have used dots; and
I have done so because I know that when a dot, and the wire
which is to bifect it, are in due proportion to each other,
the wire covering about two-thirds of the dot, the nicest
comparison possible may be obtained. It may be further
observed, that division by lines is complete in itself; whereas
that by dots requires lines to distinguish their value.

On the upper side of fig. 1, is represented the apparatus
for cutting the divisions. It consists of three pieces, J, K, L,
jointed together, so as to give to the cutter an easy motion
for drawing lines directly radiating from the centre, but in-
flexible with respect to lateral pressure; \( d, d \) are its handles.
The cutting point is hidden below the microscope \( H \); it is
of a conical form, and were it used as a dotting point, it
would make a puncture of an elliptic shape, whose longer
diameter would point towards the centre. This beautiful
contrivance, now well known, we owe to the ingenuity of
the late Mr. Hindley of York; it was borrowed by Mr.
Ramsden, (See Engine for dividing,) and applied with the
best effect to his dividing engine.

Previously to cutting the divisions, the parts now described
must be adjusted. The cutting apparatus must be placed
with the dividing point exactly at the place where the first
line is intended to be drawn, and clamped, so that the ad-
justing screw may be able to run it through a whole interval.
The microscope \( H \) must be firmly fixed by its two pillars
\( h, k \) to the main frame, with its micrometer head at \( z e r o \),
and with its only wire in the line of the radius, bifecting the
first of the 256 dots. And it should be observed that the
cutting frame and this must not vary reflecting each other,
during the time that the divisions are cut; for any motion
that took place in either would go undiminished to the
account of error. The microscope I is also fastened to the
main frame, but it is only required to keep its position un-
varied, while the divisions of the sector past once under its
notice, for it must have its wires adjusted aforesaid to these
divisions at every distinct course. The microscope I has
two wires, crossing each other at an angle of about 403;
and these are to be placed so as to make equal angles with
the divisions of the sector, which are not dots but lines.
The sectorial arc must also be adjusted to its proper radius
by the screw E, fig. 2, i.e. while the main frame has been
carried along the circle through a mean interval shown by
H, the sector must have moved through exactly 16° of its
divisions, as indicated by I.

Things being in this position, after having given the parts
time to settle, and having also sufficiently proved the per-
manence of the micrometer \( H \), and the cutting frame,
with respect to each other, the first division may be made;
then, by means of the screw for slow motion, carry the
apparatus forward, until the next line upon the sector comes
to the cross wires of I; you then cut another division, and
thus proceed until the 16th division is cut \( = 1 \text{''} 20' \); now
the apparatus wants to be carried further, to the amount of
16° of a division, before an interval is complete, but at this
point no division is to be made; we are here only to
compare the division on the sector with the corresponding
dot upon the instrument: this interval, however, upon the
circle will not be exactly measured by the corresponding
line of the sector, which has been adjusted to the mean in-
terval, for the situation of the dot 1° 4 is too far back, as
appears by the table of real errors, by \(-4.8 \) divisions of the
micrometer head. The range of the screw for slow motion
must now be restored, the cross wires of \( H \) set back to
\(-4.8 \) divisions, and the sector moved back by hand, but not
to the division 0, where it began before; for, as it left off in
the first interval at 16° of a division, it has to go forwards 5th
more before it will arrive at the spot where the 17th divi-
sion of the instrument 1° 25' is to be made, so that in this
second course it must begin at 5th short of 0: go through
this interval as before, making a division upon the circle at
every one of the sixteen great divisions of the sector; and \( H \)
should now reach the third dot, allowing for a tabular
error of \(-10.2 \), when the division 5ths of the sector reaches
the cross wires of 1. It would be tedious to lead the reader
through all the variety of the sector, which consists of eight
courses; and it may be sufficient to observe, that at the
commencement of every course, it must be put back to the
same fraction of a division which terminated its former one;
and that the wire of the micrometer \( H \) must always be set
to the tabular error belonging to every dot, when we end
one interval and begin another. The eight courses of the
sector will have carried us through \(-\text{Ist} \) part of the circle
11° 15', and during this time the roller will have proceeded
through half a revolution; for its close contact with the
limb of the circle does not allow it to return with the sector
when the latter is set back at every course. Having in this
manner proceeded from one interval to another, through the
whole circle, the micrometer at last will be found with its
wire at \( z e r o \), on the dot from which it set out; and the sec-
tor, with its 16th division, coinciding with the wires of its
microscope.
### GRADUATION.

</table>
We might have quoted several other parts of Mr. Troughton's paper for the advantage of the reader, but instead thereof, we recommend the perusal of the whole to such persons as are interested in this subject, and shall conclude our account of the present method of dividing by remarking, that it requires not more than one-fourth of the time that Bird's method does, and not much more than one-twelfth that Ramdlen's demands, and is applicable to a quadrant or sextant, &c.; that it may be performed by night, by the aid of an appropriate lamp, as well as by day; that the work is, as it were, magnified by the secteur; that any erroneous action of the roller, when verified at every interval, does not extend its influence to any distant divisions; that the divisions of the secteur very conveniently convert the 256 points into degrees and parts of a degree, while the micrometer head allows for their errors of position; that all tools liable to vary their dimensions by change of temperature are here abandoned; and lastly, that if alone is employed in ascertaining the measure of the arcs divided; on which account this method is called dividing by the eye; which appellation, indeed, might have been given to the duce de Chaulnes' method; a method which, we understand, Mr. Troughton was not acquainted with till lately, and from which it will be perceived his differs very essentially. We have no hesitation in asserting, that this far excels every other method of graduating large circles that we are acquainted with.

Soon after Mr. Troughton's paper was read at the Royal Society's room, the late Henry Cavendish, esq. F.R.S., whose death is an irreparable loss to the scientific world, contrived a new method of using the beam-compas, with a view of avoiding the difficulties of pointing the exact middle of a small space between two scratches, and of using that point again without altering its conical figure. As these difficulties had led to Mr. Troughton's new contrivances, Mr. Cavendish presumed that a removal of them would render the beam-compas unobjectionable; and that future dividers might continue the use of an instrument which long habit has rendered familiar. The method proposed, but which probably has not been adopted, if tried at all, is, to unite a microscope that has got a micrometer, with the beam-compas, in such a way, that no dots may be necessary at all in dividing or sub-dividing any arc of a circle, but that bisection, trisection, and quinquefsection, may all be performed by vision before the dividing strokes are made on the circle to be divided; we say circle, because this method is not intended to apply to a quadrant, or any other aliquot part of a circle. We will endeavour to explain the method now before us as concisely as possible. Let \( C C C \) in fig. 4. of Plate XVIII. of Astronomical Instruments, be the circle to be divided, in which we will retain the original letters of reference, and \( B B \) a frame resting on its plane so readily as to be without shake, but notwithstanding to have the power of sliding smoothly round the circumference to any given point, to which it may be adjusted by a flow motion, and there clamped; let \( d \) be a beam-compas, having its cutting point adjustable near \( b \), and let \( m \) be a microscope with two parallel hairs, one fixed, and the other movable by the micrometer, made so as to slide along the beam of the compas into any required situation. Let a point \( d \) on the frame be so chosen, that the line of \( d m \) may lie in the direction of the chord of half the arc to be bisectioned, when bisection is used, in which case the whole length from \( d \) to \( b \) must be very nearly equal to the whole chord of the said arc, and then both the centre of the field of view of \( b \), and also the point \( d \), will fall in the circle to be divided. It is not said how the fixed or central point \( d \) is to be supported, and kept perfectly steady, but as its distance from the centre of the circle must necessarily depend on the length of the chord \( d b \), it is proposed that the piece of metal that constitutes the support should be adjustable by a sliding motion of some sort, and that the beam near \( d \) should rest on a prop to guard the cutting point, when demitted low enough to make a stroke. Suppose now \( F \) and \( f \) to be the extreme points of an arc to be bisectioned somewhere near \( e \); after having placed the microscope at \( e \) or near the middle of the beam, with respect to the two points \( d \) and \( b \), and fixed the point on the refting place of \( d \), slide the frame till the fixed hair in the center, which must be exactly perpendicular to the line \( d \) in \( b \), intersects the circle at \( F \); then, lowering the point \( b \) from its prop, make a faint scratch; in the next place turn the beam-compas a little raised at the end \( b \), round its centre \( d \), till it is found over the circle, at the other side at \( D \), where it must rest on a prop for a time; slide now the frame forwards, and adjust till the fixed hair cuts the point \( f \), and there fix it; the second scratch must now be made, which will be over, or short of the first, accordingly as the microscope has been beyond or short of the middle of the distance \( d b \). It is not proposed to make a dot between these two strokes, but to bisection the space between with the hair, by the eye, or, if necessary, by the movable hair of the microscope, after it has measured the whole of this space; the bisection line being now the true line of \( f \), which we suppose brought back to the microscope at \( e \), this intersection is the extreme point of the bisectional arc \( F \) or \( f \), which must be bisectioned successively in like manner, when the point \( e \) has been adjusted. When the arcs become small, a crooked point is proposed to be used at \( e \), that it may not be in the way of the microscope; or otherwise, if that plan will not succeed, to adopt what he calls Mr. Troughton's method of bisection an odd number of contiguous divisons, which was also done, as we have seen, by the duce de Chaulnes and others. In cutting the lines of division, the microscope and point \( d \) are proposed to be very near together, and, if possible, so near at one side of another, that the stroke cut may coincide with the fixed hair, when the beam has an angular motion given, as a check on the stability of the microscope; and lastly, the point \( d \) must be so taken that the line \( d \) may now be a tangent to the circle at the cutting point.

If the whole circle could be graduated by continual bisection, this account is all that would be necessary for explaining the method of dividing here proposed, but, as trisection and quinquefsection are necessarily introduced, either before or after bisection, where the computation of chords is rejected, we must give also an account of these processes, which we believe are original. Suppose the arc \( a \), in fig. 5., to be proposed for quinquefsection, the equal measures \( a, f, e, d, b, \) and \( a \), are laid down in succession, by bringing \( a \) to the microscope, and making \( f \) nearly one-fifth of the whole, then by bringing up \( f \) to the microscope, and marking \( e \), &c. in the same way, beginning at \( e \), the points \( b, a, f, e, d, b, \) and \( a \), are made with the fame extent, which it appears was with too small an opening. Now the true point of the first quinquefsection from \( a \) will be between \( e \) and \( a \), and distant from \( a \) just one-fifth of the differential space \( d \); and the second point will be two-fifths of \( d \) from \( d \), and so on for the rest; therefore, in cutting the dividing strokes, the micrometer must measure the whole differential space, and then allow for the due proportion, after which it must be brought into the place of the fixed hair, to bisection the scratch before covered by it, and then the dividing line may be cut; in the same way allowance may be made for \( a \) this of the small space \( d \), before a second dividing stroke is made;
GRADUATION.

or, which gives left trouble, when the first quinquennating line is truly laid down, it may be transferred forward by using the fixed hair with it first, and then with the second, while the third is cutting, and so forth till they are all measured and cut in succession from the first measure repeated. This method is, however, acknowledged to be liable to the double error that may arise, first, from placing the intermediate point, and again, of sub-dividing from it. A third method for quinquenfections or trifecions is hastily proposed, but is considered inferior to the former plans, and therefore may be paffed over in silence.

We must confess there is something specious in the theory of Mr. Cavendish's proposed method of dividing, but our opinion, that it would not answer well in practice, has been confirmed by the affections of a practical artist, whose judgment in this art we estimate much more highly than our own. Supposing the point d on the frame not to be altered in shape or position by the large sweeps of the beam from right to left, and vice versa, alternately, nor yet the point injured, there must necessarily be a change of position in the hands of the operator, as well as in his whole body, at every backward and forward change of the beam, to the right and left, which circumstance will be not only unfavourable to expedition, but also to accuracy; in fact, the operator must be both right-handed and left-handed to succeed with an alternation of operations that require the greatest nicety of management, and in which the hands, the eye, and the diversified attitudes of the body, have all an equal share, and where a false stroke once made cannot be well rectified. The bisectioned arcs will not be more affected by change of temperature probably than by Bird's method, but the quinquenfections or trifecions may be sensibly affected, as some time must necessarily be taken up in ascertaining the measures by vision, while the operator breathes on the beam during the inspection of the microscope, and is also handling it in two places during the whole time of obtaining the nine points, or rather lines, in question.

Soon after Mr. Cavendish's paper on the manner of dividing astronomical instruments had been read before the members of the Royal Society, the Rev. William Lax a.M. F.R.S., Lowndes's professor of astronomy in the University of Cambridge, addressed a paper to the astronomer royal, which was also read and printed in part 2. of the year 1809, immediately after Mr. Cavendish's paper. This paper, as well as Mr. Cavendish's, was probably brought forward in consequence of Troughton's paper, printed in part 1. of the same year.

The method of examination made use of by professor Lax may be familiarly explained thus, without entering into any mathematical formula to mark the value of particular expressions, that might puzzle the ordinary reader: two microscopes were adapted by frame-work, so as to be capable of examination to any given points of the circle to be examined, and one of them, having a micrometer attached to it, was capable of measuring minute differences between a given arc of 30°, 60°, or 45°, &c. and any of the following multiples of that are taken in succession; consequently, if all the said differences marked + or -, as the case might be, balanced one another exactly, when the whole circle was gone through, the measure of the first arc was a standard measure, or the exact fraction of the whole that it ought to be; if not, a proportional part of the balance of errors would be long to it, and must be allowed accordingly. It is not necessary to be more minute in explaining the principle of examination before us, as it is of no use in graduating a circle, but is only intended as a correction on bad graduation, like the French repeating principle, to which it bears some analogy. The author's idea of ascertaining the fractional value of each division in his instrument successively, which he calculates will cost him an expenditure of 98 hours, is founded on an opinion that astronomical instruments in general do not possess that degree of accuracy in their divisions that the makers of them affirm; but he does not appear to be aware that as rigid an examination as his own is practiced by all the best instrument-makers in the final adjustment of the divisions, and that too by means of micrometrical microscopes; for that, if a posterior examination is found necessary, it must, generally speaking, be necessary in consequence of some change of figure that the instrument has undergone from carriage, accident, or temperature; in any of which cases the professor's mode of examination will be very desirable. But any one who proposes to take the trouble of making a table of all the positive and negative errors in the divisions of an indifferent instrument, will do well to have the whole of the original paper before him at the time, by which every step in the procures will be pointed out as it is wanted. Without meaning to discourage any attempt of this nature, for the proposal of which astronomers are much indebted to the learned professor, we profess a belief that three or four readings of any individual observation by as many microscopes properly arranged round the divided circle, in stationery situations, will answer every purpose of accuracy, and correct all the usual sources of error that exist at the time of making the observation; for when any table of errors is completed with the greatest care, it ought only to apply to observations made while the instrument remains in the same predilection as it was when the table was constructed.

Mr. Troughton, who is engaged with the construction of his fixed-circle for the Royal Observatory, intends, we understand, to adopt the use of four microscopic readings, two opposite each other, which will correct for eccentricity simply considered, and two at 120° distance from one of the former ones, which will check the bisectional dividing, and correct the inaccuracies of division, if any, as well as the effects of any change of figure in the circle by unequal temperature, in the room where it may be used. This proposal, coming from so skilful and experienced an artist as Mr. Troughton, we consider as a strong argument in favour of our opinion, which we expressed in favour of three readings in our article CIRCLE, before the paper in question was published, or known to us.

"I find," says Mr. Lax, "that I can read off, to a certainty, within less than three-fourths of a second, and hence I conclude that I could examine the divisions of my circle (of one foot radius) without being liable to a greater error than 93 seconds." This is stated on calculation to be the extreme limit; which, according to the doctrine of chances, can very seldom happen, but if one-half of this error is likely to happen in any one division of the whole circle, as read off by the microscopes, the result will be, that the errors of the table may be as great as those of a well-divided instrument, searching it to preserve its figure unaltered after examination. In another part of the paper before us, the author says, "we may likewise observe, that the examination we shall not only be secured against the errors of division, but against those which arise from bad centering, and from the imperfect figure of the circle, and which in general are of too great a magnitude to be neglected." From this observation we must necessarily conclude, that the distance between the microscope and micrometer, used in measuring, was not the measure of the included arc, but of the angular quantity at the centre opposite that arc; for it must be evident, that, in the axis of motion is not precisely the centre
of the divided circle, the arc, simply considered, will not be the true measure of the angle; seeing one side of the circle will be farther from the centre than the other. For instance, if we suppose the line that passes from zero to the centre of the divided circle, should also pass through the centre of motion, placed a small quantity out of the centre of the graduated circle, in this case the angles subtended by the first and fourth quadrant arcs will be greater than those subtended by the second and third; but if the line from zero to the centre of motion should pass through the centre of the divided circle, then the angles subtended by the first and second quadrant arcs will be greater than those subtended by the third and fourth. When, however, the microscopes have a cross hair, as well as a radial one, the length of the radius as well as of the arc may be measured, and consequently the true quantity of the subtended angle.

The great familiarity between the due de Chaulme's method of dividing a circle, and of professor Lax's method of examining one when divided, cannot but strike the reader; they both use microscopes, one with a micrometer attached, and both take multiples of the arc under consideration; but one corrects the errors by adjustment during the act of dividing, and the other calculates and tabulates them for subsequent corrections.

Neither will the known facts pass unnoticed between the apparatus employed by Mr. Lax, and that for the purpose of examining standard measures, described by Sir Geo. Shuckburgh (Phil. Trans. 1758); but Mr. Troughton, we know, acquires the learned professor of borrowing any thing from him.

In the spring of 1810, Mr. James Allan, of Blewitt's Buildings, Petter Lane, London, received the gold medal from the Society of Arts, at the Adelphi, for a new method of equalizing the teeth on the edge of an engine plate for dividing frets, &c., which would have been described most properly under the article Engine, but as it was not then made known, we will take some notice of it in this place, though the Society's account is not yet published. The professed method of Mr. Allan's method of racking, consists in its enabling a bad divider of a circle to correct his divisions, by what he calls a self-correction process. The contrivance is this: the usual wheel or circular plate that is raked, has a brass rim of about two inches breadth, and of the same diameter and thickness as the wheel, rabbeded over it, so as to appear as a part of the same wheel; four steady pins, at the exact distance of a quadrant from each other, keep the rim in its place by the aid of several equi-distant screws, and the rim will therefore admit of four positions on the wheel. When the wheel and rim together have been faintly raked in the usual way (see Engine by Rawsthorn) one of the other positions is given to the rim, suppose the opposite one, and then the operation of racking by the screw is resumed; when the teeth are a little formed, another position is given to the rim, and the racking resumed as before to a certain extent, and, after several changes have been gone through, it is presumed that the teeth become nearly equalized, and are exactly equal to one another at the conclusion. How far this will be precisely the case we will not pretend to assert. We conceive it to be a very nice operation to drill four holes in the wheel and rim so exactly equi-distant and concentric, that a reversed position shall not affect their relative fittings, and if there is the least deviation in this respect, it will be charged as an error on the divisions. The screws also professes to be placed so as to admit of reverting in position, and unless the steady pins fill their holes completely, these pins will, in all probability, be drawn aside by the fixing screws in some of the positions. If the wheel is truly racked in the first instance by a careful divider, and the steady pins placed with precision, the reverting of the rim will not disturb the coincidence of the two rows of teeth all round, which is the thing truly desired; but if the original division was bad, and had both negative and positive deviations from true division, in different parts of the circle, then we have a doubt whether the rim will produce the desired effect of equalizing them: a good screw will of itself equalize contiguous teeth, when fifteen teeth or upwards are acted on at the same time; but it will not equalize distant teeth, which the rim professes to do. In order, however, to answer the purpose of a self-correction, the rim must be competent to meet all cases of bad division that are liable to occur; let us suppose, in the first place, that whenever large teeth are made by the divider on one side of the wheel, teeth corresponding in smallness are to be met with at the opposite side, in this case, which is the most favourable to the operation of the rim, the errors being opposed to each other, by an opposite position of therim, will correct each other, provided they are of similar quantity, and the rim will produce its desired effect; but, secondly, if equal errors happen to be in the same direction they will not be corrected at all; and, thirdly, if unequal errors be in the same direction, they will be corrected by only half their difference; nay, arcs of the wheel, that are true at first, will, we conceive, be vitiated, unless they fall in with arcs of the rim that are also true. How far a change of temperature will affect this long process we will not affirm: but we hesitate not to give it as our opinion, that an upper plate, or wheel, revolving on the same centre as the wheel itself, would be less liable to central error than the rim with steady pins, however carefully fixed; for steady pins could not then cause any sensible eccentricity in fixing at the different positions.

It would have been desirable if Mr. Allan had given with his account of the racking, his method of making a perfect screw, which is essential in a dividing engine. We lately had an opportunity of examining one of his engine-divided reflecting circles, and found, however, the opposite verniers very well corresponding with each other all round the circumference.

Graduation of a Circle geometrically. After the description we have given in our preceding article of the various practical methods of graduating allronomical instruments, it may, perhaps, seem superfluous to give a further account of the methods that geometrical have proposed for graduating a circle theoretically; but which have been of little or no use in the practical division of circles, or circular arcs, on instruments. It is not sufficient for the purpose of the instrument-maker, that a problem be true merely, but that the means necessary for its adoption in practice be not subject to the introduction of error. The ancient geometry implies the possibility of making a straight line in practice through two given points, which cannot be effected with certainty by a ruler and pointed tool, however carefully applied, while the modern geometry of Mochneni, the Italian, rejects the use of lines altogether, and substitutes the compasses only in the division of a circle. We will gratify the curiosity of the reader with a few specimens of each method in succession.

In Adam's geometrical and graphical essays are the following problems, which imply the practicality of drawing a straight line through two given points.
GRADUATION.

Problem I.

"To cut off from any given arc of a circle a third, a fifth, a seventh, &c. odd parts, and thence to divide that arc into any number of equal parts."

Example 1. — To divide the arc \( \overarc{AB} \) into three equal parts, \( \overarc{CA} \) being the radius, and \( \overarc{C} \) the centre of the arc. Bisect \( \overarc{AB} \), fig. 1. of Plate XXI. of Astronomical Instruments, in \( \overarc{K} \), draw the two radii \( \overarc{CK}, \overarc{CB} \), and the chord \( \overarc{AB} \); produce \( \overarc{AB} \) at pleasure, and make \( \overarc{BL} = \overarc{AB} \); bisect \( \overarc{AC} \) at \( \overarc{G} \); then a rule on \( \overarc{G} \) and \( \overarc{L} \) will cut \( \overarc{CB} \) in \( \overarc{E} \), and \( \overarc{BE} \) will be \( \frac{1}{3} \) and \( \overarc{CE} \) \( \frac{2}{3} \) of the radius \( \overarc{CB} \); on \( \overarc{CB} \) with \( \overarc{CE} \), describe the arc \( \overarc{E} \); lastly, let off the extent \( \overarc{E} \) or \( \overarc{E} \) from \( \overarc{B} \) to \( \overarc{a} \), and from \( \overarc{a} \) to \( \overarc{b} \), and the arc \( \overarc{K} \) will be divided into three equal parts.

Corollary. — Hence, having a sextant, quadrant, &c. accurately divided, \( \frac{1}{3} \) the chord of any arc let off upon any other arc of \( \frac{1}{4} \) that radius will cut off an arc similar to the first, and containing the name number of degrees. Also, \( \frac{1}{3} \), \( \frac{1}{4} \), \( \frac{1}{5} \), &c. of a larger chord will exactly cut similar arcs on a circle whose radius is \( \frac{1}{3} \), \( \frac{1}{4} \), \( \frac{1}{5} \), &c. of the radius of the first arc.

Example 2. — Let it be required to divide the arc \( \overarc{AB} \), of the fame figure, into five equal parts, or to find \( \frac{1}{5} \) of the arc \( \overarc{AB} \).

Having bisected the given arc \( \overarc{AB} \) in \( \overarc{K} \), and drawn the three radii \( \overarc{CA}, \overarc{CK}, \overarc{CB} \), with radius \( \overarc{C} \) I describe the arc \( \overarc{I} \), which will be bisected in \( n \) by the line \( \overarc{K} \); then take the extent \( \overarc{I} \), or its equal \( \overarc{M} \), and set it off twice from \( \overarc{A} \) to \( \overarc{B} \); that is, first from \( \overarc{A} \) to \( \overarc{a} \), and then from \( \overarc{a} \) to \( \overarc{b} \), and \( \overarc{a} \) will be \( \frac{1}{5} \) of the arc \( \overarc{AB} \). Again, let off the same extent from \( \overarc{B} \) to \( \overarc{m} \), and from \( \overarc{m} \) to \( \overarc{e} \), and the the arc \( \overarc{AB} \) will be accurately divided into five equal parts.

Example 3. — To divide the given arc \( \overarc{AB} \) into seven equal parts. \( \overarc{AB} \) being bisected as before, and the radii \( \overarc{CA}, \overarc{CK}, \overarc{CB} \), drawn, find (by a problem referred to) the seventh part \( \overarc{P} \) of the radius \( \overarc{CB} \), and with the radius \( \overarc{CP} \) describe the arc \( \overarc{P} \); then set off the extent \( \overarc{P} \) twice from \( \overarc{A} \) to \( \overarc{J} \), and from \( \overarc{J} \) to \( \overarc{6} \), and \( \overarc{6} \) will be the seventh part of the given arc \( \overarc{AB} \); the compass being kept to the same opening \( \overarc{P} \), set it from \( \overarc{B} \) to \( \overarc{d} \), and from \( \overarc{d} \) to \( \overarc{c} \), and from \( \overarc{c} \) to \( \overarc{e} \); then the extent \( \overarc{A} \) will bisect \( \overarc{13} \) into \( \overarc{2} \) and \( \overarc{46} \) into \( \overarc{5} \); and thus divide the given arc into seven equal parts.

It is obvious, that this method of dividing any portion of a circle, into an odd number of equal parts, is subject to three sources of error in practice; 1st, the variation of the compass from expansion; 2d, the uncertainty of getting the exact points of intersection where the angles are acute; and 3dly, the probable deviation of the points in stepping; to say nothing of the errors arising from drawing the right lines, which would, in all probability, exceed all the other errors put together, even before they are doubled and trebled, &c. by stepping.

Problem II.

"To divide a given arc of a circle into any number of equal parts by the help of a pair of beam, or other compasses, the distance of whose points shall not be nearer to each other than the given chord," (by Clavius.)

Let \( \overarc{AB} \), fig. 2, of Plate XXI. be the given circular arc to be divided into a number of equal parts. Produce the arc at pleasure; then take the extent \( \overarc{AB} \), and let it off, on the prolonged arc, as many times as the given small arc is to be divided into smaller parts, namely, to the points \( \overarc{C}, \overarc{D}, \overarc{E}, \overarc{F}, \text{and} \overarc{G} \). Divide now the whole line \( \overarc{AG} \) into as many equal parts as are required in \( \overarc{AB} \); as \( \overarc{G}, \overarc{H}, \overarc{I}, \overarc{K}, \overarc{L}, \overarc{I} \), each of which contains the given line, and one of those parts into which the given line is to be divided. For \( \overarc{AG} \) is to \( \overarc{AL} \), as \( \overarc{AF} \) to \( \overarc{AB} \); in other words, \( \overarc{AL} \) is contained five times in \( \overarc{AG} \), as \( \overarc{AB} \) is in \( \overarc{AF} \); therefore, since \( \overarc{AG} \) contains \( \overarc{AF} \), and \( \overarc{4} \) and \( \overarc{5} \) of \( \overarc{AB} \), then \( \overarc{AB} \) into \( \overarc{5} \) the 14th of \( \overarc{A} \). Then, as \( \overarc{GH} \) contains \( \overarc{AB} \), plus \( \overarc{FH} \), which is \( \overarc{4} \) of \( \overarc{AB} \), \( \overarc{F} \) will be the 14th of \( \overarc{A} \). Hence, if we set off the interval \( \overarc{GH} \) from \( \overarc{F} \) and \( \overarc{H} \), we obtain two parts between \( F \) and \( I \); the fame interval, or extent, let off from these two points near \( I \), gives three parts between \( D \) and \( K \); when let off from the points from \( D \) to \( K \), it gives four parts in \( C \); and the next transfer will, from those points, give five parts from \( B \) to \( A \); so that, lastly, the fame extent will give back again the remaining divisions in succession from those between \( B \) and \( C \).

This method is liable to some of the fame sources of error as the preceding method, when compasses alone are depended on; but it is useful, according to the due de Chateline's mode of proceeding, and may be serviceable in Ramsden's method of dividing, where the points are rectified by opposite microscopes. In all probability the vernier scale owes its origin to this problem of Clavius, which problem may be variously described, to prevent the necessity of small extents; but whenever small spaces are marked out on an arc by a differential plan of this fort, it is requisite that the extent begin with should not alter during the whole process, and also that the points, once marked, should be capable of being resumed with certainty at the subsequent transfer. When, however, an error is made in any divided space by a hard particle, or otherwise, this error will recur at every multiple of the extent measured therefrom.

This problem of Clavius, it will be remarked, implies the given arc \( \overarc{AB} \) to be measured, or otherwise known previously to the proposed sub-division.

When an entire circle is proposed to be divided into degrees, the radius, which is equal to the chord of 60°, affords the means of making six equal arcs; and these arcs may be sub-divided to arcs of 15° each by bisection only; but to reduce the equal arcs to a still lower denomination, recourse must be had to either trisection, quinquesection, computation of the chords, or the differential method originally proposed by Clavius, all which have been already described.

The method of dividing a circle, proposed by L. Mascheroni, is translated into French by A. M. Carette, 1758; and is contained in the second book of his "Geometrie du Compas." This method rejects not only the drawing of lines, but all measurement from scales, and bisections of an arc by trial, as well as trisections, quinquesections, &c. but admits of stepping, and supposes the extent of a pair of compasses, once taken, to be afterwards invariable. The radius of the circle is the basis of all the other extents, which are very few in number, considering the various divisions that may be made therewith, and three points determined, one without and two within the circle, afford the means of taking all the measurements, instead of a scale; consequently, any circle divided by this method must necessarily have its plane extended considerably beyond and within the circular space to be divided, which is seldom the case in a large instrument, where a ring or coil is attached to radial bars, and forme a wheel for the body of the instrument, which construction contributes equally to greater strength and lightness; a
Graduation.

that sheet of metal, which the present method of dividing requires, is seldom, if ever, adopted in the construction of an instrument of considerable radius. The second book of the "Geometry of the Compasses," which has not yet been translated into English, and which therefore may not be known to many of our readers, contains ten problems on the division of the circumference of a circle, and one on the manner of bisecting an arc by a new process, that makes no superfluous marks, and requires no second trial: these problems are accompanied by demonstrations and corollaries, that would enlarge our article too much, were we to transcribe them entirely, but we will give much of the substance of these problems, as will enable the reader to comprehend the nature and extent of the division in question, which we apprehend will be deemed more curious than useful.

The ten problems divide the circle into the following parts, according to the order in which they are treated one another, viz. 1. 8, 12, 24, 48, 5, 10, 120, 20, and 240. Let fig. 3, of Plate XXI, be a diagram for illustrating the four first divisions or problems. Let one beam, or other kind of compass, describe the circle with the extent B A from the centre A, and let this compass have its extent preferred unaltered, to represent the radius, and be called the first compass; with this extent and beginning at B, as zero, turn over to C, D, E, d, e, and back to B again; if this is accurately done, B A E will bisect the circle, B D d will trisect it, and the fix original points will divide it into five arcs of 60° each; take now B D, the chord of 120° in the second compass, and preserve this extent unaltered; from zero B and its opposite point E, bisect the point a out of the circle, with this extent; then will the distance a A, taken in a third compass, and kept unaltered, be the chord B F of 90°; also of the arc E F, of E f, and of f B; the circle is now divided into four quadrants at the points B, F, E, and f. To obtain an eighth part of the circumference, set A B, by the compasses N ° 1, from the point a, out of the circle, to G and H in the arc on each side; then the semi-circle is divided into four, and the points g and h, in the other semi-circle, may be transferred from G to H, and from H to b, with the compasses N ° 3, or chord of 90°; and the whole circle will now be divided into eight equal arcs by the points B, O, G, E, H, f, E, and f.

To gain twelve equal arcs of the circle, with N ° 1, or extreme radius, and E a, the point a within the circle, is necessary: to avoid confusion from further sub-division, we will take another fig. (4) with familiar letters of reference as the preceding one. With N ° 3, or extent a A of 90°, intersect at the point b from the points N and O, then with a fifth extent B b set off from B to O, and the arc B Q will be the fifth part of the circumference. To bisect these five large arcs, take the sixth extent A b and set it from B to P, which will be equal to the arc P Q, and, consequently, will be a tenth part of the circumference. Again, without any further operation, the small arc Q L, already marked, will be the 120th part of the circumference; and to subdivide the whole circumference by the small arc P of 1° 30′, the arc N G of 15° must first be divided into five parts of 3′ each, without quinquesection; thus, with the extent A b = B P, step from B to the points P, Q, R, S, and it will fall next in E already marked; then with A b, as before, begin at L and put in the points q and p successively; also from I put in r; and from O put in s, by stepping the points t, s, and t; thus shall the points P, R, and S sub-divide the arc N G into five equal arcs, and will be found equal P S, or 120th part of the whole. After having obtained these five sub-divisions of 3′ and 1° 30′, the first may be transferred, with the extent N G for inference, into other arcs of 15° in succession, beginning with C G first, and using the points N, P, and C, as they occur, till the whole is gone through, after which the small arcs thus transferred may be bisected by an extent N N, going a second time over the same points in succession as before. Thus will the whole circumference be sub-divided into 240 parts of each 1° 30′.

The eleventh or last problem on this subject, is to divide any arc B C (fig. 5) into two equal parts in G. To this: with radius A B, which has described the arc B C to be divided, and from the centres B and C, the two extremities of the arc, let the arcs A D and A E be described; let A D and A E be each made equal to B C; then from the points D and E, as centres, and with radius D C or E B, and by intersecing the point F; lastly, with the radius A F, and from the centres D and E, let the point G be interseced, which will fall in the circumference, if the operation is truly performed, and will also bisect the arc B C as was required.

By the help of the three remarkable points a, b, and h, in our fig. 4, the author of the Geometry of the Compasses, has laid down in his twelfth and last book a dozen equations, some one of which may be applied to determine, by approximation, almost any small arc of a circle that shall cut off a given quantity. It would be tedious to enter minutely into his various calculations, but, for the sake of amusing the reader, we will select the solutions of a few problems, without the annexed demonstrations, which would enlarge our article too much.

Problem I.

To find the arc of one degree without the error of half a second.

Solution.—Let the arc B = z, below B, be 55° 30′, (in the circle which has been divided into 240 parts of each 1° 30′), take the distance b = z; and from the point s, a centre, describe an arc to cut the circumference in some point Z, and the arc B Z, above B, will be 52° 59′ 17′′ or 53′′ within about 25′′; then in the divisions between B and F is the division...
division 54°, or $\frac{3}{4}$ of the whole circle; there will therefore be $54° - 53° = 1°$ by approximation within the required degree of accuracy.

Solution 2.—Let the arc $BZ$ be taken $= 10° 30'$, (by the divisions existing) from the centre $a$, and with the distance $bZ$ as radius, cross the circumference in the said point $Z' = 29° 29'54''$, or $29° 30'$ without an error of half a second; then look for $28° 30'$ in the existing divisions, viz. $\frac{3}{4}$ of the circle, and the difference will be very nearly as before $= 1°$. This solution is less accurate than the former by about $4''$; the error being $29''$.

**Problem II.**

*To find an arc of 15° without an error of 1°.*

**Solution.**—Take the arc $Bz = 12°$ below B, the distance $cz$ will be the chord of $87° 15'$, with a radius of this extent, and from B, as a centre, cut the arc $BF$ above, in the point $Z'$, and the arc $BZ'$ will be $87° 15'$; but among the existing divisions of the arc is $87°$, or $\frac{5}{6}$th of the circumference; therefore, the difference of the two arcs is $= 1°$.

**Problem III.**

*To find an arc of 10° without an error of 10°.*

**Solution.**—Take the arc $BZ$ downward $= 49° 30'$, and the distance $bZ$ will be the chord of $38° 50'$, without an error of $10''$; then, the division $39°$, or $\frac{3}{4}$, being found already, their difference on the circumference taken from B upwards, will be an arc of $10°$.

**Problem IV.**

*To find an arc of $6'$ within $13''$.**

**Solution.**—Take the chord of $45°$ from B to G above, and from the point $b$ cut the circumference at $=\pi$, which will be at $40° 6', downwards from B, without an error of $13''$, but $40'$ counted downwards already exists, therefore the small arc between is $6'$. 

**Problem V.**

*To find an arc of $1'$ within $22''$.**

**Solution.**—Let $BZ$ downwards be $= 27°$; from the point $a$ as a centre with radius $bZ$, cut the circumference above at $Z$; and the arc $BZ$ will be $29° 59'$, with an excess of $22''$; therefore, the arc $BN$ being $30°$, the arc $ZN$ will be $1'$ within $22''$.

Byitch means as these an arc of $9''$ is determined; also, an arc of $20''$ within $1''$; an arc of $15''$ within $10''$; an arc of $12''$ within $1''$; an arc of $10''$ within $1''$; and an arc of $5''$ within $2''$; but these last arcs are so minute in all ordinary circles, that we omit the solutions, as being of no utility.

We have hitherto supposed the circle divided into $360°$ with their subdivisions, but the French have proposed a centesimal division of the circle to be subdivided, where each quadrant has $100°$ instead of $90°$, making $400°$ in the whole circle, with each degree subdivided by hundreds, &c. This mode of dividing has been exemplified by L. Mascheroni, in his Geometry of the Compas; and Mr. Troughton has described the method of graduating a circle in this way by his method, if it should ever prevail in England; but, as there appears to be no advantage to the divider in affording biflections lower than $25°$, and as our tables of logarithms, as well as astronomical tables, are adapted to the existing mode of dividing the circle, we are unwilling to lend our aid to the introduction of useless innovations, by entering more minutely into the subject.

L. Mascheroni is the Italian geometer, who informed, that taught Bonaparte some problems, when in one of his campaigns in Italy, with one of which he puzzled the French mathematicians, and gained the reputation of being an adept in mathematics.

**Graduation, in Mineralogy.** When a mineral is discovered which is intermediate between other known species, and in different specimens, or parts of the same specimen, approaches very near to such known minerals, it is said to graduate, pass into, pass over to, or make transitions to, such minerals. Frequently, the first of the earth graduate thus into each other, so that it is extremely difficult to define where one mineral ends and another of very different properties begins; these graduations are not uncommon between some lime-dolomite and the chert beds in them. More frequently, each mineral is separated by a thin layer or way-board of pulverulent matter, which occasions the firstrate to part freely and, often, in such cases, the parts of the interface in contact with these way-boards differ nothing from the general mass of each mineral, or there is no graduation between one mineral and the next in succession.

**Graduation of saline Liquors, in Chemistry,** is a method of concentrating weak saline solutions, by pouring them through a heap of faggots, and expelling them in this divided state to a free current of air. See *Muriate of Soda.*

**Gradus Gemonic.** See *Gemonic.*

**GRÆA, Græa,** a name used by the old Greek writers for the wrinkled pellicle which arises upon milk in the boiling.

It was also used in a figurative sense for the wrinkles in the skin of old people.

**GRÆCIA, Greece,** in Ancient Geography, a country of considerable extent, forming, as it were, the boundary or frontier between Europe and Asia, and comprehending a great number of different states and kingdoms. We have various opinions as to the etymology of the appellations Greece and Græcia. The most prevalent opinion traces the origin of these terms to Graicus or Græus, the father, as some say, but, according to others, the son of Thebæus, who gave its name to Thessaly. Salmasius supposes the name Græus to be derived from Ragus or Rau, the son of Peleg, the fourth in descent from Jem, the son of Noah, by the transposition of a letter in order to soften the sound. Péron deduces it from Graia, signifying in Celtic ancient, and applicable to the Grecians by way of contradistinction to more modern people. But it has been objected to this etymology, that the Pelagiæ and Hellenæ were a more ancient people than the Greeks. M. de Gebelin supposes the origin of the appellation to have been the word rha, or rba, denoting vaft or immense, in reference to the sea which terminated the Adriatic gulf, on the borders of which the Greeks migrated southwards, whence he forms *Rhaus,* signifying this sea, and by prefixing the guttural G to the hylial R, *Græus.* The Greeks were also called Achæans, Helles, and Pelaïgæ. The first of these appellations is supposed to have been derived from Achæus, the son of Xuthus, the son of Helen, and father of Ion; the second from Hellen, just mentioned, the son of Deucalion, and father of Dorus, from whom sprang the Dorians, and the third, from a pretended founder Pelasgus, who, taking possession of the Peloponnesus, occasioned its being denominated Pelasgia. Grotius, Salmasius, and Stillingfleet,

---

*Names*
names of considerable authority in disquisitions of this nature, suppose that the descendants of Peleg, the fourth in descent from them, the son of Noah, whom they suppose to have been the father of the Scythians, were the first who peopled Greece; and that they only fastened the name of Peleg, or Phaleg, their progenitor, and called them Pelasgians. But Bochart (in his "Phaleg") shews, that both Phaleg and Ragau, and their descendants, remained in the confines of Media and Armenia; and that the Scythians were the descendants of Magog, and not of Phaleg or Ragau. Some have asserted that the most ancient name of all is that of Iones, which the Greeks themselves derive from Xuthus, grandson to Dankalion. Josphus affirms (Ant. i. i. c. 7.) that their original is of much older date; and that Javan, the son of Japhet, and grandson of Noah, and his descendants, were the first who peopled these countries; and in proof of this position the learned Bochart has alleged several strong presumptive arguments. He first adduces the authority of Josphus, just cited; he then appeals to the name of the patriarch, יי, which, without the points, sounds more properly Ion than Javan; he next alleges the authority of Moses, who says (Gen. x. 5.) that "by thee" (the sons of Japhet) "were the isles of the Gentiles divided;" which, according to the genius of the Hebrew, mean, not islands properly so called, but all maritime countries, at any distance from Palestine, especially those which are along the Mediterranean; and he also refers to the prophets (Is. cap. ult. v. 19. Dan. viii. 21. x. 20) who call Grecia by the name יי, Ion, or Javan, and hence the Jews have always called the Greek tongue יי, Javanish. To these arguments he adds that the clear remains of Eliish, Javan’s eldest son, are still to be found in that of Elys, one of the ancient kingdoms of the Peloponnesus.

Grecia, or Ancient Greece, Geography of. Exclusively of the provinces of Epirus and Macedonia, which long remained barbarous and uncultivated, the continental possessions of the Greeks (says Dr. Gillies,) were nearly equal to Scotland in extent. In its length, comprehended between the 36th and 41st degrees of N. latitude, the whole country is almost equally divided by two opposite gulfs, compressing between them a mountainous neck of land, to the breadth of only five miles, into the peninsula of Peloponnesus, and the territory extending northwards, from the extremity of the Corinthian isthmus to the southern frontier of Macedonia. The Peloponnesus, 160 miles in length, and scarcely 100 in breadth, is every where interfected by mountains, particularly the towering ridges of Zarex and Taygetus. During the flourishing ages of Greece, this small peninsula contained seven independent communities of unequal power and fame, which ranked in the following order: the comparatively large, and highly diversified, territory of Laconia; the fruitful vale of Argos; the extensive coast of Achaia; the narrow but commercial isthmus of Corinth; the central and mountainous region of Arcadia; together with the more level countries of Elia and Messenia, which are throughout better adapted to tillage, than any other provinces of the Peloponnesus. The Grecian possessions beyond the isthmus of Corinth were more considerable, extending above 200 miles from east to west, and 150 from north to south. They were naturally divided by the long and intricate ridges of Olympus, Pindus, Oeta, and Ossa, into nine separate provinces; which, during the celebrated ages of Grecian freedom, were occupied by nine independent republics. They comprehended the extensive and fertile plains of Thessaly and Boeotia, both of which were, in early times, much exposed to inundations, and the latter, abounding in subterranean caverns, was peculiarly subject to earthquakes; the less fertile, but more fecure territory of Attica; the western provinces of Aetolia and Acarnania, encompassed on one side by dangerous seas, and confined on the other by almost impassable mountains; and the four small rocky districts of Phocis, Doris, Locris, and Megara. These provinces and divisions (says the above cited historian) which remained to the latest times, are pretty accurately marked by Homer, whose poems continued, through succeeding ages, to be the approved standard and legal code, to which neighbouring communities appealed, in adjusting their disputed boundaries. This qualification, however, must be admitted with two exceptions. During the Trojan war, the extensive province of Thessaly sent forth above a fourth part of the whole Grecian strength, and was divided among many warlike leaders. But when commerce, navigation, and the mechanic arts, enriched and adorned the middle and southern divisions of Greece, the northern district of Thessaly lost its ancient pre-eminence. The other exception arose from the extensive power of the house of Pelops, which had, by fortunate marriages and rich successions, acquired dominion over the northern and eastern parts of the Peloponnesus, formerly containing several independent principalities, and, after the misfortunes of Agamemnon and his family, again divided into the immortal republics of Sparta, Argos, Corinth, and Achaia. The following table will exhibit at one view the principal states of Greece, with some of their towns and rivers, referring to each article for a further account, and observing that we have admitted into it Macedonia, though it was not properly a province of Greece till after the reign of Philip, or rather that of Alexander, and also Epirus and Illyria.

The ancient authors who are to be consulted with regard to the different periods of the geography of Greece, are Homer, for the more remote times, in his account of the forces collected for the siege and capture of Troy; Strabo, who avails himself of ample materials to which he had access; Paulyanias, who details the results of his own travels and observations; and Ptolemy, who furnishes an useful nomenclature of the states and chief towns, with their longitudes and latitudes.

**Greece, or Ancient Greece, by P. F.** The traditions of the Greeks (says the learned historian, Dr. Gillies) agree with the authentic records of sacred history in representing the countries afterwards known by the names of Thrace, Macedonia, and Greece, as peopled at an earlier period than any other portion of the western world. The southern corner of Europe, comprehended between the 35th and 41st degrees of latitude, bordering upon Epirus and Macedonia towards the north, and on other sides surrounded by the sea, was inhabited, above 18 centuries before the Christian era, by many small tribes of hunters and shepherds, among whom the Pelasgi and the Hellenes were the most numerous and powerful. The barbarous Pelasgi venerated Inachus, as their founder; and, for a similar reason, the more humane Hellenes respected Deucalion. From his son Helen, they derived their general appellation, which originally denoted a small tribe in Thessaly, and from Dorus, Eolus, and Ion, his more remote descendants, they were denominatet by the names of Dorians, Eolians, and Ionians. The Dorians took possession of that mountainous district of Greece, afterwards called Doris; the Ionians, whose name was gradually lost in the more illustrious appellation of Athenians, settled in the less barren parts of Attica; and the Eolians peopled Elia and Arcadia, the western and inland regions of the Peloponnesus. Notwithstanding many partial emigrations, these three original divisions of the Hellenes generally entertained an affection for the establishments which had been preferred by the wisdom or caprice of their respective ancestors—a circumstance which remarkably distinguished the Hellenic from the Pelasgic race. While the former discovered a degree of attachment to their native land, feldom found in barbarians, who live by hunting or pasture, the latter, disdaining fixed habitations, wandered in large bodies over Greece, or transported themselves into the neighbouring islands; and the most considerable portion of them gradually removing to the coasts of Italy and Thrace, those that remained melted away into the Doric and Ionic tribes. At the distance of 12 centuries, obscure traces of the Pelasgi occurred in several Grecian cities; a district of Thessaly always retained their name; and their colonies continued, in the fifth century B.C., to inhabit the southern coast of Italy, and the shores of the Hellepont; and in those widely separated countries, their ancient affinity was recognized in the uniformity of their rude dialect and barbarous manners, extremely disimilar to the customs and language of their Grecian neighbours. Such is the account of the first settlers in Greece, given by Dr. Gillies on the cited authorities of Herodotus, Dionysius Halicarn., Paulyanias, Thucyddes, Diodorus Siculus, and Strabo. Modern authors, however, have entertained different opinions on this subject. Some have supposed that the Pelasgi succeeded the Hellenes, and others have considered them as the same people under different denominations. According to M. de Gebelin, Mothis, the Jewish legislator, has given us the primitive origin of the Greeks. In tracing the genealogy of the descendants of Noah he says that Japhet, one of the sons of Noah, had seven sons: that the fourth was called Ion, and that he was the father of Elia, Tharsis or Thrace, Ketim, and Dodanum; this Ion was the father of the Greeks, and M. de Gebelin labours to find among the Greeks four nations formed by his four sons. With this view, he says, that Pelasgi comprehended the whole territory between the Danube and the sea of Peloponnesus; and here we may discover, as he conceives, the respective situation of each of Ion’s four sons. Thrace acknowledges Thrarsis or Thrarsis for its founder; Ketim possessed the country of the Getae, N. of Macedonia, and Macedonia itself; Dodanum had the country that lay between Macedonia and the Peloponnesus, inhabited by the Dorians; and Elia designated the inhabitants of the Peloponnesus. This author, in so small a degree indulging his imagination, and yet exercising a very considerable degree of ingenuity and attention to facts, observes, that the history of Deucalion is the foundation of the Greek chronology and history: this Deucalion is distinguished by his deluge, his ark, and his being the father of the Greeks or Hellenes. All these circumstances afford a presumption that Deucalion and Noah were the same person. He also says, that the fabk of the Argonauts and their voyage to Colchis is a copy of the navigation of Noah. Phryxus, or the “man favored,” in the Grecian mythology, is Noah. He discovers also other coincidences, which lead him to conclude, not only that Noah and Deucalion, but that Ion and Helen, the reputed father of the Greeks, were the same persons; and that the Hellenes and Pelasgi were the same people.

According to this writer, the Pelasgi were the sole pollellers of the whole country which extended itself from the banks of the Danube, to the sea of the Peloponnesus; they peopled Thrace, Getia, Macedonia, Illyria, Epirus, Thessaly, the Phocide, Attica, and the Peloponnesus; they sent colonies to the isle of Crete, to Etruria, and to the south of Italy; and others crossed the Danube, and were designated Dacians and Getae. Greece was in this state, says M. de Gebelin, when some colonies of strangers arrived on its coasts, as Cecrops at Athens, Danaus at Argos, and Cadmus in Boeotia. Thence, he says, came not from Egypt, but from Phœnicia, a neighbouring country. The first inhabitants of Greece, whencefore they came, were, in a very considerable degree, like the ancestors of other people, barbarous and savage; and the Hellenes, whose manners were mild and gentle, contributed in some measure to civilize them; but their efforts produced effect very slowly. At length, however, the happy position of their country, forming a kind of frontier between Europe and Asia, and divided only by a narrow sea from Egypt and Syria, and not far remote from those eastern regions which were anciently most populous and flourishing, invited strangers first to visit, and afterwards to dwell among them. The Greeks were not insensible of their obligations to strangers for the most important discoveries, not only in religion, but in agriculture and the arts; but as they advanced to superiority in arts and arms, above surroundning nations, they vainly fancied that their infancy was reared by the gods: and to the gods they transferred the merit of many useful inventions, that had been communicated to them or their progenitors by their ancient visitants; and it must be acknowledged, that the worship of several deities was introduced at the same time, and by the same person, who made known to them the arts most subservient to the purposes of human life.

From the middle of the 16th to the middle of the 14th century, B.C., the inundation of Egyptians, Phœnicians, and Phrygians overflowed the Hellenic coasts. The principal colonies were conducted by Cecrops and Danaus, Egyptians, who respectively settled in Athens and Argos; Cadmus, a Phœnician, who founded Thebes in Boeotia; and Persepolis.
The invaders of Greece introduced many important and useful improvements. They brought into that country the knowledge of the Phenician alphabet; they diffused the operations of agriculture; they multiplied the rites of religion; discovered to them several uses of the metals; and, in return, adopted the Greek language, and generally conformed to the Greek customs and institutions. By the Phenicians they were taught and encouraged to brave the dangers of the sea, and to maintain a commercial intercourse with each other, as well as with foreign nations. Their country, indeed, was peculiarly advantageous for this purpose; three sides of it being washed by the sea, and being surrounded by numerous islands, and abounding in excellent harbours. Greece, however, was slow in availing itself of the advantages it enjoyed; and in making improvements in commerce, as well as in agriculture, and other useful arts. Many circumstances concur to retard its improvement.

The inhabitants of different parts of the country were unconnected on account of the greeks and rivers, as well as the mountains and promontories, that rendered Greece different from any other part of Europe. The Greek states were small; each city was at war with its neighbour, and want of union and mutual concurrence prevented their advancement in science and the arts. Besides, their coasts were ravaged by pirates, and the metals, instead of being formed into useful implements of agriculture, were converted into instruments of destruction, partly for hostility and partly for self-defence; and the inland country was invaded by Thracians, Amazons, and other northern savages.

But these invasions and ravages of the barbarians occasioned the institution of the Amphictyonic council, which restored some degree of present tranquillity to Greece, and laid the foundation of its future grandeur. This council produced, after a considerable interval of time, viz. in the year 1263 B.C. the Argonautic expedition, an undertaking which was attended with a beneficial effect on the manners and character of the Greeks. (See ARGONAUTIC.) In the progress of the Greeks towards civilization, they perceived the advantages of political confederacy, before they became sensible of the benefits of civil union; and accordingly, a federal association between different communities was formed before the members of any one state had been sufficiently united in the system of domestic policy. In order to cement such disunited communities by laws and governments, they had recourse to the wise institutions and examples of the Cretans, which are represented not only as the most ancient, but as the best regulations that ever were established in any portion of the Grecian territory. (See CRETE.) Thus, each of the Cretans communicated the Cretan improvements to the Athenians; from Athens they were diffused through Attica, and in process of time through the neighbouring provinces of Greece; and, insomuch, that at the commencement of the Trojan war, in 1193 B.C. all the Cretan states had adopted one uniform system of government, uniting the independent spirit of European freedom with the respectful veneration of Egyptian and Asiatic superstition.

Of the mythology and manners of the Greeks in the heroic ages, as well as their geography and history, Homer, whilst he has indulged his fancy, has given us an accurate delineation; and such as was conformable to the system of opinions and belief which prevailed among his countrymen. The religion, or mythology of the Greeks, was adapted to the melioration of their condition, and to the improvement of civil society. Unlike that of the rude inhabitants of ancient Germany, among whom the offices of priest and king were administered by different persons, the sacerdote, which denoted the connexion of civil power with sacred protection, was conferred, among the Greeks, on those who, while they continued the humble ministers of the gods, were appointed to be the chief and accountable guardians of the people. The same voice (says Dr. Gillies) that summoned the warriors to arms, or that decided, in time of peace, their domestic connections, conducted the order of their religious worship, and prevailed in the prayers and hymns addressed to the divinity. These prayers and hymns, together with the important rite of sacrifice (which was likewise performed by royal hands), formed the ceremonial part of the Grecian religion. The moral was far more extensive, including the principal offices of life, and the nobler virtues of mankind. The useful quality of courage was peculiarly acceptable to the stern god of war; but the virtues of charity and hospitality were still more pleasing to the more amiable divinities. To this purpose Homer says (Od. xiv. 56): "all strangers and beggars come from Jove." The submission of subjects to their prince, the duty of a prince to preserve inviolate the rights of his subjects (Il. xvi. 585), the obedience of children to their parents, the respect of the young for the aged, the sacred laws of truth, justice, honour, and decency, were inculcated and maintained by the awful authority of religion. Even the more ordinary transactions of private life were consecrated by the piety of the Greeks. They ventured not to undertake a voyage, or a journey, without soliciting the propitiation of their heavenly protectors. Every meal (and they had three in a day, viz. morning, dinner, and supper), was accompanied with a sacrifice and libation. The common forms of politeness, the customary duties of civility, were not decided by the varying tastes of individuals, but defined by the precise voice of the gods. The laws of religion were guarded and enforced by corresponding sanctions. The dread and vengeance of imaginary powers was established in the Grecian creed; and it appears from the writings of Homer throughout, that every important event, prosperous or adverse, which happened either to individuals or to nations, appeared to the Greeks, as the reward of their religion and virtue, or the punishment of their irreligion and vice. The principles above stated are confirmed not only by the writings of Homer and Hesiod, but by almost every page of Herodotus, of Pindar, as well as of the Greek tragedians and historians.

The origin of the gods of Greece has afforded a subject of elaborate discussion; and many learned writers have traced it to Palestine, Egypt, and other nations, whence the first settlers or future emigrants sprung. By the dint of light of etymology and tradition (says the ingenious historian of Greece), and the delectable glare of legend and fable, inquisitive men have endeavoured to trace the corrupted fires of Pagan worship to the pure fountain of the Jewish dispensation: and it must be acknowledged, that the general doctrine of providence, the rebellion in heaven, the state of innocence, the fall of man, atonement by sacrifice, and a future state of retribution, for which the present life is only preparatory, are tenets, all, or some of which, are found in the
the traditions of all nations, Greeks and Barbarians. (See Hefiod, Oper. and Di. v. 110, 165. Theog. v. 220, 725.) But our author observes, that the majesty of Jehovah is very feebly represented by the united power of Homer's divinities; and that the mythology of the Greeks is of such a peculiar texture, that, whereon originally derived, it must have undergone a particular modification in the Grecian foil; nor (he says) is it easy to concur with the opinion of writers who bring it immediately from Egypt, Chaldea, or Letier Asia, when we consider that there is not the smallest vestige in Homer of the judicial artology which prevailed so much in the two first countries, (Diod. Sic. i. ii. Exod. ch. vi. Plin. li. xxv.), or of the worshipping of idols, which almost universally prevailed in the last. (Old Testament, paffim.) Dr. Gillies traces the origin of the Grecian faith and worship in the natural passions of the human heart, the hopes, the fears, the wants, the misery of man, which in all ages rendered him a prey to the terrors of superstition.

The great pillar of superstition, raised by the anxious passions of men, was fortified in Greece by a peculiar sensibility of character, which exerts itself in the adornment of social affection, and strengthens, by a thousand associations, their belief in invisible and intelligent powers. The nature, the characters, and the occupations of the gods, were suggested by the lively feelings of an ardent, rather than by the regular invention of a cultivated mind. These celestial beings were subject to the blind passions which govern unhappy mortals: their wants, and their desires, were similar to those of man. But what was wanting in the dignity and perfection, was supplied by the number of the gods. Homer only describes the principal and reigning divinities; but Hefiod, who gives the genealogical history of this fanciful hierarchy, makes the whole number amount to 30,000. Every virtue had its protector, every quality of extensive power in human life had its patron, and every grove, mountain, and river its favourite inhabitants. (See Gods.) The religious creed of the Greeks, composed of materials in great measure created by fancy, formed by poetry into beauty, and improved into use by policy, became the happiest antidote against the furious renement, the savage cruelty, and the fierce spirit of wild independence, which usually characterizes the manners of barbarians. Upon the whole, the ancient and venerable superstition of the Greeks was distinguished above all other false religions, by the uncommon merit of doing much good, without seeming occasioning any considerable harm to society. The Grecian tenets, while they inoculated profound respect to the gods, had no tendency to break the spirit or to repress the courage of their warlike votaries.

In order to avert the calamities threatened by the anger of their divinities, they did not recur to the infliction of tortures on themselves, but they repaired the wrongs which they had committed against their fellow-citizens, or compensated, by new attentions, for the neglect shown to the ceremonies of their national worship. In their imitation, the doing of injury to men, and the omission of prayer to the gods, were the principal caufes of the divine displeasure, which they were anxious to avert by a diligent practice of moral duties. The dangerous power of oracles, the abused privileges of oracles, the wild raptures of prophetic enthusiasm, the abominable ceremonies of the Bacchanalia, and the horrid practice of human sacrifices, all which are circumstances that cover with deferred infamy the latter periods of Paganism, were unknown to the good sense and purity of the heroic ages; nor is there to be discovered the smallest vestige of any of these wild or wicked inventions, either in the writings of Homer, or of his contemporary Hefiod. Their religious lyftem communicated its beneficial influence to the civil and military institutions of the Greeks, to the laws of nations, as well as to the regulations of internal policy, and to the various duties of domestic as well as of social life.

In examining the political states of the Greeks, during the heroic age, we shall find that they defer the title of republics, rather than that of monarchies. The foldiers of any warlike tribe fought and conquered, in their attack of a more fertile territory than their own woods and mountains, not for their leaders, but for themselves; and the land acquired by their united valour was considered as a common property. No distinction was known among them, but that which was occasioned by the difference of personal merit and abilities. This difference raised a chief or leader to the head of each society; and his superior usefulness in this station, was rewarded by the gratitude of his tribe with a valuable portion of ground, separated from the common property. (II. xii. 516.) This person, who commanded in the field, became the arbiter and judge of their civil differences, and he was invested with the honourable office of presiding in their religious solemnities. These important functions of priest, judge, and general, conferred on the chief and bravest, in each particular tribe, were conferred, upon the union of several tribes into one state or nation, on the chief and bravest of all the different leaders. The various states of Greece formed a general confederacy, in which the council of princes regulated the revolutions of the monarch, and the voice of the assembly ruled that of the council; and so likewise in each particular kingdom, the decisions of the senate prevauled over the will of the prince, and the acknowledged majesty of the people controlled the decisions of the senate. The fame distribution of power took place in every particular village.

The civil rights of the Greeks were maintained by the same simplicity which regulated the political system. As the price of submitting to the restraints of society, a man was secured in the enjoyment of his life and property; his moveables were equally divided, at his death, among his descendants; and the unnatural right of primogeniture, which, in order to enrich the eldest son, reduces the rest of the family to want and misery, was altogether unknown to the equal spirit of the Grecian institutions. Causes respecting property were decided by the first magistrate, or by judges of delegated authority. The prosecution of murderers belonged to the relations of the deceased, who might accept a compensation in money for the loss which the family had sustained; but in defect of this composition, all the members of the tribe concurred with the aggrieved, in either punishing the murderer by death, or compelling him to leave the society.

The history of the heroic ages of Greece presents the most interesting picture of conjugal love, parental affection, and filial duty. The institution of marriage was ascribed to the gods; and it was celebrated with all the pomp of religious festivity. Adultery was held in the greatest detestation, and always mentioned with the same horror as murder. The guilty perfon might purchase immunity, but more frequently escaped death by voluntary banishment. It has been erroneously said, that, in ancient Greece, wives, as well as concubines, were the faves of their husbands, and that they were purchased by them. The attention of women was chiefly confined to domestic care and occupations, which did not require any great degree of strength, courage, or wisdom. Weaving and embroidery, which were employments of females, were practiced by ladies of the highest rank, and even by queens; and they were also en-
The Græcia.

Great and Little Bear, the Pleiades, the Hyades, Orion, and the Dog-star. Of their games, we give an account under Games and Gymnastics. As to their general character, we shall transcribe two or three paragraphs from the first volume of Dr. Gillies's History of Ancient Greece, to which we have been indebted in the compilation of this article. "The Græacas," says Dr. G., "had advanced beyond the age of rude barbarism, that uniform indolence of deportment, that fullness of facility, that perfect skill in matters, and that hardened insensibility of heart, which universally characterizes the savage state. They still preserved, however, that patient industry, that noble spirit of independence, that ardent attachment to their friends, and that generous contempt of pain, danger, and death, which render the description of the wild tribes of America so interesting to a philosophic mind. Of two principal enjoyments of life, study and conversation, they were little acquainted, indeed, with the combinations and pleasures of the first, the want of which was compensated by the Socrety, the confidence, the charms of the second. Their local affections were less comprehensive in their objects, but more powerful in their effects than those of polished nations. A generous chief rushes to certain death to revenge the cause of his friend; yet refuses to the prayers of an aged parent the melancholy consolations of interring the remains of his favourite son, till the corresponding image of his own father strikes his mind, and at once melts him to pity. (Ilid. xxiv.) The imaginary wants and artificial passions which are so necessary to urge the hand of industry, and to vary the pursuits of men, in improved commercial societies, were supplied to the Græacas by that excessive sensibility, which interceded them to deeply in the affairs of their community; their tribe, their family, and their friends, and which connected them by the feelings of gratitude even with the inanimate objects of nature. As they were not acquainted with the same diversity of employments, so neither were they fatigued with the same giddy round of dissipated pleasures which augment the splendour of infernal mirth. Though ignorant of innumerable acts which adorn the present age, they had discovered one of inestimable value, to render the great duties of life its most entertaining amusement. It will not, perhaps, be easy to point out a nation who united a more complete subordination to established authority with a higher sense of personal independence, and a more respectful regard to the dictates of religion with a more ardent spirit of martial enterprise. The generous quality of their political establishments, and their fancied intercourse with the gods, conspired to raise them to a certain elevation of character which will be for ever remembered and admired. This character was rendered permanent in Sparta, by the famous laws commonly ascribed to the invention of Lycurgus, but which will appear (under that article) to have been "almost exact copies of the customs and institutions that universally prevailed in Greece during the heroic ages." The character of the Græacas in subsequent periods will appear in the account of the several states, provinces, or kingdoms, which they occupied.

The general history of Greece may be divided into four periods, marked by as many memorable epochs. The first extends to the siege of Troy in the year 1184 B.C.; the era of its commencement is not precisely ascertained, but it may be said, that it was commencing with the foundation of the kingdom of Crete by Androgeus in the year 2050 B.C., and continued for about 1000 years. The first was properly the infancy of Greece; and comprehended the establishment of the kingdom of Sicily, of Argos, 1596 B.C. of Athens, 1596 B.C. of Troy, 1546 B.C. of Thebes, 1492 B.C. of Mycenae, 1444 B.C. the decline of Ogyges, 1764 B.C. and that of Deucalion, 1523 B.C.;
the murder committed by the daughters of Danaus on their husbands, 1485 B.C.; the introduction of the Phoenician letters into Greece, 1493 B.C.; the legislation of Minos in Crete, 1466 B.C.; the Argonautic expedition, 1263 B.C.; the exploits of Theseus, 1234 B.C.; the war of the seven heroes against Thebes, 1225 B.C., &c. &c.

The second period begins with the siege of Troy, and terminates with the battle of Marathon, 490 B.C., including about 604 years. In the year 1184 B.C., 80 years after the taking of Troy, the Heracleids, or descendants of Hercules, conducted the Dorians to the eastern coast of Peloponnesus, and having landed their followers without opposition, afforded the defencelst territories, to which they had long laid claim, comprehending the whole peninsula, except the central province of Arcadia, and the maritime district of Achaia. The five other provinces were conquered at the same time, though by different means. Laconia was betrayed to the invaders; Argos acknowledged their authority; Corinth, Elis, and Messenia submitted to their arms. The revolution was complete, and effected with little bloodshed; but not without great oppression of the ancient inhabitants, many of whom emigrated, and many were reduced to slavery.

The Heracleids divided their new acquisitions by lot. Upon the division of Peloponnesus the kingdom of Lacedaemon commenced, 1102 B.C. In the year 1056 B.C., or 88 years after the taking of Troy, the Eladians, having traversed the northern parts of Greece in quest of new settlements, crossed the Hellespont, and established themselves along the shore of the ancient kingdom of Priam. They gradually diffused their colonies from Cyzicus on the Propontis to the mouth of the river Hermus; which delightful country, together with the isle of Lesbos, from this time received the name of Eolis or Eolia, denoting that its inhabitants belonged to the Eolian branch of the Hellenic race. In the year 1070 B.C. royalty terminated in Athens upon the death of Codrus, and the Athenians were afterwards governed by Archons. In the year 1024 B.C., 60 years after the return of the Heracleids, the Ionians, blended with other emigrants, having feized the central and most beautiful part of the Asiatic coast, gradually diffused their colonies from the banks of the Hermus to the promontory of Pindus, and afterwards took possession of Chios and Samos; and all these countries were united in the year above-mentioned by the name of Ionia, intimating that the Ionians composed the most numerous division of the colony. (See Ionia.)

The Doric migration took place in the year B.C. 944 (See Doris.)

During the heroic ages we have seen, in the preceding part of this article, that the authority of kings was founded on religion, supported by gratitude, and confirmed by utility. While they approved themselves worthy ministers of heaven, they were entitled to due and hereditary honours; but they were bound to respect the rights, the sentiments, and even the prejudices of their subjects. But at length, inspired by ambition and avarice, they transgressed the prescribed limits, and trampled on those laws which their predeccessors had held sacred. The minute division of property, which had taken place, not only in Peloponnesus, but in the northern provinces of Greece, rendered the nobles and people more jealous of their encroachments, and induced them to reft their oppressions. The more independent and illustrious citizens, who from the earliest times had been accustomed to come armed to the council or assembly, communicated their grievances, and adopted proper means for removing them. Miltus, the fourth Argive prince in succession to Temenus, to whom Argos fell on the Heraclean distribution, was condemned to death for usurping absolute power. In Attica monarchy more honourably expired; it perished still more disgracefully in Arcadia; but it was gradually abolished in every province of Greece, except Sparta, from the southern extremity of Peloponnesus to the northern frontier of Thessaly. The consequence of the abolition of monarchy was the introduction of accumulated evils. These, however, were removed, or at least alleviated, by the authority of the Amphictyonic council, and by that of the oracles, particularly that of Delphi. This latter oracle confirmed by its awful function the Olympic games and Spartan laws, which had been respectively established, the former by Iphitus, and the latter by Lycurgus in the same year, 725 B.C.; and which tended to the safety of their respective territories, though in different ways; the Olympic games by rendering Elis the most pacific, and the laws of Lycurgus by making Sparta the most warlike, of all the Greek communities.

Greece, even under its kings, was divided into many independent states; and under the republican form of government, it was still more subdivided; and hence wars became more frequent, and battles more bloody and more obdurate. But the long and spirited contest between the Lacedaemonians and Messenians was the only war of that age which produced permanent effects. Of Laconia and Messenia we shall give an account under their respective articles. We shall here observe, that they were both governed by kings of the family of Hercules, and inhabited by subjects of the Doric race, and yet this kind of mutual affinity and connection was not sufficient to counteract other causes, which produced hostilities among them. Urged by reciprocal provocations which we cannot here detail, the Spartans invade the Messenian frontier and attack the small town of Amphiata; and thus in the year 713 B.C. began the first war between the Messenians and Lacedaemonians, which lasted 19 years, and terminated with the surrender of Ithome, their capital, to the Lacedaemonians, and the dispersion of its inhabitants. In the year 685 B.C. the Messenians prepare to revolt, and a second war commences, which continued 14 years, and ended with the capture of Ira, or Iera, by the Lacedaemonians, after a siege of 11 years. The conquest of Messenia rendered Sparta the most considerable power in Greece, as its subjects occupied two-fifths of the Peloponnesus. In the year B.C. 660 commenced the first "Sacred War," occasioned by an injury committed against the oracle of Delphi, and undertaken by order of the Amphictyons, and terminated by the total destruction of the cities accused of sacrilegious outrage. On occasion of the happy termination of this war the Pythian games were re-established 591 B.C.

The battle of Marathon, which closes this second period of the Greek history, terminated, after a very severe contest, in the total defeat of the Persians, and triumph of the Athenians under their commander Miltiades.

The third period of the history of Greece comprehends an interval of 167 years, that elapsed between the battle of Marathon and the death of Alexander, 323 B.C. The Athenians, in compliance with the advice of Themistocles, augmented their navy; and under his command they defeated the fleets of Erechthe and Coregyra. Themistocles, instead of allowing the Athenians to indulge themselves in security after the advantages they had gained, exhorted them to be always ready for action. In consequence of this judicious counsel, they were enabled to oppose the immense armaments of Xerxes. The Athenian fleet proved the safe-guard of Greece, and prevented a country, from which the knowledge of laws, learning, and civility was defined to flow over Europe, from becoming a province of the Persian empire, and being confounded with the mafs of barbarous nations. Xerxes was provided
provided with 1200 ships of war, and 3000 ships of burden, for his intended expedition: and his army consisted of seventeen hundred thousand infantry, and four hundred thousand cavalry, and these, joined to those who manned his fleet, amounted to near two millions of fighting men. In the year 480 B.C. he passed the Hellespont, and the vain-glorious monarch had the pleasure of reviewing the whole fleet and army near Doricus, a city of Thrace, at the mouth of the river Hebrus. In the mean while these Grecians, who, unmoved by the terrors of invasion, obeyed the voice of liberty and their country, had sent deputies to the inhabitants of Corinth, to deliberate about the common safety. A general union prevailed, and the general danger seemed to harmonize the most discordant members of the common council. The Grecian fleet failed to Artemisium, patiently expecting the arrival of the barbarians. The frigates of Thermopyla, 15 miles distant from the station of the Grecian fleet at Artemisium, and deemed the gate or entrance into Greece, was guarded by troops, confiding chiefly of Peloponnesians, under the command of Leonidas, the Spartan king. Xerxes having made his previous arrangements, sent messengers to treat with the Spartans, and to declare to them the manner of their coming, and to offer on condition of their becoming allies to the great king, but they answered, "Let him come and take them." The messengers then offered them lands, on condition of their becoming allies to the great king, but they answered: "That it was the custom of their republic to conquer lands by valor, not to acquire them by treachery." Xerxes waited four days after the return of the messengers, expecting the Grecians to retreat into their own country, or surrender their arms. On the fifth day he determined to chastise their insolent opposition. The attack was ordered, and the Persians were repulsed; it was renewed the next day with the like effect.

The Greeks, however, were betrayed by Epiphanes, a pernicious wretch of their own nation, who conducted a body of twenty thousand Persians through a passage in the mountains of Octa, several miles to the west of that guarded by Leonidas. The Athenian general had prudently guarded this important but unknown pass, which, as he conceived, chance or treachery might discover to the Persians. A body of 1000 Phocians had been appointed to this service; upon the approach of the Persians they instantly flew to their arms, and determined to repel the proffers of the enemy or to die in the attempt. Expecting to be purfued, they retired to the highest part of the mountain; but the Persians, declining to follow them, seized the passage which they had abandoned, and marched down the mountain in order to accomplish the design which had been preconcerted by the traitor Epiphanes. Leonidas, apprized of this act of treachery, called a council of war; when all the commanders of Peloponnesus, except the Spartans, determined to abandon a post which they deemed to be untenable. Leonidas, however, with 700 Thessalians, 400 Thebans, and 300 Spartans, remained in the post of danger and of glory. In the dead of night the Spartans, headed by Leonidas, marched in a close battalion towards the Persian camp, with resolution heightened by despair. The conflict was ardent and destructive, till the Greeks were favoured in their attack by the darkness of the night; but at the approach of day the Persians, who had previously fled, discovered that their fears had multiplied the number of the enemy; and therefore rallying their scattered forces, Xerxes gave orders to pursue the Greeks, who had retreated in close order to the frigates of Thermopylae. The shock was dreadful; and the battle was maintained on the side of the Greeks with pernicious treachery and deliberate slaughter. At length a barbarian dart pierced the heart of Leonidas; nevertheless, the Lacedemonians and Thessalians, though ingloriously defeated by the Thebans, maintained their firmness to the last; and they were finally not destroyed or conquered, but buried under a trophy of Persian arms. (See Leonidas and Thermopylae.) During the military operations at Thermopylae, the Grecian fleet was stationed in the harbour of Artemisium, the northern promontory of Euboea, and the numerous one of the Persians had anchored on the road that extends between the city of Carthage and the promontory of Capo, on the coast of Thrace. Here it suffered calamities, of which Xerxes had been forewarned, but which he disregarded. Themistocles, by his address, prevailed on the Athenian commander to remain at Artemisium; and as soon as the Persians recovered from the terrors of the storm, the effects of which they had suffered, both sides prepared for a battle, for the result of which see Artemisium. The Persians were again totally defeated near Salamis (which see); upon which Xerxes determined to leave Greece. Of the conduct of Themistocles on this occasion, see his article; and for an account of the battle of Platea, see Plataea. The event of this bloody engagement not only delivered the Greeks from the danger of servitude, but gave them possession of greater wealth than they ever before had expected to possess. In his precipitate retreat from Greece, Xerxes left behind him all his riches and magnificence. The battle of Platea was succeeded by that of Mycale, in which the Greeks were again victors. About 45,000 Persians perished in the field, many fell in the pursuit, and the remainder fled in disorder, nor thought themselves secure till they had reached the walls of Sardis. Their ships, their camp, the freedom of Ionia, and the undisputed possession of the Asiatic coast, formed the inestimable prize of the victors; and thus the expedition of Xerxes, undertaken with a view to enslave Europe, restored liberty to the fairest portion of Asia. The beginning of the 5th century B.C. forms the most glorious era in the history of Greece. It is, however, the peculiar glory of the Athenians, that, during their rapid career of military and naval triumphs, they cultivated, with a generous enthusiasm, the arts which adorn peace as well as war. It is observable that in the single lifetime of Pericles, the republic of Athens produced those inestimable models of poetry, eloquence, and philosophy, which, in every succeeding age, the enlightened passions of mankind hath invariably regarded as the best standards, not merely of competition and style, but of taste and reason. The name of Greece seemed thenceforth to be sunk in that of Athenian. (See Athens, and Sparta.) For an abstract of the further history of this period of Alexander's victory and empire, we have given a brief sketch under his article; we shall here observe, with Dr. Gilly, that during the later years of his reign the Greeks, deprived of the honour and delivered also from the cares of independent sovereignty, and undisturbed by their continual and often bloody dissensions, which deform the annals of their tumultuous liberty, indulged their natural propensity to the social embellishments of life; a propensity by which they were honourably distinguished above all other nations of antiquity. Their innumerable shows, festivals, and dramatic entertainments, were exhibited with more pomp than at any former period. The schools of philosophers and rhetoricians were frequented by all descriptions of men. Painting and statuary were cultivated with equal ardour and success. Many improvements were made in the sciences, and the Greeks, particularly the Athenians, still rivalled the Intellect and genius, though not the spirit and virtue, of their ancestors. Yet even in this degenerate state, when patriotism and true valour were extinct, and the vanquished republicans had neither liberties to love, nor country to defend, their
martial honours were revived, and brightened by an association with the renown of their conqueror. Under Alexander, their exploits, though directed to very different purposes, equalled, perhaps excelled, the boastful victories of Marathon and Plataea. By a singularity peculiar to their fortune, the era of their political dignity coincides with the most splendid period of their military glory. Alexander was himself a Greek; his kingdom had been founded by a Greek colony; and to revenge the wrongs of his nation, he undertook and accomplished the most extraordinary enterprises recorded in the history of the world.

The fourth period of the history of Greece, commencing with the death of Alexander, 323 B.C. and terminating 146 B.C. when the Achaean league was dissolved, and Greece became a Roman province, under the name of Achaea, comprehends an interval of 177 years. After various changes and revolutions, for an account of which, see Achaeans and Athens, it became subject to the Turks.

**Greece.**

A name given to the southern part of Italy, comprehending Apulia, Lucania, and the country of the Bruttii, and also to Sicily and several of the adjacent islands. The name of Grecia was derived from the Greek colonies, which migrated hither at different periods, and the epithet magna, or great, was derived from mere ostentation, as Pliny informs us (l. i. c. 5). This migration and settlement took place at a very early period, about 1055 years B.C. The most numerous colonies, the migration of which was occasioned by intestine faction, foreign invasion, or the restless spirit of adventure and rapine, occupied the isles of the Ionian and Ægean seas, the southern coast of Italy almost interjected by the former, and the winding shores of Asia Minor so beautifully diversified by the latter. The larger islands of Sicily, Sardinia, and Cyprus were very anciently planted by Greeks.

Whoever has observed the delineate barbarity of Calabria, or reflected on the narrow extent and pestilence weakness of Sicily, will fearfully believe, that five centuries B.C. those countries contained above 20 warlike communities, factional of whom could lend into the field 100 thousand fighting men. In order to account for this wonderful population, we must look back to the period above mentioned in the heroic ages; and consider likewise that the greater number of Greek colonies in those parts were planted during the eighth century before the Christian era, and chiefly, 1. By the Euboeans, whose principal city Chalcis, usually furnishing the conductor of the colony, gave the epithet of Chaldæan to their new settlements; 2. By the Achæans of Peloponnesus, who were of the Æolian tongue and lineage; and 3. By the Dorians of that peninsula, especially Corinth. Besides their powerful colonies in Corecyra, Lacedæmon, Arcadian, Anibarea, whose observations form such an important part of the history of ancient Greece, the Corecyraeans founded Syracusae, which soon became, and long continued, the capital of Sicily; and in the sixth century B.C. the Syracusans had extended their settlements over all the southern coast of the island. By means of these and similar establishments of a powerful kind, the Dorians acquired, and always maintained, an ascendant in Sicily; but the Achæan colonies, who were of the Æolian blood and language, commanded the Italian shore. Crotona, the most considerable city of the Achæans, and of all Italy in ancient times, was built 710 years B.C. Sybaris, its rival, was founded about the same time. The former sent colonies to Troas, Cephallenia, and Pandemia; the latter built Laxis, Metapontum, and Pothonia, or Paullum, whose admired ruins attest the ancient wealth and grandeur of the Greek cities of Italy. We may here remark, that the Ionians, who came from Eubœa, and settled chiefly near the cælar shore of Sicily, never rivalled the power and fame of their Dorian and Æolian neighbours, but fell short of those nations in Magna Graecia, as much as they surpassed them on the shores and islands of Asia. In order to account for the flourishing situation of Magna Graecia about the year 500 B.C., many causes may be adduced, besides those of a physical and moral nature, which usually contribute to the rapid growth of newly-established colonies. We might mention the natural fertility of Magna Graecia, and particularly of Sicily, which in many places produced an hundred fold; and in this connexion observe, that the Greeks who failed thither from Peloponnesus, carried with them the knowledge and practice of agriculture which had already attained a high degree of perfection in their peninsula; that the exuberant soil of Sicily, improved by cultivation, soon exhibited a picture of that rich abundance, which, in later times, made that beautiful island be entitled the granary of Rome. Besides, the peculiar situation of the Achæans and Dorians, from whom chiefly the colonies in Magna Graecia derived their origin, had a considerable influence in accelerating the population and grandeur of these new establishments. The impartial and generous spirit of the Achæan laws early compensated the natural defects of their territory, which was a long, but narrow, strip of ground, not more fertile than extensive, along the Corinthian gulf. They, however, were the first, and long the only republic of Greece, who admitted strangers into their community on equal terms with the ancient citizens. The equitable and generous policy, which they transported with them into Magna Graecia, could not fail to promote the happiness and prosperity of that delightful country. The condition of the Dorians, at the time when they planted colonies in Italy and Sicily, is not least worthy of consideration. The Dorian states of Peloponnesus were then universally subject to the gentle government of limited but hereditary princes, or to magistrates chosen from the descendants of their ancient royal families; and who, thus adorned by birth, were sometimes still more ennobled by wisdom and virtue. Moreover, the colonies in Magna Graecia, enjoying a wide extent of territory before them, were not retarded in their advancement by interference of interloc on the part of neighbouring states, but they found sufficient employment in subduing the original inhabitants of that country, without commencing hostilities either with the neighbours of agriculture or war. The kings or nobility of Magna Graecia, secure of their own importance, felt nothing of the republican jealousies which prevailed in the mother country. They received with pleasure new citizens, or rather subjects, from whatever quarter they might come. The states of Italy and Sicily, thus increasing by degrees, could soon boast, the former of Corecyra, Taranto, Sybaris, Rhegium; the latter of Syracuse, Agrigentum, Metapontum, Himera, and several other cities, which rivalled or surpassed the wealth of Athens or Corinth, and the poplufulness of Thebes, Argos, or Sparta. The wars, conquests, or oppressions, and, above all, the civil divisions, which in the sixth century B.C. disturbed and deformed the coast of Æolia, and the other Greek colonies in the islands and continent of Asia, brought frequent acceditions of inhabitants to the shores of Magna Graecia. Nevertheless, the Ionians, along with their poetry, music, and painting, communicated also their diffusive and artistic appettites to the Greeks of Italy and Sicily. It is a fact, however, that Magna Graecia, having obtained emolument by industry, diffipated it in idleness and licentiousness: insomuch that the Greek cities of Italy, and particularly Sybaris and Crotona, fell
GRAEONIUS, Julius, in Biography, a Roman senator, who flourished in the reign of Caligula, was son of a Roman knight, and greatly distinguished for eloquence, and for the study of philosophy, and he carried into practice the moral lessons which his studies led him to contemplate. He refused to obey the command of the emperor to appear as the accuser of Marcus Silius, and suffered death in consequence. Sueton says of him, that he was put to death for the sole reason, that he was too good a man to be permitted to live under a tyrant. He is mentioned by Columella, as having written a treatise concerning agriculture and the management of vines. He was the father of the illustrious Cn. Julius Agricola. Univer. Hill.

GRAEDER FORD, in Geography, a bay of West Greenland. N. lat. 63° 50'. W. long. 49° 30'.

GRAEMSDAY, one of the Orkneys, a flat, fertile island, 14 miles in length, and a mile in breadth, containing 32 families and 175 inhabitants; 10 miles S. of Stromness, near the northern extremity of Hoy. The soil of the interior part is thin and fertile; but the coast is a chain of broken and pointed rocks. It contains a bed of flint, but no fuel.

GRAEN, a town of Hindoostan, in Vifapour; 24 miles S. of Curner.

GRAENSATZ, a town of Croatia; 30 miles S. of Bihaç.

GRAEVUS, JOHN-GEORGE, in Biography, an eminent critic; was born at Naumburg, in Saxony, in 1632. Having acquired a good knowledge of the learned languages in Germany, he went to Leipsic and Rudolph under Ruminus and Strachius. After this he passed two years at Deventer, intimately connected with the celebrated Gronovius, to whom he acknowledged himself indebted for a considerable part of his acquisitions, and whom he after succeeded in his professorhip. (See Gronovius.) His great reputation induced the States of Utrecht to invite him to their university, and during forty-one years he instructed the young men there in politics, history, and eloquence, refuting various invitations to other seminaries. He died in the year 1703, at the age of seventy-one. He was the editor of many of our best classical authors, as Heid, the greater part of the works of Cicero, Florus, Cæsar, Suer-
sue, brought into contact and thereby united, as well as those of the latter supplied with nutritious matters from the former, yet their economy remains still the same. Mr. Bradley has considered it as a fort of planting; the shoot or scion rather taking root in the fock or tree into which it is inferted, than uniting itself with it, as is seen by its preserving its natural purity and utility, although fed and supported merely by a crab-rock; which it is supposed depends upon some difference in the veils of the shoot or scion from those of the fock or tree.

**Grafting**, the act of inferring a shoot or scion taken from one tree, into the flem or some other part of another, in such a manner as to unite and constitute a perfect plant of the same kind as that from which the branch was taken.

It is by this practice that particular sorts of curious fruit-trees of different kinds are capable of being raised with a certainty of their being the same, or not degenerating. It has been observed, that though the plants raised from seed are liable to run from their kinds, and afford such fruits as are not worth the trouble of cultivation; those procured from shoots taken from such trees as produce good fruit, never alter from their kind, whatever the fock or tree on which they are grafted may be; as notwithstanding the grafts receive their nourishment from the focks, their varieties are never altered by them, but continue to produce the same kind of fruit as the tree from which they were taken, the only alteration which they undergo is, that when the focks on which they are grafted do not grow so fast, and afford a sufficient supply of nourishment to the grafts, they do not make so great a progress as they otherwise would do, or is the fruit they produce so fair, or sometimes so well flavoured, or so large.

This process has the advantage, probably from the supply of nutritious matter being not only more abundant but more regular, of rendering the plants or trees which are thus raised more quick in their arriving at the state of maturity, or that of bearing.

It is on these different accounts that the practice of grafting is principally had recourse to, in raising different sorts of fruit trees, as well as some particular sorts of ornamental plants of the tree and flower kinds. It also affords the means of growing different kinds of fruits and flowers of the same fort, in the same fock or tree, as several varieties of pears and apples, &c.

There are different methods of performing this operation, and which are distinguished by different terms or names, as below.

**Rind, Shoulder, or Crown Grafting.**—This is that mode in which the grafts are set in a fort of circle or crown, upon the top of the cut-off item or branch.

It is chiefly practiced upon large trees, when either the head or the large branches are cut off horizontally, and two or more flocks or scions put in, according to the size of the branch or item; in performing which, the scions are cut flat on one side, with a shoulder to rest upon the crown of the fock; then the rind of the fock is raised up, to admit them between the wood and the bark of the fock, which must be inferted about two inches, so as the shoulders may meet, and closely join the crown of the fock; and after the whole of the flocks or scions are inferted, all the crown of the fock should be well clayed over, leaving two eyes of them uncovered with it, which will be sufficient for shooting. It is a method of grafting that was much more in practice formerly than at present, owing to the bad successes with which it has been attended; for, as the scions are placed between the rind of the fock and the wood, they are frequently blown out by strong winds after they have made large shoots, sometimes after five or six years growth.

Where this method is practiced, there should therefore always be some stakes fixed, so as to support the scions until they have almost covered the fock or branch. It is usual to perform the operation in this mode of grafting about the beginning of April, or sometimes a little later.

**Stock, Clift, or Slit-Grafting.**—This is a mode which is practiced upon focks, trees, or branches, of a smaller size, as from one to two inches in diameter, and may be used with success where the rind of the fock is not too thick, by which the inner bark of the scion will be prevented from joining to that of the fock. In performing it the head of the fock or branch must be cut off with a fnbsp; or a fnbsp; be made the contrary way, in the top of the fock, deep enough to receive the scion, which should be cut slooping like a wedge, so as to fit the slit made in the fock; care being taken to leave that side of the wedge which is to be placed outward, much thicker than the other; and in putting the scion into the slit of the fock, great care must be taken to join the rind of the scion exactly to that of the fock; for if these do not unite perfectly, the grafts will not succeed: when this method of grafting is used to focks that are not strong, it will be proper to make a ligature of bals, to prevent the slit of the fock from opening: after which the whole should be clayed over, to prevent the air from penetrating the slit, so as to destroy the grafts, only leaving two eyes of the scion above the clay for shooting. It is usually performed about the beginning of March, or sometimes a little later.

**Whip, or Tongue-Grafting.**—This is most generally practised by nursery-men, especially for small focks, or branches of an inch, half an inch, or less, as the scions much fcover the focks in this method, than in the other. It is performed by cutting off the heads of the focks flopping; then making a notch in the fock towards the upper part downwards, a little more than half an inch deep, to receive the scion, which must be cut with the fock upward, and a slit made in this fock like a tongue, which tongue must be inferted into the slit made in the fock of the fock, and the scion be placed on one side of the fock, so as that the two rinds of the scion and fock may be equal, and join together exactly; after which, there should be a ligature of bals put round to felen the scion, so as that it may not be easily displaced, the whole being afterwards clayed over as in the former methods. It may be performed in the early spring, months, with most success.

There are besides these, some other modes of performing the lumps.

**Grafting by Approach, or Inarch-Grafting.**—This is sometimes called ablation. It is performed where the focks that are designed to be grafted, and the trees from which the graft is to be taken, stand so near together, as that their branches may be bent and united. It is most commonly practiced on hardy exotic plants, and some other forts which do not succeed in any of the other methods. In performing the work, a part of the fock or branch is slit off about two inches in length, a smooth part of the fock being always chosen for the purpose; then a small notch is made in this slit downward, in the same manner as directed for whip-grafting; the branch of the tree designed to be inarched having a part slit off in the fame manner as the fock, and a slit made upward in it, so as to have a tongue, which tongue should be inferted into the slit of the fock, joining their rinds equally, that they may unite well together; after which a ligature of bals should be made, so as to keep them exactly in their situation, and afterwards this part of the fock clayed over well to keep out the air. In this method of grafting, the scion is not separated from the tree until
until it is firmly united with the stock, nor is the head of the flock or branch, which is grafted, cut off till the same time, and only half the wood pared off with a slope, about three inches in length, and the name of the scion or graft. But in this method of grafting, the operation is not performed so early in the season as the others; it being done in the month of April, when the sap is flowing, at which time the scion and stock will join together, and unite much sooner than at any other season or period of the year. It is principally employed in raising jamiines, oranges, and other exotic trees of the harder kinds.

By experience it has been found, that the walnut, fig, and mulberry will take by this method of grafting, while neither of them succeed in any of the other modes. Several sorts of evergreens may likewise be propagated by this method of grafting; but all the trees that are grafted in this way are weaker, and never grow to the size of those which are grafted in the other methods; therefore it is rarely practiced, except on such sorts of trees as will not take by the other methods of performing the operation.

Post-Grafting.—This, which is a late improved mode, is performed by cutting the smooth roots of the stocks in pieces of five or six inches long, and as large, or a little larger, than the grafts; then they are whin-grafted, and tied together very close, so as to prevent the wet from affecting the wounded parts, planting them so deep as that the graft, which should be four or five inches long, may be about half buried. In this way, the grafts themselves will root, and a nearer similitude be preserved to the tree, whences the grafts are taken; and after two or three years, the stock may be cut quite away, and the graft left to maintain itself. In practicing this method, the grafts should be an inch or two longer than the others.

Season of Grafting.—The period or season for grafting should always be regulated by the state of the weather. From the climate being so uncertain in the spring, it is best to defer it till the circulation of the sap is brisk, and the buds of the stocks begin to break into leaves; attention being had that the weak shoots of tender trees will not admit of being so long cut as the more hardy, and that the operation should never be performed while it actually freezes or rains, or there is snow upon the ground.

Proper Grafts.—In providing these, care should be taken that they are shoots of the former year, as when they are older they never succeed well; that they be always taken from healthy fruit trees, as when the trees are sickly from whence they are taken, the grafts often partake so much of the distemper, as not to get the better of it, at least for some years; that they be not taken from young luxuriant trees, whose vessels are generally large, containing to produce luxuriant fruits, and seldom proving fruitful; and that they be taken from the lateral or horizontal shoots, rather than the perpendicular ones. They should be cut off from the trees before their buds be in full leaf, which is not more than three weeks or a month before the scion is grafted; consequently when they are cut off, they should be laid in the ground, with the cut part downwards, burying them half their length, and covering their tops with dry litter, to prevent their drying; if a small joint of the former year's wood be cut off with the scion, it will preserve the better, and when they are grafted, this may be cut off; for, at the same time, the scions must be cut to a proper length before they are inserted in the stocks; but, till then, the scions should remain of their full length, as they were taken from the tree, which will better preserve them from shriveling; when the scions are to be carried a considerable distance, it will be proper to put their ends into a lump of clay, and to wrap them up in moss, which will preserve them fresh for a month or longer; but these should be cut off from the trees earlier than those which are to be grafted near the place where the trees are growing. It is, however, always the best practice to cut the grafts as near the time of their being inserted into the stocks as possible, as by that means they succeed with much more certainty.

Stocks Proper for Grafting upon.—The stocks are the trees or plants for grafting upon; which are either such old trees as are already growing where they are to remain, but the fruit of which is intended to be changed; or such young trees as have been raised in the nursery as a supply to the garden. In the former case, there is no other choice than that of the branches, which should be such as are young, healthy, well-founded, and have a smooth bark. Where these trees are growing against walls or clipears, it will be proper to graft fix, eight, or ten branches, according to the size of the tree, by which they will be much sooner furnished with branches again, than when a few number of shoots or scions are put in; but in standard trees, four, or at most five scions will be sufficient for the purpose.

In choosing young fix for grafting upon, such as have been raised from the seed, and that have been once or twice transplanted, should always be fixed upon for the purpose.

After these, those stocks which have been raised from cuttings or layers should constantly be preferred; but those which are suckers from the roots of other trees, should be rejected, as they are never so well rooted as the others, and constantly put out a great number of suckers from the roots, by which the borders and walks of the garden will be always pestered during the summer season. These, besides being unseemly, take off partly from the nourishment from the other trees and plants.

And where these stocks have been allowed a proper distance in the nursery where they have grown, the wood will be better ripened and more compact than those which have grown close, and have been drawn up to a greater height. The wood of these will be softer, and their vessels larger; so that the scions grafted in them will shoot very strongly; but they will be left disposed to produce fruit than the others; and when these acquire a good habit at first, it is difficult to reclaim them afterw'ards. The stocks most adapted to each fort will be explained under their particular genera, and in considering the nature of stocks. See Stocks.

Impl'en as proper for the Work.—These are principally a neat small hand-law, for cutting off the heads of large stocks; a good strong knife, with a thick back, to make elefts in the stocks; with a sharp pen-knife, or budding-knife, to cut the scions with; and a grafting chisel and small mallet. Other sorts of implements are sometimes necessary in performing particular sorts of grafting.

But besides these tools, other sorts of materials are wanted in performing the business, such as hafs-lodgers, or woollen yarn, to tie the grafts with; and a quantity of good tough clay, which should be prepared a month before it is wanted, and kept turned and mixed, like mortar, every other day, in the following manner:

A quantity of hard well-clay, in proportion to the quantity of trees intended to be grafted, should be provided, and some new well-fed horse-dung broken in among it; and if a little straw or hay be mixed amongst it, it will hold together the better. The addition of a quantity of salt will also prevent the clay from dividing in dry weather. These should be stirred and mixed together, putting water to them occasionally, in the manner of making mortar. The whole should be hollowed like a dish, filled with water, and kept every
every other day dried. It should be carefully kept from being exposed to frost or drying winds; and the often it is wrought over the better it will become.

Some have lately made use of another form of composition for grafting, which has been found to answer the intention of keeping out the air better than the clayey mixture. It is composed of turpentine, bees-wax, and rosin melted together; which, when of a proper consistence, is put on the flock round the graft, in the same manner as the clay is usually applied; and though it be not above a quarter of an inch thick, it keeps out the air more effectually than the clay; and, as cold hardens it, there is no danger of its being hurt by frost, which is very apt to cause the clay to crack, and fall off; and, when the heat of the sun comes on, it melts and falls off without any trouble. In the using it, a tin or copper pot is necessary, with a convenience under it to keep a very gentle fire with small coal; otherwise the cold fume condenses the mixture. It is necessary not to apply it too hot, lest the graft be injured. A person a little accustomed to this composition applies it very fail; and it is much easier for him to work with than clay, especially when the fenson proves cold.

In the pintois of grafting it is found, that in long-continued dry seasons the grafts are liable to fail in taking, which is sometimes probably owing to the improper choice of the grafts, as well as to the dry weather. Great care should of course always be taken not to graft with weak shoots, particularly those taken from near the top, but such as are taken from the lower end of the shoots, and in which the wood is plump and fresh: such as are shrivelled seldom or ever take well. When any have miffed in the spring, it has been advised to cut off, about the middle or latter end of June, some fine, healthy grafts of the sorts that are wished to graft with, and to open the bark in the same manner as for budding, covering the graft with the part of the former year's wood on it, and after this has been done, to rub in with a brush some of the composition of Mr. Forfith in a liquid state; then to warp the bafs round it, as is done for spring grafting, leaving about three eyes in the fhoot, which should be tied on with the bafs as light as possible; then covering the outside of the bafs, thus tied up, with the composition to the thickness of about one-eighth of an inch, as well as the end of the fshoot, to exclude the air and wet. In about three weeks or a month, the grafts should be looked over, to see if they have taken. When the graft begins to swell, it will throw off the composition; in which case always remember to apply more to prevent the air from penetrating the incision or wound that has been formed.

About the month of September it should be examined whether the wounds are all healed up, and the two barks perfectly united; which, if they are, slacken the bafs; and when they are perfectly healed up, it may be wholly taken off; but if not, the bafs must be again tied on, and covered with a composition as before, letting it remain till the following spring. It may then be taken off; and if it be found that the two barks have separated during the winter, with the point of a sharp knife, all the brown part of the bark (which, if left, would infallibly bring on the canker) should be cut out, and the composition rubbed into the wound. When the grafts have produced strong leading shoots, the tops of them should be pinched off with the finger and thumb; but if they have not shot strong, they should not be cut till the spring, when they may be cut down to three or four eyes, according to their strength, to make them produce horizontal shoots, and form handsome heads. This sort of grafting should always be performed in moist or cloudy weather, if possible; as under such circumstances the operation mostly succeeds better.

It has been remarked by Mr. Forfith, that rubbing a little of his composition into the incision will effectually prevent the canker, and in applying it round the graft, a much less quantity is sufficient than of the clay; as it need not be more than three inches round in grafting small limbs or shoots, and in proportion for those which are larger. It keeps the fecon moiil. When used in grafting, it should be of such a consistence as to work easily with the hand, or a knife, or small trowel, rather softer than grafting-clay generally is. This method, on a fair trial, will, he thinks, be found a sure, neat, and expeditious way of grafting.

In grafting, or budding, they should be performed as near to the upper side of a bud as possible, and the most proper place for inferring the feions or buds is at the joints, a little above the crofs fhoot.

And in respect to the sorts of trees that will succeed upon one another, it may be observed that all such as are of the same genus, that is, which agree in their flower and fruit, take upon each other; hence all the nut-bearing trees may be falsely grafted on each other, as well as all the plum-bearing trees, as the several sorts of plums, almond, peach, pear-tree, apricot, &c.; but as many of them are subject to admit gum from the parts wounded, as the peach and pear-tree kinds, it is found the surest method to bud or inoculate them.

All such trees as bear cones also do well upon each other, though they may differ in one being evergreen, and the other shedding its leaves in winter; as in the cedar of Libanus, and the larch-tree, which are found to succeed upon each other; but they must be grafted by approach, as they abound with a great quantity of resin, which is apt to evaporate from the graft, when separated from the tree before it is joined with the flock; whereby they are often destroyed. The laurel likewise on the cherry, or the cherry on the laurel. All the nut-bearing trees are also found to take upon each other, and those which have a tender soft wood do well if grafted in the common way; but such are as of a firm contexture, and are slow growers, must be grafted by approach.

It is likewise by this method that many kinds of exotic trees are not only propagated, but also rendered hardy enough to endure the cold of our climate in the open air; as by being grafted upon stocks of the same kind which are hardy, the grafts are rendered more capable of enduring the cold, and the general effects of the atmosphere.

GRAFTING. West. See W. Grafting Toot, in Engineering, signifies a kind of spade, made very strong and curving, used in digging canals, often called only a tool; see fig. 50. Canals, Plate VII.

GRAFTON, in Geography, a town of America, in Windham county, Vermont, chartered by the name of Tomlinson, but assuming its new name in 1791. It contains 1,149 inhabitants, and lies W. of Rockingham, adjoining.

Grafton County, a county of New Hampshire, bounded N. by Canada, S. by the counties of Strafford, Hillsborough, and Cheshire, W. by the lake of Virginia, and E. by the district of Maine. It is divided into 50 townships, and 17 locations, and contains 23,093 inhabitants.

Grafton, a post-town in the county above-mentioned, 13 miles S.E. of Dartmouth college, and 10 S.W. of Plymouth. It was incorporated in 1778, and contains 682 inhabitants. Lapis specularis, of the best quality, is found in this town; it lies in a mountain about 20 miles E. of Dartmouth college, adhering to the rocks of white or yellow quartz, and lying in lamintes, like sheets of paper.

Grafton, the Hufanum of the Indians, a township in Worcester county, Massachusetts, containing 985 inhabitants; 40 miles S.W. of Bolton.

Grafton, Cape, a cape on the coast of New Holland, 50
GRA

GRAPE, or GRAPEVINE, a potted-plant of Ireland, in the county of Killkenny. Here is a good bridge over the Barrow, and the tide flows up. It is 58 miles S. by W. from Dublin.

GRAIN, John Baptist Le, in Biography, was born, in 1565, at Paris, where he was educated with great care, and in early youth he was introduced to court, and attached himself to the service of Henry IV. He was appointed by that prince to the office of counsellor, and master of requells in ordinary to the queen, Mary de Medicis. His employment was in writing, and in attending on the education of his children. On their account he drew up Memoirs relative to the history of France, which remained in MS. till the chancellor de Sillery perfurred him to publish a part of them. His first publication, which he printed in his own house, was entitled, "Decade contenant l'Histoire de Henri le Grand, Roi de France et Navarre, IV. du Nom." fol. 1614, in ten books. It comprehends the period from the peace in 1559, to the king's death in 1610. He published a second decade, including the history of that king's reign, in 1618. The former decade was presented to the young king Lewis XIII., who was highly delighted with the freedom displayed by the author, and it was at his desire that the other was made public. Le Grain, though fortunate in pleasing his sovereign, made himself many enemies by the honesty and candour which he displayed in the narration. Attempts were made to procure a cenuse upon it from the Sarbonne, but they were unsuccessful, that body declaring that they found nothing in it deserving of censure. The real grounds of the objections to it were that the author had supported the liberties of the Gallican church; that he had censured attempts to introduce into France those articles of the council of Trent, which had been rejected; that he disapproved the establishment of new religious orders, and was not favourable to the persecution of heretics. For these sentiments, which ought to have endeared him to his countrymen, he was continually harassed by bigots, till at length an order was procured from the king for the suppression of all the copies of his work, which remained in his hands. The treatment which he experienced disfigured him with court, and he went into retirement on his estate of Montgeron, where he died in 1642. He left in MS. a manifesto relating to all the proceedings respecting his book, which is said to display in glowing colours the discouragements attending honest historians under an absolute monarchy. He left likewise the third decade of his history, and some chronological pieces in MS. Morel.

GRAIN, GRASSUM, primarily denotes a fruit, or seed, growing in a spica, or ear.

In this sense, grain comprehends all sorts of corn; as wheat, rye, barley, oats, &c.

Grain, Structure of. There are three particulars observable in every grain, whether it be wheat, barley, oat, or whatever else of that kind. These are, 1. The outer coat or pellicle, which contains all the rest. This in the same species of grain is found to be very different in thickness in different ears, and as it has grown in different soils.
G R A I N.

It has been advised, in order to preserve grain in a proper state after threshing it out, to have it as expeditiously as possible cleaned from the chaff, when the air is in a dry state, and put into a room, ched, or bin, which is perfectly dry and free from any sort of moisture, until it can be properly placed in the granary, or be sent away for sale. This should always be effected as early as possible, as, by delaying the cleaning of the corn, the sample is very liable to be injured.

The cleaning of the grain is performed in several different ways; but where threshing-machines are in use, they are now most contrived in such a way as to execute it at the same time the threshing is going on. The winnowing-machine is also frequently employed for the same purpose, and answers perfectly well. And in some situations the *culling-floor* and *fan*, or flat broom, as well as the *feather*, are made use of, the broom serving to remove the chaffy parts and the more minute strawy particles which are separated from the grain by the wind. This method can, however, only be employed with advantage where there is plenty of barn-room; under other circumstances the winnowing-machine is far more beneficial and proper. The practice of cleaning grain on the barn-floor, by means of the wind, is not only tedious and troublesome, but an extremely imperfect method.

In whatever way the extraneous matters have been removed from grain, it should, as soon as the operation has been performed, especially in barley and wheat, be put through a sifting-machine, which, in most of the more improved threshing and winnowing-machines, is provided with this intention, and is thereby rendered free from all sorts of small seeds and other foreign matters. In this way the ovum of different sorts of insects are also removed, and the production of the weevil, moth, beetle, &c., prevented, as well as the destruction which they commit while in their vermicular state, guarded against.

Screen machines may be had separately from the others; but the work of cleaning the grain is the most readily, cheaply, and conveniently performed, where they are connected with the other necessary machinery.

It has been suggested, that as the prevention of all sorts of corn from being affected by the different cains that have a tendency to injure it, when laid up for the purpose of keeping, depends upon its being put by in a perfectly dry condition, and on its being afterwards preserved in that situation; it is of much consequence, in these views, to keep it, from the period of its being threshed out of the straw, as much as possible from coming in contact with the earth, stone, or any other sort of floors that are placed near to, or upon the ground, as they have constantly a great disposition to communicate moisture, and in that way injure the grain that redefs upon them.

It is likewise found to be a highly beneficial practice to prevent, as much as possible, the entrance of the atmospheric air, whenever it is much loaded with humidity; as from the vast extent of surface that is exposed to its action, it is only to perceive that it must be highly prejudicial to the corn, by imparting its moisture to it, as a sort of moisture, or moulds, etc., is thereby brought on, that is attended with a mufly disgusting smell, and that prevents its keeping in a proper manner.

In regard to the means of prevention, they must be different in different cases; but much may be done in the habit of the above situations, by cautiously avoiding the too general practices of permitting the corn to remain upon the threshing-floors in the barns, particularly where they are of the earthy or slaty kinds, too long after it is threshed out, before it is cleaned from the chaff, and other useless matters; or, after it has been cleaned, by preventing its being deposited upon them, either in the loose state, or in sacks. And farther, by having great regard to the dryness of the air when the business is performed.

Influences of the latter kind much is capable of being accomplished by having proper apparatus, such as slides, fluters, and other suitable contrivances, fixed in the pipes, funnels, and other openings, designed for the purpose of ventilation in the corn-chambers and granaries, which should be preferred, condivently that in a close manner at all times when the air is much impregnated with watery particles, so as to prove hurtful to the grain. Damp and frosty weather are, of course, always improper for exposing grain to the air in, as it is in, such feasons, do great mischief. But, besides air, light is essential in the preservation of grain in these circumstances, as, where it is not admitted fairly free, a kind of vegetable mucus, or mould, as already noticed, is liable to fix upon the grain, and injure it greatly. The ingenious author of the "Philosophy of Gardening and Agriculture," has remarked, that this pollexates the same property as that of other funguses, of growing where there is fearlessly any change of air, and in places where there is little or no light, provided there be the necessary degree of warmth and moisture. On the same principle, with the intention of retaining the grain in a state as free as possible from dampness, it is suggested by the same writer, that it might be useful to have well constructed floors in the bottom parts of corn-chambers and granaries, for the purpose of occasionally communicating such moderate degrees of heat to the grain as would be sufficient to dry up and expel any injurious moisture that it might have attracted in damp wet feasons. On this idea it has, indeed, long ago been recommended as supported by experience by Mr. Tull, to preserve wheat, by expelling it to the action of a sun-flame degree of heat upon a hair-cloth, in a malt-klin, produced by the combustion of clean straw, for such a length of time as may be necessary to remove the dampness as from four or five to ten or twelve hours, according to the proportion in which it may exit. But in this method the heat should be constantly kept to moderate as not to destroy the vegetative property, or life of the grain, as, if that were the case, its putrefaction and decay would be promoted. The degrees of heat that would be the most adapted to answer the purpose, in different cases, would be easily regulated by those instruments which are in general use for measuring the heat and moisture of the atmosphere. These principles afford us much in reconciling the differences of opinion that have so long prevailed in regard to the use of air in the preservation of corn in granaries, as they sufficiently show, that when admitted in its perfectly dry and chafy state, it must be particularly useful in carrying off any moisture or disagreeable smell that the grain may have contracted by remaining closely heaped together for some length of time; as, by the thrashing that mostly accompanies the ventilation, it must necessarily operate in a very extensive manner; but that when applied in its moist heavy state, it must be detrimental in an equally proportionate degree, by imparting its humidity to the grain, and thereby caufing a fort of muilness.

It is probable that the ventilation of grain is the most completely effected by stirring it by means of proper slides, doors, or other similar contrivances made in the floors, windows, and other openings of the granaries or corn-chambers; but it is capable of being accomplished in a more flow and less economical manner by shovels, rakes, and other similar tools. And in order that the work may be more readily and more effectually performed, the grain should not be spread
GRAIN.

Spread out too thickly over the floors of the granaries and corn-rooms. From one to two feet, or two feet and a half in depth, is considered fully sufficient for the purpose, in proportion as it becomes more dry and the moisture more diffused. When grain is heaped together to too great a thickness at first, from the natural moisture which it contains, it is frequently apt to heat, and thereby greatly injure the sample. Frequent receiving should likewise be had recourse to immediately after its being deposited in the corn-rooms, and occasionally at other times as circumstances may demand.

Other points have been suggested by Doctor Darwin, as necessary to be attended to in this business, in order to perform it in the most effectual manner; such as those of having the doors, windows, and other principal apertures of the buildings placed in such a manner as to face the south, and as close to the ceiling as possible, so that the rays of the sun may enter with the greatest freedom. And in addition, the lining of all such corn-rooms should constantly be formed of such materials, as have no tendency from their coldness to precipitate the moisture from the atmosphere, which is frequently the case with particular substances, when warm, damp, south-well winds take place after cold or east ones, and in that way impart it to the grain that comes in contact with them. It is also equally necessary in all such cases that the entrance of wet and moisture should be prevented in an effectual manner, by having recourse to proper sheltering boards, slides, and other contrivances of the same kind.

There is likewise a particular sort of management necessary in the turning over and stirring of grain in order to its complete ventilation, as when the corn is first placed in the rooms it stands in need of much more frequent turning over than afterwards, when it has parted with a considerable proportion of its moisture and is become somewhat dry. For the first month or six weeks, once or twice in every week or ten days may be sufficient to anwer the purpose; but afterwards for four or five months longer, about once in the fortnight may commonly be sufficient, and from that period only once in the month, except when the season proves very moist, warm, and of course improper for keeping the grain well.

In order to accomplish this business different methods are in use; it is the custom in some places to have empty spaces left on the sides of the heaps of grain and other parts into which they may be turned over when necessary; while in others, square holes are formed in the ends of the floors, and round ones in the middle, by which means the grain is thrown from the upper to the lower chambers, and back again, and of course becomes agitated and exposed to the air in a more perfect manner. This is a method that is practised with success in some parts of the county of Kent. As, however, in these modes such frequent turnings are not only extremely troublesome, but expensive, in consequence, especially in the first case, of being performed by the shovel, the plan of having sliding shutters in the middle of the different floors so contrived, as to have an inclination towards the centre of the granaries, has been had recourse to; by the occasional removal of which, and the opening of the windows and ventilators, the grain is turned and exposed to the influence of the air at the same time with great care, convenience, and dispatch.

This mode of preferring grain was long ago found by Monfieur du Hamel to answer perfectly well, even in cafes where it had been laid up in a moist, damp, and improper state.

There can be no doubt, however, but that grain may be preferred without having recourse to the means of ventilation, by depositing it, when in a perfectly dry state, in deep wells, pits, and caverns that are free from any sort of damp and moisture, and so far below the surface of the ground that it cannot be affected by the heat or the changes that take place in the seasons. But though grain has been known to have been preferred in this manner for a great length of time in those countries where it is the practice to have it stored up for times of scarcity, it is by no means either a very safe or convenient method.

It must be observed, however, that in whatever manner grain is secured, it is essentially necessary that care should be taken that such portions as are in a soft damp state, or which have been badly harvested, should not, on any account, be laid up with that which is in a dry condition and perfectly sound; as from the quantity of moisture that is contained in it, and the tendency to germination that takes place in consequence of it, a sullty bad smell is liable to be imparted to the whole, and the sample either totally or in a great degree destroyed.

The practice of exposing grain to the free action of the atmospheric air, has been discredied by some in consequence of the ova or eggs of insects being liable in that way to be deposited among the grain, but it would seem more probable, when the economy of such insects is well considered, that their ova were either deposited originally among the grain in such situations, or brought in with different parcels of it from different places. On this account it is evident that great caution should be used in furnishing fresh parcels of grain for being laid up, and that the screen should be constantly employed before putting it into the rooms.

It is, however, pretty certain that where grain is to be preferred for much length of time, though it may without doubt be safely kept in the ways that have been already mentioned; yet it is most probably not only a much better, but more certain and economical method to let it remain unb reheled from the ear in the flacks in which it has been built, particularly where they rest upon fladdles that are properly constructed for the purpose.

It may be proper to observe, that where grain is to be long preferred after being threshed out, there should always be proper buildings of the granary kind provided for its reception, the sizes of which should be proportioned to the extent of the farm, being constantly adequate to contain about one-half of the grain-produce after it has been threshed out and cleaned.

In cafes where the grain is ground and preferred afterwards in the flate of meal, it is the usual and, by far the best mode to pack it very closely by means of treading or ramming it into dry, close, small rooms, or large sheds, as, in this way, when laid up in a proper condition, it will keep for a very great length of time quite safe and free from mischief.

But notwithstanding the custom of preferring grain in flacks and granaries, from the convenience of it, may in some instances, be beneficial, not only to the farmer, but the public, and, consequently, in some measure necessary, it is clear from the trials that have been already made, that the storing of grain in either way should be carried to as small an extent as possible; as it has been ascertained that there is a constant decrease taking place in its weight from the period at which it has been harvested or laid up, but that this loss is far greater at first, than after it has been kept some time.

In the second volume of the new edition of Georics!
GRAIN.

In regard to the preservation of grain from the depredations of insects, and other similar animals, it may probably be the belt accomplished by a timely and frequent use of the screen, with proper ventilation, as has been noticed above. Where the injury is produced by the weevil, the moth, or the beetle, it has always ceased at the period when these vermin appear, as they are, when in this state of existence, merely propagators of their several respective kinds of vermiculi, which, while they continued in that state or form, produced the injury.

In their ultimate or infect state they eat or consume very little, their business being principally that of depositing their ova or eggs, which they do by a fort of unerring instinct, in situations where the large collections of grain are sure to furnish food for their succoress during the period in which they are in the vermicular state. It is consequently a matter of great moment to prevent the generation of them, by the destruction of the eggs before they are hatched, which is usually the belt performed by having recourse to the screen, and exposure to a free air, as has been already shown. The frequent stirring of the grain breaks the cohesion of their ova, by which the nidus of such minute vermiculi is destroyed, as on hatching they collect together, and spin or weave numerous webs of a cob-web-like suffusc for their own security and protection. And a great number of grains are attached together by them to these webs, by an infinity of small threads, both for their safety and food. Consequently, when their habitation are broken and separated by the use of the screen, they fall through its small interlaces, and are capable of being easily removed with the dust and other refuse matters, and such as escape the early screenings are destroyed by those that follow, and the grain of course little injured by the operation, being only rendered more clean and free from impurities. See HARVESTING OF GRAIN, READING OF GRAIN, and STACKING OF GRAIN.

GRAIN is also applied to the fruits or seeds of divers plants, as a grain of millet, of pepper, &c.

GRAIN is also extended to a minute body, or parcel of a body pulverized. In which sense we say, a grain of sand, a grain of salt, a grain of gunpowder, &c.

GRAIN denotes also a small weight, used in estimating divers substances.

The grain is the smallest of all weights known in England. It is taken from the weight of a grain of wheat, gathered out of the middle of the ear, and well dried. By that, 12 Henry VII. cap. 7. every lighting or penny-weight was to weigh thirty-two such grains; but now twenty-four grains make a penny-weight, and twenty penny-weights an ounce. See PENNY and WEIGHT.

The grain used by the apothecaries is the same with that of
of the goldsmiths; though they make a difference in the weights raised from it. Thus, 20 grains, with them, make a scruple, \( 9 \); 5 scruples, a dram, \( 5 \); 8 drachms, an ounce, \( 8 \); &c.

The carat used in estimating the fineness of gold, as well as in weighing diamonds and precious stones, is also divided into four grains; and the carat is about the one hundredth and fifteenth part of an ounce troy, according to Mr. Jeffreys, in his treatise on Diamonds and Pearls.

Hence, the jewellers’ grain is to the troy grain, inversely, as 600 is to 480; that is, directly as four to five.

Grain, in English troy and apothecaries’ weight, is the 48th part of a troy pound = 20 grains = 14.285714 dwt. = 14.285714 drams = 23.2457586 grammes of the new weights of France = .000142857 pounds avoirdupois.

Grain, a weight in France, = 1.2189; English troy grains = .000174415 English pounds avoirdupois = .0531217 grammes of the new weights.

Grain is also used for the figure or representation of grains on stones, flints, feathers, &c. Thus we say, morocco has a bolder and richer, that is, a larger grain, than flasgreen.

In some marbles, the grain is very fine; in others coarser. Steel is known by its grain, which is much finer than that of iron.

Grain, in Mining, is applied by quarry-men and masons to the minute figures in moss blocks of stone, by which they are divided to split most easily in some certain direction, than in any other, as wood is divided to split in the direction of its grain. Best, finest, lamella, and flratula, are other terms of almost familiar import. Experienced masons can generally discover the grain of the moss homogeneous or perfect freestone blocks, or such as will cut with equal ease in any direction, and this they often do, by observing the direction of the very minute plates of mica, or silver, as they call it, which are frequently found arranged, in the stone, in the direction of the grain, or heat of the stone; which, it must be observed, is not always that of the beds or stratification, many rocks having flratula which crofs their beds obliquely, often at an angle, of from 30° to 45° with the bed or plane of the flratula; and such a flratula, not uncommonly, diverts the stone to split into flags or paviers or even tile-stones, or flates for houses, and into the moss thin and perfect lamina. Sometimes these oblique flratula crofs stone beds of very great thickness, and have been frequently mistaken, by inattentive observers, for the stratification itself, as Mr. Kirwan observes of the argillies or plates, p. 283 of his "Geological Essays." See Strata and Stratified.

Grain, Coalitional. See Cochnileal.

Grain, Scarlet. See Scarlet.

Grain, Oly, in Botany. See Mytragrum.

Grain, Tin. See Streaming and Tin.

Grains, in the Maleria Medica, or the seeds of vegetables, are distinguished into emulsive, which yield a considerable quantity of mucilage and oil, which may be separately extracted from them; such are almonds, and the seeds of almost all fruits; and tenaceous, which are entirely composed of a dry substance, easily reducible into a fine powder, called meal. Of this kind are the grains of all granious and leguminous plants.

Grains, in Rural Economy, a term applied to the remains of different substances of the grain kind after they have been employed in the brewing of beer, or the distillation of spirituous liquors. They are in much use by the farmers and cow-keepers near large towns, for the feeding of various de-
are also peculiarly expert in their manufacture of iron and metals.

The Portuguese professed for many years an independent and uncontrouled connection with this country; but in the year 1664, the English and Dutch, perceiving the advantages which were derived from their commerce, interfered, and their rivals prevailed to such a degree as to drive the Portuguese settlers into the interior parts of the country, where they united themselves with the natives; and from this intercourse sprang that mixed progeny of Mulattoes, who are more numerous here than in any part of Guinea. The small remnant of trade now professed by the Portuguese is entrusted with their perfons, to whom they give the appellation of the hidalgos or gentlemen, having prettified them to their forms of Christian faith and practice, and initiated some of them into holy orders, whom they employ in propagating their notions of Christianity.

The months most favourable to trade on this coast are February, March, and April; small vessels, which are capable of falling up the rivers into the country, are more convenient than large ships; and it should be recollected, that the S.S.E. winds begin to blow in the month of May, and bring with them heavy rains and tornadoes, with terrible thunder and lightning, extremely dangerous to shipping.

GRAINE, an island in the mouth of the river Thames, about 31 miles long, and 21° broad, separated from the coast of Kent by a narrow channel, called the "Stray," or "Yenlad." It is low, flat, and marshy, and has upon it only a number of detached hills, with some salt works. N. lat. 51° 27', E. long. 0° 42'.

GRAINED MEDALS. See Medal.

GRAINED MUSK. See Ostrich Plumage.

GRAPING, JAMES, in Geography, a physician and poet, was born at Dumf, a small town in the south of Scotland, about the year 1723. After finishing his school education, he was sent to Edinburgh, where he commenced his medical studies under professors who were highly celebrated through the medical world, and in due time he received his degree of M.D. He commenced his professional career as surgeon in the army, and in that capacity he served in Germany, under the earl of Stair, till the peace of Aix-la-Chapelle, in 1748. He afterwards settled in London, and practised as a physician. He here obtained and cultivated the friendship of several distinguished literary men, particularly of Shenstone and Dr. Percy, afterwards bishop of Dromore. While in London he published his translation of the elegies of Tibullus; but this work did not receive the approbation to which he thought it entitled, especially from Dr. Smollet, whose criticisms were the occasion of a long paper-war between them, and produced an irreconcilable difference. Probably his successes in practice in London was not great, as he embraced an offer of settling advantageously in the island of St. Christopher, in the West Indies; where, by marriage, he became connected with several of the principal families, and practised his profession with great success. He continued, however, to cultivate his attachment to the muse, and wrote, during his leisure hours, an interesting poem "On the Culture of the Sugar Cane." He likewise composed a treatise "On the Difficulties of the West Indies," for the use of the planters.

At the conclusion of the war, he paid a visit to his native country, and at the same time published his poem, with copious notes relative to the natural history of the island. He afterward returned to St. Christopher's, and continued to practice till the beginning of the year 1767, when he was elected with a fever, which then raged in the island, and died. Dr. Grainger was benevolent in his disposition, engaging in his manners, and an able physician; he ranks also considerably above mediocrity as a poet. An "Ode to Solitude," and "A West Indian Ballad," (the latter published in Dr. Percy's collection) have been much admired. He published several medical tracts. Hutch. Biol. Med.

GRAINGER, in Geography, a county of America, in the district of Hamilton, Tennessee, formed of parts of the counties of Knox, Jefferson, and Hawkins, and bounded N. by Virginia and Kentucky. Its chief town is Rutledge. It is very mountainous, interspersed with fertile valleys. It contains 13677 inhabitants, of whom 456 are slaves.

GRAINING, in Ichthyology, the name of a fish found in the Mersey, near Warrington; it resembles the dace, but is more slender, and has a slimmer back. See Dace.

GRAINING Board is a board used by the curriers, to give the grain to their leather.

It is made with teeth, or notches, running quite across; into which the soft, moistened, suppled leather being pressed, its surface readily takes the impression; See CURVING.

GRAINVILLE, in Geography, a town of France, in the department of the Eure, and chief place of a canton, in the district of Les Andelys. The place contains 393, and the canton 10,846 inhabitants, on a territory of 185 kilometres, in 32 communes.

GRAKLE, in Ornithology. See GRACULA and PARAFA.

GRAIL, the fourth order of birds, comprising those which have the bill cylindrical, and a little obtuse; tongue entire and small; and the legs naked above the knees.

GRAILATORIÆ. See Classification.

GRAMAT, in Geography, a town of France, in the department of the Lot, and chief place of a canton, in the district of Gourdon; 22 miles N.N.E. of Cahors. N. lat. 44° 47', E. long. 1° 49'. The place contains 1843, and the canton 8888 inhabitants, on a territory of 275 kilometres, in nine communes.

GRAMAYE, JOHN BAPTIST, in Geography, a writer of history, was a native of Antwerp, and flourished in the early part of the 17th century. He studied at Louvain, and became professor of rhetoric in that university. He was afterwards historiographer to the Low Countries, and obtained some other offices of trust and honour. He travelled through the greater parts of Germany and Italy, and proceeding from the latter country to Spain, he was made captive by an Algerine corsair and carried to Africa. How he obtained his release does not appear, but his writings prove that he had been an attentive observer of that country. Upon his return to his native land, he travelled into Moravia and Silesia, and in the latter province he was, by cardinal Dietrichstein, placed at the head of a college. He died at Lubec in 1635, leaving behind him many works, which shewed that he was unquestionably a man of great learning. He wrote in prose and also in verse. Of the former are "Africa Illustrata, lib. x." 1602; "Abhanc Algeriae;" "Peregrinatio Belgica;" "Antiquitates Flandeliana;" and "Hieronimo Naunierens." The first of this series of works contains a history of Africa from the remotest periods to his own times, with geographical details, and the second is the result of local observation during his captivity. Meroni.

GRAMEN, in Botany. See Gramina.

GRAMES Murorum, Histology. See Festuca.

GRAMINA, Graffes, a most natural order of plants, the fourth of Linnæus, and the fourth order of the second class in the Genera Plantarum of Jussieu, who, chooses, to alter
after the appellation of it to Gramineae. The Latin word
gramen is supposed to be derived from gradiens, going or
proceeding along, in allusion to the great increase of many
of these plants by their creeping roots.
Jullien's second class consists of monocotyledonous plants
with a superior germen. His definition of the present order
is as follows.

Calyx, (which he terms glume,) single or many-flowered,
enclosing, in the latter instance, two or more flowers,
dipped in two ranks in a little spike or ear; it is mostly of
two valves, rarely of one or of many, or altogether wanting.
Each flower has a corolla, (called calyx by Jullien,) resem-
bling the before-mentioned calyx, mostly of two valves,
rarely of only one, or altogether wanting; the outer valve
either beardlike or awned. Stamens below the germen, of
a definite number, except in the Parieta of Aulnet, gen-
erally three, rarely two, or fix, or one; their anthers oblong,
forked at each end. German one, superior, accompanied at
the base by two little scales, not always evident. Styles
often two, with two feathery stigmas; sometimes one, with
a simple or divided stigma. Seed in either instance solitary,
naked, or often clothed with the permanent inner valve of
the corolla. Embryo small, attached below to the side of
the farinaceous and much larger albumen. The lobe of the
embryo in germination is permanent and fleshy along with
the annexed albumen, attached on one side, at the bottom,
to the primary leaflet which surrounds the plumula, or bud
of the future plant.

The roots are fibrous and capillary. Stems or culms cylind-
rical, either hollow or filled with pith, jointed or sepa-
rated into distinct portions by knots, mostly simple and herbaceous.
Leaves alternate, generally solitary at each knot of the
stem, sheathing, their sheath splitting down to the knot.
Flowers either in dense clusters, or spikèd upon a common
rachis, or panicked, concealed before they arrive at maturity
in the sheath of the upper leaf. Some species are monoicous,
by an abortion of some of the organs.

Botanists have differed much about the principles on which
the genera of Graffes should be founded. Linnaeus and Juf-
lien take into consideration the number of flowers, or rather
floret, in each calyx; Haller in a great measure rejects
this, paying regard chiefly to the figure of the parts, which
indeed is of primary importance. He does not, however,
sufficiently attend to other equally important marks, as the
distinction, for instance, between Poa and Briza, consisting
in the incorporation of the seed of the latter with the larger
value of the corolla, and its deprefed figure. It was to be
wished that the arms of graffes were permanent and constant
in the same genus, or at least species, but though constant
in some, as Arven, in others, as Agrostis and Triticum, they
are not sufficient to discriminate species.

In the sexual system Graffes chiefly belong to Triandra
Digenys. Some few have proper monocious, none dioecic-
aus, flowers, and several are polygamous, having a few male
blossoms intermixed with perfect ones furnished with both
stamens and pistils, and were therefore referred by Linnaeus
to Polygonum. But this latter circumstance is so common
and variable, and causes such unnatural separations of spe-
cies or genera, that botanists have generally agreed to pay
no regard to it in this family, but to clafs all such graffes
by their perfect flowers.

Linnaeus remarks that "Graffes are the most general
of plants, constituting almost a sixth part of all the vegetables
on our globe, especially in open situations. There they
multiply, and extend themselves by creeping roots, to a vast
extent. In confined and woody places they scarcely creep,
but grow erect. They are the most important of plants,
especially as affording the chief sustenance of animals who
feed on vegetables. They furnilh the verdure of our sun-
ners, and spread a carpet over our meadows. Their bars
are not easily damaged, even by our walking over them;
and though winter destroys their foliage, and the early
spring finds them dry and withered, they revive in a won-
derful manner from apparent death. How秀丽ously has
the Author of Nature protected these plants, by giving
them such hard stems, while they are perfecting their seed,
that cattle cannot readily attack them in that state! Then,
on the other hand, they are so constituted, that the more
their herbage is cropped, or hardly used, the better they
thrive, and extend themselves the more under ground.
That they may be able to exist in almost every situation, their
narrow spiny leaves are purposely contrived to intimate
themselves between other plants.

The creeping roots of graffes are formed like a tape-
worm; and are mollously fibrous, rarely tuberous or bulbous.
They confit of numerous joints and knots, each of which
has its bud, capable of producing a new stem, and the more
they are separated by the heavy trend of cattle, the more
they multiply, thus constituting the strength of the vege-
table kingdom.

"Very few graffes have any peculiar taste, most of them
having the infirpidity of pot-herbs, though some few are fra-
grant, at least when dry. None are dangerous or poisonous,
if we except the intoxicating seeds of Lomatium tenaxum.
They are the most simply confttructed of all herbs, scarcely
any of them having thorns, prickles, tendrils, flings, bracteas,
or other appendages. Their stems are with us generally
simple; in India frequently branched. Leaves always simple
and undivided, mostly quite flat, and if one side be somewhat
rounded, it is never that next the stem. The fheath of
their leaves is often crowded with a membranous stipula,
called by some tegula, which closely embraces the stem in
growing, to keep out water.

"The fructifcation of Graffes is so different from other
plants that it was judged impossible to reduce them to order.
They were first divided into Corn and Graffes, but the
former differ from the latter merely in the greater size of
their seeds, which compose the bals of our aliments, as the
finest of the graff-seeds nourish small birds. Ray first
examined this tribe scientificaly, dividing them by their
habits or likenesses, but he traced out no juit limits. Tour-
nefort, though a more eminent botanist, was not equal
to this ingenuity. Monni followed Ray, but examined the
graffes of Italy only. John Schuchart, at the perfusion
of Sherard, undertook ample and minute descriptions of
every graff he could procure, but the herbage of all is so
similar, that his descriptions, till he comes to the infir,
cence, are too little contradicted. They are, however, very
exact. Micheli first contrived a method of arrangement
founded on the spikelets being simple or compound, with
an attention also to the sexual parts; but he subjoined some
plants, termed grändinius affinis, which have really no con-
nection with them. If the sexes of graffes be attended to,
their arrangement becomes les difficult. Their infir-
cence is either spikèd or panicked."

The principal writers on Graffes, besides those above-
mentioned, are Schreber, who wrote in German, with fine
plates, coloured or uncoloured, and who is very full on their
qualities and uses; Rottböll, who described new or rare
species, with plates; Linnaeus the younger, in a thesis
describing new genera of graffes; Hort, who has published
three folio volumes, with excellent coloured plates in the
style of Jacquin, entitled Gramina Aulphiana; Leers, who
in his Flora Herbariana has delineated and engrased all the
graffes
GRA

The grasy crown, corona graminea, was but rarely conferred, and for some signal exploit; when, through the courage or dexterity of a general, an army reduced to the last extremity had been saved, or delivered, and the enemy put to flight.

GRAMINEOUS Herbs, among Botanists, are such as have a long, narrow leaf, with no foot-fall."

- GRAMINIFOLIA, a name given by Dillenius to a genus of plants, called by Micheli and Linnaeus zanthichillia.

GRAMMAR, teaches the right use of language, or to speak, to read, and to write a language with propriety. Particular grammar teaches the principles peculiar to any one language. Thus the English grammar affords and teaches the principles which exclusively belong to, and which distinguish the English tongue. The French grammar professes the same end with regard to the French; and this is the case with the grammar of any other language.

When grammar is limited to any particular language, it is employed in its handful province, and may be considered only as a mere mechanical art, the rules of which are little investigated, and have no other foundation than the practice of those who speak and write that language. But when grammar, rising above the consideration of any one language, compares many languages together, and by this comparison traces the principles which are common to them, unfolding by that means the nature and origin of speech, the causes by which it is divided into distinct dialects, and the analogies which facilitated the growth and determined the idioms of each; grammar, in this extensive view, assumes the nature of a science, and is justly distinguished by the name of general or universal grammar.

That grammar claims the dignity of a science, in consequence of investigating the general principles of speech, is evident from the slightest consideration. All languages, however different, have many properties in common. They have in general the same parts of speech, because the ideas or things which they express exist with little or no variation in the nature of things. Men, as in all ages and countries, have the same organs of speech, which are similar in structure, however modified by peculiarities of conunciation. Finally, the same great law of allocation regulates the mind of every man, and the political, moral, and religious institutions, which direct the operations of this law, however remote in age and country, considerably resemble each other. To these causes it is owing, that the languages of all nations, ancient and modern, are, marked by a uniformity truly surprising; and the more closely they are examined, the more numerous will appear the points in which they all resemble each other. Hence may be justified the conclusion, that as all the tribes of men originated in one family, so all the languages of men are but ramifications of one original tongue.

Grammar has usually been divided into four departments, namely; orthography, etymology, syntax, and proody. Orthography teaches to form and to sound letters, to analyze or combine syllables, or to express words by their proper letters. Etymology comprehends the classification, the properties, or, more properly speaking, the derivation and composition of words. Syntax prescribes the government or the right order of words in a sentence; while proody directs the intonation, the poetical construction of words, or supplies the laws of verification. But this distribution of the parts of grammar is neither useful nor accurate, as they are not independent of each other. Etymology is a principle necessary to account for phenomena in every department, and is that upon which orthography is chiefly founded. We therefore discard these divisions of grammar, and distribute and confine our observations on this subject to
to the origin, nature, classification, and the properties of words.

The Origin, Nature, and Classification of Words.

Words have been defined articulate or significant sounds, formed by the organs of speech, and used by common consent as signs of ideas. The propriety of this definition will appear, if we attend to the mode in which words acquire their signification. The best method to teach a language, with which a youth is yet entirely unacquainted, would, if attended to, clearly unfold the nature and origin of speech in general. Suppose a book is held out before him for the first time, an impression, phantasy, or idea of that object is thus conveyed to his mind by the organ of sight. While this impression continues, suppose farther that the found book is distinctly uttered; he will then have an impression or idea of the found conveyed through the sense of hearing, which will be rendered more distinct, if the himself be taught to enumerate it. The two ideas, namely, that of the object, and that of the sound will then, if long continued, or often repeated, coalesce in his mind, and become so strongly connected, that the idea of the object shall suggest that of the found, book; and, on the other hand, the sound shall recall the object. The principle on which this coalition is founded, is a law of the human mind, known under the name association of ideas; and the progress of the learner in connecting other ideas with other sounds, is only a repetition of the operation, till the whole language is acquired.

From this brief description, naturally follow a few inferences of importance, to be observed on this subject. First, sounds, though to closely connected by frequent use of the things signified, as not to be separated from them even in imagination, have no natural affinity with them. Any other sound than book, mean for instance, might have been associated with that object in the mind of a learner, and this last name would as naturally, by use, be applied to book, as we now apply it to the object so known in the fly. And this is the reason why the same idea is expressed by different sounds in different countries, where each found is rendered equally natural and familiar by repeated associations. Secondly, as language altogether depends on an arbitrary compact between found and sense, there exist not, in any regular polished tongue, such words as natural articulate sounds. There are, indeed, in all languages, certain sounds indicating desire or averition, pleasure or pain, but these are natural cries, and not articulate sounds; and they arise more from the structure of man as an animal, than from his rank as an intelligent being, capable of forming distinct ideas, and expressing them by articulate sounds. Hence such sounds are common to him with inferior animals, and abound most among men in the savage state, where language is least formed. The above explanation farther excludes what have been called fictitious words, or words whose sound bears some resemblance to the sense. Some words, indeed, of this kind, are supposed to exist in all languages; but the supposition, we venture to affirm, is erroneous, the imagined similarity being altogether the effect of association. This principle, when a word is heard, instantly flatters its meaning, and while we overlook the suggestion, we ascribe the sense to a fancied resemblance between it and the sound. Let an idea be in your mind, when you hear a cock crow, or a bell toll, and you will immediately suppose, that the sound of the cock, or of the bell, conveyed the entertained idea. This is a delusion precisely similar to that into which we fall respecting the import of fictitious words. If there be any word in our language, or in any language naturally indicative of the sense, it is...

cock; and yet ask a foreigner, altogether unacquainted with English, what the term means, and he will not by any means be able, from the sound, to ascertain the object signified. The word is a repetition of cock cox, which exists in Greek under the form of caw, and which in Persian signifies the sound made by a strong emission of the breath. Hence the Persians express the ox kind by caw, which we have borrowed and confined to the female caw, which originally meant a lowing animal. In Chaldee, caw means a magpie, the sound of whose voice is very different from that of the cock. We cannot help remarking, that it is a limitation between found and sense obtained in any part of language, it would appear more manifest and predominant in the most ancient languages, and especially in Hebrew, which we conceive by far the most ancient, even of the Latin tongue. But we venture to affirm, that not a single instance of the kind can be produced in that tongue. And this early specimen of human language is a fair presumption, that the principle of fictitious sounds did not in the least obtain in the first formation of speech.

From the above explanation we infer, in the third place, that the names of things, at first, were names of individual objects, and that man learnt in youth, to form general ideas, solely by means of language. Thus with respect to the above-mentioned youth, when he has connected the found book with the thing so called, the word is only a sign of the individual book which was first presented to him. Presently, however, he perceives the same found applied successfully to other objects of the same kind; and this application leads, in a manner compels him to note those peculiar circumstances which distinguish each book, and those, on the other hand, which belong to that whole class of objects. As the found is not repeatedly associated with the former, he forgets, and consequently overlooks them; while he combines the ideas belonging to the class, and retains them in a closer and yet closer union, under the term which was his instrument in forming those ideas. In this manner are all our abstract ideas acquired; and language, as the mind rises by means of it, from the contemplation of one to many objects, from individuals to classes, is the sole instrument in acquiring them. Some indistinct idea of this process was probably the circumstance which led our celebrated grammarian, Mr. H. Tooke, to say, (Vol. i. p. 36.): "That the composition of ideas was merely a contrivance of language; that the only composition was in the terms, and that they are not ideas, but merely terms which are general and abstract." In another place, he denies the operations of the mind as influencing speech, and talks of the operation of language. These, and such other remarks are, however, so palpably erroneous, that we cannot ascribe it to ignorance or inattention in to enlightened a critic, but suppose them to have proceeded chiefly from a desire which pervades his works, of rejecting the ideas of others as unjust, because they were known, and contemptuously displaying his own as right, because they were new. The composition of terms in grammar, is merely the derivation or combination of terms, by such laws as extinction or analogy have previously determined. Composition of this kind, with which a grammarian, as such, has anything to do, is as distinct from the composition of ideas, as found is from sense, or grammar is from language. Language has no power but what it has derived from operation; and he who speaks of the operation of language, instead of the operation of the mind, acts the absurd part of a man who ascribes to the pen, the motion of the hand which directs it. If we can judge from his works, Mr. Tooke appears not to have studied the true theory of the human...
mind; and from the want of just ideas on this subject, he
has, as we shall see in the sequel, plunged himself and his
readers in deep and manifold errors.

As general or abstract ideas, which are the chief ma-
terials of science, are formed solely by the instrumentality
of language, we may hence see the reason why the study of lan-
guage ought to form the basis in every system of education;
and why science can flourish only among a people previously
acquainted with the arts of eloquence and composition. The
philosophy of grammar, moreover, as it retraces the track of
the human mind, in the formation of its ideas, through the
medium of speech, is the best guide to the knowledge of its
powers and operations, and consequently to their proper
direction. Hence the only systems of metaphysics and logic,
worthy the attention of a philosophical enquirer, are those
which are built on the foundation of grammatical analyses.

But further, as words in the very commencement of
every man's education denote individual objects, and become
signs of classes or kinds by the successive application of each
word to many individuals of that class, we might conclude
that in the original language of mankind, if solely the effect
of human invention, each term at first was but a proper
name of a thing or of a quality, and afterwards represented
a greater number of individuals as the mind advanced in the
principle of generalization. But this inference is contrary
to the fact. The Hebrew tongue carries us back almost to
the infancy of human society, and, whether it be the original
language of mankind or not, it presents us with much fairer
specimens of what language mult have been, than we can
gather from any modern dialect. The primitive words of
that language are founded upon the most comprehensive abstrac-
tions; and the learner, in acquiring that tongue, instead of
being carried up from the individual to the species, and
from the species to the genus, finds himself on the top of the
most extensive clafs; and in the formation of words he is
made to descend from general to specific terms, and from spe-
cific terms to proper names; so that all the proper names which
we meet with in the Hebrew records are really derived from
general appellations. This phenomenon appears to us complete-
ly to annihilate the supposition, that language is solely the
fruit of human ingenuity. Moses, in his history, obliquely
tenets, and, with his usual brevity, accounts for the fact:

"And out of the ground the Lord God formed every beast of
the field, and every fowl of the air, and brought them to
Adam to see what he would call them: and whatsoever Adam
called every living creature, that was the name thereof." The
Arabic translation, we apprehend, alone places this verse in its
proper light, by rendering it, to cause to see, i.e. to show.
The author then intimates that God showed or directed
Adam in the application of names to things. And what
can be more probable, than that He, who formed the organs
of man, should at first instruct man in the proper use of them.

Legitimately, it follows from the above explanation, that
words, as they are at first associated with ideas, are in strict
propriety signs of ideas, and not signs of things. For unless
the idea be previously in the mind, there can be no union by
association of sense with sound. The association takes place
in the mind, and where the idea of the thing, and that of the
sound do not meet, there can be no formation of articulate
sound. The learner, however, is not sensible of any distinction
between his ideas and the external objects which are their
origin or prototypes; and he refers the sound immediately
to its prototype, without being conscious that an impression
or idea of it exists in his mind. As, however, we know nothing
of things but through the medium of our ideas, and as ideas
must depend for their properties and distinction upon the
things they represent, the above oversight is not productive
of any error or inconvenience; and we may say that words
are signs of things, or of the ideas of things, without any
prejudice to philosophical accuracy. This leads us to the
classification of speech, or its division into parts.

The common division of speech in our language is into
nouns, articles, adjectives, pronouns, verbs, participles, adverbs,
propositions, conjunctions, and interjections. This division has
obtained with little variation in other modern languages, and
has been derived, on the authority of ancient grammarians,
from the languages of Greece and Rome. The above clas-
sification, however general and convenient in a popular view,
is by no means to be admitted in a philosophical grammar.
And the few writers of this kind in English, or other tongues,
have been sensible of the inaccuracy of the popular division.
The Oriental grammarians admit only three parts of speech,
the verb, the noun, and particles derived from thefe. Plato,
whose notion of language as a science must have been formed
in Egypt, mentions only two, the noun and the verb; tom.
ii. p. 261. Edit. Ser. And Aristotle mentions no more,
where he treats of propositions. (De Inter. c. 2.) But Mr.
Harris, Herm. p. 38, thinks that those philosophers were
not ignorant of the other parts of speech, but spoke with
reference to logic or dialectics, considering the effence
of speech as contained in these two, because they alone
combined to make a perfect affective sentence, which none of the
rest without them are able to effect. But Aristotle, in its
treatise of Poetry, where he was to lay down the elements of
a more variegated speech, adds the article and conjunction

to the noun and verb. The latter Stoics, improving on the
authority of Aristotle, instead of four parts, made five, by
dividing the noun into the appellative and proper. Others
increased the number, by detaching the pronoun from the
noun; the participle and adverb from the verb; and the
proposition from the conjunction. The Latin grammarians
went farther, and detached the interjection from the adverb,
within which by the Greeks it was always included as a

Mr. Harris, following Aristotle and the elder Stoics,
divides speech into words that are significant as principals,
and those which are significant as accessories, including under
the former clafs substantives and attributives, and under the latter
definitives and connectives. This division is set aside and ridiculed by Mr. Tooke, who says, vol. i. p. 47; "In
English, and in all languages, there are only two sorts of
words, which are necessary for the communication of our
thoughts, and they are noun and verb. And as to the parts
of speech, they may be either two or twenty, or more. In
the strict sense of the term, both the necessary words and the
abbreviations are all of them parts of speech; because they
are all useful in language, and each has a different manner of
signification. But I think it of great confluence, both to
knowledge and to languages, to keep the words employed for
the different purposes of speech as distinct as possible. And
therefore I am inclined to allow that rank only to necessary
words, and to include all the others, which are not necessary
to speech, but merely substantives of the first sort, under the
title of abbreviations." In this broad division, as we shall
presently see, there is neither utility nor accuracy, and the
author was betrayed to it by a secret wish to place the novelty
of his own system in the most conspicuous light, namely,
that conjunctions and prepositions are but abbreviations of
nouns and verbs.

Now it is singular, that the division which we
think the most philosophical, and, therefore, the most simple
and useful, is that which is thus proscribed in a very laboured
The division of words into those which are significant of themselves, and those which are significant by relation, is absolute nonsense, and has been productive of much error and mystery in some of the most celebrated treatises on grammar. It is indeed probable, that any attempt to establish a different classification of the parts of speech, from that which is commonly received, will be found of little utility, either in practice or in speculation. As far as the former is concerned, the vulgar division seems sufficiently commodious; for every man who knows any thing, knows when he uses a noun, and when a verb. With respect to the latter, not to mention that all the grammarians from Aristotle to Horne Tooke, have differed on the subject; it should seem to be of more importance, after having ascertained, with precision, the nature of each species of words, to determine in what circumstances they differ than in what they agree."

If these remarks be just, any attempt at a philosophical arrangement of the parts of language must be frivolous and useless. But we regard the paragraph as a manifest acknowledgment that the writer knew of no such arrangement, and that, as is often the cafe, he endeavours to console himself and his readers, under the absence of this knowledge, with the consideration that it would not be useful. We shall, however, attempt briefly to do what he thought unnecessary to be done, but what we think not only useful and necessary, but even essential, in a philosophical treatise.

An accurate distribution of our words, is but an accurate distribution of our ideas; and as in logic we cannot think jutely, unless we know how to distinguish our thoughts; so we cannot without reason in grammar, unless we have previously distinguished the parts of speech. The source of this distinction must be sought in the nature of the ideas expressed by those parts, and the enquiry, how many sorts of words there exist in human language, is merely, when directed to its proper object, how many sorts of ideas there are in human knowledge.

We have then ideas of things; we have ideas of the properties or attributes of things: we have ideas of the connection of things, i.e. of the arrangement of things, or of their increase or diminution: finally, we have ideas of the relation of things. Nor have we an idea which may not rank with one of these classes. And as language consists of terms expressing ideas, it consists of terms which express either ideas of things, or the attributes of things, or the connection of things, or the relation of things. The terms expressing things are nouns, including substantives and the personal pronouns, which are only substantives for nouns, and therefore, in their nature, names of things. Sweet is an attribute of sugar, and so is to think an attribute of a man; to fly of a bird; to be of a being that exists, and so, moreover, loving, hating; are attributes of some creatures susceptible of love and hatred; finally, the circumstances which define things or distinguish them from others, may be considered as attributes or properties of the things so defined. The terms expressing attributes may be called attributes: and include adjectives, verbs, adverbs, participles, and definitions. The terms expressing the relations of things are propositions; while those which express the connection of things are conjunctions. And thus the most comprehensive, and, as we conceive, the most philosophical division of speech is into four parts, nouns, attributes, propositions, and conjunctions or connectives; nor is there any language, however few or numerous its terms may be, which is not capable of being distributed into these four classes. As to the interjection, it must be regarded as a found which is either intercalate, or which, as far as it partakes of articulation, partakes of the nature of a noun or of a verb. Having noted this distribution, we, as not infrequently writing on grammar, shall, in our remarks, follow the popular division.

Nouns and connectives, to use Mr. Harris's language, are significant as principals, and we do not depart from philosophical accuracy, when we say that prepositions and connectives are significant by relation. Our notions of the relations and connections of things are by the principle of abstraction from our notions of the things themselves to related or connected. If all ideas of things or actions were obliterated from our minds, the ideas of their associated relations would be entirely obliterated with them. And as our notions of relation spring from the objects so related, so language, following the rise and progress of ideas, has derived those terms which express relations and connections, from the terms expressing the things and operations so related and connected. In other words, prepositions and conjunctions are words which, by association, flowed from nouns and verbs as their real sources. If this be correct, what shall we say to Mr. H. Tooke who affirms prepositions, conjunctions, and other particles, to be substitutes for those necessary words, the noun and verb. If this afflention be put in clear language, it means that the relations of things, or of the operations of things, are substitutes for the things so related; that is, the relation of cause and effect is a substitute for cause and effect; the relation of beginning is a substitute for things which begin; the relation of instrumentality is a substitute for that which is instrumental; and the relation of end is a substitute for that which ends. Moreover, the separation or concatenation of two or more affections is a substitute for the operations so separated or connected. This is not philosophical reasoning, calculated to throw light on language, but a sophistry calculated to confound the most distinct ideas which the human mind is capable of forming, and a jargon not to be equalled by any error or contradiction, which Mr. Tooke has so severely cenured and ridiculed in Mr. Harris. Besides, terms to express the relations and connections of things are not less necessary than those which denote things and their operations. A language without conjunctions and prepositions is not merely a jargon, (to use his own words,) which cannot be drawn along as smoothly, and easily, and swiftly, as a carriage with wheels, but is a jargon which has nothing to connect it with the horse; nothing to direct it in the way along which it should be dragged. The noun and the verb indeed may express a complete proposition; but the inferences in which such simple propositions occur are very few, compared with those more complicated cases where the use of prepositions and connectives is absolutely necessary. The distribution of speech into necessary words and abbreviations, is therefore, in this point of view, also frivolous and erroneous.

The Origin and Properties of Nouns.

Nouns are the names of things, or signs of those ideas by which we come to the knowledge of things. The term is a corruption of nomos, which is from nomon, while name came probably from the Persian namm, which seems to be of the same origin with the Greek word. Nouns may be divided into three classes: names of individuals, names of species or kinds, names of abstract ideas. To this may be added, as a fourth class, the pronoun, which is made the substitute or representative of all other nouns. But we shall consider this in the place usually assigned to it by grammarians. On each of the above classes we beg to make a few brief remarks.
Names of individuals do not enter into the composition of language; because individual objects are too numerous to have each a distinct name; and because language would then be changing in endless succession, each term dying away with the object it signified, and another rising to occupy its place. This is the reason why proper names cannot be translated from one tongue to another, the individuals specified by them, being confined to one time and one place, are not capable of being the prototypes of words in other times and places. Individuals, however, among men, animals, and plants, which the purposes of life require it necessary to specify, have appropriate names given them to distinguish them from all other individuals. And it sometimes happens that when individuals among men become eminent for any attainment or profession, their names are used to designate others who are eminent in the same way. Thus proper names are sometimes converted into common names. The former are called proper, as being peculiar to individuals, in opposition to such names as are common to all the individuals of a class.

The perceptions of the human mind, as we have observed, commence with individual objects: but we are not induced to consider those objects; and on comparing individuals together, we readily discern a resemblance between them in some things while they differ in others. The mind then separates the particulars in which objects differ, and collects into one idea their points of similitude. Thus it forms ideas of classes, or in logic called species, comprehending under them various individuals. After this the species themselves form become subjects of comparison; and excluding from each its individual qualities, the human mind forms those more general aggregates termed kinds, comprehending under them different species, as the species comprehend different individuals. Thus mankind classified all the objects around them, and acquired specific and generic ideas in nature, in art, and in abstract qualities.

Having, as it is supposed, first advanced in the classification of their ideas, men gave names to each class, and thus acquired those general terms which are called specific and generic terms. But we have already shown that the precedents of the human mind, in the principle of abstraction, is the reverse of this: general terms do not arise, as will appear evident if we attend to the commencement of education in ourselves and others, from general ideas, but, on the contrary, general ideas arise from general terms. The former have no existence till they are generated in the mind solely by the instrumentality of language; the learner being involuntarily and passively led by the successive application of the same word to different individuals of the same class, to compare them, to separate their component parts where they differ, and to combine them where they agree. In this point of view, grammar is the foundation of logic; and language, instead of being the offspring of human invention, is the sole medium of awakening the first dawn of intelligence in the human mind, and points for its existence to some intelligence superior to man.

Specific and generic ideas being thus formed, the subject matter of language is reduced, so as to be commensurate with the limited faculties of man; because, though individual objects are infinite, the classes comprehending them are comparatively few. The subject matter of speech by this means, moreover, is rendered permanent and universal, or confined to points of space and time; because, though particular things are local and transient, the species and kinds of things are universal and eternal. This is the reason why words which are unintelligible in one age and country are understood in other ages and countries; and may be translated from one tongue into another, without ambiguity or error, where the prototypes exist in common. Further, though general terms are often indefinite and uncertain, yet whenever they express species or kinds, they may be defined by ascertaining the several ideas which constitute those species or kinds. And as the properties which constitute each class are found complete in each individual of each class, the name of the kind is applied to each of the species; and the name of the species to each individual included under it; and thus generic and specific terms are employed by the affinities of certain adjuncts hereafter to be considered, to denote individuals.

General ideas may be considered as abstract ideas, as they are generated by the mind separating or abstracting from each object those particularities which constitute individuality. But they are to be distinguished, at least in a grammatical view, from that numerous and important class of ideas which we acquire by the more simple act of separating from a thing the quality which belongs to it. Thus, the attribute to think becomes thought; and god is converted into goodness. Abstract nouns of this kind are all, without exception, derived from verbs and adjectives, and formed by the simple power of withdrawing a property from the subject which supports it, and giving it an independent existence in the imagination. Now, it is a fact worthy of attention, that as general, so abstract, ideas are formed by the sole agency of language, and would not have existed in the flighted sense, if words had not previously been applied to express the qualities of things. For as soon as a property was marked by an appropriate word, the separate and independent existence of that word, recognized by the eye or by the ear, induced the mind, without an effort and, perhaps imperceptibly, to give the property so designated an independent existence itself. Mr. Tooke rejects the principle of abstractions, and would introduce in the room of it what he calls subdivision. Thus, according to him, goodness is that which is good; flying is that which flies; and under this erroneous and circuitous mode of explaining abstract qualities which he has borrowed from the neuter participle in Latin, he has attempted to bury out of sight the operation of the mind in forming abstract ideas. The existence of this operation, however, is too obvious to be denied with effect, and too important, in philosophical grammar, to be abandoned on the authority of any person whose acuteness of intellect may enable him sometimes rather to perplex than to unravel truth. In conformity to his own theory, Mr. Tooke supposes such words as science, diligence, which are abstract nouns, derived from the Latin scientia, diliigentia, to be neuter participles plural in entia, a supposition contrary to the analogy of the Latin tongue, which affords not a single instance of plural adjectives being converted into abstract nouns.

We cannot help noticing in this place an observation in the Encyclopedia Britannica, 13:4, as all the objects which exist must be either in the same state in which they were produced by nature, or changed from their original state by art, or abstracted from substances by the powers of imagination, and conceived by the mind, as having at least the capacity of being characterized by qualities; this naturally fugitives a division of names into natural, as man, wheat, fire, &c., artificial, as boy, horses, wood, &c., and abstract, as science, motion, temperate, &c. This division has been borrowed from Mr. Harris, in his Hermes, and borrowed without consideration. Abstract ideas are the chief materials of science, which, giving birth to art, extended to the productions of art, as its genuine offspring, the use of its own terms. Accordingly, all artificial terms are abstract.
According to Mr. Tooke, the words in Roman letters are
plenty of northern origin, while those corresponding to
them in Latin are Latin verbs derived from them. The
reversal of this position we can prove to be true. The
Anglo-Saxon or Gothic words, which this author digni-
fiies as northern primitives grafted on the Latin, are no
other than Latin words borrowed and corrupted by the
northern barbarians when they over-ran the Roman
empire. This position, if proved, will render the far greater
part of Mr. Tooke's labour perfectly nugatory; and nothing
more is necessary to prove it than to show that the origins
of the Latin words exist in Greek, or in one of the Ori-
ental tongues, and exist too in such a form, as to evince that
these are the primitives, and consequently that the northern
words are only corruptions derived from thence. Thus the
Hebrew קבּ, קֹבּ, is a hand; hence קָבּ, to take in hand,
and by softening כ to an aspirate, as is often the case,
are, to hold in the hand, i.e. to have. The Greek κτρ, over-
throw, is the parent of the Latin neca, corrupted into
hacan; κι, go, go, bigan; γιος, hena, hena, to seize;
θηναι, χωρια, to roll; χωρία, ἄγω, to go, to flow;
συν, σφαν, σφαν, σφαν, chiefly lips; hence σφαν, or σφαν,
the action of the lips in throwing out of the mouth, i.e.
σφαν, σφαν, or σφαν, to soften, to melt, to feel, σφαν, σφαν,
σφαν, σφαν, σφαν, melon, to milk; κόφα, recumbence, punishment, κοφα,
κοφα, to punish; γιος, a tail, γιος, γιος, γιος, a tail
does, i.e. to prick; γιος, γιος, γιος, to fix; γιος, γιος,
delo, to wash down, to obliterate by washing, διάγιος;
μολός, moly, Goth. mánin, to mill; ζεπτίζ, Zeptós, to
plow; μολοί, to ride, tollo, tollo; ποπος, ποπος, to spin,
twist, ποπος, ποπος, ποπος, ποπος, ποπος, to make,
touch; ποπος, ποπος, ποπος, ποπος, ποπος, food, peka,
to take, ποπος, ποπος, ποπος, ποπος, ποπος, to defile, peta, to seek, in
consequence of defiling, ποπος.

Though this lift clearly shews that the Northern language
is, in a great degree, a corruption of the Latin borrowed
from the Greek, the Hebrew, and other Oriental tongues,
yet Mr. Tooke gives it as exhibiting influences of the Northern
dialect grafted on the Latin. The primitive language of
the North could have been no other than a branch of the
primaev language of men, conveyed there by the first emi-
grants, diversified and enriched by communications with the
East on the north of Afa, by early irruptions into Greece,
as is mentioned by Herodotus, and, in far later days, by
 amalgating with the Latin, when in the dark ages the tribes
of the North invaded and dismembered the Roman empire.
In this state, the Northern language became the parent of
the English; and though a multitude of its words, especially
monosyllabic words, are, no doubt, immediately from the
Anglo-Saxon and Gothic, yet few influences, we believe,
can be produced, which may not be traced, by a competent
eytymologist, through the medium of those corrupt changes,
to their primordial purity in Italy, in Greece, and in the
East, the sole origin of language and literature. But
Mr. Tooke reverses this natural and necessary order; and,
without the testimony of historians, without any documents
of the language subsisting in the North, antecedent to that
which was spoken in the middle ages, he fixes on corruptions
borrowed from the Latin, and holds them up as the origin
whence Latin, Greek, and English have been derived. His
theory, thus far, is ridiculous and mischievous; ridiculous,
because it is a palpable error, professing important dif-
ferences; and mischievous, because, while it pretends to trace

words to their genuine roots, fl妹子 up all the true sources of information on the subject of language. As we have passed this cenfire on his fythe, we feel ourselves called upon to justify it by more numerous instances. And we think this the more necessary, as subsequent grammarians, and the public in general, seem willing to acquiesce in his positions as incontrovertibly just.

In doing this we shall adopt the words which present themselves, without much selection, referring our readers to the page where they occur in his second volume. It was impossible to err as to the derivation of right from vertum; but something ordered is not the leading idea of the term, though Mr. Tooke employs many quarte pages in explaining it on this principle. The primary sense of right is right, a relative term, denoting the means to an end. Thus, virtue is right, because it is the short or direct road to happiness. That hand is right, which does its work in the shortest way. Property is right, because it is the shortest road to the welfare of society. In this sense we may say of God, if we say it with reverence, that it is right in him, because, when he has an end to answer, right means the shortest way to accomplish it. "The left-hand is that which is leaved, or which we are taught to leave out of use on such occasion," p. 10. This appears to us nonsense. Left is the Greek δεξιός, and Latin levus, with l, the usual termination of northern words. Lex, Fr. loi, and our hand, is from lego, and means something read or dictated, and not something placed, p. 8. The Anglo-Saxon, legan, poner, is but a corruption of locare, to place. Julianus, indeed, means something commanded, jufnum, from jubo. But this left is the Hebrew מים, which, and the Arabic جاب, to answer or affirm. Hence, in Latin, jurare legem, to enact a law, i.e. to allow it to pass, and promise to obey it.

"To use is to do as the cook does," p. 21. Few people know how the cook does; but all know how a cook acts on fuch occasions. Kokum is an Eastern word, which, coming into Italy, gave birth to ciaua, to crow; and, changing r into the consonant I, is as often the case, to kokala, which, in Celtic, is klang and klighe, to act as a cook does with a hen. This, we presume, is the origin of cookah. Hen-picked is a figure of the fame nature, and from the same source. "Alert is all-crestia," p. 24. No, we presume it is all-crest, or all-art, i.e. all active. The word art, signifying skill, came to signify that diligence by which skill is attained. The opposite, which functions this etymology, is inert, not active. A known, i.e. a man cunningly skilful, came, by the fame appropriation, from γνωρις, diligent.

"Leitza, (French laizhe) of a whip, i.e. that part of it which is let lezf, p. 32. Rather from λογος, an offer. The French laizhe, or the Italian lizza, is the Latin laxare, from λαξω, to bend. To brzz, or to burn, gave birth to brand, i.e. a mark by burning;—brandly, i.e. spirits which burn;—brown, i.e. bread burnt;—brand, brunt of the battle, i.e. the heat of the battle, or the place where the battle burns. The origin is furama, an oven. Odd is not the participle woted, i.e. something owed to make up a pair, p. 38; but the Hebrew צלח, a pair, one, fingle, singular, i.e. one that has no other to make an even number, or pair, with him. Thus we fay, an odd man, i.e. a fingle man. Leitza, p. 39, i.e. we presume, from οικος, a voice heard. The Anglo-Saxon, derived from this word, has preserved the οικος, abwanna. In Celtic it is chul, that is heard in praise of a man. The Latin has rejected the guttural altogether in lada. The Greek poets have applied the epithet αεκος to such animals as λεκ; hence lowe: spheric, or spheric, burns, share, as plough share, p. 41. come from λαξη, to clip, by prefixing s, a practice very frequent in Latin; and hence the Anglo-Saxon sferan, to clip.

One of those broad analogies by which the Latin separated from the Greek, is the conversion of a guttural into a hibial, as in μολυς, φιλος, χαρος, floruit. Thus it may be, cultus becomes, as it were, dulces, dulf, dula, i.e. a cultivated ground, and not a place filled, p. 41. "Coward is the Thracian scow, to bend; but the partake of cowar, to bend, p. 42. Bread is beared, i.e. the produce of the earth, as bears, offspring, is born, somethings born, and not from the obsolete bray, to pound, which is taken from the Latin frico or jfrone; both of which originated in the Arabic بفر, phara. Fried, for is the participial termination of διης, or διες, violence, in which, as Socrates says, there is entity; while friend is the same form of gwra, a woman, (from οφις, i.e. the bearing animal,) and feems at first to mean a female loved. The letter l, being of the same organs with r, is often changed for it in all languages, as ροθομ, λυμπα; πραμος, palmo. On the fame principle, the Hebrew נג, naaph, to marry, became laph, or love. The Hebrew אב, is, and the Persian bbad, self, paffing to the North, gave birth to the pronoun ḥis, or, as it is farther corrupted, it, which, like ḥd in Latin, directs the attention to something going before, and is a substitute for it. Gothic haitan, Anglo-Saxon haten, or getan, to speak or command, is, perhaps, the Greek ἀνάω, which, in Celtic, is gawd, in English quah, and in Latin in the compound form of inquit, p. 53.

Right, i.e. tied, and the Gothic hin, is from πυκτες, to fold up, 67. Test is tortus or tofrus, and not that which is toned. Quilt is eulded, (ευδει) twilled. Draught, drag, is τραγος, a beast. Tilt is tilted, lifted, from νιλος, toldo. "Bare, i.e. barred, closed, shut," p. 72. The verbs ζημιζε, ζημιζε, parea, pora, poro, with the participles of words derived from these in all languages, owe their existence to the Arabic barron, the earth, or that which produces all things: and barren, we presume, meant primarily an animal having produced; and hence it denoted insensitivity, consequent on production, or, more generally, incapacity to produce. The Hebrew לדר, sler, denotes any thing close, sharp, or hard. Hence the Greek ρικος, form, rigid; and our fler, p. 73. The same word in Arabic means a barth or acute found, and hence seemingly the English flir. The Arabic יד, slir, which we should pronounce sler, denotes to flow, or to move as water does. Hence the Anglo-Saxon sleren, which means to cause a ship to move, which is the meaning of the hence-derived slir. Stern is that part of a ship which is thus moved. The Hebrew לזר, girs, to turn, has given birth to curr, turning or slirring cream being the means of obtaining butter, which in Anglo-Saxon is gurman, 76; to year, which is a revolution of time; toyea, which means therefore something turned or twirled, and not prepared. Port, plus, means hair on the head; hence it signified to form hair, or to grow into a head. And this is the origin of our word pile, build. Bold or bold originated in word, bodily strength naturally inspiring mental energy, 79; but bolt, p. 128, is בול or בול, the thing call, 129. Bear is the Hebrew בּאר, bamer, a sturdy stupid animal; but brown we think is not baren, but porc, porken, proken, brownen, from porcos, and therefore it means the flesh of a pig, 87.

Clip, chip, is something cut with, from κοτος. The Anglo-Saxon plkoma, to pledge, is from κοτος, κοτός, to strive, plight being a baraigne strick. Slut is the fame in fenne and fownd with the Arabic יולס, flot. The Anglo-Saxon fitan is nothing but the Hebrew יולס, flot, nates; and hence it came to signify the action of the nates in throwing away the excrements. We shall merely add the following lift, and all the words
The properties of nouns are gender, number, and case. Gender, as meaning the distinction of sex, was by no means a necessary property of nouns, for the signification was sufficient to shew the sex to which it belonged. Thus, as there-
there were but two sexes, there should have been two genders—
masculine and feminine, nouns meaning males being ranked
under the former class, those meaning females under the latter;
while the neuter or neither gender comprehended the names
of inanimate things, or such animals as had their sex not dif-
cernible, or not necessary to be distinguished. But unfortu-
ately the termination of nouns became a mark of gender
independent of their signification; and thus nouns were con-
sidered as masculine, feminine, or neuter, as they happened to
have the endings which custom usually assigned to either of
these three classes. The Hebrew tongue, in its primitive pu-
ritv, appears to have been exempt from this unhappy embar-
rassment, and the only languages known to us which have
maintained the empire of common sense against the caprice of
custom are the English, the Persian, and the Bengalee. In
Greek and Latin the dictates of reason have so far prevailed
as to cause all these nouns, whatever be their terminations,
which mean males and females, to be deemed masculine and
feminine; while the names of inanimate objects only are de-
termined by the termination. In other languages, such as
the Arabic, French, and Italian, this absurdity has been car-
ried much farther, the names of inanimate objects being
founded on reason; the neuter, which is only the negative of
sex, is excluded; and the learner has his memory loaded with
the gender of nouns which really meant things without sex,
and this without any one advantage to counterbalance so much
fruitless trouble, and such glaring facricle of common sense.
The English language, as conforming to nature in re-
gard to the distinctions of gender, has greatly the advantage
over other tongues: when rising to the rhetorical and poetical
style it addresses the fancy by perfonification. This figure is
essential to poetry. In order to interest the imagination, the
subject of discourse, when inanimate, must be invested with
the forms and attributes of living beings. Now, when things
are thus personified or spoken of as persons, they must be
represented as male or female. May they be made either?
Or is there any analogy to give one the preference over the
other? Let us hear what Mr. Harris (Herm. p. 44.)
says on this subject. Having observed that some nouns are
of such a gender from having such a termination, he thus
proceeds: "In others we may imagine a more subtle kind of
reasoning, a reasoning which differs even in things without
sex of different analogy to that great natural distinction which,
according to Milton, animates the world. In this view we
may conceive these substantives to have been considered as
masculine, which were conspicuous for the attributes of im-
partiality, or communicating, or which were by nature active,
strong, and efficacious, and that indifferently whether to
good or to ill, or which had claim to eminence either husband
or otherwise. The feminine, on the contrary, were such as
were conspicuous for the attributes of receiving, of
containing, or of producing and bringing forth; or which
had more of the passive in their nature than of the active;
or which were peculiarly beautiful and amiable; or which had
respect to such excelses as were rather feminine than mas-
culine." On this principle the for, as imparting light, is mas-
culine; the moon, as receiving it, feminine. The.fy, or other,
time, death, the ocean, the Supreme Being are all masculine;
while the earth, hop, city, virtue, religion, are feminine. And
yet Mr. Tooke roundly pronounces this reasoning fallacious.
"As for Mr. Harris's poetical authorities, the Muses are
bitter bad judges in matters of philosophy. Besides, that
Reason is an arrogant deport, who, in his own dominions, admits
of no authority but his own. And he is particularly un-
fortunate in the very outset: for his very first instances,
the fun and the moon, destroy the whole sublimity of this kind
of reasoning. For Mr. Harris ought to have known that in
many Asiatic languages, and in all the northern languages
of this part of the globe which we inhabit, and particularly
in our mother language, the Anglo-Saxon, fun is feminine, and
moon is masculine," vol. i. p. 54. The author of the
learned treatise on grammar in the Encyclop. Britannica, 17,
refuting no doubt on the authority of Mr. Tooke, thus
pronounces on the reasoning of Mr. Harris: "Such specula-
tions are wholly fanciful; and the principle on which they
proceed are overturned by an appeal to facts. Many of the
substantives that in one language have masculine names, have
in others names that are feminine, which could not be the
case, were this matter regulated by reason or nature.

The languages from which the objection to Mr. Harris's
theory is derived are not regulated in regard to the distinc-
tion of gender by reason or nature. And facts borrowed from
them are not fully to be admitted as conclusive against a
principle in a language which is regulated by reason and na-
ture. Mr. Harris deduced his theory from the English,
though he has applied it with perhaps more fancy than truth
to some inferences in the classical languages. Our own tongue,
as making all things neuter which have no life, admits the
operation of fancy in perfonifying inanimate objects; and
where perfonification is admitted, the analogy to the natural
distinction of the sexes must necessarily be admitted also.
But, Mr. Tooke and his abettor, it is fanciful because
it does not obtain in other tongues. Their argument is brieferly this:—The fun, by perfonification, is not made
masculine in English, where the consideration of gender is
founded on reason, because it is made feminine in some lan-
guages where the termination, and not reason, determines the
gender. Reasoning of this kind is not only inconclusive,
but frivolous; and the analogy flayed by Mr. Harris invari-
ably and necessarily operates on our own tongue, and would
have operated in all tongues, if, like the English, they had
conformed to the standard of nature; and we ought no more
from their caprice to agonise against the dictates of reason
and analogy, than we ought to deny a regard to the dif-
tinction of sex in the nouns of one language, because the
gender of the same nouns in others is regulated by con-
derations independent of sex.

When a noun represents its object as one, it is said to be in
the singular, and plural when meaning more than one. This
property also can hardly be said to be necessary to nouns, as
its place might have been supplied with greater accuracy by
numerical adjectives when extended to express numbers, as
two men, three men, &c. "Bengal nouns," says Mr. Hal-
hed, in his excellent grammar of that tongue, p. 68. "have
neither dual nor plural numbers, I may add that neither is
wanted. The dual is found in no modern language, and
probably never existed but in the Arabic and its branches,
in the Persian and in the Greek. That the idea of multi-
tude is not confined to the plural number, is clear beyond a
doubt, because singular nouns are used in all languages with
a collective sense, almost as frequently as plurals, thus: new
love to study, and man loves to study, are phrases perfectly
equivalent. So also we join to a noun in the singular num-
er an epithet of indefinite plurality to convey a plural
meaning: many a man is written by the Bengalees beklob man-
baqoof. Perhaps it might be safely urged that the singular
number has more occasion for an accurate specification than
the plural; at least this is the only circumstance which can
account for the extensive use of the article or representative
of unity in most of the modern dialects of Europe."

The plural number in its origin was no other than a noun.
of multitude, annexed to that preceding it, in order to mark its extension from one to many. Thus in Hebrew, whose high antiquity unfolds to the philosophical enquirer the several steps which mankind took in the formation of speech: 

מִיָּלְאָן, ָּּאָלְּבָּה, man, multitude, became, for the sake of brevity, into מִיָּלְאָן, ano-th, men. In the Chaldean and Syracia the final n was changed into n. Hence the Hebrew em in Chaldean became em, in Arabic en, in Persian an, to denote the names of animals, and its inanimate things. And from this source are derived the plural terminations in an or a in the Anglo-Saxon and German tongues. The letters n and s being of the same organ, the Chaldean em became s in the formation of the Greek, or s in the third declension of Latin nouns. Hence, too, the plural termination s in English and French; while the Italian exclusively follows the analogy of the second Latin declension in it. Thus the plural termination in all languages, ancient and modern, appears to have been derived from one source: and that confided of the annexation of a noun of multitude to the singular form of a preceding noun. And it is remarkable that in the Bengalee, which is but a branch of the Slavonic, this mode of expressing plural nouns is preferred to this day; as, пряса, a peafant, прясъл, пеаftant-people, прясъл, пеаftants: лоб, signifying people annexed to the singular noun whatever it might be. We shall only observe, that the names of classes only admit the plural form; while proper names in all languages are, by their signification, confined to the singular. Unless many individuals by accident have the same name. The names of families and nations must likewise be excepted, which, from a regard to their signification, are necessarily plural.

We come next to the consideration of cases, which are properties of nouns, perplexed and undefined, as is evident from the different, and we may add, erroneous accounts given of them by most grammarians. The belt and furest way to ascertain the nature and origin of cases, is to attend to the manner in which they were at first considered in the Peripatetic school. We adopt the words of Mr. Harris, p. 277. "The Peripatetics held the nominative to be no case, and likened the noun in this, its primary and original form, to a perpendicular line, such for example as the line

\[ A \rightarrow B, \quad C \rightarrow D \]

The variations from the nominative, they considered as if A B were to fall from its perpendicular, as for example to A C or A D. Hence, then, they only called these variations παράλληλα, сαφοῦς, καταλόγον, ορισμόν. The Stoics, on the contrary, and the grammarians with them, made the nominative a case also. Words they considered (as it were) to fall from the mind, or diffusive faculty. Now, when a noun fell thence in its primary form, they then called it παράλληλα, καταλογοῦς, as erect or upright case or falling, such as A, B, and by this name they distinguished the nominative. When it fell from the mind under any of its variations, as for example in the form of a genitive, a dative, or the like, such variations they called παράλληλα, καταλογοῦς, καταλογοῦς, oblique cases or fide-long falling, (such as A C or A D), in opposition to the other that is, A B, which was erect and perpendicular.

Hence, too, grammarians called the method of enumerating the various cases of a noun ὁμοφωνία, declination, a declension.

Vol. XVI.

We copy this account because it is very plausible, though we regard it as erroneous; the learned author and Analysts (De Interpret, p. 35), from whom he derived it, being misled by the figurative language borrowed from geometry. We believe that the nominative is said to be in the right case, not because it is an erect or upright falling from the mind, but because the nominative, the verb, and its object following each other in direct succession, form one simple proposition. The nominative is the leading noun or agent, and the accusative is the effect, in which the action straightforwardly terminates. And when other nouns are introduced, they are spoken of not directly as the agent or subject, but collaterally or obliquely, as objects to which the direct noun someway belongs. Thus the accusative as well as the nominative are right cases, or direct parts of a proposition; whereas the genitive, dative, ablative, and vocative are oblique cases, or indirect parts of a proposition.

From this simple statement, which we recommend to our readers as important, we infer, that a case did not at first mean a change in the termination of a noun, but the position or the case, or form, a noun expressing its relation to some other word in the sentence.

And our next object is to ascertain those leading relations which the position of a noun or other word may mean more specifically, expresses. God made man is a sentence in which the agent, the action, and the object follow each other in the order of nature: God, as occupying the place of the agent, is the nominative; and man, as corresponding to the effect, is the accusative. But in the sentence God is good, we cannot say God is the agent, because the verb is not to express an action, but serves only to connect the epithet good with God. The nominative, therefore, here expresses not the agent, but the subject of the attribute connected to it. The nominative case, then, is that leading finite or position which expresses the subject of a connecting verb, and the agent of an active verb. And the accusative is that position which expresses the effect of an active verb, and thus a simple position will carry us: and the nominative and accusative have evidently to each other the relation which a cause has to its effect, and that for no other reason, but that their order corresponds to the order of cause and effect.

But suppose that my purpose was not only to express a cause or agent, but the origin of that cause, or the influence by which it acts, or the end for which it acts. In such cases simple position will be of no avail. I must have recourse to some other expedient, and no expedient so well can serve as suitable words to express origin, instrumentality, and end. Thus, the Son of God redeemed mankind—he redeemed them by his death—he redeemed them for happiness. In the first sentence, of means beginning or origin; and God succeeding it, as being the origin of the title, is said to be in the genitive case. In the second, by denotes instrumentality or mediun; and as death is the instrument or medium by which Christ redeemed man, it is said to be in the ablative case, and might more properly be said to be in the instrumental or mediun case. In the third sentence for expresses the end for which Christ redeemed man: the noun happiness succeeding it, is therefore in the final case, or as it is commonly, though unmeaningly, called the dative case.

The cases, then, or those leading positions of a noun that answer the purposes of speech, are the nominative, accusative, genitive, ablative, and dative. Let it be added, that the nominative, as it implies the name of its object, is often used merely to address a person, and thus to fix his attention. In this sentence the noun is said to be in the vocative case, and the object.
sometimes preceded by the 'interjection O! But we have not yet done; the nominative and accusative are expressed by position, while the oblique cases, the genitive, ablative, and dative depend on words expressing beginning, medium, and end... Let us, then, contemplate the connection of these words, or words of the same import, when first introduced into discourse. As the relations of things are in the order of our ideas consequent upon the things so related, propositions, denoting these relations must at first have succeeded the nouns which they now precede and govern. Thus in the above instance, the order would have been God of—death by—happiness—far. And it is remarkable, that in the Tindalean pronunciation the prepositions to this day generally succeed the dependent nouns, instead of going before them, as in other tongues. The consequence of this was, that the prepositions, abbreviated perhaps into single letters, coalesced with the preceding noun, forming thereby one word with it. Thus god's, god's, god's: and the variety of terminations given by this means to the noun is the origin of cases. Modern tongues, in rejecting this variety, and substituting prepositions, have only resorted to the original purity of language.

Grammarians have generally concurred in defining cases to be changes of termination. In this, as in the above account be just, they are mistaken, not only because position is the primary and essential idea of a case; but because while they reject prepositions as marks of cases, they consider cases defined by them as only other than the prepositions which they reject. Conformable to this notion, they maintain that the English noun has no other than the possessive case: and Dr. Lowth and Mr. Lindley Murray, pursing the same error to its consequences, comprehend nouns expressing the relation of effect, the relation of beginning, the relation of medium, and the relation of end, under one unmeaning phrase of objective case, thus confounding relations the most necessary to the purposes of speech, the most distinct in themselves, and most requisite to be kept distinct in the mind.

The ideas of the most acute and learned grammarians have hitherto been confused and contradictory on the subject of cases, especially the oblique cases. And the author of the treatise in the Encyclop. Britannica has just left the matter obscure and uncertain, as he found it. *The genitive, says he, is the most general of all the cases, and gives notice that some connection indeed subsists between two objects, but does not point out the particular kind of connection. That we may infer, not from the nature or termination of the genitive itself, but from our previous knowledge of the objects connected, that the genitive denotes merely relation in general, might be proved by adding innumerable examples, in which the relations expressed by this case are different.* These observations clearly show that this writer did not himself understand the meaning of the genitive case, which, instead of expressing some connection between two objects, or mere relation in general, uniformly expresses one and the same relation, namely, that of beginning, source, and origin; and of, the mark of it, has uniformly the same sense with from. Thus a table of wood, a table from wood; wood being the origin of the table, Rays of the sun, rays from the sun, the sun being the origin of the rays. And beginning will appear to be the primary idea implied in of, if we trace it to its origin: of, ab, a-r, de, ab, percut, ftent, root. Thus also in Latin Dei gratia, the grace of God, the grace from God, the grace-of which God is the source. Of the phrase injuria regia the writer says, no man can know whether the injury mentioned be an injury inflicted, or an injury inflicted by the king. We deny this, if the terms be used in strict propriety they must mean an injury from the king, an injury of which the king is the source and author; and, if they are intended to denote an injury received by him, the expression is incorrect and ambiguous, though the ambiguity would be removed by the context; and this leads me to remark, that as the beginning of a thing is the author of it; and as the author has a full right to the fruits of his labours, so that state of the noun which expresses beginning came to signify the owner or possessor. And thus the genitive in Greek and Latin expresses the relation of possession, and answers to what is called in English the possessive case. Thus, my father's will may mean the will of which my father is owner; it means also the will which originated in my father. The possessive case, in our tongue, is an acquire abbreviation of the genitive termination of the third declension in Latin, father's house, father's house, the apotrope above supplying the place of the excluded vowel.

The same writer has not defined the meaning of the dative, though the relation denoted by it is the most obvious of all, containing himself with saying, that it has nearly the same sense with the accusative, 19. No two relations, however, can be more distinct; as the accusative expresses the effect of an action, and therefore stands immediately connected with that action; whereas the dative denotes the end to which a motion or action tends, and in which it terminates, or the point to which the attention is directed forward, as that to which something else is related. Thus, in the instance given by him, compare Virgili commoros. The imitative object of comparison is Vergil, and Horat is the point, or standard placed before me in making that comparison. The two first words express the action and its effect; the last holds to view the point to which they are directed. It is true that in this and similar inferences, the mind brings under one view the person compared and the person to whom the comparison is made; and this proximity or juxtaposition constitutes the affinity which the writer erroneously supposes to be between the two cases. Antonius loit Cicerone, and Antonius vocat Ciceroni, he further supposes to be expressions of the same import; but in this he has been misled by the genius of our tongue, which would express each phrase by Antonius dicit Ciceronem. But this is the exact meaning of the first clause only. In the second claus vocat expresses not an action, but affirms a quality. Antony was hurtful to Cicero. Antony was hurtful. Cicero was a person to whom his hurtful behaviour was directed.

The dative case stands opposed to the genitive as end to beginning. The latter is the point where motion begins, the former where it terminates, and the ablative is the medium or instrument between both. In consequence of this connection between the ablative and the genitive, on one hand, it came in Latin, by the mere impulse of repeated associations, to mean in many inferences the same relation with the genitive, and this is the reason why the same word often governs a genitive or an ablative, why in our own tongue of and, from have precisely the same signification, and why the French and Italian express the genitive by these prepositions which in Latin govern the ablative. On the other hand, as the instrument or medium is connected with the end, the ablative holds a similar connection with the dative. Hence in Latin these two cases are often used one for the other, which is certainly a great impropriety in that language, and which occasions much perplexity to the learner; while in Greek, which has not a distinct ablative, the relations of instrumentality and end are expressed by the same termination, which is certainly a great defect in that elegant and copious language. Instrumentality implies concomitance; but this is not the primary sense of the ablative, as the author of the above treatise erroneously supposes.
The Origin and Properties of Adjectives.

Things or substances are known and valuable on account of their qualities; the qualities of things therefore first engaged the attention of mankind. And as they perceived that the name quality existed in the same or in a different degree, in different things, men, however rude or uninformed, learned to form ideas of qualities independent of the substances to which they belonged. Hence they acquired that class of words called adjectives, which are only the names of qualities. Now as qualities result from things, the names of qualities are derived from the names of things; and, as moreover qualities are constant concomitants of the things they characterize, the names of qualities are constant adjuncts of substantives expressed or implied. Hence they are sometimes called nouns, because they have been borrowed from nouns; and always called adjectives, because they are always adjectives or added to nouns, and for this reason they have also the name of adjectives. From this account of adjectives we deduce the following inferences, which are worthy of attention.

First, adjectives expressing the simple qualities of natural objects, which do not imply motion or action, are derived from nouns, by the mind first abstracting the quality from the thing it qualities, and then generalizing it so as to make it an epithet expressive of a similar quality in different things. Thus in ἅλκη, a deep rock; the quality deep, contemplated first as a quality of that particular thing, the mind soon learned to consider as separate from the rock, and hence to make it a general term of the like quality in other objects. Thus was derived the adjective ἅλκης, proous, prone. And in the manner this single adjective is formed, are formed all the adjectives which exist in all languages.

When adjectives became numerous in any language, analogy or custom so arranged them a particular termination. Hence, on every conversion of a noun into an adjective, that adjective immediately assumed the ending which analogy had appropriated to words of that class. Thus ἐπίθετος, food, relish, was changed into πρόσθες, signifying agreeable food or wholesome relish. Thus also wood, wind, became woodo, wind, in our own tongue. It is obvious from this to observe, that in the earlier periods of human language, adjectives approached nearer in meaning and termination to the nouns whence they were derived; that is, they were less abstractive and generalized. But the principles of abstraction and generalization were greatly facilitated, when a quality was once expressed by an independent word; the eyes and the ears being made by that means to aid the conceptions of the mind. This is the reason why a barbarous people have few or no adjectives; and why, in the more ancient dialects of the East, the use of adjectives is far less frequent than in the more recent languages of Europe.

In speaking of the qualities of things, similitude or resemblance is an idea of high importance and frequent recurrence. A person discovering to another of something unknown, naturally says, that it is like to some other that is known. Thus in Greek ἑιδος, image; ἑιδος, form; ἑιδος, like, are combined with nouns in order to express likeness; ἑιδος, man-like, ἑιδος, having the form of Heracles, Heracles-like, i.e. the son of Heracles; ἑιδος, man-like. This last termination, by inferring ἑιδος, gave birth to the Latin adjectives in -ides, and to our adjectives in -ous, -ous, -ous; glorious. The numerous adjectives and adverbs in English are formed on the same principle. Evidently, i.e. earth-like, which is the Greek ἱδος, Gladstone is gladstone, the same with glad; same, or same being, we conceive, corruption of saints. The termination -ides is originally the Persian -ides, added to a noun to express likeness; as γλαύς, the more; γλαυσ-ides, moon-ide, like the moon; woman-ide, like a woman. The termination -ides, derived, it is allowed, from the northern language, is borrowed by that language from the Greek participles in -des. In the same manner we form some adjectives after the analogy of the past participles in -des, as θεμελ-ides, written; while that of y is the Anglo-Saxon iy; but this is only the Latin termination -ius, as unus, Anglo-Saxon ain, any.

But it must not be omitted that a very numerous class of adjectives is derived from verbs, and that independently of participles. Of this origin are all those adjectives whose qualities presuppose motion or action; and they imply greater power of abstraction than those derived from nouns. Mr. Tooke, indeed, denies this power as a principle in language; and by this rejection is led to deny the existence of adjectives as a class distinct from nouns. His definition is the following. "An adjective is the name of a thing, which is directed to be joined to some other name of a thing." (Vol. ii. p. 241.)

As his authority on the subject of language is so high in the estimation of many, we shall briefly examine and refute the above definition. His arguments are these: "I think you will not deny that gold and brass and silk is each of them the name of a thing, and denotes a substance. If then I say a gold ring, a brassen tube, a fillet string, here are the substantives used adjectively, yet names of things, and denoting substances. If again I say a golden ring, a brassen tube, a fillet string, do gold and brass and silk cease to be the names of things, and cease to denote substances, because, instead of coupling them with a ring, tube, and string by a hyphen thus (-), I couple them to the same words by adding the termination en to each of them? Do not the adjectives which I have made such by the added termination golden, brassen, fillet, convey to the hearer's mind, and denote the same things as gold, brass, and silk? Surely the termination en takes nothing away from the substantives gold, brass, and silk, to which it is united as a termination: and as surely adds nothing to their signification, but this single circumstance, viz. that gold, brass, and silk are designated by this termination en to be joined to some other substantives;" p. 439. Again he says, p. 444, "But if, indeed, it were true that adjectives were not the names of things, there could be no attribution by adjectives; for you cannot attribute nothing. How much more comprehensive could any term be by the attribution to it of nothing? Adjectives therefore, as well as substantives, must equally denote substantives; and substance is attributed to substance by the adjective contrivance." He concludes with what Dr. Jonathan Edwards says of the language of the Mohicanew Indians. "The Mohicans have no adjectives in all their language, although it may at first seem not only singular and curious, but impossible that a language should exist without adjectives, yet it is an indubitable fact."

This account, instead of unrolling that simplicity and precision which mark the progress of the human mind in the formation of language, tends to crape the very elements of knowledge, and to confound ideas the most palpable and distinct. Our ideas of qualities and ideas of things. The distinction between these classes is universal; it is common to the philosopher and the bulk of mankind; and is most readily comprehended even by children. As we have our ideas of qualities, language must have means to express those qualities, i.e. it must have adjectives; and as our ideas of qualities are in their nature distinct from, though concomitant ideas of things; so adjectives must in their nature be distinct from, though adjectives of nouns.
The first step in the formation of adjectives is abstraction; the mind being led to conceive of the quality independent of the things in consequence of perceiving it in different things. The frequent recurrence of the quality, which is one and the same, and therefore remembered, while the substances which prefix it are numerous and successive, and therefore forgotten, greatly facilitates our abstract conception. A similar facility, as we have already observed, is afforded by the independent use of words to express qualities. The dependence of adjectives on the principle of abstraction is evident from one circumstance. *Like* is a very abstract quality; and the union of this word with nouns is one copious source of adjectives in most languages of which we have any knowledge.

The next step in the formation of adjectives is association. This principle is so powerful and infallacious, that it changes the nature of a word, in consequence of its connection with other words, and of our previous experience. Thus, the ladies *fem* themselves — "The plump people *eye* the falling verdure." Because we have experienced the medium term of a simple direct proposition to be always a verb, we instantly, in the above examples, conclude that *fan* and *eye* do not here denote the things usually meant by them, but the *operations* of those things; that is, association and experience convert the nouns *fan* and *eye* into verbs, without any thing to aid or indicate that conversion but the circumstantial suggested by the collocation. This conversion of a noun into a verb by simple experience illustrates the conversion of a noun into an adjective. We place a word signifying a quality before a word denoting a substance; and as we uniformly find that qualities belong to the things which they quality, and first act upon our perceptions, we instantly infer from the collocation that the first expresses an attribute of the second; and this attribution is not indicated by the termination of the attributive, but an inference of the mind founded on experience. The termination on signifying to be added is a conceit of this grammarian, and has no foundation in truth; for it is the Greek participial termination in *on*, borrowed by the Goths. The formation of language did not require such petty, circuitous contrivances; but points to the broad and simple principles of abstraction and association as the copious sources of all its phenomena.

From this it appears, that a peculiarity of termination is not necessary to form an adjective, the collocation being sufficient to ascertain its character as such. An adjective may have the same ending with any other noun, or with the very noun from which it was derived; and it has this identity of termination in Greek and Latin, and yet no ambiguity arises as to its nature and use. The inference, which we instantly, and we may say, imperceptibly, draw from the juxtaposition in our own tongue, and from the similarity of terminations in the classical tongues, is an inerring guide in these respects. And this is the reason why, in a barbarous language, it is possible that the name of a quality may be always the same with the name of the thing to which that quality belongs, and yet abound with adjectives, i.e. abound with nouns converted into adjectives by juxtaposition. And this is all that can be meant by the testimony of Dr. Edwards, in regard to the language of the Mohigans. If there existed a language which had no verbs, but nouns converted (as in the above influence of *fan* and *eye*) into verbs without any variation of termination, a person who did not understand the nature of the human mind, and who had been accustomed to clarify words only by their endings, might say of that language, that it had no verbs.

The foundation of Mr. Toole's error, is the circumstance that most adjectives were originally nouns. As they were nouns in their origin, and as he rejected the operations of the mind in the constitution of language, he inferred with confidence, that they were nouns *still*, thus confounding in one profusionous mass our ideas of qualities, and our ideas of things; yet, notwithstanding this confusion, he writes thus: "If in what I have said of the adjective, I have expressed myself clearly and satisfactorily, you will easily observe that adjectives, though convenient abbreviations, are not necessary to language; and, therefore, are not ranked by me amongst the parts of speech; and, perhaps you will perceive, in the misapprehension of this useful and simple contrivance of language, one of the foundations of those heaps of false philosophy and obscuré (because mistaken) metaphysics with which we have been bewildered."

Adjectives, as expressing not things, but their qualities, cannot, in strict propriety, have any gender; but, as in Greek and Latin, they have the same terminations with nouns, they are said to be masculine, feminine, or neuter, merely as they have masculine, feminine, or neuter terminations.

In most languages, adjectives vary their endings to correspond with the plural form of nouns; in English they have no such variation, nor is it necessary, since qualities are not susceptible of numerical distinction, being the same, whether applied to one or to many.

There is, however, one variation which adjectives have in all languages, namely, the variation to express the three degrees of comparison. The qualities of things differ in different objects, and they must be expressed with augmentation or diminution, as they are compared with others more or less intense.

When a quality is expressed without reference to any other, the adjective is then said to be in the positive degree. When expressed with reference to the same quality or to another more or less intense, it is said to be in the comparative degree; and when in the highest or lowest degree of all, it is in the superlative. Different languages have different ways of forming the comparative and superlative; but in almost all, both these degrees are deriv'd by certain syllables added to the positive: the adjective itself, by being thus lengthened, is made to correspond with the augmentation in force, which the quality acquires by comparison. The mode of expressing the degrees of qualities being only new, and therefore very general and imperfect, while the qualities themselves vary in endless gradations, a more adequate method is aff'd, by having recourse to those attributes of an inferior order, called adverbs, as much good, tolerably good, exceedingly good, more good, most good.

As it is not our object to detail the minute rules of grammar in our own tongue, we shall conclude this part of the subject with one or two observations on the three degrees of comparison. The positive degree, though not implying an immediate comparison with the same quality in a higher or lower degree, often conveys a relative or comparative idea; and for this reason may, by the allusion of a preposition, be made to express the comparative or superlative degree, as *Blissed among women, i.e. the most bliss'd of women.* And this relative or comparative idea, implied in the positive, is the reason why the positive has sometimes after it the case which is used after the comparative. On the other hand, the comparative and superlative are used in a positive sense, or used to express a high degree without any immediate object of comparison. Thus Virgil speaks of Venus: "Trifior et lucernis cuculus fufida intentans,"—*Trifior, more fad then usual, i.e. very sad.* This is more usual in the superlative degree, *vir defignatus, a very learned man.* The comparative is used with propriety only when two things are compared; the
The superlative when a thing is compared with many. The elder of the two—the elder of all. Nevertheless it is to be observed, that multitude may be the object of the comparative, if preceded by all or whole, to give it a collective idea; as, "he is wiser than all his teachers, i.e., he is wiser than the whole body of his teachers,—he is wiser than them all put together;—or, compared with his teachers one after another, he is wiser than them all." 

The Origin and Properties of Pronouns and Definiteness.

Pronouns have been defined substituents for nouns, to prevent their too frequent recurrence. Mr. Harris accounts for pronouns, or, as he calls them, curious of the second order, in a different way; and, as his explanation is curious, we shall here place it before our readers. "All conversation passes between individuals, who will often happen to be till that instant unacquainted with each other. What then is to be done? How shall the speaker address the other, when he knows not his name? or how explain himself by his own name, of which the other is wholly ignorant? Nouns, as they have been described, cannot answer this purpose. The first expedient on this occasion, seems to have been pointing or indicating with the finger or hand; some traces of which are still to be observed, as a part of that action which naturally attends our speaking. But the authors of language were not content with this: they invented a race of words to supply this pointing, which words, as they always stood for substantives or nouns, were characterized by the name of pronouns. These, also, they distinguished into three several sorts, calling them pronouns of the first, the second, and the third person, with a view to certain distinctions, which may be explained as follows.

"Suppose the parties conversing to be wholly unacquainted, neither name nor countenance on either side known, and the subject of conversation to be the speaker himself. Here, to supply the place of pointing, by a word of equal power, the inventors of language furnished the speaker with the pronoun I; I write, I say, I desire, &c.; and as the speaker is always principal with respect to his own discourse, this they called, for that reason, the pronoun of the first person. Again, suppose the subject of conversation to be the party addressed. Here, for similar reason, they invented the pronoun thou; thou writest, thou walkest, &c.; and, as the party addressed is next in dignity to the speaker, or at least comes next with reference to the discourse, this pronoun they therefore called the pronoun of the second person.

Lastly, suppose the subject of conversation neither the speaker nor the party addressed, but some third object different from both. Here they provided another pronoun, he, she, it, which, in distinction to the two former, was called the pronoun of the third person. And thus it was, that the pronouns came to be distinguished by their respective persons."

This account, which the author, as he says, received from Apollonius, is arbitrary and erroneous. The use of the pronouns is not to supply the names of persons unknown to each other; nor can they be said to have been invented for though they answer the most useful purposes, they originated in circumstances in which design had no concern. The origin of the two first pronouns we conceive to be this. They are the adjectives one, two, losing their numeral signification, and coming to mean the speaker and the person addressed, by the mere force of affection with the verb. Let us suppose a person wished, in the infancy of languages, to express the proposition I love thee. If English were his words, he would have said, one love two. This form being repeatedly used, and the person using it accomplishing the leading term one with a consciousness of himself, that term would gradually drop its character of one in opposition to two, and derive a new character by affection from the verb, namely, one that was speaking in opposition to the other spoken to. Thus the same process which converted one in general into one speaking, converted two into the person addressed.

That the pronouns I, thou, were originally one, two, will appear probable from hence. In Hebrew, the most ancient language, the pronoun answering to I is evidently the present of the verbal numeral one; and two has a close resemblance to thou. Thus, I is 1, and ego, is 3, in Greek, and unus in Latin, and the other forms unus, euo, are also. Moreover, unius, aoi, by dropping οι seems to have produced τοι, του, thy; and his, duo, two. And in other tongues the pronouns thou and the numeral two have such resemblance as to bespeak one common origin in Hebrew. Besides, the pronouns I and thou still retain their origin in their names; I being the first person, thou the second; not because the former is the first and the latter the second in dignity, but because these were their original meaning. Moreover, the numerals one, two, must have been among the first adjectives formed by abstraction from such things as nature produced in pairs, or those which alternately succeeded each other, such as day and night. And as discourse is but an alternation or interchange of sentiments between two persons, the numeral adjectives in question were the most likely to be used on such occasions. Remains of this usage may be still traced in some languages, as we say, One thinks so, or in French, En dit; one being not as Condillac (see his Works, tom. v. p. 184.) affords, a corruption from homm, but of the Latin unus, and is not a substantive, but a substitutive for a substantive, i.e., a pronoun. Finally, we observe that no words but numerals were capable of being formed by affection into pronouns. The speaker, indeed, might use his own name, and which, when repeatedly used, the verb would convert into the first person. But on the same principle another would employ his own name, and thus the associations of one man would counteract the associations of another; and neither name would be received as the representative of the speaker.

From this statement of the origin of the pronoun, some particulars respecting its nature and use may be deduced with precision. First, the adjective, in being changed into a pronoun, loses the generality of a numeral, and assumes an individual character; that is, the character assigned to it by the verb. But as any other person may use that term in similar circumstances, the pronoun I, which was changed into the index of an individual by affection, becomes again general by succession; each speaker having a right in his turn to use it: and thus the pronouns I and thou became substitutives for the names of all persons in a change of situation. Secondly, I and thou are not, as has been hitherto supposed, substitutives for the names of the speaker and the person addressed, to avoid their too frequent repetition, nor yet substitutives for those names while yet unknown, but representatives of those persons in that limited or restricted character which they derive from the affixed verb. Now as speakers there is no difference between a man and a woman. A man that speaks and the woman that speaks, in that particular function, is the same; and the same thing holds in regard to the person addressed. The first and second persons, therefore, have not, in any language, the distinction of gender merely; because they represent human beings in that particular character which excludes the idea of sex. Thirdly, there is, properly speaking, no such thing as a third person; this being a definite, marking the subject of discourse, and said to be the third person in reference
ence to the first and second, and thus represented as something distinct from them, and not included under them. Thus ἄνθρωπος, in Hebrew, and be in English, were, as we shall presently see, but the article; and for ἄνθρωπος, we, us, them, in Greek, and bis, ils, ii, in Latin, are all species of restrictive or definitive adjectives, agreeing with the defined noun expressed or implied. As the first and second persons represent two individuals in particular circumstances, they comprehend no other noun under them; whereas the third person is only, in general a subject of discourse, and therefore it comprehends any noun in the language, excepting the first and second: accordingly every subject or agent in every language is the third person singular and plural, except four, I, thou, we, and ye, or their equivalents. The first and second person, we have seen, exclude the idea of sex, whereas it is a character often necessary to be marked in the subject or agent; for this reason pronouns of the third person have the triple distinction of masculine, feminine, and neuter.

All the three persons admit the plural number, as each is capable of representing numbers. In our own tongue I, we, thou, you or ye; he, she, it, they. Here it may be observed that ye is a corruption of you or you abbreviated; and as this abbreviation naturally takes place in the nominative or vocative, when the persons addressed are called; and as it is necessary to be distinct when expressing the addressed persons as affected by a verb, ye is used with propriety only in the nominative or vocative, and you in the accumulative. Men being usually surrounded with attendants, it became a compliment to address a person as such; in the same manner as in Greek, ἡ ὑπάρχον, those around Priam, was a respectful way of designating Priam. Hence in common discourse we use you for them; and on such occasions the verb also should be in the plural, as you were and not you went. But this complimentary style is not applied to the Supreme Being, who is always addresed by thee, from a regard, probably, to his unity, numbers being not able to add to his dignity or greatness. The royal style we has respect to the king's counsellors, who are supposed to advise the subject of discourse, and who are responsible for it. With regard to the third person, though it be convenient to mark the gender, it is not essential: for the plural they is made to represent men, women, and things, without any inconvenience or ambiguity.

The personal pronouns, contrary to the analogy of nouns, have each three terminations, or three variations, to denote cases. This is owing to their being derived from the Greek and Latin, with their respective inflexions. Their genitive, dropping the primary sense of beginning, has uniformly the secondary sense of possession. Hence it is called, in our tongue, not improperly, the possessive case.

In Hebrew, Arabic, and Persian, the personal pronouns are converted into adjectives, by being annexed to nouns, which, from their position, are called suffixes. In this state they are somewhat abbreviated and changed: but however changed when connected with nouns, they are always adjectives, but retain their personality when affixed to verbs. In our own tongue the personal pronouns are changed into adjectives from the genitive or possessive case: as mine, my; thine, thy; his, his; ours, ours; yours, yours; theirs, their; or, our; your, your; their. Thus formed, they are properly called pronounal adjectives—adjectives, as qualifying nouns, and pronounal, as derived from the personal pronouns. His must be considered, by coals, as properly an adjective of this kind, through the genitive he's. These pronounal adjectives, as derived from the genitive, may be resolved into the signification of that case: as my of me; thy of thee; his of him; though seldom in English used in their personal form. The reason is, that our tongue has a strong propensity to convert nouns into adjectives by juxtaposition, and thus to use them for the sake of brevity, instead of the genitive: as when we say felt-flying for flying of felt, and gold-ring for ring of gold.

The Greek and Latin do not abound with the same analogy, and therefore frequently use the personal pronoun in the genitive as equivalent to the personal adjectives.

The reciprocal or reflex pronoun self is added to these personal adjectives: as myself, thyself, &c. The third person singular and plural by analogy should be his, herself, and therefore: but in order to honour the ear or the organs of speech, there are changed into himself and themselves. Self means an individual in opposition to another, and is derived from the Latin solus, alone, through the medium of the Anglo-Saxon sol, sol, Anglo-Saxon self, self: hence also soul, which means that part of man in which consists the vital principle is opposition to the body: e.g., often used to precede self, is a corruption of the Anglo-Saxon egen, which by the iteration of the letter g, after the analogy of that language, is borrowed from the Latin unus. Oneself, therefore, is oneself.

Mr. Harris gives the following account of that species of adjectives called definitions or articles: 'The visible and individual substances of nature are infinitely more numerous than for each to admit a particular name. To supply this defect, when any individual occurs, which either wants a proper name, or whose proper name is not known, we ascertain it as well as we can, by referring to its species; or if the species be unknown, then at least to some genus. For example, a certain object occurs with a head and limbs, and appearing to possess the power of self-motion and sensation: if we know it not as an individual, we refer it to its proper species, and call it dog, or horse, or man, or the like. If none of these names fit, we go to the genus, and call it animal.'

"But this is not enough: the thing at which we are looking is neither a species nor a genus. What is it then? An individual. Of what kind? Known or unknown? Seen now for the first time, or seen before, and now remembered? It is here we shall discover the use of the two articles a and the. A respects our primary perceptions, and defines individuals as unknown: the respects our secondary perception, and denotes individuals as known. To explain by an example: I see an object puts by, which I never saw till now. What do I say? There goes a beggar with a long beard. The man departs, and returns a week after. What do I say then? There goes the beggar with the long beard. The article only is changed, the rest remains unaltered. Yet mark the force of this apparently minute change. The individual, once vague, is now recognized as something known, and that merely by the efficacy of this latter article, which tacitly intimates a kind of previous acquaintance, by referring the present perception to a like perception already past.

"The truth is, the articles a and the are both of them desinfects, as they circumscribe the latitude of genera and species, by reducing them for the most part to denizens. The difference between them, however, is this: the article a leaves the individual itself unascertained, whereas the article the ascertains the individual also, and is for that reason the more accurate definitive of the two.'

We give this statement as that of an eminent grammarian, without subscribing to it as just in all respects. It is not, we consider, true, to say that the individual defined by a is always unascertained, and the same not necessarily imply a previous acquaintance, by referring the present perception to a like perception already past. And we cannot help observing that, if Mr. Harris and other writers on the subject had traced these words to their sources, and thus ascertained their primary meaning, their readers would have been more inform-
ed in one paragraph, than they otherwise could by the most elaborate treatise.

The article a is in truth the numeral adjective in Greek, used in Latin, enim, &c., &c., in Anglo-Saxon: and the import of it professedly accords with its original signification of one of book is one book; a man is one man. Hence it may learn with certainty the following particulars. That it is enveloping the word in mystery to call it an article, instead of calling it by the more appropriate name of numeral adjective, or definite article. That as it means one it cannot be prefixed to plural nouns, unless those nouns be taken in a collective sense. That the usual rule, a becomes an before a vowel, should be just reversed in order to be true. "An becomes a before a consonant." That the equivalent of the article a exists in Greek and in Latin, but is rejected as useless in those languages; and that the frequent use of it in English, and other modern language is so far from being necessary, that it is an incumbrance and inelegance. I see man would be as intelligible as when we say I see a man; and they read book, as definite, as they read a book; and this, from the nature of the cafe, just as in Latin, videt hominem, legunt libros, where nouns would be both mass-efficacy and inelegant. The English I see man, and the Latin videt homo, are both equally indefinite in themselves; but they are sufficiently limited by the nature of our perception, and by previous experience. "The indefinite article," says the author of the treatise on Grammar in the Encyclopædia Britannica, "is much less useful than the other; and therefore the Greek and Hebrew languages have it not, though they both have a definite article. In languages, of which the nouns, adjectives, and verbs have inflections, we mistake the word from the want of the indefinite article; because it can always be known by the terminations of the noun and the verb, and by the whole circumstances predicated of the noun, whether a whole species or one individual be intended. But this is not the case in English. In that language the adjectives having no variation with respect to gender and number, and the tenses of the verbs being for the most part the same in both numbers, it might be often doubtful, had we not the indefinite article, whether the specific name was intended to express the whole species or only one individual. "All this reasoning, however, appears to us fallacious, and only shows that even a wife and able man, such as the writer of this article certainly is, will readily think that necessary and useful to which he has been accustomed, and therefore will seldom be at a loss for some plausible reasons to justify it. In truth, the inflections of adjectives and verbs in the learned languages alluded to, have no influence whatever in defining the extent of the general term, but serve merely to show that they qualify that term, and depend upon it. The very example adduced by this writer shews the fallacy of his reasoning: Exspectavit a patre annos multos. Here annos as clearly denotes not the whole species, but an individual, as if it was written a diem. This and that not because of the singular correspondence of annos, nor from the termination of multos. Of this there is an evident proof; for annos and multos would be still the same, though multos had a specific or collective sense. But the individual sense of the noun appears from the nature of the case, from the context, and especially from the clause, whose name was John; and these circumstances, which sufficiently define it in Greek, would be sufficient to define it in English, were it written "Man was sent from God whose name was John." It is impossible to feel in this any ambiguity; and the expression seems uncouth only because we have been accustomed to the use of a man was sent from God, &c.

Mr. Tooke derives the and that from the Anglo-Saxon verb than or thereon, to take. But these definitives exist in that language, and why should we attempt to derive them from any word, when they are already formed and employed in the same sense? He seems to have been aware of this objection. And he adds, vol. ii. p. 60, "The (our article, as it is called) is the imperative of the same verb thane, which may supply the place of the correspondent Anglo-Saxon article fe, which is the imperative of feon, edere. For it answers the same purpose in discourse to say—feo man, or take man." The English take, and the Anglo-Saxon stigen, which this writer would lead us to regard as a primitive northern word, is only the Greek toke, to accept. Take this, therefore, means, receive this.

Light is the medium of sight, and hence, in the most ancient languages, the word signifying light gave birth to verbs signifying to see. Thus the Hebrew סָנָה, סָנָה, pronounced in Arabic tha, but in Persian fea, feea, is the parent of the Anglo-Saxon seon and our see, which coincides with the Persian pronunciation, and also of the Anglo-Saxon fea or fe, or, as we found it, conformably to the Arabic, the. It is remarkable the article in Greek is founded entirely on the same principle, though derived from a very different word. For its original appears to have been the Hebrew article נ, which probably was founded on or is short, and which is but an abbreviation of עָבָד. Now the use of this last confines in directing the attention to an object, and answers to en or esse in Latin, and behold in our own tongue. And as the necessary consequence of looking upon a thing is to see it, as distinguished from other things, hence נ in Hebrew, in Greek, is the in, from signifying to perceive, through the medium of light, came to signify an effect of perception, consequently, the distinction or opposition which the thing to be seen has to other things which may be regarded in it.

From this account we may gather the following particulars respecting the nature and use of the definitive article. Its primary force consists merely in directing the eye or the attention to an object; and the definitive power alligned to it is rather an effect of the sight where the object is present, or of the mind in drawing the necessary inference, where the object is previously described or specified. If this account be just, the assertion of Mr. Tooke, that the article in combination with a general term, is a mere substitute for a particular term, (see vol. i. p. 69) is erroneous. The article is only an index; having indicated the thing intended it does no more: the eye or the mind does the rest, and the general term is defined or made particular, by being brought under immediate inspection. It is necessary to subjoin the general term to the article, because it is necessary to specify the object intended; but the restriction of the specific or general noun to that individual object is a consequence of the article, rather than a power belonging to it. The article therefore cannot be a mere substitute, to do that which is done by another principle, namely, the eye or the mind.

The article the is the name in origin, and often in use the name with that and, indeed in the Anglo-Saxon that is only the neuter gender of the, and Mr. Tooke ought to have made this remark instead of representing each as independent of the other.
This definitive is in our tongue variously applied; and the objects of its application are so distinct and different, that it has been thought to change its nature, and to belong to different parts of speech. And Mr. Tuke has the merit of being the first to show that in all circumstances, that retains one and the same character. Let us briefly consider its various applications. And first, it is used to bring under the eye of the mind, i.e. to denote individual objects; as that book. In this sense it is opposed to this, answering to ill as opposed to hic in Latin. Ill, that, denotes the remotest of two objects; hic, this, the nearer. "Alexander and Julius Caesar were great commanders, that (ille) conquered Africa; this (hic) subdued the Gauls—they, meaning Alexander as the farther off; this, Julius Caesar, as the nearest." In such a sentence it would be more usual to say the former and the latter. Secondly, that is frequently used to characterize a whole clause, which is the object of a transitive verb, thus serving to fix the attention on what is going to be said, and by that means to render it emphatic and prominent. Thus, "I wish you to believe that (that thing which I am going to say, namely,) I will not hurt a fly, by which Mr. Tuke thus resolves, I would not willingly hurt a fly; I wish you to believe that affirmation." In this application it answers to quod in Latin. Thirdly, that is also used to point out the end or purpose, which a person has in view, and as such it precedes a verb in the subjunctive mood, expressing that end thus: 'Thieves rise in the night that they may steal.'—"Thieves rise in the night, that being their purpose, namely, they might steal." In such a sentence it corresponds to the Latin conjunction ut, which, perhaps, led to the error of considering that as a conjunction in the second and third persons. Fourthly, it is an index pointing to a noun in the preceding clause, and is a substitute for that noun, or rather it agrees with that noun implied, though never expressed. "The man, that hath not music in himself, is fit for treason." Here the first clause, the man, is represented as definite, while the reader as yet is not able to recognize it as such. What man is fit for treason? To preclude the necessity of this question, a clause is introduced, that man, namely, he who hath not music in himself. In this sentence that is thought to be a relative equivalent to some, which may be substituted for it. But in reality it is still a definite, used to ascertain the preceding specified noun, which has the form of being definite without being really so; and the preceding noun is to be repeated, or, as that is descriptive, a generic or specific noun of the same import is understood to be introduced. Thus the man, namely, that fort of man, who hath not music in himself, is fit for treason. The subject of discourse may be plural, and yet the singular form of that may, on this supposition, be used. "The men that have not music in themselves, are fit for treason, i.e. the men, that fort of men, namely, who have not music in themselves, are fit for treason; and this is the solution of the apparent anomaly of that being used in both numbers, without variation, when taken relatively.

We come next to speak of the relative pronoun, which Mr. Harris thus explains, p. 77. "But besides those there is another pronoun (in Greek ἥν, in Latin qui, in English who, whom, that,) a pronoun having a character peculiar to itself, the nature of which may be explained as follows. Suppose I was to say light is a body,—light moves with great celerity. These would apparently be two distinct sentences. Suppose, instead of the second light, I were to place the prepositive pronoun it: Light is a body; it moves with great celerity; the sentence would be still distinct and two. But if I add a connective (as for example an and) saying light is a body, and it moves with great celerity; then by conection make the two into one, as, by cementing many stones I make one wall.

"Now it is in the united powers of a connective and another pronoun, that we may see the force and character of the pronoun here treated. Thus, therefore, if in the place of and it we substitute that or which, saying light is a body, which moves with great celerity; the sentence retains its unity and perfection, and becomes, if possible, more compact than before. We may with just reason, therefore, call this pronoun the subjunctive, because it cannot, like the prepositive, introduce an original sentence; but only serves to subjoin one to some other which is previous."

This account, though elegant and specious, we nevertheless deem erroneous; because the relative pronouns in all languages are the same in their origin and use with the articles or definitive pronouns. In Greek ἗ν is only the article ἵν with annexed after the analogy of that termination in Greek nouns. Hence the reason why and is, are, by the more ancient writers, such as Homer and Herodotus, used for one another, either as demonstrative or relative pronouns. The Latin hic is also the article istic with a guttural annexed—hoc; while qui, which Sculiger, and after him Mr. Troke, derive from sei, is no other than the Persian kii or kii, which, scul. Moreover, qui is the Oriental kii, who or what, and it is remarkable that in Hindoo kii is redoubled kii kii, and this has been imported into Latin qui qui. Finally, our who is the Greek ἤν, having the labial as substitutes for the aspirate, which is a broad and general analogy, by which words in Latin and the Anglo-Saxon are formed from Greek, or from the Oriental tongues. Which is the neuter termination of istic formed on the same principle as hoc in Latin, that is, a guttural is annexed to wake, who, which is made to stand for inanimate things.

As the relative and definitive pronouns have the same origin, they are also the same in use. For in Latin the relative always supposes the antecedent to be repeated, and is repeated when obscure or doubtful. In our own tongue, therefore, who never condescends with the antecedent noun, and is therefore a substitute for it, and this peculiarity in our own tongue has caused who, with other such words as whom, to drop its nature as a definite, and to become really a pronoun, i.e. a substitute for a noun. This peculiarity has also obtained in regard to he, which was the Hebrew and Greek article, ἅν, or ἵ. And this is the reason why the article in Homer may be often rendered by he in our own tongue. Dr. Middleton, not perceiving this circumstance, was led, in a voluminous work published on the Greek article, to suppose that the Greek article is in its nature a personal pronoun, and may be always resolved into a pronoun. The foundation being thus fallacious, the whole super-structure, however learned and elaborate, is frivolous and useless.

We observe farther that his, istic, and in, which are really, definitive, often refer, like qui, to a preceding noun, and for this reason have a claim equally just to be called relative pronouns. Thus, "Deus nobis habeat scutum: namque istic mihi miem Corde: illius aram fcerpe tener niloris ab ocellibus imbuat agnus." Here the istic is ille homine, or ille juvenis, meaning Augustus, elegantly kept out of sight, the reader being left to conceive of him only as a god; while illius is ilius dei, of that god. "Tres litora victis proficisci errantium, hos tota armenta sequuntur, i.e. hos cervos." "Cognoscamus Deus ex operibus ejus," we know God from the works of the same—ex dei.

Because the relative qui is thus a definitive, the defined noun, when not antecedent, is made to succeed it in Latin...
and in Greek, as “Maxima laboribus confequantur can, quam ex discedo capiunt, vulgetatem,—literally,] with
the greatest toil they purvey that, which pleasure, (for that
pleasure, which) they derive from flandy. “Qua considunt
ares, ipfa colat,”—let her inhabit which citadels the built,
for, let her inhabit the citadels which the built. In our own
tongue such an arrangement is not allowed, and even inad-
lignible, because here the relative is really a sublitate for
the noun preceding it, and refuses to coalesce with it as an
adjective. And it is obvious to remark in this place, that
with the exception of who in English, the articles or de-
finitives are not pronouns, but adjectives, numeral or reflrefive,
agreeing with a noun expressed or understood, and to be
supplied from the context or the preceding clause. We
remark, finally, that as articles are definitives, the Latin
tongue has not only one but several articles, which it is
eroneously supposed to want. Thus, hic homo, this man,
ille homo, that man, is homo, the same man, ipse homo, that
very man, are phrases, either of which is equally definite and
emphatic with our the man, and on many occasions pre-
cifically the same with it.

Before we close this subject we shall advert to a question
proposed and solved by Mr. Tooke, vol. i. p. 273. “What
is as?—The truth is that as is an article; and however,
and whenever, used in English, means the same thing as it,
or that, or such. In the German, where it still evidently
retains its original significations and use, (as so also does,) it
is written es.” Now, if Mr. Tooke had properly under-
stood the nature of the article, he would not have made this
affirmation. As indeed, like the article, is an index, but it is
an index directing the mind from one object to another, and
the consequence of its being so directed is the perception of
some resemblance between them. Accordingly as is es, an
adverb of similitude in Greek, which is being inverted (as is
often the case with monosyllabic words), has become fo.
On the other hand, the consequence of the indication con-
veyed by the article is not to the observance of some like-
ness between the objects specified, but the limitation of the
general term to the individual object, circumscribed by the
eye or the mind by being so indicated.

In a note this writer adds: “Dr. Lowth, amongst some
false English which he has recommended, and much good
English which he has reproved, says, fo-as, was used by
the writers of the half century to express a consequence in-
stead of fo that. Swift, I believe, is the last of our good
writers who has frequently used this manner of expression.
If that denote end or consequence, the third tense we have
affixed it in the preceding page, and if es, on the other hand,
signify similitude between two objects, fo as is, as Dr. Lowth
states, very improper; while fo that alone is good English
and good sense: and Mr. Tooke is himself guilty of the
charge he brings against Lowth, namely, of recommending
some false, and reproving much good English. We can-
not help observing that the object of comparison marked by
as is often implied, and is to be gathered from the context;
as in the following stanza:

Save that from yonder ivy-mantled tower,
The mourning owl does to the moon complain
Of such as, wandering near her secretower,
Moleit her ancient solitary reign.

i.e. complain of such prorsus, as those who wandering, &c.
The Origin and Properties of Verbs.

We shall begin this part of our subject also with an ex-
tract from Mr. Harris, because his opinion, though plaus-
ible, is erroneous, and has been the cause of leading other
grammarians, who followed his authority, into error. “We
are now,” says he, “to defend to the common herd of
attributives, such as black and white, to write, to speak, to walk, &c. among which, when compared and opposed to each
other, one of the most eminent distinctions appears to be
this. Some, by being joined to a proper substantive, make
without farther help, a perfect affective sentence; while the
rest, though otherwise perfect, are in this respect defective.
To explain by an example, when we say Cicero or
Cicero: wife, these are imperfect sentences, though they de-
note a sublitate and an attribute. The reason is, that they
want an affectio to show such an attributive appertaining
to such substance. We must therefore call in the help of
an affectio elsewhere, an is or to, to complete the sentence.
Cicero is wife, Cicero was eloquent. On the contrary,
when we say Cicero wriileth, Cicero walketh, in instances like
these there is no such occasion, because the words in

difl'rect imply, in their own form, not an attributive only,
but afilerion likewise. Hence it is they may be resolved
the one into is and writing, the other is and walking.

Now all these attributives, which have this complex
power of denoting both an attribute and an affectio, make
that species of words which grammarians call verbs. If we
reduce these complex powers into its distinct parts, and take
the attribute alone, without the affectio, then have we
particibles. All other attributives, besides the two species
before, are included together in the general name of adver-
tives; and thus it is that all attributives are either verbs,
particibles, or adjectives. Besides the distinction here
mentioned, there are others which deserve notice. Some
attributes have their essence in motion; such are to walk, to
fly, to strike, to live. Others have it in the privation of
motion; such are to stop, to rest, to cease, to die. And lately
others have it in subjects which have nothing to do with
either motion or its privation; such are the attributes of
great and little, white and black, wise and foolish, and in
a word the several quantities and qualities of all things.
Now these last are adjectives; those which denote motions or
their privation are either verbs or particibles.”

“Of all the constituent parts of speech,” says the writer
in the Encyclopaedia Britannica 58, “none has given the
grammarians greater trouble than the verb. The vast variety
of circumstances which it blends together in one word,
threws very confiderable difficulties in the way of him who
attempts to analyze it and ascertain its nature; at the same
time that by its eminent use in language, it is entitled to all
the attention which can be bestowed upon it. It should
seem that the first object of our investigation ought to be
the characteristic of the verb, or that which all these words
have in common, and which constitutes them verbs, disdif-
guishing them from every other species of words. Now it
is obvious to the sightful attention, that every verb, whether
active, passive, or neuter, may be resolved into the sub-
stantive verb is, and another attributive: for what is is of
the same import as is loving; and with amans of.

“But loving and amans are not verbs; whence it follows
that the characteristic of the verb, that which constitutes
what it is, and cannot be expressed by other words, must
be that which is signified by the word is; and to us that
appears to be neither more nor less than affectio.

Affection therefore, or predication, is certainly the very
effence of the verb, as being that part of its office, and
that part only, which cannot be discharged by other kinds
of words. Every other circumstance which the verb in-
cludes, such as attribute, mood, time, &c. it may be possible
to express by adjectives, participles, and adverbs; but with-
out a verb it is impossible to predication, to affect, or deny.
any one thing of any other thing. The office of the verb, when stripped of all accidental circumstances, seems to be merely this: to join together the subject and predicate of a proposition; its powers are analogous to those of the sign + in algebra, which does not affect the separate value of the quantities between which it is placed, but only indicates their union or coexistence." The writer then, in illustration of this theory, takes the examples used by Mr. Harris, and then adds, "in resolving every verb, whether active, passive, or neuter, into the substantive verb is, and another substantive, we have the honour to agree with all the grammarians."

We respect the opinion of other grammarians, and that of this writer in particular, but we cannot think it an honour to agree with him and his predecessors on this subject; but we rather think it an honour to differ with them, because we conceive them to be in an error. Now the most sure way to ascertain the characteristic of a verb, or that which constitutes its essence, is to attend to that operation of the human mind by which verbs have been formed. But as the affirmative is thought essential to all others, we shall begin with this. And Mr. Harris thus explains it, p 88, "Previous to any possible attribute, whatever a thing may be, whether black or white, square or round, wise or eloquent, writing or thinking, it must first of necessity exist, before it can possibly be any thing else. For existence may be considered as an universal genus, to which all things, of all kinds, are at all times to be referred. The verbs, therefore, which denote it, claim precedence of all others, as being essential to the very being of every proposition, in which they may still be found either expressed or by implication; expressed, as when we say "the sun is bright;" by implication, as when we say "the sun rifes;" which means, when resolved, "the sun is rising."

According to this explanation existence is the primary idea of is; and Mr. Harris is little confident with himself when, in resolving active verbs into this and another substantive, he supposes it to mean affection. But let us deduce a more adequate idea of it from examples—God is good; His food was locusts and wild honey; If we be virtuous we shall be happy. In the first of these examples is connected good with God; so in the second it connects locusts and wild honey with food, and affirms, that with regard to John they were the same. In the third instance, happy is, by shall be, represented a quality of are. For this reason the following terms would be more appropriate than any other. The head noun the subject, the thing connected the predicate, and the verb connecting them the connecting verb. Thus, God is the subject, is the connecting verb, and good the predicate; and so in all other instances.
