Cyclopædia: or, a new universal dictionary of arts and sciences.

Generation.

Generation is that function of the animal economy by which the species is perpetuated. Inanimate matter and unorganized bodies are subject to no alterations, and would never change their condition, did not external forces destroy or modify them. On the contrary, organized bodies, very different from these inert matters, are active media of new combinations and changes; they undergo alterations, and are even destroyed by the exercise of their own powers, the entire cellation of which delivers up their spoils to the grand circle of changes, which organized matter is constantly undergoing. Although some of these bodies may last for a century, while the greater number live only for a few years, days, or even hours, this unequal duration, these moments or ages of existence, are nothing with respect to nature, and the death which she allows to man, to the plant or the insect, is not the least necessary and certain. But, if individuals are sacrificed and perished, the species survives and are immortal; by a constant and general law, animated bodies never die altogether, but are renewed and perpetuated by various modes of re-production. Some terminate their vital course while others are beginning it; and never, says Lucretius, does morning or night visit the globe, without having funeral lamentations round a bier, and the plaintive cries of an infant in the cradle. There is a constant alternation of deaths and births, of losses and reparations; and the torch of life is rapidly transmitted in the series of succeeding generations; "quasi currentes vitæ lampadæ tradunt." At a certain point of elevation in the scale of animal existence, this object is accomplished by a double series of organs, executing very different functions; and re-production is effected by a true process of generation, under the influence of that physical feeling, the Venus, whose universal empire and irresistible attractions are so beautifully delineated by the Roman poet.

"Àenedum genetrix, hominum divumque voluptas,
Alma Venus! calis subter labentia signa
Quae mare navigerum, quae terras frugiferentis
Conceleras; per Te quoniam genus omne animantium
Concipitur, vixitque eortum lumina folis:
Te, Deus, te fugiunt venti, te nubila coeli,
Adventumque tuum: tibi funaves dedita tellus
Submittit flores; tibi rident azegra ponti,
Placatamque nitet diffuso lumine coelum.
Nam, timul ac species patetaceta est vera diei,
Et referata viget genitabiles aura Favoni;
Aeris primum volatres, te, Diva, tumque
Significant imitum, perculsa corda tua vi.
Inde fere pecudes perfaltant pabula leta,
Et rapidos tranant annes; ita, capta lepore,
Illecebrisque tuis omnis natura animantium
Te fequitur cupide, quo quamque incidere pergir.
Denique, per maria, ac montes, fluvioluque rapaces,
Frondiferatque domos avium, campofque virentes,
Omnibus incitans blandum per pectora amovens,
Efficiat ut cupide generatione focla propagat.

Generation is the greatest mystery presented to our view in the economy of living bodies; and its real nature is still involved in the most complete obscurity. Hitherto no observation authorizes us to admit the simultaneous formation of a living body in all its parts; that is to say, by the union of particles suddenly brought together. The comparison of generation with crystallization is supported by no just analogy: crystals are made up of homogeneous particles, attracting each other indifferently, and agglutinated by their faces,
faces, which determine the order of arrangement; while living bodies are composed of numerous fibres or plates, heterogeneous in their composition, diversified in their configurations, and defined to particular situations, so that they can only be in one place, and between other determined fibres or lamelle. Moreover, living bodies, however small they may be, possess all their parts from the first moment of their existence; they grow, not by the addition of new layers, but by the sometimes uniform, and sometimes irregular development of parts, all of which existed previously to any sensible growth. The only circumstance belonging to all kinds of generation, and consequently the only essential circumstance in the process is, that every living body, at the first periods of its sensible existence, is attached to a larger body, of the same species with itself, that it makes a part of this larger body, and is nourished by its juices for a certain length of time. Its subsequent separation confutes its birth; which may be produced simply from the life of the larger body, and the consequent development of the smaller, without the aid of any occasional cause. Thus, in its essence, generation, as far as we can understand it, is only the appearance of a small organized body upon or in some part of another and larger one, from which it will be separated, at the expiration of a certain period, in order to assume an independent and isolated existence. All the acts or organs, which co-operate in the process, in a certain clade of organized bodies, are only accessory to this primary function. When the function is thus reduced to its most simple state, it constitutes the genniparous, or generation by shoots. In this way buds are formed on trees, and developed into branches, which will form future trees, by means of slips or cuttings. The polypyle (hydra) and the sea anemone (actinia) multiply in this manner; some worms are propagated by a division of their body, and must therefore be arranged in the same division. This mode of generation requires no distillation of sex, no copulation, nor any particular organ. Other modes of generation are accomplished in appropriate organs: the germ appears in a definite fraction of the body, and the affluence of certain operations is required for their further development. These operations constitute fecundation, and suppofe the existence of sexual parts; which may either be separate or united in the same individual. The fecundated or fecundable sex, in which the germ is found, is the female; and the fecundating sex, the affluence of which is necessary for the complete development of the germ, is the male. The office of the latter is that of furnishing the fecundating or seminal fluid; but the manner in which that contributes to the development of the germ, is not yet settled by physiologists. Some, forming their opinions from the human subject and the mammals, where the germ is imperceptible before fecundation, suppose that these are created by the mixture of the male fluid, with that which they suppose to exist in the female; or that they pre-exist in the male semen, and that the female only furnishes them with an abode. Others confit that the alogy of the other clades of animals, and of plants. In several instances, particularly in the frog, the germ may be clearly recognized in the ovum of the female before fecundation; its pre-existence may be inferred, in other cases, from the manner in which it is organically connected to the ovum, when it is first visible. For it is agreed on all sides, that the ovum exists in the female before fecundation, since virgin hens lay eggs, &c. From this analogy, these physiologists conclude, that the germ pre-exists in all females, and that the fecundating liquor is a stimulus which begins on it an independent life, by awakening it, in a manner, from the species of lethargy, by which it would have otherwise constantly remained.

The origin of the germs, and the mode of their existence in the female; whether they are originally formed in all their parts in each individual by any vital proceeds, or are all pre-existent, being included in each other, or whether they are differentiated through the body, and require a concomitance of circumstances to bring them into a situation favourable for their development, are questions, which it is utterly impossible for us to decide in the present state of our knowledge. These points have for a long time been agitated by physiologists; but the discussion seems now to be abandoned by universal consent.

The combination of the sexes, and the mode of fecundation, are subject to great variety. In some instances, the two sexes are united in the same individual, and fecundation is accomplished without any extraneous aid; such are the hermaphrodite and monocious plants, the acophilous mollusca, and the echinoderms. In others, such individual po bifolies both sexes, but requires the assistance of another, which it fecundates, and by which it is fecundated. This is the case with the gasteropodous mollusca, and with several worms. There are distinct individuals, male and female, in other classes; as, for instance, in the dicocious plants, in all animals, which have a vertebral column, in the cephalopodous and some gasteropodous mollusca, in some worms; in the crustacea, and in insects; in short, in the far largest portion of the animal kingdom.

Fecundation is accomplished in plants by means of a liquor contained in small capsules, which resemble a fine powder in appearance, lodge on the female organs, and, burrowing, deposit their contents. In animals, the liquor is always applied immediately upon or about the germ; and in many cases it is not brought in contact with the ova, until they have been laid, as in the bony and ovinous fishes, and the cephalopodous mollusca: here the males and females have no commerce. Sometimes, as in the frog and toad, copulation is necessary in order to determine the discharge of the ova and semen, but fecundation is still performed out of the body. Lastly, in the great majority of insects, the seminal liquor, introduced by the male into the body of the female, fecundates the ova before they are laid. This is the case in the mammals, birds, most reptiles, and some fishes, in the hermaphrodite gasteropodous mollusca, in the crustacea and insects. The union of the two sexes, or the act by which this is accomplished, is called copulation. In all the last-mentioned orders ova may be discharged without previous copulation, as in the preceding ones. But they receive no further development; nor can they be fecundated when thus voided. The effect of a single copulation varies in its degree; it usually fecundates one generation only, and produces one pregnancy; but sometimes, as in poultry, several eggs are fecundated, and afterwards discharged successively: still, however, they only form one generation. In a very few instances, one act of copulation fecundates several generations, which can propagate their species without the aid of the male. In the plant-louse (aphis) the species has been continued through eight generations from one copulation; and in some molluscs, through twelve or fifteen.

When the germ is detached from the ovary, its means of existence may be more or less complete. In most animals, it is accompanied by an organized mass, to which it is connected by means of vessels. The absorption of this ferves for its nutrition and development, until the period of its independent existence. It derives nothing therefore from the body of the mother, from which it is separated by coverings, varying in number and solidity. The germ, together with its mass of nourishment, and the surrounding membranes, constitutes an egg, or ovum, and the animals, which produce their
young in this state, are denominated oviparous. In most of these, the germ contained in the egg is not developed, or hatched, until that part has quitted the body of the mother, or has been laid; whether it be necessary that it should be afterwards fecundated, as in many fishes, or that it requires only the operation of artificial heat for its incubation, as in birds; or that the natural heat of the climate is sufficient, as in reptiles, insects, &c. These are truly oviparous animals.

The ovum, after being fecundated, and detached from the ovariun, remains in some animals within the body of the mother, until the contained germ be developed and hatched. These are false oviparous animals, or ovo-oviparous. The viper and some fishes afford instances of this process.

The mammalia alone are truly viviparous animals. Their germ poises only no provision of nourishment, but grows by what it derives from the juices of the mother. For this purpose it is attached to the internal surface of the uterus, and sometimes by accident to other parts, by a kind of root, or infinite ramification of vessels, called a placenta. It is not therefore completely separated from the mother by its coverings: and it does not come into the world until it can enjoy an independent organic existence. The mammalia cannot therefore be said to possess an ovum, in the sense which we have assigned to that term.

According to this sketch of the subject, generation may be said to consist of four functions, differing in their importance, and in the number of animals, to which they belong, viz. 1st. The production of the germ, which is a constant circumstance: 2dly. Feculation, which belongs only to those instances where there is a distinction of sexes; 3dly. Copulation, which is confined to those kinds of sexual generation in which fecundation is accomplished within the body; lastly, Utero-sewation, which belongs exclusively to viviparous generation. The generative organs may be most naturally arranged according to this distribution of the partial functions, which they execute. The simple production of a germ, or gemmiparous generation, may be accomplished at any point of the body, and has, therefore, no peculiar organ. Sexual generation demands an organ for the production of germs, and another for that of the fecundating liquor. Modes of union are necessary when copulation takes place; and gellation requires a receptacle adapted to the abode of the foetus. Thus we have preparatory and precluding organs; intruments of copulation; and organs of education. Those of the two first classes are divided into male and female; the last belong to the latter sex only. The preparatory and precluding organs of the males secrete the semen, and the other fluids which are to be mingled with it, and retain these secretions. They confine, in their most complicated form, 11. Of the tefficles, which prepare the seminal fluid, and conduct it, either into a particular receptacle, or into a canal, from which it is conveyed out of the body, or into a cloaca, from which it is in like manner ejected: 2dly. Of the vehicle feminale, supposed to be referveirs for the former: 3dly. Of the prostat glands; and, 4thly. Of Couner's glands, which separate a peculiar fluid, mixed with the semen at the time of coition. The testicles are absent in the last classes only of the animal kingdom, where generation is performed by a simple division of the animal, or by shoots. They exist in all the classes of vertebral animals; and, of the invertebral division, in the mollusca, crustacea, insects, and most worms. Their number, structure, &c. differ very much in these various classes. The vehicle, prostates, and Cowper's glands, being less essential in their functions, are much less generally found, and are chiefly confined to the first classes of the animal kingdom. The preparatory male organs serve the purpose of developing and preparing the germs. Their existence is as general as that of the parts just mentioned; but they are much more simple in the first classes of the animal kingdom. They consist of two bodies similar in form, size, and structure, and named by modern physiologists ovaria, in order to express more accurately, than by their old name of testicles, the function to which they are destined. In fact, if their structure, considered simply in man, and most of the mammalia, leave any doubt concerning their office, its nature is so evident in the other classes, that their function cannot fail to be recognized. In all the classes which succeed the mammalia, the ovary or ovaries serve evidently for the production and preclusion of the germs or ova, which are formed in these bodies previously to the approaches of the male. Analogy leads us to conclude that the same circumstance holds good in the mammalia; and this conclusion is one of the most important results from the study of comparative anatomy and physiology.

The organs of copulation, in the male sex, consist of one or more projecting bodies, called penis, generally perforated by a canal, named the urethra, capable of being introduced into the female organs, in order to convey to the latter the fecundating liquor, or for the simple purpose of producing an irrigation necessary for conception; or they are supernumerary members, enabling the male to grasp and hold the female. In the latter sex, the copulating organs consist of canals, particularly destined to receive the male penis, or give passage to the products of conception; or of cavities, which serve also for other purposes, but which, at the time of copulation, receive the penis, and transmit the fecundating liquor to the educating organs.

The educating organs receive the germ or ovum, after its detachment, from the ovariun, retain it for a greater or less length of time, contribute in a more or less direct manner to its growth, and convey it out of the body: or they furnish nourishment to the young, when born, or afford it a temporary lodging. They are, therefore, divided into external and internal parts. The latter may be again distinguished into two kinds. The first of these are simple canals, through which the germ or ovum is to pass, either in order to be conveyed out of the body (as in the egg), or to be transmitted into the parts of the second description. The latter are very dilatable bags, to the parietes of which the germ is attached by means of vessels conveying the materials of its nutrition; and preserving it in this way until it has acquired a certain degree of growth. Organs of the first kind are formed in the four classes of vertebral animals; and are called Fallopian tubes in the mammalia, oviculus in the birds, reptiles, and fishes. Parts of the latter description belong to the mammalia only, and are the uterus. The external educating organs are, in the mammalia, the mammary glands secreting the milk by which the young are nourished; or receptacles, in which they are retained for a time, in a few genera. One kind of reptiles only possesses analogous pouches.

To fill up the outline which we have presented to our readers in the preceding sketch, would require a detailed description of organs varying almost infinitely in form and structure in the different classes of organized bodies. These details will be found in the proper articles of the Cyclopaedia, relating to vegetable and comparative anatomy: this general view has been thought necessary, as introductory and explanatory. The remainder of this article will be devoted to the anatomy and physiology of the generative organs in the human subject. The growth and development of the ovum in the uterus have been considered under the article Embryo, and the anatomy of the mammary gland will be found under Breast.

The preceding account will show what various methods are employed by nature for the perpetuation of the races of
organized beings; this seems to have been a very leading object, and one accordingly, in which she has developed all the fertility of her resources. Scarcely can such diversified phenomena be reduced, by artificial classifications, to any common and constant laws: new facts freshly modify or overturn the previous generalizations; and imagination can scarcely conceive any possible forms of propagation which observation does not soon realize.

The generative functions should be particularly attended to by those who are employed in delineating the manners of animals. They will probably find that the propensities and habits of each are intimately connected with the mode of propagation; and that the character of its wants, pleasures, and labours, its soccibility and perfection, and the extent or importance of its relations either to other species or to the various external bodies or agents, particularly depend on the circumstances or conditions to which its reproduction is subjected, and on the disposition of the organs employed for this purpose. This is certainly very much the case with man, which is the object of our present investigation.

Man belongs to one of those classes of the more complicated and perfect animals, where propagation is effected by the concurrence of two beings, whose organization, posing most circumstances in common, is distinguished by certain particular traits. He quits the womb of his mother with organs capable of refilling the impositions of the atmosphere, and of assimilating food to his own substance: he can therefore live by his own independent powers. He is not destined to remain, like the oviparous animal, included in a foreign envelope, and to continue for an indeterminate length of time in a state of inaction which hardly differs from non-existence: he does not visit until creative warmth begets on him motion and life, amid the nutritive fluids prepared beforehand by nature, like those in which the embryo of the serpent, the tortoise, or the bird swims for a long time as an invisible point. The human fetus has been supported in the uterus by fluids animalized in the vessels of the mother: it submits, immediately after birth, on milk, prepared in organs set apart for that office. The duration of gestation, that of infancy, during which the aid of the parents is indispensable, and the epoch of puberty, or the moment at which the generative faculty is manifested by sensible signs, differ greatly in the different species of animals; these circumstances are not connected together by uniform or constant relations.

Man, like all the more perfect animals, is not born with the power of reproducing the species. The organs, which are at a future period to exercise this function, are now completely inactive, and the appetites which solicit their action do not exist. The time of puberty;—the epoch at which the frame and powers of the being receive their full development, is also the period at which the generative organs, recovered from their lethargy, assume an active state, and become capable of exercising their functions. The duration of infancy is longer, and the age of puberty is later in man than in any animals; although the term of gestation is shorter than in some other species. These circumstances must have a very marked influence on the wants, the faculties, and the habits of the human race.

The characters of the generative functions partake of those which belong to the animal and organic lives. Thus, on one side, all that precedes the union of the sexes, all the impositions made on one by the charms which nature has bestowed on the other, belong to the fames; this very union is an act of the external life, to which animals are impelled by instinct, over which reason presides to a certain degree in man. The influence of habit is also perceived here; but instead of blunting the enjoyment, it renders it rather more acute, and often gives rise to factitious wants. On the other hand, the secretion of the fluid, by the emission of which man contributes to the reproductive process, the mysterious work of conception, the development of the new being, &c. all belong to the organic life.

Sexual Difficulties.—Some ancient philosophers have held on this subject opinions very injurious to the fair sex, and indeed so manifestly whimsical and ridiculous, that a simple statement of them will shew their absurdity. Woman, in the opinion of Aristotle, is an imperfect man, an ill-formed and imbecile individual; while man is characterized by the attributes of strength and power. Galen goes even further, and confounding the sexes in those very parts, where their distinguishing characters are the most unequivocally marked, admits no other differences between the male and female generative organs than such as may be deduced from development and situation. He does not regard even the addition of the uterus in the female as an objection to this opinion, but, bending nature to his hypothesis, he represents this organ as being turned inside outwards in man to envelop the glands in which the seminal fluid is elaborated. This strange paradox has been adopted by numerous writers, and is hardly yet completely abandoned. Buffon turns the ovaries into follicles, and endeavours to prove that the addition of the uterus alone constitutes any essential distinction between the male and female sexes.

Some resemblance in the unimportant points of form and arrangement gave rise to these unfounded analogies; pride and sexual prejudices, joined to the results of superficial observation, seem to have so far misled true philosophers, whose strange opinions we have just alluded to, as to make them discover, in one of the first productions of nature, a feeble sketch, and a timid production. Woman has appeared to them as a degradation and imperfect copy of the constitution of man, while, in fact, she is the most essential part of the species, as contributing by far the greatest share to the business of reproduction. A more accurate examination will destroy these supposed analogies, and prove that man and woman do not differ in the relations of more or less, but that the structure and functions of their generative organs are different in their kind; that their whole constitution has in each its peculiar type, the distinctive traits of which offer to our view a long chain of physical and moral effects more or less immediately dependent on the functions of the organs concerned in the business of generation.

The characters of sex do not therefore shew themselves in any single point; it is not merely a particular organic apparatus, nor those external forms which delight us, that constitute woman: and if she is principally characterized in some points, where the sexual physiology is the most decidedly explicated, if the superficial traits, and the sweetly rounded contours, which constitute her charms, form her most agreeable distinguishment, she is woman in the eyes of the naturalist and physician, in all her modes of existence, in her moral affections as well as in her physical fysicks, in her enjoyments and pains; in a word, all parts of her existence bear the character of sex, and present a series of contrasts and oppositions with the corresponding points in man.

It is however only at the epocha of puberty, at that period of life called by Buffon "le prin temps de la nature, la saison des plaisirs," that the assemblage of all the sexual traits is exhibited to our observation; and that man and woman, attracted to each other the more forcibly in proportion as they differ, become connected by various relations, which enlarge an existence hitherto personal, solitary and isolated. Woman may be distinguished from man by general and particular differences: the latter are so decided as to be easily discernible at all times, while the former, which are our present object
In running through a more detailed sketch of the differences observable in the two sexes, we find them differing in the first place in stature, and in the size and proportions of parts. The height is less in the female, by about one-fifth. The middle of the body in man is at the separation of the lower limbs at the pubes: in woman it is higher, and hence the lower limbs are shorter, while the lumbar region is longer. This gives to the female sex in general, and to the Americans and Negresses in particular, that elegant slenderness which distinguishes them. The arm or leg of a woman could be immediately distinguished from those of a man: the form of these parts is much more delicate, and less marked by decided prominences. The bust is not so broad, but more rounded, and particularly distinguished by the size and elegant formation of the breast, which is commonly but little developed in man, where its greater development would be regarded as a deformity. The thighs are much larger, more rounded, and further apart; they approach each other below, so that the knees are slightly turned in. The latter circumference is seen in the Venus, and the whole formation of these parts is attended with advantages in gestation and parturition, although the peculiarity in question is not seen in those females which in common opinion are the best formed. The convexities described by the lower limbs at their upper part, and uniting them by such happily rounded forms with the trunk, have a very obvious peculiarity of character in the softer sex. They are more prominent, and approach in their contour more to the hemispherical form. All other parts of the lower limbs are distinguished by their softly rounded outlines. The foot is smaller, and the base of support for the body is proportionally narrow. The leg gradually diminishes from above downwards, instead of swelling out abruptly at the calf. The outlines of the upper limbs are equally flowing and soft; thus the arm of woman is fatter and more rounded; the whole upper extremity corresponds in its comparative shortness and smallness to the general difference in stature; and is terminated by a small hand, and short, delicate and flexible fingers.

We may observe further that the head is smaller, the face shorter, and the neck longer in woman. The chisel is not so long, but deeper; the abdomen more prominent and rounded; the shoulders are carried more backwards, and stand out less from the trunk. Hence the breadth of this part is much less considerable than in man, where the shoulders are more fully developed and more widely set off, and constitute, in their comparatively greater size, a very impressionable feature of the superior strength, which is the attribute of the male sex. In the female trunk, on the contrary, the broadest part is below: the pelvis, holding the organs of generation, being principally concerned in the functions of utero-gestation and parturition, being, in short, the seat of those attributes which especially distinguish the female, is much more capacious than in the male. Hence the superior breadth of the female hips; hence the opposite characters of the trunk in the two sexes, in respect to size. The trunk of the female is a pyramid, with the broadest part below; that of the male is just the reverse. Camper has shown, that if the body of a well-formed man be delineated on an elliptical area, the shoulders pass out of the ellipse, while the pelvis falls within it; on the contrary, that the hips exceed and the shoulders fall within the line in woman. (Mémoire sur l'homme Physique.)

In these specimens of ancient art, which may be regarded as models of the most characteristic formation, the difference of breadth in these parts amounts to one-third: the outliners being fo much broader in the male, and the hips in the female. The greater breadth of the pelvis gives a broader base

...
bac of support to the female trunk: and, as it throws the thigh-bones further apart at their upper ends, produces the increased widening of the hips. Hence in progression the centre of gravity is more sensibly changed at each step; and there is a perceptible rolling of the pelvis, which characterizes the female gait. The inconvenience of this arrangement counterbalances the advantages which the broader base of support might otherwise have bestowed on the female organization; and the latter is, in truth, an imaginary superiority, since the feet, which are always small in women, offer ultimately a narrow surface for the body to rest on.

The various pieces of the skeleton, by their respective disposition and junctions, determine the essential form of the body, its position and attitudes, and the extent and variety of its motions. The characters of the general form, which we have already considered, are therefore to be retracted in the bones; and in this point of view a parallel of the male and female organization leads to very important results. It is difficult to fix the well-formed female skeleton; where the structure can exhibit or recall the leading traits of the female form. After much trouble and observation, Soemmerring met with a specimen of what he considered the best and most natural form in a young girl of Mentz, whose form had not been impaired by absurd modes of dressing, and who had been successfully delivered a short time before her death. A beautiful plate of this skeleton, with its description, is exhibited in his "Tabulae foetuli feminini, jicopt descriptione," folio, 1797. The female skeleton, on the whole, is smaller in all its dimensions, and more slender than the male. The individual bones have fewer inequalities, their prominences are less strongly marked, the grooves or impressions more superficial, all the cavities less deeply hollowed out; hence the surface seems more finely turned, and is distinguished by its smoothness. They are often actually flatter, and have on the whole a peculiarly feminine character, which cannot be easily conveyed in description. The head, with the teeth, bears a greater ratio to the weight of the skeleton, on account of the individual bones being in general more slender: the proportions are 1:6 in the female, 1:8 or 1:10 in the male. The cranium is larger in proportion to the face. The thorax is shorter, more convex in front, and more distant from the pelvis, the space between the last rib and the crista ili being greater. It is less prominent in front; so that while this part projects the further in the erect or supine position of the male, the symphysis pubis does the same in the female. The loins are longer, and the angle between them and the sacrum more acute. The disposition of the pelvis is particularly characteristic, as being so immediately connected with the sexual functions. It is larger in all its dimensions. The sacrum is turned more backwards, is broader, and more concave; the ossa coecyges, more movable and flender, project less into the cavity of the pelvis. The hip-bones (osse inominata) are broader, smoother, and expanded further in the lateral direction; therefore their crista and tuberocities are more distant, hence the space between the osse pubis is greater. The angle formed between the ramus and symphysis pubis is larger: that between the two bones of the pubes is acute in man, while it is of 80 or 90 degrees in woman; and approaches more nearly to the form of an arch. That the sexual functions are favoured by all these circumstances is very evident; but the advocates of final causes point out more particularly the reason for the wider space under the osse pubis: "Ad virum amittendum iterum pedes et musculorum inferiorum observavit Albinus de Ferreto, p. 475." The tuberocities of the ischia are more distant, larger and smoother. The clavicles are less curved, and the shoulder joints are less distant. The acetabula are further apart, and the thigh-bones more oblique in their position: the latter are also more curved forwards, and have longer internal condyles.

The muscles of the female are more flender and delicate, they are, in fact, less dense, fatter and motiler. These organs are less prominent, and their swellings, partaking of the general softness of the female constitution, have not that character of vigour which their rough prominences and strongly marked intertices imparts on the frame of a muscular man, in whom the exterior traits of sex have not been destroyed by effeminate manners or sedentary habits. The cellular and adipous tisse is more abundant in the female; and this, joined to the smaller prominence of the muscular bellies, gives to the limbs that soft roundness and delicate contour which characterize female beauty, as expressed in the most celebrated productions of great artists.

The differences just described, the comparative weaknesses of the muscles, the elegance and beauty of the external forms, belong to the very nature of woman. Education and habits may add to these characters; may increase the delicacy of organization; but their influence is not sufficiently powerful to induce us to overlook the existence of a radical innate difference in the physical structure of the sexes, occurring in all ages and amongst every people. That such differences of organization will produce corresponding varieties of function may be readily allowed: but our facts are not quite so indisputable on this point. We could undoubtedly point out many peculiarities in the sensibility of women, taking the term in its most extensive sense, in their perceptions, their mental operations, and the reactions of the nervous system on the rest of the frame. We could trace many circumstances to the influence of the generative organs, and particularly of the uterus. But the influence of education, habits and customs, is so extensive, that it is difficult to distinguish between the results of these causes, and of the supposed original differences in organization. The reader may refer on this subject to the Histoire naturelle de la Femme, by Moreau, tome 1, p. 112, &c.

We cannot draw any very strong line of distinction between the sexes in the vital and natural functions. We may apply, indeed, to this subject, the philosophical remark of Buffon concerning animals, that they differ from each other more strikingly in proportion as we compare them together in superficial points, which do not affect the nature of their existence so much as its exterior development. Yet the characters of sex are so deeply impressed, that we find traces of them even in these functions, when submitted to a rigorous examination. The pulse, ceteris paribus, is more frequent; the lungs are smaller, and the chest narrower. The appetite is less; the body grows more rapidly, and the periods of denticion, puberty, and adult stature are more early. See, for more detailed observation on this head, the work above quoted.

The voice is marked by very characteristic distinctions in the two sexes. In man it is strong, deep, less soft and flexible. In the female it is sharper, and the organs are more flexible, so that articulation can be performed more rapidly. It has also a peculiar quality or tone, which, in many instances, connotes an inexpressibly attractive charm. "Of all acute voices," says Rouelle, "it must be allowed, in spite of the prejudices entertained by the Italians in favour of the cullat- ti, that none are equal to those of women, either in the extent or beauty of the tone." The anatomy, perhaps, will attempt to explain these circumstances by observing, that the glottis is not enlarged at the age of puberty in females, as it is in males; that the larynx is considerably smaller; that the tongue, the muscles, and the organs of speech being
GENERATION.

The differences which we have enumerated are not very distinctly perceivable, until the two sexes have reached the epoch of their respective perfect development. They are concealed, in the early periods of infancy, under external forms which are nearly the same in both sexes. It is true, indeed, that we can distinguish a male from a female embryo (see EXUMA); but the leading sexual distinctions are by no means fully developed until the age we have mentioned. The muscles have not yet produced any remarkable change in the direction of the bones; the glandular and fleshly parts hardly differ either in form or volume; and the skeletons can scarcely be distinguished by the breadth of the hips and pelvis. The like confusion prevails in the moral dispositions of the two sexes: boys are not distinguished in this respect from girls. The appetites, ideas, and passions of both are the same. We cannot at present, nor perhaps shall we ever be able to determine, by what particular action the organs of generation influence the other parts of the body, direct their operations, and modify the character and order of the phenomena relating to them. The fact, however, is evident; and the influence is incontestable. For, when the natural development or actions of the generative organs is impeded, the secondary characters, by which the sexes are distinguished, do not take place.

To illustrate this subject, let us observe, that the several differences of animals may be divided into primary and secondary; the former include the differences in the parts of generation themselves, which are originally formed in the embryo, and belong equally to both sexes; the latter are all the other variations depending on these, not taking place until the parts of the first class are coming into use, and being principally, though not entirely, in the male. One of the most remarkable secondary characters in animals, generally speaking, is the superior strength of male in the male, and this strength is generally directed particularly to the organs employed in fighting. Hence it is especially noticeable in the animals whose female sexes are of a peaceable nature; e.g., the legs of the cock and neck of the bull. But in carnivorous animals, where strength is required by both sexes to kill the prey, the differences in the form of the male and female are not so striking, yet the sexes are still distinguished by some differences in their external covering, as the male lion by his mane, and the cock and hen of many birds by the plumage. The general strength of make, the hairy covering, and the voice distinguish the male from the female of the human species. Now in all animals, which are not of any distinct sex, no such alteration takes place in the form at the time of puberty. Thus, the free martin, which possesses a mixture of the generative organs of both sexes, does not exhibit in form a resemblance of either the cow or bull. It is very much like the ox or spayed heifer, being considerably larger than either the bull or cow, and having horns very similar to those of the ox. The voice is similar to that of the ox, and more like that of the cow than of the bull. The fleece, like that of the ox or spayed heifer, is generally much finer in the fibre, than that of either the bull or cow; it is supposed to exceed that of the ox and heifer in delicacy of flavour, and bears a higher price at market. (See "Account of the Free Martin" in Mr. Hunter's observations on the animal economy, p. 55.) A similar effect is produced, when the sexual parts are removed after birth; the castrated male and the spayed female have both the same common properties, and are very much like the free martin; the artificial removal of the generative organs preventing the occurrence of those changes, which would naturally have occurred at the time of puberty. Thus, by depriving either sex of the true parts of generation, they

fesk rigid, like all the other parts of the female, young girls ought to speak sooner than boys, &c. Among the several distinctions belonging to this head, we must notice the greater prominence of the thyroid cartilage in the male.

The texture of the skin is more dense and compact in men, whiter and more expanded in women. In brunettes, particularly, it has a softness and polish, which convey the most voluptuous impressions to the organs of touch. "Perfections," says Winckelmann, "who prefer such females, are captivated through the medium of feeling, rather than of vision." The skin in woman possesses also a transparency, which allows the colour of the blood to be discerned in the superficial veins, and produces the beautiful azure tint, which contrasts so charmingly with the clear whiteness of other parts. The cutaneous secretion has been considered to differ in the two sexes. "La transpiration parait beaucoup moins abondante chez les femmes; elle a surtout, dans certaines parties, une odeur, qu'il ferait difficile d'exprimer, mais qu'un odorat exercé paraissait affinement à distinguer chez les femmes qui jouissent avec plénitude de tous les attributs de leur sexe, et qui font femmes jusque dans leur atmosphère." Moreau, l. i. p. 171.

The skin of man is always, comparatively, more deeply tinted; it is thicker, rougher, and covered with more numerous hairs. In our account of this organ, too, we have to mention a very characteristic attribute of the male sex, the beard.

This production, which adorns the figure of the male, in the human species, is more or less abundant in different subjects. It does not begin to appear until the age of puberty, and is not completed developed until after some years. Its great thickness depends, perhaps, on the habit of cutting it. In old age a similar production appears in some women; here, however, it is dispersed irregularly, and has not the thickness which it possesses in man; nor does it ever acquire the fame length. Yet rare examples have been known of women with long beards. A case of this kind is mentioned in the Anatomie Descriptive of Bichat, tom. 5. p. 165, as having been seen at the hospital of the Ecole de Medicine. The woman was forty years of age; her breasts were well-formed, and had had a child. Her beard was as strong as that of a man, and numerous hairs covered the lobuli of the ears.

The characters of sex in those organs which are immediately employed in the generative functions, will be exhibited in the course of this article. We have only to observe further, that the circumference of the anus, which is covered with hair in the male, is smooth in the female subjét.

The reader may refer, on sexual distinctions, to Rouflel, Syllene physique et moral de la Femme; to the works of Moreau and Cabanis; to the French Encyclopedia, Yverdon edition, art. FEMME and VIEUX; to Ackermann, De discrimine sexum prater genitalia. Moguntio 1788, 8vo.; to A. F. Nolte, Diff. infus. mentulae quasdem circa sexus differentiam. Gottin, 8vo. The differences in the general habit and appearance of the body, the softness, delicacy, and inferior fineness of the female, as compared with the strong fineness of the male, may be seen in the two figures, hatched to have been drawn by Taine, contained in Vedius, De Corp. hum. Anat. Basil, 1442: also in the 18, 20, and 32 plates of Bidloo's work, and in the Cours complet d'Anatomie gravé par M. A. E. Gauthier, et expliqué par M. Jadelot; Nanc, 1773, folio. The unrivalled artists of Greece could not fail to perceive the same distinctions, which they have expressed most admirably in some of the finest monuments of their art, as in the Venus, the Apollo, and Hercules.
they seem to approach each other in appearances, and acquire a resemblance to the hermaphrodite. Respecting the changes, which occur at puberty, Mr. Hunter says, "It is evidently the male, which at this time in such respects recedes from the female; every female being at the age of maturity more like the young of the same species than the male is observed to be; and if the male is deprived of his testes when young, he retains more of the original youthful form, and therefore more resembles the female. From hence it might be supposed, that the female character contains more truly the specific properties of the animal than the male; but the character of every animal is that which is marked by the properties common to both sexes, which are found in a natural hermaphrodite, as in a male, or in animals of neither sex, as the castrated male or spayed female. But, where the sexes are separate, and the animals have two characters; the one cannot more than the other be called the true; as the real distinguishing marks of each particular species, as has been mentioned above, are those common to both sexes; and which are likewise in the unnatural hermaphrodite. That these properties give the distinct character of such animals is evident, for the castrated male and spayed female have both the same common properties; and when I treated of the free marlin, which is a monstros hermaphrodite, I observed that it was more like the ox than the cow or bull; so that the marks characteristic of the species, which are found in the animal of a double sex, are imitated by depriving the individual of certain sexual parts, in consequence of which it retains only the true properties of the species." (See "Account of an extraordinary Pheasant," in Mr. Hunter's observations on the animal economy, p. 75.)

The influence of the generative organs in the development of the body at puberty, and in the modifications which constitute the sexual character, is clearly evinced in the flag; whose amours are conducted in so splendid a style, and evince to remarkable an exuberance of vitality. When he is deprived, at an early age, of the sexual attributes, none of the vigour of the rutting leafton is displayed; the muscular flesh is softer, and the horns are either arrested in their growth entirely, or are imperfectly formed. Ruffel castrated a very young flag, and no horns appeared; he operated on an older one, and the horn was partially developed. When he removed one testis at a more advanced age, the opposite horn was the most completely formed; the removal of both glands from two adult flags did not prevent the appearance of the horns; but they were shorter, and neither the investing membrane, nor the horn itself, were afterwards separated.

(On the Economy of Nature in glandular Diseases.)

Facts very analogous to these may be observed in the human subject. An imperfect original formation of the sexual organs, or the removal of some of them modifies the whole character of the individual, changes the physical constitution in a very remarkable manner, and influences in a no less striking degree the moral habits and dispositions. Observers in all ages have remarked, that mutilated or imperfect animals possess an assemblage of peculiar characters, all of which have not a very direct relation to the functions of the generative organs. Not only are the sexual desires entirely lost in these degraded individuals, but the whole of their organization is affected in a very singular way. The cellular texture becomes more abundant and lax, and is more loaded with fat; the muscles are weaker; the voice more acute; and the development of the beard is impeded. The change in the moral dispositions is not less worthy of attention. It was the opinion of the ancients, that mutilation degrades man, and brings animals to perfection; the truth is, that it equally degrades both, since it alters their nature.

But, by weakening an animal, it renders him more docile, and better suited to the purposes of man; by destroying the tie, which connects him to the most powerfully to its species, it afflicts in developing those habits of obedience and attention, and those feelings of gratitude and attachment which make him so serviceable to us. A similar effect is produced in man; mutilation separates him in a manner from his species; and the fatal event, which deprives him of the most agreeable relations established by nature, between beings of the same kind, almost extinguishes in his breast the peculiar feelings of humanity.

In these young persons, to whom nature has denied either wholly or in part, the distinguishing powers of the male sex, puberty does not produce its ordinary effects. And moreover, at this time the bony and muscular organs are constantly assuming more and more of the external forms, and general character belonging to the female. These equivocal individuals have an acute voice, weak muscles, a softness and lankiness in the general organization. The pelvis, too, has that greater proportional breadth which characterizes this part in women. This circumstance, as well as the consequent breadth, and great roundness of the hips, may be particularly noticed in the castrati. The physical condition is generally accompanied in these individuals with a perfectly corresponding moral state. All these points are fully substantiated in the following account of a marine soldier, aged 23, by Mr. Home, (Observations on Hermaphrodites, Philos. Transact. 1799.) "He had no beard; his breasts were fully as large as those of a woman at that age; he was inclined to be corpulent; his skin uncommonly soft for a man; his hands fat and short; his thighs and legs very much like those of a woman; the quantity of fat on the os pubis resembled the mens veneris; the penis was unusually small, as well as short, and not liable to erections; the testicles not larger in size than we commonly find them in the female; and he had never felt any passion for women. He was weak in his intellects, and his bodily strength." Mr. Home mentions, in the same place, two other still more striking examples. A woman had three children, of which the first and third were castrated to be hermaphrodites; the second was a perfect female. The eldest, when Mr. H. saw him, was thirteen years of age, "of a most uncommon bulk, which appeared to be almost wholly composed of fat; his body, round the waist, was equal to that of a fat man, and his thighs and legs in proportion; he was four feet high; his breasts as large as those of a fat woman; the mens veneris loaded with fat; no penis; a prepucium, 7th of an inch long; and under it the mens urinarius, but no vagina.

There was an imperfect ferotum, with a smooth surface, without a raphe in the middle, but in its place an indented line; it contained two testicles of the size they are met with in the fetus. He was very dull and heavy, almost an idiot, but could walk and talk. The younger one was six years old, uncommonly fat, and large for his age; more an idiot than the other, not having sense enough to learn to walk, though his limbs were not defective. The external parts of generation differed in nothing from those just deferred, except in the prepuce being an inch long."

An interesting case is mentioned in the Mémoires de la Société médicale d'Emulation, t. 3, p. 293, which tends to confirm the preceding observations. A young man, aged 23, has no testes in the ferotum, which is only indicated by a slight corrugation of the integuments; a very small penis, which never changes its size, and two folds of skin, extending from the latter on each side of the anus, and very much resembling the female labia. His stature is below the middle size. The skin is soft, smooth, and entirely free from hair;
the place of the beard supplied by a slight down. The
voice habitually hoarse. The muscles not well marked, and
the pelvis and chest resembling those of the female. The
intellectual faculties are very dull, and the sexual appetite
entirely wanting.

The period, and the manner of mutation, have considerable
influence on the effects of the process. The complete re-
moval of all the external organs is a much more decisive
method of annihilating the propensity connected with them,
than any partial amputation, or compression, or ligation of
the spermatic cords. The operation is also more effectual,
when performed in early infancy, than after the period of
puberty. Venereal desires have been known to subside in
considerable force, and with the usual external signs, after
the removal of the teales in the adult. The moral effects of
this mutation have been strongly depicted by Cabanis.

"Eunuchs are the vilest class of the human species; cowardly
and knavish because they are weak; envious and malignant,
because they are unfortunate. Their understanding shows
the absence of those impressions, which give to the brain so
much activity, which infuse it into an extraordinary pro-
portion of vital energy, which cherish all the expansive and
generous feelings of the soul, elevate and direct all the
thoughts. Nature is almost the only very imposing excep-
tion to this rule; he is almost the only eunuch whose name
appears with glory in the page of history. Solomon, one of
the Hebrews of Balthazar, is another rare example; he
exhibited great courage and talents in the war with the
Vandals in Africa. How immoral then, how cruel and
fatal to society, is the practice of thus degrading and corrup-
ting at pleasure the human species!"

A curious case in the Philosophical Transactions for 1805,
pt. 2, in which the ovaria were deficient, shows that such a
deficiency occasions the female to approach in some points to
the male formation. The subject of this narrative died at
the age of twenty-nine. "Having ceased to grow at ten
years of age, she was in stature not more than four feet six
inches high. Her breadth across the shoulders was as much
as fourteen inches, but her pelvis (contrary to what is usually
observed in the proportions of the female skeleton) mea-
sured only nine inches from the offia finger across the facrum.
Her breasts and nipples never enlarged more than in the male
subject; she never menstruated; there was no appearance
of hair on the pubes, nor were there any indications of pu-
berty, either in mind or body, even at twenty-nine years of
age." The removal of the ovaries has been most rarely
practised in the human subject; probably the only case in
which it has ever been done is that recorded by Mr. Pot,
where these bodies were contained in inguinal herniae. A
healthy young woman, aged twenty-three, large breasted,
float, and menstruating regularly, had a painful tumour in
each groin, near the abdominal muscles. The ovaria were
removed from these tumours by a surgical operation. "She
has enjoyed good health ever since, but is become thinner
and more apparently muscular; her breasts, which were
large, are gone; nor has she ever menstruated since the op-
eration, which is now some years." (Pott's Works, vol. iii.
p. 329.) The changes which took place in the latter case
seem analogous to what has been observed in some birds.
After they have done laying, hen pheasants have been ob-
erved to acquire the plumage of the cock in some instances.
This has been noticed in wild individuals; but Mr. Hunter had
three opportunities of ascertaining the fact by his own exami-
nation. He further mentions a pea-hen, which, having produced
chickens eight times, and which, after moulting at eleven
years old, displayed the feathers peculiar to the other sex.
The tail of the cock appeared at the same time. This was
repeated for three years, and the spurs of the cock appeared
also in the third year. The animal never bred after this
change of plumage. The same fact has been noticed in the
duck, see Home on Hermaphrodites, in the Philos. Trans.,
1799. "We may conclude," says Mr. Hunter, "that this
change is merely the effect of age, and obtained to a certain
degree in every class of animals. We find something similar
taking place even in the human species; for that increase of
hair obserable on the faces of many women in advanced life,
is an approach towards the beard, which is one of the most
distinguishing secondary properties of man. Thus we see
the feses, which, at an early period, had little to distinguish
them from each other, acquiring, about the time of puberty,
secondary properties, which clearly characterize the male and
female; the male at this time receding from the female, and
assuming the secondary properties of his sex. The female,
at a much later time of life, when the powers of propagation
cease, loses many of her peculiar properties; and may be
said, except from the mere structure of parts, to be of no
sex; even receding from the original character of the animal,
and approaching in appearance towards the male, or perhaps
more properly towards the hermaphrodite." Observations
on the Animal Economy, p. 85.

Nothing can be more absurd than to seek for any mech-
anical explanation of these accidental phenomena, or even of
the more regular phenomena, of which they interrupt the
courtesy, at the same time that they elucidate the law. They
cannot surely be derived from the structure of the organs to
which they belong, nor from the known nature of the li-
quors secreted in these organs. But the consideration of
some physiological circumstances, which are very simple in
themselves, may enable us to escape from this dark abode of
ocult causes, to which the theories of the ancients were
confined, and which have been little changed, except in
name, by the moderns. The latter indeed, by sublimating,
for the opinions of the ancients, other more dogmatical
explanations, have given rise to more important and danger-
ous errors: they have inured men's minds to the pernicious
habit of attempting to determine the nature of causes, where
we can only observe effects; and in determining these causes
they have often perverted mere abstractions. In the first
place, it is a certain fact, however it may be explained,
that the muscular fibres are weaker, and the cellular tissue
more abundant, in women than in men. Secondly, we cannot
doubt that this difference is produced by the presence and
influence of the uterus and ovaria; it takes place infallibly
when these organs are originally well formed, and are de-
veloped in the natural order. This weakness of the muscles
impairs an instinctive disinclination for violent exercises; it in-
inclines the individual to amusements, and, when the age admits of it,
to sedentary occupations. The greater separation of the
hips renders progession less easy in the female, on account of
the more extensive change of the centre of gravity. The
mode of life in the female is thus indicated by a circum-
stance in their organisation, which might be regarded as
trifling, and which can hardly be distinctly observed at an
early age. Again, the habitual sense of weakness impairs
her confidence. Not poising the means of acting on sur-
rounding objects by direct force, woman seeks for more in-
direct methods; in proportion as she finds herself less cal-
culated to exit alone, does she attempt to attract the atten-
tion of others, and to fortify her own existence by that of
those surrounding beings, whom the judges most able to
protect her. These observations would be almost sufficient
to explain the dispositions, talents, and general habits of
women. They will naturally prefer those employments
which require delicate address rather than muscular force:
they will employ themselves on little objects: and their minds will conseqently acquire acuteness and penetration rather than extent and depth. Thus, as they lead a sedentary life, to which the nature of their employments confines them as strongly as the immediate propensities depending on their organization, we see in a manner a new physical and moral fytem developed in them. They perceive their own weak-ness; hence the necessity of pleasing: from the latter circumstance arises the continual observation of all that is passing around them, also their dilamation, their artifices, their manners, their graces, in a word their coquetry, which, in the present sytem of society, must be regarded as the embellishment or result of their good and bad qualities.

For reasons exactly contrary to those which have been just explained, boys acquire the opposite original and characteristic propensities: hence they naturally contract opposite manners and habits. Full of the feeling of their growing strength, and of the wish to exercise it, repose is disapprovable and irksome to them: they want lively motion, and they indulge in it with impetuosity. Thus, without entering into further details, we see that the bent of their ideas and the character of their passions are formed directly by their original dispositions, and the kind of amusements or occupations which these determine them to prefer. Now, the passions and ideas of the grown man are on the other hand materially developed and completed by the immaturity of the organs, and the personal experience of the individual. See Cabanis, Rapports du physique et moral de l'Homme, memoire cinquieme.

But nothing hitherto explains us how modifications of a general nature can depend on the conditions of certain peculiar organs. We must then accord a little higher, and inquire whether the remarkable influence exerted by the organs of generation can be at all elucidated by their structure, their functions, or their physiological relations to the other branches of the sytem. We see, in the first place, that parts supplied by nerves which come from different trunks, or are formed by different nerves united together, are either more sensible or more irritable, and almost always both at once. Nature seems to have placed the ganglia and plexuses in the neighbourhood of the viscera, where the nervous influence must be the most considerable. The epigastrie and hypochondriac regions abound with them; consequently their sensibility is very acute, their sympathies very extensive, and the corresponding portions of the intestinal canal enjoy a degree of irritability hardly equalled by that of the trunks. Now the nerves of the generative organs in both sexes, without being apparently very important by their size or number, come from various sources, are connected with those of all the abdominal viscera, and by them, or rather by the great sympathetic, which serves as a general medium of connection, with the most essential divisions of the nervous sytem.

Secondly, observation shews us that the nervous sytem (of which the original organization and mode of acting determine the general sensibility of all the organs taken together, and the particular sensibility of each considered separately) may in its turn be powerfully modified by the character of those functions, which perform the most important part in the animal economy; that is to say, in other words, by the habitual impressions conveyed to it from some of its most sensible extremities. The loss of one sense does not produce merely an increase of energy or attention in those which remain, and which seem to redouble their efforts in order to supply its place; but it changes the manner in which the nervous sytem feels and reacts, and hence arise new habits evidently connected with the unusual im-

preffions which these senses then begin to receive. The practice of medicine proves to us, by daily examples, that the affections of various organs have the most marked influence on the tastes, ideas, and passions. The moral dispositions are by no means the same in decades of the cheif, as in those of the spleen or liver. A greater or less propensity towards a particular train of ideas or feelings (as for instance towards those connected with religious belief) is experienced in particular states of animal than in others; and the greatest aptitude to those avocations, which demand either considerable strength and activity in the imagination, or long continued and profound meditation, is often experienced in a state of disease caused by the deranged functions of some of the abdominal viscera. Thus, then, nothing is more conformable to the laws of the animal economy, than that organs, endowed with a singular degree of sensibility, should exercise a very extensive influence on the machine in general; and we perceive immediately that the present is one of the most remarkable phenomena referrible to those laws.

In the work last quoted, Cabanis endeavours to explain this subject further, by observing that those organs, which seem to be the principal seats (layers) of the peculiar sensibility of the generative apparatus, viz. the ovaries and testicles, are of a glandular structure, that the various parts of the generative sytem are the principal subjects of the variations; and that the condition of this sytem altogether has a most important influence on the state of the brain, augmenting or diminishing its energy. The latter circumstance will apply with so much the greater force to a sytem, where the glands are dislinguished by their great sensibility.

Again, it has been alleged that the seminal fluid formed in the testicles, when absorbed and conveyed into the circulation, affects the general mass of blood. At all events the commencement of this fonction is marked by important changes in the voice, the muscular motions, and the physiognomy, by the appearance of the beard, &c. And we have seen, that in animals, the development of particular parts is materially modified by the presence and action of the teles. That an analogous fluid forms in the ovaries, and either furnishes the materials of the embryo, or contributes to their formation, and that its aborption produces analogous effects in the female, to those which we observe in the male, is in truth a mere hypothesis. But the influence of the ovaries in the changes at the time of puberty, whether produced in this way or not, is incontestible. Lastly, in explaining the differences in the parts in the two sexes, we must assume peculiar dispositions in the original formations of the nervous sytem, as well as in the cellular organ, the muscles, and bones. These must depend on those unknown circumstances which influence the formation, life, and development of the embryo; their explanation must be referred to that of the differences of sex, they must be regarded as simple facts, and be admitted as such, without attempting to trace them any higher.

Hermaphrodism.—Having compared together the two sexes, and mentioned the most remarkable circumstances which dislinguished the organization of each, we have to examine further whether nature has in any instances united the attributes of the male and female in the same individuals, so as to form a true hermaphrodite. The resolution of this question, which is not to be considered as satisfying idle curiosity, is equally interesting to the naturalist and the philosopher, and may influence the decisions of judicial tribunals on the important questions of impotence and flexibility. The Grecian artists have endeavoured to combine the beauties and properties of the two sexes in the same subject, and have exerted the magic powers of their chisel on figures of her-

Hermaphrodites.
G E N E R A T I O N .

Among these ideal productions, we may mention two beautiful statues in a recumbent position in the Florentine gallery. A small hermaphrodite statue is seen in the villa Albani, a very fine one in the villa Borghese, and there is another in an obelisk attitude, pointing out that it partakes of the two sexes. All these are males in the external appearance of their generative organs, females in the form of the breasts, in the features, in the elegance of the figure, and the softness of the contours. (Winckelmann, Histoire de l'Art, 4to. tome 1. p. 364.) These monuments furnish no proof on the subject; they are to be regarded as creations of art, derived from the imagination of the sculptor, and not as the representatives of any real existence. Winckelmann himself, who, in other respects, believes in hermaphroditism, classifies the chief-d'oeuvres we have just alluded to among the ideal productions. They exhibit an attempt to form a more perfect being, by uniting together the peculiar excellencies of the male and female, without attending very particularly to the genital organs. The word hermaphroditism then, as applied to these works of art, includes the notion of a very high degree of beauty and elegance, in which all that is most admirable in either sex is combined in one individual; and the works, in which such are represented, may be regarded as the inventions of the greatest masters. (See Caylus's Recueil d'Antiquités, tome 3.) The fabulous account of the transformation of Hermaphroditus and the nymph Salmacis into a most lovely being, combining the attraction and the powers of both sexes, may be regarded as an expression of the common opinions on the subject.

The vast multitude of observations and histories of hermaphrodities, recorded in various medical works, renders it necessary for us to classify them under certain heads. 1st. The true hermaphrodite? There is much reason to believe, that no instance of an hermaphrodite, in the strict sense of the word, has ever occurred in the more perfect quadrupeds, or in the human species. For, when we consider the bones of the pelvis, to which the organs of generation are connected, it is difficult to conceive in what way the complete parts of the male and female could be placed, distinct from each other; and no instance of its having happened is to be found, in any record, which can be depended on. To constitute an hermaphrodite, in the sense we are now considering, it would be necessary that the male organs of copulation and impregnation, such as the testes and their ducts, the vesicular females, prostates, urethra, and penis, should exist in the same individual with the organs employed for the purposes of conception, of receiving, nourishing, and expelling the fetus, such as a well-formed vagina, uterus, ovaries, and Fallopian tubes. The difficulty, and even impossibility of such an union, has been already recognized by Haller and Plancher. Medical authors have indeed related cases of women, who, after having many children, had impregnated other females; (see Mollerus, Traité de Hermaphrodit. cap. 2.; Blancard, Collect. Medico-Phys. cent. 3. obv. 80.) but such narratives are too obviously fabulous to require serious refutation.

The nearest approach to such an occurrence, as we have just alluded to, consists in a partial mixture of the female and male organs. This has been observed, not very rarely, in some animals. Mr. Hunter has given several instances of it in neat cattle; and it has also been seen in the dog, the cat, and the goat. The individuals, in whom such appearances have been noticed, are far from having had the properties of both sexes, that they were obviously incapable of executing any sexual function at all. Even in this restricted sense, we believe that no case has occurred in the human species, and that all the supposed hermaphrodites among men have been individuals with imperfect or monstrous formations of some parts. The case mentioned by Petit in the Memoirs of the Academy of Sciences for 1729, as exhibiting a mixture of organs, was clearly a male; and that related by Maret in the Mémoires de Dijon, t. 2, p. 177, belongs to the same class. The following case, described by Giraud of the Hotel Dieu, shews us how careful we should be in drawing conclusions from external appearances, and will convince us that no accounts of hermaphrodites can be received, except on the faith of dissection performed by experienced anatomists. The individual was essentially a male, and offered some appearances of the other sex, not from the addition of any organs, but from an unusual distribution of some parts of the male apparatus. He was received in society as a woman, and was connected by a voluntary association with a man, who had for a long time performed the duties of a husband towards him. This singular character died in the Hotel Dieu. He exhibited, externally, an assemblage of the male and female properties. The bulk has a completely masculine appearance; the chin was covered with firm hairs, very analogous to a beard; the neck was thick, the chest broad, the bosom slightly fleshy, and the nipples exactly like those of a man. The lower half of the body presented a contrast to the character. The soft and delicate contours of the lower limbs, the rounded hips, the broad pelvis, and the greater separation of the thighs, approximated decidedly to the female form. An imperforate penis, two testicles, and an appearance of vulva, were the external generative organs. The testes were well formed, the vesiculae seminales imperfecta, and the urethra opened at the cul-de-sac, which represented the vagina. Thus, instead of a double sex, the individual was an ill-formed male, entirely incapable of any sexual function. See Journal de Médecine par Sédition, tome 2, p. 519.

The last instance of mixed organs, which we shall quote, is mentioned by Dr. Balilie, to whom it was communicated by Dr. Storer of Nottingham. "The person bears a woman's name, and wears the apparel of a woman. She has a remarkably masculine look, with plain features, but no beard. She had never menstruated; and on this account the sex was likewise by the lady, with whom she lived as servant, to become an out-patient at the Nottingham hospital. At this time she was twenty-four years of age, and had not been capable of any had health, but only came to the hospital, in order to comply with the wishes of her sisters. Various medicines were tried without effect, which led to the suspicion of the being impersonated, and the menstrual blood having accumulated behind it. She was therefore examined by Mr. Wright, one of the surgeons to the hospital, and by Dr. Storer. The vagina was found to terminate in a cul-de-sac, two inches from the external surface of the labia. The head of the clitoris, and the external orifice of the meatus urinæ, appeared as in the natural structure of a female, but there were no nymphæ. The labia were more pendulous than usual, and contained each of them a body resembling a fistulous of a moderate size, with its cord. The mamma resembled those of a woman. The person had no desire or partiality whatever for either sex." (Morbid Anatomy of some of the most important Parts of the human Body, 2d ed. p. 410.) This narrative leaves very little doubt that the individual was a male, with the generative organs so imperfect as not to have exerted their usual influence on the frame in general: there is no evidence of any female organ being present here.

We repeat then, that there is not only no instance recorded, of perfect male and female organs united in the human species, as to constitute an individual capable of exercising
ercising the generative functions of both sexes—of impreg-
ating or being impregnated—but also, that there is no
clearly described instance of the smallest mixture of organs
in any human person, ascertained by actual dissection, and
testified by persons of competent anatomical skill. All the
supposed instances of hermaphrodites must then be referred
to one of the following classes; in which unusual situations
of certain organs, vicious conformations, various monstro-
fities, imperfectly developed male organs, or a greater pro-
minence than usual of some female parts, occasion a devia-
tion from the accustomed type, supposing to constitute her-
maphroditism, very capable, when afflicted by lies and fraud,
of imposing on those who know nothing of natural appear-
ances, and often mistaken by those who ought to have
known better. Hence have arisen the numerous statements,
contained even in the writings of anatomists and physicians,
and tending to prove the existence of the prodigy, of
which no well authenticated fact has hitherto determined the reality.
A sound spirit of criticism, founded on a more accurate
knowledge of natural appearances, reduces to their just
standard those singular deviations from the ordinary type,
from which ignorance, credulity, and a love of the marvell-
ous, have drawn such extravagant and ridiculous con-
sequences.

2d Clafs.—Male individuals, with unusual formations of
the urinary and generative organs; (androgynus.) Where
the ordinary type is considerably changed, an appearance is
sometimes produced, very capable of deceiving superficial observers: there is a kind of sketch, or imperfect attempt,
at a double apparatus of organs. But the male sex gene-
 rally predominates very clearly in these cases, and the am-
biguity depends commonly on the testes being contained in
separate parallel folds of the skin; the penis being im-
perfect; and the urethra opening in the perineum, on the sur-
face of a blind pouch, having a red and tender appearance,
and easily mistaken for the vagina. In such an individual
the penis, being imperfect, and probably smaller than usual,
is considered as a large clitoris; the folds of skin holding the
testes very much resemble the female labia, and the red slit,
behind which the urethra ends, is tolerably analogous to the
vagina. The imperfection of the penis, and the opening of
the urogenitary ducts near the perineum, at which their con-
nections escape, deprives these individuals of the power of
procreation; and the illiberity of their marriages, if they en-
ter into that state, in spite of their imperfect formation, aris-
es entirely from this cause. The testes and vulva of fem-
nales appear to be perfect in these cases. The individuals
experience the ordinary sexual desires, and the seminal fluids
are expelled at the unnatural opening in the perineum. A
similar deformity occurs not unfrequently in the goat and
sheep; Aristotle having observed it in the former. The
reader will find examples in Haller’s Commentationis de Her-
maphroditis, where a vast number of instances is quoted;
in Wrisberg’s Commentatio de Singulari genitalium Deform-
itate in pueru Hermaphroditum Mentiens; § 7, note b: in
Moreau Histoire Naturelle de la Femme, tom. 1. p. 224:
in Mertrud, Differtation sur la fausse Hermaphroditte,
qui paroit aux yeux du public, Paris 1749, folio: Agout,
Observations sur l’Histoire Naturelle, la phiiique, &c. avec
des planches imprimes en noir, Paris 1740. 4to. 1752.

An instance, similar to the kind just described, is related
and drawn by Wrisberg in the memoir above quoted; but
there was this difference, that the rectum, as well as the
urethra, opened in the unnatural situation in the perineum;
this male child had been christened by a female name.

Other less essential deviations from the accustomed organi-
ization have given rise to the opinion that the individuals were
hermaphrodites. A figure, of various depths, has existed
in the perineum; covered with a secretion from numerous
sebaceous glands; when all the other organs were perfect
in every respect. Wrisberg knew an instance of this kind at
Göttingen: the individual was always deemed a herma-
phrodite, but he had the natural defiles and powers of a
male. The absence of the testes from the scrotum has given
rise to the same opinions. A confinement of the penis
to the scrotum, by a particular formation of the integu-
ments, has occasioned persons to be reputed hermaphrodites.
In thefhe the urine is in the direction downwards, and the
confinement of the organ will not allow of its performing
the sexual functions. The parts may be felt free by a
sur
gical operation.

The last description of males, supposed to be hermaphro-
drites, are those in whom the urinary bladder is deficient,
together with the lower and anterior portion of the abdo-
nominal muscles and integuments, and the lymphatics pubis,
a red and tender mass of an irregular and fungous-like sur-
face, with the ureters opening on it, is placed at the lower
part of the abdomen. Considerable alterations take place in
the generative organs, in consequencc of this deformity. The
urethra is deficient, and the penis consequently imperfect.
The femoral ducts open near the fungous mass above-men-
tioned, or on the open surface of the urethra, or even ter-
minate in blind extremities. As the tuberousities of the if-
chia are at an unusual distance from each other, the crura
denis are concealed within the body for a greater length,
and the pendulous part of the organ is extremely short, felled
exceeding two inches in length, even in the adult.
The urethra appears as if it had been slit open, forming a
band or groove, instead of a perfect canal, and rendering
the glans penis blind. The situation of the urethra is also
very remarkable; for, instead of running, as it naturally
does, in the lower angle formed by the junction of the cor-
pora cavernos, it has commonly passed along the upper
angle, giving the penis and glands the appearance of being in-
verted. That the part now described is really the urethra,
is evident from its vesicular surface, with lacunar opening
upon it, from the presence of the caput gallinama, and of
the openings of the femoral ducts. In consequence of the
labia being bifid at its upper surface, the prepuce is at-
tached only to the lower half, and is connected by a frenum,
as usual. The testicles, in some instances, are contained in
the scrotum, in others in fossa of integument resembling
the labia of the female; and in some do not descend. The
ferotum is rarely pendulous, being increased in breadth in
consequence of the separation of the offa pubis. The sexual
appetite, in some of these individuals, has been weak, in
others strong, in others altogether wanting. It is evident
that they are not capable of producing the feces; in con-
sequence of the shortness and imperfectior of the penis,
and the femoral ducts opening externally. See Dr. Duncan,
jun. on this subject, in the Edinburgh Medical and Surgical
Journal, vol. 1. pp. 43 and 152: where he has collected to-
gether a vast number of cases.

3d Clafs.—Female individuals; (androgynæ.) An un-
usually large size of the clitoris, is one of those caufes which
have led to mistakes concerning the sex. This is not a com-
mon occurrence in these countries, but is said to be much
more frequent in warm climates; in so much that in a surgical
operation for removing the part is described by the Arabi-
aeas. These individuals are perfect females in all other cir-
cumstances of their organization, and the menstrual discharge
sufficiently characterizes them. In many of the recorded in-
stances of this description, there is probably exaggeration,
as any enlargement of the clitoris can hardly make it suffi-
ciently
GENERATION.

cently like a penis to give rise to mistakes. A gipsy applied to Columbus for the removal of a clitoris which incommoded her. The famous hermaphrodite negroes of Angola, exhibited in London, was in the same case with the gipsy mentioned by Columbus. Parfons has collected many facts of this kind. Mr. Home relates an instance in a female negro. 'She was of the Mandingo nation, 24 years of age, whose breasts were very flat; she had a rough voice, and masculine countenance. The clitoris was two inches long, and in thicknesses resembled a common-fized thumb; when viewed at some distance, the end appeared round, and of a red colour; but, on a closer examination, was found to be more pointed than that of a penis, not flat below, and having neither prepuce nor perforation; when handled it became half erected, and was then fully three inches long, and much larger than before; when she voided her urine, she was obliged to lift it up, as it completely covered the orifice of the urethra. The other parts of the female organs were found to be in a natural state.' A gentleman, who had practiced midwifery among the negro women, stated that an enlarged condition of the clitoris was common amongst them. Parfons and some others, in consequence of the structure just described, have ascribed all hermaphrodites to the female sex. Whether this unusual lize of the organ can be produced, 'per celeratum abuam clitoris' is very doubtful. In order to avoid all mistake concerning sex in newly born children, it must be remembered that the clitoris is proportionally very large at that age.

A prolapsus of the uterus is another circumstance which has occasioned females to be deemed hermaphrodites, and even to be publicly exhibited as such. A person of this kind came to Paris in 1693, dressed as a man, and wearing a sword. She pretended to have the organs of both sexes, and to be able to employ both, and exhibited her person to the curious for a small gratification. Besides the numbers who took up the common opinion of her being an hermaphrodite, and who could not be supposed sufficiently well-informed to judge of such a subject, several physicians and surgeons fell in with the vulgar sentiment, and gave certificates which prove incontestibly, that a great reputation may be acquired in the profession, without any real talents, or any large stock of solid information. Saviard, after inspecting the parts closely, found that the case was a prolapsus uteri, which he reduced. When the female had recovered, the presented a request to the king for permission to take again the female dress, in spite of the magistrates of Toulouse, who had ordered her to clothe herself as a man. See Saviard, Recueil d'Observations, obi. 15.

An instance of the same kind is related by Mr. Home: 'A French woman had a prolapsus uteri at an early age, which increased as she grew up; the cervix uteri was uncommonly narrow, and at the time I saw her, when she was about 25 years old, projected several inches beyond the extremity of the vagina; the surface of the internal parts, from constant exposure, had lost its natural appearance, and resembled the skin of the penis; the orifice of the os tincte was mistaken for the orifice of the urethra. This woman was known as a curiosity, and in the course of a few weeks made £cet. I was induced by curiosity to visit her, and on the first inspection discovered the deception; which, though very complete to a common observer, must have been readily detected by any person intimately acquainted with anatomy. To render herself still more an object of curiosity, she pretended to have the powers of a man.' Philos. Transact. 1799.

We have already mentioned some instances where the generative organs, although belonging clearly to one sex, had been imperfectly developed, and consequently had not produced their usual effect in modifying the form of the body, and impressing it with the sexual character. There are other cases, in which men or women, having their organs apparently of the accustomcd magnitude, partake respectively of the characters of the other sex, probably from the cause alluded to, of the sexual parts not exerting their full influence on the frame. Such individuals may be accounted neuters; and form, in the human subject, to resemble the free marten in neat cattle, where there is a true mixture of organs, but they are so imperfect that organization is not influenced by them, and the form of the individual differs both from that of the bull and cow. The persons thus circumstanced are often deemed by the vulgar hermaphrodites.

All the cases of supposed hermaphrodites may be referred to one or the other of the heads now described: they will be found to be either males, with some unusual organization or position of the urinary or generative apparatus; or females, with a long clitoris, or prolapsed uterus; or individuals, in whom the generative organs have not produced their usual effect in influencing the development of the body. Thus, it is evident, that instead of combining the powers of the two sexes, they are, for the most part, incapable of exerting any sexual function. Yet ignorance and superstition have marked out these individuals, already sufficiently unfortunate from their defective organization, as the objects of persecution, and have subjected them to the operation of the most absurd and cruel laws. The ancients, regarding them as an impure and ominous kind of monsters, dispatched them by the most barbarous deaths. It appears from Diodorus, that they had been burned by the Athenians and Romans. By the edicts of Conimantine and other princes, they were beheaded, drowned, or banished to desert islands. Livy informs us that a newly born child, of which the sex could not be ascertained, was thrown into the sea. (L. 31.) Further information on this subject may be derived from Gaspar Bruhin, De Hermaphroditorum monstroso et curioso partum natura, Ex Theologorum Jurisconsultorum Philosphorum, et Rabbinorum sententia, libri duo, Francof. 1629, 8vo. These absurd notions and practices have at present disappeared; but the subject is important on many accounts, as these unusual deviations render the sex of an individual often doubtful, and impose even on professional persons. The decision may be important in deciding the employment in life of an individual, the defec of property, the fuits for religious functions, particularly for the male or female religion in the Roman church, and the judicial decisions concerning impotence or fertility. We therefore add a few observations on the grounds of distinction in such circumstances. The greatest difficulty is experienced with respect to newly born children; for many things afford our determinations in the adult. The beard, the hair surrounding the arms, the desires excited by the presence of women, the testes and their cords, and the comparatively greater breadth of the shoulders than of the pelvis and hips, shew us that the individual is a man. The smoothness andsoftness of the body in general, the increase of the beard, and of the hair from the arms, the meatal discharge, the want of testes, and the superior breadth of the hips, prove the individual to be a woman.

A male, with a fissure in the perineum and an imperfectly developed penis, may be ascertained by the size of the penis, by the different organization of the preputium from that which covers the clitoris; the absence of nymphae and labyve, and probably the presence of testes. The different relation of the fissure in the perineum to the penis, from that of the...
meatus urinarius to the clitoris in the female, will afford the
decision, as also the want of power to pass an instrum
ent towards the situation of the uterus.
The smaller size of the clitoris, and its different shape;
the connection of its prepuce to the hymen, and the
presence of the latter parts; the separate opening of the vagina
and meatus urinarius, and the presence of the hymen; the
absence of tefficles, all prove the individual to be a woman.

An adhesion of the labia to each other at their convexities
may cause a difficulty in deciding; but here the absence
of the penis and tefficles, the discharge of the urine at the upper
corner of the labia, and the line of union between those folds,
shows us the nature of the case.

Much information on the subject of hermaphrodites may
be gained from the following works. Partors' Mechanical
and Critical Enquiry into the nature of Hermaphrodites:
Pictich, Gedanken von den Zwittern, in the Old Hamburg
de Chirurgie. Haller, num dentur Hermaphroditum, com-
mentarius, in the Commentarii faci. reg. scient. Gottingen,
tom. i.; or in his Opera Minora, vol. ii. Hunter on the Free
Man, in his Ob. on the Animal Economy. Home, the
Defilaction of an Hermaphrodite Dog, with Observations on
Hermaphrodites in general. Philos. Transact. 1799. Moreau
Hillore Naturelle de la Femme, tom. i. p. 211, et
seq. Wirser, Commentatio de singulari genitalium de-
formitate in puero, hermaphroditum mentiente, in his Com-
mentat. vol. i. p. 504, et seq.

Male Organ of Generation.—In the human subject these
constitute the tefficles, vesiculae femininae, prostate, Cow-
per's glands, urethra, and penis; making up a secretory ap-
paratus, which is double, consisting of a right and left or-
gan, in the two former parts, and single in the latter. The
peculiarities of the apparatus consist in the small quantity of
fluid which it furnishes, in the long periods for which this
fluid is retained in its reservoirs; in the particular condition
of the organ defined for its emission, essentially necessary to
that act; and in the physical feeling which accompanies the
act.

The Tefficles.—These organs, placed externally to the ca-
vum of the abdomen, and left protected against external in-
jury than molt other important viscera, are surrounded, each
of them by a considerable vascularity bundle, called the per-
titic cord, and contained in a kind of bag or cavity formed of sev-
eral membraneous layers. A middle septum divides the interior
of the bag, and separates from each other the right and left tefficles,
with their coverings, which are double with the exception of the outer one.

The latter, formed by the integuments, and
called the scrotum or purse (in French les bouries) con-
stitutes a single bag, which envelopes all the others. The
scrotum is attached to the upper and front part of the pelvis,
unconnected in every other situation, continuously lateral to
the inside of the thighs, in front to the penis, and separated
behind from the anus by an interval of two or three inches,
called the perineum. A small fold of the skin under the penis,
a slight groove below, and a prominent line behind, conti-
ued into the raphe of the perineum, mark out successively,
on the external surface, the symmetrical division of the
organ. Yet the right side of the scrotum is almost constant
ly more elevated than the left, in consequence of the cor-
responding peritestic cord being shorter, and the tefficles nearer
to the ring. The scrotum is soft to the feel, and elongated,
so that the tefficles take place and hang long, in warm wea-
thor, in old persons, after coition, and under the action of
dry caustics which have a debilitating influence on the frame
in general. It is rough and harder on the surface, and
shorter in cold weather, in young subjects, at the time of
coition, and in a strong, vigorous state of the body; con-
sequently, at such times, it is applied more exactly to the
teles, and, drawing these organs gently upwards, shortens
the cords. The sudden action of cold, and even of fear,
will produce the latter state of the organ. The wrinkles
which it exhibits at such times are effaced by extending it.

The coverings of the tefficles succeed each other in the fol-
lowing order: 1st. The cutaneous investment, or scrotum; 2ndly.
The cellular layer; 3dly. Membrane of a fibrous ap-
pearance, common to the tefficles and cord; 4thly. The serous
membrane. The reason why the dartos is not enumerated
among these coverings will appear presently.

The scrotum is continuous with the integuments of the
inside of the thighs, the perineum, and penis. It is dis-
lignified by a brownish hue from the rest of the integuments,
but follows in general the tints of the latter, being always
darker in colour. A few short hairs are scattered over its
surface, and their bulbs, obliquely implanted, form feable
prominences from the thinness of the skin, which are not
effaced by extension of the organ. In its general organiza-
tion the scrotum resembles the skin; but it is very thin, so
that the veins of the subjacent cellular tissue are visible
through it. The vital properties of the scrotum are the
same with those of the skin in general; but the contraction
produced by cold is more manifest in the former than in the
latter. The phenomenon seems to be the same in both in-
fances. It constitutes the cutis anserina of the surface in
general. This corrugation of the part has given rise to the
opinion that a muscular expansion is found under the skin in
this situation; and hence have arisen the descriptions of the
dartos. We can, however, clearly distinguish that the con-
traction is in the integuments, and not in any more
deply-seated part; they feel dense and firm at this time,
instead of being soft and loose, as in their ordinary state.

The tefficles and cord are surrounded in their situation by a
copious and loofe layer of cellular substance, placed im-
mEDIATELY under the skin, and constituting, where it divides the
two tefficles from each other, the septum of the. This is rather
more dense immediately under the cutaneous integument, and
looser at the surface of the tefficles. Several blood-veffels
ramify through it, particularly veins; and hence arises an
appearance which may have authorized the opinion concern-
ing a muscular covering on a superficial examination: but
accurate inspection can discover no muscular fibres. Many
nervous filaments are also seen in this substance, and enable
us to explain the acute sensibility observed on the removal of the
tefficles in surgical operations, a little fat is seen near the
ring and the urethra; but it is completely absent from all
other situations. Here, as in the penis, the eye-lids and
some other parts, the abundant deposition of fat would in-
tere with the functions of the organ; and its absence in
these situations seems to indicate the design and foresight
employed in the construction of the body as fully as the par-
ticular construction of any parts can do. However the size
of the body in general may be increased in corpulent persons,
the tefficles, penis, &c. always retain the same dimensions.

The absence of fat renders these parts more especially sub-
ject to the watery depositions of anaetasis; such effusions
often manifest themselves first in the scrotum, and that organ
is generally very much increased in bulk when the anaetasis
is considerable. The impulsion of air through an opening in
the scrotum demonstrates very well the nature and extent of
this cellular layer; by diffusion of this kind it resembles
cotton in appearance. Maceration in water may be employed
for the same purpose; as the fluid penetrates very minutely into the cellular interlucrices. It is continuous with the similar covering of the perineum, and with the cellular substance of the perineum and groins; so that air pales from it into these situations.

The cord and testis are closely enveloped by a condensed cellular covering, which defends from the neighbourhood of the abdominal ring, and includes the organs just mentioned, together with the membranous coverings of the latter; it constitutes the thyroid or epyphoid coat of some writers. The cremaster muscle is strongly connected with this, and contributes to the formation of the cellular sheath.

This part has been described as the tunica vaginalis of the spermatic cord, but it is entirely overlooked by many writers. Its thickness differs considerably in different subjects. It is connected to the cellular substance of the scrotum externally; and adheres, by cellular connections, to the spermatic vessels, and to the tunica vaginalis testis, on the inside. If air be impelled through a small opening, it is separated from these parts, and may be divided to such a degree that it is a distinct membrane.

It then appears semi-transparent and thin, and seems to consist of fibres variously interwoven. Its thickness is much increased in scrotal ruptures, to which it gives a complete external covering. Camper has delineated it very well in his voluminous plates edited by Socamerring, and he describes it in the following paragraph; "Cremailleres ligatit muculi sunt, ab obliquo interno et transverso abdominis oriti, per involucrum membranaceum labi cutis feroti dipheri, quocum velamentum efformans, fumiculum spermaticum et telem undeque cingens, quoque in hermiovis, crassius tamoxque sit, et ex multis fibi invicem impoisit laemelis comitare videtur, cum chirurgia hernias attingitum. Velamentum illud facile faciit hernie digitis separatur; formiis autem adhaeret vaosi spermatici." *Icones herniarum,* p. 13.

The serous membrane of the testis is called the tunica vaginalis, and the name should be confined entirely to it, as most of the anatomical descriptions apply to this part only. Like all other serous membranes, this forms an entire and unperforated bag. Its arrangement is simple. It forms a pouch-covering, and appearing to include the testis and epididymis, as the heart is included in the pericardium. When an opening is made into it, and air is impelled into it, it is elevated into a bag on the front and sides of the testis.

At the posterior edge of the organ it is reflected over its surface, covering the epididymis, and all the parts of the spermatic vessels, and the whole testis, and giving to these parts a smooth external coat. The tunica vaginalis therefore may be divided into two parts; viz. an anterior portion, forming the bag, which includes the testis; and an internal, reflected over the surface of the organ. The two are continuous at the back edge, and at the upper and lower ends of the testis. The bag-like portion of the membrane is covered by the fibrous investment already described; the reflected part adheres very closely to the epididymis and testicle. The tunica vaginalis is very thin, and very where cellular on its external surface; internally it is smooth, polished, and moistened by a serous secretion, which, in an increased quantity, constitutes hydrocele. There is hardly any seizable fluid in the ordinary state of the parts. Sometimes there are partial adhesions between the opposed surfaces of the two portions of the membrane; and sometimes a general adhesion, by which the cavity is entirely destroyed, is produced by the operation for the radical cure of hydrocele.

In man and quadrupeds the testicle consists of two parts; viz. the proper testis, and the epididymis, which adheres to it behind. Ordinarily the scrotum contains two of these glands, a right and a left one; but this number is not invariably. We shall explain hereafter how it may happen that the scrotum should contain no testis, or only one; and, if authors could be credited, we might cite examples, in which there have been three, four, or even five. We believe that the number never exceeds two, that the statements now adduced have arisen from the swellings incidental to these parts, being mistaken for testes, and that there is no observation deferring of credit by which this assertion can be contradicted. The ordinary size of the gland in the adult is an anatomical fact known to each individual; but there are some varieties in this respect. Long continued chastity probably causes a shrinking of the organ; and a similar diminution, to a much greater degree, may be occasionally observed in old subjects, when the function of the part has ceased, without any disease. On the contrary, when senile enjoyment has been habitually indulged, temporary abstinence will cause a swelling of the organ, with some pain; and this may be relieved by a spontaneous discharge of the secretion. Again, there are differences of volume from original formation. The right and left glands are not always of the same size, nor is the right particularly observed to exceed the left, as some have asserted. The figure of the part is pretty exactly oval, while the two ends placed perpendicularly, and the surface flattened in the direction of the small diameter. The extremities, which are distinguished by the epithets superior and inferior, are not in the same perpendicular line; the former is inclined forwards and outwards; the latter backwards and inwards. The two ends are sometimes almost anterior and posterior. The flat fides, which are external and internal, are turned, the former towards the thigh of the same side, and the latter towards the corresponding surface of the opposite gland. The edges of the testis, which are anterior and posterior, are placed obliquely, so as to slant from above backwards and downwards. The anterior edge is sometimes described as the interior, and the posterior as superior. The epididymis is a thin and elongated organ, placed along the back edge of the testis, to which it adheres by means of the tunica vaginalis and blood-veissels, smaller in the middle and enlarged at its upper and lower ends, and reflected at the latter, to form the vas deferens. Its upper extremity is called the caput epididymis or globus major (tête de l'épididyme); and this adheres very firmly to the upper end of the testis, being placed rather behind than almost, and may be separated from the rest of the organ by a more superficial plane, forming a fibers part of the bag of the testis, which is turned towards the thigh, but not on the opposite surface. It swells again at the lower end into the globus minor (queue de l'épididyme) and then turns up to the vas deferens. The spermatic cord is attached along the posterior edge of the gland, and the greater or lesser obliquity of the testis depends on the mode of its connection. A cord, composed of the same parts, supplies each testis in its place, but it is rather longer on the left side; a circumstance which has been noticed by painters and anatomists. The pathologist ascribes to this circumstance the frequent occurrence of urocele on the left side of the body. The distance of both organs from the ring is variable, and depends on the size of the perineum, and the cremaster muscle. These two parts generally contract together. The configuration of the gland is felt to the feel. As it is covered almost entirely by the serous membrane already described, it acquires from this circumstance a smooth and polished surface; its whiteness arises from the tunica albuginea.

*Structure of the Testis.*—The glandular part of the organ,
in which the seminal secretion is immediately effected, is a light brown pulpy mass, considerably softer than the parenchyma of the other glandular organs, contained in a strong fibrous membrane, which determines the exterior configuration of the part, and the confinement which it presents on examination. This membrane is named the tunica albuginea. It is seen through the reflection of the tunica vaginalis, which envelopes the testicle, and adheres to it very closely. Yet, notwithstanding the strength of this adhesion, the serous layer may be partially separated by dissecting from the epididymis forwards. But, over the general surface the union is so intimate to admit of separation; and consequently the serous layer and the true albuginea are described ordinarily as composing one membrane under the latter name. It is from analogy, rather than the direct testimony of anatomical observation, that we describe them as distinct parts. Along the posterior edge of the testis, the albuginea is perforated by numerous openings for the passage of the seminal and blood-vessels. From the inner surface of this membrane are detached numerous delicate processes penetrating the substance of the testis, and forming partial septa, by which the glandular mals are slightly subdivided into smaller portions. Some of these productions seem to consist of blood-vessels. The structure of this part consists in amongst the fibrous membranes; it is dense, very firm, of a peculiar white colour, and possessing some blood-vessels. Its external surface is everywhere covered by the reflected tunica vaginalis, except at the back of the testis, and its inner surface is in contact with the glandular substance of the organ. The great closeness and firmness of its texture explain to us the peculiarly hard feel of the inflamed testis, as the membrane yields with difficulty to the distention produced by the swelling of the contained vascular parts. It is manifestly thicker where the seminal tubes penetrate it; and in this situation we observe the corpus Highmori, concerning which we have further observations to make below. The albuginea possesses extensibility, and the corresponding contracility: the swellings of the testicle, from various causes, swell the former, and its subsequent return to the natural size, as well as the shrinking of the part from age demonstrate the latter. It is very subject to conversion into cartilage. Little excrescences are sometimes observed on the surfaces of the gland, about the size of a pin's head.

The tunica albuginea is filled with a soft pulpy matter, of a light brownish-yellow hue, and divided into small portions or lobuli. Imperfect cellular lepta, along which the small arteries and veins run, divide these portions; but the partitions are not merely vascular. They are attached, as we have already observed, to the internal surface of the albuginea. Behind, they unite together in a white cellular hue, running along the back edge of the testicle, from above downwards. Such are the appearances exhibited in the recent organ, without any distention or preparation. Its substance is very soft, so that when dried it loses more than eight-tenths of its weight. A more accurate examination, particularly with the assistance of maceration and putrefaction, discover that all this pulpy mass is made up of convoluted serpentine threads possessing some firmness and connected together by a very soft cellular substance. These, which are called the tubuli or ductus feminiferi testis, seem about the size of an ordinary fowling thread, and can easily be drawn out with a needle, after maceration, to the length of an inch and even more. These threads are tubular, cylindrical thick in their coats with small calibre, plentifully supplied with minute vascular ramifications, from which however injected liquors do not pass into the ducts. They do not ramify, but pass in a tolerably straight direction to the cellular line at the back of the testis.

That they are tubular is proved by the possibility of injecting them with quicksilver from the vas deferens: this indeed often fails, but in some cases the tubuli are filled in this way through the whole testis. The diameter of one of these ducts, according to Monro, is 1-2200th of an inch; or 1-120th when injected with quicksilver. By the calculations of the fame anatomist, the testis should appear to consist of 62,500 tubes, supposing each to be one inch in length; and consequently, if they were joined into one tube, it would be 326 feet and 4 inches in length. The convolutions and turns of the ducts are so numerous, that they do not continue their course, in the same straight line, for more than 1-45th of an inch.

The white and firm cellular line at the back of the testis, just at the adhesion of the epididymis, is called the corpus Highmori. Many anatomists have described it as tubular, and have assigned the office of conveying the semen to the epididymis. Such a part obviously exists in the testis, and is still more manifest in animals, as in the boar, than in the human subject. Haller, who has given the most accurate account of this subject, says, "After I had accurately filled the vas deferens with quicksilver, I observed in the corpus Highmori numerous vessels, larger than the tube of the epididymis, running according to the length of the gland, serpentine, easily torn, and communicating with each other." Elem. Physiol. v. 7. p. 445.

In these the tubuli feminiferi testis terminate; and they constitute the rete vealculorum of the organ. The ducts contained in each part of the tubuli feminiferi end in one straight tube, which terminates in the rete testis. A certain number of tubes, called the vas effrentia, convey the semen from the rete vealculorum to the commencement of the epididymis. Observe notices of these vessels may be found in various writers, and De Graaf in particular has described them. But the labours of Haller have thrown the greatest light on the subject. "When, after various unsuccessful attempts, the continued labour of an hour or more had enabled me to fill completely the vas deferens, I observed the head of the epididymis to be made up of vascular cones, amounting in number to twenty or thirty, and connected together by cellular substance before any distention had been used. Each of these cones is made up of a single small vessel, larger however than the tube of the epididymis, convoluted into innumerable folds. The base of the cone is turned towards the epididymis; its apex is a vessel proceeding downwards to the testis, perforating the albuginea, and communicating with the rete testis." Ibid. p. 447.

The epididymis, of which we have already described the position and figure, is distinguished by its greyish colour from the shining whiteness of the testis. Being placed at the point where the cord is attached to the testicle, it is surrounded by blood-vessels, of which several are distributed to itself: its surface is partially covered by the reflection of the tunica vaginalis, which adheres to it closely, except at the angle of reflection, where the connection is looser. Its structure is much more easily unravelled than that of the testis; for, when filled with quicksilver from the vas deferens, it is proved to consist of a single tube, almost infinitely convoluted upon itself, excepting only a small part of the capital, which is made up of the vascular cones. The latter uniting together form one very small tube, which by its serpentine course and turns, connected to each other by cellular substance, containing the ramifications of blood-vessels,
 Cobb, forms the body of the epididymis. As it descends along the back of the testis, it increases in diameter, and at the same time is proportionally less convoluted. In a considerably enlarged state, it is reflected from the lower end of the testis, till a little convoluted at first, but soon forming a straight tube, called the vas deferens. By carefully destroying the cellular substance, which connects together the convolutions of this tube, we can demonstrate the facts now mentioned concerning the structure of this organ. In such a proceed the tube can be drawn out to a surprising length, to five cfs, according to Dr Graaf, to 400 times the length of the epididymis in its natural state, according to Heuermann. Monro has taken great pains in measuring and calculating the dimensions of this part: he finds the diameter of the tube, on an average, to be 1-30th of an inch, its length 31 feet, and the number of its turns, as it does not go in a straight direction at any part, for more than 1-30th of an inch, 11,100. (De femine et testibus in varis animalibus, p. 31 and 32.) As a further proof, that the organ is made up of a single tube, we may observe, that if we cut it across while we continue to inject quicksilver from the vas deferens, the fluid escapes from one orifice only, and when that is tied, no more runs out.

Thus, the semen, first formed in the small vesicles tubuli sericiferi, to the termination of the epididymis in the vas deferens, the semen goes through a series of tubes, which are folded 16,890 times, and, if extended in a straight line, would exceed 42 feet in length. Moers, lib. cit.

The smallness of these tubes prevents us from ascertaining their texture, or the nature of their sides. The tubuli sericiferi possesses considerable firmness, as we may ascertain by extending them until they break, and by observing the column of quicksilver which we support, when we inject them. The tube of the epididymis possesses firm and strong sides, in comparison to its cavity.

A small tube, either straight, or slightly convoluted, is sometimes observed to arise from the epididymis, and after passing to various distances on the cord, to terminate in a cul-de-sac. Its fize is equal to that of the tube of the epididymis itself. This circumstance was first noticed by Hal- ler, who called the vesel *vasculum aberrans.* (Progr. de was. feminal.) He did not undertake to determine its termination or nature, observing that it proceeded along the cord, "in cuncto line: an lymphaticum?" The existence of the vasculum aberrans has been confirmed by Monro, who injected it in four out of sixteen testicles; and he adopts the opinion suggested by Haller, of its being a lymphatic. Mr. Cruikshank takes a different view of the matter. "It is," says he, "a lunis nature, and either forms a cul-de-sac, or, after many convolutions, returns back again upon itself, and terminates where it began. It sometimes mounts four inches upon the cord, and then terminates in a coccus, or blind end. Sometimes it is not a quarter of an inch in length. I have seen it convolute, like the epididymis itself; from which it could not be distinguished, till, by maceration and dissection, the cellular membrane had been removed. It may be compared with the diverticulum illi, so frequently met with in the human intestines." Anatomy of the absorbing Vessels.

**Vessels of the Testicle: Spemamic cord.**—Under the inferior extremity of the kidney, and about the middle of the psoas major muscle, we observe a fasciculus of blood-vessels, lymphatics, and nerves, placed behind the peritoneum, and connected to that membrane by a cellular substance; this is the commencement of the spermatic cord. It descends over the psoas muscle, passing at the same time rather outwards, crosses the ureter, continues its course over the iliacus internus, and arrives at the upper opening of the abdominal ring. Here it is increased by the accession of the vas deferens, from the side of the bladder. It now penetrates the upper aperture of the ring, going under the inferior edge of the obliquus internus, and transversus abdominis; then it turns downwards and forwards in the canal placed between the two openings of the ring, covered in front by the aponeurosis of the obliquus externus, and lying behind the fæcal transverfalis. In this part of its course, it is further increased by the accession of the cremaster muscle. The cord finally emerges through the opening in the tendon of the obliquus externus, and then turns suddenly downwards; lying not so much on the bone between the two columns of the ring, as on the outer column itself, so as to cover its infection into the tubes. Just at the point, where the cord enters the abdominal canal, it lies on the root of the epigastric artery. As it is placed behind the peritoneum, in the whole of its descent from the loins to the abdominal ring, that membrane is not perforated at the point where the cord leaves the abdomen. Nor is there any fæcal continued from the peritoneum, along the cord, to the tunica vaginalis; although such a structure has been ascribed to the human subject from the observation of animals, in which it is really found. In bunooncles, indeed, a membranous cavity, produced by a continuation of the peritoneum, lies over the cord; but this is diseased; and in a particular period of fetal existence, there is a canal leading from the abdomen to the tunica vaginalis, but this is ordinarily closed before birth. Neither is there any foundation for the description of two layers of the peritoneum, of which the ureter is said to accompany the cord. Escaping through the opening in the tendon of the obliquus externus abdominis, the cord descends in a straight course to the testis, covered externally by the fibrous sheaths already described, and growing rather larger as it approaches the organ. Copious foment cell:ellular substance, with very little fat, connects together the component parts of the cord.

The spermatic are the chief arteries for supplying the testes and their coverings. These vessels are the longest in their course, compared to their diameter, of any in the body; they were known by the ancient physicians, and called by them the *feminal vessels.* They would probably have escaped the diligence of the disector, had not the importance of the part, which they supply, been more attended to, than the fize of the tube. They arise, most commonly, from the front of the aorta, between the origins of the renal and inferior mesenteric vessels; either near together, or at a small distance from each other. This is the case in twenty-two out of thirty-five instances. They may arise from the aorta higher or lower than the point which has been mentioned. The artery of the right side sometimes comes from the right renal; but the left arises much more commonly from the renal artery, informally, that this has been described as the accustomed origin. Often a smaller branch from the renal joins...
the trunk of the spermatic. It descends at an acute or half-right angle, and goes in front of the vena cava, on the right side of the body; but has been seen behind that vein. Its course is rather tortuous; joining the vein on the psoas muscle; it descends along the cord, and arrives at the testis in two branches. It gives off small twigs to the renal capillaries, but is behind the vena cava, and is employed in supplying the pulpy substance of the organ. Some of the ramifications communicate with branches of the epigastric artery. Smaller arteries come to the spermatic cord, or testis, from the epigastric, or from the circumflex abdomen. The testis, and its cellular substance, receive twigs from the arteries of the thigh. "Hence," says Haller, "tying the spermatic arteries does not destroy the testis, on account of the supply derived from the external vessels; but as these are very small, the cerebral powers of the organ are lost." Element. Physiol. v. 7. p. 430.

It has been ascertained by many anatomists, and some of considerable celebrity, that the spermatic arteries and veins communicated together; and Eulachian has drawn large communicating channels. That injection will sometimes pass from one order of these vessels into the other, when destitute of impelled, is very true, and it holds equally good of other parts; but there is no more than the ordinary kind of communication here.

The spermatic veins, like the arteries, are two in number: the right usually terminating in the front of the vena cava, the left in the renal vein, either alone, or in conjunction with the capillary, or a lumbar, or the hemisemuy. The left spermatic may end in the vena cava; or the right in the renal vein. Sometimes the vein ends by two, three, or four branches in the cava and renal vein. The size of the vessel is very considerable when compared to that of the artery: its diameter being nearly a line and a half. When the vessel has reached the psoas muscle, it divides into branches, which unite again, and give origin to other ramifications, which also anastomose together, and so on: thus a large plexus of veins is formed, constituting the corpus pampiniforme, forming the chief bulk of the cord, and increasing in size as it approaches the testis. Branches corresponding to these arteries, which arise from the spermatic, join the vein. Valves are found in the spermatic veins, but none at their terminations: the tendency to the formation of varices in the spermatic veins, shows the necessity for the exclusion of valves. The veins of the testis, derived from the epigastric, communicate with the spermatic, and with those of the penis.

The absorptions of the testicles are numerous and large, but have not been long known. Nakc had demonstrated them by inflating the spermatic veins, and Monre rejected them when he had thrown quicksilver into the vas deferens. He observed four or five valvular veins arising from the rete testis, and ascending the cord. Haller candidly admits that he did not know much of them. "In hominie aliquoties vidi maffcula, non tamen vaide numerosa, in funiculo feminilium cum vasa ascendentia, valvat, ut tamen neque origine, neque fumus fatis accurate viderem." (Elem. Physiol. v. 7. p. 435.) Mr. Crickhank has given us the most perfect account of these vessels. "The absorptions of the tunica vaginalis," says he, "are easily discovered, lying between the reflection of that coat and the tunica albuginea. Though they are thus situated, I know that they belong equally to the body of the testicle; they are in great numbers, and I have sometimes covered the albuginea with absorptions injected with quicksilver; perhaps there is not any part of the body where the absorptions are larger or more numerous, in proportion to the part, than they are here. They soon leave the albuginea, and get upon the cord, where they are joined by others, to be described presently; but the tunica vaginalis has also other absorptions, upon the anterior and lateral parts, which have not the least connection with the body of the testicle, nor with the albuginea, and which also soon blend with the former, on the beginning of the cord. The absorptions, which arise out of the rete testis, are exceedingly large, and appear to have no connection with its coat. A very beautiful preparation of these vessels I made at Windmill-street, at least ten years ago. I injected the vas deferens with quicksilver, and had in view not only the filling of the epididymis, but the tubuli seminales. I had forced the mercury along the epididymis, and was delighted to see it get into the body of the testicle; the mercury continued to descend very quickly through the glans, and the testis. I soon found that it was not running into the tubuli, but into some vessels, which mounted along the cord: these I soon perceived were absorptions. I have also injected them from every part of the epididymis, from its superior extremity, from the middle, and from the lower end. The absorptions, having reached the cord, form from six to twelve trunks or more; some of these are sometimes larger than a crow-quill: they do not appear to anastomose with one another as they pass along the cord; at first they run straight upwards, in the direction of the ring of the external oblique muscle; after which they are bent upon themselves, and pass a little way in the direction of the spine of the ilium; after which they are bent as it were a second time upon themselves, and run over the anterior surface of the psoas muscle, and terminate at last in the lumbar glands. The reason of their termination, so different from their origin, will easily occur to those who reflect that the original situation of the testicle was at this place, and that it was natural for it, like the other viscera, to receive its blood-vessels and nerves from the nearest trunks, and to return its absorptions to the nearest glands." Anatomy of the absorbing vessels, p. 142.

The nerves, like the blood-vessels of this organ, arise from the trunks contained in the abdomen, and have consequently a long passage to their ultimate destination. They are rather numerous than large. They are produced from the renal plexus chiefly, with additions from the mesenteric and hypogastric plexuses, and from the trunk of the great sympathetic. They are closely connected to the vessels in the cord, but can hardly be traced to the testis. The spermatic and cremaster are supplied by the lumbar nerves. Although the testis does not appear to possess acute sensibility, compression of the organ causes a peculiar, dull, and intolerable sensation, of the most distressing kind.

Besides the parts just enumerated, the cord contains the vas deferens, which will be presently noticed; and the cremaster muscle, which is described under the article CRISTMASTER. A soft and loose cellular substance unites the parts which have been just mentioned; it resembles that of the testis in not containing fat generally; but in corpulent persons small deposits of adipous matter may be observed in it. It does not communicate with that of the testis, as the fibrous covering of the cord is interposed between them; and it is much less subject than the latter to ananourous actions. Indeed its quantity is proportionally less abundant. Yet in rare cases it has been the seat of aqueous infiltration, constituting a very uncommon kind of hydrocele of the cord: the latter complaint leaves itself more frequently
ly in the form of a single cyl with smooth sides, contained in the cellular substance of the part. The vas, or ductus deferens, is the tube which conveys the semen from the epididymis to the urethra. Its figure is for the most part cylindrical, and it consists of a very small tube, which will only admit a large bristle, with very thick sides. Although its calibre is so small, the diameter of the part on a section equals a line. The tubuli of its sides are very firm, and cut like cartilage; hence we can distinguish it by the feel from the other component parts of the cord, by folding them between the finger and thumb in the living subject. The intertissue of the tube is smooth. Nothing of a muscular structure can be discerned in its composition. It arises from the posterior and inferior part of the epididymis, ascends behind and a little on the outside of that organ, and then continues its course along the spermatic cord behind the vesicles to the ring. Comprehension of this part occurs the same kind of pain as is experienced when the testes are injured; and the very acute suffering observed on tying the cord in castration, has been explained by the circumstance of this tube being included in the ligature. Perhaps this explanation may be doubted, as the nerves of the testes are also among the compressed parts; however, the vas deferens is easily omitted, as its hard feel enables us to separate the vesicles which lie in front, and are connected to it by a loose cellular substance. It passes through the abdominal canal, holding the same relative situation to the spermatic vesicles. It separates from them behind the opening, and then bends downwards and backwards along the surface of the pons mafeulent, and of the iliac vesicles, to enter the pelvis. Here it becomes attached to the posterior and lateral part of the bladder, and descends obliquely from without inward, just in the situation where the peritoneum is reflected to the bladder from the side of the pelvis, connected by cellular substance on one side to the bladder, and on the other to the peritoneum, and situated in front of the rectum. In this course it descends the umbilical artery, behind which it passes; it also crosses the ureter, being placed between the lower extremity of that canal and the bladder. At the lower and back part of the latter organ it turns forwards and inwards, so as to approach towards the canal of the opposite side; it is connected to the surface of the bladder: in this direction it continues along the under surface of the organ, within the vesicae feminales, and connected below by cellular substance to the rectum. In the neighborhood of the prostate, the two vasa deferentia are placed close together, and each units just at the surface of the gland, with the anterior extremity of the vesicae feminales. The canal, resulting from this junction, sometimes called the ejaculatory duct, penetrates the substance of the prostate, from below and behind, upwards and forwards, and opens in the urethra at the site of the verumontanum. The commencement of the vas deferens is a little convoluted, and rather larger in its calibre; at the upper part of the testis it becomes straight in its course, and its area is diminished. The vesicles the bladder it is considerably enlarged again, where it lies along the inner edge of the vesicae feminales. It has here sometimes a slightly serpentine course, and possesses a flattened form. Its cavity is proportionably augmented, and, instead of a cylindrical tube, presents a reticulated texture, like that of the vesicae feminales. Its surface is irregular and tuberculated in consequence of this cellular structure. After receiving the tube of the vesicae feminales, its area is again diminished remarkably in size, and forms a small cylindrical canal. The vas deferens receives arterial and venous ramifications from the trunks, in the neighborhood of which it passes. Nothing is known of its nerves. It is by no means common in animals for the vas deferens to join the vesicae feminales in the manner already described. In all cases where there are testicles, that duct conveys the secreted fluid into the urethra, there being no vesicle in form, while in others they terminate by separate openings. The communication between the two parts in man is a very free one; and, although the canal formed by their junction proceeds in a straight direction to its termination in the urethra, yet quicksilver, or any other injected fluid, or air thrown into the vas deferens, passes into, and diverges the corresponding vesicles before it gets into the urethra. The composition of the common canal by the firm substance of the prostate, the small size of the tube and of its opening, and a particular turn made by it, have been assigned to explain this fact: If the injection is pushed further, it will go into the urethra. Fluids thrown into the vesicles also diverge the vas deferens, but are more readily admitted into the urethra, as the capacity of that vesicle is not considerable. The vesicae feminales are two soft bodies, resembling, when undisturbed by dissection, membranous tubes with blind extremities, convoluted, and therefore marked with furrows and grooves on their surface. They are situated under the inferior flattened surface of the bladder, and upon the upper surface of the rectum, being connected to both these organs by loose cellular adhesions. They are pyriform, with the apex placed forwards, and the base backwards, and convergent from behind forwards. Their anterior extremities, joined, as we have already mentioned, to the vasa deferentia, lie on the upper and back part of the prostate, and would be in contact with each other, were they not separated by the tubes just alluded to. From this point they grow gradually broader, and are divergent, terminating behind in rounded ends, which are the most distant from each other. The superior surface, in contact with the bladder, is rather flattened: the inferior, lying upon the rectum, is slightly convex. The vas deferens runs in contact with the inner margin, and the outward edge is turned towards the side of the bladder. The posterior broad and rounded ends are partly in contact with the peritoneum, and lie at the sides of the pouch, formed where that membrane is reflected from the bladder to the rectum. Numerous arterial and venous ramifications, particularly the latter, and a considerable quantity of cellular substance, surround these organs in all directions, and connect them to the neighbouring parts. In some individuals the pyriform shape is not well marked; in some the anterior and lower end is always small. The flattened appearance of its surface is altered by injection: the whole organ then appears thicker, and the tubercular furrows of the surface are more distinct. A very different appearance is produced when these bodies are unravelled by the anatomist. Each vesicula is then found to consist of a single tortuous tube, about the size of a writing quill, with a blind extremity, and several lateral appendices, which also end in cul-de-sacs. Sometimes the latter are very few; perhaps one or even none. In other instances they may amount in number to ten, or more. Haller has seen seventeen larger, besides smaller ones. Some of these are simple blind appendices; others, particularly near the anterior end of the organ, again branch out. Sometimes the whole vesicula is blind almost from its very origin; the varieties, indeed, are so numerous, that
two vesicles will hardly be found exactly resembling each other; but these variations are not important. (*See Marco de Toledo, tab. 3*.) This tube, with its appendages, is so convoluted upon itself, the turnings being closely connected together by cellular substance, containing numerous vascular ramifications, that the organ, when modified, is four or five times shorter than the unraveled tube: and a section of it in this state makes it appear to be composed of numerous coils, communicating together. This structure accounts for the knotted appearance of the organ on its surface.

The structure of the vesicula is analogous to that of the ductus deferens: its sides are not so thick, but they are still dense and strong. The external coat is of a close texture, and whitish color, covered with cellular substance externally. Nothing of a muscular nature can be discerned here, although the functions of the organ oblige us to admit that it possesses a contractile power. We cannot otherwise account for the expulsion of the contents of the vesicula.

The action of the levatores ani, which has been assigned as the efficient cause of this expulsion, is certainly inadequate to account for it; as their ordinary daily exertion is attended with no such effect, when the vesical organ is not present, and these parts are not exerted in their specific manner. We may observe, moreover, that the perineal muscles contract at the moment of evacuation; now the contents of the vesicula must be conveyed into the urethra in the previous moments. The internal surface of the vesicula is formed by a mucous lining, connected closely to the preceding tunic. Its colour is whitish, and its thickness not considerable. It is continuous with the lining of the urethra. Its surface is very minutely reticulated, and marked with extremely small furrows, not to mention the larger septa formed by the turnings and folds of the tube and its appendices.

It has, moreover, a downy or villous appearance: a similar structure characterizes that enlarged portion of the ductus deferens which lies along the edge of the vesicula. The structure of these parts, as well as the junction of the vesicula and vesicula at an acute angle, has very considerable analogy to the gall-bladder and ductus hepaticus. Both have the same reticulated internal surface; the union of the two tubes, and the supposed course of the contained fluids, are considered to be similar.

Some anatomists have described glands as being contained in the substance of the coats of the vesicula, and secreting the mucous fluid poured into these organs; but the most careful investigation does not lead us to detect any thing glandular, and the secretion is probably performed by the surface of the parts.

We proceed to describe more exactly the canal by which the vesicula and vesicula communicate with the urethra. The tube of the former assuming a smooth appearance on its internal surface, and rather diminished in size, converging towards its fellow, joins the corresponding vesicula at a very acute angle; it is still considerably larger than the latter canal. When the parts are dissected, and the connecting cellular membrane removed, as in the hepatic and cystic ducts, the junction appears to be effected at a half right angle. The canal formed by this union, and belonging equally to the vesicula and vesicula, proceeds more directly in the course of the latter, lies in close contact with its fellow, passes between the prostate and neck of the bladder, and thus arrives at the under surface of that part of the urethra, which runs through the gland. A small elongated eminence is found in this portion of the urinary canal, composed of its internal coat, broader behind, where it assumes an oval figure. Towards the front it is continued into a long prominence, which is simply a fold of the urethral lining, and disappears in the bulb, ending in one of the long stirits, of which several are seen in the urethra, and sometimes bifid, or even radiated at its extremity. It is called capit gallinnisii, or veru montanum. The elevations of the lining of the bladder, continued from the ureters, terminate in this eminence. Its oval portion is hollow, and presents a long slit leading into a cul-de-sac, which can be inflated, but which has no communication with the seminal passages. On each side of the eminence there is a small oblong opening, the termination of the ejaculatory duct, but much narrower than the calibre of that tube, which is suddenly reflected from within outwards, at nearly a right angle, and pours its contents, by this small opening, into the urethra. There is no valvular structure at these orifices. The slit and cul-de-sac already mentioned have given rise to an opinion, that the two ejaculatory ducts terminated by a common orifice, which is altogether erroneous.

The prostate is a firm glandular body, placed behind the symphysis pubis, in front of the neck of the bladder, and surrounding the commencement of the urethra. In most animals there are two separate glands in this situation, and the expression prostata has been erroneously transferred to the human subject. The size and figure of this part have been not unaptly compared to those of a large chestnut. Its broader end is turned towards the bladder, and is divided by a flight fissure into two lateral lobes, the narrower part is situated forwards. It is considerably thicker from side to side, than in the vertical direction. The superior surface corresponds to the arch of the pubes, but is rather behind that part: it is covered by a strong fibrous expansion, descending from the arch, and named the inferior ligament of the bladder. Below, the gland is connected by close cellular adhesions to the upper surface of the rectum, and the contact of these two parts is more extensive in proportion to the size of the gut, which, when much dilated, rises slightly on each side of the prostate, so as to be endangered in the lateral operation of lithotomy. The convex prominent fibres are covered by the anterior fibres of the levator ani. The bafis, or broad posterior part, which is gently concave, embraces the neck of the bladder, and the small anterior ends of the vesiculae seminales and vasa deferentia. The cellular substance, which connects it here to the bladder, is very dense and firm, and the mucular fibres of the organ are partly interwoven with it. This part presents the groove already mentioned as dividing the organ into two lateral lobes. In front, the narrower portion of the prostate is lost indefinitely on the membranous part of the urethra, to which it adheres most firmly. The bulk of the urethra, the fat and muscular of the perineum, cover the part so deeply on its anterior aspect, that it can by no means be felt from the surface: on the upper part of the rectum, however, the gland may be distinctly recognized by the finger introduced into the gut, as nothing but the intestine covers it in this situation; and it projects feebly into the tube when enlarged.

The urethra, immediately at its origin from the bladder, passes through the prostate from behind forwards, and the membrane is almost conflated with the fides of the opening in the gland. This passage does not take place at the centre, but nearer to the superior surface, so that a small portion only of the gland is above the urethra, and the chief bulk of it below and at the fides. At the inferior part of the opening, by which the urethra commences, a small portion of the gland projects slightly towards the bladder; and this
The upper surface, named the dorsum, or back of the penis, is inclined forwards; it is turned towards the abdomen, and becomes posterior in the erected state. A large vein runs along its middle, and sometimes there are two trunks. The inferior surface, turned backwards, is placed against the front of the ferotum; it forms a prominent line from the course of the urethra, and the integuments in this situation have a longitudinal rough mark, called the raphe, continuous with a similar furrow in the ferotum. On each side of this middle prominence there is a superficial depression, where the urethra is in contact with the corpora cavernosa. The two sides of the penis are rounded. The posterior extremity, which is the root of the penis, is divided into three portions, which are distinctly described, viz. the urethra in the middle, and the two corpora cavernosa, one on each side. The anterior extremity presents the glans and prepuce.

The penis is made up of various parts, each of which serves some particular purpose in the functions of the organ, considered as an instrument of reproduction. 1. The corpora cavernosa, making up its chief bulk, soft and loose in the state of repose, are so organized as to become very suddenly increased in size and hardness, in consequence of the operation of certain fluids. By thefe the penis is rendered capable of introduction into the female vagina. 2.dly. The urethra, by which the fecundating liquor is conveyed, is a membranous canal, surrounded by vascular subfequence, called corpus spongiosum, which is susceptible of the same change in erection as the corpora cavernosa. 3.dly. The glans is a small organ, consisting of a continuation of the corpus spongiosum, covered by a highly organized and acutely sensible skin, the excitation of which, in the act of coition, determines the discharge of the seminal fluid through the urethra. The penis poifefles an external cutaneous covering, which is simply contiguous to the glans, but united to the corpora cavernosa and urethra by cellular subfequence.

The corpora cavernosae, or corpus penis, are two nearly cylindrical bodies, of a very firm texture, united laterally in the greatest part of their length, but separated from each other behind, like the branches of the letter Y, and terminating by slender, conical, and pointed extremities. These, fixed behind to the rami of the ischia and pubes, advance forwards and inwards, approximating to each other. In front of the symphyses pisiformes they come in contact, or rather, are confounded together in one single body, the size of which is uniform throughout, except in front, where it terminates by a blunter extremity. The separate origin of the two lateral portions has led anatomists in general to speak of the corpora cavernosae in the plural number; but their conformation into one body has induced Sabatier, and some other modern authors, to admit only a single corpus cavernosum, bifurcated behind for a double infection into the pelvis. The single body, formed by the union of the two corpus cavernosae, to which the bulk and firmness of the penis are almost entirely owing, is flattened above and below, and presents two surfaces, a superior and an inferior, on each of which there is a longitudinal groove, corresponding to the septum, which is within the corpus cavernosum. That of the upper surface is the smaller, and lodges the great veins of the penis; the inferior, broader and deeper, receives the urethra, to which it is united.
united by a close cellular substance. The sides of the body are rounded and covered by the skin, its anterior extremity forms a blunt point, received into a cavity, at the base of the glans. The two parts are united by a very dense cellular substance, and some blood-vessels pass between them, but there is no other kind of communication; and air or injection, thrown into the cellular substance of the corpus cavernosum, do not find their way into the glans. The latter, therefore, is not an expansion or continuation of the former, as some old anatomists supposed. The posterior extremity is bifurcated, and its two prolongations form the two crura penis already mentioned. These begin in a pointed form a little above the tuberocities of the ischia, from the inner surface of the bone, to which they are attached as far as the symphyses. Below and within they are covered by the erecitors and accelerator muscles, above and without they adhere strongly to the bone. They leave between them a triangular space, filled by fat, and by the urethra, which occupies its middle. Three parts are to be considered in the corpus cavernosum, viz., an external membrane, a peculiar spongy substance, and a longitudinal septum, occupying its middle. The outer membrane is of a fibrous nature, very thick and firm, whitish in its colour, and hallowing on the body its peculiar figure. Its external surface is covered with a dense cellular tissue: on the inside it adheres closely to the spongy substance. Thinner on the crura, in the groove lodging the urethra, and at the anterior extremity, it presents in these situations a livid tint, produced by the contained blood, while it is thicker every where else, whitish, and opaque. In the former situations there are some perforations for the admission of blood-vessels. It is continuous and strongly interwoven with the periura of the orifice, and passes through the middle of the characters belonging to fibrous organs, and is made up of fibres variously interlaced, and forming several strata. It is found to be very hard and resistible, when exposed to the action of a cutting instrument. It experiences a passive dilatation from the influx of blood in erection, and returns to its former state, when this extension goes off. It does not seem to possess any vital properties.

The spongy matter of the corpus cavernosum is a cellular substance, composed of very fine and numerous plates and fibres detached from the internal surface of the fibrous membrane, and disseminating each other in every direction. Its cells are all communicated together, and are more or less filled with blood, which can be removed by forcible squeezing, or repeated washings. Various fibrous threads cross the cellular substance in different situations, and are attached to the surface of the fibrous membrane. They are said to prevent excessive dilatation of the corpora cavernosa. An artery and a vein pass through the centre of the cellular substance on each side, from behind forwards. Their minute ramifications must, undoubtedly, communicate with the cells of the organ, since injection will pass from the arteries into these cells; and injected fluids or air, after filling the corpus cavernosum, gain admission into the veins. The blood contained in the corpus cavernosum has always a dark livid appearance in the dead body; but it is red during life, as may be seen in amputation of the penis, or in living animals. Its quantity varies very considerably, according to the condition of the penis; at rest it is inconsiderable, the whole corpus cavernosum is dilated; from the bent position to the glans, it is elongated and hardened, and erection is produced.

The septum of the penis divides it longitudinally into two portions, which most anatomists consider as distinct tubes, under the name of corpora cavernosa. In order to see if well, the fibrous membrane should be cut through on each side of the penis, and all the spongy substance removed; the septum will then be found continuous, by its two edges, with the fibrous membrane, and composed of strong whitish fibres, not forming an entire plate, but leaving intervals between them, at which the two sides of the corpus cavernosum communicate freely. From this structure the name of septum pectiniforme has been derived. The intervals between the fibres are larger towards the inferior than the superior edge of the septum. At the part where the two crura meet together, the septum is complete, it degenerates into separate valvulae towards the opposite end of the organ, and the intervals between them are more considerable, as we approach nearer to the front extremity.

The dimensions of the penis are determined in great measure by the corpus cavernosum; and to this body the organ owes that firmness in the erected state, which enables it to fulfil its office in the business of generation. Each of the crura penis gives attachment at its origin to a tolerably strong muscle, named the crurum penis, probably, because when a power, capable of producing the effect indicated by that name, was sought for by anatomists, this muscle seemed to be their only resource. At present the name appears very ill adapted, since the muscles in question obviously draw the penis downwards and backwards, instead of upwards and against the pubes. Those who explain the erection of the penis, by the compression of its vein, should find out a power capable of elevating the organ against the bone, and of carrying it forwards. It has a tenacious origin, below the attachment of the crura penis, from the inner surface of the tuberocity, and ramus of the ischium. It passes forwards, upwards, and a little inwards, and is firmly implanted in the fibrous membrane of the crura penis. It will draw the corpus cavernosum downwards, for as to bring it more nearly into a direction parallel to the cavity of the vagina: it has a slight power of shortening the crura penis, and thereby expressing the blood into the anterior part of the organ, so as to increase its turgescence. Its origin and course render it completely incapable of compressing the large vein of the penis.

The urethra, which, in the female, belongs only to the urinary passages, constitutes moreover in man an essential part of the generative apparatus. Its length is very considerable, and its organization very complicated, in consequence of the latter office. It has connections with almost all the parts belonging to this apparatus; the ejaculatory and prostatic ducts open into it; it is closely connected to the corpus cavernosum, and terminated by the glans. In the male subject it forms a canal extended from the neck of the bladder to the end of the penis, and giving passage to the urine and semen. Its length, which varies in different individuals, and in subjects of different ages, is about nine or ten inches in the adult. At its origin it penetrates the prostate, passing forwards and downwards: it goes under the symphyses pubis, and then ascends in front of that part, between the two crura penis, in order to reach the inferior surface of the corpus cavernosum, and become attached to the channel which we have already described. Being thus united to the corpus cavernosum, it runs along the whole length of that body, and follows its direction. Lastly, it traverses the glans penis, and opens at its extremity, by a vertical slit with slightly rounded edges of a bright red colour. Hence the canal forms in its course curvatures resembling those of the letter S; but this is only when the penis is relaxed; for, in the erected state, the curvature in front of the pubes, of which the concavity is turned downwards, is entirely effaced, and that only remains, which is below the pubes, and of which the concavity faces upwards.
The canal is divided into three portions, distinguished from each other by their organization. The first, of about an inch in length, which passes through the prostate, has received no name; the second, of about equal extent, continued from the prolate to the bulb, is called the membranous portion; the latter corresponds above to the inferior surface of the lymphatic pubis, but is about half or three quarters of an inch below the bone. Below it is connected by cellular substance to the surface of the rectum, and at the sides, the front edges of the levatores ani are in contact with it. This part of the canal has been called the membranous portion, from a notion that the membrane of the urethra was covered here by no external investment, but in fact it is closely surrounded by a thick stratum of mucilaginous fibres. The mott interior of these are circular, and lie close upon the membrane of the urethra. Mr. Wilton has lately described some fibres, arising by a double tendon from the arch of the pubis, depending on each side of the urethra, and united under the canal. (See the Medico-Chirurgical Transactions, vol. 1.) These fibres are connected in front with the accelerator urethra and its vessels, and behind with the levatores ani. They will compress the canal when they contract, and, by doing it at the time of emission, will prevent the seminal fluid from being driven backwards by the action of the accelerator.

The third portion of the urethra, including all the rest of the canal, is called the spongy part. It begins by an oval rounded portion, named the bulb of the urethra. This is situated below the union of the crura penis, between which it makes a remarkable prominence. Below, and on the sides, it is covered by the accelerator urethra (see Accelerator), and by Cowper’s glands. Together with the two preceding parts of the canal, the bulb forms the first curve of the urethra, and its sides are strongly connected to the arch of the pubis by means of a fibrous expansion, termed the triangular ligament of the urethra. The latter part passes the figure, which its name indicates; the base of the triangle is turned downwards, the apex upwards, corresponding to the junction of the os pubis, and the sides are attached to the rami of the pubis. It is perforated by the passage of the urethra, which it holds firmly in its relative situation to the bone. In the rest of its extent, the spongy portion of the urethra corresponds above to the channel in the under surface of the corpus cavernosum, below, it is covered near the bulb by the accelerator, then by the cellular substance of the corpus, and afterwards by the integuments of the penis.

The diameter of the canal is by no means uniform in its whole length. It is large in the middle of the prolate, and smaller where it enters and leaves the gland. The canal is here rather flattened laterally. In the membranous portion it is perfectly cylindrical, but small in its size; and the narrowest part of the whole canal is just where the bulb and membranous part join. In the bulb it is again considerably enlarged, and after contracting slightly, preserves a cylindrical figure and uniform size to the base of the glans. There it again dilates, and forms what some anatomists have called the fossa navicularis; its anterior opening is somewhat narrower. Mr. Home took the trouble of ascertaining the dimensions of the canal by filing it with wax, and measuring the calt thus formed. The length was nine inches; from the external orifice to the bulb, seven. The membranous portion was 39 inches in length, and the prostatic part of the canal half an inch. The diameter of the calt, at 8 of an inch from the external orifice, was 9-20ths of an inch in a subject of 30 years, and 9-20ths in one of 30 years; at 4 in inches from the external orifice 7-20ths; at the bulb of the urethra 12-20ths; in the membranous part, immediately adjoining the bulb, 7-20ths; in the middle of the prolate 11-20ths; at the neck of the bladder 9-20ths. Home on Strictures, vol. i. p. 29, and 25.

The situation of the eminence, on which the ejaculatory ducts open, called the verumontanum, in the prostatic part of the urethra, and its figure, have been already noticed; as well as the openings of the ejaculatory ducts in the same part of the canal. In the rest of its extent, the internal surface of the canal possesses a reddish colour. In the membranous and spongy portions, longitudinal folds are observable, disappearing on extension. These are not seen in the prostatic, nor at the glans, because the firm texture of the parts which adhere so very closely to the mucous membrane, keeps it constantly smooth. Hence the diameter of these parts is nearly uniform at all times. The fides of the canal exhibit openings of numerous small oblique ducts, frequently named after Morgagni. These are only seen in that part of the urethra which is in front of the bulb, and are sometimes called lacunæ; their number and size vary in different subjects. They run from behind forwards, and terminate by simple orifice. They are almost always accompanied by the folds navicularis, from which some have explained the circumstance of this part being particularly affected in gonorrhœa. They consist of short canals, formed in the membranous sides of the urethra, lined by a continuation of the internal membrane of this canal, and about large enough to admit a large hog’s bristle. They are of various lengths, but commonly about a quarter of an inch. Sometimes several smaller join into one larger duct. If carefully examined, their whole number will not be found less than 60 or 70. No glandular apparatus can be discerned connected with them. In these tubes the mucous fluid is secreted, by which the surface of the urethra is smeared, and defended from the action of the urine. Where these lacunæ do not exist, as in the bulb, membranous portion and prostate, a protecting fluid is furnished from other sources, as Cowper’s glands and the prostrate. The fluid of the lacunæ seems to be a clear, viscid secretion, similar in appearance and consistency to the white of egg. In this form it can be expressed from the openings on the surface of the urethra. Under various circumstances of disease it is increased in quantity, and variously altered from its natural properties, as in gonorrhœa and leucorrhœa, and in stricture. In some of these instances, it is a clear, transparent, viscid fluid, being the natural secretion in a more abundant form.

The sides of the urethra are differently organized in different parts; it is lined indeed throughout by a mucous membrane, but this is covered externally by very different structures. Where the canal is passing through the prostate, the sides are formed merely by the mucous membrane, closely united to the gland by a dense cellular texture. The firm substance of the prostrate, so intimately connected with the canal, gives it to a strength and thickness in this part. The membranous portion is differently circumstanced; this is the thinnest, and least firmly supported division of the canal, and, as it is placed in the bend of the urethra, is particularly liable to injury in the employment of the catheter. Even here the membrane is covered by a dense cellular texture, continued from the prostrate, and by the mucilaginous fibres already described. In the spongy portion of the urethra, the sides of the canal are covered by a substance of peculiar organization, analogous in its effects to that which fills the corpora cavernosa penis. This is called corpus spongiosum urethrae, or corpus cavernosum. It begins in front of the membranous part of the canal, by a large protuberance already mentioned, as the bulb of the urethra. It forms an oblong rather elongated production, hanging between the crura.
crura penis and below the canal of the urethra, sometimes bearing a slight appearance of division into two lateral parts by a middle line, and terminating behind by a rounded point. The bulb corresponds only to the inferior surface of the urethra; but a thinner layer of the corpus spongiosum, continued from the bulb, covers the urethra on all sides in front of that body to the end of the prepuce. Here it is again increased in quantity, and reflected over the anterior extremity of the corpus cavernosum penis, to form the glans. The spongy substance surrounds the urethra uniformly on all sides. It is closely connected to the corpus cavernosum above by cellular substance, and by vesicles which are seen when the urethra is detached from its channel; below and on the sides, it is covered by a cellular sheath, common to it with the corpus cavernosum penis. The external surface of the corpus spongiosum consists of a thin but compact fibrous layer; and the interval between this and the mucous membrane seems to be filled by a very fine cellular network, the cells of which contain venous blood. The texture of the external layer occasions the parts to possess a livid colour, as the tint of the blood is discernible. This network is covered in the glans by a highly organized species of skin, through which the colour of the venous blood is not discernible. The corpus spongiosum does not confine, according to the common opinion, of a cellular texture; but it is made up of very small and repeatedly convoluted veins, as may be ascertained distinctly enough by inspecting attentively the surface of it, when successfully injected; this structure is more evident in some animals, as particularly in the dog. The bulk of the corpus spongiosum depends on the quantity of blood which it contains; and this part admits of the same dilatation, as the spongy substance of the corpora cavernosum penis, and for the same purposes. Air, impelled into any part, finds its way readily over the whole extent of the substance, and the same circumstance may be observed of injection. It may be readily injected from the large vein at the back of the penis; but the valves sometimes prevent the success of this attempt.

The canal of the urethra is lined by a mucous membrane, continuous with the lining of the bladder at one extremity, and with the cutaneous covering of the glans at the other, and lending prolongations into the mucous sinuses of Morgagni, the ducts of Cowper's glands, the ejaculatory ducts, and those of the prostate. Its surface is perfectly smooth, excepting the longitudinal wrinkles, which are effaced by extension. The colour is a bright red at the external orifice, and in the fossa navicularis; in other parts it appears pale, when the blood has been expressed from the corpus spongiosum. But the injection of coloured fluids proves that it receives every where an abundant supply of blood-veffels. Its substance is very thin, and the opinion of its being covered by a continuation of the epidermis does not seem to be at all well-founded, as there is a well-marked line of separation at the glans, and no cuticle can be seen in the canal. The external surface is rough and cellular for its connection to surrounding parts. No appearance of muscular structure can be discerned in any part of the membrane. The introduction of an instrument shows this membrane to possess acute sensibility; and the repetition of the practice excites the force of habit in blunting such feelings. The first time of pulling a bladder from before backwards is sometimes attended with exquisite, and almost always with sharp pain, but after a few times, no unpleasant sensation is excited. The passage of the urine is attended ordinarily with no sensation; but this becomes most acutely painful when the membrane is inflamed. It has been much disputed whether or no this canal possess a contractile power in its own lining. The phenomena are strongly in favour of the affirmative, although no muscular fibres have been demonstrated. The temporary obstruction to the flow of urine, under circumstances of disease, and the sudden cessation of this inconvenience, can hardly be explained without allowing a contractile force to the membrane. The expulsion of instruments from the canal is another phenomenon of the same kind. That the urethra is extensible, and that it returns again to its original size, is proved by the passage of instruments. Haller states that chemical inflammants will cause it to contract.

The glans is the body surmounting the anterior and upper part of the corpus cavernosum penis, and forming the front extremity of the organ, of which it augments the length in a trifling degree. It has the form of a cone, slightly flattened from before backwards, with its base very obliquely truncated. Its apex presents the aperture of the urethra already described. Below this, is placed the frenum connecting it to the prepuce; and on each side of this fold it swells into a small convex protruberance (callus glandis). This part is called by Haller 'fundi acerrimi fide.' The glans cannot be laid to extend below the urethra, as that part belongs to the corpus spongiosum. Since the bafs is to obliquely truncated, the depth of the organ is very inconsiderable at the two convexities already named; but it is much more considerable above, where it is produced over the corpus cavernosum, and terminated by a thick riving edge of a semi-lunar outline, with the convexity turned backwards, called the corona glandis. This margin, sufficiently thick and prominent to elevate the integuments, and cause a perceptible riving externally, forms the front boundary of a cupola, or gutter, caused by the reflection of the inner membrane of the prepuce over the glans. Below, the corona glandis is interrupted by a small groove, which extends to the orifice of the urethra, and gives attachment to the fold which forms the frenum. In some subjects this groove is hardly perceptible. The corneal glands are continuous below with the corpus spongiosum; the bafs of the glans is hollowed out, and the anterior extremity of the corpus cavernosum penis is received into the concavity. In consequence of this structure, although the glans appears to be an inch or more in length, it makes very little addition to the length of the penis.

The substance of the organ consists of a spongy matter similar to and continuous from that of the urethra. Air or injected fluids pass readily from one into the other. This matter is made up, as in the urethra, of convoluted veins, and it admits of the same changes of laxity and erection from the same causes. Sometimes there is an appearance as if the corpus spongiosum urethra and the glans were separated from each other by a septum. The substance of the glans is always more dense, and contains less blood than that of the urethra. The surface of the organ is covered by a very vascular and delicate production of the integuments, continuous towards the apex of the glans with the mucous lining of the urethra, and at its bafs with the inner layer of the prepuce. This covering is very thin, and smooth and soft to the touch. Its external surface is composed of a delicate epidermis; this is succeeded by a layer of the true skin, of a very soft and delicate structure, covered with numerous small villous preceles, which are more distinctly seen about the corona glandis. The most favourable method of observing these villi is to plunge the part in boiling water, which separates the cuticular covering; they are then visible in vast numbers over the whole surface, giving it an irregularity in its appearance. This circumstance in the structure of the glans was first demonstrated by Albimus (Annot. Academ. lib. iii.), and is admitted by Ruyfch and Winlow, although
although some anatomists have questioned it, probably because the demonstration is rather difficult. That the nerves of the organ are continued into these papillae, as they are in the tongue, and that the exquisite sensibility of the glans arises from this organization, is rather matter of probable conjecture, than the result of direct proof. The blood-vessels of this cutaneous production are numerous, so that a general redness is produced by minute injections. The opposed surfaces of the glans and prepuce are smeared over with a white, friable, and mucous sub stance, of a very peculiar odour, moistening the parts and preventing the effects which might otherwise follow their mutual attrition. In animals there are manifold glands to secrete this substance, and an apparatus of glandular structure defined to the same office has been described in man. This kind of sebaceous matter is formed in other situations of the body by peculiar glandular organs, as in the eye-lids by the Meibomian glands; and the notion that it is deposited by the urine, which is contrary to all observation, and to every thing we know of the properties of that fluid, would be immediately overturned by the fact, that a similar deposition occurs under the preputium clitoris of the female, where the urine could not form it. Although in many subjects no glands can be seen, they are occasionally obvious enough, and are now universally admitted, under the name of glandulae odoriferae. Morgagni, in his Adversaria, has given a very particular description of them, and Haller confirms his statements. They are hardish, white, and very small bodies, particularly observable about the corona glandis, and in the channel behind that part, where the prepuce is reflected. Morgagni also mentions them near the frenum in the prepuce. “I have seen,” says Haller, “five rows of them in the corona, but their number diminished towards the frenum, so that no more than two rows would be seen.” They can be observed most advantageously when the cuticle has been removed. That the orifices of these bodies can be seen, and their sebaceous contents squeezed out, is not so clearly ascertained; but both these facts are asserted by competent witnesses. They may be rendered more evident when enlarged in dissection; and might be mistaken for venereal pimpls, if their symmetrical arrangement did not throw light on the appearance. That the matter secreted by these glands accumulates under the foreskin, in the form of a white, soft, and greasy substance, where the necessary attentions to personal cleanliness are neglected, and that in hot weather, it may become acrid and irritating, so as to produce excoriations and even ulceration, are well known facts. The inhabitants of warm climates are chiefly exposed to these inconveniences, and the most important advantage of circumcision consists in its obviating such accumulations. Hence we know that Christian, living under the burning sun of Senegambia, submit to this operation, and that uncircumcised Europeans, living in the East, very frequently experience the ill effects arising from the foreskin just alluded to. For this reason Guido de Caulacico, a celebrated furgon of his time, about the middle of the fourteenth century, observed that circumcision was useful to many others besides Jews and Saracen: “propriae quod non congregantur fordities in radio balani et calcisulento ifum.” Chirurgia, an. vi. doct. ii. p. m. iii.

The glans penis possesses a very exquisite sensibility, particularly in perine, where it is habitually covered by the prepuce; this feeling is only observed on certain occasions, and is the source of that physical sensation experienced at the expulsion of the seminal fluid. It swells and becomes firm in the act of erection, as well as the rest of the penis. The cutaneous covering of the penis is continuous, at one end, with that of the scrotum and pubes, and at the other with the prepuce. It is thin, furnished with numerous sebaceous glands, particularly at the under surface, and marked in that situation by a rough line, called the raphé, running along the middle of the organ, and continued with a similar one on the scrotum. It is darker coloured than the integuments in general, and has a few hairs towards the root of the organ. The cellular texture connecting the skin to the penis is very loose, and contains no far except close to the pubes; hence the skin adapts itself with the greatest facility to the varying bulk of the organ, falling into wrinkles in the collapsed state, and extended more smoothly in the erected condition. It is continuous with the cellular substance of the scrotum, groins, and pubes, and air passes readily between them. Towards the surface of the corpus cavernosum it becomes more dense, and assumes the form of a regular membranous covering; it is more and more loose towards the surface, and when inflated, a cottony appearance. The suspensory ligament of the penis is placed at the root of the organ, which it unites to the lymphatic pubis. It consists of a dense, cellular, elongated, and flattened band, proceeding from the front of the lymphatic pubis, running along the cellular tisue of the organ, and expanded under the skin. Its limits and figure are not very determined, and the knife of the dissectors often influences its size and appearance.

The prepuce or foreskin is a loose fold of the cutaneous covering of the penis, continued over the glans, without adhering to it, and affording a more or less complete covering to the extremity of the penis. Its length varies in different individuals; sometimes it is produced considerably in front of the glans, and its opening is then generally small. Its external surface offers the same structure and appearance as the integuments covering the body of the penis, and is smooth or wrinkled, according to the state of the organ. The inner surface, much thicker to the touch, is in contact with the glans, to which it has a membraneous attachment below, termed the frenum. The latter is continuous, on one side, with the internal membrane of the prepuce, and fixed, on the other, to the small longitudinal groove which we have described in the under part of the glans; and it ends in this situation by a prominent line fixed to the very opening of the urethra. The frenum limits the extent to which the retraction of the prepuce can be carried; but allows the organ either to be brought sufficiently forwards to cover the whole glans, or to be carried backwards far enough to expose its whole surface. In the latter state the frenum is on the stretch; and, if the prepuce be moved forcibly in this direction, it may even be torn, as in coition: this accident is particularly likely to occur, if the shortness of the fold allows only a partial exposure of the glans. Such a disposition of parts rendering the act of copulation painful, might require a portion of the frenum. The basis of the prepuce is attached, on the inside, to the base of the glans, behind which it is reflected so as to line the small channel already described in this situation. Its apex forms a large round opening, of a sufficient magnitude, in general, to allow the part to be drawn entirely back behind the glans; and, even where it is more contracted, much larger than the orifice of the urethra. In some cases its opening is so small as not to allow the retraction of the organ, and even to obstruct the flow of urine; this constitutes phymosis: in others, it can be withdrawn, but the tightness is so great that it may not be possible to restore it; that is termed paraphymosis. It has been affected of some races in the East that the prepuce is unusually long, and that this structure particularly favours the accumulation of the matter secreted by the glandulae odoriferae; so that circumcision has been more especially necessary on that account. 

E The
The integuments of the penis, having arrived at the base of the glans, are continued forwards to its apex, as far as the opening of the prepuce. There they acquire a different organization, are folded back in a contrary direction, and terminate by a firm attachment round the basis of the glans. The two layers, of which the exterior does not differ from the skin of the penis, except in being thinner, are connected by a stratum of very loose cellular substance, perfectly free from fat. The laxity of this cellular matter is so considerable, that, when the prepuce is withdrawn as far as possible, the two component layers are no longer in contact, but separated completely. The surfaces, by which they before adhered, are now applied to the corpora cavernosa, and the integuments of the penis are withdrawn towards the pubes. The prepuce seems designed to protect the glans, and defend it from the effects of contact, and rubbing against external objects. Yet it is not essential to the functions of the organ, that it should possess such a covering, as the destruction of it by circumcision or disease proves. The covering of the glans becomes afterwards thicker and harder, but the peculiar sensibility, excited in the performance of the generative functions, does not cease to be diminished.

The arteries of the male generative organs are chiefly furnished by the trunk of the pudendal; but the prostate and vesical feminales receive branches also from the vesical arteries. The integuments of the external parts have branches from the perineal artery, and from the vessels of the thigh. The veins of the penis unite, for the most part, into a large trunk at the middle of the upper surface of the organ, which passes under the symphysis pubis, and opens into a large plexus surrounding the prostate and neck of the bladder. These end partly in the hypogastric veins, and partly in the inferior meieenteric. Besides these there are superficial veins in the prepuce and penis, terminating in the saphena and femoral vein. The lymphatics of the penis are divided into superficial and deep-seated. The former arise from the prepuce and integuments, and go to the superficial inguinal glands. The latter, arising from the urethra and corpus cavernosum, enter the pelvis in company with the branches of the pudendal artery, and join the hypogastric plexus. The nerves of the penis are of considerable size, and are derived principally from the 2d, 3d, and 4th facial pairs.

Develoqement of the Male generative organs.—As the function of generation does not commence until a considerable period after birth, the development of its organs in the human subject follows a law derived from this circumstance. They undergo no remarkable change from birth till the age of puberty, at which time the processes of nutrition is carried on in them with great activity. But they may be observed at an early period in the fetus, where, without having any remarkable predominance over other parts, they are considerably advanced, as if nature, in sketching out the organization, had wished to mark distinctly the dilating and factional traits.

In the adult state, we shall describe merely the condition of the testes and seminal cord, as these are the only parts differing essentially at that time from the state in which they are found in the newly born child. The cells of the generative apparatus undergoes no remarkable changes, until the time of birth, and we shall therefore not notice them until that time.

There is no part in the body which undergoes so remarkable a change in its situation as the testicle; and, if it be interrupted in this process, a particular disease is very commonly occasioned. This organ, which, at its first formation, lies in the abdominal cavity at the inferior margin of the kidney, surrounded by the intesines, passes in the advanced periods of utero-gestation into the scrotum, and, as the canal through which it descended is shut up, never regains its original situation. At the time of birth, or very soon after, man and most other mammalia have both testicles in the scrotum. This remarkable change was first noticed and described about the middle of the last century, when many celebrated anatomists turned their attention to it, inasmuch that it is difficult to determine with whom the credit of being the first describer falls. The peculiar kind of rupture, called hernia congenita, which takes place when the defect of the testis is not accomplished in the regular manner, was the circumstance which principally led to the discovery, and more minute investigation of the facts. When surgeons began to reason on the causes and seats of ruptures, and the structure of the hernial sac, they naturally turned their attention towards these parts, and soon discovered that kind of the complaint in which the parts occupy the canal formed by the defect of the testis, and to which the name of congenital was given, because the fate of parts favouring its occurrence commonly exists at the time of birth. The examination of the origin and peculiarities of this affection, led to a complete elucidation of the whole affair, in a series of excellent publications.

Renaulde de la Car Une, a French surgeon, who wrote a treatise on ruptures in 1726, has the first hint on the subject; he speaks of the intesines and omentum escaping through the same canal at which the testis has passed out. Among the numerous claims, which the great Swiss physiologist potatoes, to the gratitude and respect of all medical men, is that of having given the first clear account of this matter. Indeed, there is hardly any part of the subject which has not been discussed and explained in the writings of this great man; and, as the observation of La Car Une is a single and indirect hint, we must assign the honour of the discovery entirely to Haller. (See Commerc. litterar. Norimargar, 1735, p. 197; 1737, p. 3. Programm um, hermitum observationes aliquot. Goetting, 1739. Opuscula pathologica, Laufanne, 1755.) Soon after these publications, the subject was taken up in England by the Hunters. Dr. W. H. according to his brother's statement, had found both testes lying in the abdomen in a still-born child of seven or eight months, some years before the publication of Haller's "Opuscula Pathologica," and could not explain the matter to his satisfaction. Mr. J. Hunter published a very full and accurate account of the original situation, and of its change in the testes. (See Medical Commentaries, p. 1 Lond. 1762, cap. ix.) About the same time the observations of Mr. Pott were made public. The vast practical opportunities enjoyed by this gentleman enabled him to explain all the pathological circumstances connected with the defect of the testis; his knowledge of the anatomy was probably derived from the sources already pointed out. (See account of a peculiar kind of rupture frequently attendant upon new born children, and sometimes met with in adults, London, 1765. Treatise on the Hydrocele, lect. 3. p. 12. Chirurgical observations and cases relative to ruptures, lect. 2.) Camper, who waited so successfully and peculiarly in surgical pursuits, investigated this matter with considerable attention, and gave the results of his labours to the public in the Harnens Transact. v. 6 and 7. The works of Neubaur and Lobelias must not be omitted in this enumeration; that of the former is entitled, "De tunica vaginalis testis et funiculorum histrici." Giese, 1767. The dissection of the latter, "De hernia congenita, instituta in corporum testis eft," Argentorat 1771, contains a very excellent and complete account of the whole matter, both in an anatomical...
cal and surgical point of view. In addition to these we have to notice, as containing good descriptions and useful information, the following more modern works. Girard's Appendix adjuncta tabulis polihumis Santorini. Palletta nova gubernacula testis Hunteriani et tunica vaginalis anatomiae descrip- 

Until the approach of birth, the testes of the fetus are lodged within the cavity of the abdomen, and may therefore be reckoned among the abdominal viscera. They are situated immediately below the kidneys, on the fore-part of the psoas muscles, and by the side of the rectum, where this intestine is passing down into the cavity of the pelvis; for in the fetus, the rectum, which is much larger in proportion to the capacity of the pelvis, than in the full-grown infant, lies before the bladder and urethra, as well as before the facium. Indeed the face is nearly the same with regard to all the contents of the pelvis; that is, their situation is much higher in the fetus than in the adult; the ligamentum of the colon, part of the rectum, the greater part of the bladder, the fundus uteri, the Fallopian tubes, &c. being placed in the fetus above the hollow of the pelvis, in the common or great abdominal cavity. At this time the figure of the womb is much the same as in the adult, and its position is the same as when it is in the ferotum, that is, one end is placed upwards, the other downwards; one flat side is to the right, the other to the left; and one edge is turned backwards, the other forwards. But as the testis is less firmly connected to the surrounding parts, while it is in the loins, its position may vary a little. The most natural forms to be when the anterior edge is turned directly forwards; but the leaf touch will throw that either to the right side, or to the left, and then the flat side will be turned forwards. It is attached to the psoas muscle all along its posterior edge, except just at its upper extremity. This attachment is formed by the peritoneum, which covers the testis and gives it a smooth surface, in the same manner as it envelops the other loose abdominal viscera. The epididymis lies along the outer and posterior edge of the organ, in the same relative position, which it occupies at a more advanced age. This part is larger in proportion, and adheres behind to the psoas. When the fetus is very young, the adhesion of the testis and epididymis to the psoas is very narrow, the part is consequently more loose and prominent. As its age advances, the adhesion becomes broader and tighter. The blood-vessels, like those of most parts of the body, commonly arise from the nearest large trunks; viz. from the aorta and cava, or from the umbilicus. The nerves too come from the nearest source; that is, from the abdominal plexuses of the intercoidal. In respect, therefore, to its supply of nerves and of vessels, this organ may be reckoned an abdominal viscus; and this circumstance of its peculiar situation before birth accounts for its being supplied afterwards from some remote source.

The vas deferens, instead of running upwards from the lower end of the testis, as it does at a more advanced period of life, goes downwards and inwards in its whole course; it continues, indeed, in the direction of the epididymis. It turns downwards from the lower end of that organ, behind the upper extremity of the gubernaculum, which we shall describe presently; then it goes over the iliac vessels, and the inside of the psoas muscle, somewhat higher than in the adult, and passes afterwards, in the direction already described, along the bladder. The cremaster muscle turns upwards, instead of descending over the pubes, and seems to be lost on the peritoneum near to the testis.
down towards the scrotum: but when the latter and the ligament are drawn downwards, then there is an aperture from the cavity of the abdomen all round the fore-part of the ligament, apparently ready to receive the testis. This aperture becomes larger when the testis descends lower, as if the pyramidal ligament was first drawn down, in order not only to direct, but to make room for the testis, which must follow it. The aperture is sometimes so large that the testis can be pushed into it, as far as the tendon of the external oblique muscle.

From this original situation in the abdomen, the testis moves downwards, at a certain period, to its defined situation in the scrotum. Its lower extremity comes into contact with the lower part of the abdominal parietes. At this time, the upper part of the ligament, which hitherto was in the abdomen, has sunk downwards, and lies in the pannus from the abdomen to the scrotum, which is afterwards to receive the testis. As the latter pusses out, it inverts the gubernaculum, going down behind it: what was the anterior surface of that organ now becomes posterior, and compasses the lower and anterior portion of the tunica vaginalis. Mr. Hunter states, that the place where the ligament is most confined, and where the testis meets with most obstruction in its descent, is the ring in the tendon of the external oblique muscle; and, consequently, that where the testis are not in the scrotum, they are more frequently lodged immediately within the tendon of that muscle, than included in the cavity of the abdomen. The testes commonly remain for some time by the side of the penis, and descends only by degrees to the bottom of the scrotum. When it has entirely descended, the ligament is no longer visible.

While the testis is descending, and even when it has pased into the scrotum, it is still covered by the peritoneum, and is connected by its posterior edge exactly in the same manner as when it was within the abdomen. The spermatic vessels run in the same way behind the membrane, the testis is fixed backwards to the parts against which it rests, and is unconnected and loose forwards, as it was when in the abdomen. In its descent the testis brings the peritoneum with it; but the elongation of that membrane, though it resembles, in some circumstances, a common hernial sac, in others is very different. If a person can represent to himself a hernial sac reaching to the bottom of the scrotum, and covered by the cremaster; if he can imagine, further, that the posterior half of the bag covers, and is united with the testis, epididymis, spermatic vessels, and vas deferens, while its anterior half lies loose before all those parts, he will have a perfect idea of the state of the peritoneum and of the testis when it first descends into the scrotum. This gland, therefore, does not fall loose, like the parts protruded in a rupture, into the elongation of the peritoneum; but it slides down from the loins, carrying the peritoneum with it, and both continue to adhere, by cellular membrane, to the parts behind them, as they did in the loins. The ductility of the peritoneum, and the looseness of its connection to the parts surrounding the testis, are circumstances which favour its elongation and descent into the scrotum with the testis.

It is plain, from this description, that the cavity of the bag, or elongation of the peritoneum, which contains the testis in the scrotum, must at first communicate with the general cavity of the abdomen, by an aperture at the abdominal ring. That aperture has exactly the appearance of a common hernial sac: the spermatic vessels and vas deferens lie immediately behind it, and a probe passes readily through it from the general cavity of the abdomen down to the bottom of the scrotum. And if this process of the peritoneum be laid open through its whole length on the fore-part, it will be plainly seen to be a continuation of the peritoneum; the testis and epididymis will be seen at the lower part of it; and the spermatic vessels and vas deferens may be observed, covered by the posterior part of the bag, in their whole course from the groin to the testis.

Before the testis has quitted the abdomen, the scrotum is small and corrugated, and contains nothing but cellular substance. This is loose, and yielding near the ring, but more dense and close below. Some have described a pouch of peritoneum passing through the ring, and therefore contained in the scrotum, previously to the descent of the testis; but this is not generally correct. There is no such pouch while the gland remains near the kidney. The parts about the ring are surrounded by such a loose and cellular texture, that, by drawing the gubernaculum downwards, the peritoneum is carried with it to as to represent a small cul-de-sac. The testis, too, after it has passed the ring, may be drawn up again into the abdominal cavity, in consequence of this laxity of the surrounding substance.

In the human body then, when the testis has recently come down, it is contained in a membranous bag, formed of an elongation of the peritoneum, and communicating with the abdomen by means of a narrow process, descending in front of the spermatic cord. The parts remain in this condition throughout life in the quadruped, but in man the communication between the membranous covering of the testis and the abdomen is soon cut off. The upper end of the canal is closed first, and the aperture is obliterated so speedily, that there is seldom any communication in a child born at full term. The process of contraction is continued downwards, along the cord, to the upper end of the testis, at which it stops. Thus the tunica vaginalis testis, which was in the first influence a production of peritoneum, becomes entirely separated from that membrane; the peritoneal covering of the gland is the reflected tunica vaginalis.

"This contraction and obliteration of the passage seems," says Mr. Hunter, "to be a peculiar operation of nature, depending upon ready and uniform principles, and not the consequence of inflammation, or of anything that is accidental: and, therefore, if it is not accomplished at the proper time, the difficulty of bringing about an union of the parts is much greater; as in children who have had the sac kept open by a turn of the intestine falling down into the scrotum immediately after the testis. "The closing of the mouth, and of the neck of the sac, is peculiar to the human species; and we must suppose the final cause to be the prevention of ruptures, to which men are so much more liable than beasts, from their erect state of body." We feel some hesitation in admitting this reasoning as to the cause of obliteration: at all events, if we should acknowledge it, the frequent occurrence of ruptures must prove that nature accomplishes her end very imperfectly. "What!" says the same physiologist, "is the immediate cause of the descent of the testis from the loins to the scrotum? It is evident that it cannot be the compressed force of respiration, because commonly the testis is in the scrotum before the child has breathed; that is, the effect has been produced before the supposed cause has existed. Is the testis pulled down by the cremaster muscle? I can hardly suppose that it is. Because, if that was the case, I see no reason why it should not take place in the hodge-podge, as well as in other quadrupeds; and if the muscle testis had this power, it could not bring it lower than the ring of the muscle."

The process, which we have now described, is liable to some variations. In some individuals, the neck of the peritoneal elongation is not obliterated, so that the tunica vaginalis
GERATION.

nalis communicates permanently with the abdomen, as in quads pedes. Hence, we sometimes see hydroceles particularly in children, where the fluid can be made to pass into the belly by pressure. If a rupture occurs in such individuals, it is contained, together with the testicles, in the tunica vaginalis. Sometimes the testes do not descend before birth; when they pass down after this time, a part of the intestine or omentum is liable to descend with them, and is of course contained in the tunica vaginalis. One or both may remain in the abdomen beyond the usual period. When the natural process has not begun, or has been interrupted before birth, it becomes afterwards very uncertain when the descent will be completed. It takes place most frequently between the years of two and ten, while the person is young and growing, being seldom delayed beyond the age of puberty. However, one or both of these glands may be retained in the abdomen through life. In this case, Mr. Hunter conceives that there is some imperfection in their formation. "I am inclined," says he, "to suspect that the fault originates in the testicles themselves." And again, "when both testicles remain through life in the belly, I believe that they are exceedingly imperfect, and incapable of performing the natural functions of those organs; and this imperfection prevents the disposition for their descent taking place."

The writer of this article has seen two cases, where one testis had remained in the abdomen, and where the circumstances of the case and other symptoms strongly circumstantial circumstances corroborated the opinion of Mr. Hunter. In one, the body of the gland was not more than half its usual size: the epididymis, which was very imperfect, ran for an angle behind the sac of the hernia, which had occurred in this individual, and did not join the body of the testis. The other case presented exactly the same appearances. A third instance has come to his knowledge, in which both of the testes remained in the abdomen, but were formed apparently perfect in their structure. In this case, it was understood, that the ordinary functions of the glands had been executed in a healthy manner during the person's life.

The times, at which the changes in position already described take place, are most accurately noted by Wriiberg in the memoir above quoted. He gives a tabular arrangement of his observations on this subject, deduced from very numerous examinations, of which the following account contains the chief particulars. "At the age of one month and three weeks, the testes were close to the kidneys, with the smallest possible interval; the ferotum loose and defective. At two months, the testes, exceedingly small, touched the umbilicus; the gubernaculum long; no canal passing through the ring, which was perfectly closed. Four months and two weeks, the testes near the ring, with a canal of peritoneum on each side, passing to the bottom of the ferotum. Five months and two weeks, both testes in the rings; so that they could not be seen until pressed towards the abdomen, when they appeared readily. Eight months, ferotum well formed, with its surface wrinkled, but empty. The testes had passed the ring, but remained in the neighbourhood of the groin: the right could be easily pushed back into the abdomen through the process of peritoneum, which was full open; but the left could not, as the communication was already closed. Nine months, testes in the bottom of the ferotum; the canal of communication perfectly closed on the left side; it was shut on the right by a solid cellular substance easily yielding to the probe. Nine months, both canals perfectly closed."

From the foregoing facts, the following conclusions may be drawn: 11. Before the beginning of the fifth month the testes have not passed the ring on either side; but generally remains near the kidney: so that this situation may be depended on as a proof of the immaturity of a fetus. 2dly. Between the beginning of the fifth, and end of the seventh month, they are generally found about the ring; being in some instances above it, in some within the canal, and in others just below it. 3dly. The ferotum in the first months, up to the fifth, is small in proportion to the body; sometimes loose, sometimes harder, but always containing cellular substance instead of the cavity, in which the testis is to be afterwards lodged. A broad and strong falciform ligament is contained in the midid of its cellular substance. 4thly. When the testes have first descended into the ferotum, the canal of peritoneum still opens to the abdomen, so that they can be easily drawn back into the belly, and link down again. This is generally practicable in fetuses, between the 7th and 9th months.

The ordinary law of nature on this subject is that, the human subject, born at the expiration of the full term of uterine gestation, has both testicles in the ferotum. Haller's contrary statement, "ut rarius fetus in lucem edatur, cum testiculis feroto inclivi." (Element. Physiol. vol. 7, p. 413.) has been completely disproved by the testimony of subsequent observers. Whether the canal of communication be generally closed before birth, is a point on which authors are not unanimous. According to Wriiberg, with whom Vieq d'Azyr agrees, this is commonly the case. But the representation of Camp is somewhat different: this anatomist and Lobstein observe, that the obliteration takes place earlier on the left than on the right side. Of 53 newly born children examined by Camp, 23 had the canal open on both sides, 11 on the right side only, and 9 on the left only. In 4 cases, the canal was closed on both sides. In these last cases, both testicles were contained in the abdomen; and in three only on the right.

In the excellent memoir of Wriiberg, already referred to, there is a table of 103 births observed by himself, in which the position of the testes was carefully ascertained. The proportion of premature to mature and perfect births was as 9 to 49; or in round numbers 1 to 10. All the children, whose weight did not exceed 5 lbs. came into the world at the beginning of the ninth month, or in the eighth, or even in the seventh month. Three of these had both testes in the ferotum, three in the groin, and three in the abdomen of the children born towards the end of the ninth month, 69 had both testes in the ferotum, 17 one or both in the groin, eight one in the abdomen, and three, whose weights were 5½, 6½, and 7½ lbs., both in the abdomen. In the 12 out of the 103 cases, where one or both testes remained in the abdomen, they were observed to descend on the days mentioned below.
in infancy it passed down on the day of birth; the deficient took place in three subjects on the second day, in an equal number on the third, in two on the fifth, and in one on the twenty-first. In the remaining individuals, they had not appeared on the fourth and fifth weeks from the time of birth; and as the children then left the hospital, the time of deficient was not known. In three instances, the deficient was observed to be accompanied with crying and convulsive motions of the limbs. Both tests had passed into the ferument of one child, born at the end of seven months, and weighing only 3½ lbs.; which must be deemed a rare occurrence. They have been seen in the ring in a fetus of four months. Bichat, Anat. Defer. t. 5, p. 234.

The colour of the organ, while in the abdomen, is greyish, and its form elongated. The epididymis is considerably larger in proportion than in the adult, and its head lies considerably above the testis: it is more loosely connected to the body of the gland. The confidence of the testis at this time is soft and pulpy.

The penis, at the time of birth, although small, is well formed, and poises an elongated prepuce, which completely covers the glans. The integuments of the penis, as well as those of the ferument, are not distinguished in colour from those of the body in general. The rugae of the ferument are not yet well marked. There is a small quantity of fat in the ferument, and the fibrous covering, common to the cord and testes, cannot yet be distinguished. The vesicule feminile, in consequence of the position of the bladder, peculiar to this age, are nearly vertical in their direction, very small and collapsed, and not exhibiting the tubercles on their surface seen in the adult. Internally they contain a mucous fluid.

The corpus cavernosum penis is very short and small, and remarkable for the small proportion of its spongy sub stance, and the trifling quantity of blood which it contains. The latter circumstance is less striking after a few years, in consequence of the increased thickness of the fibrous membrane: hence, as erection depends principally on the swelling of the spongy part of the corpus cavernosum, the penis of children, when erected in consequence of some sympathetic excitation, is hardly increased in size, and very little in length. The urethra, in the first years of life, is long; and its direction from the bladder to below the symphyse pubis is more oblique than in the adult. These two circumstances, in the conformation of the urinary canal, arise from the bladder being situated higher in the abdomen, and from the superior aperture of the pelvis being more flattened. The prepuce is elongated, so as to give the penis a pointed termination. Its opening, always very narrow, may be so small as to prevent the discharge of the urine, or to render it impracticable to denude the glans. The latter circumstance constitutes congenital phimosis. The frenum is narrow and reaches to the opening of the urethra.

No great changes are observed in the organs of generation from the time of birth until puberty. Filled with the general organization of man, and particularly attentive to the bringing to perfection the agents by which he communicates with surrounding objects, to the putting in action the springs of his intellectual powers, nature forms, if we may use the expression, to forget the instruments of reproduction, which continue for a time stationary. If, during this long period, the organs undergo no important revolution, they partake chiefly in the general growth. Each of them, considered singly, without increasing in any very marked degree, becomes more perfect in its organization, of which the principal traits may be more easily observed some years after birth. But these changes, which take place very gradually, are trifling when compared with those which happen at puberty.

Changes in the male Organs at the Time of Puberty.—In the two or three years immediately preceding this period, the pubes is covered by a flight down, which appears generally before the beard. We may remark also, that its appearance is more gradual, and its growth more rapid. In fact, the hair on the generative organs, although it is not completely developed for some years, has gained nearly its full length and thickness, while the beard is still thin and short. At the same time that the hairs appear, the skin of the ferument and penis loses its whiteness, and becomes more or less brown in conformity with the tint which it poises in other parts of the body. The ferument, hitherto contracted, becomes longer; the testicle is removed to a greater distance from the ring, and the spheric cord proportionally elongated. The penis becomes larger and longer; the frequent erections occasion the prepuce to appear shorter, and the glans to be a little uncovered. The various layers composing the ferument are complete at this time. The testis is proportionally larger than the vesicule feminiles and penis, as the exercise of the generative functions commences here. The vesicule feminiles are still very small, even in a subject of 14 or 15 years. The canal of the urethra, as well as the other parts of the penis, is considerably increased, as may be seen by observing the stream of urine.

In old men the ferument is generally soft and pendent, and external impressions are no longer able to bring it into the state of corrugation. The cellular substance which it contains is frequently the seat of watery effusion. The fibrous covering of the testicles and cord is dense, thick, and easily demaniflurable. The testicle is small, soft, and waffled; but without any remarkable change in its organization: the volume of the epididymis, on the contrary, is equal to what it possessed in the adult. The spheric cord is rather smaller, unless the veins should be in a dilated state. The vesicule feminiles are collapsed, and the proflrate becomes hard; the penis is constantly placid.

Physiology of the male Organs of Generation.—We shall describe, in the first place, the fecundating fluid, as it appears when expelled from the body in the act of copulation; and shall then distinguish the various parts of this compound liquor. We shall exhibit the facts which have been aforcinmed concerning this interesting subject, just as we treat any other part of physiology: we must either use such language as shall be intelligible, or pass over in entire silence every thing which relates to the production and development of the new beings, and the continuation of the species.

The fluid expelled from the urethra of a healthy man, under the influence of the vesical act, is white, inclining perhaps slightly to a blueish cast. But it is not homogeneous, as it contains thicker and more opaque mixed with a more thin and semipellucid matter. The latter is more abundant in proportion as the subject is weaker, and the act more frequently repeated. From this difference in the appearance of its component parts it has been sometimes compared to coagulated milk. It is of a viscid or glutinous nature, and therefore readily entangles air; hence it becomes frothy if rubbed in a mortar. When inr dischaged, its consistence is about equal to that of a thick cream; but as it cools, the opaque maculaginous part becomes transparent, and acquires greater confluence. In about twenty minutes after its emission the whole becomes liquid; at this time, too, it is transparent, having deposited a sediment of a whiffet matter, resembling a mass of flander rag. The liquefaction is not owing to the abstraction of moisture from the air, for it loses instead of acquiring weight during its exposure to the atmosphere;
The seminal fluid, in its recent state, contains an immense number of animalcula, called sometimes vermiculi spermatici. They have a rounded head, with a gradually tapering tail, not straight, but alternately bent to either side. They are 1000 times smaller than a hair, and 10,000 times more slender than one of the tubuli testis: so that, according to Leeuwenhoek, 216,000 of them would go in a sphere, equal in diameter to the breadth of a hair. Their length has been estimated at , a 4'-th of an inch. They are found in all quadrupeds, in reptiles, birds, fishes, insects, and even in tefaceous animals. Some variations in figure are observed in different animals; but their size is nearly uniform in all. They are no larger in a whale than in a small fish. They are said not to exist in children, nor to be observable after frequent coition, nor in old subjects; but only in healthy and prolific males, so that their presence may perhaps be deemed a criterion of the maturity and perfecfness of that fluid. The seminal vermiculi were first observed by a German youth, Lewis Hanne. He saw living animals in the human semen to Leeuwenhoek in the year 1677. This indefatigable observer immediately employed himself on the subject, and in the same year sent an account of the phenomenon, with drawings of the vermiculi in the dog and rabbit, to the Royal Society at London. (See Phil. Trans. n. 143.) The communication was received with great applause, the facts were shown to king Charles II, and admitted by all. At the same time they were examined and described in France, and, as far as the mere demonstration goes, they were universally admitted in the literary world Nicolas Hartsoocker claimed the discovery, but not till the year 1678. (Essais de Dieprique, p. 227.)

It has been alleged that these animalcula are not peculiar to the semen, but that they are found in various other animal fluids. Accurate investigation has not substantiated this objection; but, on the contrary, shews that they are peculiar to the seminal fluid. Others have denied that they possessed tails; and Buffon, in particular, represents the facts very differently from Leeuwenhoek. (Histoire Nat. Gener. & Partic. t. 2. p. 175 & seq.; his representations being supported by those of Turberville Needham. (Nouvelles Observations Microcopiques, p. 213.) M. De Buffon observed the fluid from the seminal vesicles of a dead human body yet warm. It was full of filaments moving about, and branching into many parts. The filaments swelling burlly, and many oval corpora amylacea escaped, which still remained attached to the filament, as by a thread: then they oscillated like a pendulum, and during those oscillations they were extended. The corpora amylacea, at length detached from the filaments, traversed the most fluid part of the semen, along with their filaments, the extreme length of which impeded their motions, and they seemed to him to endeavour to free themselves from it. Having diluted the semen with rain water, the microscopic view was better defined. It clearly appeared that each oval corporula had a double motion of oscillation, and of progression. In two or three hours the seminal matter acquired greater fluidity, the filaments disappeared; the number of corporula increased; the threads contracted; the oscillations relaxed; and the progressive motion increased. In five or six hours the oval corporula, having loit the threads, resembled animals more than ever; not only because their quivers in humming was greater, but because they directed their course to every quarter. In twelve hours the activity of the corporula was great; and some revolved upon their axis; others changed the oval to the globular figure under the observer's eye; some divided asunder, to that one formed.

G E N E R A T I O N.

nor is it owing to the action of the air, for it takes place equally in close vessels. It has been observed that the thick flaky portion is thrown out first; while the thinner part comes after. It is heavier than any animal fluid, and sinks immediately in water: but a part swims, consisting of white shining filaments, forming a cobweb-like texture, and composing small floating masses. That which sinks in the mucous or pulpy portion, which is the greater part of the whole; but of this little membraneous-like flakes are sometimes suspended by air bubbles. These sink to the bottom and disappear on the second day, but the water remains turbid, and contains fiocculi and white shining threads. Its odorous properties are very sensible; not irritating but mawkish and unpleasant, like the farina of the Spanish chef-nut. In animals it is said to be of a more penetrating nature; so that when absorbed it infects the whole body, and renders the flesh unfit for eating, unless the testes are cut out immediately after the animal's death. (See Buffon, t. 5. p. 121, of the boa.) The taffe is at first infipid; yet there is somewhat of pungency in it, which after some time stimulates and excites a degree of warmth in the mouth.

It converts paper stained with the blossions of mallows or violets to a green colour, and consequently contains an alkali. It diffuses readily in water, after its spontaneous liquefaction: alcohol or oxymuriatic acid precipitates white flakes from this solution. Acids readily diffuse the femen, and alkalies do not decompose this solution. Lime engages no ammonia from fresh semen; but after that fluid has remained for some time in a moist and warm atmosphere, lime separates a great quantity from it. Consequently ammonia is formed during the exposure of semen to the air. When oxymuriatic acid is poured into semen, a number of white flakes precipitate, and the acid loses its peculiar odour. These flakes are insoluble in water, and even in acids. If the quantity of acid be sufficient, the semen acquires a yellow colour. Thus it appears that semen contains a mucilaginous substance analogous to that of the tears, which is engendered by absorbing oxygen. Vauquelin obtained six parts of this mucilage from 100 parts of oxygen. When exposed to the air at the temperature of 60°, a pellicle forms gradually, and in three or four days small transparent crystals of phosphatw of lime are formed. Afterwards small round masses of the same substance are observed in the pellicle. If the air is moist, crystals of carbonate of soda may be formed. The evaporation does not go on to complete evaporation, unless in a temperature of 77° with dry air. When all the moisture is evaporated, the semen has lost 0.9 of its weight; the residuum is semi-transparent like horn, and brittle. When kept in moist air, at the temperature of 77°, it acquires a yellow colour, acid taint, and putrid odour. Exposed to heat, it becomes brown, and exhalates a yellow fume, having the odour of burnt horn. When the heat is raised the matter softens, becomes black, and gives out a strong odour of ammonia. When the odour of ammonia disappears, if the semen be lixiviated with water, an alkaline solution may be obtained, which, by evaporation, yields crystals of carbonate of soda. If the residuum be incinerated, there will remain only a quantity of white ashes, consisting of phosphate of lime. Thus it appears that semen is composed of the following ingredients:

100
At the end of one day the number diminished; and, upon the third, none were to be seen. In other fermen, which seemed to be entirely ameliorous, the ovular corpuscula did not proceed from the filaments; but those, dividing in two, were metamorphosed into corpuscula. They were embrittled by a thread. The longer it was, the more it impeded their motion; but it gradually contracted, and was at last completely destroyed. The figure of these ovular corpuscula resembled that of those of infusions. They swam with a progressive motion, though, at first, the thread occasioned a simple oscillation. He observed similar phenomena in the feminal fluid of other animals. Sometimes the corpuscula altered their figure; sometimes they divided into two. Buffon conceives that they cannot properly be deemed animals, and lie forms of them a particular class, under the term of *organic molecules*, which are particles disfigured through all matter, original, incorruptible, animated, and always active. Nor does he hesitate to confide the formation of the animated universe to these molecules. Subsequent researches have not confirmed these opinions of the French naturalist. That the feminal vermiculi have tails is proved by numerous accurate observers, and is particularly supported by the testimony of Haller. (Elem. Physiol. t. 7, p. 521.) It seems questionable whether Buffon ever saw the real feminal vermiculi; for the latter live at most only for a few hours after the discharge of the fluid, while these observed by him remained for some days. And his remarks on the whole seem much more applicable to the microscopic animalcula observed in vegetable infusions, as well as in all liquors exposed to the air. This point seems clearly proved by the labours of Spallanzani, who made a vast number of observations on the subject, and set the whole history of the spermatic animalcula in clear light; that no doubt can remain on the subject. The general result of his researches tends completely to confirm the original remarks of Leeuwenhoek. (See his Treatise on the Nature of Animals and Vegetables, Edinb. 8vo. 1799.) He observes that his experiments on fresh human femen presented him with totally different results from those described by Buffon, but as he could not regard Buffon's statements as purely chimerical, he thought the contradiction might be reconciled by supposing that the French naturalist had described animals of a different kind. "I had remarked," says he, "that there is no part of an animal which, when injured, does not give evidence to a particular kind of animalcula. They are produced differently, by the muscles, brain, nerves, membranes, tendons, veins, and arteries. The same holds good of the blood, serum, milk, chyle, saliva, &c. mixed with water, or even by themselves. I had not yet made experiments upon the human fermen for this purpose; but it was most probable, that the putrefaction of this liquid would give evidence to particular beings. May not M. de Buffon have confounded these with the feminal vermiculi, and ascribed to the latter those properties and phenomena exhibited by the former? I determined to ascertain this fact by observing what happened successively to the fermen, when long preserved in a watch-glass. I made my first experiments on the human feminal fluid. The vermiculi died in three hours and a half, and were precipitated to the bottom of the glass. Upon the fifth day, the feminal fluid began to exude a hectic and disagreeable odour; but I could perceive no animal being; only, upon taking some drops from the bottom of the glass, I observed the dead bodies of the vermiculi apparently very entire. The seventh and eighth days I saw no change, but the factor increased. On the ninth I discovered very minute animalcula, their size nearly equalizing that of spermatic vermiculi; but they had no tail, and greatly resembled molt minute spherules. Like animalcula of infusions, they sometimes flopped at little fragments of corrupted fermen; sometimes their course was very rapid, retrograde, rising and sinking in the liquid; in a word, they performed every property of infusion animalcula. They were seen in every stratum of the fermen; and those at the bottom put in motion the dead bodies of the feminal vermiculi, which were full entire, and remained fome days longer." Two or three successive generations of these animals were observed, as in the case of other animalcula. When the fermen was exposed to a greater degree of heat, they appeared at a more early period, even as soon as twenty-three hours from the removal of the fluid from the dead body. In one instance they were observed to propagate by a spontaneous transverse division of the body. "These facts sufficiently satisfied me that Buffon had erroneously ascribed to the spermatic vermiculi properties belonging only to the animalcula of infusions. Let us, in a few words, collect the circumstances. According to this author, after a certain time, the vermiculi were deprived of their tails. He should have said that the animalcula of infusion came in the place of the vermiculi, which were already dead, and precipitated to the bottom of the liquid. He was arrested by their first appearance; and took them for feminal vermiculi deprived of their tail, which in truth they often very much resemble. When deflagraged from the tail, Mr. Buffon adds, they acquire greater activity. This was a necessary consequence of the first mistake. When the infusion animalcula had taken place of the vermiculi, their increased agility could not be unobserved, since the animalcula move with much greater quickness than the vermiculi. This erroneous supposition being admitted, Mr. Buffon had to relate, as he has done, the remainder of the phenomenon. He had to speak of the imaginary changes of the vermiculi, of their division, and their diminution, with the more confidence, as his opinions had to be confirmed by a repetition of his experiments, if not upon all, at least upon many species of infusion animalcula in the fermen." p. 135-142. The following account of the spermatic vermiculi is taken from the work of Spallanzani already quoted, which contains the most complete account of the subject.

When the femen begins to dissolve, if it be examined with a magnifier of small power, the irregular parts seem to be in an indistinct fluid agitation, produced by globular corpuscula, of which each poffesses a form of filament, or short appendage, about six times the length of the body. They have two motions; one oscillatory, from right to left, and vice versa, in which the appendage is curved from one side to the other; the other is progressive, the vermiculus transporting itself by oscillation. They strike against every obstacle, and when in considerable numbers, make a thousand contortions to escape, at last taking that way where they feel the least resistance. Thus they are in continual motion. In twenty-three minutes the motions of oscillation and progression had diminished; and in an hour and a half it had lessened so much, that a very small number of corpuscula possessed any power of motion. In general, the progressive motion ceases before the oscillatory; so that, at last, the corpuscula merely bends from right to left, and reciprocally. They continue fixed to the same spot, until the oscillatory motion insensibly dies away. After all motion is gone, the corpuscula remain entire in the fluid, and then they are better seen than even when the liquid is diluted with water. Each corpusule is not properly globular, but elliptic, and the appendage is not only longer than it appears, but the breadth is not equal throughout like a thread, but increases
as it approaches the body. Water or other fluids rendered them immediately motions. They may be sometimes observed, in the clots of the semen, before they have dissolved, attached by their appendages to the filamentous matter: they struggle to disengage themselves, and then swim about in the fluid. The motion continues much longer when the temperature of the atmosphere is increased; at 36° all motion had ceased in three quarters of an hour: at 49° in two hours; at 59 in three hours and a half: and at 61° they lived for seven or eight hours. The spermatica were seen in the fluid obtained from the epididymis and deferens of various living and recently dead animals. That they are not formed, according to the sentiment of Buffon, from the filamentous part of the fermen, is proved by this; that they are molt abundant in the fluid part, and even do not exist at all in the clots, where they are examined in a very recent state, and freed as much as possible from the thinner part of the seminal fluid; while the latter, at the same time, abounds with them. Nor are they generated, as Needham affected, by exposure to air. For Spallanzani saw them in the usual numbers, when the time employed in taking the fluid matter from the seminal vessels still warm, to present it to the microscope, did not exceed a second; and they were observed in the same numbers in seminal fluid carried without delay from the epididymis of a living ram to the microscope.

Great care and attention are necessary in oberving the appendages of these vermiculi, and hence they escaped the notice of Buffon. It is wonderfully slender, and at the same time transparent, so that too strong a light confounds it with the seminal fluid: the slider should be fine and thin, and the drop of fluid very thin, and a microscope of a single lens is preferable to the compound one.

They live longer in close vessels, than when the semen is exposed to the air: and they also live longer in vacuo. The difference of time at which they die in these different situations amounts even to one, two, or three hours. These facts prove that the air is noxious to the vermiculi, and the following prove that it is the cause of their being in continuall agitation. With the blow-pipe I formed capillary tubes; one end of which I immersed in recent semen; it ascended the cavity, filling the tube to a certain height. Breaking the tubes near the part to which it ascended, I prevented this extremity to the blow-pipe, and immediately sealed it hermetically. I did the same to the other end, by which means the seminal fluid was deprived of all communication with the external air. I drew out the tubes, so that the spermatica of the tubes permitted me to see the vermiculi within. The peculiarities presented by the vermiculi in the tubes were very different from those of the rept. All, or at least most of them, had a singular mode of moving. Some had that sort of activity observed in thefey, which experience the influence of the open air. Others had a continued irregular motion; they changed from quickness to inactivity, and reciprocally. Others stopped entirely, and, after resting some minutes, resumed their former velocity; besides, they were not observed to run against the solid portions of the semen, but to avoid them by turning aside or retreating. These peculiarities always succeeded better, and with more uniformity, when the tubes were kept warm. I have before said that the longest period of life, of the human spermatic vermiculi, was four or eight hours, when exposed to the open air, but this period is greatly prolonged when they are included in tubes. In summer I have succeeded in preserving them two days or more; and in spring and autumn they have lived almost three years. P. 158.

Cold, near to that of freezing, renders the vermiculi motionless; but they are recovered by the application of heat.

Vol. XVI.

A temperature of 131° kills them; but the animaeula produced in the semen by putrefaction are destroyed by a temperature of 108°.

To this account of the feminal vermiculi we subjoin the following reflections on them by Bonnet, observing only that we are in a state of the most profound ignorance of all the points alluded to in his queries.

"The vermiculi are, of all the animaeula of liquids, those which have most excited my curiosity: the element in which they live, the place of their abode, their figure, motion, secret properties, all, in a word, should interest us in so fingular a kind of minute animated beings. How are they found there, how are they propagated, how are they developed, how are they fed, and what is their motion? What becomes of them when the liquid they inhabit is returned by the vessels, and mixed with the blood? Why do they appear only at the age of puberty; where did they exist before this period? Do they serve no purpose but to people that fluid, where they are so largely scattered? How far are we from being able to answer any of these questions?" Spallanzani's Tracts, p. 179. The reader may also consult, on this subject, W. F. von Gleichen über die Saumen-unck infusions-thierchen, Norimb. 1778, 4to.

The opinions of Leeuwenhoeck concerning these vermiculi; viz. that they are of different sexes, that they copulate, become impregnated, and produce young; and that they are the rudiments of the future beings, to be conveyed by copulation into the body of the mother, and there developed; are destitute of all proof, and completely chimerial.

We have no accurate accounts of the sensible properties, nor any chemical history of the fluid separated in the testes. When observed in the vas defecres or epididymis of man, after death, it poisons a light-brown or yellowish colour, and approaches in fluidity to water. It may be seen in animals, on cutting into the testis or epididymis, much thicker, viscous, and of a grey colour. At least it has this appearance in a dog. The whole gland, in a healthy animal, is tinged with this fluid. The contents of the vescicle feminales differ in their appearance from the secretion of the testes. It is a brownish or yellowish fluid of light colour, semi-transparent, and often containing flakes or coagula, so as to vary in consistence in different parts of the bag. Expose to the air produces no change in its consistence, as it does in the semen. Sometimes the contents of these bags are a clear mucous fluid. Mr. Hunter took the trouble of observing them, in two healthy persons killed suddenly, immediately after death. In one the fluid in the vescicle was of a lighter colour than is usually found in men who have been dead a considerable time; but it was not any means like the semen either in colour or smell. In the other the contents of the vescicles were of a lightish whey colour, having nothing of the smell of semen; and in this fluid a flat, as to run out on cutting into them. Ob. on the animal Economy, p. 289. Thus it appears that the fluid of these bags differs both from that contained in the testis, and from the semen emitted in coition; consequently, that they are not merely reserves for the matters separated in the testis, but that they add to the secretion that gland some considerable bulk of fluid, separated by their own vessels. The peculiar organization of their internal surface would have led us to expect this, as it exhibits an arrangement of parts found only where some secretion is performed. The same argument will lead us to allign a similar function to the enlarged portion of the vas deferens lying by the side of the vescicle feminales. The exact nature of the fluid separated in the vescicle
GENERATION.

is not known; nor have we any chemical analysis of it. In many instances it looks like a simple mucus; and there can be very little doubt, that in all cases the contents of these bags consist chiefly of their own secretions.

The opinion, that the vesicles perform a particular secretion, was held by Haller: "I have," says he, "no experiments of my own to prove that any thing is separated in these organs, and mixed with the fluid formed in the testes. I suspect, however, that a secretion takes place here in the gall-bladder." (Elem. Physiol. 7. p. 542.)

Galen conceived that the semen was generated in these parts; and Riolan, Rayuch, and Swammerdam, were of opinion that they added something to the seminal fluid. The point has been most clearly proved by Mr. Hunter in a paper contained in his Observations on the Animal Economy, and entitled "On Observations on the Glands situated between the Rectum and Bladder, and called Vesicles feminales." His chief argument is derived from the examination of the organs in persons who have lost one of the testes by accident, or in consequence of disease. It is well known that this loss does not affect the generative powers, and that such individuals retain their normal appetites and the faculty of procreation. We may consequently premise that they have afterwards had connexion with women, and consequently had the action of emission, which must have emptied the vesicle of the castrated side, if it had contained semen; and, as the removal of the testis must have cut off all source of supply from that quarter, it should be found empty after death, on the supposition of its contents being ordinarily derived from the testis.

Such cases also afford an opportunity of making comparative observations between the vesicle of the perfect and that of the imperfect side.

"A man," says Mr. H., "who was under my care in St. George's hospital for a venereal complaint, died there, and was discovered to have lost his right testicle. From the cicatrix being hardly observable, it must have been removed some considerable time before his death; and the complaint, for which he was received into the hospital, is a convincing proof that he had connexion with woman after that period. I inspected the body in the presence of Mr. Hodges, the house surgeon, and several of the pupils of the hospital. Upon dissecting out, and examining the contents of the pelvis, with the penis and urethra, I found that the vesicula deferentis of the right side was smaller and firmer in its texture than the other, especially at that end next to the abdominal ring, near to the part that had been cut through in the operation. The cellular membrae surrounding the duct on the right side was not so loose as on the left; neither were the vesicles which ramified on the right vesica fo full of blood. But upon opening the vesicles, both appeared to be filled with a kind of mucus similar to that which is found in other dead bodies; and the vesicle on the right side was rather larger than that on the left. Whatever, therefore, may be the real use of these vesicles, we have a proof from this direction, that in the human subject they do not contain the semen.

"In a man who died in St. George's hospital with a very large bubonoele, the testicle of that side was discovered to have almost lost its natural texture from the pressure of the bursa; and upon examining the testicle with attention, there was no appearance of vesicles till we came near the bladder, where it was almost as large as usual. The vesicle of that side was found to be as full as the other, and to contain the same kind of mucus.

"I extinguished the left testicle of a Frenchman on account of its being diseased. He was a married man, and died about a year afterwards, having been extremely ill for several months before his death. On examining the body, the vesicle were both found nearly full; more especially that of the left side, which I suppose might be accidental. But upon examining the vesicles of the left side, where it lies along the side of this bag, and where it has a similar structure with the vesicle, I found it filled with the same kind of mucus; and this, I believe, is always the case, whether the testicle has been removed or not.

"A young man, a coachman, who had a diseased in his left testicle, had it removed, at St. George's hospital, by Mr. Walker, in August 1755; and in February 1786 he returned again to the hospital, on account of uncommon pains all over him, and for which he requested to be put into the warm bath. But as he was going from the ward to the bath, he dropped down, and died almost immediately. The body was inspected, with a view to discover the cause of his death, and upon an examination of the vesicles, the bag of the left side was as full as that on the right, and the contents in both were exactly similar.

"In dissecting a male subject, in the year 1755, for a diseased view of the contents of the pelvis, I found a bag on the left side, lying contiguous to the peritoneum, just on the side of the pelvis, where the internal iliac vessels divide above the angle of reflection of the peritoneum at the union of the bladder and rectum. The left vesicula deferentis was seen passing on to the bag; and, what is very singular, that of the right or opposite side crossed the bladder near its union with the rectum to join it. I traced the left vesicula deferentis to the testicle; but on following the right through the ring of the external oblique muscle, I discovered that it terminated at once, about an inch from its passage out of the abdomen, in a blunt point, which was impervious. On examining the seminal cord from this point to the testicle, I could discover no vesicula deferentis, but by beginning at the testicle, and tracing the epididymis from its origin about half way along, where it lies upon the body of the testicle, I found that it at first became straight, and soon after seemed to terminate in a point. The canal at this part was so large as to allow of being filled with quicksilver, which however did not pass far, so that a portion of the epididymis was wanting; and the vesicula deferentis for nearly the whole length of the seminal cord of the right side. On the left side the vesicula deferentis began, where the epididymis commonly terminates; and there was a deficiency of nearly an inch of the extremity of the duct. I then dissected the bag above-mentioned, which proved to be the two vesicula; for by blowing air from one vesicula I could only inflate half of it; and from the other vesicula, the other half. They contained the mucus commonly found in these bags; but upon the most accurate examination I could discover no duct leading from them to the prostate gland, nor any remains of one. In this subject it was evident that there was no communication between the vesicula deferentis and epididymis; nor between these bags and the urethra. The caput gallinae had the common appearance, but there were no orifices to be seen. The testicles were very full; and the ducts from them to the epididymis were very manifest, and full of semen." P. 30—32.

Mr. Hunter observes further, in support of his opinion, that these bags are as full of mucus in bodies much emaciated, where the person has died from a lingering disease; as in strong robust bodies where death has happened from violence or acute diseases; and they are nearly as full in the old as in the young; which most probably would not be the case if they contained semen. Ibid. p. 33.

The secretion of the prostatic is the last ingredient in the seminal fluid; and it contributes very largely to the bulk of
what is expelled in copulation. Its opaque whitened and
ccdent is completely obscure the properties of the fluid ex-
ited in the testis, and beded on the femoral liquor most
ous obvious characters. The opinion which supposes that the
femen is formed, or that part of it is produced in the prostate,
is not that which is so far from the truth. A thick, white,
and opaque liquor may be expressed in considerable abundance
of the prostatic ducts on each side of the caput gallinagi-
ies after death. Physiologists ascribe to the prostatic fluid
the office of increasing the bulk of the semen, and of thereby
augmenting its impetus, so that it may arrive with greater
force at the place of its destination.

It has been conjectured that a nervous fluid is mixed with
the semen, and hence the weakness of the male after copula-
tion has been explained. We may be excused from discoursing
this opinion until we know what nervous fluid is. The
convulsive exertion of the whole frame, which occurs in the
venerale organs, will sufficiently account for the sense of
fatigue that follows it.

It appears from what we have said, that the fluid expelled
in copulation is furnished in a small proportion only by the
testis; that a peculiar secretion of the vesciculae feminales is
added to this, and that the chief bulk is made up of the
prostatic liquor. An important question arises here, which
of these is the essential and immediate agent in impregnation?
The general practice in the East, continued from ages of the
most remote antiquity, of entrusting their females to the
care of eunuchs, and the common operation of gelding, as
performed on various domestic animals, lead us to assign this
prerogative to the fluid secreted in the testis. In emascula-
tating animals, or men, the testes are cut or torn out, or they
are comprized so as to destroy their organization, or the
cord is squeezed or brunned so as to annihilate the functions of
the part. Yet, under the circumstances just enumerated, we read of numerous examples where venereal defiles have been
experienced, where erection, copulation, and emission
have taken place, and even where children have been be-
gotten. These examples, however, are too repugnant to the
general effect of castration, as observable in man and animals,
to allow of our admiting them.Ordinarily we observe not
only that no defiles are felt, but also that the lost of the
organs, in which the natural and leading stimulus resides, oc-
casions the other parts concerned in the business of gener-
ation to be much diminished in size, and altered in appear-
ance. Where emasculatio has been performed merely by
comprizing the cord or testis, the organization of the part
may not have been destroyed sufficiently to interrupt its
functions, and such an animal might be still capable of fecun-
dating; but no well authenticated instance can be produced of
impregnation being effected where the testes had been cut
out in any male animal. Yet it cannot be doubted that
eunuchs may have erections, since the heat of the physical
feeling is in the glands, and the whole apparatus concerned in
erection remains entire after the loss of the testis. A
man, after the latter occurrence, like one who has lost his
powers through age, may at times be flattered by the re-
collection of past joys. Hence, in the East they value
those eunuchs most highly, in whom the penis as well as the
testes has been removed; no caufe for the slightest jealousy
can then remain. The prostatic liquor, or that of the vesi-
culae feminales, might be discharged in the eunuch. If an
animal has impregnated another after castration, there may
have been some semen remaining in the vesciculae feminales.

Besides the facts now enumerated, we may observe that
all animals which copulate have testes; but that several have
either no prostate or no vesciculae.

The secreted semen is either expelled from the body, ful-
filling the purposes of its formation; or it is retained in its
receptacles, and taken up by the-absorbsents. The femoral
veins are always full of their peculiar fluids, which are only
discharged at considerable intervals, and often only at peri-
ods of some months or years. As the testis and vesciculae
feminales possess numerous absorbes, we cannot doubt that
the contained fluids are conveyed by these vessels into the
general circulation. It has been a general opinion that this
abssorption produces many of the changes which are well-
known to take place at puberty; and which obviously depend, as we have already shown, on the testes. We refer
to a former part of the article on this subject. The males
of animals, when the rutting season approaches, have their
whole bodies penetrated by a singular fector, so that they are
 unfit for food. The flesh at this time putrids more rapidly
than at other seasons in the flag. That absorbed semen is
the cause of this factor; is rendered probable by the fact,
that the removal of the testis destroys it; and by its absence
from castrated animals of the same species. The same cau-
horns has been ascribed to the phenomena consequent on concep-
tion in the female; but this seems very doubtful. This
absorbed semen has been supposed by physiologists to act as a
stimulus on the heart, and the organs of motion, to increase
the muscular strength, and to contribute thereby to health
of body and strength of mind. Hence, too, they have ex-
plained the softness and impudence of the flesh observed in
some animals after the copulating season; as, for instance,
in the boar. The flesh of the feline is remarkably charged
in colour and flavour at this time. Castration produces de-
bilitating effects both on the body and mind of man and
animals; the ferocious and powerful bull is changed into the
milky and patient ox. The influence of the same proceeds in
mankind has been already noticed; and we have sufficiently
proved that the remarkable development of the frame at the
time of puberty arises entirely from the influence of the
testicles. And it is not less true that the rest of the femail
organs are particularly affected by the presence and activity
of the testicles. In this country we have little or no oppor-
tunities of observing in eunuchs the effect of the mutilation on
the other organs of generation; but we can see the con-
sequences in animals. In Mrs. Hunter's opinion, the penis,
urethra, and all parts connected with them, are so sub-
ervient to the testicles, that he conceives that few of them
would have existed if there had been no testicles in the or-
ginal construction of the body; these parts would then have
been so formed as to assist merely in the expulsion of the
urine. To illustrate this opinion, let us observe what is the
difference between these parts in the perfect male, and in a
male that has been deprived of the testicles when very young,
at an age when they have had no such influence on the ap-
imal economy as to affect the growth of the other parts. In
the perfect male the penis is large; the corpora cavernosa
being capable of dilatation. The corpus spongiosum is
very muscular; and that part of the canal which is called
the bulb is considerably enlarged, forming a cavity; the mus-
cles accelerators urine, as they are called, are strong and
healthy. In many animals which have long penises, they are
continued forwards to the end of it, and in others they are
not extended so far, but are very large. On the contrary,
in the castrated animal, the penis is small and not capable of
much dilatation; the corpus spongiosum is less muscular; the
cavity at the bulb is little larger than the canal of the
urethra; and the muscles are white, faint, and have a lig-
amentous appearance. The latter observations are true, if ap-
plied to the eunuchized penis. The penis of the perfect male
is of sufficient length, when erected, to reach to the furth-
er end of the vagina of the female. In the castrated animal ft
is much shorter; and erections having thus become unneccessary, the parts which should project often adhere to the inside of the prepuce. The prolate, Cowper's glands, and the glands along the urethra, of which the lumen are the excretory ducts, in the perfect male, are large and pulpy, secreting a considerable quantity of a thin mucous, which is soft to the touch, is most probably for the purpose of lubricating those parts, and is only thrown out when the animal is in vigour for copulation; while in the castrated animal they are small, flabby, tough, and ligamentous, and have little secretion." Animal Economy, p. 39.

It must be acknowledged that we have no direct proof that any actual absorption of semen takes place from the testicles or vesicular, and from physiologists deny it altogether. "I very much doubt," says Blumenbach, "whether real semen be ever absorbed from its vesicular reservoirs in a healthy man;—still more of what has been occasionally ascertained, that it is immediately conveyed into the neighbouring veins; and most of all, that such absorption (supposing its existence to be granted) should be considered as a provision against premature venereal stimuli. On the contrary, if we compare the phenomena observed in animals, the impetuous irresistable nature of their desires at particular seasons of the year, with the constitution of such as are castrated, we shall rather deem such absorption the cause of that ungovernable and almost furious appetite. I conceive that a very different means (peculiar, as far as I know, to the human subject) has been adopted to answer the purpose just alluded to; viz. nocturnal emissions, which I refer to the natural excretions of man, inasmuch as their more rare or frequent occurrence, according to varieties of temperament and constitution, serves to liberate him from the troublesome and inconvenient consequences of an abundant seminal secretion. It may be readily granted that barbarous nations, of a phlegmatic temperament, and practising irregular sexual intercourse, do not require such an excretion: yet, I think it must be deemed a very natural and suitable relief in a young unmarried man, of a furnace temperament, plethoric habit, lively and warm imagination, particularly if he indulges in a luxurious mode of life and enjoys perfect health. See Chr. Rud. Arenich de pollucione nocturna. Götting, 1790, etc., Inst. Physiol. sect. 36.

The length of course, and the small diameter of the spermatic artery, together with the impotibility of forcing any injected fluid from its branches into the secretive tubes of the testicles, have led physiologists to conclude that the secretion of the seminal fluid is performed very slowly. But various circumstances are capable of accelerating this process.

"Princeps et amor," says Haller, Elem. Physiol. 7. 551. "Nemo forte fuerit, quin in juventute suam feminam concupiscent; quin si castra fuit, in ejus familiaritate ignes conceperit occultus: quia semen cum dolore et incommodo sibi tetes intumescere, et vasa feminah; dolore certe tanta, ut vix tangere poffet eam regionem, vix incedere. Manifesto in hoc malo accelerata est secrerio feminun, ejusque liquoris major penes tellent diffundit. Id mal genus e reddita tranquillitate animi, et abstinentia amote feminze sedatur; et culerus etiam fanaturn frutine capite puelae, et fœnurn remedium acceserit in difficiles tumores abire poterit. Quare in univcrsim, ut plurrimum ad movendam venerem irritamenta fœciunt defecatar feminem, aut imagines aspicet lubricae, aut alia quacunque, quae per legem affociationem ideorum voluptatis memoriam renovant; ita abstinent ejusmodi stimuli, et cogitaciones perpetuas ad alia aerever, ipsoque religio, ita minuent feminis generationem, ut multo minori copia gignatur, neque molestum fit, et denuo vasa feminis pene confectum, et genitalium moles ipsa diminuatur." A healthy and strong state of the animal, nutritious and perhaps rather generious food, and a certain warmth of the weather, promote the seminal secretion. All these circumstances dispose the organs for action, when the natural feelings are duly excited; and the opposite causes, as infirm health, fatigue, insufficient or bad food, and considerable cold, prevent the feelings or dispositions necessary for the action of the generative organs from taking place. The reproductive function is so much influenced by the season in animals, that it is only carried on at a particular time of the year; and the leading organs (the testicles) are reduced in many instances to a very small size in the winter. But in man, and in such domesticated animals as are not in a state of nature, no such change takes place in the testicles; they are consequently always in good condition, and in that state to which other animals that are left to themselves, can only attain in the warmer season.

That the semen, secreted in the very same tubuli of the testis, is conveyed from them into the epididymis, and thence into the vas deferens, is sufficiently obvious from the anatomical structure. De Graaf proved it still further, by tying the vas deferens of a dog before copulation; all the secreting tubes were diffused to the utmost, and the testis considerably swelled.

We cannot doubt that the secretory vessels of the testis propel their contents by some contractile power; although the specific manner in which this is effected escapes our observation. Does the elevation of the testis to the ring, by the action of the cremaster, constantly observed to accompany emission, promote the progress of the secreted fluid? The immense length and numerous turns of the feminal tubes must render the passage of this fluid from its first secretion very slow: hence, when the supply contained in the vesicle is entirely exhausted, an intermission of some time is necessary for the reproduction of a sufficient supply; hence too, in the dog, where there are no vesicle, the act of copulation is unumultaneously prolonged.

It has been generally considered that the fluid produced in the testicles is deposited and retained in the testes feminales, as in revours, until occasion occurs for its discharge. Mr. Hunter has endeavoured to shew that these bags are not to be regarded in the light of receptacles for the semen, but as defined to perform a peculiar secretion. The common opinion rests on the facts of the very free communication between the vasa deferentia and vesicule, on the course which injected fluids take in the dead body, and the extreme minuteness, numerous convolutions, and great length of the feminal tubes, which seem very unfavourable to the production of semen in the sudden way, and at the very short notice at which it must be formed, if we do not suppose it to come from the vesicule. We have already detailed the proofs by which it appears that these organs perform a secretion; but none of those facts shew that the contents of the vesicule may not confill, in part, of matter formed in the testis. We know that the gall-bladder produces a copious secretion of its own; but that it also receives bile from the hepatic duct by the ductus cysticus. Mr. H. endeavours to adduce a decisive argument from comparative anatomy: he states that in many animals, the parts corresponding to the human vesicule feminales have no communication with the vasa deferentia, and moreover, that their structure, in several instances, seems little calculated to make them revours. Where the obvious structure is so different, we are by no means warranted in concluding that the functions are exactly similar. To argue that the semen does not pass into the vesicule of man, where the vasa deferentia are so intimately connected to those bags, because the analogous parts are not connected in other animals, is not more reasonable, than it would be to
affirm that the fluid of the vasa deferentia pales into the vesicle in animals, where the two are not connected, because the structure leads us to infer that it does so in man.

Mr. Hunter continues, "we may likewise infer, from what has been said, that the semen is not retained in receptacles after it is secreted, and kept there till it is used; but that it is secreted at the time, in consequence of certain affections of the mind stimulating the testicles to this action: for we find, that if laborious ideas are excited in the mind, and the paroxysm is afterwards prevented from coming on, the testicles become painful and swelled from the quantity of semen secreted, and the increased action of the vesicles; which pain and swelling are removed immediately upon the paroxysm being brought on and the semen evacuated; but if that does not take place, the actions of the vesicles is still kept up, and the pain in the testicles will generally continue till the paroxysm and the evacuation of the semen are brought on, which renders the act complete; without which a drop cannot be put to the action of the vesicles that produce the secretion, nor the parts be allowed to fall back to their natural state. There is at this time no sensation felt in the situation of the vesica femorales. The pain in the testicles, in consequence of their being filled with semen, and the action being incomplete, is far more considerable as to make it necessary to produce an evacuation of the semen to relieve the patient." Animal Economy, p. 33.

We certainly admit with Mr. H. that the vesica femorales of the human subject perform a particular secretion; but we do not conceive him to have succeeded in proving that they are not also receptacles for the semen.

The opinion, which denies the vesica femorales to be receptacles for the semen, is defended also by J. A. Chaptal, in the "Journal de Physique," February 9, 1787, p. 101. Solembering has refuted it in the third vol. of Blumenbach's Medicinische Bibliothek, p. 87.

The transmission of the semen, from its ducts or vesica, into the urethra, takes place under the influence of a particular fluid of mind; and its expulsion from the body is effected, in all animals which have a penis, by mere action of what is called the erection of that organ. In the human subject, this is an increase of volume produced by the dilation of the three corpora cavernosa. Among the exciting causes of this process, we may enumerate, in the first place, the presence of a sufficient supply of seminal fluid: when this is present, any additional stimulus easily produces the effect. Hence, we observe, that the venereal powers of animals are the greatest, when their testes are of the largest size; hence, too, we may perhaps explain the erection sometimes observed after a full meal. A fecond and more powerful excitement is derived from mental causes. "Alterca causa," says Haller, "in fano homine eft imaginatio, quae cupidum vened, quod ex quacunque caufa orta, lectione, viia pictura, memoria voluptatis prifine, confabulatione, tactu, et aliis cauis, in fano homem continuo in ereessment crumpit. Eadem nocturnam illam et solitariam venerem folam abolescit, qua fe natura nimii feminis onere liberat variis, pro varia feminis abundarius, et feno acorbi aut obtufiori, intervallis. Nam puere facillima, femibus ex venus rarior eft, aut nulla. Soli homo data eft, forte quod homo potifsimum memoria et imaginatio valeat. Imaginacionem folam, non erectionem, fed plenam venerem, etiam in vigilan- 

tibus perfecte adfunt testimonium. Quae poterit abfque imaginatione excitata unquam hoc opus perfici; ut turpi, ne

que habentis adamant in femina venus vix exerceri posset. Inde ille impotentia et vereundis, ex imaginaria depletatione, quod fecemum revocat, aut ex odio, quod quidem species cum relativa potestate conjuncta eft. Hinc manifesta iniquitas ejus legis, quam ex congresso de virilitate mariti judicabat, quoniam in exofo uxor, post funeralm injuriam palam, in conspecus tot hominum, feruam opartcter effe, ut ius cum imper- 

dimentis venerae vurae perficit. Quare in Gallia anno, 1677, die 18. mensis Januarii, ridicula lex abolita fuit, cum Marchio de Langey, a judice poti congreffum pro impio 
dente damnatus, disfunto matrimonio, cum alia uxor multis filios generatet." (Element. Physiol. 7. 557.) The peculiar odor exhaled from the female organs, particularly at certain seasons, is a very powerful incentive of venereal feelings in the animal kingdom. Haller considers that this cause acts in the human race also. "Propius partes gentiles ipas adicit, et excretionem extortur, auget et perficit, frictis glandis, et potissimum collicularum, qui sunt rubis urethrae, quonqueque fide modo ca frictio administratur. Sed ea cum voluptate peculiari, fumbo, pene anima, conjugitur, aqua iterum manifeflo in nervos, ut vel ex acuto femina glandis conjiceret licet." Elem. Phys. ibid.

Erection of the penis takes place from various causes, not enumerated under the foregoing heads; and then it has no concern with the expulsion of the seminal fluid. When a person wakes in the morning, with the bladder tolerably full (it is an organ commonly erect); but it becomes flaccid when the water is evacuated. Striking the base of the penis with a rod is well known to produce erection; and has sometimes been reported to raise dormant passions. Calculus, strangury, and hemorrhoids are sometimes attended with this symptom; which has been occasionally observed in other affections. It is often particularly troublesome in gonorrhea; and has been observed many times after death, particularly in those who have been hanged. (See Morgagni de Sed. et Caf. Ep. xiv.) Mechanical obstruction to the return of blood from the part will produce erection, and even such a swelling as ends in gauging, if the obstacle be considerable and long continued. Ligatures, thoughtlessly placed on the penis by children, and the stricture produced by the retracted glands in paraphymosis, come under this description. In the same way dangerous swelling has been produced by drawing a ring over the penis. The effect of intercepting the return of blood is clearly shown, in an experiment made by Mr. Hunter on the dog. "In April 1676, in the presence of Mr. Blunt, I laid bare the penis of a dog, almost through its whole length; traced the two veins that came from the glans (which in this animal makes the largest part of the penis), and separated them from the arteries by dissection, that I might be able to compress them at pleasure, without affecting the arteries. I then compressed the two veins, and found that the glans and large bulge became full and extended; but when I irritated the veins in order to see if there was any power of contraction in them, which might occasionally stop the return of the blood, no such appearance could be observed." Animal Economy, p. 40, note a.

That erection is produced by blood being sent into the penis faster than it can be returned, and that the increased size of the organ is entirely produced by this languidous dilatation, are points clearly ascertained. The obstacle to its return is so complete, that no mechanical pressure applied to the body of the penis can force the blood on into the veins. The exact mode, in which this object is accomplished, has not, we believe, been as yet ascertained. There certainly is no power capable of directly compressing the veins; and the erector penis in particular, by drawing the organ away from the symphysis pubis, would rather free them from prejudice. The accelerometer urging, by squeezing the blood forwards from the bulb, may make the front of the corpus spongiosum and glans rather more firm when they are erect, but can produce no effect on the penis in general.
Neither is the phenomenon at all like those produced by muscular contraction: it is a quiet and gradual increase, and it often lasts for hours. Muscular action is sudden, and not of such long duration. There are other examples of analogous effects, which are totally inexplicable by muscular action. The nipple, when left to itself, is soft and flaccid, short, and retracted: when excited by gentle friction, it rises into a cylindrical form, swells, grows red and warm: yet there is nothing like a muscle in the part. The red flabby organs about the head and neck of some gallinaceous birds undergo a similar process.

It appears, therefore, that the change termed erection, may take place in animal structures, without the influence of any muscular power; and it is by no means certain, that any muscle is concerned in the particular case now under consideration. All that we can ascertain on the subject is, that the blood is sent into the corpora cavernosa in much greater quantities than it can return. If a mechanical obstacle does not produce that rigid state of the organ, which is created by the immediate action of desire, we conclude, that a more sudden and complete congestion is produced by the latter than by the former cause. We cannot explain how the proportion of blood, which arrives, is thus altered in relation to that which returns, any more than we understand the analogous phenomenon in inflammation. It does not seem possible to ascertain the mechanism of the process by actual observation. The circumstances already mentioned render it probable that the nerves are materially concerned.

Erection varies considerably in its degree. The organ at first swells, but continues soft; it then grows considerably longer, thicker, more firm and warm; and the glands become redder. The corpora cavernosa are first dilated, and the glands subsequently. In the state of greatest rigidity, it is proved, by ridiculous experiments, that considerable weights can be supported by the organ. The mere act of erection is not attended with those remarkable effects on the frame which accompany emission; it may be repeated or continued for any length of time without any injurious operation on the animal economy: hence, it is much more frequent than the latter act. Under the influence of certain feelings of the most acute kind, excited in the act of copulation, the female fluids are expelled from the excretory ducts into the urethra. The pleasurable sensation is raised to its highest pitch, and is attended with a convulsive agitation of the whole frame, before this effect follows. Maxima certe er in venere convulso, et late patens tremor, ut femina, cui clitoris titillatur, acque se fulinire potest, acque genus concrece, et tremant, et in albis rea in plenum epilipam crumpit: nihil audit necque sentit animal in venerea tentitigne. Sunt, qui animo in venere linctuant, et feminae; tum non rari, qui in grato nimis opere perierint. Eas autem omnino major maris voluptas, etiam in plerique animilibus; non maries, praeter paucas exempla, feminas sequuntur, et nonnullum pene invitus vi subigitur: eas in viris, femnus venere praecipuam fecerunt, nullo quam clitoris major, et certe in venere tumilior. Et si aliquis feminus in sylvio uteri interiori, quando tamen eo percent, manifesti tamen mas in egerendo feminam: majoribus, quam feminam in toto venere, futilis agitatur. Quia omnino faptitidinis confiliis hacta sunt, ut virum roborare armatur, amoris dulcedo feminam redderet aequorem. Dernum et cordis vires vehementer incentitant, et pullus accelerantur, et cor palpitat, et respiratio laborat, et eadem, quae in nixu, phantoma orintur. Element. Physiol. 7. 567.

After this tumultuous agitation of the whole frame, and when the feeling of the pains and glands has reached its greatest extent, the seminal fluid is thrown into the urethra. The anus is closed by its sphinctera, and it is said that the levatores ani, by their mechanical pressure, squeeze out the contents of the prostate and vesicula into the urethra. Probably the coats of the vesicula and vasa deferentia posses some contractible power, by which their evacuation is assisted. The contents of the prostate and vesicula are collected in the bulb of the urethra, which is enlarged so as to form a kind of reservoir for them: and are expelled with force, by successive spasmodic contractions of the accelerator urethra. As soon as this is finished, the temporary agitation subsides, the blood returns from the cells of the penis, and that organ regains its original magnitude. A degree of languor follows, proportioned to the previous excitement; the irritation of the heart goes off, the hurried respiration is quieted, and the strength slowly returns. The frequent weaknaess is greater, in proportion as the act has been more frequently repeated, and at shorter intervals. In many animals, where the sexual appetites are only excited at a particular season, and where the powers are exhibited and exercised on a much greater scale than in man, the debilitating influence is very strongly marked. The venereal powers of the human subject certainly appear very limited, when compared to those of most animals: with a due regard to health, he cannot much exceed the limits assigned by Hailer. Homo adae modice sunt, ut non multo plus, quam bis in septem diebus coire possit, et forte accri amore percussus, put longam calmatem. Sema concupita potitus, aliquoties possit femen emittere. Sed ex multum repeti possit, neque durare. An attention to the dictates of nature will certainly enjoin temperance in these enjoyments. The performance of a function, so necessary to the continuance of the species, has been ensured by the physical pleasure associated with it: but the effects of too frequent repetition produce those serious confusions which the universal and violent influence of the act on our bodies would naturally lead us to expect. Severe nervous affections, impaired mental faculties, and premature death, are the sure concomitants of excessive venereal enjoyments. Whether the convulsive agitation of the body, or the emission, be the most injurious under these circumstances, cannot, perhaps, be decidedly ascertained. Omnia illa major et coeretia, et minus cumbus manu obtemperatur, suam illa detectabilis juvenium circe, a qua amor she, et in qua semen, multum in natura operes diffusius, elicet. Ab eo erit corrupta impotenentia infansale superius, et feminas fluxus involutaries perpetua, obigua rigiditas, tabes intra triumfum fucta, anisula judicii vis, et omne facere malorum genus, quod voles velis avertere. Elem. Physiol. 7. 573.

These circumstances render it very plain that polygamy is not suited to the organization and powers of man; and afford a much stronger argument against the practice, than the alleged superior numbers of females in Eastern countries would be in favour of it, even if the fact were well proved; which we by no means admit. We may collect also, from the foregoing account, that the sexual functions ought not to be exercised, until the growth and strength are complete; and that all attempts at exciting the venereal appetites, before the natural period of their development, must be prejudicial. On this subject we should bear in mind the observation of Tacitus concerning the ancient Germans; "Sera juvenum Venus, etque innumera pulbetas." Men is capable of exercising the generative functions through a certain portion only of his life. We have explained that the organs are in a state of very imperfect development during the early periods of his existence. Boys have erections, but they are not produced by those stimuli which act at a more advanced age. In the middle of Europe, a facte-
а secretion of seminal fluid generally takes place about the twelfth or fourteenth year, insomuch that it is commonly discharged from the effect of dreams. Soon after this time there is a complete capacity of performing the sexual functions; and there is a well-known infatuation of a prince who begat twins in his 16th year. The approach of puberty is regulated to a considerable extent by the climate, and also by manners; in warm countries it comes on earlier than we have mentioned, and later in colder regions. In the higher ranks of society, where the feelings are prematurely and artificially excited, and encouraged by a copious and generous diet, and loose morality, the generative functions may be called into exercise more early, than under the opposite circumstances. As the individual approaches to the 55th year, the venereal susceptibility is considerably diminished. Sexen is still fettered, but hardly ever emitted during sleep, even after the longest abstinence. The venereal act is more slowly performed, but is equally efficacious in producing pregnancies. From this time the powers are gradually diminished; but a man of 62 may still become a father, although some legislators have chosen to determine otherwise. A longer continued and more powerful irritation is required to produce erection and emission at this age. In rare examples men have been known to retain their powers of propagation even to the age of 100 years; and it is very well authenticated that Thomas Parce married at 120, and performed the duties of a husband until the age of 130. These latter examples must, however, be regarded as deviations from the ordinary course; and we have equally remarkable instances of the generative functions being performed at an unusually early age. Perhaps the most remarkable case of this kind is a boy now living in London, of whom an account is given in the Medico-Chirurgical Transactions, vol. i. p. 276, &c. At the time of birth this child had much long hair on the head, and the features of the cranium were perfectly formed. At the end of the first year these changes took place which usually happen at puberty. The penis and testes increased in size, hairs appeared on the pubes, and the tone of the voice was evidently altered. From this time his body grew very rapidly, and the expression of his features, as well as the general organization, had a completely manly character. The prominence of the thyroid cartilage, and the voice, resembled those of a youth of 16. "The pubes and pectorum are covered with black curling hair. The penis and testes are as large as I have seen in some adults. The latter are firm and perfect in their formation, and the color may be distinctly felt. The usual brown appearance of the integuments of these parts is here to be observed." There has been a secretion of semen from the end of the second year. This account was drawn up when he was three years old. In his "Anecdotes de Médecine," Borden mentions three boys who had strong venereal desires between 10 and 11 years of age: the generative organs were unusually large in these individuals, and were fully capable of exercising their ordinary functions at this time. "Ils ne peuvent qu'en plaisir physique de l'amour; ils ne semblent avoir autre sensation que celle de cette passion; ils se fontaient, pour ainsi dire, en femmes; ils traitaient leur carrière individuelle de l'organisme féminin."

The most subtle and natural state after the age of puberty, is that of marriage. If the doings of nature are not fulfilled; if, by refusing to satisfy the impious call of love, we prevent the excess of vital energy, which soon animates the generative organs, from being carried off in its natural channel, the accumulated irritability of these organs will frequently disturb the whole frame by its re-action. The physical feeling of love, the impulse of reproduction, has generally a remarkable character of violence and energy in animals. The phenomena of the rutting season show the effects of this powerful appetite in a much stronger point of view than they are seen in the human subject; as the influence of the passion is here heightened by its being reduced within a short period of time. Great herculean, impetuous motions, and often some convulsions are the effects of the new want in many animals. Parrots, canaries, birds, and bull-bitches experience attacks apparently of an epileptic kind, when separated from their females. The physical appetite is rarely accompanied with such phenomena in man. With many individuals, the observance of the laws of chastity hardly requires an effort. However, if the influence of the generative organs should predominate so far as to constitute a well-characterized erotic temperament; if an ardent imagination and a forced state of ebullency should strengthen this temperament, its influence on the constitution may be excessive, and cause various kinds of general disorder. Under the influence of such circumstances, a folder seized and attempted to violate a girl in public at Montpellier. Neither the publicity of the situation, nor the cries of his victim, nor the exclamations and blows of the surrounding persons, could prevail with him to relinquish his attempt, for which he was hanged. (Borden, Anecdotes de Médecine.) The unnatural-inclination observed from mistaken notions of religion, has produced very remarkable effects in some cases. Anecdotes of this mention by Buffon, in whom the feelings were very strong, fearing he should be tempted to break his vow, cut away the organs. The same author relates the sufferings of another individual during a kind of erotic delirium, which lasted for six months, and seems to have amounted nearly to mental derangement.

Female Organs of Generation—Woman contributes more largely than man to the business of reproduction; and the apparatus destined to this function includes the generative organs, properly so called, and the breasts. These isolated parts are appropriated to the execution of a common object, to which each contributes in its own way, and their development is regulated by a common law. They are called into activity at the same epoch, and their respective functions coöde, or at least their capacity of fulfilling them coësates at the same time. The close sympathy which connects them has been remarked at all times. The breasts, however, are manifestly dependent on the generative organs; while the former exercise but a very slight influence on the latter. As the male organs are calculated by their formation to convey the prolific fluid, so the female are constructed with a view to its reception; and the two differ completely from each other. Yet there is a considerable resemblance in some parts of the apparatus in both sexes. Thus the clitoris, which is concealed under the pubis in the superior commissure of the labia, resembles the penis in many points; differing from it by having no connection with the urethra, and consequently being imperforate, also in being very small in well-formed individuals. The most convenient arrangement of the subject, for anatomical description, is that in which the organs are divided into the external and internal. The latter include the essential agents of the generative process in the female; viz. the vagina, with the uterus and its appendages. The former consist of a longitudinal slit, placed between the thighs, containing the termination of the urethra and vagina, and certain prominent parts comprised chiefly of folds of the integuments.

The external organs, which can be seen without the aid of dissection, are the mons veneris, the vulva or pudendum, the labia, frenulum, fossa navicularis, clitoris, nymphae, meatus urinarius, and opening of the vagina.

A broad prominence, placed in front of the pubes, and
between the gynoii, is called the mons veneris. At the time
of puberty, this part becomes more convex, and is covered
with hairs, of which the number, length, and colour, vary
in different individuals. These very seldom advance along
the middle line of the abdomen, towards the navel, as in
man. Their eminence is formed simply by the accumula-
tion of an adipous cellular substance at this particular point,
and it consequently varies in size, according to the eminen-
t point of the individual. A longitudinal suture, or slit-like
cavity, extends from the mons veneris, towards the thighs,
to within an inch of the anus; this is called the vulva, or
puddendum, (which names sometimes include, in a more large
application, the external organs,) or anus pudoris. This
excavation is larger in women who have had children, than
in virgins. The space left between the posterior end of the
vulva and the anus, which may be about one inch in length,
is the perineum, in which the raphé can hardly be traced.
The labia, or alae majores, are two elongated cutaneous
eminences, filled with adipose substance, descending from
the mons veneris towards the anus, and forming the lateral
boundaries of the cavity just mentioned. They have been
named, from a comparison with the lips of the mouth; but
the suture between them is vertical, instead of being tran-
verse, as in the other female. Their length, which is nearly
the same in all instances, and may be somewhere between
two and three inches, determines the extent of the vulva.
Their size and prominence vary according to the general
embossing of the individual. These folds are thicker
above than below; their external surface, which corresponds
to the upper and inner side of the thighs, is covered with
hairs similar to those of the mons veneris, and possesses some
sebaceous glands. The internal surface, formed by a mucous
membrane, is smooth, soft, to the touch, is contiguous to that
of the opposite side, and to the nympha. In virgins the
colour of this surface is red; it acquires afterwards a pale
and rather livid cast. The upper edge of the labia is adhe-
rent, and continues externally with the integuments, on the
inside with the covering of the nympha; the inferior margin
is unconnected, convex, rounded, and covered with hairs,
and exhibits the continuity of the integuments with the mucous
membrane. The anterior, or superior extremity, is con-
founded with the mons veneris: the posterior, growing
gradually smaller, ends in a point, and is united with that of
the opposite side behind the fossa navicularis. From this
union a sharp prominent ridge results, called the commissure
of the labia, or frenulum, and in French la fourchette.
The following parts enter into the composition of the labia;
1st, a continuation of the skin forming their external surface
and inferior or convex edge, provided with sebaceous glands,
in the secretion of which the distinguishing odour of these parts
refides: 2ndly, a mucous membrane covering their internal
surface, continuous on one side with the integuments, and on
the other with the mucous covering belonging to the whole
vulva; 3dly, an adipous tissue filling the interval between
these layers, and giving to the parts their various degrees
of thickness and prominence. The latter texture resembles
on the whole that of the mons veneris, with which it is con-
tinuous, but it presents, in addition, some membranous la-
minal descending from the ischium and pubes to the loofe edge
of the labium. It does not contain so much fat as the mons
veneris, and hence, like the cerumen of the male, it is a part
in which anaesthetic deposits are frequently observed.

The labia cover all the other external organs of generation,
which, by this means, are constantly moistened with a mucous
fluid, preventing the effects of friction, and preparing the
acute sensibility of the parts. In the ordinary attitudes of
the body, these organs are in a state of mutual contact, and
therefore completely conceal the parts which we are pro-
ceeding to describe: they are separate only when the thighs
are thrown widely apart; they receive an extraordinary de-
velopment during parturition, and thereby increase the capa-
city of the vulva. When the labia are separated, the fol-
lowing parts may be observed in succession from above
downwards: 1. The clitoris, which appears as a small tu-
brcle, more or less prominent, separated from the upper
commisure of the labia by a small smooth surface: 2. The
nympha, alae minores, or petita leaves, arising from the in-
ferior lateral parts of the clitoris, descending and diverging
as they descend, and lost on the sides of the opening of the
vagina: 3. A triangular surface slightly concave, bounded
above by the clitoris, below by the meatus urinaris, on the
sides by the nympha, and sometimes called vestibulum: 4.
The meatus urinaris, situated about one inch below the
clitoris: 5. The orifice of the vagina, with the hymen, or
caruncula myrtiformes, placed immediately under the meatus:
6. The fossa navicularis, a small transverse depreflion, sep-
arating the entrance of the vagina from the frenulum: 7. The
frenulum, or posterior commisure of the labia; behind
which is the perineum. The clitoris occupies the upper
part of the vulva, and forms a reddish flatly elevated tu-
brane. It is nearly the same height in virgins and chil-
dren, but in the latter the organ does not exceed the level of
the labia. Its figure is obtusely conical, something like that of
the end of the penis; this is called the glans clitoridis, and
is covered by a loose fold of the mucous membrane lining
the vulva, and named preputium clitoridis. Besides, the
difference of its size, the want of a perforation at the
extremity, sufficiently distinguish it from the penis. A
small part only of the organ appears on external examination;
the larger portion, which is concealed, and can be brought
into view only by dilation, lies over the vagina, and under
the arch of the pubes, and bears a great analogy to the
penis, as it consists of two crura or corpora cavernosa, with
erector muscles. These arise from the inner and even po-
terior surface of the rami of the ossa innominata; ascend,
approaching to each other, and unite into a small cylindrical
body, terminating in an obtuse extremity, called the glans.
These crura are made up of a firm fibrous membrane, con-
fluged with the perioleum, forming a tube filled with a cellular
or spongy substance, into which blood is ejected from the ar-
teries, to be again taken up by the veins, as in the penis.
There is a complete septum between the two crura, so that
they are distinct throughout. The spongy substance of the
crura is more dense than in the penis, and consequently admits
of less dilatation; hence the size of the organ is not greatly
increased in the erect state.

The erector clitoridis muscle is analogous in every re-
spect to the erector penis of the male; its origin, termination, and
probably use, are similar, but the size is smaller in propor-
tion to that of the crura. It arises from the inner surface of the
ischium, ascends and palies forwards, and is implanted in a
tendinous form, in the inferior and posterior extremity of the
crus clitoridis.

The substance of the glans is not different from that of
the body of the clitoris, as there is no urethra in this organ,
and consequently no peculiar corpus cavernosum. It is
rounded above and slightly bithel below. The loofe and
folded prepuce covers it above and at the sides, but not be-
low, being attached to the two sides of the slit, by which the
part is marked in this situation. A white, friable, sebaceous,
and concreting substance, similar to that formed by the gland
ulose odoriferæ of the penis, is deposited under the preputium
clitoridis.

This secretion, being liable to accumulate, and becoming ir-
ritating in warm countries, as is the case with the analogous
substance
The clitoris corresponds above to the arch of the pubes, to which it is fixed by a kind of fulpenoxy ligament; below to the urethra, to which it is united by a loose cellular tissue.

It resembles the penis in its acute configuration: "fenus minis vehement, ut tota crura ab eis particular sollicitatione contineantur, feminique toto extra feponantur, nihilique passit prope necare. Quam extra venerem, in cafta feminam parva fuerat, sed ei mado argirit et intumescit, ut prepositae veneri inferiore passit, multoque su ejs turbidum denique moles eis augerat, ut omnia membra furent, cubus multum utiuram. Quae caufla videtur suIfie, cur orientales populi, accurati caftitatis mallebris cultvdo, hane particular in nuper natis puellis amputaverint, aut tertae ferro decorataverint." Element. Physiol. lib. 28. § 26. We have made some observations, concerning the occasional increase in size of this part, in the remarks on hermaphrodites.

The nymphs are two membranous folds, connected above to the prepuvium clitoris, and descending as far as the middle of the aperture of the vagina. They are thin and flattened, broadest in the middle, and narrower at the two extremities. Their external surface corresponds to the inside of the labia, while the internal, approximating above to that of the opposite side, corresponds below to the meatus urinarv and orifice of the vagina. Their adherent edge is tolerably thick; while the loose margin is thin and convex: the latter is sometimes wrinkled or notched, so as to have occasioned a comparison of the part to a cock's comb. The superior extremity arises from the prepuvium or glans clitoris; the inferior ends at the side of the vagina. They are smooth and of a red colour in young women, and acquire a darker hue in older subjects, and particularly such as have had children. They are formed of duplicatures of the membrane lining the vesuvia, filled internally with a cellular substance, free from fat; and they contain sebaceous glands, the excretory ducts of which form very obvious pores; they differ very much in size. Ordinarily, they are completely covered by the labia, when approximated. Sometimes they form scarcely perceptible prominences, while at others they are very large, and hang down between the labia, so as to form an inconvenient obstruction to the sexual functions; in this case their surface is irregular, being grooved and tuberculated. Such formations are more frequent in the inhabitants of warm climates, where it is not unusual to cut off some part of them; and the operation is even occasionally practised in European countries. Frequently one is larger than the other. They possess considerable sensibility. The chief use assigned to them is that of affiling, by their development, the enlargement of the vulva during parturition: the dilatation of the parts by the passage of the child destroying the fold. The name of nymphae was given to them from a supposition that they regulate the jet of urine; but as women evacuate this fluid with the thighs apart, and as the direction of the stream seems to depend fo entirely on that of the urethra, we cannot adopt this supposition. And we are further confirmed in rejecting the opinion by the existence of these folds in males where they can have nothing to do with the action of uriine.

We have nothing further to say concerning the vestibulum, except that the surface is smooth, and that it is terminated below by the opening of the urethra, which is about three quarters of an inch, or an inch from the clitoris. The description of this canal, and its termination, will be found, together with that of the female bladder, under the article Kidney.

Immediately under the orifice of the urethra is the entrance of the vagina, called sometimes the os externum uteri: the diameter and appearance of which vary very considerably in different individuals. In virgins this opening is very narrow; it is broader after the sexual act has been performed, and most ample in women who have had many children. The narrowness in the first case arises from the presence of a duplicature of the mucous membrane, called the hymen, which contracts the opening so considerably, that marriage cannot be consummated without its being ruptured; hence, after this laceration, the entrance of the canal is more free.

As the parts are vallcular and sensible, more or less bleeding and pain generally attend this dilatation of the aperture; and these circumstances are expected in some countries as the necessary proofs of virginity in the bride. However, they do not always attend the first coition; and it should be, by the following quotation, that the existence of the hymen hangs by a very slender thread: "L'hymen, pendant le premier age, est tres mince, il rompt facilement et se detruit, lorsqu'on effuse avec trop peu de manegement les parties exterieures de la generation, fort leregue l'enfant humain, avec ou sans intention, contracte des habitudes. Les biennes, prepare et difpofe anfi aux plaisirs folitaires, des organes qui sont a peine echoues." Morcan Hist. de la Femme, tom. i. p. 53.

The hymen is a duplicature of the same membrane which lines the entrance of the vagina, and has the same texture and properties. It is soft, red, vallcular, and sensibile. Generally it has the shape of a crescent, with the concavity turned upwards or forwards. The convex edge is attached, the concave loose; the former is fixed to the inferior part and sides of the vagina, the latter is turned towards the urethra. The orifice of the vagina, in the virgin, is the space bounded in front or above by the meatus urinarv, below or behind, and at the sides, by the loose concave edge of the hymen. The dimensions of this opening must depend thereforo on the breadth of the hymen, which differs much in different individuals; ordinarilv, it will admit the little finger without any stretching. This crescented or faithful figure of the hymen is seen only when the labia are drawn apart, and the sides of the vagina gently stretched; for in the ordinary attitudes, the membrane is thrown into longitudinal folds, the sides of the vagina coming into contact with each other, so that the entrance of the canal is completely shut. However, the space left between the urethra and the edge of the membrane will always allow the escape of the menstrual discharge. The lower part of the hymen is the broadest, and the horns of the crescent, where they advance along the sides of the aperture, grow gradually narrower, until they are completely lost.

Sometimes the hymen is continued under the orifice of the urethra, so as to form a complete membranous circle, perforated in the middle, instead of a crescent. Indeed Haller, and many other very accurate anatomists, have found the fold, when the parts were carefully examinied in water, generally continued under the urethra; but very narrow at that part. In more rare cases the hymen is an imperfect circular membrane, attached to the edge of the orifice of the vagina in every part, so as to close the canal completely. Such females have been termed ossetae, by a word derived from the Greek, and signifying imperforate. As there is
no aperture in such cases for the discharge of the menstrual fluid, it accumulates in the uterus and vagina, and must be evacuated by a surgical operation, consisting of a puncture of the hymen. For the various appearances which this part exhibits in different individuals, the reader may consult J. G. F. Tolbeng, de varietate hymenial, Hal. 1791, 4to.

It has generally been affected, that the hymen does not exist in quadrupeds; but the statement of Couffer, in his Leçons d'Anat. comparées, tom. 5, leçon 29, fect. ii. art. 2, renders this point very doubtful. The general opinion of its non-existence in the other mammalia is no doubt more powerful man, and the circumstance of its being found in women only; at a particular period of life, and even then not universally, has led many anatomists to deny its existence in the human subject. But the fact is so clearly proved by the concurrent testimonies of all modern anatomists, who have enjoyed considerable opportunities of dissection, that we wonder to find Buffon still contending the point; any of his anatomical friends might justly have convinced him by ocular proof. Though we are fully convinced, by repeated observation, that Buffon's opinion is incorrect in point of fact, we cannot help admiring the eloquence with which he inveighs against the disgraceful opinions and practices which have prevailed on this subject. "Les hommes," says he, "jaloux des primâtes en tout genre, ont toujours fait grand cas de tout ce qu'ils ont cru pouvoir poffeder exclusivement et les premiers; c'est cette espèce de folie, qui a fait un être réel de la virginité des filles. La virginité, qui eût un être moral, une vertu qui ne consiste que dans la pureté du cœur, est devenue un objet physique dont tous les hommes se font occuper; ils ont établi sur cela des opinions, des ufages, des cérémonies, des superstitio, et même des jugemens et des peines; les abus les plus illicites, les contraintes les plus déshonorantes ont été autorisées; on a founis à l'examen de matrones ignorantes, et exposé aux yeux de médecens prévenus, les parties les plus fragiles de la nature, sans songer qu'une pareille indécence eût un attentat contre la virginité; que c'est la violer que de chercher à la reconnaître; que toute situation honteuse, tout état indécen, dont une fille eût été obligée de rompre intérieurement, eût une vraie dégradation. Je ne permets pas de faire à détruire les préjugés ridicules qu'on s'est formés sur ce fujet; les choses, qui sont faites à croire, feront toujours crues, quelque vaine et quelque déraisonnable qu'elles puissent être; cependant, comme dans une histoire on rapporte non feulemte la fuite des évènemens, et les circonfiances des faits, mais aussi l'origine des opinions et des erreurs dominantes, j'ai cru que dans l'histoire de l'homme je ne pourrais me dispenser de parler de l'idole favorisée à laquelle il sacrifie, d'examiner quelles peuvent être les raisons de son culte, et de rechercher si la virginité eût un être réel, ou ce n'est qu'une divinité fabuleuse."

It is not so easy to explain the use or purpofes of this membrane, as to establish the fact of its existence. The partifans of final causes have been much puzzled in attempting to display the wisdom or goodnefs of the Creator, as evinced in this part of our anatomy, and have as yet assigned no rational explanation of it. We subjoin from Haller a statement of the commonly received notions, which, however, appear to ourselves entirely unfatisfactory. "Vix tamen dubites, cum folo in hominum fit reportus, etiam ad morales fines efie conceitum figum pudicitiae, et vitium illatum cogitofarum, et pars virgo decus fuam potius tueri, et ipse maritus de culpitate foamente facile convictur, eo facilis, quod præterea in illa virgine anguilla fit. Ete enim potius heri, ut luxus, ut parvis fit hymen, atque prima venus aliquid ab affine fanguine abfolvatur, acque hymen rumputur; eth artificem porro in param pudica

femina linguos posuit celi; eti tenere virgines aliquando etiam in altero coitu figum necéu reddant, et membris fluentes vaginae laxant: tamen in univerfo debet prima venus cruentu eft, coquenfigno pudor virgines adefit, cum vis potissim plena venas obtineri, quin fuperior margo partis majoris hymenis laceratur. Quare et modicum leges, et multorum populorum confuetude, hoc figum fervata cafalitatis et requirant et offenfent, et de exemplis in virginiis etiam rarius certus fum, qua illegitum in prima venere fanguinis fucturae fum paffa."

Elem. Physiol. lib. 29, fect. 2, art. 17.

After the hymen has been torn, the entrance of the vagina presents some flemily prominent tubercles, called carunculae myrtiformes, and varying in number and size. These are generally considered to be the remains of the lacerated membrane; "et corrupte adeo pudicitiae indicia." The carunculae are generally largest at the sides of the vagina, where the hymen is narrowed; so that all these prominences cannot well be referred to the origin just mentioned. Some are found behind the hymen, and exist previously to the laceration of that membrane; these are the prominent, obtuse, and callous spicés of the columns of the vagina. Lastly, there are projections at the termination of the mucous ducts, which may be enumerated among these carunculae: and warts are sometimes found in this situation. Whatever their origin may be, we find from two to five or fix round and firm, or thin and loofe prominences, of a red or livid colour, about the entrance of the vagina.

The frenum, or fourchette, is a cutaneous fold of a crescent shape, with the concavity upwards, placed behind and below the entrance of the vagina, visible in the virgin state, when the sides of the vulva are drawn apart, but not well marked when the parts are collapsed. It lies between the two labia, not quite at the lower extremities, and is extended almost to the nymph, protecting in some degree the entrance of the vagina. It is near to the hymen, which it resembles in some respects. The act of copulation does not injure it, but repeated perturbations entirely efface it. A very manifefl transverse cavity, named the foffa navicularis, is intercepted between the frenum, the hymen, and the labia; and this cavity is lost of course when the frenum disappears, fo that it may not be recognizable in married women.

A mucous membrane, by which the penial and urinary organs are united in the female, is continued over all the parts contained in the vulva, and even forms many of them. It arises on the loose convex edges of the labia, and at their commissures; covers the internal surface of these folds, the space below their anterior commissurum, and the foffa navicularis, then forms the nymph and preputium cliteridis, covers the vestibulum, is continuous with the lining of the urethra, and with that of the vagina, after forming the hymen or caruncula myrtiformes. It is confefted to the subjacent parts by a copious and loose cellular texture, in which, generally speaking, there is very little fat. Its colour is of a tolerably bright red in young women; but it attains darker shades in more advanced ages, particularly when the sexual functions have been much exercised. The texture of the integuments changes gradually into this mucous surface, so that there is no abrupt line of diffinition, and an epidermis can be distinctly demonstrated at its origin.

The colour proves that it is copiously supplied with blood. The membrane is soft on its surface, and plentifully bedewed with a mucous fluid, poured out from small tubes, which commence by open orifices, and run into the subflance of the membrane, where they terminate by cul-de-faces. These, which are called lacunae, are similar to what we have described.
The internal Organs of Generation.—The vagina, or canals uteri, is a membranous canal, extending with a very slight obliquity from below upwards, and from before backwards, from the vulva to the neck of the uterus. Its anterior portion is nearly transverse; the posterior ascends towards the urinary bladder. It lies in the middle of the inferior aperture of the pelvis, between the uterus and bladder, which are in front of it, and the rectum which is behind it. The ordinary length of the canal is from five to six inches, and the breadth one inch; but as it is very extensible, these dimensions are subject to change. It is narrower, but at the same time longer in the virgin, than in married women; during parturition its size is equal to that of the child’s head; it is very capacious after delivery, so as to be three inches in diameter; but it soon regains its previous size, never however returning to the narrowness of the virgin state. Its form is nearly cylindrical, but somewhat flattened towards its anterior extremity. It is slighly bent towards the pubis; its two extremities are obliquely truncated, so that the anterior surface is shorter than the posterior. We shall describe in it an external and an internal surface, and two extremities.

The external surface may be divided into an anterior, a posterior, and two lateral regions. The anterior, sloping upwards and slightly convex, corresponds to the bladder and urethra, being connected to the former by a loose cellular texture, and very intimately united with the latter by a dense and firm substance. The posterior region, sloping from above and behind downwards and forwards, is gently convex, and corresponds to the rectum; its superior half, being covered by the peritoneum, is simply contiguous to the intestine; while the inferior part, possessing no such covering, is connected to the intestine by cellular substance. This connecting medium is much looser above than below; and in the latter situation it is difficult to separate the two organs without cutting one or the other. The lateral regions are narrower than the parts just described, and surrounded by much cellular substance. They correspond to the ucters, to the plexus formed by the blood-vessels of the uterus and vagina, and below to the levatores ani. The internal surface of the organ presents a great number of folds and prominences, which make it irregular throughout. These cellular rugosities exhibit a most elegant arrangement in the fetus and in the virgin; they are indistinct and partially obliterated by parturition, but are very soon restored, and may often be very distinctly observed even in old women. In some subjects, however, the whole vagina is nearly smooth. The half of the canal next to the uterus contains the fewest and least remarkable irregularities; the folds here are soft, moderately transverse, but sometimes partly oblique. These prominences are jagged laminae, ending in a thin edge, turned towards the opening of the vagina, differing in size and variously interwoven with each other. On the anterior half of the canal are raised two prominent columns: an anterior and a posterior one. These are beset with hard and nearly cartilaginous warty prominences, closely arranged, of a roundish figure, and circumferentially grooved. The anterior column is the largest, and corresponds to the orifice of the urethra. Frequently this is bifold towards the front, and its two portions, joined by transverse ruggae, end in the hymen. The front end of this column sometimes projects like a papilla at the orifice of the vagina. The posterior smaller column is exactly opposite to the anterior, and corresponds to the rectum; sometimes it is hardly distinguishable. This ends also in the hymen, and in some instances projects anteriorly like the anterior column, but less considerably. From each of these columns, hard, cartilaginous, transverse or oblique folds are extended; they project downwards.
have a jagged edge, and are mixed with verrucous and other left prominent laminae in various directions. Between the two columns is a reticulated surface, formed from the transverse productions. The use of this structure does not seem very obvious. It may possibly facilitate the dilatation of the organ. "Voluptatem et etiam angere cedere, nihil in uteri cervix imitates valvulae recte. Ancient tamen emittendo vaginam; et inferior columnar partis glandis feminae vicinae occurrunt. Scilicet vaginam etiam facere credas, quod ob has veluteras et inpa magis constrictur. Infinicibus tamen funeste lego," Haller, Elain. Physiol. lib. 28.

All the generative apparatus abounds with mucous, and this moisture is obviously convenient in many of the functions of the part. In the female, it appears as a white, milky kind of fluid; and it is a true mucus in the adult. The floor of the generative canal seem to be merely a dilated tube of this secretion. Round livid spots are frequently observed on the smooth part of the vagina, near the uterus; their cause and nature are unknown. Numerous pores are observable among the folds and rugae of the vagina. Epithelium noticed linings in the membrane; i.e. tolerably large slits, sometimes ramified, and containing mucus. No glands can be discovered in the organ.

The inferior extremity of the vagina is united to the inferio part of the neck of the uterus. It embraces the latter organ obliquely, so that the anterior surface of the vagina is nearer to the os uteri, and the posterior is more remote from it; and the cavity between the vagina and the neck of the uterus extends higher behind than before. The inferior extremity occupies the lower and posterior portion of the vulva, in front of the anus, and ends there by the orifice which we have already described. The sides of the vagina possess considerable thicknes and strength. The upper half of its posterior surface is covered by peritoneum. The chief substance of the canal is a thick, close, and firm texture of a greyish colour, poliling large vessels, and having fibres in various directions, so as to give it somewhat of a muscular appearance. It appears to be continuous above with the substance of the uterus. Below it is surrounded by a kind of corpus cavernosum, of about an inch in breadth, and two lines in thicknesses, composed apparently of veins, and called the plexus rectiformis. A determination takes place to this part at the time of coition, and it experiences a kind of swelling analogous to erection. On the whole, the membrane of the vagina is not so thick as the dilatation which it experiences in parturition might lead us to expect. Excepting where it is covered by the peritoneum, and by the plexus rectiformis, the surface is surrounded by a copious cellular substance, containing many vascular ramifications.

The vital properties of the sides of the vagina are not well understood. Some ascribe to it a contracible power, excited, as it is laid, in coition and felt by the hand when introduced in the process of midwifery. The phenomena of parturition shew that it possesses a high degree the powers of extension and subsequent contraction.

The internal surface of the canal is lined by a mucous membrane, to which the peculiar tuffice of the vagina already mentioned adheres very closely. It is continuous with the membrane of the vulva; and, after lining the vagina, is extended over that portion of the cervix uteri, which projects into the canal, and communicates, at the os, with the lining of the uterus. This mucous lining forms all the inequalities already described; it is thicker near the vulva, and grows manifestly thinner towards the uterus. At the entrance of the canal it has a red colour, which changes further into a grey or whitish call, diversified near the cervix uteri by the livid spots already mentioned, which give it a marbled appearance. The almost cartilaginous hardcnes of the membrane in some parts is peculiar to the vagina, as well as the permanent folds in its structure; in other mucous membranes the inequalities are occasioned by some external cause, and disappear by extension. Some anatomists ascribe an epidermis to the vagina; but this point is doubtful. The organs, by which its mucous fluid is secreted, have been already mentioned.

The place of the accelerator urine of the male subject is occupied in the female by the sphincter vaginae, which covers the plexus rectiformis. It depends on each side from the body of the clitoris, behind the cecum; surrounds the anterior extremity of the vagina, immediately behind the labium, where it presents considerable breadth, and terminates below, on each side, in the lateral fibres of the sphincter ani. It must have the power of contracting the front orifice of the vagina.

The arteries of the vagina come from the internal iliac; its veins join the venous plexus, which surrounds the canal. The lymphatics are not weli known; the nerves come from the facial trunks.

The uterus is the organ in which the fetus and its coverings are contained until the time of parturition. It is almost always fleshy; in some rare cases there have been two uteri. There is some variety in these instances; either there may be two uteri and two vaginas, or one fleshy vagina divided by a septum in its whole length, or only in its upper half; or one of the uteri may open into the rectum, and the other into the vagina. In some cases the uterus is divided internally by a longitudinal septum, either confined to the neck, or prolonged to the orifice of the vagina. Sometimes the uterus is altogether deficient. A vast number of references to authors who have related examples of all the above-mentioned unusual formations may be seen in Voigtel's Pathologische Anatomie, b. iii. p. 452—456.

This organ is situated in the pelvis, behind the urinary bladder, before the rectum, below the convolutions of the ilium, and above the vagina. Its situation is oblique, the fundus being placed downwards and rather backwards, the neck downwards, and slightly inclined forwards. Two broad folds of peritoneum, named the ligaments lati uteri, fix it to the side of the pelvis. Other ligaments assist in maintaining this situation; viz. the round, the anterior, and the posterior ligaments.

The broad ligaments extend from the sides of the uterus to the sides of the containing cavity. Together with the uterus they form a complete transverse partition, dividing the pelvis into an anterior and a posterior cavity, of which the former and smallest contains the urinary bladder, the latter and largest, the rectum. These ligaments are flattened from before backwards and quadrilateral. Their two surfaces are smooth, and unattached; the anterior being turned directly forwards, towards the bladder, the posterior directly backwards, towards the rectum. The upper edge is divided into two prominent lines; of which the anterior and highest contains the Fallopian tubes, the peritoneum, the ovary and its ligament. The three other margins are adherent; the inferior, to the lower part of the pelvis; the external, to the side of the cavity; and the internal to the lateral margin of the uterus. These ligaments are formed by two layers of peritoneum, between which are placed the vessels and nerves of the uterus, the ovaria and their ligaments, the Fallopian tubes, and some cellular substance. They fix the uterus in its situation, and give it a covering, in proportion as it increases in size during pregnancy; they consequently become much narrower at the time; in the latter months, indeed, they
they are almost entirely effaced, so that the tubes and ovaries, which they contained before the enlargement of the uterus, are now applied immediately to the lateral and inferior parts of the uterus, in consequence of the manner in which this organ has separated the two layers of peritoneum. The anterior ligaments are two small folds formed by the peritoneum, as it is reflected from the back of the bladder to the front of the uterus. They are visible only when the two uterine vessels are separated from each other, and they appear under the form of crescents, with the concavities directed upwards. The posterior ligaments are two other folds of the same membrane, where it is continued from the back of the uterus to the rectum. They resemble the former in every respect. The round ligaments are two whitish cords, extended from the upper angles of the uterus, in front and rather below the Fallopian tubes, to the groins. They pass first outwards and rather upwards, in the broad ligaments, on the front surface of which they form a remarkable prominence, they then pass on the inner surface of the iliac veins, behind the peritoneum, to the upper opening of the abdominal ring. They traverse that canal in a direction obliquely downwards and inwards, just as the sacrogenic cord does in the male subjacent, and escape to the lower orifice. They then separate into several threads, which are lost in the cellular substance of the mons veneris and labia. These ligaments are slightly flattened in their whole extent, and broader at their two extremities, than in the middle. They are arched, so as to describe altogether a semicircle.

The round ligaments are composed of longitudinal fibres, confining apparently only of a dense cellular tissue, very slightly susceptible of extension, of blood-vessels and lymphatics, and nerves. As they are swelled in pregnancy, and in some affections of the uterus, this circumstance has been employed to explain the pains, in the groins experienced by females on such occasions. They contribute to fix the uterus in its position, and to limit its motions.

The ligaments, which we have just particularized, are so disposed, as to allow to the uterus, in its natural state, a certain degree of mobility. Hence its situation may be slightly changed in all the considerable motions of the abdominal viscera in general; coming to the ground on the feet with much force, a violent exertion in raising a considerable weight, a deep, forcible, and long continued inspiration, all tend to force the uterus downwards into the vagina, and thereby to produce the affection termed prolapsus or defect of the uterus. Dilatation of the bladder, or of the rectum, occasions changes in the position of the uterus. But age and pregnancy produce the most signal effects in the position of this organ.

In an adult and unprimiparous female, its length is about 2½ inches, its thickness one inch, its breadth at the fundus 1½ or 2 inches, and at the cervix about 1½ lines. Although it returns after parturition to its original size, it never becomes again so small as it was in the virgin. Its figure is whole on the triangular, with the base upwards, and the apex downwards, and flattened from before backwards. It is divided into two parts, a superior and broader, named the body; an inferior and narrower, called the neck. The body of the uterus is nearly oval externally, with the greatest diameter transverse. We observe in it an anterior and a posterior surface, a superior, an inferior, and two lateral sides. The anterior surface, slightly convex, slopes gently downwards and forwards, and corresponds to the bladder. The posterior, more convex, is incised in the same direction, and is contiguous to the rectum. The superior edge, which is named the fundus, and which extends from one Fallopian tube to the other, is gently convex, and supports the convolutions of the small intestine. At the ends of this upper edge angles are formed between the fundus and the lateral sides of the vificus. To these angles of the uterus the round ligaments, the Fallopian tubes, and the ligaments of the ovaries are attached. The inferior edge, much shorter than the superior, is continuous with the neck of the organ; and indeed the line of separation is imaginary. The lateral sides are very short, slightly convex, and converging; they give attachment to the broad ligaments, and are concealed by them.

The neck of the uterus resembles a cylinder, slightly flattened from before backwards, and continued downwards from the body. Its long axis is perpendicular to the transverse diameter of the body. We describe in it an anterior and posterior surface, two lateral margins, and a superior and inferior extremity. The two surfaces are convex and smooth; the former corresponds to the bladder, and the latter to the rectum. To the sides, which are straight, the broad ligaments are attached. The superior extremity is continuous with the body of the organ; the inferior is obliquely embraced by the vagina, in which it projects, more considerably on the interior than on the posterior part. This extremity is perforated by an oval opening, with its long diameter placed transversely, named the os uteri, os internum, or os tine. The latter name has been given to it from a comparison to the mouth of the trench; the end of the uterus is obtuse, and as the aperture is transverse, there is some resemblance to two thick lips. In a newly born child, the length of the opening is two lines; in a girl of twenty years, three lines; in women, who have had children, five to eight lines. The orifice is always naturally gaping, but it is more or less, in proportion as women have had many children, or none. Instead of being exactly in the middle it is rather behind; so that the anterior lip of the orifice is the thickest. That portion of the cervix uteri, which projects into the vagina, and forms the os tine, is about four or five lines long in front, and rather more behind; it measures about eight or nine lines transversely, and fix or eight from before backwards, being slightly flattened in that direction. This part of the uterus is sometimes much longer and thicker, without any displacement of the organ, or swelling of its neck. In women who have had many children, the neck of the uterus is generally thicker, and more rounded. Its orifice is almost always very gaping, and the lips more or less irregular, presenting generally one or more grooves or chops, separated by a kind of tubercles. The os tine may however be as regular in its figure in women who have had children, as in others; and, on the contrary, it may present in the latter those irregularities which are more usual in the former. Hence the inferences drawn from the state of this part, in infancies where infantilism is suspected, or where parturition is supposed to have been concealed, are very liable to uncertainty.

The cavity of the uterus is proportionate to the bulk of the organ when it is empty; the parietes are contiguous, and leave between them no further vacuity than suffices to hold a little mucous fluid. In this hollow the menstrual discharge flows, and the produce of conception is received. It is divided into two parts, one belonging to the body, the other to the neck of the organ. Of these, the former is the largest; its figure is nearly triangular, especially when the uterus has experienced no alteration in its bulk. We have to notice in it an anterior and a posterior surface, three edges and three angles. The two surfaces are smooth and contiguous to each other. On each of them a slightly prominent longitudinal line may be observed, dividing
dividing them into equal right and left parts. Of the three margins one is superior, and two lateral; they are slightly concave, particularly in women, who have had many children. The superior, which makes the basis of the triangle, and is continued from one Fallopian tube to the other, is usually the shortest; sometimes, however, it is the longest. Of the three angles, two are superior, and one inferior. The former may be considered as two slender appendages of the cavity, terminating at the Fallopian tubes. The inferior angle presents an opening of about four lines in extent, communicating with the cavity of the cervix. The cavity of the body of the uterus is lined by a mucous membrane, on which the blood forms the menstrual blood terminate.

The cavity of the cervix uteri is a kind of canal, flattened from before backwards, and more capacious at the middle than at the two extremities; so that it has the figure of two cones, joined by their bases. Such is the figure which it constantly exhibits in women who have never borne children; but, from the time of conception, that extremity of the canal, which opens into the vagina, is dilated; and after parturition has once taken place, it is always found much wider than before. It then represents a cone, with the bases towards the vagina, and the apex towards the uterus. The cavity of the cervix uteri has an anterior and posterior surface, and a superior and inferior orifice. A great number of hard, and as it were callous rugulations, differently disposed in different subjects, may be observed on each of the surfaces. In order to see their arrangement to advantage, the uterus of a newly-born child, or of one not very old, should be selected. They will then be observed in an arborececent form (arbor Morgagni) on each surface. A hard ridge extends along the middle of each surface, and ends above in a flattened point, which is often continued with the line dividing the corresponding surface of the body of the uterus. The inferior end is prolonged to the os tinnne. From this kind of trunk laminae are extended laterally on each side; the superior ones forming nearly half right angles, and the inferior more open angles. The number of these plates may amount to about 15. They are continued outwards, describing a curve, of which the convexity is always towards the uterus, and the concavity towards the vagina. Their margin is grooved, except towards the outer end, which is smooth. The breadth of the lamina diminishes insensibly, and they disappear on the sides of the cavity, where the anterior and posterior ones are confounded with each other. The superior are broader than the inferior. These laminae are not simple, they produce other smaller ones. More or less deep grooves separate the plates from each other: in the bottom of these are observed small eminences, like the teeth of a comb, passing from one lamina to another.

The disposition of these wrinkles is regularly such as we have described in newly-born infants; but, when the cervix uteri is enlarged in pregnancy, the eminences are flattened, and the whole structure is confused; this is still more remarkably the case just after parturition; the laminae are then nearly destroyed, and the arborececent appearance almost entirely effaced.

The superior opening of the cavity communicates with that of the body, so that they form indeed but one. The inferior has been already described under the name of os tinnne.

In the cervix uteri we may notice the openings of numerous lacunæ or short ducts, ending in cul-de-sacs, concealed among the rugulations already described. Most of these are small; some are larger and longer. There are fix or seven just above the os tinnne, the fundus of which is towards the inferior end of the uterus. These are large, and receive the terminations of several smaller ones. They are filled with a mucous fluid, which can be squeezed out, and they will often admit of a fine bristle for a certain length. They are best seen in a woman who has just been delivered, or who has died in the latter periods of utero-gestation; the prominences being flattened, the lacunæ are more exposed. These organs secrete the mucous fluid, with which the cervix uteri is moistened.

We see also sometimes in this cavity a considerable number of round or oblong, larger or smaller follicles, formed of a thin membrane, filled with a clear mucous fluid, and not poising any excretory duct. They adhere to the trunk or branches of the arborececent structure already described, and their number is not constant. Sometimes they are half buried in the substance of the uterus, sometimes they are completely isolated, and held only by a pedicle. Their nature and use are not known. Probably they are one source of the mucous secretions of the part although we cannot explain how the secreted fluid is evacuated.

The thickens of the sides of the uterus varies from four or six lines to fifteen; but it is not uniform in all parts of the organ. It is much the same on the surfaces and edges. The fundus is generally the thickest; and this is thicker in the middle than towards the angles. The neck is rather thinner than the body. The substance of the organ is of a greyish colour, and a firm consistence, especially towards the neck, which is more compact than the rest of the organ. It consists of an external membrane, or a proper tissuc, of an internal membrane, of arteries, veins, lymphatics, and nerves.

The external membranous covering is contributed by the peritoneum, which is reflected from the posterior surface of the bladder over the uterus, of which it covers the anterior surface, the fundus, and the posterior surface, is continued to the upper half of the posterior surface of the vagina, and is reflected from that viscus to the rectum. It adheres everywhere to the proper tissuc of the uterus by means of a very fine and close cellular texture, without any fat. It is very difficultly separable, particularly at the fundus.

The proper tissue forms nearly the whole thickens of the organ. It is a greyish, dense, and very compact substance, very resiliency to the scapal or seffuous, cutting almost like cartilage, and containing numerous small vessels. This substance, which appears cellular, spongy, and to contain fluids, is manifestly fibrous; but the order and arrangement of the component fibres cannot absolutely be determined in the unimpregnated state, on account of their being so inextricably interwoven. They are paler and more condensed in the cervix than in other situations, where they are softer and more red. Although in the empty state of the organ these fibres have scarcely any of the characters of mucularity, their nature seems to be sufficiently pointed out by the contractile powers which they exhibit in parturition.

The external membrane of the uterus is continuous on one side with the mucous lining of the vagina and gives origin, on the other, to two prolongations, which enter into the Fallopian tubes. It is extremely thin, and so closely united to the proper tissue of the organ, that it seems to form one fibrous membrane with it. It is reddish in the body of the uterus, and whitish in the neck. It is perforated by an infinite number of pores, which are merely the extremities of exhalant vessels, and give sile to the menstrual discharge.

Appendages of the Uterus.—Under this name are included...
the round ligaments which have been already described, the ovaries, and the Fallopian tubes.

The Fallopian or uterine tubes are two (a right and left) conical, tortuous, and vermiform canals, arising from the superior and lateral parts of the uterus. They float loosely in the cavity of the pelvis, being enveloped in the upper and anterior edge of the broad ligament, and fixed by their inner extremities. Their length is four or five inches; and the direction of their course is very uncertain: it may be stated in general that they go transversely outwards, and that they bend backwards at their outer ends, so as to turn towards the ovaries. But, as they are in great measure loose, and as the edge of the broad ligament restrains them but slightly, the intestines, when distended with air or aliment, may displace them in different directions. The caliber of the tube is so narrow towards the uterus, that the orifice by which it communicates with this viscus will only admit a hog's bristle. It enlarges gradually to the middle, where it is slightly contracted, and dilates again to terminate by an aperture which communicates with the cavity of the abdomen. The tube is considerably broader at its end than at the uterus, but rather the contrary in that portion of the peritoneum which constitutes the tube. The internal membrane of the tube, together with the external, which is formed of peritoneum, is produced to some length beyond this orifice, and forms round it a fringed and radiated kind of ornament, called the fimbricai (pavillon de la trompe; moreau frangé). When this part is examined in water, it has a very beautiful appearance, and seems composed of small separate leaves, like some flowers. The breadth of this membranous fringe is not equal at all parts: its circumference has somewhat of an oval figure. All the portions into which it is divided are not of the same length: the longest extends to the ovary, and is firmly fixed to its outer extremity, so that the fringed end of the tube is constantly retained near to that body. The fimbricai are conceived to possess a muscular structure.

The Fallopian tube is composed: 1st. Of an external membrane, furnished by the peritoneum, which covers it as it does the intestines; 2. Of an internal, soft and pulpy membrane, the surface of which presents every where more or less prominent longitudinal lines, considered by some anatomists to be muscular fibres. Indeed the office of the tubes seems to require the existence of contractile fibres in their composition: 3. Of a spongy tisue, compared to that of the urethra and corpus cavernosum, but the real nature of which is not understood. Very numerous blood-vessels are distributed in this substance, which appears to swell and experience a kind of erection in the act of copulation: in consequence of this the fimbricai are applied to the surface of the ovary; 4. Of blood-vessels, derived from the spermatic arteries and veins, of lymphatics, and nerves furnished by the renal plexuses.

That the office of the tubes is immediately connected with the baffices of generation, and that they convey the germ from the ovary to the uterus, cannot be doubted; but we do not understand how they execute this function. We may observe that they form a communication between the uterine cavity and that of the abdomen: and, as the former communicates externally through the medium of the vagina, the serous membrane of the abdomen has thus a continuity with the surface of the body:—a circumstance that is observed in no other instance.

The ovaries, called by the ancients the female testicles, are two oblong, flattened, and whitish bodies, placed at the posterior surface of the broad ligaments, in which they are included. They nearly equal the size of small pigeons' eggs in the adult; but their flattened form gives them a different figure. Their long diameter is placed transversely. They present two surfaces, two edges, and two extremities. The surfaces and the upper edge are left, and present nothing remarkable except slight tubercular risings. The inferior margin adheres to the posterior edge of the broad ligament. The external extremity is connected to the longitudinal of the Fallopian fimbricai; and the ligament of the ovary is attached to the internal end. This ligament is a small fibrous cord, about 1/8 inch long, contained in the posterior part of the broad ligament, and fixed to the angle of the uterus behind the Fallopian tube. Some old anatomists regarded it as a canal defined to convey into the uterus the semen, which they supposed to be secreted by the ovaries; but it is in reality a solid fasciculus, similar in its nature to the round ligament, and having no other office than that of fixing the ovum in its place. Yet the latter organ possesses considerable mobility; its situation in the broad ligament, which is itself moveable, gives it a power of motion. The intestines and the urinary bladder may make it change its position; and we know that it has sometimes been contained in a rupture.

The ovaries are composed: 1st. Of an external membrane, derived from the peritoneum following the broad ligament; 2. Of a proper membrane, of a white colour, and firm fibrous texture, hardly separable from the proper tissue of the organ; 3. Of a spongy substance, which is dense on the outside, more soft on the inside, where it is greyish, and in some degree cellular and spongy. In this substance are lodged some small, roundish vessels, amounting in number to between fifteen and twenty. Scarcely visible in infancy; these are very apparent in adult and fruitful women. Generally, in old women, these vessels are no longer visible, and their place is occupied by hardish tubercles. The vessels are not all of the same size: those which are near the surface of the organ are as large as hemp-seeds; while the others, being more deeply seated, are considerably smaller. These bodies are placed in the cellular or spongy substance of the ovary, in which they may be said to be enclosed; but they form for the most part small prominences under the external membrane. Others are completely elevated on the surface of the organ, and others again are concealed in the interior. They are not supplied by fillets, nor do they form any particular cells different from the cellular matter comprising the parenchyma of the ovary. They were very particularly described by De Graaf, and have often been called, after him, ova, or ovula Graafiana. They are generally regarded as so many germs, or rudiments of new beings. They are composed of a simple and very thin membrane, smooth internally, and containing a clear, sometimes yellow or reddish liquor, coagulable by heat and alcohol, and forming white threads, like the albumen of an egg.

The arteries of these parts are derived from two sources; viz. the spermatic branches of the aorta, and the uterine branches of the internal iliac. The former are more tortuous than the corresponding vessels in the ovaries; passing between the two layers of peritoneum, which form the broad ligaments, and are chiefly distributed to the ovaries. But they send numerous ramifications to the Fallopian tubes; others to the sides of the uterus, and some along the round ligaments, which communicate with small branches of the epigastrics. The chief arteries of the uteri are the uterine branches of the internal iliac trunks; the right and left. This artery first runs downwards, then runs up at the neck of the uterus, and enters between the layers of the broad ligament. It gives large branches to the vagina, then runs along the side of the uterus, from the neck towards the sinus, producing numerous arteries, which ramify over the organ in every direction. These have a tortuous course, and communicate freely with each other, and with those of the opposite side.
Some ascends to the upper edge of the broad ligament, are distributed in the Fallopian tube and round ligament, and communicate with the spermatic.

The veins, like the arteries, may be referred to two divisions; the spermatic and uterine. Numerous branches come from the uterus, ovary, and Fallopian tube, and form a large venous plexus in the upper part of the broad ligament; under the name of corpus pampiniforme, this ascends towards the loin, and terminates in forming a single vein, which has the same termination in the male subject. A great number of venous ramifications accompany the arteries all over the vasa, but are of general less tortuous. They communicate freely with the spermatic. They form a large plexus running along the side of the uterus, with the uterine artery, and end in one or more considerable venous trunks, which join the internal iliac.

The uterus possesses numerous lymphatic vessels, which are divided into three orders: one of these ascends with the round ligaments, and goes to the inguinal glands; another joins those of the vagina, and passes to the pelvic glands; and the third, together with those of the ovary and tube, ascends with the spermatic vessels, to terminate at the glands in front of the aorta and vena cava near the kidneys.

The nerves come from the great sympathetic (the hypogastric and spermatic plexuses), and from the faecal pairs.

**Vital Properties of the Uterus.**—Until the period of impregnation, this organ seems to possess only that modification of sensibility and contractility, which are necessary for the purposes of nutrition, and the menstrual evacuation. It seems doubtful whether or no it is endowed with animal sensibility in its healthy state. It has been imagined, and asserted, that the contact of the gland penis with the os tunicæ, in coition, is one source of the physical sensation experienced by the female on that occasion: this we conceive to be problematical. Haller states, that a wound of this organ by a leaden bullet produced very violent symptoms; viz. repeated faintings, and speedy death. It must be doubtful how far this could be referred to the uterus merely, as much other injury must have been inflicted in such a case. Animal sensibility is certainly developed in the uterus by disease, whether it exist in the natural state or no. The same observations may be applied to the vital properties of the Fallopian tubes and the ovaries. However obscurely the vitality of these organs may be exhibited, when not immediately engaged in the exercise of their important functions, it is manifest in a much more striking point of view by the sympathies established between them and other parts of the body. We have already shown, that the removal of the ovaries at an early age entirely changes the subsequent characters of the animal; affecting even the organization of the bony and muscular parts of the frame. From the time of puberty, when the organs now under consideration acquire a fitness for exercising their particular functions, we shall find that their condition and various changes affect in the most striking manner all the other vital phenomena of the female constitution. The previous symptoms, the commencement and periodical returns of menstruation; the first impulses of love; the change to a new temperament; pregnancy and its various epochs; parturition and its consequences; lastly, the cessation of the sexual life, and the symptoms of the critical age, are so many remarkable changes in the organization of the female, keeping up a constant alternation of suffering and relief, of lively impressions, nervous and spasmodic affections, the influence and general result of which must be carefully attended to in appreciating the nature of woman, and the part which she has to fill in society. When we consider these facts, and reflect that the inclinations, the appetites and tastes, in a word, all those qualities which impress the distinctive character on any animal, flow from the conformation and predominating influence of certain organs, and are modified by their degree of perfection, and the energy of their functions, we shall have little hesitation in referring the peculiarities of the female frame and constitution to the action of the generative organs taken altogether; an opinion which is expressed in a more limited way by Van Helmont, "proper uterum folum, nulli elidit quod eft."
mark, is nearly white, and does not exhibit those successive
plades which, at a more advanced age, distinguish its orifice,
itself, and its posterior extremity. In the newly born
child, and during the first three years of life, the uterus does not
occupy the cavity of the pelvis: together with the ovar-
ias and tubes, it is placed above the superior aperture. At
this time it is very small, and has a very different figure from
what it presents when perfectly developed. The neck is
larger and thicker than the body, which narrows, and elong-
gated, has not the triangular figure. The parietes of both
are thin, and the cavity very small. The tubes are propor-
tionate in length to their future state.

From birth till puberty, the generative organs of women experience fewler changes than those of men: yet they
grow in proportion as the body enlarges; and thence, which
at first were remarkable for their size, as the clitoris and
labia, gradually lose this distinction. The uterus appears
below elevated above the pubes, in proportion as the pelvis
changes its form and proportions, and as the superior ap-
erture becomes less inclined. It enframes principally in breadth
and thickness, but its growth is not very rapid. The changes
which occur at the time of puberty, considered in an anato-
mical point of view, are not considerable: there is a remark-
ably revolution in the vital powers of the generative system,
rather than any considerable increase of the organs.
the internal parts, however, at this time, have acquired their
complete size, and the external organs become covered, in
the situations particularly adapted, with hairs.

In extreme old age, the generative organs of the female, already reduced for a considerable time to complete inaction,
bear the marks of decrepitude common to the whole frame.
The vulva presents the most remarkable changes; this is the
part most affected by the performance of the sexual func-
tions, and many parts of it partake the general emaciation.
The prominence of the mons veneris is nearly effaced, and a
great part of the hair, which covered it, is lost; the remain-
der becoming grey and straight. The labia and nymphae
are soft and flaccid; the latter sometimes can scarcely be
seen in the vulva: the membranous membrane is whitish, or at least very
pale in its colour. The state of the vagina presents nothing
very remarkable. The volume of the uterus is diminished,
its parietes having become thinner. The tubes and round
ligaments are also in some degree reduced. The ovaries do
not exceed half the size which they had in the adult age;
they are sometimes very dense, and marked with deep
grooves, so as to render the surface tubercular; in other in-
stances, their substance is removed, so that they are reduced
to a very thin appearance. The vessels contained in their
parenchyma are no longer discernible.

State of the Generative Organs during Pregnancy.—The
uterus, intended to serve as a receptacle for the fetus, di-
lates after it has received the gurm from the ovari, and en-
larges in proportion as this is developed: its blood-vessels
bring an additional quantity of fluid, from which the fetus
draws its support: lastly, at a certain period, fixed by the
laws of nature, it discharges the product of conception by
virtue of the vital properties, with which it has been endow-
ed, during the remarkable change of its organization. Such
are the threefold objects, to the attainment of which are
directed the new dispositions acquired by this organ during
pregnancy.

The anatomy of the gravid uterus has been most fully
elucidated by Dr. William Hunter, whose splendid and beau-
tiful plates form an epoch in the history of our knowledge of
this subject. 'The Anatomical Description of the human
gravid Uterus and its Contents,' London, 1794, drawn up
by Dr. Bailie, from the papers of Dr. Hunter, contains
a very clear account of the subject; this, with the plates
already mentioned, is the source from which the following
description is principally derived. The observations, unless
where it is otherwise expressed, apply to the state of the
organ as it is found in the 9th month.

Considerable variety exists in the size of the organ. The
child and placenta may be twice as large in one case as in
another: there may be six or eight times more water in one
cafe than in another; to mention the differences arising
from there being only one child or twins, &c.

The development of the uterus appears to be immediately
produced by the general dilatation of the liquid surrounding
the fetus, and not by the fetus itself, since the latter does
not come in contact with the organ. The size of the part
depends principally upon the quantity of the liquor amni.
For, though women who have twins, or a very large child,
are commonly observed to be very big, yet the greatest num-
ber of those who are really very much swelled out, are fo
only from a vast quantity of water. In such cases there is
frequently but one child, and that very often a small one.

The general figure of the uterus is oviform; the fundus
answering to the largest extremity of the egg, and the cerv-
xix and os uteri to the small end: but the fundus is larger and
more flat, or less pointed, in proportion to the lower extrem-
ity of the uterus, than one end of an egg is to the other;
and the whole uterus seems more or less compressed, so as to
be broader from right to left, than it is from the forepart
backwards. Besides these more constant changes, the fi-

gure of the uterus differs from the regular oviform, from a
variety of accidental causes, as it adapts itself to the neigh-
bouring parts, to the attitude of the body, and to the posi-
tion of the contained child. In order to conceive these va-
rieties more easily, we must remember that in most cases the
uterus is not so completely filled as to be upon the full flretch.
Were it out of the body, and filled artificially, it would easily
contain more than it actually does. Thus the uterus, like
a bladder of water not quite full, is plastic, and moulds itself
into various shapcs from accidental circumstances.

The figure of the organ, in particular situations, is modified by
the pressure of the surrounding parts: the brim of the bony
pelvis has the effect of a belt girding the lower part of the
organ, and the projections of the spine, and of the psoas mus-
cles and iliac vesels, mould the outside of the uterus into cor-
responding cavities. The attitude of the body influences
the figure of the uterus, as the parts against which it rells
vary in different postures. The position of the child is an-
other caufe influencing the figure of the uterus. Not only in
dead bodies do we see the parts of the child making various
different projections on the outside of the uterus; but we
can frequently observe the same variety in the living fetus,
by examining the outside of the abdomen. The round projec-
ting ball, made by the child's head or buttocks, is commonly
very perceptible, and in many instances smaller parts, as the
knees or elbows, can be distinctly felt. Dr. Mackenzie met
with a case of twins, where the uterus, instead of making one
compacted oval body, had stretched itself into two distinct
bags, for containing the respective fetuses; so that its outside
was marked by a notch, dividing it into two apartments, as deep
and distinct in proportion, as that in the heart represented
on cards. The organ often stretches unequally in the corre-
sponding opposite parts; so that either the right or the left
half may be considerably larger than the other. It may
swell unequally on the front or back part, so that the di-
tance between the insertions of the Fallopian tubes may be
much smaller either before or behind than in the opposite di-
rections. In the unipregnated state, it has commonaly one
triangular cavity: but it is sometimes subdivided, at its upper
part,
part, into two lateral cavities, so as to bear some analogy to the two horns of the uterus in a quadruped. This peculiar conformation may explain the unequal extension of the two sides in some cafes of pregnancy; and may elucidate the above-mentioned case of Dr. MacKenzie.

The small or lower end of the organ is placed in the cavity of the pelvis. This generally contains the greater part of the child’s head, and fills up the cavity so completely, as to press the bladder against the pubes, and the rectum against the facrum. The os uteri is directed against the coccyx, or the lower part of the facrum. The body and fundus, which contain the rest of the child and the placenta, are so placed in the front of the abdomen, from the brim of the pelvis upwards to the epigastric region, as to be under and before all the other bowels, and in immediate contact with the parietes abdominis, and to occupy the whole space from one hip-bone to the other, and a proportional extent from these bones upwards. As it rises up from the cavity of the pelvis into the hypogastric and umbilical regions of the abdomen, the loofe connections of the intestines and omentum easily account for these parts being pushed up before it.

The axis of the uterus is oblique, its lower end being turned backwards, and the upper proportionally forwards. This obliquity is changed by the attitude of the body, and by many other causes. In the erect posture, the weight of the uterus presses the forepart of the organ into a greater rotundity, and its axis then approaches the nearest to a tranverse or horizontal line. In the recumbent posture, the contrary situation is exhibited. In a first pregnancy, the uterus fleshes itself higher up in the epigastric region, and its axis comes nearer to the longitudinal or vertical direction, because the parietes of the abdomen do not easily give way; but in a woman who has had many children, the abdomen, by repeated dilatation, is rendered more loofe and pendulous, and the uterus extends forwards rather than upwards. This position is more remarkable in very fhort subjects; because in them the chell is fo near the pelvis, that the uterus is stopped in afeint. The fame circumstance happens, and for a fimilar reason, when the pelvis is very narrow; as no part of the organ, in fuch a cafe, can be lodged in the pelvis, it muft be placed proportionally higher. In a very fhort and crooked woman, on whom the cafarcan fcction was performed, the fundus uteri was not only turned forwards, but even a little downwards. As the laws upon the table, the navel could not be seen, as it was placed on the posteriour and inferior part of the abdominal tumour. In order to expofe that part of the abdomen to the surgeon, it was necessary to lift up the fundus uteri, without which the hypogastric region would have been inaccessible. The deviation of the organ towards the right or left fide cannot, in general, be very coniderable; as it poiffeles nearly the whole space between the hip-bone, and its lower extremity is fixed to the pelvis. A fmall lateral obliquity is very common; and we can easily fuppofe, that in a reclin’d posture, the projeftion of the lumbar vertebrae will throw rather more than one-half of the uterus into the lateral cavity between the fpine and one hip-bone. We know, indeed, that in all the laft months, the abdomen is often more full on one fide than on the other. Women lay in fuch a cafe, that the child lies on one fide, and they judge rightly. Where the child lies the bulk muft be both more coniderable and more permanent, but where there is only uterus, plaencta, and water, the swelling will be fouter, and project fets. The prefure of the child, when it lies more in one fide than in the other, makes the limb of that fide weaker, more benumbed, and more liable to cramps, and edematous swellings.

Of the Ligaments, Tubes, and Ovaria of the Pregnant Uterus.—It has been commonly observed that the ligaments and tubes of the pregnant uterus are attached lower upon the fide of the organ than they were in the unimpregnated state; and the reafon is very obvious. The periftonal coat of the uterus makes the broad ligament on each fide, much in the fame manner as the analogous membrane of the inteffinal tube makes the mefeiery. When the woman is not pregnant, the ligament is of confiderable breadth, the fpermatic veifels pass between its two laminae, the round ligament runs downwards and outwards, on its anterior furface, and the tube runs in loofe ferpentine turns on its upper edge.

But in proportion as the circumference of the uterus grows larger, the broad ligaments become narrower, their posterior lamella covering the posterior furface, and their anterior lamella the anterior furface of the uterus itself. We obferve now, that the round ligaments do not run down on the fore-part of the broad ligaments, but upon the forepart of the body of the uterus itself. In proportion as the fundus rises upwards, and increases in fize, the upper part of the broad ligament is fo fretched, that it clings clofe to the fide of the uterus, fo that in reality the broad ligament disappears, no more of it remaining than its very root; namely, its upper and outer corner, where the group of fpermatic veifels passes over the iliacs, to the fide of the uterus. In this flate, although the small end of the tube opens into the fame part of the uterus, as before impregnation, yet the tube has a very different direction; instead of running horizontally outwards, it falles downwards, closely attached to the fide of the uterus. Behind the fimbrace lies the ovarium, also connected to the uterus. The fimbrace and ovarium are commonly placed upon the iliac veifels, or flefty brim of the pelvis, behind the group of fpermatic veifels.

The round ligaments run almost perpendicularly downwards from the fundus uteri to their paffage through the muscles; they are confiderably enlarged in thickness, and are fo vascular, that when injected they ftm to be little more than a bundle of arteries and veins. Their arteries are all conflouled. Both their arteries and veins proceed principally from the fpermatics, and amalgamate evidently with the external veifels in the groin or upper part of the labia. Even in this enlarged flate of the round ligaments, it is very difficult to fay how they terminate in the groin; they appear to be infenfibly lost. The tubes are more flefty, vascular, and fift in their fubflance, and are lefs conflouled than in the unimpregnated flate. The fimbrace and internal rugae are larger and much more beautiful, expeffially when their veifels are well injected. The ovarium, excepting that which contains the corpus luteum, feem to have undergone no remarkable change. The latter body can be diftinguifhed by a rounded fullness; and frequently a coniderable prominence, fenfible both to the fight and touch, upon the middle of which there is a small pointed cavity or indentation, like a cicatrice. Upon ftitting the ovarium at this part, the corpus luteum appears a round body, of a very diftinct nature from the reft of the ovarium. Sometimes it is oblong or oval, but more generally round. Its centre is white, with some degree of tranparency; the reft of its fubflance has a yellowish cast, is very vascular, tender and ftible, like glandular flesh. The larger veifels appear round its circumference, and fend smaller branches inwards. A few of the larger veifels are situated at the cicatrice or indentation on the outer furface of the ovarium; and are there fo little covered, as to give that part the appearance of being bloody, when
when seen at a little distance. When there is only one child, there is only one corpus luteum; and two in case of twins. There may be, in the latter case, two distinct ones in one ovarium, or one in each ovary. The sex of the fetus has no relation to the corpus luteum being formed in the right or left ovary.

**Thicknefs of the Uterus.**—Those who say that the uterus grows thicker in proportion as its bulk is increased, have probably been deceived by examining the uterus of a woman who died some hours or days after delivery. In that contracted state the uterus is often found even two inches thick: but in the natural diffolved state, though there may be some difference, the thickness, in general, is but little more considerable than before impregnation. When not injected, its ordinary thickness is from one to two-thirds of an inch; when its vessels, and particularly the veins, are pretty well filled with wax, its thickness is thereby considerably increafed, more especially where the placenta is fixed, on account of the number and size of the vessels at that part. For this reason only, perhaps, the uterus is thick at that part, and for the same reason it is thicker towards the fundus than near the cervix. Much variety may be observed with respect to thickness; and such inequalities in the same individual, that even where the placenta did not adhere, the uterus may be almost twice as thick at one part as at another. On opening the organ, its thickness is generally found more considerable than external examination would have led us to expect. For its substance is soft, and a fluctuation, like that of water in a thin bladder, may be felt.

**Blood-vessels.**—There is no circumstance, in which the gravid uterus differs more from the unimpregnated, than in the size and termination of its vessels. The arteries, both spermatic and hypogastric, are very much enlarged. There are infinite numbers of anastomosing arteries through the whole substance of the part, so that the whole fyltem makes a general net-work, and the branches are convoluted or ferpentine in their course. None of the larger ramifications are seen for any length of way upon the outside of the uterus. As they branch from the sides, they disappear by plunging deeper and deeper into the substance. The arterial branches, which are much enlarged, are those which run towards the placenta; so that, wherever it adheres, that part appears evidently to receive by far the greatest quantity of blood; and the greatest number, both of the large and small arteries at that part, pass through to the placenta, and are necessarily torn through upon its separation. The veins of the uterus appear to be still more enlarged, in proportion than the arteries. From the sides of the uterus they ramify through its substance, running deeper and deeper as they go on, and without following precisely the course of the arterial branches. They form a plexus of the largest and most frequent communications which we know of among the vessels of the human body. And this they have in common with the arteries, that their larger branches go to, or rather come from that part of the uterus to which the placenta adheres; so that, when the venous syphon of the uterus is well injected, that part is evidently the chief source of the returning blood. Here, too, both the large and small veins are continued from the placenta to the uterus, and are always necessarily broken upon the separation of these two parts. The veins are without valves, and are therefore easily injected. In injecting them, we observe that at first they become turgid, and project on the outer surface of the uterus; but in proportion as we throw a greater quantity of wax into these vessels, they grow more flat and obscure; because the uterus itself becomes more filled and tense, which has the effect of com-

preffing the veins that run in its substance. On account of the large size of these vessels, and the appearance of cavities, which they exhibit on a section, the name of *funnet* has sometimes been given to them.

The lymphatics are more numerous, and many of them larger than could have been imagined. They pervade the substance of the organ universally. Its peritoneal coat appears, like that of a calf's fleece, to be interwoven with a crowded plexus of these vessels; and where they get to the sides of the uterus, when filled with mercury, some of them are even larger than a goose's quill. Some are remarkably varicose, or enlarged at particular places.

We do not know that any change takes place in the nerves of the uterus during pregnancy.

**Muscular Fibres of the Uterus.**—The substance of the organ is rendered remarkably soft and loose in its texture by pregnancy; so that, when an incision is made into it, the wound can be easily made to open wide; or if a narrow strip be cut out, it can readily be extended to at least twice its original breadth. This laxity appears to depend on two causes: viz. the great quantity of large vessels in its composition; and the loose connection between the fasciculi of its fibres. When we speak of the muscular fibres, it is difficult to treat the subject with precision. We neither know their external appearance, nor their internal composition. They only manifest themselves to our senses, when numbers of them are collected into bundles, and make what we commonly call muscular fasciculi. In the quadruped, as, for instance, the cat or rabbit, the muscular action of the uterus is seen as evidently as that of the intestines, when the animal is opened immediately after death. In many places, particularly of the internal surface of the uterus, these fibres have the same striking fusciculated appearances as we observe in common muscles; yet they are of a paler colour and harder texture. Dr. Hunter examined the fibres very carefully in a woman who died seven days after delivery. He stretched it gradually in warm water, and then inverted it, to have a full view of the inner surface. The remains of the decidua had passed off with the lochia, so that the fasciculated stratum of muscular fibres appeared to be bare, and to make the internal surface of the uterus. In many places, but particularly where the placenta had been fixed, the facciculi left oval spaces between them, for the passage of arteries and veins, somewhat like those separations in the tendinous fibres of the abdomen and loin, where vessels pass out to the cellular membrane and integuments. The cervix uteri, where the rugae are situated, had not such regular nor so large fasciculi as the rest of the uterus. In the body of the organ the fibres were very regularly circular. The fundus was made up of two planes of concentric fibres, at the very centre of which was the orifice of the Fallopian tube. When this internal stratum was removed, the fasciculated appearance and regular direction of the fibres was lost and lost apparent, in proportion as the distinction was continued outwards; which seemed to be owing in great measure to the infinite number of branches and communications of the large veins. Afterwards, says the doctor, I had the most favourable occasion that could be devised, for examining the fibres on the inside of the uterus. It was in a woman who died at the end of the ninth month, without being in labour, and without having any flooding or discharge of waters. When I had examined, and taken out all the contents, I attended particularly to the internal surface of the uterus. I found it every where covered with a thin stratum of the decidua, through which the muscular fibres appeared, but with some degree of obscenity. Upon rubbing off this tender membrane with a cloth, it gave me pleasure.
pleasure to see how exactly the above description agreed with the appearances.

The existence of mucular fibres in this organ has not, however, been universally acknowledged. "Respecting the alleged mucular texture of the uterus," says Blumenbach, "I must observe that all the human uteri, which I have carefully examined both in the pregnant and unimpregnated condition (and I have had opportunities of such investigations, not merely in preparations, but in the most recent state after death) have not exhibited any thing that could be taken for genuine mucular fibres. The advocates for the mucularity of this organ must allow that the fibres differ most remarkably from all others in the body. I am more and more convinced every day that the uterus poiffeys no true irritability; but that it poiffeys, if any part of the body can be said to poiffeys, a peculiar modification of vitality (vita propria) corresponding to its peculiar motions and functions, and not referrible to the common laws of irritability. These functions appeared fo singular and peculiar to the old physicians and philosophers, that they called the uterus an animal contained in an animal." Phyiolog. Institut. Phyfiolog. p. 422.

The mouth of the uterus differs considerably in the different times of utero-gelation. For the greatest part of the nine months, that is, till the cervix uteri be fully diffented, there is a projection of both the anterior and posterior lip of the os tinctae; and in some women this continues till the very time of labour. But in most women, when they are at their full time, or very near it, the os uteri is flat, and makes only a small rugous hole, often not readily discooverable by the touch on the lower or posterior part of the rounded lower end of the uterus. The border of this orifice, and the internal surface of the uterus, for an inch or more all around, is full of little irregular cavities. These contain a tough gluten, which floats across, and plugs up the inner part of the orifice. This gluten is commonly squeezed out from all the lacerae, by the dilatation of the os uteri in the beginning and progress of the labour; and so loosing its hold, it falls out. In the dead body, when the part is kept some days in water, the gluten swells out more and more from all these cavities, and then separates entirely. Then the innumerable lacerae, which contained it being empty, are very visible. And if the gluten be thus carefully taken away, and be floated in water, its external surface is seen beautifully ornamented with all the procedees which were drawn out of the innumerable lacerae.

Dr. Hunter gives us the following account of the uteri in the earlier months of pregnancy. "In the third and fourth months, the substantia of the uterus is become more soft than before conception, and all its veiles being proportionally enlarged, it appears to be much more vascilar. We may, therefore, reasonably believe, even if we knew nothing from defections of quadrupeds, that the uterus changes its nature in that respect from the time of conception, and receives a greater quantity of blood. Its thickness is only a little increased in its natural state, but conferndly when the veins and arteries are artificially diffented with any fluid. At this time the conception is lodged entirely in the fundus uteri, or in that part which in the unimpregnated state has a smooth internal surface; no portion of the conception stretching then down into the cervix uteri, or that part of the uterus, which is narrow and rugous within."

The cervix uteri remains contracted and hard in its substantia, and contains a tough and firm jelly, which cements and fills up its cavity so completely, that upon attempting to push a probe through it, the probe will as readily force its way through the hard substantia of the uterus itself, as through the cementing jelly. When the uterus is kept a considerable time in water, six or eight days perhaps, this cementing jelly swells, grows in proportion fatter, and at last comes away, or falls off in one mass. Then the internal surface of the cervix exhibits a most beautiful appearance; being variegated with projecting rugae, and innumerable intermediate narrow, but deep cavities, which lodged so many proceedees of the jelly. In separaring the jelly, when by previous maceration it had been fit for such an operation. I have seen these proceedees drawn out of the little cavities as distinctly as we can see a hand drawn out of a glove; and when the jelly is carefully separated and floated in clear water, it preserves its figure, and exhibits a most elegant appearance, produced by the proceedees that shoot out from its surface all around.

"The os uteri, or very extremity of the uterus, is in some women narrow or pointed, with a very small orifice, that will just admit the point of a very small finger; and in some it is large, soft, or spongy to the touch, granulated upon its surface, and the orifice so wide as to admit the end of the finger full half an inch up with great ease. There the passage becomes narrow, and is closed with the gelatinoas cement. The os uteri, all around its pauffage, is crowded with small cavities, containing the fame fort of jelly, which by maceration swells, puhes out from the cavities, and comes away, leaving the cells void. This, no doubt, is part of the jelly which naturally comes away in labour. Some women have much more of it than others; and, in comparing different defections, I have observed more of the jelly within the cervix uteri, and more likewise in the cells round the os uteri, in one subject than another.

"The uterus, at the time of three or four months, is by no means so tightly filled but that it would easily contain more. It is like a bladder therefore, so filled with water, that it would easily contain a third part more. Hence it is soft and sponging, and easily changing its shape, accommodates itself to the neighbouring parts.

"The situation of the uterus, which at first is in the cavity of the pelvis, but afterwards gradually rises up into the cavity of the abdomen, and the changes which its ligaments undergo, may be easily conceived by any person acquainted with the state of those parts before conception, and who has considered what has been already said about the same things in the ninth month of pregnancy.

"The peculiarities of the ovarium are very different at the different periods of utero-gelation. In the earlier months the corpus luteum is considerably larger and more vascilar; and within it there is a considerable and evident cavity containing a fluid. When the uterine veins have been injected, I have observed that the wax very easily extravasates into that cavity. On the outside of the ovarium there is a little pit, which looks like a hole, leading into the cavity of the ovarium. But in the cases which I have seen, no brililes would pass; it appeared to be an obliterated duct, or pauffage grown together."

The serous covering of the uterus, derived from the peritonem, undergoes very considerable extension during the enlargement of the uterus in pregnancy. We have already shown that the broad ligaments nearly disapper at this time, but there is no accession of the fame kind either before or behind, as the bladder and rectum full continue to be covered to the usual extent by that membrane. The increased surface of the peritonem must be ascribed therefore to an extension of the membrane.

As the mucous surface of the organ is the medium of communication between the uterus and the feuminalides, its changes refer to the purposes accomplished by this connection. In the natural state, it exhibits merely the fine orifices of exhal-
haling vessels, but after conception a large number of con- 
derable arteries and veins pass from it to the surface of the 
ervum; and these are more numerous and large in the situa-
tion of the placenta than elsewhere. These communicating 
vessels have been described already in the article EMBRYO. 
Toward the latter periods of gestation the utrva becomes 
swollen and relaxed, assuming a flat which favours its dilata-
tion in the act of parturition.
The vital properties of the uterus, as well as its organiza-
tion, are considerably altered after conception. The organ 
acquires unusual liveliness; hence they feel the motions of 
the child, and even experience very considerable pain in 
particular positions of the fetus; hence too the sharp pains 
felt in parturition. We do not know whether much pain is 
experienced by the incision of the uterus in the caesarean 
section. But, supposing that it is not, the fact would not 
prove that the organ is not possessed of animal sensibility.
Its powers may render it susceptible of some stimuli and not 
of others. When no circumstances interrupt the ordinary 
phenomena of pregnancy, we have no proof, until the natural 
period of this condition arrives, that the organ possesses its 
strong contractile power as that which we see exerted in 
parturition. We might even believe that this property is not 
developed until the end of pregnancy; but there is no epocha 
of gestation, from the first presence of the germ in the ute-
rus, at which this contraction may not be excited by the 
action of particular causes, which, under certain circum-
crances, are powerful enough to produce the expulsion of the 
child. Violent contusions of the abdomen, and penetrating 
wounds affecting the uterus, are frequently followed by 
abortion. Violent passion may cause this premature expulsion 
of the fetus. The same effect is produced by the evacuation 
of the waters of the amnios, independently of any other 
cause; the uterus, when no longer disturbed, contracts, 
and abortion ensues. This contractile power, with which 
the uterus becomes endowed on the change of its organiza-
tion, partakes of the characters of animal contractility and 
of irritability. The inactivity of the uterine parietes, until 
the termination of utero-gestation, resembles, in some re-
pects, the quiescent state of the voluntary muscles, when 
they are not excited by the influence of the brain; and the 
contraction, by means of which this organ expels its contents, 
can be compared only to the exertion of those muscles. On 
the other hand, the contractility of the uterus is independent 
of the cerebral influence, and its exercise is absolutely invo-
luntary; this circumstance particularly characterizes irrita-
bility in those organs which possefs it in the most remarkable 
degree, as the heart. Like the latter power, it may be symp-
pathetically roufed, when the action of the uterus is suf-
pended during or after parturition; and it continues for 
some time after apparent general death.
The attention of physiologists has been much occupied in 
investigating the immediate cause of parturition; that is, 
the cause which calls into action the contractile power of the 
uterus at the end of utero-gestation. Many adopt the follow-
ing explanation. They admit a species of opposition 
between the body and neck of the uterus, during gestation, 
the resistance of the latter overcoming the tendency of the 
former to contract. As the neck is gradually obliterated, 
it opposition is diminished, and it then gives way to the con-
tractions of the body and fundus. Against this explanation 
we may urge that the supposed struggle between two op-
poing forces is purely hypothetical, that there is no evidence 
of any contraction or attempt at it during pregnancy, and 
that it comes on quite suddenly at the expiration of the 
term. It is this sudden exercise of the contractile power, at 
the end of the ninth month in the human species, that marks 
the term of gestation, and for which we can assign no other 
cause than the immutable laws by which the operations of 
nature are regulated. However this question may be decided, 
it is clear that the contraction of the uterus alone does not 
accomplish the expulsion of the fetus. The diaphragm and 
abdominal muscles aid in the operation; and hence partur-
tion is in some degree voluntary, is accelerated in some cases 
by the courage of the individual, while in others it cannot 
be concluded without the assistance of art, in consequence of 
the strength being exhausted. Yet this action of the abdo-
nominal muscles is not so indispensable, that the uterus can 
get rid of its contents without such aid. We know the ex-
traordinary facility with which parturition takes place in 
some women, who, in consequence of particular circum-
crances in their condition, exert themselves even to retard 
the process; and the expulsion of the child is sometimes com-
pleted at the approach of death, when the abdominal mus-
cles can hardly be supposed to contribute.

After the expulsion of the child, and of the secundines, 
the action of the uterus still continues, and the organ is gra-
dually reduced in its bulk. For a short time its parietes 
are in a state of increased thickness; the vessels, being com-
presseed by this permanent state of contraction, pour out but 
a very small quantity of blood, notwithstanding the preceding 
dilatation of their orifices. This blood, effused very slowly, 
is soon succeeded by an abundant secretion of mucus from 
the surface of the uterus, constituting a species of discharge 
peculiar to women recently delivered, and known by the 
name of lochia. This evacuation lasts for a longer or shorter 
time, and probably does not cease altogether, until the 
uterus has regained its original state. The contraction 
of the organ is owing at first to the evacuation and contraction 
of its vessels; but soon nutrition is carried on in it with 
less activity, while absorption proceeds vigorously until the 
excess of matter deposited for its development has been re-
moved.

**Phylogy of the Female Organs of Generation.**

**Puberty and Menstruation.**—From the uterus of every 
healthy woman (at least with very rare exceptions) who is 
not pregnant, or who does not give suck, there is a discharge 
of blood at certain periods, from the time of puberty to the 
approach of old age (during a period in general of about 
35 years); which, from the periods or returns of the dis-
charge, is called the menstes or catamenia, and, from the 
general regularity of its appearance, is termed in French les 
regles. The commencement of menstruation is coeval with 
that equal revolution in the female constitution, which in-
dicates the power of executing the generative functions, and 
may be regarded as the development of the sexual life. It is 
therefore one of those circumstanes which, taken altogether, 
mark the period of puberty in females. At the same time 
their complexion is improved, their countenance is more ex-
pressive and animated, their attitudes graceful, and their 
conversation more intelligent and graceful; the tone of their 
voice becomes more harmonious, their whole frame, but 
particularly the breasts, are expanded and enlarged, and 
their minds are no longer engaged in childish pastimes and 
amusements. These phenomena have been described very 
elegantly by Harvey: "ne minus notum est, quam virgo 
acerrimo contingat, inrecreante primum et tepefacto 
uteris; pudefit nempe, coloratione oculit, mannae prae-
truant, pulchrior velutum ridet, splendent oculi, vox canora, 
inceput, gellus, ferro, omnino decoris sunt."

The whole human race is subject to this law, and the ac-
counts of some travellers, stating that the Brazilian or Sa-
moied women are exempt, have not been confirmed by more 
recent
recent and accurate inquiries. It is a general and essential phenomenon in the life of woman, and if different climates, or the varieties of the savage and civilized states, are capable of modifying the phenomenon, their influence is not sufficient to annihilate it altogether, even in the frozen and inhospitable regions, where some writers have supposed that it does not occur in a constant and regular manner. It is hardly necessary to refute an opinion, which has prevailed very generally, that the whole nations, particularly Americans, are not liable to this discharge. In their visits to those countries, Europeans saw numerous females in a state of nakedness, without observing any signs of the discharge, which may be accounted for by two circumstances. The women at that time are generally supposed to be in an impure state, and to communicate a malignant influence; they are consequently compelled to flum society while the discharge lasts, and to avoid the sight of man by hiding themselves in solitary huts. Travellers have also observed that their curpulous attention to personal cleanliness, and to the modest attitude of the lower extremities, would prevent the spectator from discovering any traces of the catamenia. The discharge is peculiar to the females of the human species, whereas, in the language of Pliny, it is the only "animal menstruate." Many naturalists, says Blumenbach, and among others Buffon, have ascribed a periodical flux of this kind to some other animals, particularly of the monkey kind. But having had the opportunity of observing several individuals for many successive years, I discovered that these supposed catamenia did not exist at all in some, while in others there was a small occasional uterine hemorrhage appearing at no regular intervals. (Institut, Physiol. sect. 37.) There is a great determination of blood to the organs in animals when they are in heat; this is attended with a mucous secretion, and sometimes even blood has been discharged, to give rise to the erroneous notion of their being subject to the menstrual flux. Such a casual and unfrequent occurrence can by no means be compared to the regular periodical discharge observed in women almost without an exception. On the other hand there are examples of women who have never menstruated, and of others, in whom this discharge has not appeared through long periods of their lives, without any ill consequence. Dr. Denman knew two instances in which the menopause had never been discharged; the individuals married, but had no children. (Intro. to the Pract. of Midwifery, 4to. p. 115.) Some continue to menstruate during the time of suckling, and the circumstance is not very rare, although it is the general rule that the discharge should cease at this time. The vital powers are differently employed, and their exercise has a different object and direction. Pregnancy almost invariably interrupts the process. The important functions carried on in the uterus at this time require all the powers of the mother; and the adhesion of the ovum to the uterus seems to form an insuperable mechanical obstacle to the discharge. Hence Mr. Denman states that he has never known an instance of menstruation during pregnancy. The ejaculation of the discharge without the presence of any unhealthy cause, is the only gap by which women know that they have conceived. Authors relate many examples, however, where the catamenia have flowed during gestation; but very strong evidence would be necessary to prove a circumstance so unlikely in itself.

The menopause may appear prematurely in some women, from peculiarity of organization, as the phenomena of puberty have occurred at unnaturally early periods in men; and the circumstance must be referred to original difference of constitution. Haller knew a girl of good family, nine years of age, well constituted both in mind and body, who had been subject to the regular periodical return of the catamenia for some years, without any other apparent disadvantage than that of being rather short and delicate in her make. He mentions another instance in Switzerland of a girl having a child by her uncle at nine years. Many of the accounts of menstruation in early infancy must be deemed morbid or symptomatic discharges, and cannot be referred to the catamenia. When the female constitution from any cause is disposed to, or requires a fangmous discharge, it is commonly made from the vessels of the uterus.

The early or late appearance of the menopause may depend upon the climate, the constitution, the delicacy or hardiness of living, and upon the manners of those with whom young women converse. In general, the warmer the climate the sooner the menopause appear. In Greece, and other warm countries, girls begin to menstruate at nine, and, ten years of age. According to Thevenot and Chardin they even marry and bear children at eight and nine years of age in some parts of Asia. The discharge does not appear in Europe until the female has nearly attained her full growth. Haller mentions the twelfth and thirteenth years as the usual periods in Switzerland; the discharge appears sooner in the more southerly countries of Europe, and later as we approach to the north. According to Linnæus, in his "Flora Lapponica," the women of Lapland do not menstruate until a mater age, and then in small quantities, at long intervals, and sometimes only in the summer. But if the process does not go on according to the general prevailing rule in the country, they suffer equal inconveniences as in warmer climates, where the quantity discharged is much greater, and the periods shorter. In this country girls begin to menstruate from the fourteenth to the eighteenth year of their age, and sometimes at a later period, without any signs of disease; but if they are luxuriously educated, lying upon down beds, and sitting in hot rooms, menstruation usually commences at a more early period.

The variety in the time at which women arrive at puberty has given rise to some moral deductions. It has been assigned as the reason why women in hot climates are almost universally treated as slaves, and why their influence is so powerful and extensive in cold countries, where personal beauty is in less estimation. In hot climates, women are at the height of their beauty when they are full children in underlining; and when their understanding is matured, they are no longer the objects of love. In temperate climates their persons and their minds acquire perfection at the same time, and the united power of their beauty and faculties is irresistible.

At the approach of old age women cease to menstruate, but the time of the cessation is commonly regulated by the original early or late appearance of the menopause. About the fortieth year, a little sooner or later, the regular periods of the catamenia are interrupted; and before the fiftieth year, profuse discharges occur followed by long intervals; about the time last mentioned, the catamenia generally cease, and the power of reproduction is lost. With those who began to menstruate at ten or twelve years of age, the discharge will sometimes cease before they arrive at forty; but if the first appearance was protracted to fifteen or eighteen years of age, independently of disease, such women may continue to menstruate until they have passed the fiftieth, or even approached the sixtieth year of their age. In this country, the most frequent time of the cessation is from the forty-fourth to the forty-eighth year, after which women never bear children. By this constitutional regulation of the menopause the propagation of the species is, in every country, confined to the most vigorous
vigorou part of life, and, had it been otherwise, children might have become parents, and old women might have had children, when they were unable to supply them with proper or sufficient nourishment. Yet the rules just mentioned are not free from all exceptions. The catamens, with powers of fecundity, have continued in particular instances much beyond the age we have specified. Some of these have had regular catamens; in others, after a long suppression, the discharge has returned. We must be careful, however, here, as in the case of premature appearance, not to confound with the menstes accidental and morbid hemorrhages. A relation of Haller's has two sons after her fiftieth year, and in colder countries, where the access of puberty is late, children have been born when the mother was even above 60.

The proper menstrial blood is generally preceded, sometimes for many months, by a whitish ferosus fluid. Symptoms of more or less violence, indicating the accumulation of blood about the hypogastric vessels, such as pain in the loins and about the pelvis, latitude with painful affection of the lower extremities, and various nervous and hysteric feelings, are then observed. Pains in the head, flushing of the cheeks, and even simiply appearance in the face sometimes take place. In danger begins these symptoms are milder, and in the different instants often go off spontaneously: but they return with greater intensity, attended with considerable colic pains, and quick and strong pulse, until a bloody flux, and then more genuine blood flows more or less rapidly from the vulva. The duration of the flux is uncertain; it may be accomplished in three or four days, or be protracted till the seventh or eighth. The quantity is subject to no settled law: it is greater in warm countries, where it may amount to a pint or more; while in colder regions it does not exceed five, four, or three ounces. "Yet," says Dr. Dennan, lib. cit. p. 118, "there is a common quantity, to which, under similar circumstances, women approach, and it may be estimated in this manner. Supposing the quantity to be about eighteen ounces in Greece, and two ounces in Lapland, there will be a gradual alternation between the two extremes, and in this country it will amount to about six ounces." Manners and way of life make a considerable difference. Luxurious and lascivious women have a more copious discharge: while those who take much exercise, or are weak or insufficiently nourished, furnish a more sparing quantity. The pain subsides as the discharge proceeds; the inflammatory symptoms about the uterus go off as the determination to that organ ceases, the pulse is diminished, and the blood is followed by a ferosus fluid. Signs of debility succeed, with a hollowness about the eye, and a dark circle surrounding the organ. The first appearance in a young girl is generally followed by an interval of from one month, and this period approaches gradually to a full month; so that a healthy woman, in whom the discharge is established, will have it return on the same day of the month for many succeeding years. If seven or eight days are occupied by the flow of the catamenis, there is an interval of twenty-two or twenty-three, making up the menstrial period. Such is the course observed in healthy temperate females, whose bodily and mental powers are not abused or overstrained. Improper regimen and manners may precipitate or retard the discharge. Luxurious manners, with high living, may occasion return after fifteen days: under various other circumstances there is a similar protracion of the period, which recurs however at regular intervals. Similar symptoms to those which attend the first menstruation, but in a milder form, accompany each return. In this respect considerable varieties are observed; the affection recurring with considerable violence, at every period, in some women, while others do not seem to suffer at all.

The nature of the discharge fluid has not been ascertained by any accurate investigations, but its obvious characters are so exactly like those of blood, that it has been generally considered and called blood. This remarkable difference, however, at least, seems to distilful the two fluids; viz, that the catamens do not coagulate. They are blood deprived of fibris. Coagula are sometimes seen, but are considered to denote unhealthy menstruation, as they occur when the procès is obviously disturbed, and attended with great pain, &c. Opinions have been very generally received that the menstrual discharge pollutes some peculiar malignant properties. Thes notions seem to have originated in the East; they appear in all their force in the ordinances of the Jewish legislator, were adopted by the Arabian physicians, and have been credited in most countries. The severe regulations which have been made in some countries, for the conduct of women at the time of menstruation, the expessions used, the disposal of the blood discharged, or of any thing contaminated with it, the complaints of women attributed to its retention, and the effects enumerated by grave writers, indicate the most dreadful apprehensions of its baneful influence. The following quotation exhibits these absurd notions in very elegant language. "Painis cum menematur facultas concumbendi excisatur; si novella vitis coagatur, in perpetuum editerit; iteriles hunt tactae fruges; moribundit in ultimatur; exsuntur bortorum germina; haller praeidam alterius menstruum supergregidant, ant illis circumstius, abortum facit; inamet, quia utrocrucia, conchiplum seidem inopia; pargant simпитur, et vaporab o arcepe etatae chronic obsura obturat. Gratus hic sanguis eases in r obedient, homines vero diris cruciatibus abigite; comitabant morbum, pilarum effluvium, aliaque elephantiocrum vita inducat; idcirco a veteribus inter venena relatus; peri malignitate exsuntur, atque sanguinis elephantiocr potus." De Graaf.

Under peculiar circumstances of health, or states of the uterus, particularly in hot countries, if cleanliness be not observed, and the evacuation take place slowly, the discharge may easily become acuminious and offensive. But there is nothing of this kind belonging to healthy menstruation in a cleanly woman, where the effused fluid differs from any other blood only in the circumstians already mentioned. Nay, when the catamenis are retained in the body for 24 months, in cases of imperforate uterus, the discharge produces so ill effects, whatever, and are distinglished by so particular odour or offensive qualities when discharged by an operation. We have, therefore, no reason for thinking otherwise than that this discharge is of the most insufficient nature.

That the catamenis come from the uterus is tolerably evident from the change in the lining of that organ during the period of their flow. Its mucous surface is rendered lofter and more viloinous: and exhibits bloody spots, with numerous pores, from which the fluid may be expelled. The appearance of the menstrial blood in its cavity during the period is a further proof: to which we may add the suppuration of the discharge in various morbid conditions of the uterus, and in pregnancy, where its surface is occupied by the adhesion of the ovum. Direct evidence of the fact is furnished in cases of prolapsus, where the fluid may be actually seen distilling from the os. These arguments we may add the obvious connection of the menstrial flux with the functions of the uterus. Some have contended that the vagina is partly or wholly the source of the catamenis; but the opinion rests on no sufficient ground: the structure and function:
functions of the vagina, as well as the direct evidence of facts, strongly oppose the opinion.

Whether the menes come from the arteries or veins of the uterus has been a point of discussion with physiologists; and also whether it be a simple efflux of blood from the vessels or a secretion. The structure of the organ refembles that of glands, and the appearance of the fluid, on many occasions, differs widely from mere blood; which indeed it never resembles entirely in the healthy state; so that we are disposed to consider it as a secretion performed by the uterus like fluids that are formed by any other glands. A circumstance is sometimes observed in this process, which must be referred to the secretory action of the uterine vessels. This is the discharge of the membraneous substance, of the figure of the uterine cavity, smooth on one surface, and flocy on the other, and much resembling the decidua on the whole. This fact is mentioned by Dr. Dinsen, who first saw it in married women, and afterwards in unmarried ones under circumstances which proved undoubtedly that it was formed independently of connubial communication. The menstruation has been painful in all these cases, and conception has never occurred while the habit remained.

The efficient cause of menstruation has afforded an ample field for those who delight in speculations and hypotheses. As the periods of the moon agree nearly with those of the discharge, the influence of this body has been referred to in explanation of the occurrence. If we admit the fiction, the effect of lunar attraction ought to be very different in the various relative positions of the moon and earth; but the observation of several individuals will immediately show that there is no day of the month in which fever do not begin to menstruate, and that the moon's apogee or perigee has no influence at all in this respect. We shall see, too, that the discharge begins in some, is diminished or entirely ended in others, at the very same time; consequently that the moon can have nothing to do with the matter. Moreover, as the menstrual period rather follows solar time, the same woman menstruates at one time in the new moon, and at another in the full moon. The existence of some ferment, causing an intertine motion in the vessels of the part, meets now with no advocates. Local or general plethora have been assigned as the reasons of the menes, and many of the circumstances which accelerate or increase, or on the contrary retard and diminish the flow, favour these opinions. But we will not adopt the opinion; the loss of several times the quantity of blood previous to or in the very act of menstruation, from the arm, or any other part of the body, does not prevent or interrupt the flowing of the menes; and in those complaints which arise from their obstruction, greater relief is afforded by a few drops of blood from the uterus itself, than by ten times the quantity from any other part. A curious circumstance must be noticed respecting the effects sometimes produced by obstructed menes; viz. that their place is supplied by periodical emissions of blood from various other parts of the body, as the mouth, lungs, ears, eyes, breasts, and almost every other part. These probably should be deemed in many cases rather as discharges belonging to some disease under which the patient may labour, than as connected with menstruation. Hemorrhages of every kind, in either sex, are frequently observed to be periodical.

That the catamenia are a secretion from the mcosa lining of the uterus, of which we cannot understand the direct mechanism, any more than the method in which any other secretions are performed; and that we are ignorant of the causes which determine their appearance to the monthly period, seems to be nearly the sum of our knowledge on this subject. It is clear that the process, being a part of the healthy operations of the organ, and therefore indicating its general condition, is necessary to prevent the uterus in a state fit for conception. Observation has fully proved that women, who do not menstruate from the uterus, or who are tending in a state fit to menstruate, cannot conceive, even though they should have a periodical discharge of blood from any other part of the body. All animals, at the time of their being fabulous, or in a state fit for the propagation of the species, have a discharge, analogous and perhaps equivalent to menstruation, which is generally mucous, but in some instances, in any hot seasons and climates, becomes sanguineous.

That the menstrual blood contributes to the formation or nutriment of the fetus may be reasonably doubted. The time of the discharge is not the most favourable to conception, which occurs most readily just after the period. Since all animals, whether they menstruate or not, supply the offspring with nourishment of a proper kind, and in a sufficient quantity to bring it to perfection, we may conclude that the end is accomplished by some more common principle. The mucous discharge from the generative organs of animals, proves that they are in a state favourable to the propagation of their species, and the catamenia prove the same circumstance in women.

From the time when the phenomena of puberty announce the aptitude of the female for the exercise of her sexual functions, the generative organs exert an influence which modifies the whole organization, and beffows on woman the most striking traits of her physical and moral character. The various revolutions to which her constitution is subjected, the nervous affections, the frequent returns of indisposition and suffering, the strange and unaccountable anxieties and caprices, and sometimes the increased acuteness of the imagination and judgment; all depend on this influence; and if it be true that man is male only at certain times, while woman is female during her whole life, it must be attributed chiefly to this cause. It is this that constantly recalls woman to her sex, and marks her whole existence with fo characteristic a physiognomy. We shall not be surprized to find, that a cause of such power and extensive influence is liable to irregularities which have very marked effects on the constitution. When the new powers with which the organs are endowed exceed the just standard, and deviate into a kind of unnatural irritability, they affect sympathetically the whole frame, and particularly the nervous system. This, in an extreme degree, constitutes furor uterinus. Generally, however, this excessive vitality of the sexual organs, without going to such an extent, produces various spasmodic and nervous symptoms, constituting what are called hysterical disorders, and arising evidently from the artificial and forced state of celibacy. These affections are removed by marriage, which re-establishes the balance of the various functions by giving its natural employment to an organ, whose excessive sensibility deraigned the whole system. Other and very various phenomena may be referred to the same cause; and those physicians who have collected, in particular works, observations on the diseases occasioned by celibacy, or by the imperfect and unnatural enjoyments of the cloister, present us with an alarming catalogue. "Ut reliqui illiuti a natura dati inobsequi os punitum, ut et venerem abscissiam, ut nature imbecillam, hee ipsa uilecticur. Ipsa animalia ex defiderio veneris languentur et pereunt. Cyprini eex retentis ovis laborent. In facris edibus, de quibus fere religio venerem arcet, multa, parum cognita, neque famabilia morborum genera vigere idoneus auclor exsultat. Frequentem ex potilium, quae veneris dulcedinem deglutintur, quae nunc privatum, in chlorophy, in hylterica mala, in conjugatione, ..."
GENERATION.

The generative process is subject to very different laws in animals and in the human species. In the former, particular seasons of the year are appropriated to these functions, and the organs undergo certain physical changes, by which they are rendered fit for the process. It is a peculiarity belonging to the human race, that they are confined to no season in exercising these functions. Most animals, and particularly birds, copulate in spring; and that warmth has much influence in the affair is evident from this, that animals of warmer countries seldom copulate or are fecundated in Europe. Perhaps women conceive rather more frequently in spring; at least accoucheurs have observed that there are more labours in the months of December and January. As the effect of sexual communication is so important, it cannot be indifferent to the design of nature to what part of the uterine system the semen should be conveyed. It admits of no doubt, that it either remains in the vagina, passes into the uterus, or else extends its course along the Fallopian tubes to be applied to the surface of the ovaries, which it stimulates, and from which the new animal derives its existence; but the question whether it be one or other of these, has given birth to more physiological controversy than perhaps any other operation of a living animal. Those who have entered the lists have ranged themselves either on the side of application of the semen to the ovaries, by means of the tubes; or on that of the instability of this process. These latter contend for an absorption of this fluid by the vagina, and a peculiar excitement of the whole frame as a consequence, of which excitement the changes produced on the ovaries are to be regarded as the local effects. The advocates for the first opinion allege, that the semen has been seen both in the uterus and tubes, and quote as their authority the observations of Morgagni for the former, and Ruyfch for the latter. When seen in this last situation, some have thought that it was conveyed thither by the muscular power of these parts, in the manner of a peristaltic motion, beginning at the uterus, and ending at the eminated termination of the tube; and when at this last, it was supposed that the semen was applied to the surface of the ovaries, and impregnated them by actual contact. Various analogies, drawn from the animal and vegetable kingdoms, have been adduced for and against these different opinions: but such arguments must be received with caution. Where different instruments are employed to produce the same ultimate effect, we may reasonably conclude that the means used are essentially different. On this principle no direct conclusions can be drawn respecting the human species, from observations either on vegetables, or even on frogs, toads, and newts. The impregnation of birds, being effected by semen conveyed into the body, resembles that of the human subject more than the former; but they differ so widely in the mode of perfecting the factus from the ovum, that we cannot rest with much confidence on their general analogy.

To the observations of Morgagni and Ruyfch a numerous train of facts has been opposed, ascertained by the experimental labours of Harvey, De Graaf, Haller, and others, in which no semen was ever seen beyond the vagina in animals, examined at various periods after coition. One experiment of Haller, on a sheep, constitutes a single exception to this observation: he once saw semen in the uterus forty-five minutes after coition. These facts bring the advocates for the necessity of a contact of semen with the ovaries into a dilemma, from which they attempt to extricate themselves by contending, that fecundation does not require the application of semen to the ovaries in a palpable form; but that there is exhaled from it a subtile fluid in a vaporific state, called aura feminina, and that the contact of this vapour is sufficiently to impart to the ovaries their due quantity of stimulus.

The opinion, that the presence of the semen in the vagina alone was sufficient to account for impregnation, was defended by the statement of cases, in which, from some anatomical peculiarities, it seemed almost impossible that the fecundating fluid could be conveyed into the uterus; yet in several of these cases impregnation really took place. Those who hold a contrary opinion either cavil at the accuracy of the statement, or draw a different conclusion. In order to throw some light on this subject by direct arguments, Dr. Haighton undertook a series of experiments, the results of which are detailed in the 8th vol. of the Philosophical Transactions. He divided the tubes which form the cornua uteri in rabbits, and admitted them to the male, when they had completely recovered from the experiment; but this operation seemed to destroy entirely not only the power of conception, but also the disposition to employ the means. After several ineffectual trials, he varied the experiment by dividing one tube only, and in many instances the animals conceived afterwards. Corpora lutea were found on both sides of the body, but fetuses only on the found side. If the former bodies are produced only after conception, which the doctor affirms, then conception must have taken place here, although the direct access of semen to the ovary was interrupted; for the operation in question completely obliterates the tube. It must be acknowledged that the proof is incomplete in these cases; we cannot justly assert that conception has taken place, when no fetus was formed. Dr. H. attempts to elude this objection, by shewing that the division of the tube at any period after coition, but before the passage of the germs from the ovary, will equally prevent the appearance of fetuses; accordingly no fetuses were seen in the tube, when it was divided as late as forty-eight hours after coition. But if the operation be deferred until the time at which the rudiments of the new animal have passed into the tube, the actions of the parts suffer no interruption, and fetuses are formed in the tube of the mutilated side. "If," adds the Dr. "the ovaries are susceptible of their proper excitement only from the contact of semen, how did it happen that the effects of that excitement were not more obvious where nothing had been done to intercept its course for 48 hours, than in those where all communication between the uterus and ovary had been cut off before the means of impregnation had been employed? I think it must appear, on tracing nature's
flaps through the different stages of this work, that they are the product of that law in the constitution, which is called sympathy or consent of parts. That the femen first stimulates the vagina, os uteri, cavity of the uterus, or all of them. By sympathy the ovarian vessels enlarge, project, and burst. By sympathy the tubes incline to the ovaries, and having embraced them, convey the rudiments of the fetus into the uterus. By sympathy the uterus makes the necessary preparation for perfecting the formation and growth of the fetus. And, by sympathy the breasts furnish milk for its support after birth.

Phylogographers have certainly not yet ascertained, by direct observation, whether or not the semen enters the uterus and tubes; and consequently all explanation of the mode in which it co-operates in conception must be, in a great measure, hypothetical. If we cannot speak from actual knowledge on a point, which must be so important as the present, in the generative process, and the determining of which must be so essential towards forming right notions of the nature of the business, how uncertain must our representation be of the more intricate and obscure parts of the subject!

The circumstances just described do not appear to be essential to the business of fecundation; they contribute to the important object of reproduction in a secondary manner. The strong desire implanted in all animals, and the physical gratification experienced in its indulgence, ensure the union of the sexes, and consequently the continuation of the species. The celebrated Spallanzani has given to the world a very interesting series of experiments, by which it is proved that impregnation in many cases may be effected by artificial means. He proved the first in the case of various amphibians, as the frog, newt, and toad: and afterwards in the bitch. He experimented on a spaniel bitch, which had before had whelps. He confined her very closely till she was in heat, and then proceeded in the following manner: A young dog, of the same breed, furnished me, by a spontaneous emission, with 10 grains of seed, which were immediately injected into the matrix, by means of a small syringe introduced into the vagina. As the natural heat of the feed in animals of warm blood may be a condition necessary to render fecundation efficacious, I had taken care to give the syringe the degree of heat which man and dogs are found to polite, which is about 30. Two days after the injection, the bitch went off her heat, and in twenty days her belly appeared swollen, which induced me to set her at liberty on the twenty-sixth. Meanwhile the swelling of the belly increased; and sixty-two days after the injection of the feed, the bitch brought forth three lively whelps, two male, and one female, resembling in colour and shape not the bitch only, but the dog also from which the feed had been taken." (Dissertations, vol. i. p. 250.) The experiment was repeated with success by Dr. Ross, ibid. 476. We have an account of a similar trial in the human subject, made at the suggestion of Mr. Hunter. It was in an instance of malformation, where the urethra opened in the perineum. "Under these circumstances the person married. When he had connection the emission was complete, which proved that the furtbicles were perfect, but the femen always passed out at the perineum. The late Mr. Hunter was consulted to remedy, if possible, this inconvenience, and to enable the person to beget children. He advised that the husband should be prepared with a syringe fitted for the purpose, previously warmed; and that, immediately after the emission had taken place, it should be taken up by the syringe, and injected into the vagina, while the female organs were still under the influence of the coitus, and in the proper state for receiving the femen. This experiment was actually made, and the wife proved with child.

"On a subject of this kind it is proper to speak with caution; but, from all the attending circumstances, no doubt was entertained by Mr. Hunter, or the husband, that the impregnation was entirely the effect of the experiment." Home on Hermaphrodites, in Philos. Transact. for 1799.

Various circumstances have been enumerated, as proofs that conception has taken place; as peculiar feelings during coition, horripilation, and even fibrillor dentium, &c. Haller's sensible remarks on this subject seem to us to be nearer the truth. "Hec omnia quidem nibhi nusia videntur, et difficiliima expertv. Neque enim feminia, dum maritum admissit, ottio eff ad experimentum animo: neque, nisi longo abhinc temporae nusit fore se concephile, quando dno ejusmodi phena de memoria clapa fuit. A feminis certe, a quibus verum poteram expectare, nihil de horripilatione, neque de dolore potui difceere." Ibid.

The opinions concerning the effusion of a seminal fluid by the female, and its mixture with that of the male, are altogether imaginary. That a mucous fluid is sometimes poured out in coition, from the apparatus already described in the external organs and the vagina, is undoubted; but this happens only in lascivious women, or such as live luxuriously; it confines merely of mucus, and is discharged externally, instead of passing into the uterus.

Circumstances do not admit of the internal changes which accompany and follow copulation and conception, being accurately ascertained in the human subject; and, consequendy, these have been investigated in various animals. Mr. Cruickshank gives the following description of the parts of a rabbit at heat. The orifice and internal surface of the vagina are as black as ink from the great deternination of blood. The ovaria had, under their external surfaces, a great number of black, round, bloody spots, somewhat less than mulberry-seeds. These black spots are the calcies or cups which secrete the ovum; they are extremely vascular; the ovaria themselves are transparent, and carry no visible blood-vessels. These calcies, on the expulsion of the ovum, enlarge and become yellow, projecting above the external surface of the ovaria, and form the corpora lutea: a certain mark of conception in all quadrupeds, and in women themselves, whether the embryo is viable or not. The ule of the corpora lutea is not yet made out; but the orifice, through which the ovum bursts into the Fallopian tube, is often extremely manifest, and always has a ragged border, as lacertated parts usuall
GENERATION.

usually have. The Fallopian tubes, independent of their black colour, were twisted like washing worms, the peristaltic motion still remaining very vivid; the fimbric fibers were also black and embraced the ovaria (like fingers laying hold of an object.) so closely and so firmly, as to require no force, and even laceration, to disengage them. Haller and other observers support this statement of the erection of the tube, and its close application to the surface of the ovarium. But Dr. Haighton seems not to have found it so until a later period. He examined a female rabbit in high season a few minutes after coition, and found the fimbric in their natural situation. He found, moreover, from a regular series of observations made on different rabbits, at every hour between the first and the ninth, that the fimbric remained nearly in their usual situation; and the only difference he noticed in the half hours was a greater turgescence of vesi,

fs if preparatory to some important act. That the prominent vesi or calyces of the ovaria, already mentioned, burst, and allow something to escape into the Fallopian tube, which conveys it into the uterus, is what all observers seem to agree in: and they concur, moreover, in representing the corpora lutea as produced by a particular process carried on in the empty ovaria calyces, and consequently, as exhibiting incommutable proofs of impregnation having been effected. These circumstances have all been ascertained by the observations of animal bodies, and transferred by analogy to the human subject; in which, indeed, the formation of a corpus luteum is very evident, although the earlier stages of the process have not been traced. Observers by no means agree as to the time at which these changes are effected. Mr. Cruikshank represents the bursting of the calyces as following a fruitful coition very speedily. "I opened," says he, "a female rabbit two hours after she had received the male: the black bloody spots just mentioned now projected much above the surfaces of the ovaria, some of the ruptured orifices were just visible; but in many of these spots there was not the least veilage of an orifice: whence I conclude that they heal very quickly in general." The narrative of Dr. Haighton's experiments would lead us to conclude that this escape of the germ from the ovaria calyces does not take place till a much later period. In twelve hours after coition "several of the vesi evidently projected; they had lost their transparency, and were become opaque and red. When punctured a fluid of the same colour escaped. The corpora lutea, which are formed by the thickening of the parietes of the vesi, were not very evident." At 24 hours after coition the fluid in the vesi was similar to that of the late experiment. They projected more evidently, and their thickened parietes, manifesting the commencement of corpora lutea, were become more apparent. At 48 hours past coition, the vesi seemed to be in the very act of bursting, and a semi-transparent substance of a mucous-like consistence was beginning to protrude from some of them; others, indeed, were less advanced. The limbrated extremities of the Fallopian tubes were preparing to receive their contents, as appeared by their having quitted their usual position, and embraced the ovaria in such a degree, that only a small portion could be seen until the tubes were taken away. Sections being made into the thickened vesi, the formation of corpora lutea appeared to have made rapid advances. From the appearance of an incident rupture of the vesi in this experiment, it was but reasonable to expec
t that their contents would soon have escaped. In two days and twelve hours after coition the facial rudiments had escaped; but the cavity of the ovarian vesi had suffered but little diminution. Brillié were easily introduced by the ruptured orifices. In this experiment the advances to-

wards the formation of a perfect corpus luteum were such as the period of examination would naturally lead us to expec

t. The contents of the vesi having escaped, it was but reasonable now to look forwards to a speedy obliteration of the cavity. I therefore examined these parts, under similar circumstances, on the 3d, 4th, and 5th days. In the last experiment there was but little veilage of cavity, consequently the corpora lutea might be considered as perfectly formed."

That a somethings which is the germ of the future animal, and is supposed to be of a vascular figure, escapes from the ovaria after conception, is received into the Fallopian tube, and conveyed by it into the uterus, is rendered highly probable by the facts just related; and various additional proofs may be adduced on this subject. Almost the whole human kingdom poifefs ovaria, in which the rudiments of the future being are obviously contained previously to impregnation; and it is the development of these rudiments after impregnation that forms the future animal. The formation of the germ in the ovar, and its passage into the ovum, are particularly clear in birds and reptiles; and analogy strongly leads us to assign to the ovaries of the mammalia the same function of producing these germs. The removal of these bodies renders the woman completely sterile; and Mr. Hunter has shown that the extirpation of one has a very marked effect on the fecundity of the animal. In the Philosophical Transactions for 1787 he has detailed the result of "an experiment to determine the effect of ex-irating one ovarium on the number of young produced." He selected two fows of the same colour and size, and one boar from the same fowc, and removed one ovarium from one of the fows. About the beginning of the year 1779, they both took the boar; but the one which had been spayed earlier than the perfect female. The distance of time, however, was not great, and they continued breeding at nearly the same times. The spayed animal continued to breed till Sept. 1783, when she was six years old, which was a space of more than four years. In that time she had eight farrows, conRitting of 76 pigs; but did not take the boar afterwards. The perfect animal continued breeding till December 1785, when she was about eight years old, a period of almost six years, in which time she had thirteen farrows, conRitting of 163 pigs. "From this experiment," says Mr. Hunter, "it seems most probable, that the ovaria are from the beginning defined to produce a fixed number, beyond which they cannot go, though circumstances may tend to diminish that number; that the constitution at large has no power of giving to one ovarium the power of propagating equal to two; for, in the present experiment, the animal with one ovarium produced ten pigs less than half the number brought forth by the pig with both ovaria. But that the constitution has so far the power of influencing one ovarium, as to make it produce its number in a less time than would probably have been the case, if both ovaria had been preferred, is evident from the above recited experiment." Certain irregularities in the process throw much light on the subject, and tend to strengthen the argument just adduced. Fetus may be detained in the ovarium, and develop itself to a certain point. Or, the germ may escape from the ovarium, and not be admitted into the Fallopian tube; in which case it has often become attached to some part of the abdominal cavity, instead of the uterus, constituting what is termed a conotal extra-uterine fetus. After it has attained a certain degree of development, labor pains come on, but parturition cannot be effectecd; and the bones of the child are, perhaps, discharged through an abces, or gain admission into the alimentary canal, and are

I 2

ved.
voided per annum. Lastly, the germ may be detained in the Fallopian tube, without arriving at the uterus. The structure of the part does not allow it to dilate sufficiently to contain a full-sized child, and it accordingly bursts, in general, long before that time, and the patient perishes from bleeding.

We must allow, that the escape of any thing from the ovaries in the human subject, or other mammalia, is rather inferred than directly proved; and that we cannot see the germ in the Fallopian tube, on their passage to the uterus; in so obscure a state are the rudiments of the future animal at the time, and immediately after conception.

We have represented the corpus luteum as the consequence of a fruitful copulation; but there is some doubt whether the latter circumstance be an essential condition of its production. It is well known that birds lay eggs without the concourse of the male, and such eggs are unproductive. Valerier aetists, that he has seen corpora lutea in the ovaries of virgins; and Blumenbach appears, in the following quotation, to agree with him in opinion on the subject.

"Porro ova ovium minus verum est inexputas aves ejusmodii ovum: ut feminae ex machinica titillationi genitalium concinere posse, quod quidem physiologic dispersarum Aristoteles, et pretecto seculo octoanticifimus Harveius animadvertit, quorum hic adaebo libidinosissimus interdum aves efferent, ut si dorsum curam manu folum leniter tangas, siiinam procurant, et orificium uterinum nudent et expirragint, quod si blandite digemelis, vago mormare, alarumque gefcillatione, gravem veneris dulcedinem easdem exprimere; quin etiam femellas ovum inde concinere, in turdo, merula, alioque efeo expertum. Idem de pappaco referat, quem uxor ejus diu in delitis habuerat, ferpe hunc ludibundum et lascivum fedentis greylum adiefe ubi dorsum ibi demulceri getluerit quasfifque aei et blandie firepitum hymnum animi sui lietiam teftatus fuerit. Non diu autem poti blandas has contrectiones eumdem aggradation, cerbrique tandem coavulsionibus obortis exsiprallae. Difficile itaque cadaver ovum ferre perfectum fe in utero ejus reperirei; feb, ob defectum maris, corrossum. Ignominious mares itarum virginitis, si luteca in carum ovaris corpora non absumilem originem agnosiee fupicor; utpotfe qui in pelliculo corpore, non minus quam in turdis et merulis eundem acti venirei in ovarii veiculis effectum esse reor, sive iis amplexu, sive lebico quandum artificio excitatus. Quadrant in fam scopicationem, qusx dominus circumstantiae, fab quisque corpora lutea in inexpitas obseruant noactores; etas feliicet, a decimo quarto ino anno, lyterica quamdam affectio, &c. Num climati quoque aliquid tribuenatum, decedere non male, annotans tantummodo, quoquin huius artesius apud noactores occurrexunt ejusmodii hard inficiantibus causis, eos non nisi in Italiciqve virginitus observatris suae." — Specimen physiologic comparare, Gottingae, 1769, p. 4.

Physiologists have questioned whether a second impregnation can take place after a fruitful copulation. Influences of twins, born with different degrees of development, have been considered as proofs of superfection. The reasoning does not seem very conclusive, the fact does not clearly prove that the two foetuses were conceived at different and distant periods, since the growth and development of one germ may have been prevented by various causes. The question is, whether a woman, having only a single uterus, can conceive two or more months after a fruitful copulation; and at present we have no facts to prove the affirmative, while presumption is strongly against it. The thing appears more easy, if we suppose the two conceptions to be separated by a very short interval. Thus we can conceive that the American lady mentioned by Buffon, who received the embraces of her husband, and of a negro slave, in the same morning, may have brought forth twins of different colours.

On the subjects of the preceding paragraph, the reader may refer to the ample collection of facts, in the eighth volume of Haller's Elements; to Spallanzani's disquisitions relative to the natural history of animals and vegetables, vol. 2d; to Haighton's experimental inquiry concerning animal impregnation, in the Philosophical Transactions for 1797; to Cruikshank's experiments, in which, on the third day after impregnation, the ova of rabbits were found in the Fallopian tubes, and on the fourth day after impregnation in the uterus itself, with the first appearances of the foetus; ibid.

The various opinions concerning the source from which the new animal is derived, and the manner in which its formation is effected, form the last subject of the present article. In the science of life, as in all others, the speculations and hypotheses concerning any matter are in an inverse ratio to the number of ascertained facts; and persons are disposed to talk more, in proportion, as they know less. Hence the vast abundance of theories of generation, which almost exhausted the patience even of Haller, and extorted from him the following very sensible observations. "Iterum ingratisimii mihii impendat opus, scribere de his, quse multis a natura circumventis tenebris velata, fenfuum loci incomprehensum, hominem agitantur opinionibus; erit de is ferenda tentantia, in quibus quod dubitasse, quod infirmum sit, ubique fe offert, id autem parciillme, in quos animas, tanquam in firma aliquo fundamento, adiacet. Erunt libranda cum phemenonem contraria phemenonem, cum argumentis contraria argumentis, ut demum nihil doceam certius, quam nihil me docere. Et eft tamen etiam in desperatione de problematis solutione futur utilitas, proximamque eft vero, nihil docere, quod faltum fiet." The first subject of our inquiry will be, from what quarter the materials of the new animal are derived; then, by what causes these materials are formed into an animal, such as we have been shown to be produced in the female by conception. The opinions concerning the source of the offspring may be reduced to three; one gives to woman only the humble office of affording a proper nidus for the due evolution of the foetus, which, according to this theory, already exists in the male semen, and requires only a fruitful habitation. Another directly reverses this position; it puts the female in possession of every requisite for the formation of a new animal, and considers the male a mere stimulating engine, to call the latent powers of the female into life. The third gives not pre-emience to either sex, but, with the mutual embrace, supposes a mutual effect to be produced; it regards both the male and female, as concurring essentially in the work of reproduction, by each affording something, which, when united under proper circumstances, becomes the proximate cause of impregnation.

The ancients admitted a femal liquor in both sexes, and concluded, not unnaturally, that the foetus was formed by the union of these. Hippocrates and Aristotle held this opinion, and conceived that the sex of the offspring depended on some predominance in quality of one or the other fluid. However obscure the mode of this mixture may seem, specious arguments are not wanting in support of the opinion. The necessity of the co-operation of the two sexes, in producing a foetus, in almost every instance in the animal kingdom, may be alleged in favour of the doctrine. Also the existence of different sexes in almost all plants; the fecundating power of the male duii, and the perpetual preference of the seed before fecundation; which, however, remains unfruitful without the influence of the former. The refemblance
blance of the foetus to both parents in the human race, in animals and even in plants, may be urged in support of the same doctrine.

The old opinion, which supposes that males are produced by the right tefts and right ovaey, and are contained in the right side of the uterus, while females are formed on the left, is delusive of all foundation. A male with one tefts has produced children of both sexes; and male or female foetuses are seen indifferentiy in the right and left corners uteri of animals.

The hypothesis of Hippocrates and Aristotle was adopted by Buffon, and is presented in his natural history with all the advantage it can derive from his warm imagination and eloquent diction. But figurative language recompenses us very imperfectly in scientific matters for want of observation, and hasty generalizations; and the theory of Buffon is so delusive of foundation, that we can hardly think it worthy of notice. He conceives that there is a matter in nature, composed of incorruptible molecules, always living and active, and defined to the nutrition and evolution of all organized beings. These particles are received in the food, and are applied to every part of a plant or animal. Every animal is an inferior mould, by which these particles are fashioned to their particular shape. When there is more of this matter than is required for purposes of nutrition, the surplus is conveyed from all parts of the body to the telicules of each sex, which are its reservoirs. It exists here in a liquid form, and contains molecules analogous to all parts of the frame, sufficient to form a smaller being, exactly similar to the large one, from which it is produced. The molecules compounding the new being are analogous to those of all parts of the body, from which they have been conveyed to the telicules, and may be deemed a kind of extract of the old body. This matter, having passed through the interior mould, and finding the uterus in a favourable state, generates a new animal. We shall not abuse our reader's patience by the further detail of such vague chimeras; they more than justify the sarcasm of Voltaire in his "Homme aux quarante ecus." "Ah! monsieur le favant, says the man aux quarante ecus, could not you inform me how children are made? no, my friend! replies the favant; but I will tell you what philosophers have imagined on this subject, or, in other words, how children are not made." This jeu d'esprit contains a lively ironical account of the various theories of generation, which the reader will find much more entertaining, and quite as instructive as the original accounts of these reveries.

Of these, who consider that the father has the principal share in producing the child, Leeuwenhoek is the foremost. He considers the spermatic vermiculi as men in miniature; and conceives that one of these crawls in some way or other into the ovarian vehicle, and is there developed.

That the foetus is produced by the mother has been more generally supposes; and seems more probable on the first glance, since the child most certainly comes from the mother, although it is by no means clear that it ever went to her from the father. The analogy of almost all animals, and of plants, favours this opinion. The generation of the aphides has been adduced in its support; where a single fecundation suffices for several generations. In the frog and toad, and in the bird, it is very clear that the foetus pre-exists in the ovary; and that the contact of the semen produces at first no perceptible change in its appearance. Indeed the wonderfully small portion of fecundating fluid necessary to produce the requisite effect in the frog or toad would lead us to conclude that I cannot excite any very great change at the first moments of its application; and this circumstance, together with the obvious existence of the sometbing, which is afterwards evolved into a tadpole, in the ovarium before copulation, clearly proves the pre-existence of the germ in the females of this species of animals. "A quantity of feed," says Spallanzani, "far more inconsiderable than we should ever have imagined, is sufficient to animate a tadpole. We have seen that it is not necessary to cover the foetus completely with this prolific fluid: a drop will suffice. Further, three grains mixed with twelve, and even with eighteen ounces of water, communicate to every part of it the power of fecundation, since tadpoles placed in any part of the mixture are fecundated. The three grains of feed must therefore have been diffused through the whole mass of water. But what an enormous division of its particles must such a diffusion occasion! How small a share of prolific liquor must fall to the share of each tadpole! Yet there are facts which prove that the semen still retains its virtue after this excessive division; for I have found a globule 1/50th of a line in diameter, taken out of a mixture of three grains of feed with eighteen ounces of water, was often capable of fecundating a tadpole. Depriving of the proportion, which the tadpole (that of a frog is 2-3ds of a line in diameter) bears to the particles of feed diffused in a drop of this dimension, I have found, on calculation, that it is as 1:64:7777777 to 1. How infinitely small, therefore, is the quantity of feed in comparison with the bulk of the facts, which it fecundates! This deduction led me to calculate the weight of the particles of semen diffused in this drop of water: it is 1/78864, or 1/8 of a grain. That I might view these particles under every possible aspect, I reduced their bulk to cubic lines, when it appeared to be about equal to 7777777 of a cubic line." Differtations, vol. ii. p. 212. The researches of Haller, and of others on the formation of the chick, have clearly proved the pre-existence of the factus in the female of birds.

But, although this hypothesis appears to be supported by the most numerous and satisfactory proofs, there are difficulties opposed to its adoption. "It is very certain," says Haller, "that children often resembile the parents in the human race; so that you may distinguish one brother by his resemblance to another, or know a man by his likeness to the father or mother, or even grandfather or grandmother. All the individuals of some families are characterized by particular lines or countenance. My own family have now been distinguished for tallness of stature for three generations, without excepting one out of many grandfathers descended from one grandfather. Families of red-haired persons are not uncommon: the disagreeable colour being derived from the father or mother or grandmother. But this resemblance of children to parents is dependant most plainly when there is any defect or peculiar formation transmitted from one to the other. The transmutation of diseases may perhaps not be deemed so surprising, since nobody denies that the masts of fluids is derived from the mother; but the father contributes the smallest drop possible, if any. Yet we find various diseases, or dispositions to diseases, passing from either parent to the offspring. This is matter of common notoriety with respect to gout, rheumatism, insanity, scrofula, consumption, &c. but there is more doubt of some others, as cancer, hernia, aneurism, squinting, harleips, clubfoot, faciety, &c. of which, however, authors relate many examples. We know a very remarkable instance of two noble females, who got husbands on account of their wealth, although they were nearly idoits, and from whom this mental
defect extended for a century into several families, so that some of all their descendants fill continue idiots even in the fourth and fifth generations. Perhaps the resemblances of the mother are rather the most common. The ill-made Per-rians have improved themselves into a very beautiful nation by their repeated marriages with the celebrated Georgian females. The offspring of Negroes and Europeans partakes of the characters of both parents in their general form, those of the lips, nose, &c; and we may observe in general, of all such mixed breeds, that the children produced seem to constitute a mean between the father and mother. Peculiarities of formation are not uncommonly transmitted; as a very hollow palate, which I myself have seen, and many others. A man covered universally with black, clack, cylindrical, warty excrescences, begot sons and daughters with the same deformity. An excess in the number of thumbs (four) parted from the father to the children; and there are curious examples of similar facts in individuals possessing five fingers on each hand. Pliny mentions that Q. Horatius, who had this birture, begot two daughters resembling him in this respect. A family mentioned by Reaumur is more remarkable: the grandfather had a supernumerary finger on each hand, and a toe on each foot. His first son produced three children with the same peculiarity: the second, who had the usual number of fingers, but in whom the thumb was very thick, and appeared as if composed of two united together, had three daughters with the supernumerary members: the third had the natural structure. A daughter, with a very thick thumb, brought forth a boy with the additional finger. That too much influence may not be attributed in this case to the influence of the male, it may be observed that another daughter, who had large thumbs, produced some sons with supernumerary members. Maupertuis has also recorded a family of children distinguished by this character, produced by a mother with the same peculiarity. The thick lip in the Austrian family was introduced by the marriage of Mary of Burgundy with Maximilian. It is ascertained that such muta- tions, as blindness, &c. have been transmitted to the offspring, in horses; and from the plan of employing Arabian stallions rather than mares for improving the breed. There is a peculiar breed of four-horned sheep, descending from the female, and another of pigs with undivided horns. The difficulty of the subject is increased by the circumstance that these defects and peculiarities do not in general pass to the offspring. Blind, lame, or mutilated parents have perfect children. In the family with the supernumerary fingers, already mentioned, several individuals had the ordinary formation. Foals without the rump breed with the common kind of chicken, both with and without that particular formation; and the same mother has children like herself and the father, and others without such resemblance." Elements of Physiology, lib. 29, sect. 8.

The phenomena afforded by hybrid generations are curious. It is only in the cases of animals very nearly allied in their general characters that any hybrid offspring is produced: and this has the mixed characters of both parents. The re- lations of women in Africa breeding with monkeys are not sufficiently authenticated. "The mule (produced from the mare by the ass) does not," says Haller, "seem to me to be an ass, which however it resembles in its tail, ears, and obstinacy, since the form of the body, the strength and size, the hocks, the hair, and colour are those of the mother. The voice is more like that of the father, and there is a further resemblance of the ass in the peculiar hollow of the larynx. As the mule seems to be stronger and more lively than the ass, so the high begotten by the stallion on the thr-er, seems rather to follow the mother: it is said to have the ears of the horse, the mane and tail of the ass; and to be smaller than the male. The offspring of the common he-goat with the Angora he-goat has the long hair of the father, while that of the Angora female with the European male has not that character. The fine hair of the former breed was continued in Sweden to the third generation. This fact shows the prevalence of the male, which, being born in a warmer region, exceeds in fliture the European animal. The pheasant breeds with the common hen; the offspring has the mother's colour, with the form of the father, whom on the whole it most resembles. If the animal produced from such a connection breeds again with the male pheasant, the young are complete pheasants. When these and various other analogous facts are compared, we remain in as much doubt as before. It appears that the offspring is affected by both parents, in some cases more by the father, and in others more by the mother. And I think, that where the father is greater in size, his characters prevail, and vice versa." Ibid.

Neither is it merely the form and external appearance that are changed in the cases of hybrid animals; we have already observed that the mule has the peculiar laryngeal cavity of the ass; and it is further known that this animal, and all other hybrids, very rarely propagate: so that we may con- clude that some general internal change is effected in these cases. A more accurate anatomical description of hybrid animals would probably contribute to illustrate the subject: the facts at present in our possession lead us to conclude that the fetus is not produced entirely by the mother or father, that both parents contribute something to the offspring, and that the new being is rather generated de novo than evolved.

In considering the powers by which the admirable structure of the animal frame is raised, we encounter a vast host of the most wild and visionary hypotheses: we defend, to use the expression of Haller, from twilight into regions of utter darkness. In the first place we reject entirely the operation of fortuitous causes: the notions concerning equivocal generation have been sufficiently refuted by modern naturalists, even in the lower orders of animals, where the phenomena, on a superficial view, tend to confirm the vulgar opinions, and there is not even the shadow of probability in favour of such explanations in any of the higher classes.

In these times, however, men of considerable reputation have not been wanting to defend opinions very much resembling the hypothesis of equivocal generation. Buffon has contended that all the parts of an animal are not formed at once, but successively, by epigenesis. His observations concerning the organic molecules of the semen have been already noticed; he even admits the formation of new beings by putrefaction and by the fortuitous concourse of particles. His associate, Turvilliere Needham, does not allow of equivocal generation, but supposes the existence of a power, which forms the body from the smallest germ by the assimilation of aliment. He thinks that the primitive germs alone are created at once, but that there are no compound germs at all resembling animals. He quotes the phenomena observable in vegetable infusions; and conceives that animal and vegetable substances are the same in their origin, and admit of being changed into each other. The first germ of an organized body is very simple, and not yet organized, nor possessing any lineaments of the animal. Hence the smallest animalcula, as consisting of the fewest germs, are formed the soonest; and those of a more compound structure, more slowly. The whole affair of vegetation consists of an expansive force relying in matter, and a retarding power. The former is perfectly elastic, and exerts
in every sensible point of matter; it is ascribed by heat. There is a power, in every point of vegetable matter, to produce filaments, from which microscopic animalcula may be formed. A real generating cause exists in nature. The expansive force is increased, and the resistance diminished, when matter is elevated to a state of vitality. This is effected by the development of the active principles; it returns again to a vegetable nature, when the contrary causes obtain. He does not, however, admit of equivocal generation, but conceives it necessary, that the seminal fluids, both of the male and female, characterized by their peculiar properties, should be present.

In this hypothesis the power of the fermen is not neglected, nor is any attraction or fortuitous confluence of atoms admitted. But the experiments on infusion animalcula are employed to authorize conclusions, which cannot be very easily admitted. We find a great difficulty in admitting how any blind force, not regulated by design, can form animalcula designed for certain purposes, and sit to fill their place in the chain of beings. Hence we find that these animalcula are not produced when the experiments are so conducted as to remove all possibility of the introduction of ova from without. The experiments of Spallanzani clearly prove this point.

The system of epigenesis met with an able defender in C. F. Wolf; see his Theoria Generationis, Haller, 1759, 4to. He explains the mode of growth, and the formation of parts in animals and vegetables, by the action of a power which he calls vis effentiales, without any mould or model. This power, together with the fixation or coagulation (futia defecentia) of juices, accomplishes the whole work of formation. The heat of the air in plants, and the heart in animals, are accessory causes of generation. The primordia of animals are globules, which cannot be reduced into smaller component parts; neither arteries, veins, nor heart exist in the egg at 24 hours. The vis effentiales, different from the power of the heart, now begins to act; and, in the globular matter of the area umbilicalis, forms grooves, which gradually grow red, and constitute vessels. These at first are large intervals of the globular matter, but gradually become smaller. Membranes are formed round these passages. All parts are first fluid and inorganic, and then formed into vessels. Trunks are formed in the branches, and at last the great trunk of all, the heart. New parts are formed, from the juices of the first; and thus the organs appear in succession, one after the other. Haller refutes this theory from his accurate observations on the formation of the chick; he shews that in fact parts exist, distinguished by their form and other characters, when superficial observation would lead us to infer that there was only an inorganic homogeneous mass. The transparency of the whole prevents the outline and distinction from being visible, but conglutination by acids brings these differences into view. Because the original gelatinous mass, which forms the animal, seems to have no obvious structure or smaller distinguishable component parts, we are not therefore to conclude that it has none. Spirit of wine, poured on this jelly, hardens it so, that we can see fibres, vessels, and viliers, where there seemed at first to be a mere transparent concrete.

There is no essential power in the alcohol to model rude matter into an organic structure; but the destruction of the transparency allowed the outlines of parts to be distinguished; similar explanations may be given of all his observations on this subject. Moreover, we can by no means understand how this single power can form such different parts always in the same place in one animal, and according to one archetype, if the materials be inorganic, mutable, and susceptible of any configuration. Why should this matter always produce, without any error, a chicken in the common fowl, a pea-chick in the pea-fowl? Nothing is affirmed but a dilating force acting progressively; this might give origin to a vascular net-work, growing constantly larger as long as the expansive force exceeded the resistance; but how does it produce a heart, a head, brain, and kidneys? Why is a peculiar order of parts formed in each animal?

Some again have explained the formation of the body according to mechanical principles, by the power of fermentation, &c. We cannot, says Haller, conceive that any power, unless guided by intelligence, can act on matter in a manner constantly changing, and so directed, that inorganic materials are formed into bones, muscles, vessels, and viliers, arranged in a certain order with respect to each other. All spontaneous productions, as for instance the beautiful figures seen in snow, are arranged in an uniform and invariable manner. Let any person, in order to estimate the value of such hypotheses, reflect merely on the eye. How can this organ be moulded by any expansive force into such various successions of layers, all differently fabricated, where the light pâtes through transparent bodies, every where surrounded by others perfectly opaque, and so arranged, that in the millions of men and animals the rays of light constantly converge on the retina? Yet this blind material cause knows nothing of light, nor of the laws by which it is refracted, although we must suppose it to have adapted all the parts so accurately, even to the hundredth part of a line, in order to the collection of the rays in the retina. Again, this unintelligent cause has furnished the eye with eye-lids and eye-brows, and has given to the iris a power of contraction and dilatation, by which the organ is accommodated to too great or too small a quantity of light.

Buffon supposes the nutritive matter to penetrate all parts of the body, and to be formed in them, as in an internal mould; and he conceives that the superfuseful particles are carried back to the semen, conveying into that fluid every thing necessary to the production of a new being, similar to the former. The seminal fluid of either sex contains the particles necessary for forming an individual of the same sex. Thee must be mixed for the production of a new being. The generative organs are the baits of the new animal, and these are first formed of themselves: the other organic particles of the body are arranged round them as a centre, according to the order, which they held in the body, from which they were produced. That sex prevails, of which the particles are the most numerous. The author of this hypothesis considers that it explains completely the resemblance of the offspring to either or both parents, the formation of twins, &c.

The illustrious name of Buffon can hardly induce us to animadvert seriously on such dreams. In the first place, what is an internal mould or model? The authors of the hypotheses are so far from satisfying us on this fundamental point, that they confine we could not understand it, unless we had a seventh sense. How then came they to know it? So far from understanding what this model is, we have no hesitation in asserting that its existence is purely ideal. But if we should grant this, there are still insuperable difficulties remaining.

Many children are unlike both parents, and they sometimes have parts which both the father and the mother wanted, and with which, therefore, neither parent could have supplied them; this is the case with the offspring of mutilated individuals, and particularly with the male children of fathers who had lost one testis; a case which was not uncommon when castration was an ordinary mode of treating ruptures. The mother cannot bellow on her daughter the hymen, which she has lost; nor can we see the source from which the foramen ovale, the ductus arteriosus, and venous, the
G E N E R A T I O N .

The umbilical vessels, the placenta, the cord, &c. are derived. The teeth too must puzzle us greatly. The various trans- formations, and every other phenomenon in the lower orders of animals, are altogether incomprehensible with the hypothesis. The adult frog has no branches, which are yet seen in the tadpoles. In the bee kind, the males, females, and working bees differ in structure. The offspring might resemble the father or mother, but whence do the working bees come, which resemble neither parent, and have no generative organs? How entirely does the caterpillar differ, in all points of its organization, from the butterfly? How can the particles unite, when the male and female are so entirely different, as in the case of many insects, where one is winged, and the other not, &c.

The supposition of the successive fixation of parts round the generative organs is quite inadmissible; for those very parts cannot be recognized until a comparatively late period, and after others have been some time formed. This fact was confirmed, says Blumenbach, by an observation which I lately made on abortive twins of different sexes, about sixteen weeks old. Although these were remarkable for the beauty of their proportions, and were most perfectly formed according to the standard of their tender age, the difference of the sexual organs could be ascertained only by the most careful investigation; in every other respect, as in the figure, physiognomy, measurement of the limbs, &c. they resembled each other completely. Inhabit. Physiolog. P. 387.

In reply to some of these objections it has been affirmed, that those parts of the fetus, which the parents have not, are formed by intelligent nature from the superfluity of the organic molecules; that she adds a second telific from the excess furnished by the single gland of the father; and that the placenta and fetal coverings are produced in the same way, from the excess of nutritious molecules; but if nature can make wings, intestines, nerves, feet, telels, placenta, membranes, &c. without any mould, why should not the main body in the same way: and, whence arises this abundance of particles, produced by the tefts of a man, who has only one gland, when the mould must be one half less than in a perfect individual? How came this intelligent nature to be so suddenly produced in a human machine, when we had before heard nothing of her? Can any one understand how particles transmitted from so vast an extent as the father's whole body, can occupy so small a space, even when united to those of the mother, as to be invisible for several days after conception? In short, there is no female seen, nor corpus lutenum beforecopulation, and consequently no fluid from the mother to be mixed with that of the father, and convey to the fetus the female generative organs, the manse and the other distinctions of the female sex.

A very different theory from that which we have just considered, and a very old one, ascribes the formation of the fetus to a formative power of the mind or soul (anima structrix, vis platica): and some conceive that the object is effected by the mind of the fetus. The partisans of these opinions rely much on the effects said to be produced on the body of the fetus by causes operating on the mother's mind. They allege that the structure of the offspring is often materially changed and impaired by the longing of the mother, or by various violent emotions: that these effects are produced, not from any corporeal cause, but from the action of the mind on the anima structrix of the fetus: that there is a harmony between the mind of the mother and her body, and between the bodies of the mother and child. Various attempts have been made to explain the manner and nature of this influence and connection. But it would have been better to have established the fact incontrovertibly in the first place. The records of medicine abound with instances of almost all imaginable effects produced on the fetus from the causes above-mentioned:—of the likeness of fruits or flowers, &c. on the body, of various animals, of bruises:—of parts being cut, destroyed, or otherwise injured, &c. &c. That credulity and ignorance have given birth to most of these narratives, cannot be doubted. Our faith in them must be most seriously shaken, when we observe that there are endless examples of the most vehement mental disturbances, as terrors, longing, passion, occurring repeatedly during pregnancy, particularly in delicate and hysterical women, without any thing unnatural appearing afterwards in the child, even when the mother has expressed her strong persuasion that her child would be mutilated. Nor can women forget when the marks above alluded to (nuxis) will appear. Deformed and monstrous children, and others marked with nuxis, have been repeatedly observed by the most judicious and accurate observers, when the mother was not conscious of any such cause as those above alluded to. Children are born blind of healthy parents without the circumstance being considered as extraordinary or requiring anything accidental to account for it. When women observe any deformity in their offspring, they recall to their memory every thing which has happened during their pregnancy; and if they can remember any fall or fright, or suddenly feeling any uncommon animal, the carcasse of a beaf opened, or a wound, &c. they immediately set it down as the cause of the phenomenon. And, from the various turns which superflitious and whimsical fancies take in different countries, the same appearances are ascribed to very different causes.

In weighing the testimonies of authors, we shall find that the most experienced and judicious adopt the common notions about nuxi much less than others. In the numerous collections, where monsters and extraordinary productions of all kinds are carefully collected and preserved, we find no example of a genuine nuxus, according to the common notion, that is, of the resemblance of a fetus, or of some foot, or a wound, &c. in any part of the body of a fetus. In further support of our opinions we may quote the numerous instances of monsters, vegetable productions, which cannot be ascribed to any power of imagination, or any mental affection whatever. We cannot doubt that the seed and the ovum contain the cause of the future structure, which is always preferred uniform in the same species. That various external circumstances, as a copious or deficient supply of nutrition, and many causes of a nature entirely unknown to us, may have an effect in altering or variously modifying the original fabric, within certain limits, we do not pretend to deny.

If the phenomena of nuxi afford no proof of a plastic soul; if we acknowledge that the beautiful structure of an animal body cannot be reared by chance, nor by any blind force with which inorganic parts may attract each other, it remains for us to consider whether the fetus is formed before the time of conception, according to the hypothesis of evolution. This opinion has been chiefly held in modern times; it is ably defended by Haller, and has been supported by the experiments and writings of Spallanzani and Bonnet.

If, says Haller, the germ or original of the fetus be contained in the mother, if it be already formed in the ovum, and to far perfected as to require merely a supply of nourishment for its growth, the grand difficulty of forming such an artificial and complicated structure from inorganic matter is overcome. In this hypothesis, the Creator, with
with whom nothing is difficult, forms the machine: he has arranged dead matter, in conformity with his previous designs, and according to the archetype fixed by his wisdom, before the accession of the influence furnished by the male. In the same way you may in plants a perfect flower, capsules, and well-formed seeds, differing from fruitful seeds only in the circumstance, that they would not grow into a new plant. The metamorphoses of insects have been added in support of this notion of evolution: the butterfly, so entirely different from the chrysalis, was entirely contained in the former, and needed only to be differentiated by the removal of the skin, and have its parts unfolded. The rudiments of the organs, which are to contain air in the bee, exit in the fatty fulness of the worm from which the perfect insect is formed, and numerous examples of a similar description might be adduced. The phenomenon of incubation, and the successive appearance of various parts until the whole animal is completed, afford a convincing argument for the hypothesis of evolution. After recounting the gradual and progressive unfolding of the body of the chicken, Haller observes, that the progress is nearly the same in quadrupeds. "In the human fetus, which at first seems a more unorganized mass, Lavoisier already discerned, by means of his microscopes, did three generation. Thus it is manifest that an animal without any limbs, or discoverable arrangement of parts, is gradually changed by various stages into a perfect being, nourished by food, and susceptible of voluntary motion. It may be inferred, whether the animalculae, before it can be recognized by the senses of the dissector, exits in the father or the mother: whether it were formed by epigenesis, or the successive union of particles; or suddenly produced. Epigenesis is altogether impossible. Whoever has contemplated the structure of the body with a little attention, must be convinced that an animal could not exist without a heart, since the principle of life and motion exists in that organ. But the heart must be furnished with arteries to carry the vital fluid to all parts, and with veins to carry it back again. It is easily proved that the fetus does not consist of a mere skeleton of blood-vessels. Vicera must accompany thef, of which, with some cellular substance, they are entirely composed. But no one has seen the viscera composed by particles successively deposited: they are perfect, although small, as soon as they can be discerned. Muscles must have been present from the first: for the young animal, in the incubated egg, is capable of motion, and from its first flat blade bends the body. It is moreover irritable, and must consequently have muscles, although they are concealed under the appearance of a mere gelatine. The heart is large, and the eyes are visible among the first parts, together with the heart. The muscles require the presence of nerves, the brain must have been present with the head and heart." The hypothesis then, to which these arguments lead, is, that the perfect animal exists previously to conception; that nothing now is generated, but that the parts, which were folded up, and contracted into a small space, are expanded, unfolded, enlarged, and rendered conspicuous. In this mode of explanation, we must, it seems, admit, that the germ of all the human race, as well those who have already lived, as those who may hereafter be born, were contained in the ovari of Eve; a proportion of so far a nature, and so completely un- susceptible of proof, that we cannot value very highly the hypothesis, which renders it necessary.

The pre-organized germ would remain in a kind of torpid state in its ovarian receptacle, were it not stimulated by the

Vol. XVI.
fitted for those of the female plant. The same circumstances will occur in the human species if the offspring of an European woman by a negro be fecundated by a negro; and the produce of that conception again by a negro, &c. Thus, at last, the preformation of the material form has been preserved since the creation of the world, avails nothing, but yields entirely to the formative power of the male fluid, which, according to the hypothesis of evolution, should merely excite it to action. We may affirm, in short, on the whole, that all the phenomena adduced in support of this hypothesis, not one can be established sufficiently clear to be admitted as a proof; while there are numerous unexceptionable observations directly opposing it.

But, in proportion as this hypothesis of evolution is in conflict with the phenomena, and in the rules of philosophizing, so, on the contrary, the opinion, not that any fictitious germs are evolved by means of conception, but that the new being is in fact generated, and gradually and successively formed from the generative fluids, commends itself to our approbation by its simplicity, and its accordance with the other proceedings of nature.

Since this affair of a true generation by successive formation has been variously explained by physiologists, I conceive that we shall approach most nearly to the truth, by adopting the following propositions. 1. The materials, of which organized bodies, and consequently the human frame is composed, differ from all other matter in being regulated simply and exclusively by vital powers. 2d. Of these, the most remarkable, and that, whole existence and agency can be the least questioned, is the force which acts on organized matter, when prepared for its definition, but not yet moulded into shape, and bellows on it, according to its various natures, various but determined and definite forms. In order to distinguish this vital power properly from all others, I give it the name of nihus formativus. 3d. This nihus formativus is imparted to the materials of generation, when they are contained in a mature state, under the requisite conditions, in the uterine cavity, builds up in it the rudiments of the embryo, and gradually forms its organs to correspond to their pre-ordained purposes; it perfects the same structure by the processes of nutrition, as long as life continues; and it obviates the effects of casual mutation, as far as that can be accomplished, by means of reproduction.

This gradual formation of new organized bodies can be most manifestly discerned in those, which combine, with a considerable magnitude, a rapid growth, and such a kind of delicate semi-transparent texture, that they can be clearly seen through, particularly in a sufficient light, and with moderate magnifying powers. This is the case in the vegetable kingdom, with some simple aquatic productions, as the conca repitalis, which is propagated in the early part of spring; in the bloodclots divisions of the animal kingdom, with the polypes (hydras); in the animal kingdom, with the incubated egg, on the first appearance of the chicken, and its subsequent daily development.

It must be observed here, that the expression nihus formativus is employed simply for the purpose of distinguishing this from the other kinds of vital powers, and by no means with any intention of explaining the cause of generation. I believe the latter to be concealed by no less impenetrable darkness than that which involves the causes of gravitation and attraction; and which are only names for effects, recognized like the nihus formativus, a posteriori. I have employed the word nihus chiefly in order to denote that the nature of this force is truly vital, and to distinguish it as clearly as possible from the merely mechanical powers, by means of which some philosophers formerly endeavoured to explain the births of generation. The very point on which the whole of this doctrine concerning the nihus formativus hinges, and which alone sufficiently distinguishes it from the vis praecipitata of the ancients, the vis centriales of Wolf, and other hypotheses of the like nature, consides in the combination of the two principles, by which the nature of organized bodies is explained, viz. the physico-mechanical and the teleological.

I hold it most probable, that in the first place, a definite time is required for the various fluids of each sex, which seem to be united in the cavity of the uterus after a fruitful copulation, to be more intimately mingled, and brought to maturity. When the period of this preparation is completed, the mature and intimately blended fluids become animated by the nihus formativus, by which the hitherto unformed materials of generation are partly moulded into the elegant coverings of the ovum, partly into the figure of the contained embryo. Hence we can understand, why the smallest vestige of a formed fetus cannot be discerned, even with the assistance of the excellent modern dioptrical instruments, during the first week after conception, excepting the unformed fluids contained in the uterine cavity; while the embryo appears as it were on a sudden in the third week.

I should exceed the limits of these institutions, if I were to recount at greater length those arguments drawn from nature herself, by which the influence of the nihus formativus in generation seems to me to be rendered very highly probable. I shall advert very shortly to a few of these points, the force of which will be easily discovered by a more attentive consideration. On this principle I explain the memorable experiment, in the history of hybrid productions, where parental hybrids, fecundated during the various seasons, by the male seed of the same species, have produced an offspring, gradually deviating from the original maternal form, and assuming the characters of the father, until at last the former has been completely changed into the latter by a kind of arbitrary metamorphosis.

The well-known fact of the great frequency of monstrous productions in some species of domesticated animals, particularly swine, and their rarity in the wild condition of the same animals, can only be explained on the principles already stated. The evolutionists are compelled to assert that all these monstralties must have existed in the germ from the first creation of things. The phenomena of re-production, taken altogether, can be much more aptly explained by the agency of the nihus formativus, than on the notion of pre-existent germs; and some particular examples, as, for instance, of nails growing on the middle, after the loss of the first phalanx, cannot well be solved on any other principle.

After considering, and carefully weighing the arguments on both sides of the question, it appears, that even those who affume pre-existent germs, must allow to the male seminal fluid a considerable formative influence, in addition to the exciting power, which they recognize in it, and consequently that the doctrine which they defend requires, in fact, the affinities of the nihus formativus; while the latter sufficiently explains the phenomena of generation, without the aid of pre-existing germs. Whatever theory of generation we adopt, we must ultimately ascend to the agency of the Creator, the primary cause of all existence.

The circumstances belonging to the state of pregnancy; the period and phenomena of parturition and its consequences, are treated under those articles of the Cyclopaedia which relate to the subject of midwifery.
GEN

GENERALITY, in Natural History, the word used to signify all the species of natural bodies, which agree in certain essential and peculiar characters, and therefore all of the same family or kind; so that the word used as the general name equally expresses every one of them, and some other words expressive of the peculiar qualities or figures of each are added, in order to denote them singly, and make up what is called a specific name.

Thus the word rofe, or rose, is the general name of the whole series of flowers of that kind, which are distinguished by the specific names of the red rose, the white rose, the apple rose, &c. The ignorance of former ages, in the true principles of natural history, has occasioned the bodies, which are the objects of it, to be arranged into very unnatural series under the name of genera; and these have been called by names as improper as the characters they were distinguished by. Linnaeus has done a great deal in explaining the bad generic names in botany, and Artedi has applied his rules about the formation of these names with very little difference to the subjects of ichthyology.

Many of the generic names of fish, till the time of this author, were so barbarous and obscure, that it was not easy to trace them to their original, or to find whether they were truly Teutonic, English, Dutch, Swedish, French, Italian, Spanish, Portuguese, Latin, or Indian. The ignorance of the writers on these subjects, or their too copious adherence to the customs of their predecessors, seem to have been principally the causes of this, and often an entire negligence. Artedi’s rules for generic names for fish are these: whatever fish there are which agree in the same generic characters, and are properly of the same genus, these ought all to be called by the same generic name, their differences being only expressed by specific ones. This appears to plain, to just, and to necessary a rule, that it is almost a shame to lay it down; yet the writers on fish, till the time of this author, had very seldom observed it.

Another barbarism and improbity in the generic names of fish among the old authors, is the using of the same words to express them, which are also the names of other animals, quadrupeds, birds, and reptiles. These are subject to great objection; because when they are used, it is not easy to judge, in some cases, whether the author is speaking of a bird, a beast, or a fish. It is therefore one of the general rules of Artedi, that all these names are to be abolidished, as also all those which are common to fish, and to plants, minerals, and to the tools of husbandry, or other services.

Another rule of this excellent author is, that generic names that are composed of two whole words, unnaturally tied together, are to be abolished, it being easy to contrive names less barbarous, and as expressive: next to these are to be exploded these names which are formed of two generic words before in use, the one broken or cut short, the other preserved entire.

Another general rule in regard to these names is, that all such as are not of either Latin or Greek origin, are to be proscribed and wholly rejected. This rule cuts off a prodigious number of barbarous words, which with which we find the books of authors of former ages on these subjects crowded.

A fifth rule for the regulating generic names is, that all such are to be abolished as terminate in iodes, as expressing a resemblance often imaginary, and often alluding to something unknown, or rendered difficult to trace from the changes which the names of other things have undergone since the time when it was formed. These words convey no idea of the character of the genus expressed by them, except that they are like the other thing alluded to in some external, though perhaps not essential, character; of this kind are the rhomboidei, scorpoidi, &c.

A seventh rule in regard to these names is, that all such are to be rejected as are barely diminutives, and terminate in ulus or us. These convey no other idea but that of the fish being like some other fish, only less: now bignes is no generic character; therefore if this genus, and that re-
ferred to, differ only in size, they have no general differ-
ence at all; if they do differ otherwise, they should be
expressed. What makes many of these names also more
intolerable is, that they allude not to fish, but to other
things so different in their nature, that there must needs be
many other more effcient variations between them, before
size.

Another general rule is, that such general names as are
pure Latin, but are mere adjectives, are to be exploded,
there being no reason for using them as substantives.

A ninth general rule is, that such names as are formed of
Latin words, unknown to the ancient Romans, and formed
by the latter writers, are to be expelled as barbarous, and
others of better credit placed in their stead.

Finally, such general names as have been given to fish
from the places where they are caught are to be rejected;
the name that is the ferdelis and fardila from the island of
Sardinia, and the furio from Asturias, a province of Spain.
The fefs of names can convey no idea of the nature of
the fish, and may belong as well to one genus as to another.

Arded, Ichthyolog. p. 106, 69, 73, 79.

These rules of profession banished to many of the receiv-
ed general names of fish, that it might be supposed
the whole number was exhausted, and all the fish in
the world to be named anew. But this is not the case; the
genera are in reality much fewer in number than they have
been usually supposed, and therefore fewer words will serve
to express them, and there yet remain many truly Latin
words used by the ancient Romans, by which the far greater
part of the genera may be expressed, and the few remaining
may be best denominated by compound Greek words, ex-
pressive of their real characters.

Among the true and genuine Latin, and Graeco-Latin
names of the genera of fish, are these: acipenser, amia,
antias, batzena, blemius, clupea, cobites, cyprinus, del-
phius, elops, eels, eocetes, gobiini, labrus, lamia, lipa-
ris, mugil, mulius, murana, perca, phylter, pristis, raja,
falmo, falpa, scarus, scobomer, silura, sporus, squamus, thyn-
nus, torpeado, triton, turbo, uranocopus, xiphias, zeus.
These will go a great way toward the naming of the true ge-
extra, and which he has laid down,
specific names of fish; and the rules he has laid down,
thus given at large, may, with little variation, be made to
serve for any other author, in whatever branch of know-
ledge he has occasion to write.

GENERALIS Secondi. See Secondi.

GENEROUS, a Gentlewoman. See Gentlewoman and
Spinster.

GENEROSITY, Order of, an order of knighthood,
established in 1685, by Frederick III., elector of Branden-
burg and king of Prussia, whilst he was electoral prince.
The badge was a gold cross of eight points enamelled azure,
beading in the centre this inscription "LA GENEROSITÉ;"
and pendant to a blue ribbon.

GENESAN, in Geography, a town in the Arabian Trak;
90 miles S. of Bagdad.

GENESAR, or GENESABETH, called also Chalres, and
afterwards Tiberias, a town of Palestine on the lake of the
same name, called also Sea of Galilee, which fee.

GENESEE, a township of America, in the state of New
York, and county of Ontario, having 217 electors.

GENESSEE, a county, a large tract of land in the state of
New York, deriving its name from Genesee, one of its rivers,
and bounded N. and N.W. by lake Ontario, S. by Penn-
sylvania, E. by the western part of the military townships in
Ondago county, and W. by lake Erie and Niagara river.
This is a rich tract of country, and well watered by lakes
and rivers, it is flatish, its rivers are sluggish, the soil is
moist, and its lakes are numerous.

GENESSEE, or Genesee River, rises in Pennsylvania, near
the most elevated spot of this state, where also the cfferent
water of Alleghany river, and Pine creek, a water of Sus-
quehanna, and Tioga river rise. It has several falls, which
furnish excellent mill-feats, that are improved by the inhab-
itants. After a course of about 100 miles, chiefly N.E.
by N., it discharges itself into lake Ontario, 43 miles E.
of Irondequay, or Runaghat bay, and 80 miles E. from
the falls of Niagara. The settlements on this river, from
its mouth upwards, are Northfield, Northampton, Hart-
ford, Genesee, and Williamburgh. When the western can-
als and locks are completed, there will not be any carrying
place between the city of New York and Williamburgh.
The Genesee flats lie on the borders of this river, about
20 miles in length and about four in breadth. These are
probably the isle of the Indians.

GENESSEE, or Genesee County, is bounded N. by lake On-
tario, W. by Niagara river and like Erie, S. by Pennsylvania,
and E. by the counties of Tioga and Onondago. It com-
prehends the counties of Ontario, Steuben, and Genesee,
and contained, in the year 1800, upwards of 17,000 per-
sons. This county is finely watered by the Genesee river
and its tributary streams, several creeks, and also lakes,
which are from 20 to 40 miles in length. The southern
part is watered by several branches of the Susquehanna.
This county is large, and comprehends the western part of
the state of New York.

GENESIS, in Biblical History, the first book of the Old
Testament, containing the history of the creation, and the
lives of the first patriarchs.

The book of Genesis stands at the head of the Pen-
tateuch, which fee. Its author is held to be Moses: it contains
the relation of 2369 years, viz. from the beginning of the world
to the death of Joseph. The Jews are forbid to read the begin-
ing of Genesis, and the beginning of Ezekiel, before thirty
years of age.

The Hebrews called this book Birshebith, because it be-
gins with that word, which in their language signifies in
principio, or in the beginning. The Greeks gave it the name
Genesis, praxeis, q. d. production, generation, because it be-
gins with the history of the production or generation of all
beings.

This book, besides the history of the creation, contains
an account of the original innocence and fall of man; the
propagation of mankind; the rise of religion; the general
defection and corruption of the world; the deluge; the re-
formation of the world; the division and peeling of the
earth; and the history of the first patriarchs to the death of
Joseph. It was easy for Moses to be satisfied of the truth
of what he delivers in this book, because it came down to
him through a few hands; for from Adam to Noah, there
was one man, viz. Methufelah, who lived so long as to fee
them both; in like manner Shem conversed with Noah and
Abraham; Isaac with Abraham and Joseph, from whom the
records of this book might easily be conveyed to Moses
by Amram, who was contemporary with Joseph.—Pa-
trick.

GENESIS, in GeometrY, denotes the formation of a line,
plane, or solid, by the motion or flux of a point, line, or
surface. See each respectively; also Fluxion and Curve,
and Generation.

The genesis, or formation, e. g., of a globe or sphere,
is conceived by supposing a semi-circle to revolve upon a
right line, drawn from one extreme thereof to the other, called
its axis, or axis of revolution: the motion or revolution
of that semi-circle is the genius of the sphere, &c. See GLOBE and SPHERE.

In the genius of figures, &c. the line or surface that moves, is called the deficient; and the line round which, or according to which, the revolution or motion is made, the dirigent.

GENEST, CHARLES-CLAUD, in Biography, was born at Paris in 1639. Being of an unsettled disposition, he resolved to go to the Indies to seek his fortune, but the vessel in which he failed having been captured by the English, he was brought to London, where he fulfilled for some time by teaching the French language. On his return to his own country, he obtained the post of preceptor to Madeleine de Blois, afterwards duchess of Orleans, and other considerable offices among the great. He became a member of the French academy in 1668, and died at Paris in 1719. Though a courtier, he was sincere and simple in his manners, and estimable in his character. He derived a taste for natural philosophy from the lectures of Rohault, the disciple of Descartes, and for metaphysics from the instructions and conversation of Bossuet. He was an elegant scholar, and greatly devoted to poetry and polite literature. His works are numerous, of which the principal are "Principes de Philosophie," in which he adduces many arguments in defence of a God, and of the immortality of the soul.

GENEST-DAMBRESTER, Sr, in Geography, a town of France, in the department of the Vienne; seven miles W. of Châtellerault.

GENEST-MALLISANT, Sr, a town of France, in the department of the Loire, and chief place of a canton in the district of St. Etienne; four miles S. of St. Etienne. The place contains 1657, and the canton 5648 inhabitants, on a territory of 150 Kilometres, in five communes.

GENET, FRANCIS, in Biography, was born at Avignon in the year 1640; here he received his grammatical learning, and having acquired a considerable knowledge in the Latin and Greek, he entered upon philosophy, and was for a time a disciple of Scotus, but he afterwards relinquished his studies, and became zealously attached to the philosophy and theology of Aquinas. In 1670, he was admitted to the degree of doctor in civil and canon law at Avignon, and acquired much reputation by the theses, which he delivered on that occasion, against simony. His talents recommended him to the notice of the archbishop of Aix, for whom time made use of him in the management of the ecclesiastical concerns of his metropolitan district. He was afterwards employed and patronized by M. Le Camus, bishop of Grenoble, who engaged him in the composition of a system of moral theology, which was afterwards published in six volumes 12mo. under the title of "Morale de Grenoble." This work was well received, has gone through many editions, and has been translated into the Latin language. Soon after its publication, the pope, Innocent XI. created M. Genet canon and prebend of the cathedral church at Avignon, and in 1685 appointed him bishop of Vaison. He discharged all the duties of his episcopal functions with exemplary watchfulness and zeal, till the year 1688, when he was professed for having admitted into his diocese the religious belonging to a new convent at Touloufes, which Louis XIV. had suppressed. By the arbitrary mandate of the king, the good bishop was arrested, and imprisoned for fifteen months in the ile of lle, whence he was released by the intercession of the pope. He was accidentally drowned in 1702. Moreiri.

GENEA, or Genes, said to be derived from form, bone nature, in the Manager, &c. a small-sized, well-proportioned Spanish horse.

Some also give the name genta to well-made Italian horses.

GENET, ORDER OF, an order of knighthood, instituted in France by Charles Martel in the year 726, for commemorating a signal victory, which he obtained in that year over the Arabian army, commanded by Abdaramo. The badge of the order was a garter, enamelled azure, spotted or fleeced gules, and collared or. On a mount vert, enamelled with flowers proper. This badge was worn pendent to a collar composed of three chains of gold interlaced with red enamelled rosettes. This order was instituted for sixteen knights, and continued in great repute till the reign of king Robert, when it was abolished on his devising the order of the star, in honour of the holy virgin.

GENETHLIA, in *Antiquity*, a solemnity kept in memory of some person deceased.

GENETHLACI, formed of the Greek genethlos, origin, generation, nativity, in *Astronomy*, persons who erect horoscopes, or pretend to foretell what shall happen, a man, by means of the stars which preceded at his nativity.

The ancients called them *Chaldaei*, and by the general name *mathematici*: accordingly, the several civil and canon laws, which we find made against the mathematicians, only respect the genethlaici, or astrologers.

They were expelled Rome by a formal decree of the senate; and yet found so much protection from the cedulity of the people, that they remained therein unmolested. Hence an ancient author speaks of them as "honinum genus, quod in civitate non firumperet & vetabitur, &c."

Antipater and Archinapulus have shewn, that genethlogi should rather be founded on the time of the conception, than on that of the birth. Vitruvius.

GENETHLLLLC, GENETHLACI Poem, is a composition in verse, on the birth of some prince, or other illustrious person; wherein the poet promises him great honours, advantages, successes, victories, &c. by a kind of prophecy or prediction: such is the eulogy of Virgil to Pollio, beginning,

"Sicelides Mufas, paulo majora canamus."

There are also genethlaici speeches or orations, made to celebrate a person's birth-day.

GENETIDES, in Natural History, a name given by the ancients to the fome more generally known under the name enchymonies. This was the spcr incertid on the top of the sides of the caverns, which they supposed daily to bring forth more, and therefore gave the powder of it to women at the time of their lying-in, to promote their speedy delivery.

GENETTA, To ride à la, is to ride in the Spanish fashion, i.e. with the stirrups short, that the spurs beat upon the flanks of the horse. This is deemed a piece of gallantry in Spain, but not among us.

GENETTA, in Zoology, a species of *Pomer*, which see.

GENETTE, in the Manager, a Turkish bit, the curb of which is all of one piece, and made like a large ring, and placed above the liberty of the tongue. When they bridle a horse, they make their chin pass through this curb, which surrounds his head. This sort of bit was much used at the court of France when Guillet wrote.

GENETYLLIS, in *Antiquity*, a solemnity celebrated by women, in honour of Genetyllis, the goddess of that fex.

GENEVA, or GIS, a popular name for a compound water,
GENEVA.

water, which is, or ought to be, procured from the berries of the juniper-tree, distilled with brandy or malt-spirits. See Juniperus.

The word is formed from Geneva, the French name of the juniper-berry.

The best geneva we now have, is made from an ordinary spirit, distilled a second time with an addition of some juniper-berries; but the original liquor of this kind was prepared in a very different manner. It was a custom in the distilling of spirits from wo, or other fermented liquors, to add to the working some aromatic ingredient, such as ginger, cortex Winteranas, or grains of paradise, to take off the bad flavour, and to give a pungent taste to the spirit. Among other things used with this intent, some tried the juniper-berries, and finding that they gave not only an agreeable flavour, but very valuable virtues also to the spirit, they brought it to a general custom, and the liquor sold under this name. The method of adding the berries was to the malt in the grinding: a proper proportion was allowed, and the whole was reduced to meal together, and worked in the common way. The spirit thus obtained was flavoured of the berries, and exceeded all that could be made by any other method. Our common distillers leave out the juniper-berries entirely from the liquor they now make and sell under that name. Our chemists have let them into the secret, that the oil of juniper-berries, and that of turpentine, are very much alike in flavour, though not in price; and the common method of making what is called geneva in London, is with common malt spirit, and a proper quantity of oil of turpentine distilled together. Shaw's Essay on Distill. p. 7. See Distiller.

Geneva, in Geography, a city of France (since the revolution), principal place of the district, and capital of the department, but formerly the capital of a republic, in alliance with the Swiss; situated on the confines of Savoy, France, and Switzerland, at the southern extremity of the lake of Geneva," or "Leman lake," upon the narrowest part of it; where the Rhone issues in two large and rapid streams, which, from afterwards unite, and, passing through the city, divides it into two unequal parts. The adjacent country is uncommonly picturesque, and abounds in magnificent views, formed by the town, the lake, the numerous hills and mountains, particularly the Salève and the Môle, rising suddenly from the plain in a variety of fantastic forms, backed by the glaciers of Savoy, with their frozen tops glittering in the sun, and the majestic Mont Blanc rearing its head far above the rest. Geneva, which stands partly in the plain, upon the borders of the lake, and partly upon a gentle ascent, is irregularly built: the houses are high, and many in the trading part of the city have arcades of wood, which are raised even to the upper stories. These arcades, supported by pillars, give a gloomy appearance to the street, but are useful to the inhabitants in protecting them from the sun and rain. This is the most populous town in Switzerland; and the inhabitants are estimated to be from 23,000 to 25,000. This population is owing to the industry and activity that prevail in this place, to its extensive commerce, to the facility of purchasing the burgheiship, and to the privileges which the government allows to all foreigners. The members of this city are distinguished into citizens and burgesses, inhabitants and natives, besides a fifth class, established after the revolution in 1782, and called "domestic," who receive from the magistrate an annual permission to reside in the city. The citizens and burgesses were, under the old police, admitted to a share in the government; the inhabitants are strangers allowed to settle in the town with certain privileges, and the natives are the sons of these inhabitants, who possess additional advantages: these two last classes form a large majority of the people.

The liberal policy of this government, in receiving strangers, and conferring the burgheiship, is the more remarkable, as it is contrary to the spirit and usage of the Swiss. Here it is peculiarly necessary; as the territory of this state is so very small, that its very existence depends upon the number and industry of the people; for, exclusively of the city, there are scarcely 16,000 persons in the whole district of the Genevois.

Geneva borrows, and not without reason, of its antiquity. The precise time of its commencement is not known; but it existed before the Christian era, and is particularly mentioned by Cæsar. (De Bell. Gall. i. c. i.) It belonged to the Allobroges (see this article), and flourished under the succourers of Cæsar. The Christian religion was introduced among the Genevans in the third century, and about the middle of the 4th century Geneva appears to have been the seat of a bishop. It suffered, however, in a considerable degree, and in common with other parts of the western empire, from the incursions and ravages of the northern barbarians. About the middle of the fifth century the Vandals, who, having settled in the country of Vaud, and built several strongholds, assumed the name of Bourguignons, or, according to modern orthography, Burgundians, had possession of it; and in the year 629, it was transferred to the Franks. Towards the end of the 8th century, Charlemagne convened an assembly of his states at Geneva, to consult about a war with the Lombards, and confirmed both the civil and religious privileges of this city. In the year 1032, it was annexed to the German empire; but the authority of the emperor was little regarded in distant provinces, and they found it expedient to protect associations of the common people, and to enlarga their liberty, in order to counteract the tyranny of the lords and clergy. In process of time, the clergy acquired a great degree of secular power and jurisdiction in connection with their spiritual authority; and thus the bishops of Geneva had obtained of the emperor the title of princes and sovereigns over the town and the adjacent country. On the other hand, the counts of the Genevois, or of the district in the vicinity of Geneva, who were originally officers of the empire, though afterwards they became vassals of the bishops, aspired to an exclusive administration of justice both in the town and the country. The people availed themselves of the contest between their superiors in rank and power to confirm and extend their own privileges. In the mean time, the liberty of the city was exercised by a third power, no less formidable than either of the other two. The counts of Savoy became powerful by the successive possession of several provinces; and among the rest the Genevois favourable pretensions of the ancient counts, and aspired to the sovereignty of a flourishing town, which was also a convenient and strong frontier.

It would not be very interesting to recite, in minute detail the contests that were from time to time renewed between the Genevois and the counts of Savoy. We shall content ourselves with observing that in the year 1415, the emperor Sigismund visited Geneva, and that two years afterwards he erected Savoy into a dukedom in favour of Amadas, the 8th count, who, in the year 1420, petitioned the pope for the sovereignty of the city. The duke's suit was referred by the pope to the bishop, who summoned a general assembly of the people, to deliberate upon the duke's request, which had obtained the approbation of the pope. The inhabitants unanimously rejected it, and at the same time required the bishop to be true to his charge, assuring him of their con-
GENEVA.

currence in maintaining his just rights, and those of the city. This noble spirit encouraged the bishop, and produced a most excellent act in favour of liberty; for he entered into a formal agreement with the people and the syndics, never to alter the constitution without their consent. This act, having been engraven in Latin, and the observance of it sworn to by the bishop, the syndics, and the council, was subscribed by all the magistrates, commonality, and clergy of Geneva; and in the following year was confirmed by the emperor Sigismund, who declared Geneva to be an imperial city, under the title of "Nobile Imperii Membrani," and took it into his immediate protection against all powers, the duke of Savoy in particular. The Genevese, however, maintained their liberties against the repeated attacks made upon them by the dukes of Savoy under very great disadvantages. Nevertheless, they persevered till about the beginning of the 16th century, when an alliance was entered into between Geneva and Friburg, the contest continued, and was the occasion of many acts of oppression and persecution. When the treaty was concluded, in consequence of the active interference of a young citizen of Geneva, named Berthelier, two parties arose in Geneva, one of which retained an attachment to the interest of the duke of Savoy, and the other declared itself on the side of liberty. Those of the latter description were called "Eignots," which in Swiss, or High German, signifies "confederates by oath," and from which the term "Hugonots" is probably derived; whilst those of the former were denominated "Mamalukes," in reference to the Egyptian field-soldiers, who being originally Christians, renounced both their religion and liberty, to become slaves to the sultan. The duke, irritated by this conduct, entered Geneva with an armed force, and compelled the people to renounce their new alliance, whilst he persuaded Friburg to withdraw from the treaty, promising not to injure the liberties of the Genevese. Berthelier, the Genevan patriot, was however sacrificed to his vengeance, and the magistrates of the city were deposed by the bishop. In the year 1526, a new alliance was formed between the towns of Bern, Friburg, and Geneva, which the duke of Savoy was not able to prevent, and occasioned wars of long continuance between the republic and Savoy. This alliance was confirmed by the bishop; and may be considered as the true era of the independence of Geneva. Soon after this period, viz. in 1533, the doctrines of the reformation were preached at Geneva by William Farel, a native of Gap in Dauphine, and Peter Viret, of Orbe; and the people, animated by the enthusiasm of liberty, determined to emancipate themselves from the yoke of bondage, both ecclesiastical and civil. The bishop, who had always acted a weak and deceitful part, became despicable both to the Genevese and to the duke; and by his imprudent menaces and precipitate retreat, served to strengthen the cause of the reformation. In 1535, the doctrines of the reformation were adopted in full council; and in consequence of this decision, the canton of Friburg resumed the alliance. In the following year, the famous John Calvin, driven from France by persecution, arrived at Geneva, and completed the reformation, that had been already begun by Farel and others. So great was the ascendancy which Calvin, though a foreigner, acquired over the citizens, that he policed considerable influence even in civil matters; and was eminently instrumental in settling the political constitution. To this end, as well as to encourage theological erudition, he prevailed upon government to establish a public academy, the presidency of which he obtained for his friend and fellow labourer, Theodore Beza. In this new seminary, Calvin, Beza, and others, eminent for their superior knowledge, read lectures with such uncommon reputation and success, as attracted students from all quarters. It had also a public library, which owed its origin about this period to the liberality of Bonnivard, prior of St. Victor, who was twice imprisoned for having affrighted, against the dukes of Savoy, the independence of Geneva. He was a principal promoter of the reformation by gentle means and gradual infraduction. He closed his benefactions to his beloved city, by the gift of his valuable manuscripts and books, and by bequeathing his fortune towards the establishment and support of the seminary. Geneve was now regarded as the asylum of the reformed religion; and by the accession of persecuted protestants from other cities and countries, its arts and commerce flourished, and its population increased.

In 1584, Geneva concluded a treaty of perpetual alliance with Zürich and Bern, by which it formed a part of the Helvetic confederacy. The last attempt of the house of Savoy against Geneva took place in 1602, when Charles Emanuel attacked the town during a profound peace. The inhabitants, however, nobly defended themselves, repulsed the enemy, and obliged him to abandon his treacherous design. This perfidious attack was followed by a war, which was terminated in the following year by a solemn treaty. Since that period, uninterrupted peace has been maintained between Geneva and the duke of Savoy; although the king of Sardinia did not, till the year 1754, formally acknowledge the independence of the republic. From that period, the history of Geneva contains little more than a narrative of contents between the arithmetical and popular parties. The constitution of Geneva, which had then been established, and which continued for several years, under a certain modification and improvement of the year 1768, was a kind of mean between those of the arithmetical and popular cantons; more democratic than any of the former, as the sovereign and legislative authority were vested in the general assembly of the citizens; but more arithmetical than the other, because the powers entrusted with the great and little councils were very considerable. The salaries of the magistrates were so inconsiderable, as not to offer any temptation of pecuniary emolument; and the revenues of government, at the highest calculation, generally amounted to 30,000 pounds a year. Their constitution, indeed, was defective, as they had no precise code of penal law; but that of civil law was the most perfect part of their government. In Geneva, as well as in all the other principal towns of Switzerland, a public granary was established, and they had always in reserve a sufficient quantity of corn to supply the inhabitants during a year and a half. Geneva was the only republic in Switzerland which had no regular companies of soldiers in any foreign service. Geneva was always more or less distracted by internal dissensions and tumults. In 1782, these had prevailed to such a degree, that the kings of France and Sardinia, together with the canton of Bern, interfered, and threatened to besiege the city. The peasants of the territory joined the Genevese, and offered to serve in their cause without pay, to mount guard, and work at the fortifications. M. de Jaoulcurt, the commander of the French troops, threatened, in case of refusal, to enter the town by force, and inflicted that no person should appear in the streets, that all arms should be delivered up, and that the chief of the "representants," as the popular party was called, should retire from Geneva, and that the deposed magistrates be reinstated. Relentless in these circumstances must have been altogether unwavering, and must, indeed, have terminated in the destruction of the city. The representatives, therefore, restored the confined magistrates to liberty, and left the city in a body. The Sardinians, who first entered the gates, found the city almost deserted; and soon after the two other commanders
commanders made their entry at the head of their respective troops, with drums beating and colours flying. The aristocratic party celebrated their triumph with balls, feasts and every species of public diversion. A committee, appointed by the great and little councils, prepared, in concert with the three generals, an edict for new modelling the constitution, which, being approved at the courts of Verfaillies and Turin, and by the canton of Bern, was confirmed by the great and little councils. Much as the Genevans seemed to demand the consequences of this revolution, the change that was made in their constitution, and the diminution of liberty, to which they had been accustomed, and to which they ascribed the in crease of their population and riches, the ferment soon subsided: and excepting the principal leaders, those of the popular party who were banished, and some few others who renounced their country under the influence of their political principles, the greater number of the emigrants returned, and again settled in the place of their nativity. According to Mr. Coxe, this revolution caused fearfully 600 persons to leave Geneva. The emigrants principally established themselves at Bruffles and Constance; where they introduced manufactures of linen and of watches. A plan was also formed for giving an asylum to the Geneva emigrants in Ireland. (See New Geneva.) The form of government established in 1782 underwent another very considerable change in consequence of the revolution in 1789. The aristocratic party was obliged to yield, on this occasion, to the tumultuous demands of the people; and when the solicitor-general, in the name of the citizens and burghers, requested the recovery of their ancient liberties, the permission of bearing arms, the re-establishment of the militia, and of their circles or political clubs, the removal of the garrison from the barracks, and the recall of the representatives banished in 1789; such moderate demands were received with satisfaction: and the new edict of pacification, under the title of "Modifications à l'Édit de 1782," was approved by the Senate, Great Council, and General Council. In this latter council, the "Modifications" were carried by 1321 suffrages against 52. The publication of the new edict was followed by loud acclamations and general rejoicings. This new constitution was judiciously modelled into a mean between the too popular form established in 1768, and the too aristocratic form established in 1782. It is natural to imagine that the widely extended influence of the French revolution would very soon reach the Geneva republic. Many, seduced by the principles of infidelity actively disseminated by Voltaire, and fascinated by the system of general equality laid down in the "Social Contract" of Rousseau, whom they proudly stiled the philosopher of Geneva, became the apostles of irreligion and democracy. Accordingly, a large party was pro-difposed to admit the French doctrines; and in the beginning of 1791, a club, called the "Circle of Light," gave energy and direction to the advocates of general equality. Their efforts were opposed by all the friends of the constitution, and two parties were again formed, which threatened the renewal of past commotions. In this crisis, emigrants from France excited an insurrection among the peasants of the Genevains, and a large body of them marched towards Geneva, to demand the extension of the burgesseship. Although this last hostile attempt proved unsuccessful, the government, apprehensive of another insurrection, and anxious to remove every cause of complaint, granted additional privileges to the natives, and particularly general admission to the burgesseship for the small sum of five francs. (March 1791.) Soon after the abolition of monarchy, the Briffotine party, in conformity with their plan of surrounding France with a chain of petty republics, proposed to separate Geneva from the Helvetic confederation, and either form it into a small independent commonwealth, or incorporate it with the French republic. Although this attempt failed, the independence of Geneva was at length annihilated, and it was incorporated, together with its territory, with the French republic in 1793, and now forms part of the department of Leman, (which see.) Geneva, according to this new division, comprehends three cantons, 22 communes, on a territory of 125 square miles. N. lat. 46° 17'. E. long. 6° 8' 39". Mod. Ul. Hill. vol. xxii. Coxe's Travels in Switzerland, vol. ii.

Geneva, a post-town of America, in the county of Ontario, and state of New York, in the great road from Albany to Niagara, situated on the bank of the N.W. corner of Seneca lake, about 74 miles W. of Oconia castle, and 92 W. of White-town. It has nearly 100 houses. N. lat. 42° 52'. W. long. 74° 6'.

Geneva, Lake of, or Lake of Leman, a large lake of Switzerland, which stretches from Geneva to Villeneuve, being in length 54 miles, in the shape of a crescent; the hollow is formed by Switzerland, and the convex part by Savoy; the greatest breadth, from St. Sulpice to Grande Rive, is 12 miles. Savoy affords a rude and awful boundary of aspiring Alps, craggy and covered with ice of long standing. From Geneva to the environs of Lausanne the country slopes for a considerable distance to the margin of the lake, and is enriched with all the varieties which nature can bellow: the long ridge of the Jura, fertile in pasturage, and varied with woods, backs this beautiful tract. Near Lausanne the banks are very considerably, and form a most charming terrace. A few miles beyond is a rapid defile. Near Veyas begins a plain, which is continued far beyond the end of the lake, but contracting, by the approach of the mountains, towards the lake. The colour of the water is extremely beautiful, clear, and at a distance seems of a most lovely blue.

Near Geneva the coast abounds in small pebbles covered with a brown incrustation; from thence, as far as Lausanne, the shores are sandy; between that town and Chillon appear ledges of rocks, hard and calcareous; and the extremity of the lake is a marsh formed by the collected mud of the Rhone. The depth is various; M. De Luc affirms, that on sounding it, he had found the greatest depth to be 160 fathom. The surface of the lake is said to be 1250 feet, and its greatest part 837 feet above the Mediterranean; like all inland lakes enclosed within high mountains, it is subject to sudden storms. The sky is often clouded with a dark shadow, which appears in December and retires in February, because this lake is almost totally dellitute of reeds and rushes, in which they form their floating Neil, are an elegant article of luxury, and sell for about 12 or 14 shillings each. This lake abounds in fish, remarkable both for their quality and size.

Geneva is also a lake in Upper Canada, which forms the western extremity of Lake Ontario, to which it is joined by a short and narrow isthmus.

Geneva, New, a thriving post-town of America, on the bank of the Monongahela river, just below George's creek, about 18 miles N. of Morgantown; this town is rendered famous as a place of much business, partly by the glufs-works in its vicinity, which not only supply the neighbourhood with window-ghost bottles, &c. but feed large quantities down the river. Here is also a paper-mill, and a manufactury for mullets. Small boats are also built in this place.

Geneva, New, a village of the county of Waterford, Ireland, nearly opposite to Dunkannon fort, where many good houses were erected several years ago by government for the reception of the expatriated citizens of Geneva, but they
they having relinquished the design of settling in Ireland, the place remains uninhabited.

Soon after the revolution of 1782, a memorial, signed by more than 1000 Gennsians of both sexes, who were either persons of some property, or veried in trade or manufactures, expressing a desire of settling in Ireland, was presented to earl Temple (marquis of Buckingham) then the lord-lieutenant of Ireland. His excellency, apprized of the advantage which would redound to Ireland from the reception of so many industrious artists, many of whom possessed property in the English, Irish, and French funds, communicated, in September 1782, the proposal to the privy-council of Ireland for giving an asylum to the Genevans emigrants. This proposal, patronized by the lord-lieutenant, and unanimously confirmed by the privy-council, was approved by the king. The Irish parliament voted 50,000l towards defraying the expenses of their journey, and building a town for their reception; lands were purchased for 8000l. and part of the town was actually completed at the expense of 10,000l. a charter was granted, with very considerable privileges; the standard of gold was altered for the accommodation of the new manufacturers; the foundation of an academy, approved, upon an useful, extensive, and economical plan; in July 1783, several Genevans landed in Ireland; and when the nation had expended near 50,000l. the project was suddenly relinquished, and the settlement finally abandoned. The failure has been attributed to delays in the arrangement of so complicated a plan, occasioned by the high demands of the Genevan commissioners, who, in preparing the charter, required many privileges, that were contradictory to the laws of the land, and by the building of New Geneva. In consequence of these delays, and the renunciation of the Genevans, many returned and took the oaths of allegiance to the new government. The project became gradually less popular; the few Genevans, who prematurely landed in Ireland, were discontented, from not finding the new town ready for their immediate reception; and the emigrants who possessed small property, having withdrawn their names, the rest, with the desire of a sufficient capital to settle in a foreign country, and to establish an extensive manufacture without further assistance. In consequence of this deficiency, the Genevan commissioners petitioned to appropriate 10,000l. of the 50,000l. for the purpose of forming a capital. But, as that fund had been voted by parliament for other purposes, the petition was rejected; and the Genevans, in an address to the duke of Rutland, who succeeded lord Temple as lord-lieutenant, relinquished the settlement, and soon afterwards quitted Ireland.

GENEVIEVE, St., a town of France, in the department of Paris; 6 miles W. of Paris.—Also, a town of France, in the department of the Aisne, and chief place of a canton, in the district of Fapolet; 27 miles N. of Rhoned. The town contains 12,411, and the canton 60,777 inhabitants, on a territory of 175 kilometres, in 17 communes.—Also, a town, or village, of America, in Louisiana, on the western bank of the Mississippi, 12 miles N. of the town of Charters. It contained, some years ago, more than 100 houses, and 465 inhabitants, besides negroes. N. lat. 37° 35'. W. long. 90° 44'.—Also, a town of Canada, on the Baltic. N. lat. 46° 38'. W. long. 72° 14'.

GENEVIEVE, St. Geneviève, or St. Genevieve, fathers or religious of St. Geneviève, the name of a congregation of regular canons of the order of St. Augustine, established in France.

The congregation of St. Geneviève is a reform of the Augustinian canons. It was begun by St. Charles Feare, in the abbey of St. Vincent de Senlis, whereof he was abbot, in the year 1618.

In the year 1634, the abbey was made collegiate; and a general chapter, composed of the superiors of fifteen houses who had now received the reform, chose F. Faure coadjutor of the abbey of St. Geneviève, and general of the whole congregation. Such was its beginning.

It has since increased very much, and has confided to it of above a hundred monasteries; in some of which the religious are employed in the administration of the parishes and hospitals; and in others, in the celebration of divine service, and the instruction of ecclesiastics in seminaries for the purpose.

The congregation takes its name from the abbey of St. Geneviève, which is the chief of the order, and whole abbot is the general of it. The abbey itself took its name from St. Geneviève, the patroness of the city of Paris, who died in the year 512. Five years after her death, Clovis erected the church of St. Geneviève, under the name and invocation of St. Peter, where her relics have been preserved, her shrine visited, and her image carried with great processions and ceremonies, upon extraordinary occasions, as when some great favour is to be intreated of heaven.

GENEVIEVE, in Geography, a bay on the W. coast of Newfoundland, in the straits of Belleisle; 20 miles N. of St. John's bay.

GENEVOIS, or DUCHY OF GENEVA, a province of Savoy, bounded on the N. by the Swiss territories, on the E. by Faucigny, on the S. by Savoy Proper, and on the W. by France, from which it is separated by the Rhône. Geneva and its territory formerly made a part of it. It is now annexed to France.

GENEVRAY, a town of France, in the department of the Ile; 10 miles S. of Grenoble.

GENEURO, a mountain which divides Piedmont from the ancient Dauphiny, in the road from Briançon to Susta.

GENGA, GIROLAMO, in Biography, a painter of very considerable celebrity in his day. He flourished at the early period of the revival of the art, being born at Urbino in 1476. At the age of 15 he studied under Luca Signorelli of Cortona, then in great esteem, and acquired his manner in the midst of his undertakings in different parts of Italy, but particularly at Orvieto, being acknowledged the best disciple of that school. He afterwards spent three years with Pietro Perugino, at the same time that Raphael was under the tuition of that artist; and that intercourse laid the foundation of a most cordial friendship between Raphael and Genga, which never was impaired.

He was highly encouraged by Guido-Baldo II, and his successor, Francesco Maria III, dukes of Urbino, in their palaces and theatres, and in designing triumphal arches. In Rome, Sienna, Forli, Pefaro, and many other places, he left behind him an incalculable number of works, both in painting and architecture, which were held in great esteem, and which procured him honour and riches. He died of a fever in 1551, aged 75, leaving two sons, one of whom, Bartolomeo, followed the profession of his father in the same style, and was moreover an eminent literary and architect.

GENGA, BERNARDI, a doctor in philosophy and medicine, was born in the duchy of Urbino. He was a teacher of anatomy and surgery at Rome about the middle of the 18th century; and, according to Mangeti, surgeon to the hospital of the Holy Ghost in that city. He was a man of firm understanding, and maintained the doctrine of the circulation of the blood, when it was not generally admitted in Italy; but he attributed the discovery of it to Paul Sarsi.
He also ventured to accuse Hippocrates of committing such errors, in the care of several bygone disciplines, as would not be pardoned in a student. His works are, 1. "Anatomia Chirurgica;" or, "Historia dell' olla e mucidi del corpo umano, con la descrizione de' vari;" Rome, 1675, 1687. 2. "Anatomia per furo ed intelligenza del deligno;" Rome, 1691. This work contains some good figures of the ancient statues. Genza prepared the bodies, by diffusing the bones and muscles in the forced attitude of the gladiators in their combats: and Lanciani added explanations of the figures. 3. "Commentaria Latina et Italeca ad Hippocratis Aphorismos; ed Chirurgiam pertinencia;" Rome, 1634, 8vo. Bonon. 1697, 8vo. Ely. 

GENGENBACH, in Geography, an imperial town of Germany, in the circle of Schwäbisch, situated on the Kinzig, in the Orient: in this town is an abbey, whose prelade was a prince of the empire. Among the indemnities agreed on at Ratibona in 1802, this town and abbey were given to the margrave of Baden; 15 miles S.E. of Straßburg. N. lat. 48 27'. E. long. 8 1'. 

GENGOULÉ-ROYAL, St., a town of France, in the department of the Saône et Loire; celebrated for its wine; 11 miles N. of Cluny. 

GENIAL, GENIALIS, an epithet applied by the ancients to certain deities, whom they suppos'd to preceed over generation. 

They were thus called a geri-do, from bearing: or, according to the correction of Scaliger and Vossius, a genemio, to yeem, produce: yet Fellus says, that they were also called geruli, which seems to require the farmer reading. M. Dacier, in a note, shews that genere has the sense of παθην. 

Among the genial gods, dii genialis, says Fellus, were water, earth, fire, and air, which the Greeks called elements. The twelve signs were sometime also ranked in the number: as also the sun and moon. 

GENICULATUS, CULUS, in Botany, a shrub bent like the knee, as in Althœcus geniculatus; see Culmus; and CAULIS, d. 19. 

GENICULI, the joints or knots which appear in the shoots of plants; whence botanists call those marked there-with geniculate plants. 

GENIE. See GENIUS. 

GENIES, St., in Geography, a town of France, in the department of the Aveaire, and chief place of a canton, in the district of Epernon; 18 miles E.N.E. of Rhôdes. N. lat. 44° 28'. E. long. 3° 3'. The place contains 33,323, and the canton 79,838 inhabitants, on a territory of 2032 square miles, in 8 communes.—Allo, a town of France, in the department of the Gard; 3 miles N.W. of Nîmes.—Allo, a town of France, in the department of the Lower Alps; 6 miles N.E. of Sillery. 

GENI, in Mythology. See GENIUS. 

GENILLÉ, in Geography, a town of France, in the department of the Indre et Loire; 3 miles N. of Loches. 

GENICULATUS, in Anatomy, (from genus, the chin; and gulosus, the tongue,) a large muscle belonging to the tongue. See Dissection. 

GENICULATUS, in Anatomy, (from genis, the chin; and gulosus, the tongue,) a large muscle belonging to the tongue. See Dissection. 

GENIUS, in Botany, from genus, a head, and s-, the mouth, because the orifice of the flower is bofed with a dense fringe. Forst. Gen. t. 12. Scherb. 131. 

GEN. Ch. Col. Perianth inferior, tunicate, permanent, with five acute segments. Cor. of one petal, funnel-shaped; tube dilated upwards, longer than the calyx, its orifice bearded; limb spreading, in five deep, ovate, rather pointed segments, as long as the tube. Stam. Filaments five, short, in the tube of the corolla; anthers oblong, prominent. Fil. German superior, ovate; style thread-shaped, longer than the tube; stigma cylindrical, obtuse, furrowed. Pericarpule oblong, of two cells. Seed enormous, somewhat angular, ranged along a thread-shaped receptacle. 

Eff. Ch. Corolla funnel-shaped, bearded at the mouth. Calyx inferior, with five segments. Stigma cylindrical, abrupt, furrowed. Pericarp of two cells, with many seeds. 

1. G. rugulata. Forst. Forst. Prod. 17. Native of rocky places in the island of Tanna. Stem shrubby, climbing without tendrils, branched in an opposite manner, round, with a smooth grey bark. Leaves opposite, about three long, elliptic-lanceolate, pointed, entire, slightly wavy, smooth, opague, with one rib, and a few remote, curved, interbranching veins. Peduncles slender, smooth, cuneilled, half an inch long. Stipulas intrafoliaceous, united, short, acute, rather membranous. Flowers small, in solitary, forked, opposite, somewhat downy, axillary panicles, rather longer than the flower-tubes. Bracteas short, acute, united at their base, in pairs under each fork of the panicle. Calyx minutely fringed. Corolla apparently reddish.—From one of Forster's own dried specimens. Jussief probably never saw the plant; or we think he would have referred it to his Genes. No figure has been published, except of the fruitification. 

GENIPA. (See GARDENIA.) The name is barbarous, of West Indian origin, and appears to be sometimes called Guaret. See Tournefort, 678. 

GENEBABU, in Geography, a river of Brasih, which runs into the Atlantic, S. lat. 5° 75'. W. long. 34° 46'. 

GENIS, St., a town of France, in the department of the Lower Charente, and chief place of a canton, in the district of Jonzac; 24 miles S. of Saintes. The place contains 682, and the canton 12,600 inhabitants, on a territory of 2122 square miles, in 17 communes.—Allo, a town of France, in the department of Mont Blanc, and chief place of a canton, in the district of Chambery, near the conflux of the Rhône and Guiers; 15 miles W. of Chambery. The place contains 1550, and the canton 7622 inhabitants, on a territory of 1124 square miles, in 12 communes. 

GENIS la Val, St., a town of France, in the department of the Rhône, and chief place of a canton, in the district of Lyons; 4 miles S. of Lyons. The place contains 2450, and the canton 15,532 inhabitants, on a territory of 972 square miles, in 10 communes. 

The left, or Curnar fort, may likewise be raised by sowing the seeds in pots of good garden mould in the spring season, but the aid of a moderate hot-bed is necessary to bring them forward. As soon as the plants have acquired a little growth they should be removed into separate small pots, and be immediately replanted in the hot-bed. In their after-management they demand the same fort of attention as other tender kinds of greenhouse plants.

Each of the first fix arts are proper for the more forward parts of the clumps and borders in ornamented grounds, and have a good effect from the fine appearance of their flowers.

The left kind produces a variety among other evergreen plants in the green-house collections.

*GENITA* BRITANNICA, in Geography, a town of America, in Powhatan county, Virginia, 156 miles from Washington.

In *Meditations*, a goddef who preferred over birth-child, to whom the Romans sacrificed a dog.

**GENITAL, GENITALIA**, in Anatomy, something that relates to generation; which fec.

**GENITALIUS, genitales**, are sometimes used in the ancient Roman poets for those we otherwise call *indigetes*.

Aconites, in the argument of the fourth book of the *Aeneid*, takes the word in a different manner: the *di genitalia*, he observes, were such as were not born of human parents, and were not thus called *quasi geniti ex hominibus*, but rather because they themselves had begot human children.

**GENITALIA, or GENITORES**, in Anatomy, a name sometimes given to the testes or testicles of a man, on account of their office in generation, which fec.

**GENIETE, in Geography, a town of France, in the department of the Correze; 18 miles W. of Drive.**

**GENIETE, in Grammar. See GENERATED.**

**GENITIVES, PATER, or Genites, among the Hebrews, those that descended from Abraham, without any mixture of foreign blood.**

The Greeks distinguished by the names of genities such of the Jews as were fuced from parents who, during the Babylonish captivity, had not allied with any gentile family.

**GENITIVE, in Grammar, the second case of the declensions of nouns.**

When one thing is represented as belonging to another, in the relation of cause, origin, or author, its name has a termination given to it, called the *genitive case*; and as the author is properly the owner of a thing, the genitive is also called the *possessive case*.

In English, the genitive case is made by prefixing the particle *of*; or it is expressed by an apoprophe, with the letter *s* coming after its as "thy father's house." when the plural ends in *s*, the other *s* is omitted, but the apoprophe is retained, as "on eagles' wings." Sometimes also, when the final terminations in *s*, the apoprophe is not added; as "my right shoulder." In French the genitive is expressed by *de*, or *des*, &c. though, in the to this, there are no cases at all, or at most only two, in either of these languages, inf--much as they do not express the different relation of things by different terminations, but only by additional prepositions. (See Case.)

An ingenious grammian observer, that though the termination called the genitive case be rendered by *of*, it means invariably from, beginning, motive; and this, he says, seems to be the true signification of *of*, if we regard its etymology, it being taken from *ex*, *ect*, *ab*, *from*; and though custom seems to have assigned it some different undefinable meaning, it is in all cases referable into the
GEN

GEN

The fene of from. Thus, a table of wood is a table from wood, wood being the origin or beginning of it. Again, he is sick of love, i.e. sick from love, love being the cause of his sickness; and in all other inferences. And this is the reason why some prepositions which signify origin or beginning in Greek, Latin, and French, are rendered in our tongue by *genius*. 

In the Latin, this relation is expressed in divers manner, thus we say, caput hominis, the head of a man; color reo, the colour of a reft; opus Dei, the work of God, &c.

As the genitive case serves to express very different, and even opposite relations, there sometimes arises an ambiguity from this circumstance; thus, in the phrase, *voluum Achilis*, the wound of Achilles, the genitive, Achilis, may either signify passively the wound Achilles has received, or actively the wound Achilis has given; thus in that passage of St. Paul, *Cersius funt, quaeque mori, quaeque vita, et nos patrem*; the genitive *Dei* has been taken by interpreters in two different senses; some giving it the relation of object, understand the passage of the love which the elect bear to God in Jesus Christ; whereas others give it the relation of subject, and explain it from the love which God bears the elect in Jesus Christ.

In the Hebrew tongue, the genitive case is marked after a manner very different from that of the Greek and Latin; for whereas in those languages the noun governed is varied, in the Hebrew the noun governing undergoes the alteration. 

GENITO, St. in Geography, a town of Naples, in Calabria Cirta; 21 miles N. W. of Bifighano.

GENIUS, in Mythology, a good or evil spirit, or daemon, whom the ancients suppos'd to pervade each person, to direct his birth, accompany him in life, and be his guard until death. Tho' those that attended women were females, and called Junonis, but those that attended men were males, and called Geni. They seem, in their original, to be nothing else but the particular bent and temper of each person defined; and as every one's own temper is in a great measure the cause of his happiness or misery, each of these were supposed to have, and have an equal feeling in all the enjoyments and sufferings of the persons they attended. (See Horace, lib. ii. ep. ii. ver. 189.) The ancients had their Genii of nations, of cities, of provinces, &c. Nothing is more common than the following inscription on medals: GENIUS POPULI ROM. "the Genius of the Roman people:" or, GENIO POP. ROM. "to the Genius of the Roman people." The ancient Gauls acknowledged Geni, who took care of each particular province and canton: but the foundation of the worship, which they paid to their deified cities, or rather to the genius who protected them, and became their tutelar divinity, was to engage them to take care of them, to defend them against enemies, and to remove from them all evils, with which they might be afflicted; such as epidemical distempers, and other calamities. The names of these tutelar Genii were kept secret, lest, if they should be known, they should be conjured away, and forced to abandon the cities that were committed to their charge, and pass to others, where they were promis'd a more solemn worship.

In this sense, genius and lar were the same thing; as, in effect, Conferonius and Apuleius affirm they were.

Of these genii or demons, Plato supposes that every man has his own, who is his guardian, and the withefs, not only of his actions, but of his very thoughts; but that, at death, the genius delivers up to judgment the person who had been committed to his charge; and if, when the person is interrogated by the judge, his answer be found not agreeable to truth, the genius censures and reprimands him very severely, as, on the other hand, he pronounces an encomium upon him when what he says is true; and it is upon the approbation of the genius, that the doom is pronounced; for this demon knows whatever passeth in the man, even his most secret thoughts.

Although Plato and Jamblichus were of opinion that every individual had but one of these geni to conduct him, and to preside over all his actions, other philosophers of the same school were persuaded, that he had two, the one good, the other bad. To this purpose Servius upon Virgil (En. l. vi. c. 745.) says, "Volunt unicusgenium opponitum, Demone bonum et malum; hoc est, rationem quae ad meliorem rem portatur, et libidinem quae ad pejor; hic est Larva et genius malus; ille bonus genius et Lar. "They will have it that every one has two genii, the one good, and the other bad; that is, reason, which always excites men to good, and lust, which prompts them to ill; the latter is what they call "Larva," or evil genius; the other good Genius, or "Lar."

The Platonists, and other eastern philosophers, supposed the Genii to inhabit the vital region, or extent of air, between earth and heaven. They were a fort of intermediate powers, who did the office of mediators between gods and men. They were the interpreters and agents of the gods; communicated the will of the deities to men; and the prayers and vows of men to the gods. As it was unbecoming the majesty of the gods to enter into such trilling concerns, this became the lot of the genii, whose nature was of a middle kind between the two; who derived immortality from the one, and pulions from the other, and who had a body framed of an aerial matter. Most of the philosophers, however, held that the genius of particular men were born with them, and died. Thus Plutarch attributes the ceasing of oracles partly to the death of the Genii.

The heathens, who considered the Genii as the guardian spirits of particular persons, believed that they rejoiced and were afflicted at all the good and ill fortune that befel their wards. They never or very rarely appeared to them; and then only in favour of some person of extraordinary virtue or dignity. They likewise held a great difference between the Genii of different men; and that force were much more powerful than others; on which principle it was, that a wizard in Appian bids Antony keep a distance from Octavius, because Antony's Genius was inferior to, and flood in awe of, that of Octavius.

There were also evil Genii, who took a pleasure in percuting men, and bringing them evil tidings: such was that in Paterculus, &c. which appeared to Brutus the night before the battle of Philippi. These were also called larus, and lemures.

According to the theology of Hebra, the men of the golden age became demons, or good genii; tho' he, according to him, are the guardians of men, the earth having fallen to their lot. Tho' of the silver age were changed into manes, or substerraneous genii, happy though mortal. Tho' of the brazen age went down to the infernal regions. Tho' of the heroic age took possession of the Fortunate islands, or the Ellysiinn fields, situate at the extremities of the world. See DEMON, and DEMON OF Socrates.

The Mahometans also admit the existence of Genii, suppos'd by them to be a class of intermediate beings, between angels and men; of a groffer fabric than the former, and more active and powerful than the latter. Some of them are good, and others bad; and they are, like men, capable of future salvation or condemnation.

Genius is more frequently used for the force or faculty of the soul considered as it thinks or judges.

Thus, we say, a happy genius, a superior genius, an elevated genius, a narrow confined genius, &c. in like sense we also say, a work of genius, a want of genius, &c.
Genius is also used, in a more restrained sense, for a natural talent, or disposition to one thing more than another. In which sense we lay, a genius for verve, for the sciences, &c.

Dr. Bihir, in his "Lectures on Rhetoric, &c." (vol. i.) distinguishes between Taste and Genius. Taste, he says, confines in the power of judging; Genius, in the power of executing. One may have a considerable degree of taste in poetry, eloquence, or any of the fine arts, who has little or hardly any genius for composition or execution in any of these arts. But genius cannot be found without including taste also. Genius, therefore, deserves to be considered as a higher power of the mind than taste. Genius always imports something inventive or creative; which does not rest in mere sensibility to beauty, where it is perceived, but which can, moreover, produce new beauties, and exhibit them in such a manner, as strongly to impress the minds of others. Refined taste forms a good critic; but genius is further necessary to form the poet, or the orator. Besides, genius is a word, which, in common acceptation, extends much further, than to the object of taste. It is used to signify that talent or aptitude, which we receive from nature, for excelling in any one thing whatever. Accordingly, we speak of a genius for mathematics, as well as a genius for poetry; or a genius for war, for politics, or for any mechanical employment. This talent or aptitude, for excelling in any one particular, is received from nature; and though it may be greatly improved by art and study, it cannot by them alone be acquired. As genius is a higher faculty than taste, it is more limited in the sphere of its operations. While we find many persons, who have an excellent taste in several of the polite arts, such as music, poetry, painting, and eloquence, all together; it is much more rare to meet with one who is an excellent performer in all these arts. Indeed, an universal genius, or one who is equally and indiscriminately turned towards several different professions and arts, is not likely to excel in any. The rays must converge to a point, in order to glow intensely. A genius for any of the fine arts always supposes taste; and the improvement of taste will serve to forward and correct the operations of genius. But genius, in a poet or orator, may sometimes exist in a higher degree than taste; that is, genius may be bold and strong, while taste is neither very delicate, nor very correct. This is often the case in the infancy of a art; a period when genius frequently exerts itself with great vigour, and executes with much warmth; while taste, which requires experience, and improves by slow degrees, is not yet attained in its full growth. Homer and Shakespeare may be referred to as examples in proof of this assertion. (See Taste.) Longinus, in his "Treatise on the Sublime," remarks, that liberty is the nurse of true genius; it animates the spirit, and invigorates the hopes of man; excites honourable emulation, and a desire of excelling in every art. It is observable, that writers and artists most distinguished for genius have generally appeared in considerable numbers at the same period. Besides the moral causes which have been alleged to account for this phenomenon, such as favourable circumstances of government and manners, encouragement from great men, and emulation excited among men of genius, the Abbé du Bos, in his "Reflections on Poetry and Painting," has collected a great many observations on the influence which the air, the climate, and other natural causes, may be supposed to have upon genius. The opinion of the Abbé du Bos, that genius chiefly depended on soil, food, air and climate, has been favoured by Montesquieu in his "Spirit of Laws"; and it occasionally occurs in other writers. Mr. Hume, however, has attacked this hypothesis with great ingenuity and strength of reasoning in his "Essay on National Chari-

In that Essay he has clearly proved, that the differences we observe in nations, with regard to genius, science, and manners, arise from moral, and not from physical causes. (See Climate.) The fact, however, is unquestionable, that some periods or ages of the world have been much more distinguished than others for the extraordinary productions of genius. (See Age, in the History of Literature, &c.) If we institute a comparison between the ancients and moderns in this respect, we must allow, that while the advancing age of the world brings along with it more science and more refinement, its earlier periods may lay claim to more vigour more fire, more enthusiasm of genius. Among the ancients, we find higher conceptions, greater simplicity, more original fancy; among the moderns, sometimes more art and correctness, but feebler exertions of genius. Admitting this to be in general a mark of distinction between the ancients and moderns, it cannot be admitted without exceptions; for, in point of poetical fire and original genius, Milton and Shakspere are not inferior to any poets in any age.

Genius, is not a musical term, nor does it appertain to one of the polite arts; more than another; but Roufseau (Diction de Mus.) has ventured an article for it among musical terms, and has written it with peculiar eloquence and enthusiasm.

Roufseau, paradoxical on almost all other subjects, is sometimes not only capricious, but mischievous; yet his bitterest enemies admit, that music is his bright side; and though he is not allowed by the present French musical critics to be a profound contrapuntist, yet his taste in music and poetry was refined, and of the highest class; and his views concerning dramatic music were enlarged, rational, ingenious, and free from all caprice and paradox.

GENLIS, in Geography, a town of France, in the department of the Côte d'Or, and chief place of a canton, in the district of Dijon. The place contains 707, and the canton 8599 inhabitants, on a territory of 1874 kilometers, in 27 communes.

Gennaba, a town of Peria, in Farilitan, in the Persian gulf; 15 miles N.W. of Bender Rigk.

Gennadius I., in Biography, patriarch of Constantinople, was elected to that dignity, having been some years an ordained prebender of the church, in the year 458, on the death of Antoninus. In the following year, in a council of 73 bishops, he procured the pulling of a canon against liminal for the government and manners of the church, which had been endeavour to claim for the patriarch's treasurers, should thenceforth belong to the officiating clergy. He died in 471, leaving behind him a high character for great zeal and disinterestedness in correcting the relaxed state of discipline which prevailed in his see. He is placed by those who lived about the same period among the ecclesiastic writers of the day, and is applauded for the extent of his learning and the elegance of his style. The proofs of this have not come to us, excepting in "A synod Epistle" against simony, inserted in the fourth volume of the Collect. Concil.; and fragments against the anthems of Cyril of Alexandria, quoted by Facundus, bishop of Hermia, and another from a treatise addressed to Parthenius, and quoted by Leontius. Moreri.

Gennadius II., another patriarch of Constantinople, in the fifteenth century, assumed the name upon embracing the ecclesiastical life, having, prior to this, the name of George Scholarius. He was a native of Constantinople, where he was educated, and attracted much notice by his talents and remarkable progress in the different branches of learning. He became secretary to the emperor John Palaeologus, and
and afterwards chief judge of the Greeks. In 1438 he accompanied the emperor to the council at Florence for the purpose of bringing about an union between the Greek and Latin churches: it is, however, a matter of much doubt whether Scholarius was in favour of the measure which his duty to his master required him to function and support. After his return to Constantinople he united with Mark of Ephesus, in opposing the reception of those terms of union to which the emperor had acceded, as well by his influence as by his writings, which brought on him for a time the displeasure of the emperor. After the death of Palaeologus in 1445, Scholarius was as violent as ever against the proposed union, and finding that his opposition must subject him to danger with the new emperor, Constatine, he resolved to relinquish his civil employments, and to embrace the ecclesiastical life. He accordingly, in 1459, after finding a valedictory oration to the emperor, entered as a monk into a monastery adjoining Constantinople, and lived a secluded life for two years, which is supposed to have been the result of the emperor's orders, to prevent him from taking part against the proposed union. During his retreat from the world he composed several homilies, which could offend no one; but he did not engage in any controversy until the union was completed. This called forth his zeal in behalf of the Greek church: he wrote letters to all the ecclesiastics of Constantinople, and to the different monastic orders, exhorting them to adhere to the faith of their ancestors, and not to submit to the Florentine union: he also renounced with the emperor the subject of the union, but the monarch was not to be turned from his plan, and made every effort, by perjury and by threats, to bring over Gennadius. The attempt was futile: he had gone too far to retract, and had obtained a multitude of adherents whom he had converted by his writings and exhortations, which represented the union to be a desertion of the cause of God and his truth. The emperor subordinated the act of union at Constantinople, as it had been ratified in the council of Florence. On the 12th of December 1452, the two nations, in the church of St. Sophia, joined in the communion of sacrifice and prayer. But the dregs and language of the Latin priest who officiated at the altar were objects of scandal; and it was observed, with a feeling of horror, that he consecrated a wafer of unbleached bread, and poured cold water into the sacramental cup. From the dome of St. Sophia, the inhabitants of either sex, and of every degree, rushed in crowds to the cell of Gennadius to consult him, as the oracle of the church. He was invisible, and entered, as it should seem, in deep meditation, or divine rapture; but he had expounded on the door of his cell a tablet, on which were written these words: "O miserable Romans, why will ye abandon the truth; and why, instead of confiding in God, wilt ye put your trust in the Italians? In abandoning your faith, ye will lose your city. Have mercy on me, O Lord! I protest, in thy presence, that I am innocent of the crime. O miserable Romans, consider, pensive, and repent! At the same moment that you renounce the religion of your fathers by embracing impurity, you submit to a foreign servitude." This was the signal for insurrection, (see Constantinople) and, after the capture of the city, the sultan Mahomet, with the innumerable inhabitants who had survived the inhuman slaughter made by his army, and of recalling the Greeks, who had escaped, to their deserted houses, ordered Gennadius to be brought, and offered him to the choice of the clergy and people, by whom he was immediately elected their patriarch. In the election and investiture of Gennadius, the ceremonial of the Byzantine court was revived and imitated. With a mixture of satisfaction and indignation, they beheld the sultan on his throne, who delivered into the hands of Gennadius the pastoral staff, the symbol of his ecclesiastical office, who conducted the patriarch to the gate of the fortress, presented him with a horne richly caparisoned, and directed the viziers and bailiffs to lead him to the palace which had been allotted for his residence. The churches of Constantinople were shared between the two religions; their limits were marked, and till it was infringed by Selim, the grandson of Mahomet, the Greeks enjoyed above sixty years the benefit of this equal partition. Gennadius presided over the see of Constantinople between five and six years, when he resigned his dignity, and retired into a monastery. He died about the year 1460. He was author of "An Explanation of the Christian Faith, delivered before the Turkish emperor Mahomet." This work was the result of a long conversation which he had with the emperor, soon after his installation, when Mahomet suffered him to produce all the arguments he was able to produce in support of the truth of Christianity. It is to be found in Crusius's Turkish-Greek. and is also in David Chytrzeus's "De Rerum Ecclesiae in Graecia," Gennadius wrote likewise a treatise concerning predilection, and another on the trinity. He composed many homilies in the early part of his, which were delivered before the emperor, as orations, which laymen were, in that age, accustomed to pronounce in the imperial dining-room. Moreri. Gibbon's Hist.

GENNADUS, an ecclesiastical writer, flourished towards the close of the fifth century, and became prior of Marcella. He was a great writer, and is said to have composed eight books against all heretics, six against Nestorius, three against Pelagius, and a treatise concerning the millennium and the book of Revelation; but the only works remaining of this author are entitled "De viris illustribus," which is a continuation of St. Jerome's catalogue of Ecclesiastical Writers; and a treatise "De Fide, leu de dogmatibus Ecclesiae Libri ad Gelatam Papam mitit." This last was for a considerable time attributed to St. Augustine, and was generally inserted in the editions of his works. The time of Gennadius's death is not known, but it did not take place before the year 605. Gennare, Cesare, and Benedetto, two brothers who both made painting their profession. They were nephews, heirs, copyists, and imitators of Guercino; they frequently repeated his pictures, but not with adequate sweetness or force. At first they wrought together at several places in Italy; but separating, Cesare remained at Bologna, and Benedetto went to England, where there are many of his works, particularly at Windsor Castle, divisible by a labourious, dry imitation of Guercino, with a mixture of the flutter and parade exhibited by the French painters of that period. He was made painter to James II. and executed a picture of that prince and his family. At their expulsion he returned to Italy: and as his manner, by the mixture of French art he had introduced, was novel, he obtained applause and employment. He died in 1715, aged 82.

GENNE, in Geography, a town of France, in the department of the Maine and Loire, near the Loire; 9 miles N.W. of Saumur.

GENP, a town of France, in the department of the Loir, situated on the Niers, near the Meuse. It contains two churches, one for Roman Catholics, and another for Protestants; 9 miles S. S.W. of Cleves. N. lat. 51 47'; E. long. 5 50.'

GENNES, a town of France, in the department of the Maine and Loire, and chief place of a canton, in the district
GENOA.

trict of Saumur; 5 miles N.E. of La Guerche. The place contains 1,433, and the canton 8,249 inhabitants, on a territory of 190 kilometres, in 15 parishes.

GENOA, and since the French revolution the "Ligurian republic," is a small, mountainous territory, in the northern part of Italy, forming a kind of cleft along the Mediterranean sea on the south, and covered on the land side by the Apennines, which separate it from the countries of Milan, Piedmont, the Montferrat, the Milanese, and Parmesan. It length from the town of Vintimiglia on the west, almost to the territory of the republic of Uccle on the east, is about 150 miles, and its greatest breadth, from the sea to the interior of the country, is not more than 20 miles. The mountains that enclose it are, in some places, covered with forests, in others they are barren rocks, and in some few parts they yield excellent pastures. There is but a small quantity of arable land in this country, so that it is under a necessity of seeking a supply of corn from Naples, Sicily, and other places; but the inhabitants avail themselves of every spot which is capable of cultivation. They are furnished throughout the year with excellent legumes and vegetables for the table; they also make a considerable quantity of wine, and are amply provided with various kinds of fruit, especially citrons, oranges, pomegranates, almonds, and figs. They raise a great number of mulberry trees for feeding silk-corms, and olives grow in great plenty, particularly round the gulf of Spezia. Salt is produced for exportation. The Apennines, and some other hills, supply them with excellent marble, while Polzevera, in the Boccella, yields the beautiful stone so called, being ferpen
tine of various colours veined with marble, which is easily conveyed by a magnificent road formed, in 1778, from the Boccella, or mountains to the north of Genoa, through the Polzevera, by three years' labour of from five to eight hun
dred men, at the expense of one patriotic and noble family, the Cambias. The inhabitants of this country, amounting to about 450,000, are Roman Catholics, though the papal power is not much venerated; the people being devoted to commerce, and disposed to receive mafloned heretics, without any religious scruples. The manufactures were formerly very considerable, but they have of late declined; the principal are velvet, plush, damask, different kinds of silk, for which they are supplied with the raw material from Mef
tina and other places; gold and silver ruffs, heco, gloves, stockings, ribbons, foap, paper, &c. Other articles of commerce are, oil, fruit, macaroni, confectionery, Par
desan cheese, anchovies, &c. Although Genoa is a free port, Leghorn, which is likewise free and indulged with greater liberty, interferes with its trade, and diminishes it.

This country is part of the ancient Liguria (see Liguria); which, in the second Punic war, espoused the interest of the Carthaginians; but the city of Genoa, which was then a celebrated emporium, taking part with the Romans, was plundered and burnt by Mago the Carthaginian. It was afterwards rebuilt by the Romans, and continued under their dominion, together with the rest of Italy, till the conclusion of the fifth century, about A. D. 298, when Theodoric, king of the Goths, having defeated the usurper Odoacer, was proclaimed by the army king of Italy, even with the consent of the emperor Zeno. Genoa was after
tswards recovered by Beliarus, when he entirely subdued the Goths; and when the Lombards invaded Italy, this city remained for some time un molested, deriving an accession of wealth and inhabitants by the refugees who fled from the vicinity of the Po, in order to escape the fury of the invaders. At length, in the seventh century, Genoa was plundered and burnt by the Lombards, and remained under their power till Italy was conquered by Charlemagne, when the territory of Genoa, distinguished by its wealth and popula
tness, was erected into a marquisate. It soon after
ds became so powerful, under the Genoese empire, and after it had obtained a kind of independence, that, in 868, it reduced the island of Corsica, and in 935 defeated the Saracens, who had plundered and burnt the city, in their return to Africa, on the coast of Sardinia. About the year 950, when the Franks having lost all authority in Italy, the Genoese began to form themselves into a kind of aristocratical republic, under a chief called doge, (see Doge,) elected every two years, and to be governed by their own magistrates, who were freely elected, and took the name of consuls. In order to maintain their independence, they applied, with great ad
duity, to navigation and commerce, and thus became rich and powerful. Their commerce extended from Spain to Syria, and from Egypt to Constantinople, and was carried on in vessels, that were fitted for war as well as traffic. In the year 1017 they united with the Pisans in an expedition against Sardinia; and about 33 years after this expedition, the Genoese and Pisans were engaged in a destructive war, which lasted nearly 15 years; but when a treaty of peace was concluded between them, they concerted in a successful expedition against the Moors, in Africa. What contributed more than any other circumstance to the opulence and grandeur of the Genoese, was the part they took in the crusades, and the important services they rendered to the religious warriors, towards the close of the eleventh and commencement of the twelfth centuries. During the latter century, they subjected the half of Sardinia, and the city of Syractse; they also made themselves masters of the Black sea, formed establishments in the Crimea, and in the suburbs of Persa, at Constantinople, where they remained till the Turks took that city. In the thirteenth century, they added to their conquests the towns of Albengo, Savona, Vintimiglia, and others in their neighbourhood; and for the superiority of the sea, they engaged in a long and obstinate contest with the Venetians, which did not terminate till the year 1381. In their various conflicts with neighbouring powers, their strength was enfeebled, so that, in 1471, they were expelled from the Crimea; though their maritime power still continued respectable. Exhausted by the Venetian war, in particular, Genoa offered voluntary subjection to France and to Milan; but after many revolts and conflicts, with a view of recovering their independence, they were at length, in 1528, reduced from the dominion of foreign princes, by the vigorous exactions of Andrew Doria. Doria, having driven out the French, and gained possession of Genoa, assembled the nobility, and restored the government into their hands, declaring that he pretended to no greater share in it than became him as a nobleman. He re-established the ancient form of the republic, and received from his country all those testimonies of gratitude, which a conduct so disinterested deserved to receive. (See Doria.) Towards the end of the sixteenth century, Genoa was distracted by a civil war; but after a reconciliation had been effected between the two contending parties, distinguished by the appellations of the old and new nobility, the republic enjoyed peace and felicity for an interval of 48 years, during which period scarcely an incident, domestic or foreign, occurred, that is worth recording. In the year 1624, a dispute arose between the republic and Charles Emmanuel, duke of Saxony, in which Lewis XIII. bore a share; and a treaty was concluded between France and Savoy, that was hostile to the Genoese. On this occasion the Spaniards declared in favour of Genoa; and a peace
peace with France and Savoy restored the republic to its former situation, at the commencement of the war. In 1636, the Spaniards attempted to besiege the city, but the enterprise was frustrated; and from this time till the year 1656, Genoa enjoyed all the blessings of peace and commerce. In the following year Hippolito Centurioni, the Genoese admiral, gained several advantages over the corsairs of Barbary, which paved the way for a treaty of commerce that was concluded with the piratical states, and the grand signor. The treaty with the Porte was considerably extended by the marquis Durazzo, who went in quality of ambassador to Constantinople in the year 1666. The result of this treaty renewed the vigour of the Genoese trade, to a pitch beyond what any of the maritime towns had experienced since the Dutch founded their commercial republic, and extended their trade not only to the Levant, but to every quarter of the globe. For some years Genoa lived in peace with all the neighbouring powers, enjoyed domestic harmony, and affluently cultivated commerce, and whatever should render the republic powerful and happy. Some petty jealousies and differences arose between her and Venice, the father and rival republic; but they were such as terminated amicably, and never caused any disturbance to the repose of Italy. In the year 1684, the Genoese unfortunately incurred the resentment of Louis XIV., who looked with jealousy on their attachment to Spain; and could not permit them to support the republic under the protection of that crown. His attempts for humbleing them proved too successful; but in consequence of their submission, and the interruption of the peace, peace was obtained. The terms stipulated by the French were peculiarly severe and oppressive; among others, they required that the doge and four censors should appear in person at Versailles, in order to sue for pardon; and that the state should disarm all their galleys, fix excepted, with a promise not to fit out more, without the knowledge and consent of the king. During the ensuing war, kindled by the ambition of Lewis, which embroiled the greatest part of Europe, the republic of Genoa adhered with the neutrality, and enjoyed the advantages of peace and commerce, while the dominions of their neighbour, Victor Amadeus, duke of Savoy, underwent all the calamities of war. In 1713, Charles VI. sold the marquise of Finale to the republic for a considerable sum of money. In 1743, the queen of Hungary, having at the treaty of Worms ceded to the king of Sardinia all her rights to the town and marquise of Finale, and demanding that the Genoese should deliver up the marquise, they entered into an alliance with France, Spain, and Naples; and, in 1745, declared war against the king of Sardinia who had made himself master of a great part of the state; several Genoese ports were bombarded by an English fleet; and the Imperialist's feizes upon the city of Genoa; but after a dreadful slaughter on both sides, they were again driven out by the inhabitants; and, in 1747, miscarried in their attempt to recover it. The treaty of Aix-la-Chapelle, in 1748, restored its tranquillity. The ancient nobility confit of 28 families, whom Andrew Doria, in 1528, separated from all the rest, and declared to be only capable of holding the chief offices and dignity of doge; all the other inhabitants being reduced by him to the class of commoners. Since that time it has been found necessary to create other nobility. The nobility of Genoa were allowed to keep manufactures of velvet, silk, and cloth, to farm the duties, and to have stores in merchant vessels; but all other business and handicrafts were forbidden. The form of government in this republic was aristocratical; the chief being called doge. This government continued till the year 1798, when the French form was chosen, and the new style assumed of the Ligurian republic, confirmed by the more recent treaty of February 1801. The troops of this state, including the militia, may amount to about 30,000; and the fleet, recently celebrated for its victories over the Saracens, the Pisans, the Venetians, Spaniards, and Turks, and for maintaining during a long period a considerable dominion over Sardinia, Corsica, Malta, Majorca, Minorca, Candia, Cyprus, and many other places in and near the Mediterranean and Archipelago, and even the Black sea, the Crimea and other parts, is now reduced to a few galleys.

**Genoa, or Janua, frequently, though corruptly, called by the Latin writers Januata, is the capital of the country described in the preceding article. It is situated partly on a level finbad near the sea, and in part rises gradually to the top of the hill. It is about 10 miles in circumference, and is defended towards the land by a double wall. Several bastions are erected along the sea-shore, on rocks which appear above the water. The streets are in general narrow, but clean and well paved; two of which, called the "Strada Nuova" and "Strada Balbi," are filled with magnificent palaces, fronted with marble. It is the seat of an archbishop. The cathedral is built in the Gothic style, and paved with black and white marble; in the treasury is preserved a curious hexagonal dih, said to be made of a female emerald, found at Cariarca in the time of the Crusades, which the Genoese received as a token of their valour. Besides the cathedral, it contains 32 parish churches, some of which are magnificent, and adorned with sculptures and pictures by the best masters. The doge's palace is large, without decoration, except two statues of John Andrew Doria, and Andrew Doria, larger than life, at the entrance. The arsenal contains arms for 34,000 men, models for bridges, the armours worn by a number of the Genoese women in the crusades, a shield containing 120 pistols, made by Julius Caesar Vaches, for the purpose of affrighting the doge and senates at one time. Other public buildings are the Albergo, which serves as a poor-house, and house of correction, where is a beautiful relic, the Virgin supporting a dead Christ, by Michael Angelo, and the assumption of the Virgin, in white marble, by Puget, an inimitable piece of sculpture; a large hospital for the sick of all nations and religions; the conservatory, for educating and portioning 300 poor girls; and a great number of palaces belonging to the nobility; and the number of convents for men and women is reckoned to be 69. Such was the state of Genoa before the late revolution; what devastation it has suffered by its new masters, we are not able to say. It is certain, that the siege in 1799 was very destructive. The harbour is large and deep, but exposed to the south-west wind; but it has a mole for the security of galleys and small vessels; nevertheless the city is much exposed to a bombardment. The number of inhabitants is estimated at 80,000. N. lat. 44° 2' 56". E. long. 8° 57'.

**Genoa Bar, a reef of rocks, extending some miles from the north coast of the island of Bahama. N. lat. 26° 20'. W. long. 70° 36'.

**Genoa Balsam, in Medicine, the name of a famous composition, called also the balsam of Aquapendente. Its great virtues are the curing pains in the extremities of the body, and allaying the violent pains in the bowels, to which many women are subject after delivery. The prescription is given at large in Vellutius, but the medicine is now out of use.

**Genol. in Geography, a town of France, in the department of the Stura; three miles N. E. of Savigliano.

**Genolhac, a town of France, in the department of the...
the Gard, and chief place of a canton, in the district of Alais; 15 miles N.W. of Alais. The place contains 1,502, and the canton 9,5 9 inhabitants, on a territory of 195 kilo-
metres, in 13 communes.

GENOPLESIUM, in Botany, from gen., a genus, and pleion, a early akin, indicating its great affinity to Prospophy-
lum, another new orchidaceous genus of Mr. Brown's. The name is but too expressive of many genera recently established, infomuch that it is wonderful no writer has hit upon it before. Brown Prod. Nov. Holl. v. 1, 319. Chas. and order, Gynandra Monandria. Nat. Ord. Orchide. 

Gen. Ch. Cal. Perianth ringlet, helmet-like in front, its two lower or posterior leaves longer and spreading. Cor. Petals, (inner calyx-leaves of Mr. Brown,) attached below to the column. Nectary, or lip, ascending, undivided, hooded at the base, without a spur. Style; or column, cloven half way down, without any lateral incised or mem-
ments, in which last particular alone it differs from Prospophy-
lum. Anter parallel to the stigma, permanent, its cells close together. Males of pollen not observed. The only species is 

G. Baueri, seen by Mr. Brown growing near Port Jack-
son, New South Wales, but the above character was drawn up by him from Mr. Ferdinand Bauer's coloured figure.

GENOSA, in Geography, a town of Naples, in the pro-
vince of Otranto; 10 miles S.E. of Otranto.

GENOVESI, Anthony, in Biography, a man of letters, and
philosopher, was born of parents of very moderate cir-
cumstances, at Castiglione, a small town in the district of Salerno, in the year 1712. He was intended for the church, and received an education suitable to the purpose. An early attachment to the daughter of a neighbouring penant in-
duced his father to place him, at a distance from home, under the care of a lay ecclesiastic, who was an able classical scho-
lar, as well as deeply skilled in theology and jurisprudence. Here the young man made such progress in learning as astonished all about him. His resolution to marry the object of his love created in him a zeal and diligence that sur-
mounted all difficulties; before, however, he was in a situa-
tion to maintain a wife, he, at the instigation of his father, married. This disappointment made him resolve to devote himself to the church, and he was in due time consecrated a priest, and obtained the patronage of the archbishop of Canza. Unfortunately for Genovesi the prelate died, which made him repair to Naples, to follow the practice of the law, an employment highly lucrative in that city. He was soon dissatisfied with his pursuits, and after diligently stu-
dying the elements of modern and ancient philosophy, he obtained the office of extraordinary-professor of metaphysics. He began his lectures in November 1741, and his school was crowded with pupils; the boldness of his manner, and the novelty of many parts of his syllabus, excited his enemies, who accused him not only of impiety, but of opening the door of free-thinking in Italy: merely, it is said, because he recommended the works of Galileo, Grotius, and Newton. His friends, however, powerfully supported him, and by the influence of Gabai, the director of the Neapo-
litan universities, he was appointed to the office of pro-
fessor of ethics, which afforded him ample field for combating the ignorance and prejudices of the schools. The principle of his syllabus was, that the happiness of man is the only object of the philosophical doctrine of morals, and he deduced his duties from analytical considerations. He in-
tervened in his lectures the history of the human passions,

VOL. XVI.

and enlivened them by a boldness and spirit peculiarly his own. He compiled a new system of logic, which he dictated in his lectures, and which was afterwards published in 1745, under the title of "Elementorum Artis Logico-critici, Libri quinque." This might be considered as an introduction to his metaphysics, the first part of which had been published before this period, but the second and third parts made their appearance in the years 1747-1751. In 1748, he put up for the vacant chair of theology, but, as this was always connected with the episcopal dignity, he was imme-
diately regarded as unfit for so high an office in the church, on account of his heretical notions. His enemies now dis-
covered the most serious and alarming doctrines, in the pub-
lished and unpublished pieces of which he had been the author. He was obliged therefore to renounce the science of theology, and to suppress some valuable works on this subject. He now turned his attention to political economy, and in a few years he not only made himself master of every thing deserving of notice on this science, but struck out some new lights. He published, in 1753, the first fruits of his re-
searches, entitled "Essays on Agriculture, with Considera-
tions on the True Object of Sciences." He was now, at the influence of his friend Interni, made professor of political econ-
omy, with a considerable salary. The office had been intuited solely for him, and it was agreed that the lectures should always be delivered in the Italian language, a circumstance, at that time, wholly unknown at Naples. His lecture room was crowded, and in a short space of time he was obliged to take a still larger place for the display of his talents, which also was insufficient to contain all who came to be benefited by his instructions. His chief and avowed object was, while he taught the principles of political econ-
omy, to inspire the Neapolitan youth with the social and civil virtues, and above all with a public spirit of patriotism, without which no nation, he contended, could attain to that height of prosperity which it is susceptible. He caused to be translated Carey's History of the English Trade into
the Italian, and then published it with useful notes. After this he pointed out in a short treatise the causers of the decline and neglect of agriculture in the kingdom of Naples. In 1765 he published another work, in which he examined the question, "Why countries, the most fruitful by nature, are often exposed to the miseries of scarcity." He was author of many other works, but his master-piece was the "Italian System of Morality," of which the first part was published in the year 1767, under the title of "Dioecysis." His health now gave way, and he was unable to prosecute his studies, and, in 1768, he was obliged to discontinue his lec-
tures, and in the following year he expired, in the fifty-
fifth year of his age. He had attained, as a man of science, a very high reputation, and his moral character was in every respect worthy of a true philosopher. He professed a lofty abject love of truth, and a desire to extend its dominion, in which he was aware the happiness of his fellow-creatures was deeply concerned. He was," says his biographer, "an irreconcilable enemy to injustice and deception; his countenance displayed cheerfulness, tranquility, and invin-
cible courage. He was too proud to float to flattery in order to become rich, and was contented with a very mode-
rate income." He died poor, and would have been in disreputable circumstances in the latter years of his life, had not the sovereign supported him unreservedly. He was held in high estimation by pope Benedict XIV. and many of the cardinals; and by inspiring the breasts of his pupils an ardent love of their country, with a well regulated zeal for
its chief interests, he was the means of introducing them to offices of distinction, which they filled with honour to themselves, and high advantage to the chief interests of the state.

GENS D’ARMES. See GENDARMES. 

GENSERIC, in Biography, a famous king of the Vandals, succeeded his brother Genseric in his Spanish dominions in the year 428. He had already signalized his courage and skill in war, and was enured to toil and hardships of every kind. Soon after his succession he invaded Africa, at the head of 50,000 men, and made himself master of the greater part of the country on the sea-coast. The perfecution of the Donatists was an event highly favourable to the designs of Genseric. Seventeen years before he had landed in Africa, a public conference was held at Carthage by order of the magistrate, which ended in a most severe persecution. Under these circumstances, Genseric, himself a Christian, but an enemy of the orthodox faith, avowed himself the vindicator of the rights of the Donatists, who, in their turn, looked up to him as their deliverer, from whom they might reasonably expect the repeal of the odious and oppressive edicts of the Roman emperors. Genseric obtained the mostsignal victories over his enemies, but notwithstanding his success, he agreed to a treaty with the emperor Valentinian, whom he consented to leave in possession of the three Mauritania. He delivered to the Romans his own son Hunneric, as a hostage for the observance of his treaty; but they, trusting to his good faith, sent back the youth. Genseric abjured this indulgence by seizing upon the city of Carthage in 439, at a time when the empire was engaged in a war with the Goths. From Carthage he failed with a large fleet, and landed in Sicily. He ravaged almost the whole of that island, and made a vast booty, but was unable to effect the conquest of Palermo. The object of this prince was to render himself formidable by sea; and he succeeded so completely, that the eastern and western emperors, Theodofius and Valentinian, thought it necessary to join against him. They fitted out a powerful fleet, with a large army, defined for the recovery of Africa; but Genseric defeated them by proposals of accommodation, and the interruption of the Huns obliged Theodofius to recall his forces.

When Maximus ascended the western throne, he compelled Endo, the widow of Valentinian III., to marry him; and in a short time secretly applied for the dangerous aid of Genseric to free her from his tyranny. He, seizing the occasion, appeared at the mouth of the Tiber with a numerous fleet; and in the contest Maximus was slain, which afforded Genseric an opportunity of marching to the gates of Rome, where he was admitted almost without opposition. For fourteen days the city was abandoned to all the licentiousness of a barbarian soldiery; and on his return he carried away an immense quantity of treasure, besides multitudes of captives, chiefly of the female sex, among whom were the empress and her two daughters, one of whom he married to his son Hunneric; and after the lapse of several years, he restored the other and her mother to their native place. Genseric continued to annex to his dominion the remaining Roman provinces in Africa; and then sent a fleet, consisting of sixty galleys, into the Italian sea, which was destroyed. But the loss of his ships did not prevent him from renewing his ravages on the coast of Italy, till his power received a severe check from the emperor Majorian, who now began to act on the offensive, and formed the spirited resolution of attacking the Vandals, in Africa. He fitted out a formidable fleet for the purpose, which obliged Genseric to sue for peace. His suit being rejected, he sent out a squadron, which coming unawares upon the Roman navy, in the bay of Carthagena, almost destroyed it. Peace was now made between the two warriors, the terms of which were observed till the death of Majorian, in 461. After this, Genseric prepared to repent his aggressions, and he again ravaged the coasts of Italy and Sicily, and even took possession of Sardinia. He extended his dominions to all parts of the Mediterranean, and frequently indulged in acts of the most brutal atrocity. At one time he is reported to have massacred five hundred citizens of Zacynthus, and to have thrown their dead bodies into the sea. Leo, the eastern emperor, refused to make an effort to free his dominions from this terrible scourge, and made vast preparations for the invasion of Africa. The conduct of the expedition was given to Baiulicus, who might have extinguished for ever the kingdom of the Vandals, had he seized the moment of confusion, and boldly advanced to the capital. Genseric beheld the danger with firmness, and clutched it with his veteran dexterity. He professed himself ready to submit his person and dominions to the will of the emperor; but requested a truce of five days to regulate the terms of his submission. Baiulicus conformed to the fatal truce; and during the short interval, the wind became favourable to the designs of Genseric. He manned his largest ships of war with the bravest of the Vandals and Moors; and they towed after them many large barks filled with combustible materials. In the obscurity of the night these destructive vessels were impelled against the unguarded and unsuspecting fleet of the Romans, who were soon awakened to a sense of their imminent danger. "Their close and crowded order," says the historian, "affiliated the progress of the fire, which was communicated with rapid and irresistible violence; and the noise of the wind, the crackling of the flames, the din of the cries of the soldiers and mariners, who could neither command, nor obey, increased the horror of the nocturnal tumult." Baiulicus returned ingloriously to Constaninople with the remainder of his shattered fleet; and thus the fruits of all this mighty effort were lost. Genseric put to sea, recovered Sardinia, which had been taken from him, reduced Sicily and all the islands between Italy and Africa, and became a greater terror to the empire than ever. In 476, he made a peace with Odacer, king of Italy, to whom he restored Sicily, but on condition of receiving tribute. The emperor Zeno likewise relinquished to him and his successors all claims to the African provinces. Genseric died in the year 479. In his early youth he had renounced the orthodox communion; and as an apostate he could neither grant nor expect a sincere forgiveness. He was exasperated to find that the Africans, who had fled before him in the field, still pressed to dispute his will in synods and churches; and his fierce mind was incapable of fear, or compassion. His Catholic subjects he oppressed with intolerable laws, and arbitrary punishments. The language of Genseric was furious and formidable; the knowledge of his intentions might justify the most unfavourable interpretation of his actions; and
the Arians were reproached with the frequent executions which stained the palace, and the dominions of the tyrant, Gibbon. Univer. Hist.

GENTIAH, in Geography, a town of Asia, in the country of Affan; 370 miles E. of Patna. N. lat. 25° 10'. E. long. 92° 10'.

GENTIAN, in Gardening, the common name of a large hardy perennial herbaceous plant, which has a root that affords an extremely strong bitter. See Gentiana.

GENTIANA, in Botany, of the genus of the Greeks, named after Gentius, a king of Illyria, who is said to have discovered it, or at least to have first experienced its virtues as a cure for the plague, which infected his army. Gentian, or Bell-wort. The latter name, we presume, is derived from fel-gull, alluding to its extreme bitterness, and not from fell, the north-country appellation of a mountain. It therefore ought to be, as Gerarde writes it, Fel-wort.—Linn. Gen. 126. Schleg. 175. Willd. Sp. Pl. v. 1. 1331. Mart. Mill. Dict. v. 2. Sm. Fl. Brit. 284. Juss. 141. Lamarrk Illust. t. 109. Gerar. t. 114. Clas and order, Pentandra Dignesia. (Monogynia; Lamarrk.) Nat. Ord. Rotacae. Linn. Gentianae, Juss.

Gen. Ch. Col. Perianth inferior, in five deep, oblong, acute, permanent segments. Cor. of one petal, tubular in the lower part, without pores; in the upper five-leaf, regular, various in form and direction, withering. Stam. Filaments five, awl-shaped, shorter than the corolla, connected with its tube; anthers oblong, simple, sometimes united into a cylinder. Pfr. German superior, ovate or oblong, cylindrical, as long as the stamens; styles none; stigmas two, ovate, recurved. Peric. Capsule oblong, roundish, pointed, slightly cloven at the summit, of one cell and two concave indented valves. Seeds numerous, small, flattish. Receptacles two, affixed longitudinally to each valve.

Eff. Ch. Corolla tubular at the base, ditrifoliate of ne克拉iferous pores. Capsule superior, of one cell and two valves, with many seeds.

Obs. The figure of the fruit is constant, but the corolla is very different in different species, being either wheel-shaped, bell-shaped, or funnel-shaped. In some there are small intermediate segments, in others a fringe to the corolla; in some it is plaited, in others plain. A few species have a four-leaf tetrandrous flower; but the remark in Linn. Gen. 176, that there is a species with three additional parts of the flower, alludes to Chelone, once reckoned a Gentiana. Linnaeus has erased the line from his own copy, and his editors might easily have made the same correction. G. lutea, and some others, however, have frequently a superabundance of divisions and stamens in a few of their blossoms. The upper part of the germen so much resembles a style, that Lamarrck has perhaps offered no great violence to nature, or the Linnean system, in considering it such.

This very noble and beautiful genus of herbaceous plants is chiefly of alpine origin, where the lovely blue flowers of many species enamel the turf in a most splendid manner. Most are perennial, some few annual. All are intensely bitter in flavor, especially the roots of the larger perennial kinds, G. lutea, Woodv. Med. Bot. t. 156, which is the official Gentian; purpurea, Fl. Dan. t. 50, which is the Curcula of the Edinburgh Pharmacopoeia; pannonica, Jacq. Annl. t. 175; pulvinea, ibid. app. t. 28; and campanulata, t. 29. These are scarcely ever seen in gardens, except the first, which is not easily established; but few plants are more rately and ornamental. The North American G. foetida, Curt. Mag. t. 1039; and the alpine aperlae, Curt. Mag. t. 1078, are both very handsome, and we have found the latter thrive for many years in a bed of peat, earth and loam, as well as on its native mountains. See Curt. Mag.—G. alpina, Curt. Mag. t. 52. Eng. Bot. t. 1594, is one of the most common in gardens, but requires rather a pure soil. G. verne, nearly allied to it in habit and beauty, see Eng. Bot. t. 493, though wild in the mountainous parts of Durham, and abundant on the Swiss and Italian Alps, will scarcely live in a garden at all. G. Punctum, ibid. t. 20, found on very heaths in many places, is likewise very handsome, and rather impatient of culture. We have never seen the culture of the annual kinds attempted; such are nivea, Eng. Bot. t. 896; Amarrella, t. 256; and campyliora, t. 237.

Linnaeus was by no means well acquainted with the different species of this genus, having never visited the more southern Alps of Europe, where alone they are to be rheed to advantage. Hence his verne and barbara are one species, and he confounded with lutea, which he seems never to have seen, or at least to have afterwards forgotten, the G. floribus, Lamb. diephalas, G. alpina, Pall. and Rott. t. 97. Hence the erroneous remark under lutea, "petal punctis spatios creberrimis flaga." There is some doubt whether G. futila, Sims in Curt. Mag. t. 1239, be the same as Pallis's t. 92, f. 2. In the former the flower appears to us very rarely, if ever, with more than five divisions, nor do the habits of the two figures accord. Willdenow has fifty-six species of Gentiana, some of which among the annual kinds we are not able to determine to our satisfaction. He quotes a monograph by Frolich, which appears to have great merit, but which has not come to our hands.—Six species only of this genus are wild in Britain, the Chelone and Chelonia being now, with the greatest possible propriety, separated from it.

GENTIANA, in Gardening, comprises plants of the hardy, herbaceous, perennial, flowery kind; of which the species cultivated are the yellow gentian (G. lutea); spotted flowered gentian (G. pulvinea); swallow-wort-leaved gentian (G. aperlai); and the dwarf gentian, or gentianella.

Method of Culture.—In the three first kinds it is easily effected by sowing the seeds in pots soon after it is ripe, as when kept till spring it will not succeed; the pots should be placed in a shady situation, and kept clean from weeds. Some advise their being sown where they are to remain, but the first is probably the best method. In the spring the plants appear, when they must be duly watered in dry weather, and kept clean from weeds till the following autumn; then be carefully shaken out of the pots, so as not to break or injure their roots; and a flaky border of loamy earth should be well dug and prepared to receive them, into which they should be put at about six inches distance each way, the tops of the roots being kept a little below the surface of the ground, and the earth pressed close to the roots. If the following spring prove dry, they should be duly watered to forward their growth. The plants may remain here two years, by which time they will be fit to transplant where they are destined to grow, removing them in the autumn as soon as their leaves decay; great care being taken in digging them up not to cut or break their roots, as that greatly weakeneth them. They require afterwards no other culture but to dig the ground about them early in the spring before they begin to shoot, and in the summer to keep them clean from weeds. The roots continue many years, but the flasks decay every autumn;
the same roots not flowering two years together, or seldom oftener than every third. When they flower strong, they have, however, a fine appearance among other similar plants.

In respect to the last fort it is mostly propagated by offsets or parting the roots, and planting them where they are to remain in the early autumn; but in order to have the plants flower well, they should not be often transplanted or parted. And they are also capable of being raised from seeds managed in the same way as in the first kinds.

All these plants succeed the most perfectly in moist loamy soils, where there is a degree of shade afforded.

They are useful as ornamental plants, for the clumps, borders, and quarters of pleasure-grounds; those of low growth being planted towards the fronts, and the latter kinds more backward in them.

**Gentiana**, *Gentian*, in the *Materia Medica*. The root, which is the only medicinal part of the plant, has little or no smell, but to the taste it manifests great bitterness; a quantity which is extracted by aqueous, spirituous, and vinous menstrua, though not in so great a degree by water as by spirit; and the extract of this root, prepared from the watery infusion, is less bitter than that made from the spirituous tincture. Gentian is the principal bitter now employed by physicians; and as the intense bitters are generally admitted to be not only tonic and floridich, but also anthelmintic, antifeptic, emmenagogue, antirheumatic, and febrifuge, this root has a better claim to the poffeifion of these powers than most of this kind. Many dyspeptic complaints, though arising from debility of the stomach, are more effectually relieved by bitters than by Peruvian bark; and hence may be inferred their superior tonic power on the organs of digestion; but we are told by Dr. Cullen (Mat. Med. vol. ii.) that the gentian, joined with equal parts of tormentil or galls, coniunctly succeeded in curing intermittent, if given in sufficient quantity. As a simple bitter the gentian is rendered more grateful to the stomach by the addition of an aromatic; and for this purpose orange-peel is commonly employed. The official preparations of this root are, the "Infusum gentianae compositum," and "Tinctura gentiana composita," (Ph. Lond.) and the "Infusum amarum," "Vinum amarum," "Tinctura amara," five "Elisir Floridichum" (Ph. Ed.) which latter is said by Dr. Cullen to be the same as Stoughton's elixir, (see Stomatic Elixir) and by both Pharmacopoeias the extract is directed. The "compound infusion" is prepared by taking gentian root sliced and orange-peel dried of each a dram of fresh lemon-peel two drams, and boiling water twelve ounces; and macerating for an hour in a covered vessel, and then draining the liquor. For the "tincture," take of gentian root dried, two ounces, orange-peel dried, an ounce, cardamon seeds bruised, half an ounce, and proof spirit two pints; macerate for fourteen days, and strain. For the "extract," take of gentian root sliced, a pound, and boiling water, a gallon; macerate for twenty-four hours, then boil down to four pints; strain the hot liquor, and evaporate it to a proper consistence. The extracts are made into pills, with or without aromatic additions. Wines and malt liquors are likewise impregnated with the virtues of this root in different proportions. An ounce of the gentian root, the same quantity of fresh lemon-peel, and two drams of long pepper, communicate by maceration, without heat, a grateful warmth and bitters Jews a quart of mountain. There is an Indian gentian brought from America by the Portuguese, of a pale yellowish colour, jointed and marked with knots and circles like ipecacuanha, more intensely bitter than any of the official bitter drugs. This root is greatly commended in obilinate intermitents, and other disorders; a scruple is said to be more effectual than repeated half drams of bark.

There was a mixture of hemlock root brought over some years ago with the common gentian, which occasioned violent disorders, and in some instances proved fatal.

This root is of a paler colour than gentian, and its longitudinal wrinkles finer and closer; the poisonous root, when cut, appears white, without any degree of the yellow hue, which is deep in gentian; and its taste is not bitter, but mucilaginous. Phil. Tranf. vol. xlv. p. 240. Lewis's Mat. Med. Woodville's Mat. Med.

**Gentian Water.** See Water.

**Gentiana**, the forty-sixth natural order of plants in Jullieu's Syllun, or the thirteen his of his eighth class, so named from the principal genus contained in it. The character of this eighth class is *Coryleus* two. Flowers of one petal, inserted below the germs, regular or irregular. *Calyx* of one leaf. *Stamen* of a definite number, inserted into the corolla, and usually alternate with its divisions, when they agree in number. *Germ* superior, simple; *Hylo* one, (sometimes none in the Apocineus, with a double germ) *Stigma* simple or divided. *Fruit* superior, comifing either of naked seeds, or for the most part enclosed, either in a pulpy or a capsular feed-veil, of one or many cells.

The characters of the Gentiana are these. *Calyx* divided, permanent. *Corolla* regular, often withering before it falls, with a limb equally divided, whose segments agree in number with those of the calyx and are most commonly five, sometimes oblique. *Stamens* as many, inserted into the middle or upper part of the corolla; anthers incumbent. *Style* one, or rarely, by splitting, double; * stigma* simple or lobed. *Capsules* simple or of two parts, of two valves, and one or two cells, the valves inclosed at the margin, involute where there is but one cell, flat and constituting the partition where there are two. *Seeds* numerous, small, inclosed into a marginal receptacle connected with the valves. *Stem* herbageous, rarely somewhat thorny. *Leaves* opposite, mostly undivided and fesible; floral ones occasionally smaller, referring broader, the flowers in pleasant clusters, as it becomes, as it were, doubly bracteated,--The first flower has a simple capsule, of one cell, and contains Gentiana, Lutea of Schreber (Pothia of Aublet), Piarum of Schreber (Coryleus of Aublet), *Seweria* and *Chloria*; the second, with a simple capsule of two cells, contains *Exacum*, *Lijantis*, *Myriaceae* of Schreber (Tachia of Aublet), *Chloris* and *Nigra*; the third with a didymous or two-leaved capsule of two cells, contains only *Spigelia* and *Opobrazia.* In a fourth fiction it seems as a kind to this order, by itself, *Nicandra* of Schreber (Petalia of Aublet.) The plants of this natural order are chiefly remarkable for their intense bitters, and consequent floridich virtues. Their flowers are usually beautiful, either blue, yellow or red, scarcely white, except by occasional variation of the blue or red.

**Gentianella**, in Gardening, the common name of the dwarf gentian, and which properly signifies the little *gentian*, which has a broad leaf and large flower. See Gentiana.

**Gentile, Gentilis**, a pagan, or person who adores false gods. The Hebrews apply the name Gentile, nation, to all the people of the earth who were not Hebrews or Egyptians. Some will have it that the gentiles were thus called in contradiction to the Jews, because the latter had a positive law
GENTILE.

law to observe in matters of religion, whereas the gentiles had only the natural law: hence they are called "gentiles, quia sunt uti gentii fuerunt," because they remain as in a state of nature.

The Jews apply the denomination gentiles much as the Christians do that of infidels. St. Paul is called the doctor, or apostle of the gentiles, which appellation he first gave himself, Rom. xi. 13. "As I am the apostle of the gentiles, I magnify mine office."

The culting of the gentiles to Christianity had been predicted in the Old Testament, as it was accomplished in the New. See Psal. ii. 8. Isa. ii. 3. Jer. ii. 29. Matt. viii. 11. xii. 18. Acts xi. 18. xlii. 37. 48. xxviii. 28. Rom. i. 5. iii. 29. xi. 12, 13. 25. Eph. ii. 11. Rev. xi. 2. xxxii. 2.

Some account may not be improperly given in this place of the state of Christianity both before and after the time of Constantine's conversion. The opposition of the Jews to its reception and prevalence appears in the Acts of Apollos, and the epistles of the New Testament. Our present object is to consider, first, the state of its progress in gentile countries, and under heathen emperors, from about the middle of the first century, when it began to be preached among the gentiles, and to make some progress among them, to the period when Constantine embraced the Christian religion; and, secondly, its state under the Christian emperors, and their treatment by the gentiles. In the former period, we find from St. Luke's account in the Acts of the Apollos (ch. xiv. 19. 20. ch. xvi. 19-24.) that St. Paul met with some difficulties in preaching the gospel in gentile cities; but no imperial edicts were issued against the Christians, before that of Nero in the year of Christ 64 or 65, at which time the two apostles, Peter and Paul, were put to death. For an account of the ten persecutions, as they have been usually reckoned, which the Christians suffered under heathen emperors, we refer to the article Persecution. These persecutions were ordered by edicts of emperors, beginning with Nero's and ending with Diocletian's. During the whole of this period Christianity had been in a state of persecution. At the commencement of the second period, in 313, Constantine and Licinius issued a law or edict, giving liberty to all men, Christians and others, to follow that way of worship which should be most agreeable to them. However, it appears that Constantine did not strictly observe his own edict; for, according to the utmost of his power, by various methods, by laws, institutions, rewards and encouragements, he endeavoured to root out the ancient religion, and to promote the Christian doctrine. Conceiving that neither he nor the Roman empire could be safe, as long as the ancient superstition fulfilled, he openly opposed the gods of the gentiles, and their worship, as dangerous to the public welfare. After the death of Constantine in the year 337, the whole empire was divided between his sons. Conflans, with whom his brother Constantius concurred, passed a law 341, ordering superstitious and sacrificial exercises to be abridged; and the practice of sacrificing to be abolished; under the menace of a proper and convenient punishment. This law was followed by another law of Conflans in the next year, 342, forbidding the demolition of temples, which stood without the walls of the city of Rome. Another law, which was the first of Conflantius, and passed, as it has been supposed, in the year 353, ordained that in all places, and in all cities, temples should be immediately shut up, and that the people should abstain from sacrifices, under the penalty of death and the confiscation of their estates to the treasury. The second law of Conflantius, in the same year, prohibited nocturnal sacrifices; and a law, published by the same emperor in the year 356, appointed capital punishment to such as were convicted of per-
or not. In which sense the word occurs in Ammianus, Au-
tonius, and the Notitia Imperii.

Gentilis was also used, in a more peculiar sense, for all
strangers, or foreigners, not subject to the Roman empire;
as we see in the Theodisi Code, in the title "De Nuptis
Gentilium;" where the word gentilis stands opposed to pro-
vinciales, or the inhabitants of the provinces of the em-
pire.
The word is likewise used, in this sense, in the Greek; but
it was not introduced either into that, or the Latin
tongue, till after Christianity was established; it being taken
from scripture. See Esquire and Gentleman.

Gentilesci, Orazio, in Biography, a painter, born
at Pisa in 1563. His parental name was Lomi, but he chose
to adopt that of his maternal uncle. He first learnt the art
under his half-brother Aurelio Lomi, but afterwards studied
at Rome. After diffilling himself at Florence, Turin, and
Genoa, he passed to Savoy and France, and thence was
invited into England by Charles 1. who gave him lodgings,
and a considerable salary; and employed him in painting
ceilings, &c. at Greenwich. He was also employed by Villiers,
duke of Buckingham, at York House, on a picture of him-
self and his family. After residing here about twelve years,
he died at the age of 84, in 1647. The charms and brilli-
ance of the stile in which he painted may be seen to the
greatest perfection in a picture at Hampton Court of Joseph
and Potiphar's wife. He made King Charles a present of
a large book of drawings, and was deservedly respected and
admired for his abilities.

Gentilesci, Artemisia, daughter of Orazio, and
his pupil, who obtained almost as much skill and credit as
her father. She followed him to England, where she prac-
ticed in portraits with great success. She also exercised her
talents in historical painting, and has left many highly credit-
able works behind her.

Her picture of Judith with the head of Holophernes at St.
James's palace, is in the same style of design as her father's,
but though very skilful, is not so bright, or so finely wrought
as his pictures usually are. After the death of Orazio, she
retired to Naples, where Graham says she became as famous
for her amours as for her skill in painting. She died in
1642.

Gentili, Alberico, was born in 1550, at Caf-
tel S. Genesio, in the marches of Ancona. He studied
the law, and took his degrees at the university of Pe-
rugia, and was proctor at Ascoli, when his father, becom-
ing a convert to the reformed religion, determined to quit
Italy, and take with him his sons Alberico and Scipio.
The former, the subject of this article, came to England,
and in 1582 was chosen professor of jurisprudence in the
university of Oxford, which he held with much reputation
till his death in 1608. He was a man of great learning, and
published various works. One, entitled "Six Dialogues on
the Interpreters of Law," he dedicated to his patron the
card of Leicester. He is author of three books "De Jure
belli," which are highly applauded by Grotius; of three
others "De Legationibus," and several tracts relative to
antiquities. His "Lectiones Virgilianae" prove that he
had cultivated polite literature very successfully. Bayle.

Gentili, Scipio, brother of the preceding, was born
in 1563, and, while a child, was sent to Tubingen for his
education. Here he distinguished himself in the study of
the classics and jurisprudence, which he afterwards pursued
with increasing success at the universities of Wittenberg
and Leyden. In 1589 he took his degree of doctor at Basli,
and then went to Wittenberg as a public expounder of the
law. Shortly after he removed to Altdorf, and became prin-
cipal professor of law. His fame extended very far, and he
received invitations to settle at several universities, and one
from pope Clement VIII. to settle at Bologna, which he declined.
He died at Altdorf in 1616, leaving behind him many works
as monuments of his deep erudition. These were afterwards
collected and printed in 8 vols. 4to.; they are chiefly
on subjects connected with jurisprudence. As a teacher, his
manner was clear and interesting. He was a good Latin
poet, and translated several of the Psalms, and the first
cantos of Tasso's Jerusalem. Bayle.

Gentilis, Gentilis, was born at Foligno, in Italy,
about the year 1320. He studied medicine under the tu-
tion of Thaddeus of Florence, with great diligence and re-
putation, so that on his return to his native place he was
regarded by his fellow-citizens as the first physician of the
time; and his fame soon extended through Italy. He was
also esteemed one of the best commentators upon Avicenna,
whose writings were then held in high estimation in most of
the universities of Europe. Gentilis died at Bologna about
the year 1310, and left several treatises, which were col-
lected and published at Venice, in four volumes folio, in 1484,
1486, and 1492. The following works were likewise print-
ed separately: 1. "Expositions in textu Avicennae."—
Commento Aegidi Monachi Benedictini Libri de Judiciis
Urinarum, et Libri de Pullibus." Ibid. 1494.—4. "Con-
hiis peregrinatis ad quos seriorum totus corporis genera,
with some other tracts, Venice, 1563.—5. "Questiones et
Tractatus." Ibid. 1536, with the surgery of Dius de Gar-
bo.—7. "De proportionibus Medicinarum," with many
differencies upon the subject of doses of medicines by the
most celebrated physicians, Pedua 1556, &c. See Eloy.
Ditf. Hist.—Several other individuals of the family of
Gentilis were distinguished for their knowledge of medicine and
the sciences.

Gentilis, John-Valentine, was born at Cofenza in
Calabria. Educated in the principles of the Roman Catho-
ic religion, and becoming a convert to the principles of the
Reformation, he was obliged to quit his native country, and
take refuge in Geneva, where several Italian families had
already formed a congregation. His enquiries did not stop
by the open renunciation of papal errors; he became dissatisfied
with the orthodox doctrine of the Trinity. He was required
to subscribe to the articles of faith which the persecteur John
Calvin had established against hereby, to which a promise was
annexed, never to do anything, directly or indirectly, that
should controvert the doctrine of the Trinity. At first Gent-
ilis refused the task, but was afterwards prevailed on to com-
y, dreading probably, in case of his refusal, a similar
treatment to that to which Servetus had experienced. What
his hand had signed, and his tongue confirmed, his heart ab-
horred; and in private he did for ever resolve, by the truth,
which coming to the ears of the magistrates, they commit-
ted him to prision. From the dungeon he endeavoured to
expostulate with his persecutor, dehowning the insufficientness
of his opinions, but their hearts were steeled against the sup-
lications of a heretic, till he offered to abjure his errors,
and committed to the ears of the law, and take an oath not
to quit Geneva without leave of the magistrates. Being thus,
in a measure, freed from suspicion, and feeling conscious that
he would be justified in breaking an oath which had been ex-
torted by terror, he withdrew from the city, and finding no
place of safety he returned, was again imprisoned, but in a
short time liberated. From this period he seems to have
wandered from place to place, and we find him at Lyons, in
various parts of Poland and Germany, in Savoy, and at
at Bern, where he was accused of heresy. He underwent a long and tedious trial, and being convicted of obstinately upholding the mystery of the Trinity, he was sentenced to lose his head. This sentence was carried into execution, but death, which, at a greater distance, seemed too formidable to him, was now disarmed of its terrors, and by a manly fortitude he was enabled to triumph over his enemies, who expected that his mind was ill-adapted to so trying a scene; his last moments were probably the happiest of his life. He died exulting that he was thought worthy of suffering for the cause of truth, and that he was admitted to seal, with his blood, the doctrine of the supremacy and unvailed glory of the Father.

GENTILLET, SACRA, among the Romans. See SACRA.

GENTILITIUS, an epiphel used by some authors to express diseases propagated from father to son, and running through whole families; such as are more usually called hereditary disorders. Such are the gout very frequent, and often many others.

GENTILLET, VALENTINE, in Biography, a native of Dauphine, who flourished in the sixteenth century. He had in early life studied jurisprudence, and was a civilian by profession. He: was an advocate in the parliament of Toulouse, and afterwards a scribe of the republic of Geneva, and at one period of his life he was president of the parliament of Grenoble. He became distinguished by his writings against popery, but by the edicts published in France against those of the reformed religion, he was driven into exile. His principal works are, "An Apology for the Proteslants," which went through several editions in the French, and was afterwards translated into Latin and enlarged, under the title of "Apologia pro Christianis Gallia Religionis. Evangelici fac Reformata, qua doctor hujus Religionis fundamenta in Sacra Scriptura jacta eft," and "Le Bureau du Concile de Trente, &c." This was published in French in 1580, and in the same year a Latin translation of it was published, which was frequently reprinted at different places. Its design is to show that many of the decrees of that council were contrary to the ancient councils and canons. He was author also of "Anti-Michiel," and the "Anti-foe," Bayle.

GENTINANETOUR, in Geography, a town of Hindoos, in the Carnatic, 39 miles W. of Cuddalore.

GENTIQUX ET PALLIER, a town of France, in the department of the Creuse, and chief place of a canton in the district of Aubusson; 9 miles S.W. of Pellellet. The place contains 907, and the canton 6,507 inhabitants, on a territory of 327,584,000 square feet.

GENTLE PIR ONE, in Mineralogy, a name given by our miners in Saffex, to a kind of iron ore found in considerable plenty in that county, and very readily running in the fire, though not over rich in metal. It is a strong substance, and lies in several parts of that county in form of a moderately thick stratum. It is of a dusky brown colour, and in some places much paler than in others. It has always a great number of sparkling splinters in it, and very often contains foible flats, and other extraneous substances in it.

GENTLEMAN, a person of good family, or descended of a family which has long borne arms, the grant of which adds gentility to a man's family.

The word is formed of the French gentilhommes, or rather of gentil, fine, fashionable, or becoming; and the Saxon man, q. d. hombys, or hompe lice natur. The same signification has the Italian gentilhommi, and the Spanish bidejos, or byedож, that is, the son of somebody, or of a person of note. If we go farther back, we shall find gentlemen originally derived from the Latin gentilis homo, which was used among the Romans for a race of noble persons, of the same name, born of free or ingenious parents, and whose ancestors had never been slaves, or put to death by law. Thus Cicero, in his Topices, "gentiles sunt, qui iner se eundem funt nomine ab ingenius oriundos, quorum majorum nemo fivitum verius serviti, qui captivus sunt diminiqt, &c." Some hold that it was formed from "gentil, i. e. pagan; and that the ancient Franks, who conquered Gaul, which was then converted to Christianity, were called gentiles by the natives, as being yet heathians. Others relate that towards the declension of the Roman empire, as recorded by Ammianus Marcellinus, there were two companies of brave soldiers; the one called gentilis, and the other factionarius; and that it was hence we derived the names gentleman and esquire. This sentiment is confirmed by Pauly, who supposes the appellation gentilis and cossiers to have been transmitted to us from the Roman foldiery; it being to the gentiles and factionarii, who were the bravest of the foldiery, that the principal benefices and portions of lands were alligned. (See BENEMER.) The Gauls observing, that during the empire of the Romans, the factionarii and gentiles had the best tenements, or appointments of all the foldiery on the frontiers of the provinces, became infensibly accustomed to apply the same names, gentilhommes, and cossiers, to such as they found their kings gave the best provisions or appointments to. Pafy, Recol. bib. ii. cap. 15.

In fictitious, Chamberlayne observes, a gentleman is one whose ancestors have been freemen, and have owed obedience to none but their prince; on which footing, no man can be a gentleman who is not born free.

Among us, the term gentleman is applicable to all above yeomen; so that noblemen may be properly called gentlemen.

In our statutes, gentilis homo was adjudged a good addition for a gentleman, 27 Edw. III. The addition of knight is very ancient; but that of esquire, or gentleman, was rare before 1 Hen. V.

We read that J. King斯顿 was made a gentleman by King Richard II.

As it may justly be asked what constitutes a gentleman with us? the reply is easy; being a gentleman, is being entitled to bear arms. And Mr. Camden observes, that the distinction of a gentleman of coat-armour, or an upstart, and a gentleman of blood, is the bearing of arms from the grandfather; and that he who bears arms from his grandfather is to all intents and purposes a gentleman of blood, for which cause it is requisite by the statutes of the Bath that every knight, before his admission, proves himself to be so qualified, which done, it carries with it, if its merit be equal, a passport also to the order of the Garter. Notitia Anglicana, p. 24. See Mr. Dodridge's Honour's Pedigree, p. 147.

Smith, De Reptil. Angl. & Forticell, vol. 82.

Guillim, in his chapter of gentlemen, says, that they have their beginning either of blood, as being born of worthy parents; or that they have done something, either in peace or war, whereby they deserve to bear arms, and be accounted gentlemen. He farther says, chap. xxiv. if a gentleman be bound apprentice to a merchant or other trader, he hath not thereby lost his gentility; and he doeth it may he remembered, for the honour of trade, that King Henry VIII. thought it no dishonour to him, when he quitted his queen, to take to his wife Anne, the daughter of Thomas Bollen, some time mayor of London. To which may be added the thought, that the first William, who founded our royal race, was the grandson of a tanner.

Sir Edward Coke says, that esquires and gentlemen are only.
Gentlemen. See Bed-Chamber.

Gentlemen of the Chapel, are officers whose duty and attendance are in the royal chapel, being in number thirty; ten whereof are priests, and the other twenty called clerks of the chapel, who assist in the performance of Divine service. One of the first ten is chosen for confessor of the household, whose office it is to read prayers every morning to the household servants; to visit the sick, examine and prepare communicants, and administer the sacrament.

Another, well versed in music, is chosen first organist; who is master of the children, to instruct them in music, and what is necessary for the service of the chapel; a second is likewise an organist; a third a lutenist; and a fourth a violist.

There are likewise three vergers, so called from the silver rods they usually carry in their hands; being a verger, yeoman, and groom of the velvet; the first attends the dean and fal-dean; finds surplices and other necessaries for the chapel; the second has the whole care of the chapel; keeps the pew, and seats the nobility and gentrey; the groom has his attendance within the chapel-door, and looks after it.

Gentlemen Pensioners. See Pensioners.

Gentle, in Geography, a town of Germany, in the duchy of Magdeburg; 30 miles N.E. of Magdeburg.

Gentlewoman, Generous, is a good addition for the estate and degree of a woman, as generosus is for that of a man; and a gentlewoman be named spinster in any original writ, appeal, &c. it hath been held that the may abide, and quash the same. (2 Inst. 666.) But it seems that spinster is in general a good addition for an unmarried woman, as single woman is for one who, being unmarried, hath had a bastard.

Gentoo, in Modern History, according to the common acceptation of the term, denote the professors of the religion of the Brahmans (see Brahmans), who inhabit the country called Hindoostan, in the East Indies, from the word jtan, a region, and hind or hindu; which Ferdhach, as we learn from colonel Dow's translation of his History, appoises to have been a son of Ham, the son of Noah. It is observed, however, that Hindoo is not the name by which the inhabitants originally styled themselves, but according to the idiom of the Shanckit, which they use, jnaddey, from jnana, a jucull; an animal common in their country, and deep, a large portion of land surrounded by the sea, or territabant, from khan, i. e. a continent, and tharrus, the name of one of the first Indian rajahs. It is also observed, that they have assumed the name of Hindoos only since the era of the Tartar government, to distinguish themselves from their conquerors, the Maffulmen. The term Gentoo, or Gent, in the Shanckit dialect, denotes animal in general, and in its more confined sense mankind, and is never approbated particularly to such as follow the doctrines of Brahma. There are divided into four great tribes, each of which has its own separate appellation; but they have no common or collective term that comprehends the whole nation under the idea affixed by the Europeans to the word Gentoo. Mr. Halhead, in the preface to his translation of the "Code of Gentoo Laws," conjectures that the Portuguese on their first arrival in India, hearing the word frequently in the mouths of the natives, as applied to mankind in general, might adopt it for the domestic appellation of the Indians themselves, or, perhaps, their bigotry might force from the word Gentoo a fanciful allusion to gentle or pagan. The Hindoos, or Gentoos, vie with the Chinese as to the antiquity of their nation. They reckon the duration of the world by four ages, or distinct ages; the first is the Suttee juge, or age of purity, which is said to have lasted about 3,200,000 years, during which the life of man was 100,000 years, and its stature twenty-one cubits; the second, the Tirtha juge, or the age in which one-third of mankind were reprobrates, which consisted of 2,400,000 years, when men lived to the age of 15,000 years; the third, the Dwaapar juge, in which half the human race became depraved, which endured to 600,000 years, when men's lives were reduced to 1,000 years; and fourthly, the Collee juge, in which all mankind were corrupted, or rather diminished, which the word colle imports. This is the present era, which they suppose will sublill for 400,000 years, of which near 5,000 are already past, and man's life in this period is limited to 100 years. It is suppos'd by many authors, that most of the Gentoo jugeurs or scriptures, were composed about the beginning of the Jollat juge, or col juge, of which, according to Mr. Dow, the year of Christ 799 was the 428th; but an objection occurs against this supposition, viz., that the slaters take no notice of the deluge; to which the Bramins reply, that all their scriptures were written before the time of Noah, and the deluge never extended to Hindoostan. Nevertheless it appears from the slaters themselves, that they claim a much higher antiquity than this; insinuates of which are recited by Mr. Halhead.

After all, it must be allowed, that perons of fagacity and good judgment have made it appear with sufficient evidence, that the oldest accounts of the Hindoo nation do not, in reality, go further back than to the deluge mentioned in the books of Moses, and that their religious institutions were consequently posterior to that event. Sir William Jones says, (Dissertation relating to Asia, vol. i. p. 199.) that the first corruption of the purest and oldest religion, which confitit in the worship of one God, the maker and governor of all things, was the fystem of the Indian theology, invented by the Brahmans, and prevailing in those territories, where the books of Mahabah, or Men, is at this time the standard of all religious and moral duties. In his preface to the "Institution of Men," (see Men) he says, they are suppos'd by the Brahmans to have been promulgated by Menn, the son or grandson of Brahma, or the first of created beings. This work he suppos'd to have been written about 350 years after the Vedas, or about 1280 years B. C. Sir W. Jones is of opinion, that the origin of the Hindoo nation and government is to be looked for in Iran, or Peria, where a great monarchy was established before the Aryan, called by the oriental historians the "Pihadadian dynasty;" and they say, that
that the first of these ancient monarchs, whom they call Mithab, or Merm, received from the creator a sacred book, in a heavenly language, meaning the "Vedas." (Diff. relating to Asia, vol. ii. p. 111.) This first monarch, they say, divided the people into four orders, the religious, the military, the commercial, and the servile. (Diff. &c. vol. i. p. 197.) In the reign of Huthang, the third of the Pindadian races, a reformation, he says, was made in the religious systems, when the complex polytheism of the preceding times was rejected, and religion was reduced to what is called "Satavani," which consisted chiefly in the worship of the sun, moon, and stars; but it is probable, that ancient, being a more simple form of religion than that of the Hindoos, must have preceded it. The laws of Mahabab, however, were retained, and his imperative veneration for fire. Upon this change, the followers of the old religion retired to Hinduastan, and their old religious laws forbid them ever to return, or to leave the country they now inhabit.

Another reformation, or change, in the system, was made, he says, under Gultiap, in the next, or "Kainate dynasty," thought to have been the same with Darius Hydaspis. This was effectuated by Zerathush, or Zoroaster; he introduced genius, or angels, propelling over months and days, new ceremonies in the veneration of fire, and gave out a new work, which he laid from heaven, but at the same time established the adoration of the Supreme Being. This work was laid at the conquest of Persia by the Mahometans; but the priests of that religion have composed another from what they were able to recollect of their institution. It is called "Zendavadha," which ele. The followers of Zerathush, now called "Gebre," or "Parsi," perverted the religion immediately preceding; and these also took refuge in India, where they wrote a number of books, which are now very scarce. They reform, according to the account of Sir William Jones, the Hindoo sects of "Sauras," and "Sagunna," of which the last is very numerous at Benares.

Another innovator in the religion of the East, before the Christian era, was "Buddha," (see Doonit), generally supposed to have been the same with the Po (see Po) of the Chinese, the "Somomocodori" of Sham, the "Xaca" of Japan, and the "Odi" of the north of Europe. According to Sir W. Jones, he disapproved of the Vedas, because they enjoined the sacrifice of cattle; and made his appearance in the year 528 B.C. His disciples were thought to have been the same with the "Somonhav," who were opposed to the Brahmanes of the Greek historians. But these Somonhav were, it is probable, of much greater antiquity, as was also Somomocodori. The followers of Buddha gave great umbrage to the Brahmas, who never ceased to persecute them till they had effected their extinction from Hindoostan by fire and sword, about 400 years ago. There is, however, a great resemblance between the system of the Hindoos and that of Buddha; and perhaps with a view to conciliate these people, the Brahmas of Cais made Buddha the 9th avatar or transformation of Vishwok. This religion is that which prevails in India beyond the Ganges; it was received in China A. D. 65, and is established in Japan. A religion, very similar to this, is also that of the Lamas of Thibet. Indeed, all deviations from the original Hindoo system, retained the same general principles. The advocates of these all held the doctrine of the present-existence of souls, their futurity, and re-action independently of bodies, and their transmission into other bodies after death. They had the same low opinion of matter, and the same veneration for the elements of fire and water, as purifiers of the soul. They had similar restrictions with respect to food, the same abjurations, and the same idea of the use of corporeal substances for the exaltation of soul.

There can be no doubt of the very high antiquity of the religion of the Hindoos, and it is not improbable that the commencement of all those systems which deviated from the religion of the patriarchs, preferred in the writings of Moses, was prior to the general dispersion of mankind. A system so ancient as that of the Hindoos must have been formed about the same time with that of the Egyptians, from which that of the Greeks, and other western nations, was in some measure derived; and accordingly many points of resemblance have been observed between them; too many, and too striking to have been altogether fortuitous. Even some of the inhabitants of Ethiopia appear to have been of the same origin with those of Hindoostan (see Diff. relating to Asia, vol. i. p. 112); and both the Egyptians and Ethiopians seem to have had some connection or intercourse with the Hindoos; but of what kind it was, or when it subsisted, we have no certain account; and they have been so long separated, that at present they are in total ignorance of each other. According to Eusebius and Syncellus, some people from the river Indus settled in the vicinity of Egypt in the reign of Amenophis, the father of Sedoitis, and many Egyptians, banished by their princes, settled in other countries, and came to far as India. It is also supposed, that many of the priests of Egypt left the country on the invasion of it by Cambyses. But such circumstances as these are not of themselves sufficient to account for the great resemblance between the two systems. The Hindoos themselves say, that their sacred books came from the west, (see Eziouvedan, p. 15-17.) But the Hindoos, as well as their books, most probably came from that quarter, and their sacred books were composed while the seat of the empire was in Persia. The affinity of the Egyptians and Hindoos may be inferred from the similarity that subsists between some Egyptian words and those that occur in the ancient language of Hindoostan. The names and figures of the 12 signs of the zodiac, among the Hindoos, are nearly the same with ours, which came from Egypt through Greece, and each of these is divided into 30 degrees. Moreover, both the Egyptians and Hindoos had also the same division of time into weeks, and they denominated each day by the names of the same planets. The resemblance between the oriental and occidental systems extends much farther than Egypt. The office and power of the Brahmas in the northern parts of Europe did not differ much from those of the Brahmas; and the Etruscans, from whom the Romans derived the greatest part of their learning and religion, had a system very much resembling that of the Persians and Hindoos, and they wrote alternately to the right hand and left. (See Etruscans.) Several remarkable "general principles" were held alike by the ancient Egyptians and the modern Hindoos. They both believed that the souls of men existed in a prior state, and that they go into other bodies after death. They had the same idea of the body being a prison to the soul, and imagined that they could purify and exalt the soul by the mortification of the body; and from the idea of the great superiority of spiritual to corporeal substances, they held all matter in great contempt. They also both believed that plants had a principle of animation. Several religious ideas and customs were common to both countries. The Egyptians of Thebes represented the world under the figure of an egg, which proceeded from the mouth of Chaos; and this resembled the first production according to the Hindoo system. Several of the Egyptian deities were both male and female, which corresponds to the figure of the "lingam" with the Hindoos. This obscene figure, or at least the "phallos,"
was much used in the Egyptian worship, and from Egypt it was carried into Greece, where it was used in the mysteries of Bacchus. Besides, the licentious postures of the Egyptian women before their god Apis, were the same with those of the Hindoo women, before their idols, (see Brahmans); and, moreover, the Hindoos chule their sacred bulls by the same marks that were used by the Egyptians. The Egyptians worshipped the Nile, as the Hindoos do the Ganges: the pyramidal or conical form of the Egyptian temples resembled that of the pagodas; and the onion, which was held in veneration by the Egyptians, is not eaten by the Hindoos. Besides this resemblance of general principles, and religious customs, it is observable, that the Hindoo Egyptians, and Greeks adopted the same gods, and paid homage to them under similar representations or images. The Egyptians held cows in much greater veneration than any other animal: they were sacred to Isis, and never sacrificed. That the cow was respected by the Hindoos is well known. Upon the whole, it is undeniable that a sytem, very similar to that of the present Hindoos, must have been of very great antiquity, and prior to the general dispersion of mankind. For though similar situations may lead to similar sentiments, and corresponding practices, the above-mentioned similarity, which might be traced in a much greater number of influences, extends to too many particulars, to admit our accounting for it in this way: nevertheless, it is impossible that a system, so extensive and complex, and implying such abstruse metaphysics, as that of the Hindoos, should have been completed at a very early period. This must have been subsequent to the rudest age of mankind: and, therefore, we may well imagine, that it could not have had its origin long before the time of Moses. Whether the Jewish law-giver was acquainted with it or not, it will appear to any candid as well as accurate examiner of the one or the other, that he was far from deriving any advantage from it; nor is there in his writings any allusions to books pretended to be sacred, such as the Vedas, but only to such practices as were common to the Hindoos and other heathen nations.

The Hindoos seem to have preferred the knowledge of the Supreme Being, when the Greeks, and other more polished nations in the western parts of the world, had lost sight of him; their attention being ingrossed by inferior objects of worship. Some of their deprivations of the deity are just, and truly sublime. In the “Institutes of Menu” he is said to be “one whom the mind alone can comprehend, whose essence eludes the external organs, who has no visible parts, who exists from eternity, the soul of all beings, whom no being can comprehend.” They also say, that “goodness is the very essence of God.” (See Brahman.) Nevertheless, the most sublime conceptions of Deity entertained by the Hindoos fall far below those that were formed of him by the Hebrews, and which are recorded in the sacred writings. In the Hindoo sytem the first production of the Supreme Being was something similar to the chaos of Moses, an earth covered with water; and they speak of the “spirit of God” as moving upon it. One of the Hindoo fables, related by father Bouget (Ceremonies of Religion, p. 48.) bears some resemblance to the masonic history of Paradise. The Hindoos say that the first man was called “Adam,” and the first woman “Manana.” The Hindoos have also a peculiar day of the week, which they appropriate to acts of religion, as prayer and fasting; and in agreement, at least in part, with the account of Moses, the Hindoos say that in the first ages of the world men were greatly superior to the present race both in the length of their lives, and in the powers both of body and mind; but that, in consequence of vice, they gradually declined. The Hindoos have also preserved an unambiguous tradition of an universal deluge; and according to the “Purans,” books which are said to contain a faithful account of their doctrines, eight persons escaped the general deluge. A curious account of the intoxication of Noah, and of the behaviour of his three sons on the occasion, is given us from the Hindoo writings in the third volume of “Antiquity Researches.” The 4th and 5th “avatar” of the Hindoos, as for W. Jones says (Diff. ex. v. p. 115) relate to the punishment of impiety, and the humiliation of the proud; and refer, as he thinks, to the deluges from Babel. In the “Bhagavady” there are besides the masonic account of the deluge, the principal circumstances of the history of Ikma, and the sacrifice of Iasa. Several things occur in the Hindoo traditions, which greatly resemble some in the history of Abraham; and Brahma, the Hindoo law-giver, very much resembles this ancient patriarch.

The several institutes contained in the collection of the Gentoo laws, which we shall presently notice, are interwoven with the religion of the Gentooos, and revered as of the highest authority. The curious reader will discover an alluring similarity between the institutes of this code and many of the ordinances of the Jewish law, between the character of the Brahmins or priests, and the Levites; and between the ceremony of the scape-goat, under the Mosaic dispensation, and a Gentoo ceremony, called the “golmanned jag,” in which a horse answers the purpose of a goat. In this code we find some of the more extraordinary laws and customs of the Hebrew nation, such as were never received in the western part of the world; as that of a man taking the widow of his brother, in order to keep up his family. Polygamy appears also to have been allowed to the Hindoos, as it was to the Hebrews. Many obsolete customs and usages, alluded to in many parts of the Old Testament, may also receive illustration from the institutes of this code. It appears from the code, that the Brahmins, who are the priests and legislators of the country, have renounced all the secular and executive power into the hands of another cast or tribe; and no Brahmin has been properly capable of the magistracy since the time of the sattegogue; the only privilege of importance which they have appropriated to themselves is an exemption from all capital punishment; they may be degraded, branded, imprisoned for life, or sent into perpetual exile; but it is every where expressly ordained, that a Brahmin should not be put to death on any account whatsoever.

Among the Hindoos there is a considerable difference of opinion on the subject of creation; but in the following general outline they seem to be all agreed. They say, that, after the Supreme Being had exiled alone from all eternity, he resolved to produce other beings. But this production was wholly from his own substance; and after a certain period, they believe that every thing will be absorbed into him again, when he will exilt alone as before. There will, however, be a succession of these creations and absorptions without end. At what time the first creation took place they do not say; but according to them, every thing that now exists has existed before, and will hereafter exist again. The great superiority of the spiritual to the corporeal part of man is the fundamental doctrine of the Hindoo sytem; and hence springs the satisfaction which the Hindoo always expresses on the separation of them. From the Indian philosophy it is probable that the Manicheans had their idea of an original difference in souls, force being morally good, and others bad. That all nature is animated, and that the souls which animate the lowest forms of things are capable of rising to the highest state, is asserted in the “Institutes of Menu.”
Menu. Thus it is said, "the souls that animate worms and insects, serpents, moths, bees, birds and vegetables, attain heaven by the power of devotion."

The doctrine of transmigration is one of the distinguishing tenets of the Gentoos. With regard to this subject it is their opinion, according to Mr. Holwell, that those souls which have attained to a certain degree of purity, either by the innocence of their manners, or the severity of their mortifications, are removed to regions of happiness, proportioned to their respective merits; but that those who cannot so far surmount the prevalence of bad example, and the powerful degeneracy of the times, as to deserve such a promotion, are condemned to undergo continual punishment in the animation of successive animal forms, until, at the flated period, as other renovation of the four journies shall commence, upon the dissolution of the present. They imagine fix different spheres above this earth, the highest of which, called fuzee, is the residence of Brhimah, and his particular favourites. This sphere is the haunt of those men who never uttered a falsehood, and of those women who have voluntarily chastised themselves with their husbands; the propriety of which practice is expressly enjoined in the code of the Gentoos laws.

This code, printed by the East India company in 1776, is a very curious collection of Hindu jurisprudence, which was compiled by the most experienced pandits, or lawyers, from curious originals in the Sanscrit language, who were employed for this purpose from May 1773 to February 1775; afterwards translated into the Persian idiom, and then into the English language, by Mr. Halhed.

We have already observed, that the Hindoos are divided into four great and original tribes, which, according to the Gentoos theology, proceeded from the four different members of Brhimah, the supposed immediate agent of the creation under the spirit of the Almight. These tribes are the Bramins, which proceeded from his mouth, and whose office is to pray, read, instruct, and conduct the sacrifices; the Chelethees, which proceeded from his arms, whose office is to draw the bow, to fight, and to govern; the Bice, proceeding from the belly or thighs, who are to provide the necessaries of life by agriculture and traffic; and the Sooder from the feet, which are ordained to labour, serve, and travel. See CAST.

Few Christians, says the translator of the Gentoos Code, have expressed themselves with a more becoming reverence of the grand and impartial designs of Providence in all its works, or with a more extensive charity towards all their fellow-creatures of every profession, than the Gentoos. It is, indeed, an article of faith among the Bramins, that God's all-merciful power would not have permitted such a number of different religions, if he had not found a plenty in beholding their varieties.

Mr. Holwell, and even Mr. Dow, attempt to elucidate the Hindoos from the charge of polytheism and idolatry. "Let us well assured," says the latter, "that whatever external ceremonies of religion may be, the same infinite being is the object of universal adoration." But though the Hindoos acknowledge one Supreme Being, from whom all power is derived, they suppose that the immediate government of the world is placed by him in other hands. To these inferior deities their prayers and religious services are externally directed; and this worship is encouraged and enjoined in their sacred books. According to their system, there sprung from the Supreme Being, as emanations of his divinity, an infinite number of subordinate deities and genii, of which every part of the visible world was the seat and temple. These intelligences did not barely reside in each part of nature; but they directed its operations, each element being under the guidance of some being peculiar to it. These inferior gods, being of various and opposite disposition and character, their worshippers adopted different methods of deprecating their anger, and soliciting their favours. Hence proceeded a great variety of whimsical and absurd, and also of cruel and dreadful, as well as impure, rites. The description of the Hindoos for the images of their gods subjects them jujilly to the charge of idolatry and polytheism; although the learned Bramins pretend, that they do not worship the visible idol, but the invisible being represented by it. Mr. Sommert says that, besides those whom the Hindoos place in the rank of gods, they have also "fauns," whose pictures they place in their temples, and that they address their prayers to them as well as to their gods. Nor let it be said that these are the accounts of travellers. In the sacred books of the Hindoos mention is made of various deities besides the Supreme Being. The worship of the fun, says Sir W. Jones (Diff. &c. v. i. p. 481.) is principally recommended in the Vedas. The "Institutes of Menu" say, that "the Supreme Being created an assemblage of inferior deities, and divine attributes, and pure souls, and a number of genii exquisitely delicate." In this work mention is also made of "orders of demi-gods that are wafted in airy cars, semi of the rigus and lunar mantic, &c." The worship paid to the deities, or anicones, is a great article in the Sutrin, and it is mentioned almost in every page of the "Institutes." All the neighbouring nations whose religions have some affinity to that of the Hindoos are polytheists. The ancient religion of the northern European nations was, in several respects, similar to that of the East; and we find among them the acknowledgment of one Supreme God, with the worship of several inferior ones. Thus, their deities, Odin the god of war, Frea his wife, and Thor the god of thunder, were the principal objects of worship to all the Scand-navians.

It has been said that the polytheism of the Hindoos, and others, was mild and tolerant in its nature; but the fact is, that like the ancient Egyptians, they quarrelled with one another on account of their attachment to different deities, especially in Malabar; and mild as the religion of the Hindoos appears to be, and gentle as are their general manners, they can assume a very different character when their religion is concerned. The Bramins exterminated the Sammanians, and the followers of Boddhis, with fire and sword, leaving none of them on the west side of the Ganges, under a pretence of their being atheists; and when any Hindoo is converted to Christianity, he is not only banished from his tribe, but abandoned to the inflicts of the whole nation. Such also was the treatment of those who were excommunicated by the Druids. The Hindoos regard all Christians with the utmost abhorrence and detestation, as much below the lowest of their own sects. The Bramins themselves are cruel and malignant, where their religion is concerned. Nevertheles, when the Hindoos converse with Christians on the subject of religion, they profess to believe, as we have already observed, that the Supreme Being is equally pleased with all religions, and intended that all the different modes of it should be adopted by different nations.

Although there are many points of resemblance between the religion of the ancient Egyptians and that of the Hindoos, yet in many respects they are exceedingly different; so that though they may have gone together at the first, they must have separated at a very early period. The Hindoos never worshipped living animals, which is a principal feature in the religion of the Egyptians; and the names, the characters, and the images of their deities have very little resemblance to each other. But between the religion and mythological fables of the Greeks and those of the Hindoos, there
there is a very remarkable resemblance; though we are unable to trace any connection that ever subsisted between them.

The religion of the Hindoos seems to be much too complex to have been, as Sir W. Jones supposes, the old Sytem of polytheism and idolatry. It is evidently a refinement on something much more simple, and this seems to have been the system of the "Samhans," whom the Greek writers mention as a sect of philosophers in India, opposed to the "Brahmanas," and to be the same as those who are now called "Sahamans" in Siberia. See SAMHANAS.

Nothing can be more humiliating than the situation to which the Hindoo institutions reduce the female sex. According to the Vedas, the souls of women, as well as those of all individuals of the inferior castes, are condemned to continual transmigrations, till they are regenerated in the bodies of men. The fame unfavourable character is amply justified by the representations that occur in the "Institutes of Menu," and the "Code of Gentoo laws." Such being, in the opinion of the Hindoo law-givers, the natural character of women, it is no wonder that little regard is paid to their evidence in courts of justice; nor can we be surprised, that the birth of a female is no cause of rejoicing in a Hindoo family. In perfect agreement with such degrading ideas of the female character, the women must always be under the absolute control of men; nor has the subject of the wife to her husband any bounds. As women are treated in this disrespectful manner, and considered as unqualified to read their sacred books, they are in general very ignorant, so that few of them can either read or write.

The devotion of the Hindoos is supposed to comprise all other duties; but their devotion consists in the frequent repetition of the names and attributes of God. The first thing in their prayer is to pronounce the word ona, then excluding all sensible objects, even forbearing to breathe, and to think only on God. This kind of prayer serves for the pardon of sin and purification. This word ona, on the pronunciation of which so much is supposed to depend, signifies, according to Sir W. Jones, Brahman, Vichon, and Sor; or the three powers of creation, preservation, and destruction. This mythical word, he conjectures, may be the Egyptian On, commonly supposed to mean the sun, and by the ancient idolaters the solar fire. The religion of the Hindoos consists principally in oblations to the gods, i.e. to the inferior deities, and to the manes of their ancestors; and these oblations are accompanied with many frivolous ceremonies. Moreover, a great part of their religion consists in the sacrifices to which they subject themselves. Among other things, all fermented or spirituous liquors are forbidden, and they submit to various restrictions with regard to their food. To a genuine Hindoo nothing appears more heinous than the killing, and much more the eating of any thing that had life. The Hindoos are much devoted to pilgrimages for the purpose of bathing in distant rivers; and they generally prefer the Ganges. In their pilgrimages, they practice singular austerity. Their feats in honour of different deities are of long duration, and are very strictly observed; and they are thought to have singular efficacy in effacing all sins. See FAIRIES.

It is not uncommon with the Hindoos to devote themselves to certain and very painful death, under the influence of their wretched superstition. They throw themselves on the large iron hooks that are fastened to the wheels of the carriages, which carry the images of their deities in procession. Others lie flaying on the ground for the wheels to pass over them, and crush them to death. But the most affecting instances of involuntary death are those of the Hindoo women, who burn themselves alive with the bodies of their deceased husbands. In this way of terminating life they indulge the hope of attaining the same state of happiness with them after death. This is deemed a kind of religious duty, though it is not regarded as of universal obligation. On the deaths of persons of high rank and celebrity, these victims of superlition, voluntary or involuntary, are sometimes very numerous. At the death of a king of Trancore, no less than 600 of his concubines leaped into the flames, and 400 burned themselves at the funeral of a vaque, of Madura. (Maurice's Ind. Antiq, vol. ii. p. 165.) The Hindoo religion, which has been extolled as the midst of all religions, formerly enjoined and countenanced human sacrifice; and Sir William Jones says, that the ancient Hindoo sacrifice of the Hindoos was that of a man, a bull, and a horse. Among other superlitions notions and practices prevalent among the Hindoos, we may mention their excessive veneration for the cow, and also for the elements of fire and water. Penances of a singular and severe nature were enjoined for killing cows without malice; and if this crime was maliciously committed, it admitted of no expiation whatever. Mr. Wilkins informs us, (Sketches relating to the history, &c. of the Hindoos, vol. i. p. 234.) that the Brahmins are enjoined to light a fire at certain times, and that it must be produced by the friction of two pieces of wood of a particular kind; that with a fire thus procured their sacrifices are burned, the murtial altar flames, and the funeral pile is kindled. Their veneration for water, especially that of the Ganges, has already been mentioned; and performs clufs to the indians from an idea, that the soul passing through the water, as it leaves the body, is purged from its impurities.

The Hindoo religion is little, if at all, more unexceptionable than the ancient Egyptian, with regard to the extravagance and indecency of many of its ceremonies. Indulges occur at their pagodas, which we have already noticed under the article BRACHMANS, and which it is needless here to repeat. (See also TAGODA.) Charms are also held in estimation among the Hindoos; a regard to them is authorized by their sacred books, and the practice of incantation is professed by their learned Brahmins. From a veneration for the elements of fire and water, and an opinion of their producing somewhat of divinity, they have been deemed proper texts of guilt, or of innocence. Hence has proceeded the trial by Ordal: which see. With regard to the Hindoo doctrine of a future state, Mr. Dow says, that men first sit for their crimes in hell, where they remain for a space of time proportioned to the degree of their iniquities; then they rise to heaven, to be rewarded for their virtues, and thence they will return to the world to re-animate other bodies. The more learned Brahmins, he says, affirms that the hell which is mentioned in the Vedas is only intended as a hog-bear to the vulgar; agreeably to the doctrine of the Greek philosophers. On the other hand, Mr. Holwell, contrary to all other accounts, which represent future punishment as in all cases finite, says, that whoever shall free himself by violence from this mortal body, shall be plunged in "Onderah" for ever. According to another account of the religion of Malabar, they who destroy themselves go neither to heaven nor hell, but flyroll among the "Spirits," under the power of the chief of the devils. Sometimes they enter into men, and then they become demons, and go about naked and mad, to disturb the neighbourhood, eating grass and raw fish. According to the Indians, says P. Dilla Valle, some very wicked men become devils. To conclude our account of the Hindoos, or Gentooos, we observe, that notwithstanding the
the unreasonable fields which they lay on mere external observances of various kinds, there are not wanting in their writings some excellent moral maxims, similar to many in the books of the Old Testament, which represent every thing of this kind as insignificant, without moral virtue. A peculiar fields, we find, even too great, is laid on the duties to parents; so as to supersede the obligation, and to depreciate the importance of other duties. Upon comparing the Hindu systen with that of Moses, the absurdity of the former is as apparent as the superior wisdom of the latter. With the Hindus we perceive the rudiments, and more than the rudiments, of most of the arts and sciences, especially of that of astronomy, of which most other nations are wholly ignorant. And yet while the Hebrews made no discoveries in science, they had a religion perfectly rational; and that of the Hindus was absurd in the extreme. This, therefore, is an argument of the internal kind in favour of the divine origin of the Hebrew religion, almost as irreproachable as any argument from miracles. From the preceding sketch of the Hindu religion, we must be led to acknowledge the necessity and utility of a divine revelation.

Those who are deliberate of being farther acquainted with the principles, manners, and various institutes of the Gentoo, may consult Holwell’s Interesting historical Events, &c. 1766. Dow’s History of Hindoostan, 4to. 1768. and the Code of Gentoo Laws. Prieckley’s Comparison of the Institutions of Moses with those of the Hindus and other Ancient Nations, 8vo. Northumberland, in America, 1799. For a further account of the religious tenets and practices of the Gentoo, see Brachmans. See also Shastanah and Viedan.

GEN-TSING, in Geography, a town of China, in Setehu; 87 miles N.W. of Hoecho.

GENUFLEXION, cf. genu, kneae, and flexis, I bend, the act of bowing, or bending the knee; or rather of kneeling down.

The Jesuit Roswey, in his Omanofican, shews, that genuflexion, or kneeling, has been a very ancient custom in the church, and even under the Old Testament dispensation; and that this practice was observed throughout all the year, excepting on Sundays, and during the time from Easter to Whitmas, when kneeling was forbidden by the council of Nice. Others have shewn, that the custom of not kneeling on Sundays had obtained from the time of the apostles; as appears from St. Irenæus and Tertullian; and the Athiopie church, scrupulously attached to the ancient ceremonies, still retains that of not kneeling at divine service. The Ruffians esteem it an indecent posture to worship God on their knees. Add, that the Jews usually prayed standing. Roswey gives the reasons of the prohibition of genuflexion on Sundays, &c. from St. Bafil, Anaphalaeus. St. Justin, &c.

Baronius is of opinion, that genuflexion was not established in the year of Christ 58, from that palliaxe in Acts xx. 56, where St. Paul is expressly mentioned to kneel down at prayer: but Saurin shews, that nothing can be thence concluded.

The same author remarks, also, that the primitive Christians carried the praclice of genuflexion so far, that some of them had worn cayolites in the floor where they prayed: and St. Jerome relates of St. James, that he had contrived a hierolind on his knees equal to that of camels.

GENUS, in Systematic Botany, from γένος, a family, implies one or more species of plants, differing essentially in their parts of fructification from all others, and agreeing together in the general structure of those parts, as well as in one or more peculiar marks or characters. If a genus be perfectly natural and distinct, such characters in the fructification are accompanied with more or less decided distinctions in the other parts of the plant, as well as in its general habit or aspect. On this principle it is contended by Linnaeus and his school, that all genera are, or ought to be, natural, and that the genus ought to give the character, not the character the genus. The same principle is extended to the animal kingdom. Botanists of the French school, on the contrary, maintain that all such distinctions and differences are merely arbitrary, serving to facilitate the study of plants, but not at all founded in nature. It is singular that, with such ideas, these philosophers should not only scrupulously contend for a natural system of arrangement, but object to the Linnaean method, whose facility cannot be disputed, merely because it is not natural, terming it in their language lex naturae. If genera are not natural, certainly the more comprehensive assemblages, of such genera into orders and classes, can, in no sense, be so. We nevertheless do not scruple to allow, that the principles of all such distinctions are founded in nature, though we readily admit that no system has as yet applied them correctly to practice, even with regard to genera, and far less to classified, distinctions. The latter indeed have been scarcely found capable of definition, or in no vague a manner as to leave us most in doubt where precision is most wanted; and were it not for that intuitive, or least practical, perception of affinities and differences, which is, by the French, contended to be inscrutable in judging of genera, we could certainly come at no knowledge of most of the natural orders of these learned writers.

Examples of natural genera, each characterized by an essential character of its own, which distinguishes it, not only from every other genus in its natural order, but from every one hitherto discovered, are found in Quercus the Oak, whose acorn affords such a character; in Trops, whose singular quadrangular nut is armed with spines that once constituted the calyx-leaves in Paragia, so well marked by the fringes and lacid balls that border its nectaries; in Solanum with its many-cleft monopetalous corolla, and Eleusine, whose polypetalous one is similarly clothed in Griffita, the only known instance of a papilionaceous flower with such a drupée; not to mention a great number besides. Inflammation of good natural genera, distinguished by some one essential character from all others in their natural order, are found in Echium, whose irregular corolla keeps it distinct from all others of the Aphi rodia; Corence, known from all other gracies by its remarkable involucrum; Pinpinella distinguished from its allies by the globose figmin; Remana, by the nectariferous pore in the cowl of each petal; Vella by the prominent dilated partition of its pouch, extending twice as far as the valves; to which may be added many genera of the class Didynamia Gymnospermaea, see Smith’s introd. to Botany, 434. The Linnaean lepidodria Polyneca affords one of the most perfect examples possible of a natural class and order, of which all the genera are natural, and so well distinguished in habit, that any person at all observant of plants may know them by their foliage, inflorescence, or general appearance, while their fruit affords clear essential generic characters. The natural family of Orchizes, as arranged by Swartz and Brown, come very near the same point of perfection, but their differences of habit are less obvious. Such instances ought to stimulate the philosophical botanist to go on from one degree of perfection to another,
another," though, like the Christian moralist, he cannot hope to reach the summit.

Lamarck has very well traced the indissoluble origin, and gradual improvement of generic knowledge among botanists. In an early stage of the science, some general affiliations were formed, though founded on vague and unphilosophical principles. The idea and name of a rofe soon embraced many different species, and hence the dog-rose, the white-rose, the damask-rose, &c., were distinguished from one another, and a fort of generic and specific nomenclature arose, finally extended systematically to every plant by Linnaeus. Calpin Baulin in his Linneum, anno 1623, first distributed plants under a kind of generic sections, with some mention of the peculiar characters of each; but he did not profit, as he ought to have done, of the great principle first inculcated by Conrad Geyer, that the parts of the flower and fruit afford the only clue to a scientific distribution of vegetables; a principle to which "the very existence of botany, as a science, is owing." Tournefort at length, adopting this maxim, undertook the arrangement of all known plants into genera, illustrating each by a figure of the parts of fructification, so as to display their distinguishing characters; but it was referred for Linnaeus to define these characters in words, and thus to perfect the plan of Tournefort, as well as to reform it in many points, and correct some fundamental defects. He extended moreover his improvements to the clear definition and nomenclature of the species, which Tournefort had, without discrimination, merely collected, by their old appellations, under each of his genera, except indeed that he preferred an uniformity in their generic names.

Linnaeus did not at once hit upon the better manner of defining his genera. His first aim was to describe all the seven parts of fructification in each, so that their differences might appear, which is the plan of all the editions of his Genus Plantarum. At length, in the sixth edition of his Systema Nature, published in 1737, he undertook a Synopsis table of the chief essential characters of the genera, and in the tenth he carried this plan nearly to the perfection in which he left it at his death. It has been adopted, not only by his pupils, and the followers of his system of classification, but even by the celebrated Jussieu and his scholars, who have widely differed from the learned Swede as to other principles of arrangement, and who have certainly not improved upon his style of definition, terminology, and nomenclature. Jussieu indeed has, like Gowan, subjoined to the generic characters taken from the fructification, very useful indications of the habit, which invention of the latter botanist was highly applauded by Linnaeus.

Linnaeus termed the full descriptions in his Genus Plantarum, the natural character of each genus. They ought to accord with every species of each, but in large genera, many species of which have been discovered subsequently to their establishment, this is scarcely possible. Such characters as serve merely to distinguish each genus from every other in its artificial order, in the Linnaean, or any other artificial system, are called fictitious; these are much better extended so as to include sufficient marks of discrimination between the genus under consideration and every other, and they then become the affinities characters above-mentioned, which ought in every systematical botanical work to stand at the head of each genus, or at least to be indicated by a reference. Lamarck, though much disposed to criticise the great Swedish botanist, and differing totally from him respecting his opinion of natural genera, very candidly allows that "these essential characters are the result of one of Linnaeus's most happy ideas, and cannot but contribute greatly to the perfection of Botany." The same able writer affirms entirely to the Linnaean maxim, founded on the good sense and penetration of Conrad Geyer, that "generic characters ought always to be taken from the parts of fructification alone;" "at least," says Lamarck, "if that be always practicable." When it is not, he would borrow characters from any thing very decided in the habit; nor does he perceive that any inconvenience would result from it. To this we object the uncertainty of such characters, even when taken from what is least exceptional, the inflorescence. Of this no more striking example can be found than the Umbellata, as distributed by Linnaeus after the principles of his friend Artedi, in which, however it may be dissembled by sophistry, the inflorescence makes a leading part. Those who justify, like Lamarck, complain of the errors, unjustly termed by him arbitrary and voluntary errors, which are found in this part of Linnaeus's system, cannot but allow that they all originate from his having had respect to the inflorescence, that is, to the umbels and involucres, instead of the flowers and seeds, which if truly observed are fully sufficient in this, as we believe, in every other natural order. Indeed the more we consider the subject, the more we are convinced that, although the inflorescence ought, like every part of a plant, to enter into our general contemplation before we decide upon a genus, it ought never to form a part of the technical or essential character. It is tempting enough to botanists who are not endowed with clear mathematical powers of discrimination and definition, to amplify their generic characters with any thing that, as they suppose, may give them additional strength. But characters, when too long, rather indicate feebleness in themselves and in their authors, and endanger a return towards barbarism in a science, which has been raised to its present pitch of perfection by the didactic precision and decisive brevity of Linnaeus. S.

Genus, Kind, in Logic and Metaphysics, is that which has several species under it; or it is the origin and matrix of divers species, joined together by some affinity, or common relation between them. See Classification.

Genus is a nature, or idea, so common and universal, that it extends to other general ideas, and includes them under it. Thus, animal is said to be a genus, in respect of man and brute; because man and brute agree in the common nature and character of animal; so a right-lined figure of four sides is a genus in respect of a parallelogram, and a trapezium; and so, likewise, is sublimate in respect of sublimates, which is body; and thinking sublimate, which is mind.

A good definition, say the schoolmen, confides of genus and difference.

In the general, genus may be said to be a class of a greater extent than species; and which is not convertible therewith: for though we may say, that all body is substance: yet it cannot be said all substance is body.

Add, that whatever may be said of the genus may likewise be said of the species under it: e.g. whatever is said of ran, being, will equally hold of the body.

The schoolmen define the genus logicum to be, an universal which is predicabie of several things of different species; and divide it into two kinds: the one, the fiumum, which is the highest, or most general; and has nothing above it to respect as a genus; the other, the fakulter, which they likewise call divus.

Genus fiumum is that which holds the uppermost place in its class, or predicament; or that which may be divided into several species, each whereof is a genus in respect of other species placed below it.

Thus,
Thus, in the predicament of things subprocessing of themselves, substance has the place and effect of genus sumnum, and is predicated of all the things contained in that class: for Plato, and man, and animal, and even spirit, are properly called substance.

Accordingly there are as many summa genera, as there are classes of predicaments, or categories.

Genus, fabulorum, is that which, being a medium between the highest genus and the lowest species, is sometimes considered as a genus, and sometimes as a species.

Thus, bird, when compared with animal, is a species; when to a crow, an eagle, or the like, it is a genus.

Genus, again, is divided into remotum, remote, where between it and its species there is another genus; and proximnum, or next, where the species is immediately under it; as man under animal.

Genus is also used for a character, or manner applicable to every thing of a certain nature or condition. In which sense it serves to make capital divisions in divers sciences: as mutual, rhetoric, botany, anatomy, &c. &c. &c.

Genus, in Mujic. See Genera.

Genus. By the word genus, in Natural History, we understand a certain analogy of a number of species making them agree together in the number, figure, and situation of their parts in such a manner, that they are easily distinguished from the species of any other genus, at least by some one article. This is the proper and determinate sense of the word genus, whereby it forms a subdivision of any clafs or order of natural beings, whether of the animal, vegetable, or mineral kingdoms, all agreeing in certain common and distinctive characters. See General name, and Classification of Animals.

Genus, in Rhetoric, is one of the common places or topics, and consists under it two or more sorts of things differing in nature. From this head logicians reason thus: Because every animal is mortal, and man is an animal, therefore man is mortal (See Genus, in Logic.) But orators make a further use of this argument, which they call descending from the hypothesis to the thesis, that is, from a particular to a general. As if a person, speaking in praise of justice, should take occasion from hence to commend and thus the excellence of virtue in general, with a view to render that virtue more amiable. For since every species consists in the whole nature of the genus to which it relates, besides what is peculiar to itself, whereby it is distinguished from it; what is affirmed of the genus must, necessarily, be applicable to the species.

Besides, authors distinguish the art of rhetoric, as also orations, or discourses, produced thereby, into three genera, or kinds; demonstrative, deliberative, and judicial. See each term.

Genusium, in Ancient Geography, a town of Italy, in that part of Magna Graecia called Messapia. It was situated little S. of the road that led to Tarentum.

Genzano, in Geography, a town of Naples, in Bassilicata; 12 miles S. E. of Venosa — Alto, a town of Campagna di Roma, in Italy; 3 miles W. of Veltrici.

Genzgen, a town of France, in the department of the Rhone and Mollon; 5 miles N. E. of Creutznach.

GEOCENTRIC, of earth, and centro, centre, in Astronomia, is applied to a planet, or its orbit, to denote it concentric with the earth; or, having the earth for its centre, or the same centre with the earth.

All the planets are not geocentric: the moon, alone, is properly geocentric.

Geocentric latitude of a planet, is its latitude seen from the earth; or the inclination of a line connecting the planet and the earth, to the plane of the earth's (or true) ecliptic.

Or it is the angle which the aforesaid line (connecting the planet and the earth) makes with a line drawn to meet a perpendicular let fall from the planet to the plane of the ecliptic. See Latitude.

Thus in Plut. XIII Astronomia, fig. 116, the angle $\alpha$ is the measure of that planet's geocentric latitude; when the earth is in $\beta$ and the angle $\alpha + \beta$ the measure of it when the earth is in $\gamma$.

Geocentric place of a planet, is the place wherein it appears to us, from the earth, supposing the eye there fixed: or, it is a point in the ecliptic, to which a planet, seen from the earth, is referred.

Geocentric longitude of a planet, is the distance measured on the ecliptic, in the order of the signs between the geocentric place and the first point of Aries.

Geodesia, that part of practical geometry which teaches how to divide, or lay out, lands, or fields, between several owners.

The word is Greek, geodesia, formed of $\gamma$, terra, earth, and $\delta$, divide, I divide.

Geodesia is also applied, by some, to all the operations of geometry which are performed in the field.

This is more usually called surveying, (which see,) when employed in measuring of lands, grounds, roads, countries, provinces, &c.

Vitalis defines geodesia the art of measuring surfaces and solids not by imaginary right lines, as it done in geometry, but by sensible and visible things: as by the sun's rays, &c.

Geodesia, in Natural History, is applied to a universe of hay, corn, &c. See Stack.

Gen. Ch. Col. Periarch of one leaf, inferior; bell-shaped; five-leaf half way down; its two upper segments diverging, spreading. Cor. papilionaceous; standard roundish, emarginate, flat, reflexed; wings equal to it in length, obtuse, concave; keel compressed, the length and shape of the wings. Stamina in two forms (ingle and nine-leaf), the style of the keel, orers roundish. Pith. Germf superior, roundish; style awl-shaped; stigma obtuse. Paris. Drupa nearly ovate, large, with a longitudinal furrow at each edge. Seed. Nut nearly ovate, somewhat woody, a little compressed, with a furrow along each edge, acute, of two valves.

(Umari);
"Spinos. Leaves oblong, obtuse." — Native of Brazil, and the country about Carthage. In woods on a sandy soil near the sea. Jacquin describes it as an indelicate tree, twelve feet high, with a few spines on the trunk and larger branches, which are unshaped, and generally an inch long. Leaves pinnate, about seven pair, with an odd one, of oblong, obtuse, smooth, entire leaves, on a stalk four inches in length. Clusters nearly as long, axillary, simple, dense. Flowers on short partial rachis; their colour a dirty orange, and their scent extremely powerful and offensive. Fruit like that of an almond in its coat, slightly downy, greenish-yellow; the pulp soft, sweet, but of a nauseous smell, yellowish, staining the hands with a rusty hue, very difficult to wash off. This coat adheres firmly to the nut, whose kernel is white, mealy and altrigent. Jacquin was fully surprised at meeting, for the first time, with a drupa to a papillaceous flower, but he judiciously named it, in spite of some preconceived theory.

3. G. insinui. Swartz. Prod. 166. Woodv. Med. Bot. t. 112. (Cabbage-bark tree of Jamaica; Wright in Phil. Trans. v. 67. 527. t. 15.) — "Without spines. Leaves lanceolate." — Native of Jamaica and Martinico. A tall tree, whose wood is white, and so tough as to be preferred beyond all others for the shafts of carriages. The bark is a celebrated remedy for worms in the intestines, administered in a decoction, syrup, powder, or extract, and given in gradually increased doses, till a nausea is produced. The leaves consist of five or six pair, with an odd one, of elliptic lanceolate, pointed leaves, about three inches long. Flowers light-red, in very large much-branched, terminal, downy panicles. Fruit the size of a small plum.

GEOFFREY, or GEOFFROY, insermis, cabbage-bark tree, or warm-bark tree, in the Materia Medica, is a native of Jamaica. (See the preceding article.) The bark of this tree, which has a mucilaginous and sweetish taste, and a disagreeable smell, was first noticed as a vermifuge by Mr. Peter Duguid (Eff. and Obs. Phylic. and Liter. vol. 2. page 264.) But the fullest information concerning this tree, in respect to both its medical and botanical characters, has been communicated by Dr. Wright, who has been a long time in Jamaica. According to his account, the bark of this tree is powerfully medicinal, and its anthelmintic effects have been established in Jamaica by long experience. It may be given in different forms, as in decoction, syrup, powder, and extract; and the manner of preparing, and exhibiting thefes, are particularly stated by Dr. Wright. For the decoction, take fresh dried or well-prepared cabbage-bark, one ounce; boil it in a quart of water, over a slow fire, till the water is of an amber colour, or rather of a deep-coloured Madeira wine; strain it off, sweeten it with sugar, and let it be used immediately; as it does not keep many days. In order to obtain the syrup, add a double portion of sugar to any quantity of the above decoction. This syrup will retain its virtues for years. The extract is made by evaporating the strong decoction in balneo maris to the proper confidence; it must be continually stirred, as otherwise the refuse part rises to the top, and on this, probably, its efficacy depends. The powder of well dried bark is calyce made, and looks like jupan, though not of equal specific gravity. As this anthelmintic has also a narcotic effect, it is proper to begin with small doses, which may be gradually increased till a nausea is excited, when the dose for that patient is ascertained. A strong healthy grown person may at first take four table-spoonfuls of the decoction or syrup, three grains of the extract, or thirty grains of the powder for a dose. The dose must be diminished for younger persons; and children two or three years of age, may take a table-spoonful of the decoction or syrup, one grain of extract, or ten grains of the powder; and children of a year old, half the quantity. Cold water must not be drank during the operation of the medicine, as it is apt to occasion sickness, vomiting, fever, and delirium. In this case the stomach must be washed with warm water, several times, and kept in a state of fermentation; but some fatal accidents have attended the imprudent use of it, chiefly from overdoing the medicine.

Phil. Trans. vol xlvii. p. 597.

GEORGEY of Monmouth, in Biographia, an early historian of our own country, who flourished about the middle of the 13th century, was first archdeacon of Monmouth, and then bishop of St. Asaph. On account of tumults in Wales he quitted his diocese, and obtained the abbacy of Abingdon in commendam. His clergy applied to him to return, which he refused, thinking he might still keep his abbacy; in this he was disappointed, and was left without any preferment.

As an historian he is known by his "Chronicon quinque Historia Britannim." This work has been frequently reprinted. Bayle. Moreri. New Anmual Regist. vol. iv.

GEORGEY, ETIPHEE FRANCOIS, a physician, was born at Paris on the 15th of February, 1672. His father was a professed apothecary, and had held the offices of sheriff and constable. While the young Georgey was perfecting his studies under his paternal roof, his father held regular scientific meetings, at which Caffini attended with his pupils, Schahoff with his machines, and Joublet with his magnets, and at which Du Verney performed his experiments, and Hoenberg his chemical experiments. After an excellent foundation of general science was thus laid, his father sent him, in 1692, to Montpellier, to study his own profession of pharmacy under an experienced apothecary. Here he attended the courses of the most celebrated professors of the university, and afterwards travelled through the southern provinces before he returned to Paris. Already he had acquired considerable reputation; and, although not yet a physician, he was appointed to accompany the duke de Tallard, as his medical attendant, on his embassy to England, in 1698. In London he was much esteemed by Sir Hans Sloane, and other men of science, and was elected a member of the Royal Society. From England he went to Holland; and afterwards to Italy in 1700, with the abbé de Louvain. Natural history and the materia medica were among the principal objects of his inquiries; for his father intended him for his successor in his establishment at Paris; but he aimed at the higher walk of the profession, and with the consent of his father at length took the degree of bacheler in 1702, and that of doctor in 1704. His disposition was mild
mild and kind to his patients, who, on his outset in practice, were alarmed by the solemn air which his sympathy for their sufferings occasioned him to assume, but his reputation from increased, and he was called in consultation even by the most distinguished members of the profession. In 1720, he was appointed by Louis XIV. to the professorship of medicine, vacant by the death of Tournefort. In his new office he undertook to deliver to his pupils a complete history of the materia medica, upon which subject he had been for a long time collecting information. He completed his account of the mineral substances employed in medicine, of which he gave a more correct and ample history; and was employed on the vegetable kingdom, which he treated alphabetically, and carried no farther than the article Melia: on the animal kingdom he had not touched; but the whole of what he had delivered in his lectures was found among his papers in good order, and afterwards published. In 1712, he succeeded Fagou as professor of chemistry in the king's garden. In 1726, he was elected dean of the faculty, in the exercise of the functions of which he was led into some active and anxious disputes, which, together with the duties of his profession, and of his other offices, destroyed his health, which was naturally very delicate. He lingered from the beginning of the year 1730 till the 6th of January, 1731, when he died. Notwithstanding his malady, however, he had the resolution to complete a work, which had been deemed necessary by preceding deans, but never accomplished; namely, a pharmacopoeia, containing a collection of the compound medicines requisite to be kept by apothecaries, "Le Code Medicamentaire de la Faculte de Paris," of which two editions, enlarged and corrected, were afterwards published. His papers on the materia medica were published under the following title: "Traite de la Matiere Medicale, ou elementary de l'Alchimie Historique, virtute, et effet," Paris 1741, 2 vols. 8vo, under the inspection of Antoine de Jullien. Several editions have been subsequently published. It was translated into French by Ant. Bergier, who published 7 vols. 12mo, in 1733, and the remainder in 3 vols. in 1753. Arnaud de Nobleville, and Salerne, physicians of Orleans, published a continuation of this work, under the title of "Histoire Naturelle des Animaux," Paris 1756, 1757, in 6 vols. 12mo, which is deemed not unworthy to be ranked with the production of Geoffroy. Eloy. Dict. Hist.

GEOGLOSSUM, in Botany, from γογγυς, the earth, and γλωςις, the tongue. Porron Syn. Fungi. 607. Class and order, Cryptogamia Fungi. Nat. Ord. Fungi.—See. class. forms. Efl. Ch. Receptacle club-shaped, fleshy, generally compressed, short, with a prominent margin next to the stalk. This genus of Fungi is founded by Peiron on the Clavaria oligoblastiodes of other authors, with some different species which resemble it, and which have the appearance of a little tongue, growing out of the earth upon a stalk. It enumerates and defines seven species. His G. bisulcatus is Clavaria oligoblastiodes of Sowerby's Fungi, t. 93; his G. chlorum is a smaller and smooth fungus, very like the fructifying spike of the fern Ophioglossum, except in being nearly black.

GEOGNOSY. See GEOLOGY and MINERALOGY.

GEOGRAPHICAL. Mile is a minute, or the sixtieth part of a degree of a great circle. See DEGREE and MILE.

GEOGRAPHICAL Table. See MAP.

GEOGRAPHY, formed of γεω, terra, earth, and γραφειν, I write, I describe; the doctrine or knowledge of the earth, both as in itself and as to its situations; or a description of the terrestrial globe, and particularly of the known habitable part thereof, with all its subordinate divisions. Geography constitutes a branch of mathematics, of a mixed kind; because it considers the earth, and its affections, as depending on quantity; and consequently as measurable: viz. its figure, place, magnitude, motion, celestial appearances, &c. with the several circles imagined on its surface.

Geography is distinguished from cosmography, as a part from the whole; this latter considering the whole visible world, both heaven and earth.

From topography and choreography, it is distinguished, at the whole from a part.

Golitsa considers geography as either exterior or interior: but Varennes more justly divides it into general and special: or universal and particular.

GEOGRAPHY, general or universal, is that which considers the earth in general, without any regard to particular countries, or the affections common to the whole globe; as its figure, magnitude, motion, land, sea, &c. And this may be subdivided into alpabic geography, which respects the body of the earth itself, its parts and peculiar properties, &c., relative, which accounts for the appearance and accident, owing to celestial causes; and comparative, which explains those properties that arise from comparing different parts of the earth together.

GEOGRAPHY, special or particular, is that which considers the constitution of the several particular regions, or countries, their bounds, figure, &c. with the mountains, forests, rivers, seas, waters, plants, and animals, &c. therein; as also their climates, fevers, heat, weather, distance from the equator, &c. and their inhabitants, arts, foods, commodities, customs, language, religion, policy, cities, &c.

Special geography may be subdivided, with regard to the several periods of its progress, into ancient, including a description of the earth, considered by the knowledge which the ancients had till the decline of the Roman empire; of this kind Cellarius's Ancient Geography is an excellent summary: the geography of the mean age, which extended from the fall of the Roman empire to the reformation of learning; and modern geography, comprehending the actual description of the earth since that time. With regard to its objects and uses, special geography may be divided into natural, which treats of the divisions and distinctions which nature has made in the surface of the globe, and the complexion, language, &c. of its inhabitants; historical, comprehending the different revolutions which any country or town has undergone; civil, or political, including the government of any country; sacred, describing the countries and places that are mentioned in scripture and ecclesiastical history; ecclesiastical, giving an account of the ecclesiastical jurisdiction established and exercised in various countries; and physical, which considers not only the surface of the globe, but also its intrinsic nature and substance. Geography is very ancient, at least the special part thereof; for the ancient writers fearfully went beyond the description of countries. Of this kind is the geography which we find in the books of Moses, written about the year 1452 B.C. and that of Homer, in his Iliad and Odyssey, who flourished, according to the Arundelian marbles, 907 years B.C. The geographical knowledge we derive from Herodotus, who flourished about 445 years B.C., is very partial and imperfect. It chiefly relates to certain parts of Asia, and divers others unknown, as well as the northern and western parts of Europe; and also Africa, Egypt and Lydia excepted.

It appears (see Phil. Geog. I. c. 9.) that the early geographers, being delirious of mathematical in-
from the form and colour of certain animals which were to be found in these different countries. The appearance of negroes, or of those called by them Ethiopians, and of animals of the larger size, such as the rhinoceros and elephant, suggested to them the line of division, where the limits of the Torrid Zone began towards the north, and terminated towards the south. This groser manner of dividing their climates must be considered as the first rude outline of geography in the more illiterate ages of the world. However this be, the Chaldeans and Egyptians, who were distinguished by their skill in geometry and astronomy, were of course the first persons that paid any particular attention to geography; and it is said that the first map was made by order of Necho I., who conquered Egypt.

This Egyptian king, says Enniathius in his epitome, prefixed to his commentary on Dionysius's Megaran, having traversed great part of the earth, recorded his march in maps, and gave copies of his maps not only to the Egyptians, but to the Scythians, to their great astonishment. The Jews also seem to have had surveyors among them; and hence some have imagined that they had made a map of the Holy Land, when they gave the different portions to the nine tribes at Shiloh. (John xviii. 4. 8. 9.) And Josaphus tells us (I. v. c. 1.), that when Joshua sent out people from the different tribes to measure the land, he gave them as companions persons well instructed in geometry, whose skill would prevent their deviating from the truth. We may therefore reasonably presume that a geometrical survey was then made of the Holy Land; though we cannot absolutely determine whether their measurement was only taken down in numbers, or regularly projected and digested into a map.

Besides the method of dividing countries by climates, already mentioned, the Egyptians and Babylonians adopted another, which was that of determining the situation of places, or their distance from the equator, by observing the length of their longest and shortest days. This they performed by means of a gnomon, erected upon a horizontal plane, by which they were enabled to measure the length or shortness of the shadow in proportion to the height of the gnomon. For an account of this invention, and of the method of applying it, see Gnomon.

From the days of Thales and his immediate successors, who flourished in the fifth century before Christ, geography seems to have received little improvement for 200 years, till the establishment of the famous school of Alexandria; although Pythagoras and his disciples were rightly informed with regard to the true system of the world, as they placed the sun in the centre, and inferred to the earth both its diurnal and annual revolutions. During this period we have an astronomical observation of considerable importance to geography, and the first Greek observation upon record; which is that of Meton and Euclides, who observed the summer solstice at Athens on a day corresponding to the 25th of June, 432 years B. C. This solstitial observation might have given them an opportunity of determining the latitude of Athens at the same time, if they had known the simple manner of deducing the conclusion; for as the length of the shadow of the gnomon was attentively watched at the moment of the solstice, the proportion of that to the gnomon's height was easily known, by which the angle of the sun's altitude would be given; and though the sun's greatest declination was not then accurately known, yet still the latitude of Athens might have been determined within the limitations of the error respecting the declination. We have reason to believe that Timocles and Arisdillus, who began to observe 295 years B. C., were the first who introduced the manner of determining the position of the stars, according to their longitudes and latitudes taken with respect to the equator. This we know from Ptolemy, who has preferred many of their observations in his "Almagest;" and particularly one, which gave rise to the famous discovery of the Precession of the Equinoxes: that is, it was after the precession of the equinoxes was fully established by Ptolemy, that the longitudes and latitudes of the stars were uniformly referred to the equatorial instead of the equator. It was therefore, by an early transition, that Hipparchus would be led to adopt and dispose the different parts of the earth according to latitude or longitude; this being only a new application or transposition of that artifice, which had been already so happily introduced in the arrangement of the constellations, and therefore equally proper to be adopted in tracing the meridians and parallels of the earth. Hipparchus must be universally allowed to have laid the solid foundation of geography by uniting it to astronomy, and thus rendering its principles self-evident and invariable.

Pliny (N. H. I. ii. c. 12.) confirms this, when, after mentioning Thales and Sulpicius Gallus, who had both predicted eclipses, he adds, "that Hipparchus had foretold the revolution (of the eclipses) of the sun and moon for 600 years, comprehending the months, days, and hours of different nations, and the situation of places," by which it would seem that the latitudes and longitudes of these places were particularly given. But the fullest and strongest authority for appropriating this invention to Hipparchus, is that of Ptolemy in his "Geography," (I. i. c. 4.) who says, "that Hipparchus was the only author who had given the elevations of the north pole of a few cities, in proportion to the great number that were to be delineated, and such too as lay under the same parallels, &c. &c." And yet it is somewhat remarkable that though latitudes and longitudes were in this manner introduced and pointed out by Hipparchus, yet they were so little attended to till the days of Ptolemy, that none of the intermediate authors, such as Strabo, Vitruvius and Pliny, all of whom minutely described the geographical situation of places according to the length and breadth of the gnomon, have ever given us the least hint of the latitude or longitude of any one place whatever in the language of degrees and minutes.

When the true principles of geography were thus pointed out by this new invention of latitude and longitude, it was no wonder that maps were at once made to assume a new form of projection essentially different from those in use prior to this period. For the history of the construction of maps, see Map.
GEOPGRAPHY.

were measured or surveyed with the utmost care by the Romans."

Vegetius De Re Mil. (I. iii. c.6) has well described the surveys of particular provinces, with which every Roman general was regularly furnished before his march. "Ethi- cus, in the preface to his "Cosmographia," further informs us, that Julius Caesar ordered a general survey to be made of the whole Roman empire by a decree of the senate: selecting for this purpose persons well instructed in every branch of philosophy. The three surveyors were Zenodorus, Theodorus, and Polyeuctus, each of whom was appointed to survey a different division of the empire. This survey commenced in the conship of Julius Caesar and Marc Antony, in the year 44 B.C., and continued for twenty-five years one month and ten days, to the con- ship of Septimius Severus and Lucrinus Cnina, in the year 19 B.C. The Roman itineraries that are still extant, evidently show with what accuracy their surveys were made in every province; and Pliny has filled the 36, 46, and 46th books of his Natural History with the geographical distances that were thus measured.

Before the Romans engaged in this business, Necho, king of Egypt, ordered the Phoenicians to make a survey of the whole coast of Africa; which they accomplished in three years; Darius procured the Ethiopic sea, and the mouth of the Indus, to be surveyed. Thales of Miletus, Anaximander his disciple, who is said to have constructed the first map; Democritus, Eudoxus, &c., who made the use of maps common in Greece; Aristocrates of Miletus, who presented to Chrenon, king of Sparta, a table of bals, on which he had described the known earth, with its seas and rivers; and other Greeks, availing themselves of the elements derived from the Chaldeans and Egyptians, prosecuted the study and enlarged the extent of this science. It appears that in the time of Socrates geographical maps were used at Athens; for this philosopher humbled the pride and boast of Alcibiades, by defining him to point out his territories in Attica in a map; and Pliny relates (I. vi. c. 17) that Alexander, in his expedition into Asia, took two geographers, Dio- setus and Acheta, to measure and describe the roads, and that from their itineraries the writers of the following ages took many particulars. Indeed, this may be observed, that whereas most other arts are sufferers by war, geography and fortifi- cation have been improved thereby. We also learn from Strabo, that a copy of Alexander's survey was given by Xenocrates, his treasurer, to Patrocles the geographer, who, as Pliny informs us, was an immortal of the schools of Socrates and An- tieuchus. His book on geography is often quoted both by Strabo and Pliny: and it appears that this author furnished Eratothenes with the principal materials and authorities for constructing the oriental part of his map of the then known world. For the voyages of Patrocles under Socrates, upon the Caspian sea, and elsewhere, were a kind of supplement to those measurements given by Bucrot and Dionysus already mentioned, and by Nearchus and Onesicritus, the two admirals who were employed under Alex- ander, and therefore Pliny quotes them immediately after. It appears likewise from the same passage, that Megasthenes and Dionysius were two surveyors sent into India by Ptolemy Philadelpbus, for the purposes of geography: and their authority was sometimes set in opposition to Patrocles by Hipparchus, in his criticism upon Erato- thenes's geography. (Strabo, lib. ii. passim.) From the memorable era of Alexander's expedition and conquest, and those of his immediate successors, geography began to assume a new face and form. For Eratothenes, who is de-

termediately considered as the great father of chronology, distin-
guished himself by the cultivation of the science of geo-

graphy. (See the article Eratothenes.)

We shall now recite the names of some of the principal persons who have contributed to the improvement of geography. Pytheas, the famous geographer of Marseille, flourished in the time of Alexander; and Aristotle seems to have been no less conversant with geography than philosophy: after Alexander, Seleucus Nicanor, Theophrastus, the disciple of Eratothenes, who published three books of geographical commentaries, and corrected a chart of Anaxi-

mander, Hipparchus, who corrected the observations of Eratothenes, and thus furnished occasion for a dispute which greatly contributed to the improvement of geogra-

phy, Agatharcides of Chiusus, who lived under Ptolemy Philomotor, and Meles, who, about fifty years after him, published a description of the whole world; Artemi-
dorus of Ephesus, who gave a description of the earth in eleven books, often cited by Strabo and Pliny, and many others, whose names it would be tedious to enumerate, distinguished themselves by the cultivation and improvement of this science. Geography was transferred, with the other arts, from Greece to Rome, as we have already mentioned. Varro's works contain many geographical remarks: Zenodorus, Theodorus and Polyeuctus were em-

ployed under the conjubium of Julius Caesar and Marc Antony, in surveying and measuring the globe. (See the preceding part of this article.) The commentaries of Caesar are well known. Ptolemy encouraged Posidonius, who made an imperfect memoir of the earth by celestial observations, in different places under the same meridian. (See Degree). Augustus was a distinguished patron and promoter of this science; under whom Strabo published his geography. And the taste for the study and advance-

ment of geography was greatly encouraged under Tibnius, Claudius, Vespasian, Domitian, and Adrian. Iulius of Charax, who lived to the commencement of the first century of the Christian era; Pomponius Mela, who published a book entitled "De Situ Orbis"; Metius Pomponianus, who, having depicted the earth on a parchment, fell a sacrifice to the jealousy of Domitian, the emperor suspecting that he aimed at the empire; Pliny the naturalist, who has de-

scribed the countries known in his time in the third, fourth, fifth and sixth books of his Natural History; Marinus the Tyrian, who corrected and enlarged the discoveries of preceding geographers; and the emperor Antonius, de-

serve particular mention. This abstract of the history of ancient geographers, notwithstanding whole successive peri-

ods geography was still in a very imperfect state, brings us to a period, about the 150th year of the Christian era, in which Ptolemy of Alexandria contributed greatly to the improvement of this science, by a more ample and accurate description of the terrestrial globe than any had yet given of it. He availed himself of numerous observations and ancient charts; he corrected the mistakes and supplied many defects of others; and by reducing the distances of places on the earth to degrees and minutes, after the manner of Posidonius, making use of the degrees of longitude and latitude, and setting the situation of places by astronomical observations, he reduced geography into a regular system, and laid a foundation for those further discoveries and improvements, which naturally resulted from the progressive, and at present advanced state of geometry, astrono-

mtry, navigation, and commerce.

In order to form a proper judgment of the benefits accruing to geography from the labours of Ptolemy, we ought to take into account the materials that were extant in his
time, and which he had actually in his possession. These
confided of various particulars, some of greater and others
of a less degree of authenticity. The principal were the
"proportions of the gnomon" to its shadow, taken by dif-
cerent astronomers at the times of the equinoxes and solstices;
"calculations" founded upon the length of the longest day;
"the measures" or computed distances of the principal
roads contained in their surveys and itineraries, and the
various "reports of travellers and navigators," who often
determined the intervals of places by hear-day and gueas-
work. All of these were to be compared together, and
digested into one uniform body or system, and after this, were
converted and translated by him into a new mathematical lan-
guage, expounding their different degrees and minutes of
latitude and longitude, according to the invention of Hippar-
chus, but which Ptolemy had the merit of carrying into
full practice and execution, after it had been neglected for
upwards of 250 years. We have no reason to suppose, that
Ptolemy had in his possession real astronomical observa-
tions sufficient to determine all the latitudes and longitudes
which he has given; so that we ought always to remember, that
their degrees of accuracy depended upon the veracity of the
fact or suggestion communicated to him, from which they
were afterwards deduced. We have therefore no reason to
be astonished at the multitude of errors that are to be found
in it, when his original materials were so imperfect for ex-
cecuting so large a work, as that of fixing the longitudes and
latitudes of all the places, coasts, bays, and rivers of the then
known world; an undertaking which, even in our days,
has not hitherto been brought to any sufficient degree of ac-
curacy. The mistakes of Ptolemy ought to be regarded
with candour, as they arose from the ignorance of the age
in which he lived, which could give him no better information,
and not from ignorance or inattention on his own part.
Nevertheless, Ricciolus, Cellarius, Paul Mulerus, and Sal-
narius have been too severe in their criticism and cenfures;
as if they were disappointed in not seeing this science in its
full maturity in the writings of Ptolemy, at a time when it
was evidently on the point of beginning to advance beyond the
 verge of its earliest infancy. They might with equal justice con-
demn the modern geographers for giving no better account
of Nova Zembla, or New Holland, or of those continents
and islands that lie on the northern or southern extremities of
the great South sea towards the two Poles; of which the
knowledge which they could obtain was very imperfect.
The principal mistakes in Ptolemy took their rise from cer-
tain astronomical observations and surveys, which were sup-
pounced to have been made with accuracy in a prior age, and
which were adopted by this great geographer as genuine;
and they have been, for want of better information, copied
by succeeding geographers and inserted in their maps, as
being, in their opinion, of acknowledged and unexceptionable
authority. These mistakes, thus introduced, maintained
their places in all maps, by a kind of unquestioned prescrip-
tion, even to the commencement of the last century, and it
unequally happened that these errors related to that part
of the world which was best known to the ancient Greeks and
Romans. Thus, Ptolemy states the latitude of Byzantium
to be 43° 5' instead of 41° 1', the latitude according to mo-
dern observations. In this particular mistake was misled
by Hipparchus, who is mentioned by Strabo (i. i.) as
having visited Byzantium, and made this observation in per-
son. The latitude of Marseilles, which was supposed to
be under the same parallel with Byzantium, was not, however,
to such a mistake, as by modern observations it has been
found to be 43° 17' 45"; and allowance being made for the
now acknowledged diminution of the obliquity of the
ecliptic, (see Ecliptic,) the result will be nearer the truth.
Another error of Ptolemy relates to the latitude of ancient
Carthage, which he has placed in 32° 20' instead of 36° 52',
the true latitude according to the best observations. This
erroneous latitude seems to have been copied or transcribed
from a passage in Strabo (i. ii.), in which it is stated that
Carthage, the gnomon has the same proportion to the
equinoctial shadow, which 11 has to 1' , whence by plain
trigonometry we shall have the latitude of 32° 28', very
near that of Ptolemy. The third capital mistake of Ptolemy
relates to the length of the Mediterranean, which is generally
measured from the straits of Gibraltar to the bottom of the
bay of Ifiss, where Alexandria, or Scanderoon, now
stands, whole ancient name was Alexandria ad Ifium.
The difference of longitude of Alexandria ad Ifium and Gibraltar,
according to Ptolemy, is 62° 1'; whereas the difference of longitude
between these two places, according to the latest
observations, is 41° 28', and Ptolemy's error is 20° 52'. This
error, which continued in all our maps, more or less,
till the beginning of the last century, took its rise from the
supposed surveys of persons of reputation, recorded by
Strabo. (See Degree, Earth, and Longitude.)
But to return from this digression,—many valuable geographical
works appeared under Dioctefian, Conftantin, and
Maximian, &c. Under the emperor Theodosius the pro-
cvincial and itinerary chart or table, since known under
the name of Peutinger, was digested and formed; and the lat-
work, that ought to be chiefly with those of the ancients,
was the Notitia Imperii, attributed to Ethicus, who lived
between the years 400 and 450 of the Christian era. The
ages of barbarism succeeded the fall of the Roman empire;
and the arts and sciences were obliged to seek refuge and pro-
tection from the Arabians and Orientalists in Asia; the
principal of whom distinguished by their attention to geo-
graphy, were Almamom, caliph of Babylon, and Abulgeda,
a Syrian prince. (See Degree.) After the revival of
learning in Europe, and particularly during the two last
centuries, geography has derived very considerable accessions
from travel, voyages, and a variety of nautical and astro-
nomical observations.
The great misfortune of ancient geography, and which
indeed confined it to such a lingering state of infancy, was
that the true method of determining with accuracy the dif-
ference of longitudes was a matter of such difficulty,
and remained so long unknown. One of the first attempts
to rectify the length of the Mediterranean was made under
the auspices of M. de Peirset in 1635; and he also, with a di-
rect view of correcting the errors in the longitudes of
different places, took particular pains to get observations made
at Marseilles, Aleppo, and Grand Cairo, of an eclipse
of the moon, which happened August 27th 1635. Before
that time the difference of longitude between Marseilles and
Aleppo had been supposed to be 45°, but by these ob-
servations it was found only to amount to 30° (the real dif-
ference has been since found to be 31° 58'); so that by this a
very considerable correction was made in the length of the
Mediterranean, by taking off the difference of one whole
hour, or 15°, at once. About this time eclipses of the sun
and moon were thought sufficient to determine the longitudes
of all places with a tolerable accuracy. But, in the event,
the ablest astronomers soon found that from these eclipses,
have carefully observed, no clear deduction could be
made of the longitude of any one place to any sufficient de-
gree of exactness. Hence several eminent astronomers,
thus Fournier, Kircher, and even Ricciolus, who had
connected the observations of no less than 56 eclipses of the
sun and moon, between the years 1560 and 1658, gave up the

GEOGRAPHY.
the correction of geography by the application of eclipses of the sun and moon alone, as a frutile and desperate undertaking. At length recourse was had to the eclipses of the satellites of Jupiter, and they were found effectual for the purpose. It was some time, however, before the theory of the secondary planets was regularly reduced to tables; and though Simon Marius first, and after him Baptista Horderus, composed ephemerides of their motions, nothing of that sort was found to be sufficiently accurate for the purposes of longitude, till M. Cassini published his tables of the revolutions and eclipses of the satellites in 1668. The first opportunity of effectually applying this theory to the rectifying of geography was suggested by M. Cassini, and taken by M. Picard in 1671 and 1672, who, at the observatory of Tycho Brahe at Uranibargh, observed two conjunctions and three eclipses of the first satellite of Jupiter, which were afterwards compared with the fame observed by M. Cassini at the observatory at Paris. This first experiment gave at once the difference of longitude in the clearest manner beyond the possibility of a doubt; and it likewise afforded the certain prospect of rectifying the whole extent of geography as to longitude, upon principles that were self-evident, and not liable to any mistake whatever. In consequence of this success, M. Picard and M. De la Hire, were immediately employed in correcting the map of France; in doing which they were obliged to contract it every where within the limits of boundaries than it was supposed, according to their former maps, to have occupied; inasmuch that Lewis XIV. jealously feared, that he found by their journey he had suffered a loss of part of his kingdom. Other academicians determined by the same method the longitude of the cities of Goree, near cape Verd, on the coast of Africa, and of Guadaloupe and Martinico in the West Indies. And when M. Cassini had corrected his tables of the satellites of Jupiter, and published a new edition of them in 1693, M. Chazelles was sent up the Levant, to observe the longitudes and latitudes of Scanderonoo, Alexandria, and Constantinople, in order to determine the length and breadth of the Mediterranean, which he executed with great ability.

Since the correction of longitudes has been introduced by means of the satellites of Jupiter, other methods have been also adopted and devised, which are as accurate and effectual for that purpose; such as the "transits of Mercury and Venus" over the body of the sun; "occultations" of the fixed stars by the moon; and since the lunar tables have been improved by M. Mayer and others, another mode, equally applicable to this important object, has occurred, by measuring from time to time the exact "differences of the moon from the sun," and "from a fixed star" of the first and second magnitude. In this mode there is a limitation of error, which so far gives a degree of satisfaction, and prepares the way for bringing the point that is thus unfetted to a more speedy and certain determination. Instruments of observation have also been improved; and time-pieces have been constructed, free in a great degree from the error and uncertainty of those that were formerly in use. See CHRONOMETER and CLOCK. See also Ephemeris and Longitude.

For a fuller account of the history of ancient geography see the preface to Bertius's edition of Ptolomey's Theatron Geographiae Veteris, fol. For a brief history of the rise and progress of geography, see Varinius's Geog. and the Introduction to Blaixe's Tables of Chronology.

The art, however, must needs have been exceedingly defective; as a great part of the globe was then unknown; particularly all America, the northern parts of Europe and Asia, with the Terra Australis, and Magellanica; and as they were ignorant of the earth's being capable of being divided round, and of the torrid zones being habitable, &c.

The principal writings on this art, among the ancients, are Ptolomey's eight books; among the moderns are, Johannes de Sacroboce, De Sphaera, with Clavius's comment; Riccioli's, Geographia and Hydrographia Reformata; Waghelius's Speculum Terrae; Dechales's Geography, in his Mundus Mathematicus; and above all, Varinius's Geographia, with Jorn's additions; to which may be added, Leibnitz's Elementa Geographiae generalis; Suring's Compendium Geographicum; Wallis's Geography, in his Elementa Mathematica; the Preface to M. Robur's Atlas; the introduction to Budaich's Geography; the works of Duval, Breu, Delille, D'Anville, Boume, Briache, Mentelle, the Sansons, Homann, Muller, and Martinieri; Pinkerton's Geography, Gordon's, Salmon's and Guthrie's Grammars, &c. Hornit Orb. ant. delineation, Clavius, Cellarius, Pomp. Molia, &c. &c.

The reader will find under the appropriate terms in this Cyclopaedia, such information concerning the subjects which they express, as is consistent with the nature and limits of the work; and it would be, therefore, altogether superfluous to detail them in this place; and, to avoid that which would be, in the future, to transcribe articles that will be found in their proper places. See ALTITUDE, ASPHICLON, ANTIPODES, ALTITUDES, CIRCLES, CLIMATE, COLORS, DEGREES, EARTH, ECLIPSE, EQUATOR, EQUINOCTIAL, GLOBE, HORIZON, LATITUDE, LONGITUDE, MAP, MERIDIAN, MOUNTAIN, OCEAN, PARALLELS, PERILOM, POLE, SPHERE, SPHÈRE OBLIQUE, PARALLEL, and RIGUT, TROPICS, ZONES, &c. &c. &c.

GEOLOGY, in a strict sense of the word, or Geog

ography, is the science which illustrates the structure, relative position, and mode of formation of the different mineral substances that compose the crust of the earth. This interesting part of mineralogy principally owes the distinguished rank it now holds among the sciences to the celebrated professor of Freiburg, who has however separated geology, or the science to which the above-mentioned definition applies, from geology in the sense in which the word is taken by him; considering the latter as a merely speculative branch of knowledge, and as having nearly the same relation to the former which astronomy has to arithmetic. While geology, left unattended upon enquiring into the primordial state of the globe, is contented with the merit of observing, of collecting and arranging simple facts in order to ascertain what can be known respecting the relative situation and ages of mineral substances.

Geology (in the sense in which the word is taken by Wernher) aspires to the higher merit of recording the events of periods, when the planetary system of which the earth forms a part was yet uncreated, and of ascribing causes to effects, and explaining phenomena, before it is ascertained whether they really have existence, or are merely the offspring of fancy and ignorance. The framers of some of the theories of extravagant notions, known by the appellation of theories of the earth (see Earth and Theories of the Earth,) have been satisfied with a very moderate share of materials for their structures, not to mention that most of them were utterly unacquainted with the nature of the substances, the origin of which they undertook to elucidate. Nothing is better calculated to suffer false than to be mentioned as the creator of a theory of the earth; nothing safer, with a moderate share of imagination and less knowledge of facts, than to frame a new theory sufficiently distinct from all its rivals to be noticed; and nothing safer than to broach opinions which, though they cannot be proved true by their authors,
are certain to be left unfretted by others. And who would be daring to waste his time in refuting, or even remembering, all the theories of the earth now extant? Their number, amounting already to above half a hundred, appears to be daily increasing, and finds its need of clarification to affit the memory; which, it must be allowed, might be more profitably employed in retaining those general observations which, unconnected with any theory of the earth, or with the Mosaic account, have in latter times been presented to the world by a few unprejudiced geognosts. Instead of prematurely endeavouring to accommodate the little geognostic knowledge we possess to the events hinted at in the sacred history of creation, which was by no means intended for a fable of geology, we should commence our researches in this field of knowledge with subjecting to a careful examination what nature produces as it were under our eyes, such as the manifold alterations that have taken place in the physiography of tracts of country almost within the memory of man. How little are we acquainted with the means which nature employs to form the very soil on which we tread, by converting into mould the various animal and vegetable causes! How few are the genuine observations we possess on the processes of alluvial deposition! on the detritus accumulated at the foot of mountains by means of the decomposition of the various rocks! how little do we know of the processes employed to produce petrifications! and how little of the circumstancies under which the latter occur! And yet many of these, and other phenomena within the sphere of human observation, will admit of considerable elucidation, and may lead to very interesting results, by applying to them found principles of logic and induction. But researches of this nature require what few are inclined to bellow upon them, the patient observation of many years; and what falls to the lot of few observers, a facility of combining and generalizing isolated facts. As an instance both of the difficulty and utility of such researches, if properly conducted, and of the little attention that has hitherto been paid to considerations that should precede any attempt at framing a system of geology, we advert only to the highly interesting discoveries made within the last twelve years, by Cuvier in the neighbourhood of Paris. It is in the confined space of the well known gypsum-formation of that part of France that this incomparable naturalist has found the ossesous remains of no less than fifteen quadrupeds, unlike any species now known to exist. Have these organized beings, it may be asked, lived in the places where their remains are found, or have they been carried thither? and are they still to be met with living, or to be considered totally or partly destroyed? It is obvious that the causes to be assigned for the occurrence of these petrifications must be diametrically opposite according as these two simple questions are answered in the affirmative or negative; and yet somebody has thought it worth while to satisfy himself respecting this circumstance; nor have any of the authors of the ten or twelve hypotheses that profess to explain the formation of the basin of Paris, been aware that in a solitary small corner of that basin, namely, at Grignon, there have been discovered by Lamarck, in the course of several years, about six hundred unknown species of shells, besides forty or fifty, of which the prototypes are supposed to be still existing.

We shall not attempt in this article to give a history of geology, which would be nothing more than a chronological exposition of the different theories of the earth (see Earth, and Theories of the Earth): nor is it to naturalists of earlier periods than the latter end of the last century, that we are indebted for genuine observations in this department of science. But much as we owe to the exertions of a Lehmans, Deluc, Dolomieu, and particularly Saffiure, who, in his celebrated agenda, has proved how well he knew the desiderata of geology, and what remained to be done to give this branch of knowledge all the perfection it is susceptible of; yet the merit of arranging, into a harmonious whole, a multitude of materials furnished by an intimate acquaintance with the internal structure of a considerable and highly interesting tract of country, is entirely due to Werner; who, being afflicted by the most profound knowledge of the various mineral sublunaries, and gifted with a happy faculty of generalizing facts, has produced a system of geology, at once simple and practical, and much more free from gratuitous assumption than all the rest. Professor Janson is the first in this country who has given an exposition of the Wernerian geognosty, composing the third volume of his "Mineralogy." The following is intended only as a brief sketch of this system, fuller details of which will be found under the various articles referred to.

The surface of the globe, considered relative to its inequalities, is divided into highland, lowland, and the bottom of the sea. The highland comprises, 1. Alpine land, composed of mountain groups or series of mountain chains; 2. Mountain chains, formed by a series of those fill more simple inequalities, called 3. Mountains; in the former we consider their length, height, form, and connection; the parts of the latter are the foot, the acclivity, and the summit. See Mountains, and Mountain Groups.

Lowland we call those extensive flat tracts which are almost entirely destitute of small mountain groups, which latter, if they occur in them, generally occupy the middle part of the lowland. The principal lowland in Europe is the eastern part of Great Britain, the north of France, the cedevant Netherlands, the northern part of Germany and Silezia, the whole of Poland, the N. W. part of Russia, towards the Ural mountains, a very small part of Sweden, namely, Gothland. The second extensive lowland plain is in the centre of Asia; it is known by the name of the Steppes, and includes almost the whole N. E. part of Russia; some smaller ones are in Arabia. The extent of the lowland of Africa is not known. America has two considerable lowland plains: the one, in its northern half, is traversed by the Mississippi and Mifouri, and borders towards the east by the Apalshian mountains, and the West India islands; the second, in South America, borders on the Andes. With these plains of the lowland are connected the river-coasts, or river valleys, in which we have to consider the bed of the river and the holm or hough land, the high and low bank of the river. (See River-coast.) The considerably rising ground with which the lowland plains are frequently marked, is, by German geognosts, called Land-hoeken when they are nearly of equal length and breadth, and Land-rücken when they have an elongated form.

The bottom of the sea, or that part of the globe which is still covered by water, may equally be considered with a view to its depressions and elevations; to the latter belong the flat, the rocky bottom, the shoals, reefs, and islands. See Sea and Island.

It is only after a diligent study of the inequalities just pointed out, that we can with advantage undertake to explore the means employed by nature to produce them; and the first step is to proceed to the examination of the physical causes of the flow, but unconspicuous changes of the globe. Observation teaches us, that most of the elevations and hollows we meet with on the surface of the earth owe their origin to the action of the atmosphere, to that of the ocean, and to volcanic fire. These powerful agents may be considered
GEOLGY.

considered with regard to their destroying, and, in consequence of this destruction, with regard to their forming effects. The waters of the ocean poison the former of these powers in a superior degree; whole maritime districts are known to have been overwhelmed by their irregular action upon the land; but also the regular motion of the sea, ebb and flood tide, currents, &c. considerably contribute to gradually changing the face of the bottom of the sea, and of the shores on which they act. The destroying effects of the atmospheric waters are both mechanical and chemical; the former are produced by long continued rain, water-spouts, ice, snow, thaws, and consequent floods, by which considerable portions of rocks are detached and carried, together with other loose materials they meet, to more or less distant places, according as the bulk of these materials or the nature of the country, either favours or impedes their progress. The chemically destroying effects of water are less rapid, and depend on the solubility of the different rocks over which they flow. The forming effects of water, both mechanical and chemical, are the natural consequence of its destructive effects; examples of the former are sandbanks, changes of coasts, &c. Of the latter, beds of salt, calcareous, and other depozitions, &c. See Waters, Atmosphere, and Ocean.

The effects of volcanic fire are destroying by means of the consumption of the inflammable materials, by defeciation and fusion; and forming by sublimation, and by the production of lavas and other volcanic ejections, by sublimation, &c. See Volcano.

From the description of the inequalities of the surface of the earth, and of the means employed in forming them, the Wernerian School proceeds to the consideration of the internal structure of the earth, the knowledge of which we derive from a careful examination of the order which nature has followed in the deposition of the mountain masses, and which is principally laid open to view in the chasms and clefts produced by floods, &c. in natural caverns and in the interior of mines. By these means we may become acquainted with four different structures, besides that of the simple fossil, which is the object of Oryctognosy; 1. The structure of rocks or mountain rocks; these are either simple (such as limestone, clay-flate, serpenite), or aggregated, in which case the principal kinds of texture of the component parts are granular, clay, porphyritic, and amygdaloidal. (See Rocks.)

2. A more general structure is that of mountain masses; these have either a simply stratified structure, &c. when a mountain, or mountain masses are composed of one species of rock divided into parallel tabular masses or strata; or they consist of alternating strata of different rocks, which in this case are called beds. Mountain masses also display what is termed forced structure, in which distinct concretions on a large scale are observable, such as the columnar, the large globular, and the club-shaped structure, several modifications of which are observed in basalt. Another variety of this structure is called tabular forced structure, which is not unlike stratification. (See Mountain Masses, and Strata.)

A still more general structure is 3. The structure of formations, which term Werner applies to a determinate alleniage of several similar and dissimilar rock masses which constitute an independent whole. If the mass is uniform throughout; if, for instance, it consists entirely of sand-flone, granite, &c. it is termed simple, whereas it is a compound formation, if it exhibits dissimilar masses, such as black coal with flint-trap, &c. Some formations constitute the principal mafs of a mountain in which they occur, (granites, clay-flate, porphyry, &c.) while others occur only imbedded (porphyry, lime-flone, &c.); and these beds, if they occur in different principal formations, and always under the same circumstances, notwithstanding the difference of the rocks in which they are found, and if, moreover, they form members of a series of formations, are considered as, and designated independent formations. If the reverse of all this is observed in single beds, they are called subordinate to the formation in which they are imbedded, as is the case with the beds of roc-flone, in the second sand-flone, &c. For some further distinctions, see Repositories, mineral. The most general of the structures we know is, 4. That of the crust of the earth, composed of rock formations, which cover each other in certain directions, and in a regular manner. As to the original extent of formations in general, Werner terms universal formations those which, without great interruption, surround the whole globe, and thus constitute the greater part of its crust; to it belong almost the whole of the primitive, transition, and flint-formation. Partial formations, on the other hand, are those that appear only in detached spots, and exhibit characters distinct from those of the universal formation; thus the deposition at Whran in Lusatia (which Werner suspects to be the result of a small and partial flood) is composed of flint-flone, lime-flone, bituminous slate and iron-chly, which all rest on loofe sand. The present extent and continuity of formations are so far different from the original, that those called universal often appear broken into small detached portions, frequently resembling partial formations, and they receive different names according to their different shapes, and the situations in which they are found. Other considerations relative to the structure of the crust of the globe are derived from the position and direction of the strata in regard to the fundamental or subjacent rock, from the direction of the strata without reference to the fundamental rock, and from the relation of the outcrops (i.e. the upper extremities of the different strata as they appear at the surface of the earth), to the exterior of the mountain; for which see Strata.

A comparison of the different classes of rocks, and their succession and stratification, points out the following distinctions. The class of rocks on which all others rest, and which, on that account, is considered as the oldest, is the class of the primitive rocks, whose texture is often more or less crystalline, a quality denoting previous chemical solution. They comprehend granite, gneifs, micaceous-flate, slate-flate, hornblend-flate, fucicte, porphyry, serpentine, and lime-flone. These rocks are mostly disposed in conformable and unbroken stratification, each newer stratum with lower level, as is the case with gneifs, mica-flate, and clay-flate, while the granite beneath will sometimes appear to rise up through them, encompassed, in various manners, by the other rocks. (See Rocks, Primitive.) The rocks next in succession are such as are likewise principally composed of chemical productions, but in which mechanical deposition is observed more abundantly the nearer they approach the following class; the rocks constituting this intermediate class are called transition-rocks. Lime-flone occurs more frequently in this than in the preceding class; the other rocks it contains are principally grey-wacke, grey-wacke flate, and clay-flate. (See Transition-Rocks.) To this succeeds, as of still later origin, the class of flint-rocks, in which the mechanical deposits occur in greater abundance, at the same time that the chemical precipitation disappears. (See Flutez-Rocks.) The next class which bears the character of still more recent formation, is entirely composed of mechanical deposits, such as sand, clay, &c. (See Rocks, Alluvial) But, besides these formations, the outgoings of which show gradually diminishing levels from the older to the newer, there are two others, the strata...
of which, instead of having parallelism with, are superin-cum-
butent on the outgoings of the other strata: they are called
the newer flate-trap, and the newer porphyry formation, and
are seen to rest both on flate-trap of very recent formation,
and on elevated primitive mountains. The former of these
formations is particularly interesting, as including rocks,
whose origin has been, and continues to be, a subject of
controversy between the Neptunists and Volcanists, such as
bafalt, wacke, &c. all of which, according to Werner, are
the results of a deluge, or sudden rise of the water at
a more recent period than that in which the flate-mountain
were formed. (See Fletz-Rocks and Trap-Formation.)
The second of these great formations, occurring in the
same unconformable stratification, consists of porphyry,
fyeneite, and pitch-flone, and is supposed of much older
origin than the newest flate-trap-formation, with which,
however, it agrees in many respects. See PORPHYRY.

No geologist before Werner has pointed out the succes-
sion in which the different suites of formations have been
deposited from the water at different periods; a succession
which shows the alterations that the fluid has undergone with
regard to the substances it held, at different times, either
chemically dissolved, or mechanically floating. Thus the
oldest of the primitive rocks contain metals almost peculiar
to them, and which, therefore, were not again deposited in
subsequent periods, such as tin, molybden, and tungsten;
and in several cases, one and the same substance, (such as
lime-flone,) though it be repeated at considerable intervals,
still adopts in each of them a peculiar character. These
suites are, 1. That of the lim-flone formation, beginning
with the primitive crystalline granular lime-flone, and
pausing, by insensible gradations, through the transition,
and flate-lime flones, into the lowermost links of the series,
viz. chalk and calcareous tuf. 2. That of the flate form-
ation: its central point is clay-flate (from which this
formation derives its name), pausing, on one hand, through
mica-flate into gneises, when the flate structure gradually
disappears, and a paillage is formed into the oldest member,
namely granite; and, on the other hand, through transition-
flate, grey-wacke flate, and grey-wacke, into the series of
flate sand-flones, and from thence into the alluvial series,
containing a flate clay, loam, sand, and gravel. 3. The trap-
formation suite: palaces from the primitive hornblende-flate,
characterized by its crystalline nature, and from the primiti-
ve green-flone, and green-flone flate, through the transition
flate-flone, into the flate-trap, formed chiefly of amygdaloid,
and from thence into the newest flate-flate-formation, con-
stituting principally of basalt, and wacke, unconformably
superincumbent on rocks of various antiquity. 4. The por-
phyry formation suite is equally characteristic in its different
members, from old primitive porphyry, down to that mentioned
above, as of similar origin with the newest flate-flate for-
mation: the nature of the different members of this formation
stands, however, in need of further examination. (See
PORPHYRY.) 5. The syenite-formation comprehends three
principal members, the oldest of which, or the primitive gyp-
sum, occurs in mica-flate and clay-flate; the second and
third are flate-gypsum, the former of them accompanying the
following, or 6. Salt-formation, which constitutes two series,
one of which occurs only with flate-gypsum, (see Fletz-
Rocks,) while the other is still forming on the bottom of
lakes, &c. (See Rock-Salt.) 7. The coal-formation suite,
comprising, besides the independent coal formation, various
varieties of coal belonging to the flate-trap formation, and
to alluvial depositions; the members of this suite require
further investigation. (See Fletz-Rocks, and Coal.) 8. The
serpent-formation suite is composed, as far as we know, of two
members, the first or older occurring with primitive rocks,
especially primitive lime-flone, in conformable stratification;
and the second or newer, found in an unconformable and
overlying position on the older rocks. See SERPENT-
LINE.

For further particulars relating to the Wernerian style
of geology, we refer to the articles STRATA, VEIN, and
WATER. Diminution of.

GEOMANCY, GEOMANTIA, a kind of divination, per-
formed by means of a number of little points, or dots, made
on paper at random; and considering the various lines and
figures which those points present; and thence forming a
pretended judgment of futurity, and deciding any question
proposed.

The word is formed of the Greek γεω, terra, earth; and
μαντις, divination: it being the ancient custom to cast
little pebbles on the ground, and thence to form their
conjectures; instead of the points afterwards made use of.

Polydore Virgil defines geomancy a kind of divination
performed by means of cards, or sticks made in the ground,
and takes the Persian Magi to have been the inventors
thereof.

GEOMETRICAL, something that has a relation to
geometry.

Thus we fay, a geometrical method, a geometrical genius,
geometrical truths, geometrical construction, geometrical
demonstration.

Geometry itself seems to lead us into errors; after once
reducing a thing to geometrical consideration, and finding
that it answers pretty exactly, we pursue the view, are pleased
with the certainty and agreement of the demonstrations,
and apply the geometry farther and farther, till we often
run nature.

Hence it is, that all machines do not succeed: that all
compositions of music, wherein the concords are the most ri-
gidly observed, are not agreeable: that the most exact astron-
omical computations do not always foretell the precise time
and quality of an eclipse, &c.

The reason is, that nature is not a mere abstract;
mechanical levers and wheels are not geometrical lines and
circles; as they are often supposed to be: the taste for tunes is
not the same in all men; nor at all times in the same man:
and as to astronomy, as there is no perfect regularity in the
motions of the planets, their orbits hardly form reducible
to any fixed, known figure.

The errors, therefore, we fall into in astronomy, music,
mechanics, and the other sciences to which geometry is ap-
p lied, do not properly arise from geometry, which is an in-
fallible science, but from the fallacy of the, or the misap-
lication of it.

GEOMETRICAL Construction of an equation, is the
contriving and drawing of lines and figures, whereby
to demonstrate the equation, theorem, or canon, to be
g eo metrically true. See Construction of Equations.

GEOMETRICAL Line or Curve, c als o algebraic line or
curve, is that whereby the relations of the abscissas to the
fem-ordinates may be expressed by an algebraic equation.
See CURVE.

Geometrical lines are distinguished into classes, orders,
or genera, according to the number of the dimensions of
the equation that expresses the relation between the ordinates
and the abscissas; or, which amounts to the same, accord-
ing to the number of points in which they may be cut by a
right line.

Thus a line of the first order will be only a right line:
hence the second, or quadratic order, will be the circle,
and the conic sections; and those of the third, or cubic order, will be the cubical and Nelian paraboloids, the cissoid of the ancients, &c.

But the curve of the first gender (because a right line cannot be reckoned among the curves) is the same with a line of the second order; and a curve of the second gender, the same with a line of the third order; and a line of an infinitesimal order that which a right line may cut in infinite points; as the spiral, cycloid, the quadratrix, and every line generated by the infinite revolutions of a radius.

However, it is not the equation, but the description, that makes the curve a geometrical one; the circle is a geometrical line, not because it may be expressed by an equation, but because its description is a postulate; and it is not the simplicity of the equation, but the efficacy of the description, which is to determine the choice of the lines for the construction of a problem. The equation that expresses a parabola is more simple than that which expresses a circle; and yet the circle, by reason of its more simple construction, is admitted before it.

The circle and the conic sections, if you regard the dimensions of the equations, are of the same order; and yet the circle is not numbered with them in the construction of problems; but by reason of its simple description is preferred to a lower order, viz. that of a right line; so that it is not improper to express that by a circle, which may be expressed by a right line, but it is a fault to construct that by the conic sections, which may be constructed by a circle.

Either, therefore, the law must be taken from the dimensions of equations, as observed in a circle, and so the distinction be taken away between plane and solid problems; or the law must be allowed not to be strictly observed in lines of superior kinds; but that some, by reason of their more simple description may be preferred to others of the same order, and be numbered with lines of inferior orders.

In constructions that are equally geometrical, the most simple are always to be preferred; this law is so universal as to be without exception. But algebraic expressions add nothing to the simplicity of the construction; the bare descriptions of the lines here are only to be considered; and these alone were considered by those geometers, who joined a circle with a right line. And as these are easy or hard, the construction becomes easy or hard: and therefore it is foreign to the nature of the thing, from anything else to establish laws about constructions.

Either, therefore, with the ancients, we must exclude all lines beside the circle, and perhaps the conic sections, out of geometry; or admit all according to the simplicity of the description; if the trochoid were admitted into geometry, we might, by its means, divide an angle in any given ratio; would you therefore blame those who would make use of this line to divide an angle in the ratio of one number to another; and contend, that this line was not defined by an equation, but that you must make use of such lines as are defined by equations?

If, when an angle were to be divided; for instance, into 1001 parts, we should be obliged to bring a curve defined by an equation of above a hundred dimensions to do the business; which nobody could describe, much less understand; and should prefer this to the trochoid, which is a line well known, and described easily by the motion of a wheel, or circle; who would not see the absurdity?

Either, therefore, the trochoid is not to be admitted at all in geometry; or else, in the construction of problems, it is to be preferred to all lines of a more difficult description, and the reason is the same for other curves. Hence, the trochoid, of an angle by a conchoid, which Archimedes, in his Lemmas, and Pappus, in his Collections, have preferred to the invention of all others in this case, must be allowed to be good; since we must either exclude all lines, before the circle and right line, out of geometry, or admit them according to the simplicity of their descriptions; in which case the conchoid yields to none except the circle. Equations are expressions of arithmetical computation, and properly have no place in geometry, except as far as quantities truly geometrical (that is, lines, surfaces, solids, and proportions) may be said to be some equal to others: multiplications, divisions, and such sort of computations, are newly received into geometry, and that apparently contrary to the first design of this science; for whoever considers the construction of problems by a right line and a circle, found by the first geometers, will easily perceive that geometry was introduced that we might expeditiously avoid, by drawing lines, the tediousness of computation.

It should seem, therefore, that the two sciences ought not to be confounded together: the ancients so industriously distinguished them, that they never introduced arithmetical terms into geometry; and the moderns, by confounding both, have lost a great deal of that simplicity, in which the elegance of geometry principally consists. Upon the whole, that is arithmetically more simple, which is determined by more simple equations; but that is geometrically more simple which is determined by the more simple drawing of lines; and in geometry, that ought to be reckoned best which is geometrically most simple.

Geometrical Locus, or Place, called also simply locus. See Locus.

Geometrical Medium. See Medium.

Geometrical Method of the Ancients. It is to be observed that the ancients established the higher parts of their geometry on the same principles as the elements of that science, by demonstrations of the same kind; and that they seem to have been careful not to suppose any thing done, till by a previous problem they had shown how it was to be performed. For less did they suppose any thing to be done that cannot be conceived, as a line or series to be actually continued to infinity, or a magnitude to be diminished till it becomes infinitely less than what it was. The elements into which they resolved magnitudes were finite, and such as might be conceived to be real. Unbounded liberties have been introduced of late, by which geometry, which ought to be perfectly clear, is filled with mysteries. See Maclaurin's Fluxions, Int. p. 39, seq.

Geometrical Office. See Curve, Evolute, and Osculum.

Geometrical Pace, is a measure consisting of five feet. See Pace, and Foot.

Geometrical Plane, in Architecture. See Plane.

Geometrical Plane. See Plane.

Geometrical Progression. See Geometrical Progression.

Geometrical Proportion, called also absolutely, and simply, proportion, is a fimilitude or identity of ratios. See Ratio.

Thus, if A be to B, as C to D, they are in geometrical proportion: § 8, 49, 50, and 15, are geometrical proportionals. See Proportion.

Geometrical Solution of a problem, is when the problem is directly solved according to the direct principles and rules of geometry, and by lines that are truly geometrical.
In this sense we say, geometrical solution in contradistinction to a mechanical, or instrumental solution, where the problem is only solved by ruler and compasses.

The same term is likewise used in opposition to all indirect and inadequate kinds of solutions, as by infinite series, &c.

We have no geometrical way of finding the quadrature of the circle, the duplicature of the cube, or two mean proportionals; but mechanical ways, and others, by infinite series, we have.

The ancients, Pappus informs us, in vain endeavoured at the trisection of an angle, and the finding out of two mean proportionals by a right line, and a circle. Afterwards they began to consider the properties of several other lines; as the conicoid, the cissoid, and the conic sections; and by some of their endeavours to solve those problems. At length, having more thoroughly examined the matter, and the conic sections being received into geometry, they distinguished geometrical problems into three kinds; viz.

1. Plane ones, which, deriving their original from lines on a plane, may be regularly solved by a right line, and a circle.

2. Solid ones, which are solved by lines deriving their original from the consideration of a solid; that is, of a cone.

3. Linear ones, to the solution of which are required lines more compounded.

According to this distinction we are not to solve solid problems by other lines than the conic sections; especially if no other lines but right ones, a circle, and the conic sections, must be received into geometry.

But the moderns, advancing much farther, have received into geometry all lines that can be expressed by equations; and have distinguished, according to the dimensions of the equations, those lines into kinds; and have made it a law, not to construct a problem by a line of superior kind, that may be constructed by one of an inferior kind.

**GEOMETRICAL SQUARE.** See SQUARE.

**GEOMETRICAL TABLES.** See PLAIN TABLE.

**GEOMETRICALLY PROPORTIONALS.** are quantities in continual proportion; or which proceed in the same constant ratio: as 6, 12, 24, 48, 96, 192, &c.

They are thus called, in contradistinction to equi-different quantities; which are called, though somewhat improperly, **arithmetically proportionals**.

**GEOMETRY,** the science, or doctrine of extension, or extended things; that is, of lines, surfaces, or solids.

The word is Greek γεωμετρεῖς, formed of γῆς or γεωργίας, earth; and μετρεῖς, to measure; it being the necessity of measuring the earth, and the parts and places thereof, that gave the first occasion to the invention of the principles and rules of this art; which has since been extended and applied to numerous other things; inasmuch that geometry, with arithmetic, is now the general foundation of all mathematics.

Hercodotus, lib. ii. p. 102. edit. Weffelingii, Diodorus, lib. i. § 81, or vol. i, p. 91. edit. Amori. 1746. and Strabo, lib. xvii. vol. ii. p. 1159. edit. Amori. 1707. affir. that the Egyptians were the first inventors of geometry; and that the annual inundations of the Nile were the occasion of it; for that river bearing away all the bounds and landmarks of men's estates, and covering the whole face of the country, the people, say they, were obliged to dilucidate their lands by the consideration of their figure and quantity; and thus, by experience and habit, formed themselves a method, or art, which was the origin of geometry. A farther contemplation of the draughts of figures, of fields thus laid down, and plotted in proportion, might naturally enough lead them to the discovery of some of their excellent and wonderful properties; which speculation continually improving, the art became gradually improved, as it continues to do to this day. Josephus, however, seems to attribute the invention to the Hebrews; and others, among the ancients, make Mercury the inventor. Polyd. Virgili. De Invent. Rer. lib. i. cap. 18.

From Egypt geometry passed into Greece, being carried thither, as some say, by Thales; where it was much cultivated and improved by himself. Pythagoras, Anaxagoras, Chrysippus, and Plato, who testified his conviction of the necessity and importance of geometry in order to the successful study of philosophy by the following inscription on the door of his academy, _αὐτῷ τὸν μαθητῶν ἡ ἐπιστήμων, ut no one ignorant of geometry enter here._ Plato, conceiving that geometry was too much refined and restricted an appellation for this science, substitut ed for it the more extensive name of "Menfruration," and others have denominated it "Pantometry." Other more general and comprehensive appellations are more suitable to its extent, more especially in the present advanced state of the science; and accordingly some have defined it as the science of inquiring, inventing, and demonstrating all the affections of magnitude. Proclus calls it the knowledge of magnitudes and figures, with their limitations; as also of their ratios, affections, positions, and motions of every kind. About fifty years after Plato, lived Euclid, who collected together all those theorems which had been invented by his predecessors in Egypt and Greece, and digested them into fifteen books, entitled the Elements of Geometry; and those propositions which were not satisfactorily proved, he more accurately demonstrated. (See Euclid.) The next to Euclid of those ancient writers, whose works are extant, is Archimedes of Susa, who flourished in the time of Ptolemy Euergetes, about two hundred and thirty years before Christ, and about a hundred years after Euclid. (See his biographical article.) The third ancient geometer, whose writings remain, is Eratosthenes of Cyrene, who was famous about the same time with Archimedes. (See Eratosthenes.) We can only mention Eudoxus of Cnidus, Archytas of Tarantum, Philolaus, Eratosthenes, Arifarchus of Samos, Diocedes, the inventor of the quadratrix, Mencius, his brother and the disciple of Plato, the two Aristeues, Conon, Thaetides, Nicoteles, Leon, Theodorus, Heronius, and Nicomedes, the inventor of the conchoid; besides whom, there are many other ancient geometers, to whom this science is indebted.

The Greeks continued their attention to geometry even after they were subdued by the Romans. Whereas the Romans themselves were so little acquainted with this science, even in the most flourishing time of their republic, that they gave the name of mathematicians, as Tacitus informs us, to those who pursued the chimera of divination and judicial astrology. Nor were they more disposed to cultivate geometry, as we may reasonably imagine, during the decline, and after the fall of the Roman empire. The case was different with the Greeks; among whom we find many excellent geometers since the commencement of the Christian era, and after the translation of the Roman empire. Ptolemy lived under Marcus Aurelius; and we have extant the works of Pappus of Alexandria, who lived in the time of Theodosius; the commentary of Eutocius, the Aequidens, who lived about the year of Christ 540; on Archimedes's
GEOMETRY.

Archimedes's mensuration of a circle; and the commentary on Euclid, by Proclus, who lived under the empire of Amalarius.

The conquent inundation of ignorance and barbarism was unfavourable to geometry as well as to the other sciences; and those few who applied themselves to this science, &c. were calumniated as magicians. However, in those times of European darkneas, the Arabsians were distinguished as the guardians and promoters of science; and from the ninth to the fourteenth century they produced many astronomers, geometers, geographers, &c. from whom the mathematical sciences were again received into Spain, Italy, and other parts of Europe, somewhat before the beginning of the third century. Some of the earliest writers after this period are Leonardo Pisano, Lucas Pacioli or de Burgos, and others between 1520 and 1560. After this period appeared many editions of Euclid, or commentaries upon his Elements; e.g. Orontius Finaeus, in 1582, published a commentary on the first five books; as did James Peletarius in 1577; and about the same time Nicholas Tartaglia published a commentary on the whole 15 books. We might here mention other editions or commentaries; such are those of Commandine, Clavis, Bilingly, Schémbelius, Harlins, Dafylodius, Ramanus, Herigon, Stevins, Saville, Barrow, Tucquet, Dechales, Turnier, Scarborough, Keill, Cuff, Stone, and many others. (See Elements.)

At the revival of letters, there were few Europeans capable of translating and commenting on the works of the ancient geometers; and geometry made little progress till the time of Des Cartes, who published his Geometry in 1637. However, not to mention all those who extended geometry beyond its elementary parts, such as Theobaldus in his Spheres, Serenus in his sections of the cone and cylinder, Kepler in his Nova Stereometria, &c.; in 1635, Bonaventure Cavalierus, an Italian of the order of Jefuits, published his "Geometry of Indivisibles:" Torricelli his "Opera Geometrica:" Viviani, his "Divinaciones Geometricas," "Exercitatio Mathematica," "De Locis Solidi," "De Maximi et Minimi," &c.; Vieta, his "Effetto Geometrica," &c.; Gregory St. Vincent, in 1647, published his treatise, entitled "Quadratura Circuli & Hyperbolae," a work abounding with excellent problems and paradoxes; and Pascal, about the same time, published his treatise of the cycloid. Geometry, as far as it was capable of deriving aid and improvement from the arithmetic of infinities, was indebted to the labours of Fermat, Barrow, Wallis, Mercator, Boucker, J. Gregory, Huygens, and others, to whom we may add Newton and Leibnitz. (See Fluxions.) But for Isaac Newton contributed to the progress of pure geometry by his two treatises, "De Quadratura Curvarum," and "Enumeratio Linearum Tertii Ordinis" (see Curve); and still farther by his incomparable and immortal work, entitled "Philosophiae Naturalis Principia Mathematica," which will always be considered as the most extensive and successful application of geometry to physics. We cannot forbear transcribing in this place the compliment paid to this author by the editors of the Encyclopaedia, who, considering the various monuments of the author's genius, and that he had made his principal discovery before the age of twenty-four, are tempted, they say, to subscribe to the words of Pope, that the sagacity of Newton astounded even celestial intelligences, and that they contemplate him as a being occupying a kind of middle station between man and themselves; or at least they cannot forbear exclaiming, "bonum homini quid praestat, quando differt, quod unum in multitude sit, et unum in multitudine alterum!"

The modern geometers are innumerable; and the names of Cote, Maclaurin, R. Simfon, T. Stewart, T. Simfon, &c. not to mention living writers, will always be held in esteem and veneration by those that are devoted to the study of geometry and mathematics. See Elements.

The province of geometry is almost infinite: few of our ideas but may be represented to the imagination by lines, upon which they become of geometrical consideration: it being geometry alone that makes comparisons, and finds the relations of lines.

Astronomy, music, mechanics, and, in a word, all the sciences which consider things susceptible of more and less, &c. all the precise and accurate sciences, may be referred to geometry; for all speculative truths consisting only in the relations of things, and in the relations between those relations may be all referred to lines. Consequences may be drawn from them; and these consequences, again, being rendered sensible by lines, they become permanent objects, which may be constantly exposed to a rigorous attention and examination; and thus we have infinite opportunities both of enquiring into their certainty, and purifying them farther.

The reason, for instance, why we know so dif tinely, and mark so precisely, the concords called octave, fifth, fourth, &c. is that we have learnt to express sounds by lines, &c. by chords accurately divided; and that we know, that the chord, which sounds octave, is double of that with which it makes octave; that the fifth is the sesquialterate ratio, or as three to two; and of the rest. The ear itself cannot judge of sounds with such a nice precision; its judgments are too faint, vague, and variable, to form a science. The finest bent-tuned ear cannot distinguish many of the differences of sounds; whence many musicians deny any such differences; as making this sense their judge. Some, for instance, admit no difference between an octave and three dittones; and others, none between the greater and lesser tone; the comma, which is the real difference, is insensible to them; and much more the chroma, which is only half the comma.

It is only by reason, then, that we learn, that the length of the chord which makes the difference between certain sounds being divisible into several parts, there may be a great number of different sounds contained therein, useful to music, which yet the ear cannot distinguish. Whence it follows, that had it not been for arithmetic and geometry, we should have had no such things as regular fixed music; and that we could only have succeeded in that art by good luck, or force of imagination; i.e. music would not have been any science founded on incontestable demonstrations; though we allow, that the tunes composed by force of genius and imagination, are usually more agreeable to the ear than those composed by rule. So, in mechanics, the heaviness of a weight, and the distance of the centre of that weight from the fulcrum, or point by which it is sustained, being susceptible of plus and minus, they may both be expressed by lines; whence geometry becomes applicable to this science; in virtue of which, infinite discoveries have been made, of the utmost use in life.

Geometrical lines and figures are not only proper to represent to the imagination the relations between magnitudes, or between things susceptible of more and less; as spaces, times, weights, motions, &c. but they may even represent things which the mind can no otherwise conceive, e.g., the relations of incomensurable magnitudes.

It must be observed, that this use of geometry among the ancients was not strictly scientific, as among us; but rather symbolical: they did not argue, or deduce things and properties unknown, from lines; but represented or delineated by them things that were known. In effect, they were not used as means or instruments of discovering, but as images or characters, to preserve, or communicate, the discoveries that were already made.
"The Egyptians," Gale observes, "used geometrical figures, not only to express the generations, mutations, and deflations of bodies; but the manner, attributes, &c. of the spirit of the universe, who, diffusing himself from the centre of his unity, through infinite concentric circles, pervades all bodies, and fills all space. But of all other figures they most affected the circle and triangle; the first, as being the most perfect, simple, capacious, &c. of all figures: whence Hermes borrowed it to represent the divine nature; defining God to be an intellectual circle or sphere, whose centre is everywhere, and circumference nowhere." See Kirch. Ædip. Ægyptiac. and Gale Phil. General. lib. ii. cap. 2.

The ancient geometry was confined to very narrow bounds, in comparison of the modern. It only extended to right lines and curves of the first order, or conic sections; whereas into the modern geometry new lines of infinitely more, and higher orders are introduced.

Geometry is commonly divided into four parts, or branches; planimetry, altimetry, longimetry, and stereometry; which see respectively.

Geometry, again, is distinguished into theoretical or speculative, and practical.

The former contemplates the properties of continuity; and demonstrates the truth of general propositions, called theorems.

The second applies those speculations and theorems to particular uses in the solution of problems.

Geometry, speculative, again may be distinguished into elementary and sublimer.

Geometry, elementary or common, is that employed in the consideration of right lines, and plane surfaces, and solids generated from them.

Geometry, higher, or sublimer, is that employed in the consideration of curve lines, conic sections, and bodies formed of them.

The writers who have cultivated and improved geometry may be distinguished into elementary, practical, and those of the sublimer geometry.

The principal writers of elements, see enumerated under Elements.

Those of the higher geometry are Archimedes, in his books De Sphaera, Cylindro, and Circul Delineamento; as also De Spirallibus, Conoidibus, Spheroideibus, De Quadratura Parabolae, and Arenaria: Kepler, in his Stereometria Nova; Cavalierius, in his Geometria Individivilibium; and Torricellius, De Solidis Spheraulis; Pappus Alexander, in Collectibis Mathematicis; Paulus Galilaeus, in his Mechanis and Statibus; Barrow, in his Lectiones Geometricae; Haygus, De Circuli Magnitudine; Ballalidas, De Lineis Spirallibus; Schooten, in his Exercitationis Mathematicae; De Billy, De Propriitate Harmoniae; Lalva, De Cycloide, For. Erneft. Com. ab Harfenheim, in Diastome Cirellorum; Viviani, in Exercit. Mathematic., De Formacione & Menatura Punctum; Bap. Palma, in Geomet. Excercitation, and Apoll. Pergamin, De Sectione Rationem. For practical geometry, the fullest and completest treatises are those of Mallet, written in French, but without the demonstrations; and those of Schwenter and Cantzlerus, both in High Dutch. In this class are likewise to be ranked Clavius's, Tacquet's, and Ozanam's Practical Geometries; De la Hire's Ecole des Arpenteurs; Reinhold's Geodez; Hartman Beyers's Stereometria; Voigtel's Geometria Subterranea; all in High Dutch: Hufhus, Galileus, Goldmannus, Scheffelt, and Ozanam, on the Sector. &c. &c. &c.

The science of geometry is founded on certain axioms, or self-evident truths (see Axiom); it is introduced by definitions of the various objects which it contemplates, and the properties of which it investigates and demonstrates, such as points, lines, angles, figures, surfaces, and solids:—lines again are considered as straight or curved; and in their relation to one another, either as inclined or parallel, or as perpendicular:—angles as right, oblique, acute, obtuse, external, vertical, &c. —figures, with regard to their various boundaries, as triangles, which are, in respect of their sides, equilateral, isosceles, and scalene, and in reference to their angles, right-angled, obtuse-angled, and acute-angled; as quadrilaterals, which comprehend the parallelogram, including the rectangle and square, the rhombus and rhomboid, and the trapezium and trapezoid; as multilaterals or polygons, comprehending the pentagon, hexagon, heptagon, &c.; and as circles:—and as solids, including a prism, parallelepipedon, cube, pyramid, cylinder, cone, sphere, and the frustum of either of the latter. We shall not here attempt to compile a complete system of geometry, as it would occupy too many of our pages, in a work from its nature protracted and enlarged to a very great extent; and this is the less necessary, because the method will find under the titles above enumerated, and others naturally connected with and derived from them, the most essential and important principles of geometry, together with the operations that are founded upon them; and because any person who is desirous of acquainting himself with the science of geometry, in its whole extent and application, will have recourse to one or other of those numerous treatises, in a more enlarged or more compendious form, which may be easily procured. The Elements of Euclid by Dr. R. Simpon occur first to our recollection, and deserve particular recommendation; but the object of the geometrical student may be satisfactorily attained by T. Simpson's Geometry, or by the treatises of Emerson, Hutton, Bonnycaill, Leibfe, &c. &c.

But as the analytic method of treating geometrical questions is less generally known, and as complete treatises on this subject are only to be found in foreign works, we have been induced to devise a considerable space to this part of the science; the following treatise is chiefly compiled from the "Feuilles d'Analyse" by Monge, which were published in separate portions for the use of the polytechnic school, and afterwards collected in a quarto volume. A more elementary work has lately been published by Garnier in octavo, to which the reader is referred.

Geometry, Analytic.—Method of defining the position of a point in a plane.

A point M (Analyzis, Plate VIII, fig. 1.) is defined by referring its position to two lines, as AY, AX, generally at right angles to each other, but they may be inclined at any given angle.

If M Q be drawn perpendicular to AY, and M P perpendicular to AX, then QM, MP, are called the co-ordinates of the point M; the distance of the point from A Y is usually denoted by x, and its distance from A X by y.

The point of intersection of the two lines AY, AX is called the origin of the co-ordinates, and the lines A Y, A X, produced each way to Y' and X', are called axes.

If the distance of the point M from these axes is given, viz., M Q = a, M P = b, then x = a, y = b is the equation to the point M.

But if the point M be situated in any other of the angles, the sign of a and b will vary, and these variations are governed by the same rules, as the lines and coines in trigonometry.

For instance, if the point M is situated in the angle Y A X,
Y A X, then \( x = \pm a, y = \pm b \). The equation of \( M' \) is \( x = -a, y = \pm b \). The equation of \( M' \) is \( x = -a, y = -b \). If the point M is situated on the line A X, then \( y = c, x = a \).

If it is situated on A Y, then \( x = c, y = b \), and at the point A, \( x = 0, y = c \).

The point M may likewise be defined by the length of the line A M, and by the angle \( \varphi \), which makes with the axis A X. If this length be expressed by \( s \), and the angle by \( \varphi \), \( s = \varphi ; \varphi = A \).

\( \alpha \) being the number of degrees contained in the angle \( \varphi \), and \( \varphi \) the value of \( \alpha \).

The position of a straight line is determined in a plane by the co-ordinates of two of its points, or by the co-ordinates of a single point, and the angle which it makes with one of its axes; the latter is the method most usually employed.

If the line passes through the origin of the axes, its position is determined by the angle which it makes with the axis.

We shall first consider this case as being the most simple. Let it be proposed to determine the relation between the co-ordinates of any point in such a straight line.

Let us take, for example, a point M (fig. 2.) whose abscissa is \( A P = x' \), its ordinate \( M' = y' \); these co-ordinates, like those of the other points, make an angle \( \varphi \) with each other, which is that of the axes, we shall have this equation:

\[
\frac{y'}{x'} = \tan \alpha \]

and for the points \( M', M'', \&c. \) whose co-ordinates would be \( x', y' \); \( x'', y'' \), &c., we have

\[
\frac{y''}{x''} = \frac{\tan \alpha}{\tan (\varphi - \alpha)} \]

If \( x, y \) represent the co-ordinates of any point in A L, the general equation will be

\[
y = \frac{\tan \alpha}{\tan (\varphi - \alpha)} x \] ........................ (1)

Thus \( x \) becomes successively \( x', x'', \&c. \) changes to the corresponding ordinates \( y', y'', \&c. \). The formula (1) is called the equation of a straight line; it is the algebraic enunciation of a property common to all its points, and is thus written:

\[
y = \frac{\tan \alpha}{\tan (\varphi - \alpha)} x \] ........................ (2)

The abscissa \( x \) being given, the ordinate \( y \) may be deduced.

When the angle \( \alpha \) varies, the line changes its position, turning round the point A; thus another ordinate \( y \) corresponding to the same abscissa \( x \), which also happens if \( \alpha \) varies, but it is essential to observe that for all the values both of \( \alpha \) and \( \varphi \), the equation (2) retains the same form.

If it should be required to find the relation between the co-ordinates of a point of a straight line \( R'L' \), situated in any manner whatever, then if A L be drawn parallel to \( R'L' \), passing through the point A, we shall observe that for the same abscissa \( x \) every ordinate of A L, for example; \( P'M' \) will be augmented by the same quantity \( AR = b \); let \( y + b \) be represented by \( y \), equation of \( R'L' \) will be according to (2);

\[
y = \frac{\tan \alpha}{\tan (\varphi - \alpha)} x + b \] ........................ (3)

Here \( a \) and \( b \) give the position of the straight line \( R'L' \); when these quantities are known it may be constructed, but if the line be subject to any particular conditions, \( a \), to pass through a given point; to be either parallel or perpendicular to a given line; to pass through two points, \( \&c. \) \( x \) and \( b \) become unknown quantities, as we shall see immediately.

Let us suppose the quantities \( a \), \( \varphi \) and \( b \) given, and that it is required to construct the straight line \( y = \frac{\tan \alpha}{\tan (\varphi - \alpha)} x + b \); the problem is reduced to finding two of these points; we endeavour to find the points in which the line cuts the two axes A X, A Y (fig. 3) the intersection R being the only point of the line in which \( y = c, \) and \( R' \) the only point of the same line in which \( y = c \); we suppose, successively, \( x = c, y = c \), and we shall find \( y = \frac{\tan \alpha}{\tan (\varphi - \alpha)} b = A R' \); taking, then, A R' on the other side of the point A, if it is negative, and A R on A Y if it is positive, the line drawn through these two points will be that belonging to the equation.

If the equation to a straight line \( y = x + 1 \) be supposed to refer to two axes, making an angle of 45° with each other, and the inclination \( \alpha \), which the line makes with the axis X be required; since \( \frac{\tan \alpha}{\tan 45° - \alpha} = 1 \), \( \tan \alpha = \frac{1}{\sqrt{2}} \),

\[
\frac{1}{\sqrt{2}} \tan \alpha \] ........................ (4)

The value of \( b \) remaining constant, the line takes every possible position round the point R (fig. 2.) for every possible angle from \( \alpha \) to 360°; for every angular value of \( \alpha \), taken with every ordinate \( b \), positive and negative, the line will pass through every point of the axis Y Y'. There exists, therefore, no line in the same plane which cannot be defined by equation (3), provided \( b \) and \( a \) are taken of a proper value.

The angle \( \beta \) has no influence on the position of the line; the variations of this angle only affect the inclination of the ordinate upon the axis of the abscissa; so that for the same abscissa, the ordinate corresponds with another point in the line.

But, in general, the co-ordinates are supposed rectangular in which case, \( \tan \beta = \tan 90° = 1 \), and \( \frac{\sin (\varphi - \alpha)}{\cos \varphi} = \cos \alpha \); and equation (3) becomes \( y = x \tan \alpha + b \), \( a + b \) being the angle of slope.

When the straight line passes through the origin of the co-ordinates, its equation becomes \( y = ax \).

This equation is constructed by taking \( A P = 1 \) radius, and then setting off from a scale of equal parts the value of \( a \) on the perpendicular P M (fig. 4); P M being equal to \( a, M \) will be a point in the required line.

We may now construct the equation \( y = x + 1, y = -x - 1 \).

The two lines cut the axis A X in the same point, and are situated similarly to it, one above, the other below; they are moreover perpendicular to each other.

The straight lines \( y = -x - 1, y = -x + 1 \), are parallel, because they make the same angle with the axis, having the same tangent, \( -1 \).

The straight line expressed by the equation \( y = x \sqrt{x - 1} \) is reduced to a point on the axis Y below the origin, and distant from it by a quantity equal to unity, for every other value than zero, the ordinate is imaginary.

The
GEOMETRY.

The problems relating to a straight line, in general, require the unknown quantities \(a\) and \(b\) to be determined, so that the required line \(y = ax + b\) (1) may have the required position.

PROBLEM I.

To make a straight line pass through two given points. Let the co-ordinates of one point be \(x', y'\), and of the other \(x'', y''\); which signifies that when the ordinate generally expressed by \(y\) becomes \(y'\), the ordinate \(x\) becomes \(x'\); and when \(x = x'\), \(y = y'\), we have therefore two equations of condition:

(2) \(y' = ax' + b, \ y'' = ax'' + b \) ........ (3)

from whence we obtain

\[
a = \frac{y'' - y'}{x'' - x'} = \frac{y'' - y'}{x'' - x'};
\]

and by substituting for \(a\) its value, we have

\[
b = \frac{y'' - y'}{x'' - x'} x' = \frac{y'' - y'}{x'' - x'} x'.
\]

Or equation (2) may be subtracted from equation (1), then

\[y - y' = a (x - x') \] which determines the line parallel to the axis \(A X\).

If \(y' = y\), then \(y = y\), or \(y = y\), which denotes that the line becomes a straight line parallel to the axis.

If \(x' = x''\), \(y = \frac{y'' - y'}{x'' - x'} = \infty\), the angle which the line makes with the axis is in this case a right angle.

PROBLEM II.

To determine the distance between two given points in a plane.

The distance \(M' M''\) (fig. 5.) is the hypotenuse of the right-angled triangle \(M' M'' M'\); if it be represented by \(D\), then

\[D = \sqrt{M' M''^2 + M' M''^2} = \sqrt{(y' - y'')^2 + (x'' - x')^2}\.\]

If the point \(M\) is at the origin, the co-ordinates \(x, y\) become expressions, and the preceding expression is reduced to

\[D = \sqrt{y'' - y' + x'' - x'}.\]

Then the equation to the straight line is \(y' = x' y'; a'\); and as this also takes place when \(x = x', y = y'\), it gives \(y' = ax + b\).

PROBLEM III.

To determine the equation of a straight line that shall pass through a given point, and be parallel to a given straight line.

These two conditions are sufficient to determine the two elements of position for the required straight line.

Let the equation of the given straight line be \(y = ax + b \) (1), and that of the line required \(y = ax + b + \) ........ (2); \(a\) and \(b\) are, in this case, given, and \(a'\) and \(b'\) required. Let \(x', y\) denote the co-ordinates of the given point; and since this point is in the required line, we have \(y' = ax' + b\) ........ (3).

From equation (1) take equation (3), and \(y - y' = a (x - x') \) ........ (4).

The same result may be obtained by taking the value of \(b'\) in equation (3), and substituting it in equation (2). Moreover, the two straight lines being parallel, their trigonometric tangents are the same, that is, \(a = a'\); introducing this condition in equation (4), that of the line required will be

\[y - y' = a (x - x') \] ....... (5).

If the given point be taken on the given line, then \(y'\) is the value of \(y\), which corresponds to \(x = x'\); and equation (1) becomes

\[y' = a x' + b.\]

Substituting this value of \(y'\) in equation (5), we obtain

\[y = ax + b\]

which shows that the required line and the given line are identical, which is, indeed, self-evident.

PROBLEM IV.

The equation of two straight lines being given to determine the angle which they make with each other, (fig. 6.)

The angles \(C A X, C B X\), are given, the angle to be found is \(A C B\). Put \(C A X = \alpha, C B X = \alpha'; C A B = V,\) tang. \(\alpha = \alpha, \ tan. \alpha = \alpha';\) then \(\alpha' = \alpha + V,\) and tang. \(V = \tan. (\alpha' - \alpha) = \frac{a' - a}{1 + a a'}\). If the straight lines are parallel, tang. \(V = \infty, \) and \(a' = a;\) if they are perpendicular, tang. \(V = \infty, \) or \(\frac{1}{\tan. V} = \infty;\) therefore \(1 + a a' = 0.\)

PROBLEM V.

To determine the equation of a straight line that shall pass through a given point, and make a given angle with a given straight line. Let the equation of the given line be

\[y = ax + b \] (1) and that required \(y = ax' + b' \) ........ (2) \(a\) and \(b\) are given; from whence \(a\) and \(b\) are to be determined by the conditions of the problem. Since the required line is to pass through a point whose co-ordinates are \(x', y',\) its equation must satisfy when \(x = x', y = y';\) hence

\[y' = a' x' + b' \] (3), and consequently

\[y - y' = a (x - x') \] (4).

Let \(b'\) be determined from one of the conditions, it remains to determine \(a'\) from the other. Now, \(m\) being the trigonometric tangent of the angle which the two lines make with each other (by Problem IV.), \(m = \frac{a' - a}{1 + a a'};\) hence \(a' = \frac{a + m}{1 - m a}.\)

Substituting this value of \(a'\) in equation (4), we have the equation required,

\[y - y' = \frac{a + m}{1 - m a} (x - x') \] (5).

PROBLEM VI.

To determine the condition under which three lines, drawn from the angles of a triangle, will meet in a single point. Let \(x', y', x'', y''\); \(x', y'\); \(x'', y''\) be the co-ordinates of the angles \(D, B, C\) (fig. 7.) the equations to the three straight lines drawn from these angles will be

\[y - y' = a' (x - x') \; y - y'' = a'' (x - x'') \; y - y' = a'' (x - x'') \]

\(a', a'', a''\) being the trigonometrical tangents of the angles which the lines make with the axis \(A X.\) For these lines to meet in a point, it is requisite that the same value of \(x, y\) should satisfy for the three equations, which is equivalent to finding the value of \(x, y\) by means of any two of them, and making the result of their substitution in the third
third equal to zero; we thus find the equation of condition
\[ a'(y'' - y') + a''(y'' - y') + a'''(y - y') + a' a''(x'' - x') + a' a''(y'' - x') + a'' a''(x'' - x') = 0 \]

Let us suppose the required straight lines to be perpendicular to the sides of the triangle, and then examine if, upon this supposition, the equation (1) subsists.

The equation to BC is \[ y - y'' = \frac{y'' - y'}{x'' - x'} (x - x') \]
and that of the straight line drawn through D is \[ y - y'' = a'(x - x') \]
Now as this latter straight line should be perpendicular to the other, the equation \[ a'' + 1 = 0, \]
ought to exist between the trigonometrical tangents; but here \[ a = \frac{y'' - y'}{x'' - x'}, \]
therefore \[ a' = \frac{y'' - y'}{x'' - x'}. \]
The straight line drawn through B being perpendicular to DC, we conclude
\[ y - y'' = \frac{y'' - y'}{x'' - x'} (x - x') \]
and the straight line drawn through C being perpendicular to DB, we have likewise
\[ y - y'' = \frac{y'' - y'}{x'' - x'} (x - x') \]
Hence the values of \( a' \), \( a'' \), are
\[ a'' = \frac{x'' - x'}{y'' - y'} \quad a'' = \frac{x'' - x'}{y'' - y'} \]
and likewise
\[ a' a''(x'' - x') = \frac{(x'' - x')(x'' - x')(y'' - y')}{(y'' - y')(y'' - y')} \]
\[ a'' (x'' - x') = \frac{N}{D} = \frac{(y'' - y')(y'' - y')}{(y'' - y')(y'' - y')} \ 
(2) \]
We deduce \( a'' = \frac{2 y'}{x'' - x'} \); and as this is found to be the value of \( a'' \) that is, of the trigonometrical tangent of the angle which the line DM makes with AX, it may be concluded that this third line passes through the point of intersection of the two first.

Let us consider the perpendiculars drawn from the centres of the sides of the triangle A D C, to the equation of A D is \[ y = \frac{y'}{x} \]
of D C, \[ y = \frac{y'}{x} \]
of A C, \[ y = 0 \]
The equations of the perpendiculars to these sides are, \[ y - \frac{y'}{x} = \frac{y'}{x} (x - \frac{y'}{x}) \]
\[ y - \frac{y'}{x} = \frac{y'}{x} (x - \frac{y'}{x}) \]
\[ x = \frac{x''}{2} \]
The equation of condition may be immediately formed by determining \( x \) from the two first equations, and employing this value in the third; which ought to be satisfied by this substitution if there exists a point of intersection; now \( x \) is found to be \( \frac{x''}{2} \); therefore these three lines intersect in a point.

**Method of determining the Position of a Point in Space.**

Let AX, AY, AZ, be three straight lines reciprocally perpendicular to each other (fig. 10a) at the point A; each of them will be perpendicular to the two others, because it is perpendicular to two straight lines which intersect at its extremity in this plane. Therefore each of these planes will be at the same time perpendicular to the two others. These three planes form then the three faces of a rectangular parallelepiped, and the solid trihedral angle A. Let us suppose the planes ZAX and ZAY vertical, and the plane YAX horizontal. Let a point in space be represented by \( M \), situated out of the planes ZAX, ZAY, YAX in real position, for example, before the first plane, to the right of the second, and above the third; and let us suppose perpendiculars \( M'M' \), \( MM' \), \( MM' \) from the point \( M \) to these three planes; these perpendiculars will measure the shortest distances from the point to each of these planes. The planes drawn through the perpendiculars \( MM' \) and \( MM' \), \( MM' \) and \( MM' \), \( MM' \) and \( MM' \) will enclose the parallelepiped, and the point \( M \) will be the summit of the solid trihedral angle \( A \) opposite to the angle \( A \).

The distance \( MM' \) from the point \( M \), to the plane ZAX is in real length equal to \( MM'' \); the distance \( MM' \) from the same point to the plane ZAY is \( MM'' \) or \( Mm \),
and the distance from this point to the horizontal plane \( \mathbf{XY} = \mathbf{M}' \) or \( \mathbf{M}' \) or \( \mathbf{M}' \). Thus these distances may be found on the fixed lines \( \mathbf{AY}, \mathbf{AX}, \mathbf{AZ} \).

The points \( \mathbf{M}', \mathbf{M}', \mathbf{M}' \), of the perpendiculars let fall from the point \( \mathbf{M} \) on the planes to which we refer the position of this point, are called the **vertical** and **horizontal projections** of the point \( \mathbf{M} \), **vertical** in considering \( \mathbf{M}' \) and \( \mathbf{M}' \), and **horizontal** when considering \( \mathbf{M}' \).

Two of these projections are sufficient to determine the point; for if from each of them perpendiculars be drawn to the plane which contains it, they will intersect in the point \( \mathbf{M} \).

The third projection evidently results from each of the two others, as may be seen in the figure.

Since the position of a point is completely defined by its distance from three rectangular planes of projection, if we denote the distance of the point from the plane \( \mathbf{YA}Z \) by \( x \), its distance from the plane \( \mathbf{YA}X \) by \( y \), and its distance from the plane \( \mathbf{YA}X \) by \( z \), and the linear

values of these distances be denoted by \( a, b, c \), its position will be indicated by \( x = a, y = b, z = c \); the formula \( x = a, z = c \), denote the position of the projection \( \mathbf{M}' \); the formula \( y = b, z = c \), denote the projection \( \mathbf{M}' \); and these two projections are sufficient, as we have seen, to find the position of the point; and these two systems of formula comprise the data of the three distances. When the point is in the horizontal plane, \( x = 0 \), and its position is fixed by \( x = a, y = b, z = c \); when it is in the plane \( \mathbf{YA}X \), \( y = 0 \), and its position is determined by \( x = a, z = c \); and if in the plane \( \mathbf{YA}X \) we have \( x = 0 \), \( y = 0 \), \( z = c \).

For a point situated on the axis \( \mathbf{AX} \), we have \( z = 0 \), \( y = 0 \); the point on the axis \( \mathbf{AY} \), \( z = 0 \), \( y = 0 \); and if on \( \mathbf{AZ} \), \( x = 0 \), \( y = 0 \).

At \( A \), the origin of these distances, we have \( x = 0 \), \( y = 0 \), \( z = 0 \).

Every point in the plane, \( \mathbf{M}' \) and \( \mathbf{M}' \), and consequently the plane itself, is denoted by \( x = a \), because \( a \) is the common distance of each of its points from the plane \( \mathbf{YA}Z \).

The plane \( \mathbf{M}' \) is denoted by \( y = b \), and the plane \( \mathbf{M}' \) is denoted by \( z = c \).

The position of these three planes gives that of the point \( \mathbf{M} \), and consequently this point will be defined, as we have already said, by the formula \( x = a, y = b, z = c \).

Of the Equations of a Straight Line.—The equations of a straight line situated in space, express the relation which exists between the co-ordinates \( x, y, z \), of any point whatever of the straight line: let us suppose it projected on the planes \( xz \), and \( yz \); these projections will be the other straight lines, which have for their equations

\[ x = a, y = b + z \]

eliminating \( z \) from these equations, the resulting equation is \( b x - a y = b a - a \rho \), which belongs to the plane \( \mathbf{xy} \).

The equations of these three projections, of which any two imply the third, are the equations of the straight line, whose position in space depends on the constant quantities \( a, b, \rho \).

To obtain the co-ordinates of the points in which this straight line cuts the three planes, we must make successively the three values \( x = 0, y = 0, z = 0 \), which gives \( x = a, y = b, z = c \), for the point where the straight line intersects the plane \( xz \); \( z = - \frac{b}{a} x + a \) for the point where it

intersects \( xz \); \( z = - \frac{a}{b} y + b \) for the point where it intersects the plane \( zy \); \( y = \frac{x}{a} b + 0 \) for the point where it

meets the plane \( yz \).

The straight line, whose equation is \( x = az + a \), makes, with the axis \( x \), an angle, whose tangent is \( a \); it cuts the axis \( x \) in a point, whose distance from the origin of the co-ordinates is equal \( a \), since, if in this equation \( z = 0 \), \( a = a \).

If two straight lines are situated in the same plane; suppose that of \( x, z \), then let the equation to the first be \( x = az + a \), and to the second \( x = az + a + \beta \); for these straight lines to be parallel, \( a' \) must be \( a \), and, if perpendicular, \( a' + a' \) is \( a \), or \( a' = - \frac{1}{a} \).

The equation of two straight lines, situated in space being, for the first,

\[ x = a + a y = b + \beta \]

the equation, which expresses that these lines meet each other, is \( (a' - a) (b - b) - (a' - b) (a' - a) = 0 \), which results from the elimination of \( x, y, z \), from the four equations of the two straight lines.

**Problems relating to a Straight Line.**—**Prob. I.** To draw a straight line through a point given in space parallel to a given straight line. Let the three rectangular co-ordinates be \( x, y, z \); be the co-ordinates of the first point; \( x', y', z' \), of the second, the straight line passing through the first point, its equations will be of the form

\[ x - x' = a (z - z') \]

\[ y - y' = b (z - z') \]

of which any two imply the third.

**Prob. II.**

To determine the equation of a straight line drawn through two points given in space. Let \( x', y', z', \) be the co-ordinates of the first point; \( x'', y'', z'' \), of the second, the straight line passing through the first point, its equations must also be

\[ x - x'' = a (y - y'') \]

\[ y - y' = b (z - z'') \]

\[ z - z'' = c (y - y'') \]

\[ a, b, c \] being eliminated from their four equations, the equations of the required straight line will be

\[ x (z' - z'') = y (x' - x'') + x'' z' - x' z'' \]

\[ y (z' - z'') = z (x' - x'') + y'' z' - y' z'' \]

The co-ordinates of the two extremities of a right line being \( x', y', z', \) for the first, and \( x'', y'', z'' \), for the second, the distance between the extremities, or length of the line joining them, will be

\[ \sqrt{(x' - x'')^2 + (y' - y'')^2 + (z' - z'')^2} \]
Of the Equation to a Plane.—A plane being given by its inter-
teraction with two co-ordinate planes, it may be conceived
as generated by one of these planes moving parallel to itself in
the direction of the other.

Let \( z = \alpha x + \gamma y + \beta \) and \( z = \beta y + \gamma \), be the equations to
the two given intersecting lines, the generating plane being
parallel to itself, and to the intersecting line on the plane
\( x, y \), its equations in any one position will be
\[ z = \alpha x + \gamma y, \gamma = \beta. \]
But if it should meet the second line, whose equations are
\[ x = 0, \]
\[ z = \beta y + \gamma; \]
hence this equation of condition
\[ \beta + \gamma = \gamma; \]
from which it follows, that the equation of the generating
plane, in any given position, depending on \( \beta \), are
\[ z = \alpha x + b \beta + \gamma \]
\[ z = \beta y + \gamma. \]
Eliminating \( \beta \) from these two equations, that of the plane
is obtained,
\[ z = \alpha x + b \gamma + \gamma, \]
in which \( \alpha \) and \( b \) are the tangents of the angles which
the intersections of the planes make with the axes \( x \) and \( y \); \( \gamma \) is the
co-ordinate \( z \), corresponding to the origin of the ordinates;
therefore, if in the equation of the plane, \( x \) and \( y \) are made \( = 0 \),
\( z = \gamma \). This equation may be more commodiously expressed
by the following form:
\[
A x + B y + C z + D = 0,
\]
in which, of the four constant quantities, \( A, B, C, D \), three
\[
\begin{align*}
A & = a \\
B & = b \\
C & = c.
\end{align*}
\]
only are necessary; hence
\[
\begin{align*}
x & = 0 \\
y & = 0 \\
z & = b y + \gamma.
\end{align*}
\]

The equation of a plane has been determined from its inter-
terctions with the planes of the co-ordinates. Thee inter-
terCTIONS may likewise be determined by the equation to the plane.

Let \( a x + b y + c = \gamma \), make successively \( x = 0, y = 0, z = 0 \),
and there result
\[
\begin{align*}
\begin{cases}
a x + b y + c & = 0 \quad (x = 0) \\
y = 0 \\
z = b y + \gamma,
\end{cases}
\end{align*}
\]
which equations belong to the interections
of the given plane with the three planes \( x, y, z \), and \( x, y \).

The equation of a straight line, situated in one of the co-
ordinate planes, is likewise that of a plane passing through
this line, and perpendicular to the plane of the co-ordinates
which contains it. When the plane is perpendicular to one of
the axes, as \( x \), its equation is \( x = \gamma \) (constant); \( y = \beta \),
\( z = \gamma \), are the equations of two other planes, one perpendi-
cular to the axis \( y \), and the other perpendicular to the axis \( z \).

In the equation to the plane make successively
\[
\begin{align*}
x & = c \\
y & = c \\
z & = c
\end{align*}
\]
\[
\begin{align*}
\begin{cases}
x = c \quad (x = c) \\
y = c \\
z = c \quad (x = c)
\end{cases}
\end{align*}
\]
values will then be obtained for \( x, y, z \), which are the distances of the origin of the co-
ordinates from the points of intersection of the plane with
the axes of the co-ordinates; let the equation to the planes be
\( z = a x + b y + c \); these distances will be \( -\frac{c}{a}, -\frac{c}{b}, c \).

Two planes which are parallel have parallel interections;
therefore, if the equation to the first plane be
\[ z = a x + b y + c, \]
the second, \( z = a' x + b' y + c' \)
the condition of parallelism will be expressed by the equa-
tions \( a = a', b = b' \).

Problem I.

Problems relating to a straight Line and a Plane.—To
draw a plane parallel to a given plane, let the equation to the
given plane be
\[ z = ax + by + d \]
and that of the plane required
\[ z = a' x + b' y + d \]
then the condition of parallelism will be
\[ a = a', b = b'. \]

Problem II.

To determine the equation of a plane which shall pass
through three given points, let the co-ordinates of the given
points be \( 1, \ldots, x', y', z' \),
\[ 2, \ldots, x'', y'', z'' \]
\[ 3, \ldots, x''', y''', z'''. \]
The equation of the plane required being supposed
\[ A x + B y + C z + D = 0 \]
the three following conditions are obtained ;
\[ A x'' + B y' + C z = 0 \]
\[ A x'' + B y'' + C z'' + D = 0 \]
\[ A x'' + B y'' + C z''' + D = 0. \]
from which are deduced the following equations:
\[ A = y'' (z'' - z') + y'' (z'' - z') + y'' (z'' - z'), \]
\[ B = x' (x'' - x') + x' (x'' - x') + x' (x'' - x') \]
\[ C = x' (y'' - y') + x' (y'' - y') + x' (y'' - y'), \]
\[ D = x' (x'' - x') + x' (y'' - y') + x' (y'' - y'). \]
The three co-efficients to determine are \( A, B, C, D \) from
the same number of equations. If the triangle formed by
the straight lines joining the given points he projected on the
three planes \( x, y, z \), the areas of these respective pro-
jections will be \( 2, 2, 2 \), and it will be shown that \( D \) is six
times the solidity of a pyramid whose base is the triangle in
space, and whose vertex is the origin of the co-ordinates.

Let a triangle, as \( x'' y'' z'' \), represent the projections of
the above three points on the plane of \( x z \), the area of the
trapezium \( x'' y'' x'' z'' \) will be
\[ \frac{1}{2} \]
the area of the trapezium \( x' z'' y'' x'' \) will be
\[ \frac{1}{2} \]
and that of the trapezium \( x' z' y'' x'' \) will be
\[ \frac{1}{2} \]
From the sum of the two first surfaces, take the last, the
difference will be the area of the triangle projected on the
plane \( x z \), which will be \( -\frac{1}{2} \). In the same manner, \( t \)
and \( t'' \) representing the projections of the same triangle on the
planes \( y, z, x \), we have
\[ t = \frac{1}{2} A, t'' = \frac{1}{2} C. \]

Problem III.

Given the co-ordinates of a point, and the equations of a straight line, to find the equation of the plane which
passes through the straight line and the given point, let
\( x', y', z' \) be the co-ordinates to the point;
\[ x = a x + \gamma \\
\]
\[ y = b y + \gamma \\
\]
\[ b = (x - a) = a (y - \gamma). \]

Then

Vol. XVI.
GEOMETRY.

Then since the plane, whole equation is required, passes through the given point, and likewise through the point where the given line intersects the plane \( x'y' \), the co-ordinates to which points are \( z = 0 \), \( x = \alpha, y = \beta \). If the equation to the plane be supposed

\[ z = Ax + By + D, \]

in which \( A, B, D \), are co-efficient to be determined, then

\[ z' = A'x' + B'y' + D \quad \ldots \ldots \quad (1) \]

\[ z = A + Bz + D \quad \ldots \ldots \quad (2) \]

Now the right lines being in the plane, suppose them both moved parallel to themselves till the plane passes through the origin of the co-ordinates, the equations there will be, for the straight line,

\[ x = ax + y = b z, ay = bx \]

and for the plane \( x = Ax + By + B \).

In this position the line is still in the plane, so that their co-ordinates are still the same; therefore,

\[ z = A'z + Bz, \quad z = A + Bz \]

The equations, \( 1, 2, 3 \), will give \( A, B, D \) in terms of \( a, b, \alpha, \beta \); and the equation of the plane will be

\[ (x - x')(y' - b z' - \beta) - (y' - x') (x' - a z - \alpha) \]

\[ + (z - z') \cdot (b x' - a) (y' - \beta) \cdot = 0 \cdot \]

**Problem IV.**

Given the equations of a straight line, and of a plane to determine the conditions; 1st, that the plane and straight line may be rectangular; 2nd, the co-ordinates of the points where they meet; 3rd, the distance of this point from a given point, either in the given line or given plane.

When a plane is perpendicular to a straight line, the intersection of the plane with the co-ordinate planes and the projection of the line with these main planes are perpendicular to each other.

Let \( x = ax + ay = b z + \beta \) be the equations to the line; \( z = Az + By + C \) the equation to the plane; the equations to the intersections of the plane with the rectangular planes of \( axz \) and \( xy \), are \( z = Ax + C \), \( z = By + C \), but the plane being perpendicular to the line \( \alpha = a, B = b \); therefore the equation of a plane parallel to the line, is \( ax + by + z = C \); combining this equation with those of the straight line \( x = ax + ay = b z + \beta \) we may deduce the values of \( x, y, z \), the co-ordinates of the point of intersection, and the plane may be expressed in this form

\[ a (x - x') + b (y' - y') + z' = C - ax - by' - z' \]

Let \( X', Y', Z' \), be the co-ordinates of the point of intersection of the plane and perpendicular, then

\[ Z = z' + C - ax' - by' - z' \]

\[ Y' + b (C - ax - by' - z') \]

\[ X' = a (C - ax' - by' - z') \]

The length of the perpendicular comprehended between the points \( X, Y, Z \) and the points \( x', y', z' \), is

\[ \sqrt{(x - x')^2 + (y' - y')^2 + (z' - z)^2} \]

\[ \sqrt{C - ax' - by' - z'} \]

Hence it follows that the perpendicular drawn from the origin of the co-ordinates upon a plane whose equation is

\[ ax + by + z = C \]

\[ \sqrt{1 + a^2 + b^2} \]

Having the equations of a straight line \( \{x = a + \alpha, y = b + \beta \} \)

the equation of a plane perpendicular to this line drawn through the point \( x', y', z' \), is

\[ a (x - x') + b (y' - y') + z' = 0 \]

To find the co-ordinates of the point of intersection of the plane, the equations of the straight line may be put under the following form;

\[ x - x' = ax + a - x' \]

\[ y - y' = bx + bx - y' \]

Let \( X', Y', Z' \), be the co-ordinates of the points of intersection; then

\[ Z = a (x' - x) + b (y' - y) + z' \]

\[ Y = b (x' - x) + b (y' - y) + z' \]

Then

\[ X = a (x' - x) + b (y' - y) + z' \]

Substituting for \( X', Y', Z' \), their values in the radical

\[ \sqrt{(X' - x')^2 + (Y' - y')^2 + (Z' - z)^2} \]

an expression is obtained for the perpendicular contained between the given point of the straight line, of which the co-ordinates are \( X', Y', Z' \). When the straight line passes through the origin of the co-ordinates, its equations become \( x = ax \), \( y = by \), and the radical

\[ \sqrt{X'^2 + Y'^2 + Z'^2} \]

expresses the length of the straight line, drawn from the origin of the co-ordinates to its intersection with the perpendicular let fall from the point \( x', y', z' \), upon it; on this supposition, \( x = ax + ay = b z + \beta \)

\[ Z' = a x' + b y' + z \]

\[ y' = b x' \]

\[ Y' = b z' \]

\[ X' = acz \]

therefore

\[ \sqrt{X'^2 + Y'^2 + Z'^2} = \sqrt{a^2 + b^2 + c^2} \]

This expression is used in finding the angle which two straight lines make with each other.

4th. The equation of two straight lines being given to find the angle which they make with each other, and if they do not intersect each other to determine the angle which their projections form on a plane that is parallel to them, let the equations of the given lines be

\[ \{x = ax + a, y = by + b \} \]

\[ \{x = ax + a, y = by + b \} \]

If they intersect, the angle which they make is equal to the angle formed by their parallels which pass through the origin of the co-ordinates; the equations to their parallels being

\[ \{x = ax + a, y = by + b \} \]

\[ \{x = ax + a, y = by + b \} \]

If a point be taken on the second parallel, whose co-ordinates are \( x', y', z' \), and a perpendicular be let fall from this point to the first parallel; then in the right-angled triangle formed by this perpendicular, and by the straight lines drawn from the origin of the co-ordinates to the two extremities of this perpendicular, there are given the two sides which contain the required angle; the expression for one of these sides is

\[ \sqrt{} \]
GEOMETRY.

\[ \sqrt{x^2 + y^2 + z^2} \]
the other, as found in the preceding

Therefore the cofine of the required angle is equal

\[ \frac{a \cdot x' + b \cdot y' + c \cdot z'}{\sqrt{1 + a^2 + b^2}} \]

But \( a' = a \cdot z', \quad y' = b \cdot z' \); therefore the cofine of the

angle formed by the two given straight lines

\[ \frac{1 + a \cdot a' + b \cdot b'}{\sqrt{1 + a^2 + b^2} \times \sqrt{1 + a'^2 + b'^2}} \]

It appears from this expression, that when two straight lines have for their equations

\[
\begin{align*}
1 & \quad x = a \cdot z, \quad y = b \cdot z \\
2 & \quad x = a' \cdot z, \quad y = b' \cdot z
\end{align*}
\]

if they are perpendicular to each other, the following equation of condition will be obtained, \( 1 + a \cdot a' + b \cdot b' = 0 \), which equation may be likewise obtained directly as follows: the plane perpendicular to the first line drawn through the origin of the co-ordinates has for its equation \( a \cdot x + b \cdot y + c \cdot z = 0 \). But the perpendicular to the first straight line must be contained in the plane perpendicular to it; therefore the equations to the perpendicular \( x = a' \cdot z, \quad y = b' \cdot z \), and the equation of the plane must be obtained at the same time; therefore \( 1 + a \cdot a' + b \cdot b' = 0 \). The angle of the two planes may be thus determined. Let \( a \cdot x + b \cdot y + c = C, \quad a' \cdot x + b' \cdot y + c = C' \) be the equations of the planes; then make with each other the same angle as the straight lines which are perpendicular to them, and which are drawn from the origin of the co-ordinates; therefore the cofine of the angle formed by the two given planes, is

\[ \frac{1 + a \cdot a' + b \cdot b'}{\sqrt{1 + a^2 + b^2} \times \sqrt{1 + a'^2 + b'^2}} \]

If the angle be required between one straight line and one plane, then suppose a parallel drawn to the given lines through the origin of the coordinates, and a perpendicular to the plane, the angle contained between these two straight lines will be the complement of the required angle; and consequently, the cofine of the angle of the two lines is the sine of the angle required.

The straight line, whose equations are \( x = a \cdot z, \quad y = b \cdot z \), makes with the axes \( x, \quad y, \quad z \), the angles whose cofines are

\[
\begin{align*}
\sqrt{x^2 + y^2 + z^2} & \quad \sqrt{x^2 + y^2 + z^2} \\
\sqrt{1 + a^2 + b^2} & \quad \sqrt{1 + a'^2 + b'^2} \\
\sqrt{1 + a'^2 + b'^2} & \quad \sqrt{1 + a^2 + b^2}
\end{align*}
\]

The same expressions are the values of the cofines of the angles which a plane perpendicular to the straight line, and whose equation is \( a \cdot x + b \cdot y + c = 0 \), makes with the co-ordinate planes \( x, y, z \). If the equation of the plane is \( A \cdot x + B \cdot y + C \cdot z + D = 0 \), the cofines of the angles which it makes with the co-ordinate planes are

\[
\begin{align*}
\frac{A}{\sqrt{A^2 + B^2 + C^2}} & \quad \frac{B}{\sqrt{A^2 + B^2 + C^2}} \\
\frac{C}{\sqrt{A^2 + B^2 + C^2}} & \quad \frac{D}{\sqrt{A^2 + B^2 + C}}
\end{align*}
\]

and the expression found above for the perpendicular, let fall from the origin of the co-ordinates on the plane, becomes

\[ \frac{D}{\sqrt{A^2 + B^2 + C}} \]

It has been already remarked, that if \( T \) be the triangle formed by the three lines which join, two and two, the three given points, and \( t, \ t', \ t'' \) its projections on the co-ordinate planes, then \( t = \frac{1}{2} \cdot A, \ t' = \frac{1}{2} \cdot B, \ t'' = \frac{1}{2} \cdot C \); therefore the solidity of a pyramid which has for its base the triangle \( T \), and whose vertex is the origin of the co-ordinates. Now the solidity of this pyramid is the product of the base \( T \), by one third of its height \( \frac{D}{3} \); and substituting for \( A, \ B, \ C \) their values \( t, \ t', \ t'' \), \( T = \frac{1}{6} \cdot t + t' + t'' \).

If \( S \) be the area of another triangle whose projections are \( t, \ t', \ t'' \), and situated in the same plane as the triangle \( T \); then \( S = \frac{1}{3} \cdot t + t' + t'' \).

Since \( T = \frac{1}{2} \cdot \sqrt{A^2 + B^2 + C^2} \) \( T = \frac{1}{2} \cdot \frac{1}{\sqrt{A^2 + B^2 + C^2}} \)

in like manner \( T = \frac{1}{2} \cdot \frac{1}{\sqrt{A^2 + B^2 + C^2}} \)

which signifies that any triangle is to its projection on one of the co-ordinate planes as radius to the cofine of the angle which the plane of the triangle makes with the plane on which it is projected.

But the triangle \( S \) being in the same plane with the triangle \( T \)

\[ \frac{T}{S} = \frac{T'}{S'} = \frac{T''}{S''} \]

therefore if the equation \( T' = t' + t'' + t''' \) be put under this form, \( T = \frac{1}{2} \cdot t + t' + t'' \) it will become

\[ T = \frac{1}{2} \cdot t' + t'' \]

\[ T = \frac{1}{2} \cdot t + t' + t'' \]

Taking in the same manner in the same plane a third triangle \( R \), whose projections on the rectangular planes are \( r, \ r', \ r'' \), it may be shown that \( \frac{1}{2} \cdot (R + S + T') = (r + r' + r'') \)

hence if any plane figure whatever be projected on three rectangular planes, the square of the area of this figure will be equal to the sum of the squares of the areas of its three projections.

PROBLEM V.

Two straight lines being given, to determine the equations to a straight line perpendicular to each of them on which their shortest distance is measured; 2d, to find an expression for this shortest distance.

The direction of a plane parallel to two straight lines given in position may be determined: this plane being drawn through any point in space, we may conceive a plane to pass through each of the straight lines perpendicular to it: the intersection of these two planes is evidently the line required, therefore the equations to these planes will be those of the line required.

Let \( x = a \cdot z + a, \quad y = b \cdot z + b \), be the equations to the first line, it will meet the plane \( xy \) in a point \( P \), of which the co-ordinates \( z = c, \quad y = b, \quad x = a \).

The second straight line having for its equations \( x = a'z + a', \quad y = b'z + b' \), it meets the plane \( xy \) in a point \( P' \), whose co-ordinates are \( z = c, \quad y = b', \quad x = a' \).

The equations of the planes drawn through the points \( P \) and \( P' \) parallel to the two given straight lines are of the form

\[ A (x - a) \]
GEOMETRY.

\[ A (x - a) + B (y - \beta) + z = 0 \ldots \ldots (c) \]
\[ A (x - a') + B (y - \beta') + z = 0 \ldots \ldots (c') \]

A and B being two constant quantities determinable by the following equations

\[ 1 + A a + B b = 0 \]
\[ 1 + A a' + B b' = 0 \]
\[ A = \frac{b - b'}{a - a'} \quad (1) \]
\[ \frac{a' - a}{b' - b} \]

The perpendiculars to these parallel planes drawn through the points \( P, P' \) have their equations

\[ x = A \alpha + \alpha' ; \quad y = B \alpha + \beta \]
\[ 2d \quad x = A \alpha + \alpha' ; \quad y = B \beta + \beta' \]

The plane drawn through the first of these perpendiculars, and the first given line, has for its equation

\[ L (x - a) + M (y - \beta) + z = 0 \quad (E) \]

\[ L' (x - a') + M' (y - \beta') + z = 0 \quad (E') \]

L and M being given by the two equations

\[ 1 + L A + M b = 0 \quad (3) \]
\[ 1 + L a + M b = 0 \quad (4) \]

The equation of the plane drawn through the second perpendicular, and the second given line is

\[ L' (x - a') + M' (y - \beta') + z = 0 \quad (E') \]

L' and M' being determinable by the equations

\[ 1 + L' A + M' b = 0 \]
\[ 1 + L' a' + M' b = 0 \]

Now each of these last planes contains the required line, therefore the equations of their line of intersection will be those required.

The equations \( (1) \quad (2) \) give the values of A and B, and combining them with equations \( (3) \quad (4) \) the following values are obtained for L, M, L', M':

\[ L = a - a' + b (a b' - a' b) \]
\[ a (a' - a) + b' (b' - b) \]
\[ L' = a - a' + b (a b' - a' b) \]
\[ a (a' - a) + b' (b' - b) \]
\[ M = a (a' - a) + b (b' - b) \]
\[ a (a' - a) + b' (b' - b) \]
\[ M' = a (a' - a) + b (b' - b) \]

Substituting these values in equations \( (E) \quad (E') \) we have

\[ (x - a) \left\{ a - a' + b (a b' - a' b) \right\} + (y - \beta) \left\{ b - b' - a (a' - a) + b (b' - b) \right\} \]
\[ = 0 \quad (x - a') \left\{ a - a' + b (a b' - a' b) \right\} + (y - \beta) \left\{ b - b' - a (a' - a) + b (b' - b) \right\} \]
\[ = 0 \quad \left\{ b - b' - a (a' - a) + b (b' - b) \right\} + \left\{ a (a' - a) + b (b' - b) \right\} \]
\[ = 0 \quad \left\{ b - b' - a (a' - a) + b (b' - b) \right\} + \left\{ a (a' - a) + b (b' - b) \right\} \]

From these two equations which represent the required line, its projections on the planes \( y, z, x \), may be found by successively eliminating \( x \) and \( y \).

It remains now to determine the absolute length of the shortest distance between the two lines.

If from the origin of the co-ordinates a perpendicular be let fall on each of the parallel planes, these, having the same direction, will become one and the same straight line; their difference, or the distance between the two planes, will be the shortest distance required. The length of these perpendiculars will, by the last problem, be

\[ P = \frac{A a + B b}{\sqrt{1 + A^2 + B^2}} \]

for the plane

A \[(a - a') + B (y - \beta) + z = 0 \]; D being = A x + B \beta; \]

and \[ P' = \frac{A a' + B b'}{\sqrt{1 + A^2 + B^2}} \]

for the plane

A \[(a - a') + B (y - \beta) + z = 0 \]

where \( D' = A x + B \beta \).

The difference \( P = \frac{A (\beta - \beta') + B (\beta' - \beta)}{\sqrt{1 + A^2 + B^2}} \)

Substituting for \( A, B \) their values

\[ P' - P = \frac{(a' - a) (b' - b) - (\beta' - \beta) (a' - a)}{\sqrt{1 + A^2 + B^2}} \]

When the straight lines meet each other, this distance being nothing, \( (a' - a) (b' - b) - (\beta' - \beta) (a' - a) = 0 \)

the same equation, as has been already found, expressing the right lines which intersect each other.

On the transformation of the co-ordinates—Given the co-
ordinates of a point in relation to three rectangular planes, to determine the co-ordinates of this point, in respect to three other planes.

The three new planes being given in position in respect to three primitive planes, their equations are given.

Let these be, for the

1st, \[ A x + B y + C z = D = 0 \]
2nd, \[ A' x + B' y + C' z + D' = 0 \]
3rd, \[ A'' x + B'' y + C'' z + D'' = 0 \]

These three planes intersect each other two by two in three straight lines which are the new axes. The new co-
ordinates of the point are measured on the lines drawn through this point parallel to the new axes. The length of any one of these new co-ordinates is the part of one of these lines contained between the point, and the plane of the co-ordinates to which this line is parallel.

Let \( x, y, z \) be the co-ordinates of the point in relation to the primitive planes, and \( x, y, z \) its co-ordinates in relation to the three new planes. For conciseness let

\[ (A \quad C \quad B') + B (A' C' - A'' C)+ C (B' A' - B'' A') \]
\[ (C B' - C' B) + B (A' C' - A'' C)+ C (B' A' - B'' A') \]
\[ (C B' - C' B) + B (A' C' - A'' C)+ C (B' A' - B'' A') \]
\[ (C B' - C' B) + B (A' C' - A'' C)+ C (B' A' - B'' A') \]

The values of the new co-ordinates will be

\[ x = \frac{A x + B y + C z + D}{L} \]
\[ y = \frac{A' x + B' y + C' z + D'}{L'} \]
\[ z = \frac{A'' x + B'' y + C'' z + D''}{L''} \]

If the three new planes be supposed perpendicular to each other, then \[ A A' + B B' + C C' = 0; A A' + B B' + C C = 0; A' A'' + B' B'' + C' C'' = 0 \].

Multiplying the first of these equations by \( B' \), the second by \( B' \), and subtracting, we have \[ C (B' A' - B'' A') = (A' A'' + B' B'' + C' C'') = 0 \].

Multiplying the first by \( B' \), the second by \( B' \), and subtracting, we have

\[ B' A' - B'' A' = (A' A'' + B' B'' + C' C'') = 0 \].

Multiplying the first by \( B' \), the second by \( C' \), and subtracting, we have
GEOMETRY.

A \((A' C'' - A'' C') - B (C B'' - C' B') = 0\).

By means of these three equations the expression for \(L\) is reduced to \(\sqrt{A'' A + B'' B + C'' C}\).

By a similar calculation,

\[L' = \sqrt{A'' A' + B'' B' + C'' C'}\]
\[L'' = \sqrt{A'' A'' + B'' B'' + C'' C''}\]

which gives for the new co-ordinates \(a, v, \omega\),

\[a = A' + B'y + C'z + D' \sqrt{A'' A' + B'' B' + C'' C'}\]
\[v = A' + B'y + C'z + D' \sqrt{A'' A' + B'' B' + C'' C''}\]

The values of \(a, v, \omega\), might have been determined directly, since they are the perpendiculars drawn from the points \(x, y, z\), upon three planes, whose equations are known.

If it be required to transform one system of rectangular co-ordinates into another system likewise rectangular, and having the same origin as the first, the new axes may be given by the equations of the three new rectangular planes. Of the six constant quantities which enter these equations, three are determined by the condition that the planes are perpendicular to each other, and their values are to be calculated from that which is assigned to the three others; but this calculation may be avoided by determining the position of the new axes by means of any three angles \(\alpha, \beta, \gamma\). This transformation is useful in the application of analysis to mechanics. The following method is that used by La Place in the "Mechanique celeste."

Let the primitive planes be designated by two of the three co-ordinates \(x, y, z\), which they contain, and the new planes by two of the co-ordinates \(x', y', z'\).

Let \(\alpha\) be the angle of the two planes \(x,y\) and \(x''y''\),

\(\beta\) the angle which the axis \(x\) makes with the line of intersection of the plane \(x'y'\) with the plane \(x,y\),

\(\gamma\) the angle which this line makes with the axis \(x''\).

It is now required to find the values of \(x'', y'', z''\), in terms of \(x, y, z\), and of the three angles \(\alpha, \beta, \gamma\).

Let \(x', y', z'\), be the co-ordinates of a point referred to the rectangular axes, reckoned upon the three following lines:

1. The intersecting line of the plane \(x'y'y''\) with the plane \(x,y\).
2. The projection of the axis \(z''\) on the plane \(x,y\).
3. The axis \(z''\).

Then \(x = x' \cos \alpha + y' \sin \alpha\),

\[y = y' \cos \beta + x' \sin \beta\],

\[z = z' \cos \gamma\].

Let \(x', y', z'\) be the co-ordinates of a point referred to the rectangular axes, reckoned upon the three following lines:

1. The intersecting line of the plane \(x''y'y''\) with that of \(x,y\).
2. The perpendicular to this line on the plane \(x''y''\).
3. The axis \(z''\).

Then \(x'' = x' \cos \alpha + y' \sin \alpha\),

\[y'' = y' \cos \beta + x' \sin \beta\],

\[z'' = z' \cos \gamma\].

"\(x'', y'', z''\) being the co-ordinates of the point relative to the three axes \(x', y', z'\), we have

\[x'' = x' \cos \alpha + y' \sin \alpha\],

\[y'' = y' \cos \beta - x' \sin \beta\],

\[z'' = z' \cos \gamma\].

Hence \(x = \{x' \cos \alpha + y' \sin \alpha\} \cos \beta + \{x' \cos \alpha + y' \sin \alpha\} \sin \beta\)

\[y = \{x' \cos \alpha + y' \sin \alpha\} \cos \beta + \{x' \cos \alpha + y' \sin \alpha\} \sin \beta\]

\[z = z' \cos \gamma\]

Multiplying these values of \(x, y, z\) respectively by the coefficients of \(x''\) in these values, we have

\[x'' = \{x' \cos \alpha + y' \sin \alpha\} \cos \beta + \{x' \cos \alpha + y' \sin \alpha\} \sin \beta\]

\[y'' = \{x' \cos \alpha + y' \sin \alpha\} \cos \beta + \{x' \cos \alpha + y' \sin \alpha\} \sin \beta\]

\[z'' = z' \cos \gamma\].

And by multiplying the values of \(x, y, z\) respectively by the co-efficients of \(y''\) in these values, and afterwards by the co-efficients of \(z''\), we have

\[x'' = \{x' \cos \alpha + y' \sin \alpha\} \cos \beta + \{x' \cos \alpha + y' \sin \alpha\} \sin \beta\]

\[y'' = \{x' \cos \alpha + y' \sin \alpha\} \cos \beta + \{x' \cos \alpha + y' \sin \alpha\} \sin \beta\]

\[z'' = z' \cos \gamma\].

Another transformation is sometimes used; a point being referred to three rectangular planes by the co-ordinates \(x, y, z\), a straight line is drawn from this point to the origin of the co-ordinates; the length of this line is given, as likewise the angles which it makes with the three rectangular axes. If \(r\) represent this line, and \(\alpha, \beta, \gamma\) the three angles, then \(x = r \cos \alpha, y = r \cos \beta, z = r \cos \gamma\).

Of these three angles two only are necessary; because

\[x' = x \cos \alpha + y \cos \beta + z \cos \gamma\]

When the position of a point is thus determined by a line \(r\) and two angles, \(r\) is called the radius vector, and the origin of the co-ordinates becomes a pole, from which proceed the radii-rectors of different points in space.

Sometimes the radius vector is projected upon one of the rectangular planes, supposing on \(x, y, \) the angle of the radius, with its projection, is given, as likewise the angle of the projection with the axis of \(x, y, \) if \(\phi\) represent the first, and \(\psi\) the second of these angles,

\[x = r \cos \phi, y = r \cos \psi, z = r \cos \gamma\].

If the point, referred to three rectangular planes by the co-ordinates \(x, y, z\), belongs to a surface, we have between these three co-ordinates an equation, \(F(x, y, z) = 0\). If the co-ordinates are transformed, and the new ones become \(u, v, w\), we must substitute in \(F = 0\) for \(x, y, z\), their values in terms of \(u, v, w\), and the resulting equation will belong to the new surface referred to the new planes.

If in the equation \(F = 0\), for \(x, y, z\), we substitute the values given in equations (1) and (2), it will become what is termed the polar equation to this surface.

When a curve is given by two equations \(f(x, y, z) = 0\), \(f(x, y, z) = 0\), in substituting in these equations the values given by equation \(F(x, y, z) = 0\), we obtain an equation to the curve, relating either to three new planes by the co-ordinates \(x, y, z\), or to a pole, by the radii-rectors, and their angles.

Of the centres of surfaces, and of their diametral planes.

The centre of a surface is defined to be a point, in which all the chords passing through this point are divided into two equal parts.

A diametral plane is that which divides a system of parallel chords, each into equal parts.

Hence, if a surface has a centre, all the diametral planes which it can have, necessarily pass through this centre.

Having given the algebraic equation of a surface, to determine, 1st, if it has a centre; 2d, if it has a diametral plane.

If the proposed surface has a centre, let it be referred to three planes, the origin of whose co-ordinates is the centre itself.

Any straight line drawn through the origin of these co-ordinates will be a diameter, and will cut the surface in two points, the co-ordinates of the first being \(x, y, z\), and of the second \(-x, -y, -z\). Therefore, the equation to the surface must satisfy in taking \(x, y, z\), positive or negative; to satisfy this condition, the sum of the exponents of the three co-ordinates in every form must be the same in every part of the surface proposed, that is, if even, even, if odd, odd. Thus,
if \( \zeta (r, s, t) = 0 \) be the equation to the surface referred to, any three planes, then, in this equation make

\[ r = x + a_s = y + b_t = z + c; \]

and an equation of the surface will be obtained in terms of \( x, y, z \) referred to three new planes parallel to the first, and passing through the point supposed to be the centre of the surface; if, by the three particular values assigned to \( a, b, c \), the terms can be made to disappear, in which the sum of the exponents of the three co-ordinates are of a different denomination as to even or odd, then the degree or dimension of the equation \( \zeta (r, s, t) = 0 \), the proposed surface will have a centre.

**Of dihlral Planes.**—When, in all the terms of an equation of a surface, the exponent of one of the co-ordinates is an even number, the plane of each of the other co-ordinates divides the surface into two equal and similar parts.

The equation being \( \zeta (x, y, z) \) if in all its terms the exponent of \( z \) is an even number, the plane of \( x \) and \( y \) will be a diametral, for it will give for \( z \) a value \( a_o \), function of \( x, y \), and constant quantities, and \( z = o \) will satisfy this equation; therefore, to the same values of \( x \) and \( y \), two values of \( z \) will correspond, differing only in the sign; therefore, the plane of \( x, y \) will be diametral, and for the same reason the two other planes of the co-ordinates will be diametral; when in each term the exponents of \( x, y \) are even numbers.

Let \( \zeta (r, s, t) = 0 \) be the equation of the proposed surface; by the transformation of the ordinate, the surface may be referred to three new planes, then \( A \beta + B \beta + C \zeta + D = 0 \); \( A' \beta + B' \beta + C' \zeta + D' = 0 \); \( A'' \beta + B'' \beta + C'' \zeta + D'' = 0 \); in which equation there are nine constant quantities.

The surface proposed has diametral planes, when, by assigning real and particular values to these constant quantities, the terms in which the exponents of the co-ordinates which are odd numbers, may be made to disappear. The real root of the equation, obtained by making the co-efficients of these terms equal zero, determine the number of diametral planes.

In considering surfaces of the second degree, great use may be made of these principles, in determining the centres and diametral planes of these surfaces.

**Of Surfaces of the Second Degree.**—Let the general equation of the second degree, between three variable quantities \( x, y, z \), be \( a x' + b y' + c z' + d x y + e x z + f x z + g y z = 0 \); \( a' x' + b' y' + c' z' + d' x y + e' x z + f' x z + g' y z = 0 \); \( a'' x' + b'' y' + c'' z' + d'' x y + e'' x z + f'' x z + g'' y z = 0 \); the equation there are nine constant quantities.

Making \( x' = x + a_o \); \( y' = y + b_o \); \( z' = z + c_o \), the equation becomes \( a x' + b y' + c z' + d x y + e x z + f x z + g y z = 0 \); \( a x' + b y' + c z' + d x y + e x z + f x z + g y z = 0 \); \( a x' + b y' + c z' + d x y + e x z + f x z + g y z = 0 \); which equation there are nine constant quantities.

This equation, in which the centre, there are three terms in which the sum of the exponents of the co-ordinates is an odd number; these terms may be made to disappear, by making their co-efficients equal to zero, which gives \( g' = 0 \); \( k' = 0 \); \( k'' = 0 \), making this substitution and taking only the terms multiplied by \( x', y', z' \),

\[ 2 a z + d y + f x + g = 0; b z + d o + e y + b = 0; 2 e y + e o + f x + b = 0. \]

These equations being linear in \( x, y, z \), their quantities have real values; therefore, surfaces of the second degree have a centre.

If a certain relation be established between the constant quantities \( a, b, c, d, f \), this centre may be placed at an infinite distance from the origin of the co-ordinates. In effect, the value of \( x, y, z \) are fractions whose common denominator is \( a c' + b f' + c d - 4 a b c - d f = 0 \), therefore, when the following equation fulfils between the constant quantities of the general equation of a surface of the second degree, viz. \( x^2 + b y^2 + c z^2 + 4 a b c - d f = 0 \), the co-ordinates of the centre of this surface are infinite. The surface of the second degree has likewise diametral planes, for by transposing the ordinates it may be referred to three new planes, containing nine constant quantities; taking \( u, v, w \) for the new co-ordinates, the general equation becomes \( A u^2 + B v^2 + C w^2 + D u v + E u w + F v w + G u + H v + K w + 1 = 0 \); eliminating those terms in which the exponent of any one of the co-ordinates is odd, the fix following equations are obtained; \( D = 0, E = 0, F = 0, G = 0, H = 0, K = 0 \); (A). Of nine constant quantities, fix only are determined by these equations; hence it follows, that these planes may cut a surface of the second degree in four equal and similar parts in an infinite number of ways; it has therefore an infinity of diametral and conjugate planes, and of these three perpendicular ones, which intersect each other on the three straight lines on which are reckoned the axes of the surface. This property is analogous to that of curves of the second degree, which have an infinity of conjugate diameters, and in these curves there are two conjugate diameters perpendicular to each other, called axes. The three equations which express that the new planes of the co-ordinates are rectangular joined to the six equations (A), determine the nine constant quantities which enter into the equations of these planes.

Taking for granted what however may be demonstrated, that these constant quantities have always real values, we may suppose, that referring the surface of the second degree to its rectangular co-ordinates, its general equation will always be of this form, \( L x^2 + M y^2 + N z^2 = 1 = 0 \). We shall first consider the surfaces comprehended under the general equation, and next the case where the centre is removed to an infinite distance from the origin of the co-ordinates.

Every surface of the second degree intersected by a plane, has for its section a curve of the second degree; for whatever be the planes, it may become, by the transformation of its co-ordinates, one of the planes to which the surface is referred, to that after this transformation, the equation to the surface is full of the second degree; moreover, the equations of the sections made on a surface by the planes of the co-ordinates cannot be of a higher dimension than the equation of the surface, therefore every surface of the second degree cut by a plane has for its section a curve of the second degree likewise.

If the intersecting plane moves parallel to itself, the section remains always similar to itself; its axes remain always parallel, and its centre is always on the same diameter of the surface, which may be thus demonstrated.

The equation of a curve of the second degree may always be reduced to this form,

\[ L x^2 + M y^3 + N z^3 + p x + q = 0. \]

If in this equation \( f x \) and \( f y \) be substituted for \( x \) and \( y \), \( f \) being a constant quantity, the new equation which results from this substitution belongs evidently to a curve similar to the first, and similarly situated; it only differs from the first in the constant term, for after having divided all the terms by \( f \), it becomes

\[ L x' + M y' + N z' + p = 0. \]

Therefore all curves of the second degree, whose equations are of this form, differing only in the constant term, will be similar and similarly situated.

The general equation to a surface of the second degree being

\[ L x^2 + M y^2 + N z^2 - 1 = 0. \]
GEO

Let the equation of any intersecting plane be

\[ z = A x + B y + C. \]

The projection of the intersection of the curve with the surface on the plane \( x y \) will have this equation,

\[
x^2 + (L + N A') + y^2 + (M + N B') + 2 A B N x y + 2 A C N x + 2 B C N y + N C' = 1\]

If the intersecting plane be supposed to change its position by moving parallel to itself, \( A \) and \( B \) will remain constant, and \( C \) only will change its value; hence it follows that the coefficients of \( x', y', x, y \), in the equation of projection, will remain the same, whatever be the value of \( C \). But by the transformation of the co-ordinates this equation may be reduced to this form;

\[ l u^2 + m v^2 + n w^2 + p = 0; \]

in which the coefficients \( l, m, n \) only contain \( A \) and \( B \); \( p \) alone being some function of \( C \). If \( C \) be made to vary, the value of \( p \) may be supposed to become \( p'' \), and the preceding equation to become

\[ l u^2 + m v^2 + n w^2 + p'' = 0, \]

which as it only differs from the former in the constant quantity, evidently belongs to a similar curve; hence it may be demonstrated that all parallel sections are similar, and similarly situated. Moreover, the locus of the centres of these sections is a diameter of the surface.

If in the equation \( L x^2 + M v^2 + N z^2 = 1 = 0 \) we substitute for the co-ordinates \( L, M, N \), the constant quantities \( \frac{1}{a^2}, \frac{1}{b^2}, \frac{1}{c^2} \), where \( a \) being greater than \( b \), and \( b > c \); it becomes

\[ b' c^2 x^2 + c a^2 y^2 + a b^2 z^2 = a' b' c' (E). \]

The advantage of this substitution is to render the sign of each term of the equation independent of the particular values of the co-efficients, and to introduce as constant quantities (in the equations of the sections of the surface by the planes of the co-ordinates) only the principal axes of these sections.

From the different combinations of the signs three distinct cases arise from equation \( E \); for a full investigation of which we must refer our reader to the original work from which this article was principally extracted. (Vide Application de l'Analyse à la Géométrie, par M. Monge.)

The three equations are

\[ b' c^2 x^2 + c a^2 y^2 + a b^2 z^2 = a' b' c' \]

for \( L x^2 + M y^2 + N z^2 = 1 = 0 \) in the ellipsoid and the two others to two different species of hyperboloids.

**Geometry, Character in. See Character.**

**Geometry, Spherical.** See SPHERICAL.

**GEOMORI, Pers.** in Antiquity, the division or class of the ancient Athenians employed in agriculture.

**GEONOMA, in Botany, from geona, a batter out, or distributor of land, alluding to the mode of growth of the first species of the genus in question, as hereafter described.**

Gen. Ch. . . .

Female, Calyx and Corolla like the male. Style one, lateral. Stigma of two lobes. Drupa dry, with one seed.

1. G. pinnatifrons. "Fronds pinnate; the pinnas abruptly jagged."—Native of the Caucasus, in shady woods on the lofty mountain of Bueneva. Brecklay.-The trunk is simple and slender, an inch in diameter, smooth, rising to the height of fifteen feet, when, by the power of the wind on its ample foliage, it is blown down, but soon produces new shoots and roots from the top, whence a new trunk springs up to the same height of about fifteen feet, and in its turn is quickly laid prostrate like the former. The fronds (rather leaves) are pinnate, their pinnas irregular, somewhat folded, jagged abruptly at the summit. *Spatha* double, of two valves, wedge-shaped, somewhat compressed, acute, three inches long. *Spathix* fifteen inches in length, branched at the top, the branches round, bearing each from seven to nine alternate, cylindrical spikes, of the length of three inches each. *Flores* conjunctly three, fimbriate in a little hollow of the spike, two of which are male, one female. *Drupa* dry and fibrous, the size of a pea. *Nut globosse*, black.

2. G. simplicifrons. "Fronds simple, wedge-shaped, cloven."—Found at the Caucasus with the former. Brecklay.—The trunk of this is permanently upright, ten feet high, an inch thick. *Fronds* (or leaves) a foot long, simple, wedge-shaped, taper at the base, cloven, and divaricated at the summit, supported on very long flanks. *Spatha* double, of two valves. *Spathix* bearing at its extremity three or four cylindrical spikes. *Flores* imbricated in little cavities, like the former. Wilckens.

**GEOPONIC,** something describing or relating to agriculture. Cato, Varro, Columella, Palladius, and Pliny, are sometimes called geoponic writers.

**GEORG,** in Geography, surnamed the Cappadocius, was made bishop of Alexandria when Athanasius was driven from that see by the persecutions of the emperor Constan- tius, about the year 355. (See ATHANASIUS.) He was a native of Epiphania, in Cilicia, where his father pursued the business of a fuller. From this obscure situation the son raised himself, it is said, not by the most honourable means, to the lation of a prelate in the church. At first he obtained a lucrative appointment as purveyor of bacon to the army; not contented with the regular profits of his office, he made use of every art, however base and corrupt, in the accumulation of wealth; so as to render a mean employment truly infamous. His depredations on the public purse became so notorious, that he felt it extremely dangerous to wait the issue of a suit commenced against him. He fled from the pursuit of justice, and contrived to take with him his ill-gotten wealth. The place of his retreat was Alexandria, where he professed, great zeal for the Arian system of theology, and being a man of superior talents, he acquired considerable influence with his disciples in that city. Here he collected a large and very valuable collection of books, which the emperor Julian afterwards made the foundation of the noble library established by him in the temple erected in honour of the emperor Trajan, but which was burnt by the connivance of the emperor Jovian. When Athanasius was driven from Alexandria, George was elected bishop by the prevailing party. In this faction his conduct was in the highest degree cruel and oppressive. He persecuted the Catholics with an unrelenting hand, and the other inhabitants of this vast diocese were objects of his tyranny and avarice. The merchants he impoverished by unjust monopolies and cruel taxes; the Pagans, who had been excited with the hopes of freedom and toleration, did not escape his rapacity, and the rich temples of Alexandria were either pillaged or insulted by him, who exclaimed, in a haughty and threatening tone of voice, "How long will these sanguine be permitted..."
mitted to stand." The people endured all these acts of oppression till their patience was exhausted; they then rose as one man, and expelled him the city. With much difficulty he regained his authority, which he held till the year 362, when the accession of Julian to the empire was the signal for the downfall of the bishop. He, and two other persons, who had been ministers of his cruelties, were ignominiously dragged in chains to the public prison. Here, after a confinement of a few days only, they were attacked by the Pagan populace, which forced open the doors of the dungeons, and with cruel insults massacred the vile wretches. Their lifelike bodies were carried in triumph through the streets on the back of a camel, and after having suffered every indignity, they were thrown into the sea, with the avowed intention of disappoiting the devotion of Christians, who, they foresaw, would gladly canonize the tyrant as a martyr and saint. The fears of the Pagans were just, but their precautions ineffectual. The meritorious death, as it was commemorated, of the prelate, obliterates the memory of his life, and the infamous George of Cappadocia has been transformed into the renowned St. George of England, the patron of arms, of chivalry, and of the garter. The facts of Cappadocia, Baal, and the Gregories, did not acknowledge their companion, and pope Gelasius, about the year 496, is the first Catholic who acknowledges St. George, and who placed him among the martyrs of the churches. He rejects his acts as spurious, and as the composition of heretics. His fame and popularity in Europe, and especially in England, proceeded from the crusades. Gibbon, vol. iii. and iv. Moreri.  

**George of Trebizond**, a learned modern Greek, was born in 1395, in the isle of Crete, of a family originally from Trebizond, from which he derives his name. He came to Italy about 1429, and obtained the patronage of Francis Barbaro, a noble of Venice, through whose means he was invited to a professorship of Greek at Vicenza. Thence he removed to Venice, where he acquired great reputation as a grammarian and instructor in Greek eloquence. After this he obtained an invitation from pope Eugenius IV. to settle at Rome, and, during the life of the pontiff, he was occupied in teaching rhetoric and philosophy, and in translating several ancient Greek authors into Latin. He was engaged in a similar manner by pope Nicholas V., under whose patronage George might have lived happily, had not his own temper involved him in many disputes with the learned men about the papal court. With Poggio he came to blows, and it was necessary to refer to the authority of the apostolic secretaries to part them. His own conduct at length forced him from Rome, and he took refuge, in 1452, at Naples, where he was graciously received by king Alphonso, but he did not partake of his liberality, and had great difficulty, at this period, in maintaining his family. It is supposed, that by the interference of his friend Fileflo, he was reconciled to the pope, and that he returned to the papal city; but in 1459 he was at Venice, where he presented to the doge his version of Plato's book on laws, and was then engaged as a professor of belles lettres. In 1464 he went to Crete, and pulled thence to Constantinople. On his return he found his own feliciter Paul II. on the papal throne, which led him to visit Rome, but his treatment there did not, probably, correspond with his expectations; he was, for some offence not known, call into prison, where he was kept during a space of four months. He died about the year 1469. He lived a good old age, and was author of many works on rhetoric and philosophy connected with polite literature; and he translated many others, particularly of the fathers, from the Greek into the Latin. He is esteemed very highly for the share which he had in introducing Greek literature into the West. His Latin style was so far from pure, and in controversy he dealt much in invective. The comparison which he instituted between Aristotle and Plato gave great offence to the adherents of the latter, particularly to cardinal Bellarmino, who wrote an answer to him. Gibbon.  

**George**, called also Amico, flourished about the close of the 16th century, and was at Rome under the pontificate of Clement VIII. He published "A Syriac and Chaldee Grammar" in 4to. in 1596. He was, after this, elected Patriarch of the Maronites, among whom he introduced the afix, and explained the principles, of the Gregorians calendar. He died about the year 1641. Moreri.  

**George Lewis I.**, king of Great Britain, and elector of Hanover, the son of the elector Ernest-Augustus, by Sophia, daughter of Frederick elector-palatine, and grand-daughter of James I., king of England, was born in 1660, and trained to the profession of arms under his father. When he had arrived to the state of manhood, he engaged in the service of the emperor against the Turks, and became illustrious as a warrior in three campaigns in Hungary. He next distinguished himself in the war between the empire and France, and in the year 1700 he succeeded, on the death of his father, to the electorate. In the following year he marched to the assistance of the duke of Holstein, who was attacked by the king of Denmark, and obliged the Danes to raise the siege of Tanningen. He joined the alliance against France in the succession war, and forced the princes of the house of Wolfenbuttle to quit their alliance with the French. The command of the army of the empire was conferred upon him in 1707, but after the duties of three campaigns, in which he had been able to act only on the defensive, he resigned his command, and left his own troops in the service of the allies. At the peace of Ratisbon, Lewis XIV. recognized the electoral dignity in the house of Lunenburg, as he had before, at the peace of Utrecht, the succession of the same house to the crown of Great Britain. This event happened on the death of queen Anne in 1714, when the prince, now George I., was in the fifty-fourth year of his age. He was already celebrated for the wisdom and justice of his government, and his personal qualities, though limited in his views by the interests of a German prince, and but little acquainted with the character of the nation he was about to rule. "It is evident," says an historian, "that the title of this prince was founded solely on the choice of the parliament, that is, of the people, and that the usual order of succession was entirely superceded. For, admitting the male line of the house of Stuart to have been extinguished in the person of James II., the right of blood rested in the house of Savoy, descended from Henrietta, Duchess of Orleans, daughter of Charles I." Thus the rights of the people were fully exercised, and the family on the throne is in truth an elected family, though the general law of succession remains unaltered. The king threw himself into the arms of the Whig party, who, indeed, alone openly maintained those principles upon which the right of his crown was founded. Of these the fundamental one was the superiority of the national will, in appointing a chief governor, to any claim derived from hereditary right. Such a principle had been already affirmed, and was the only one that could justify the nation in setting aside the more immediate heirs to the crown, on the plea of difference of religion. (See Whigs.) As soon as this prince was settled on his throne, the late Tory ministry were called to account for their conduct, particularly with respect to the treaty of Utrecht, and several of the heads of it were impeached, and either imprisoned,
prisoned, or driven into exile. These measures were the
cause of great dissatisfaction; tumults were excited in
various parts of the kingdom, and at length, in 1715, the earl of Marl set up the standard of rebellion, and
proclaimed, with due honours, the pretender. The plan
was ill concerted, and very weakly supported, and early in the
following year it was entirely quelled, but several of the
leaders left their lives on the scaffold. Still a large body of
the people were disaffected to the new family, and the
power of the Tory party was so formidable, that the ministry,
with the consent of their authority, had recourse to septennial
parliaments, instead of triennial ones, according to the law of
the land. It was agreed by men of all parties, who were not
personally interested in the change, that this innova-
tion was a most grofs violation of the principles of the
constitution, which no temporary necessity could
justify. The king had, about this period, acquired by
purchase the duichies of Bremen and Verden, in order to
extend his power as elector of Hanover. By the acquisition
he was involved in a quarrel with Charles XII. of Sweden,
who threatened to invade Scotland in favour of the claims of
the pretender. The czar Peter also concurred in the scheme
To obviate the danger, the king entered into a triple alliance with
Holland and France, a fleet was sent up the Baltic to
awe the Swedes, and all commercial intercourse with that
nation was suspended; but the death of Charles XII. in
1718, and the subsequent changes in the politics of Sweden,
put an end to the alarms in that quarter, and secured George
in the quiet possession of his newly acquired continental
ac-
quitions. The ambition of the court of Spain, governed
by cardinal Alberoni, disturbed the peace of Europe, and
occasioned a quadruple alliance between the three powers
above-mentioned, with the accession of the emperor. The
feizure of Sardinia, and invasion of Sicily by the Spaniards,
gave a pretext for sending a powerful English fleet into the
Mediterranean under Sir George Byng, who fell in with, and
almost totally destroyed the Spanish fleet. This success
was followed by the recovery of Sicily and Sardinia, and Spain
was under the necessity of acceding to a peace dictated by
the allied powers. A pacification of the north of Europe was
also effected by the mediation of England. The na-
tional delusion and calamity in the year 1720, (see BUBBLES)
recalled the king from a visit to his German dominions, and
the prudent measures of parliament produced the restoration
of public credit. In 1722 a new conspiracy against the
government was discovered, and several persons were apprehended
in consequence of it, among whom was Dr. Atter-
bury, bishop of Rochester, who was punished with perpe-
tual banishment. The ministers of France and England,
Flurry and Walpole, being friendly to peace, preferred a
good understanding between the two countries for many
years. Several treaties were negociated under the pretence
of maintaining the balance of power, but trifling other priv-
ete ends were to be answered by them. The leading
principle of George I. was the fcurity and prosperity of his
German dominions, to the interets of which, those of
Great Britain were, on various occasions, said to be sacri-
ficed. In 1725, a treaty between the emperor and the
king of Spain excited the jealousy of king George so much,
that he counterfeited it by another at Hanover, comprizing
most of the other European powers, and he sent a fleet to
the Weft Indies under admiral Hosier, in order to block up
the Spanish galleons at Portobello. The death of the ad-
miral and most of his crew from disease, was considered as
one of the most inglorious disasters of the reign. The Spa-
niards then besieged Gibraltar, but all differences were finall
settled by a negociation. The king of England seemed at
length to have surmounted all his political difficulties, and a
prospect of permanent peace and tranquility appeared to
encourage him. The arts, letters, and sciences, which he had flourished during his whole reign seemed at last to
be rewarded with glory, happiness, and repose. He thought
every circumstance was favourable to his visiting his elec-
toral dominions, and embarked for that purpose at Green-
wich, June 5, 1727. He landed in Holland on the 7th,
but in his journey from thence to Hanover he suffered a
paralytic seizure, and feeling that he was near the end of his
long journey, he exclaimed to his attendant, "C'est foi de
moi." He reached the palace of his brother, the bishop of
Olmuth, but could not advance farther. He died June 11,
1727, in the sixty-eighth year of his age, and the 15th of
his reign. He has been characterized as plain and simple in
his appearance, grave and sedate in his manner, but easy and
familiar among his intimates, in whose society he was fond
of relaxing from the cares of the state. He possessed much
natural prudence and good fen's, and well understood his
interests, at least as far as the objects nearest his heart were
concerned. Accoding to the crown of Great Britain when
far advanced in life, he seemed ever to consider himself rather
as elector than as king, and the influence and power of Great
Britain were of little estimation in his eyes when directed
to any other end than the aggrandizement of his native
country. In the view of Europe at large, he influenced the
character of a prudent, able, and fortunate prince. His
government was not without defects in the administration,
but he was unquestionably a zealous friend to civil and
religious liberty. He had female favourites, but was not
governed by them. He had little or no taste for literature and
science, and was unable to appreciate their value, yet
he founded in each university a professorship of modern
history. He was, however, a lover of music; and soon
after his accession established regulations for the conduct
of this part of the service in the royal chapel. He had married
in 1681, his cousin Sophia Dorothea, daughter of the duke
of Zell, a match that was attended with little domestic
happiness. He left behind him one son, who succeeded
him in his crown.

George Augustus II. king of Great Britain, son of
the preceding, was born in 1683, and came to England with
his father in 1714, where he received the rank and title of
Prince of Wales. In 1716, he was appointed regent during
the king's absence. After this, on account of some private
difference between father and son, the latter lived for some
time in a state of estrangement from the court.
He succeeded to the throne in 1727, and adopted the same
ministers and measures which had governed the nation during
the life of George I. He inherited also, in full force, the
attachment which his father shewed to his German interests,
which swayed the councils of his cabinet, though it was
frequently obliged to give way to other considerations.
Europe, for some time, was in a state of peace, through the
influence of the treaties of Seville and Vienna, the latter of
which guaranteed the Pragmatic function, or the law by
which the female heirs of the emperor Charles V. were to
succeed to the hereditary dominions of Austria. In 1732
Walpole introduced into parliament the financial scheme of
a great extension of the excise; but the violent opposition it
met with, from the nation obliged him to relinquish the
object. What the people refused to submit to at that
period has been since adopted almost without a murmur.
In the year 1737, complaints were made against the govern-
ment for abridging liberty, by a bill for limiting the number
of playhouses, and submitting dramatic writings to the
inspection of the lord chamberlain. Debates had long pre-
valled

Vol. XVI.
vailed between Spain and England, on account of the trade carried on in the West Indies by their respective subjects. In 1739, the matters in debate were compromised by a convention settled by the respective courts, but its terms were so little satisfactory to the traders, that Walpole found himself obliged by their clamours to prepare for hostilities. War was declared, and Portobello taken by admiral Vernon. The war, however, did not turn out so successful as the people expected, so that a clamour was raised against the minister, and Sir R. Walpole was obliged to resign in the year 1742.

At the same period France, and the other powers in league with her, seemed determined, on the death of the emperor Charles VI., to strip his daughter Maria Theresa of her inheritance, which had been guaranteed to her by the Pragmatic sanction. In defence of her just rights, George sent an English army to the continent, and also a large body of forces from his electorate, who were taken into British pay. The king himself joined the army, which was under the command of the earl of Stair, and displayed great bravery. Victory declared itself in favour of the Britons, but they were forced to leave their wounded to the care of the enemy. Soon after, the command of the allied army devolved on the king's second son, the duke of Cumberland, who was reckoned very deficient in talents as general of a great army. Under him was lost the bloody battle of Fontenoy in 1745, and the French maintained an undoubted superiority in Flanders during the remainder of the war. In the following year the adherents of the pretender encouraged him to try his fortune by a descent, in the northern part of the kingdom, where he might expect an immediate and decisive declaration to be made in his favour. His ion, accordingly, under the protection of the court of France, landed on the coast of Scotland, in the month of July. He was received with much respect and affection, and was immediately joined by several of the clans, with whom he proceeded to the south, enlarging his small army with all those who would join in his cause. At Perth he proclaimed his father king, and immediately after took possession of Edinburgh, defeated a body of the royal troops at Preston Pans, and marched into England, where he had the strongest assurances of being powerfully reinforced. He proceeded to Derby, but found the people no where zealously inclined to support his cause; at length the duke of Cumberland arrived from Flanders, with several English regiments, engaged and defeated the rebels, and thus put an end to the hopes of the pretender, who could no longer be considered as an object of terror or alarm. The government of the house of Brunswick was from this period more firmly established; and it appeared that the greater part of the nation had indubitably connected the interests of religion and liberty with the support of those principles which called the family of the reigning prince to the throne. In 1748, peace was negociated, and established by the treaty of Aix-la-Chapelle; this treaty did not correspond with the expectations of the people, but it was welcomed as a relief from the burthens necessarily imposed by a state of war.

In 1751, the king left his eldest son Frederic, who had lived a considerable time at variance with his father, but who had made his peace with the court after the dismission of Walpole. This prince, the father of our present sovereign, was amiable and well disposed, and the fond and gouty hopes had been entertained of the patroition which he would be exhorted to bestow on the person to which he was heir, and of which he was deprived by an early death. In 1755, a war broke out between Great Britain and France, the events of which, though truly important to the kingdom, are in no great degree connected with the character of the king. To his appreciations for the safety of his German dominions, was imputed the alliance formed with the king of Prussia, and the employment of a large force in continental warfare. This was the least glorious part of the public transactions: and during the early years of the conflict events were very unfavourable to England; but when, at the demand of the people, the king summoned to his councils the great William Pitt, afterwards earl of Chatham, the tide of success set full in upon the measures of government. The French power in the East Indies was annihilated; and in America the reduction of Louisburg was followed by that of Canada. The island of Guadalupe, and the British settlement of Senegal, fell under the British dominion, and the famous battle of Minden exalted the reputation of the British soldiery. The navy of England reigned triumphant over the seas, while that of France was reduced to insignificance, from which it never after completely recovered. Notwithstanding all this success the German war was unpopular, and ministers were reproached for the sacrifices which they had made, or were supposed to have made, to the personal wishes of the king.

In this state of affairs George II. suddenly died from a rupture of the right ventricle of the heart, which, without any previous illness or suffering, terminated his life on the 25th of October 1760, in his seventy-third year, and in the thirty-third of his reign. During this long period he had experienced many vicissitudes of fortune, but he lived to see himself the most successful of all the English monarchs. He was endowed by nature with an understanding by no means comprehensive, and he had taken little pains to improve and expand his original powers by intellectual cultivation. Equally a stranger to learning and the arts, he saw the rapid increase of both under his reign, without contributing in the remotest degree to accelerate the progress by any mode of encouragement. He was hasty and obdurate in his temper, yet a natural goodliness of heart, a love of justice, and an honest openness of disposition, conciliated the affection of his people, and have infused respect and veneration for his memory. He was a firm friend to the established laws and liberties of the kingdom, and it must be admitted, highly to his honour, that the general principles of his administration, both civil and religious, were liberal and just. Many of the penal statutes, which still remain unrepealed, were in the reign of this prince modified, and virtually suspended, by the mildness and equity of the executive government. And he will long be remembered for his declaration, "that during his reign, there should be no persecution for conscience sake." On various occasions he had given signal demonstrations of personal bravery, nor did the general tenour of his conduct afford proofs less striking of his rectitude and integrity. If he cannot be ranked among the greatest, he is certainly entitled to be classed with the most respectable princes of the age in which he lived.

George, St. a name whereby several orders, both military and religious, are denominated. It took its rise from a saint famous throughout all the East, called by the Greeks ΑΡΙΣΤΟΣ ΓΕΡΜΩΝ, q. d. great martyr.

On some medals of the emperors John and Manuel Comneni, we have the figure of St. George armed, holding a sword or javelin in one hand, and in the other a buckler, with this inscription; an O, and therein a little P A, and ΓΕΡΜΩΝ, making Ο ΑΡΙΣΤΟΣ ΓΕΡΜΩΝ, O Holy George. He is generally represented on horseback, as being supposed to have frequently engaged in combats in that manner.

He is highly venerated throughout Armenia, Muscovy, and
and all the countries which adhere to the Greek rite: from the Greek, his worship has long ago been received into the Latin church; and England and Portugal have both chosen him for their patron saint. See George of Capadocia.

George, St. is particularly used for an English order of knights, more commonly now called the order of the Garter. See Garter.

George, knights of St. There have been various orders under this denomination, most of which are now extinct.

The order of St. George, at first called the order of the "Golden Angel," is said to have been instituted by Constatine the Great, in the year 312. The collar is composed of fifteen oval plates of gold, richly chafed on their edges, and enameled blue. On 14 of these plates is the cypher of the name of Christ, composed of the Greek capital letters Χ and Π between the two capitals A and N, signifying that Jesus Christ is the beginning and end; but on the centre oval, which is edged with laurel leaves, the cypher ΧΡ is placed on a cross potence gules, edged or, and having on its points the letters I, H, S, V.; and pendent from the bottom was the figure of St. George killing the dragon. The habit of the knights was a long cloak of sky blue velvet, lined with white silk, tied at the neck with a cord of crimson silk and gold intermixed, terminating at each extremity in a large tassel; on the left breast of the cloak was embroidered the cross of the order.

The order of St. George in Austria and Carinthia was instituted, as some say, by Rudolph, count of Habsburg, the first emperor of the house of Austria, about the year 1273 or 1293; or, as others say, by the emperor Frederic III. in order to guard the frontiers of Germany, Hungary, Austria, Carinthia, and Styria, from the inroads of the Turks. The badge of the order was a plain purple cross edged with green.

The order of St. George in Burgundy was founded, in the year 1400, by Philip de Milans, a gentleman of Burgundy, on account of his having brought from the East some relics of St. George, which he deposited in a chapel erected for the purpose, near the parish church of Rougemont. The badge of the order is a St. George on horseback, overthrowing a dragon, similar to that on the collar of the order of the garter. It was worn pendent to a blue ribbon tied to a button-hole. Women were admitted into this order.

The order of St. George in Austria was re-founded by the last emperor Maximilian, who directed that the badge of the order should be a cross crozets bottonnee gules, encircled on the upper arm with a diamond coronet or, and worn pendent from three chains of gold.

The order of St. George at Genoa was instituted in 1477. The doge of Venice is perpetual grand master of the order. The ensign of the order is a plain red cross, worn round the neck, pendent to a ribbon.

The order of St. George in Rome was founded by pope Alexander VI. in the year 1492. The collar of the order was a gold chain, to which was pendent, in enamel, the figure of St. George on horseback, throwing down a dragon, and piercing it with a lance. The badge was a gold cross within a circle of gold, like an open crown.

The order of St. George at Ravenna is supposed to have been instituted by pope Paul III in 1534. It was abolished by pope Gregory in 1572.

The order of St. George, defender of the immaculate conception of the blessed Virgin Mary, was instituted at Munich by Albert, elector of Bavaria, in the year 1729, and confirmed by the pope. The perfon admitted into this order must prove his fertility for five generations both on his mother's and father's side. The badge of the order is a star of eight points; on the centre is enamelled the image of St.

George on horshack, slaying a dragon; the cross is enamelled blue, and edged with white, and cantonned with a smaller cross, enamelled blue and white; which, pendent to a sky-blue watered ribbon, edged with white, is worn scarfiwife. On the left breast the knights also wear the same star embroidered, having on the centre a red cross. On festivals they wear a collar composed of oblong plates with crowns at each end, and columns surmounted with globes; each column supported by two lions, holding in their anterior paws key-mitaris, joined together with lozenge-chains enamelled blue and white; on the oblong plates is the following motto:—

"In fide, justitia, et fortitudine." The military order of St. George in Russia, called also the order of "Merit," was instituted by the emperors Catherine II. in 1769, has the precedence over that of St. Anne of Holstein, and was divided into four classes. —

The badge is a cross of gold, enamelled white, on the centre of which is a medallion, with the figure of St. George slaying a dragon. This is worn pendent to a black ribbon edged with orange colour, and two stripes of orange on the black. Those of the first class wear it under their coat, passing from right to left; and on the left breast of their coat is a star wrought in gold, in the shape of a lozenge; on the centre of the star are embroidered the figure of St. George and the dragon. Those of the second class wear the badge pendent to a ribbon passing round their neck, and a star on their left breast. Those of the third class wear the badge pendent to a narrow ribbon which passes round their neck; but they have no star. Those of the fourth class wear the badge pendent at the button-hole of their coats. Each knight of the first class receives an annual salary of 500 roubles = 1400; each of the second class has 400 roubles = 800 a per annum; each of the third 200 roubles or 200 a per annum; and each of the fourth 100 roubles or 100 a per annum. The fund of this order, assigned by the emperors for the payment of their salaries, and other expenses, is 40,000 roubles = 80,000 a per annum. Of this 1,680 is devoted to the payment of the order for the first class; and 2000 for each of the remaining three. The number of knights is unlimited. In 1778, the first class, which is confined to commanders in chief, contained only four; the second class comprised only eight knights; the third, forty-eight; and the fourth two hundred and thirty-four. No person can obtain this order without having performed some gallant exploit, or having served in the rank of an officer 25 years by land, or 18 by sea.

The order of St. George of Alkama, or the order of Menteia, an order of knights in Spain. When the order of knights-templars became extinct in Spain, an order was instituted, about the year 1317, to supply their places, and in consequence of a permission for that purpose obtained from pope John XXII. at which time Montefia in Valencia was selected as a proper place for the residence of the knights. In the following year, James, king of Aragon and Valencia, built at Montefia a noble college for their habitation, and dedicated it to St. George; and hence the order assumed its appellation of the order of St. George of Montefia. The habit of this order is a white mantle, on the left breast of which is embroidered a plain red cross. The badge of the order is a plain red cross, enamelled on gold, which is worn scarfiwite, pendent to a broad red watered ribbon. The order of St. George of Alkama, was instituted about the year 1201, at a town of that name in the diocese of Tortosa. In 1399 this order was united to that of Montefia, by pope Benedict Xuli, and that union was confirmed in the council of Constance.

George, Religions of the order of St. Of these there are divers orders and congregations; particularly canons regular of St. George in Alga, at Venice, established by authority of

R 2
of pope Boniface IX in the year 1404. The foundation of this order was laid by Bartholomew Colonna, who preached, in 1396, at Padua, and some other villages in the state of Venice. Pope Pius V. in 1570, gave these canons precedence of all other religious. Another congregation of the same institute in Sicily, &c.

St. George's Cross. See Cross.

George noble, a piece of gold, current at six shillings and eight-pence in the reign of King Henry VIII.

George Bank, in Geography, a rocky islet, near the west coast of Sumatra. N. lat. 3° 48'. E. long. 96° 12'.

George Cape, a cape on the S. coast of Kerguelen's Land. N. lat. 49° 54'. E. long. 70° 13'.—Also, a cape on the W. coast of Newfoundland. N. lat. 42° 28'. W. long. 59° 17'.—Also, a cape on the N. coast of the island of South Georgia. S. lat. 54° 17'. W. long. 30° 32'.—Also, a cape on the coast of Peru. S. lat. 23° 50'.—Also, a cape on the coast of New Holland, discovered on St. George's day by lieutenant Cook, and so called by him. S. lat. 35° 10'. W. long. 208° 51'.

George, St., Cape, a cape on the W. coast of Newfoundland. N. lat. 45° 30'. W. long. 59° 40'.—Also, the southern extremity of New Ireland. S. lat. 3°. E. long. 152° 15'.

George Creek, a town of America, in Allegany county, Maryland; 152 miles from Washington.—Also, a river of America, which runs into the Potowmac; 12 miles S.W. of Fort Cumberland.

George Island, an island of America, lying between lake Superior and lake Huron. N. lat. 46° 15'. W. long. 84° 20'.

George's Islands, two islands in the South Pacific ocean, discovered by Commodore Byron in 1765, and so called by him in honour of his majesty. They were again observed by captain Cook in 1774, in the passage from the Marqueñas to Otaheite. One of these islands, called by the inhabitants "Tiookea," was of an oval shape, and about 10 leagues in circuit, lying in the direction of E.S.E. and W.N.W., and situated in S. lat. 14° 27' 30", and W. long. 144° 56'. The inhabitants of this, and probably of the other low isles, are of a much darker colour than those of the higher islands, and seem to be of a much merrie disposition; which captain Cook attributes to their situation. Nature not having bestowed her favours on these low isles with that profusion she has done to some others, the inhabitants are rigidly induced to the food for their subsistence; consequently they are exposed to the sun and weather, and thus become much dark in colour, and more hardy and robust; for without doubt they are of the same nation. They were observed to be stout, well-made men, and on their bodies was marked the figure of a fish;—a very good emblem of their profession. The other island was similar to the former, extending N.E. and S.W. near four leagues, and from five to three miles broad. It lies S.W. by W., two leagues distant from the west end of Tiookean; and the middle is situated in S. lat. 14° 37'. W. long. 145° 10'. The natives of these islands appeared to be armed with long spears and clubs; their aspect and movements were hostile: some of them, however, appeared to captain Cook to manifest a friendly disposition; but they seemed to have no inclination to maintain any intercourse with him. They supplied him with dogs, which were plentiful, and cocoa-nuts, which were the only fruit they had. These furnished them with almost all the necessaries of life, particularly food, fish, cordage, timber, and vessels to hold water; and with a view to this use of them, their habitations, which were mean low hovels, thatched with coco-nut branches, were females near groves of these trees. Scurry-grafs was obtained in great abundance. Their canoes, which they are dextrous in navigating, are large and curiously constructed. Commodore Byron observed the shore to be covered with coral, and the shells of very large pearl-oysters; and he conceived that a very profitable pearl-fishery might be established on these islands. The women had a piece of cloth, appearing to be fabricated of the same stuff with their falls, which hung from the waist as low as the knee; but the men, were stark naked. Near the huts of these people were buildings, that appeared to be burying-places, from the structure of which it was inferred that they had great veneration for the dead. Fresh water is scarce. Each of these islands has in it a lagoon, or large salt-water lake. The people are much addicted to theft.

George Lake, a lake of East Florida, which is an enlargement of the river St. Juan, or St. John. It is also called "Great Lake," being about 15 miles wide, and generally about 15 or 20 feet deep, except at the entrance, which has a bar with 8 or 9 feet of water. This lake is beautified with two or three fertile islands, the largest of which is about two miles broad, commanding an extensive prospect, bearing evident marks of a large town of the Aborigines, and appearing to have been the chosen residence of an Indian prince.—Also, a lake that lies to the southward of lake Champlain. The portage between the two lakes is one mile and a half. The water of this lake is very clear, and was formerly used by the French in Canada for sacramental purposes, whence the lake was denominated lake "Sacrament." This lake is about 36 miles long, and from one to seven wide. It embosoms more than two hundred islands; or, as some say, three hundred and sixty-five; most of which are barren rocks, covered only with heath and a few cedar, fpiece, and hemlock trees and shrubs, and abounding with rattle-snakes. The remains of Fort George stand at the south end of the lake, about 14 miles N. by W. of Fort Edward, on Hudson river. The famous fort of Ticonderoga, which stands on the north side of the outlet of the lake, where it discharges its water into lake Champlain, is now in ruins.—Also, a lake in Upper Canada, situated below the Falls of St. Mary, and N. of Muddy lake; it is about 25 miles long, with very shallow water.

George's Stand. See NOOTKA.

George, St., the largest of the Bermudas islands, about 15 miles in length, and 8 in breadth, containing about 500 houses, surrounded and defended by a chain of forts, which extend some way into the sea, so that ships can approach it only in two places, and not without the assistance of an experienced pilot. It is divided into nine parishes or districts. It has a town of the same name, containing a town-house, where the governor, council, and magistrates assemble, a handsome church, and a library. N. lat. 32° 40'. W. long. 63° 32'. (See BERMUDAS).—Also, a town, or rather village, nearly in the centre of Newchester county, in the state of Delaware, N. America; situated on a creek of the same name, which falls into the Delaware river four miles below it, and a little above Reedy island; 45 miles S.W. of Philadelphia.—Also, a town and capital of the island of Grenada, and also one of its five parishes, formerly called by the French "Fort Royale." It is situated in a spacious bay, on the west side of the island, not far from the south end, and possesses one of the fairest and most commodious harbours in the English West Indies, which has been lately fortified at a great expense, and being one of the ports of entry belonging to the island was made a port of entry by 27 Geo. III. c. 27. The town of St. George is built chiefly of brick, and makes a handsome appearance. It is divided by a ridge, which, running into the sea, forms on
on one side the carenage, and on the other the bay.—Accordingly here is the “Bay-town,” which has a handsome square and market-place, and the “Carenage-town,” in which the principal merchants reside; the ships lying landlocked, and in deep water close to the wharfs. On the ridge between the two towns flanks the church, and on the promontory above it is a large old fort, which was probably constructed by the first French inhabitants. It is built of stone, and is large enough to accommodate an entire regiment. N. lat. 35° 35'. W. long. 59° 31'. Edwards' "Well Indies," vol. ii.—Allo, one of the Azores islands, about 10 leagues in length, and two in breadth. The soil is generally level, except towards the north, where it is rocky and barren; it is elsewhere fertile in corn, and the other necessaries of life. It is chiefly remarkable for a great number of lofty and full-grown cedars, with which the natives carry on a considerale trade. N. lat. 38° 58'. W. long. 24° 37'.—Allo, a small island in the Grecian Archipelago, three miles E. of Milo.—Allo, a small island in the Grecian Archipelago, at the entrance of the gulph of Sardarick. N. lat. 39° 48'. E. long. 26° 43'.—Allo, a small island in the Gulf of the Nile, near the coast of Egypt; four miles from Goa. Allo, a town of France, in the department of the Maine and Loire; 20 miles S.S.W. of Angers. Allo, a large and deep bay on the W. side of Newfoundland. N. lat. 48° 12'. Allo, a river of America, or rather an arm of the sea, in Lincoln county and state of Maine, lying about two leagues S.W. of Penobscot bay. This river is navigable for brigs and ships of a large burden to the narrows; and from thence about four miles higher, to nearly the head of the tide, for sloops and schooners of 80 or 90 tons. It is about half a league wide up to the narrows. The navigation is in winter. This river abounds with all kinds of fish. Allo, a river of St. Mary's county, in Maryland, which is a broad but short creek, having its mouth between Piney point and St. Mary's river on the north bank of the Potomack; opposite to the island of the same name. St. George's Bank, a fishing bank in the Atlantic ocean, in the Massachusetts, E. of cape Cod. It extends from north to south between 47° 15' and 43° 22' N. lat., and between 67° 50' and 68° 40' W. long. St. George's Bay, a bay of the Pacific ocean, on the S.E. coast of New Ireland, between cape St. George and cape Orof. St. George's Channel, that part of the Atlantic ocean which is situated between Ireland and Wales. Allo, a strait of the Pacific ocean between New Britain and New Ireland, 500 miles in length. Allo, a strait between the little Nicobar and Sandwidge islands, in the East Indian sea. St. George's Iland, a small island in the mouth of the river Potomack. N. lat. 38° 13'. W. long. 76° 34'. St. George's Ilands, a cluster of small islands near the coast of East Florida, opposite to the mouth of the Apalachicola. Allo, small islands in the Atlantic, near the coast of Maine in America. N. lat. 43° 50'. W. long. 68° 10'. St. George's Key, was one of the principal British settlements in the bay of Honduras, taken by the Spaniards during the American war, but retaken by the British soon after. The British settlements on the Mosquito shore, and in the bay of Honduras, were surrendered to the crown of Spain at the Spanish convention, signed at London on the 14th of July, 1786. N. lat. 17° 35'. W. long. 88° 43'.
to the western country. Alto, a post-town and port of entry in Montgomery county, Maryland, and in the territory of Columbia, pleasantly situated on a number of small hills, on the northern bank of Potomac river, separated eastward by Rock creek from Washington city, and distant 4 miles from the capital, and 9 N. from Alexandria. The houses, which are about 250, are elegant and commodious. The Roman Catholics have established a college in this place, which is in a flourishing state. The town carries on a small trade with Europe and the West Indies; 46 miles S.W. by W. from Baltimore, and 148 S.W. from Philadelphia. 

The six towns in the state, and in the county of Oglesby, 50 miles S.W. of Augusta, in the midst of a poor country, but indicating prosperity. Alto, a large maritime district in the lower country of South Carolina, situated in the N.E. corner of the state. Horry and Marion districts have lately been taken from this territory, leaving 29,532 inhabitants, of whom 16,620 are negroes. Alto, a post-town, and port of entry, and capital of the last-mentioned district, situated on a spot near which several streams unite their waters, and form a broad water called "Winyaw" bay, 13 miles from the sea. It contains 3 or 400 dwelling-houses, built chiefly of wood. The public buildings are a court-house, jail, and academy; four churches for episcopalians, baptists, presbyterians, and Methodists respectively. The place carries on a small trade with the West Indies; 60 miles N.E. by N. from Charleston, and 681 from Philadelphia. N. lat. 33° 57'. W. long. 79° 35'. Alto, a town of Kentucky, on the Elk-horn; 26 miles E. of Frankfort. N. lat. 38° 5'. W. long. 84° 50'. Alto, a town of New Brunswick, on the river St. John. N. lat. 45° 48'. W. long. 66° 12'. Alto, a town on the east coast of the island of St. John, on the gulf of St. Laurence. Alto, a town of the slate of Georgia; 20 miles N. of Waynesborough. Alto, a town of Scotland, in Perthshire, with some barracks, at the end of Loch Rannock; 31 miles N.W. of Perth. N. lat. 56° 41'. W. long. 4° 25'.

GEORGIA, in Botany, Ehrhart Bev. v. i. 176, so named by that author after his majesty George III. king of Great Britain, when he established, as a new genus, the flowers called by Linnaeus Minumium pillulatum. All botanists, nevertheless, have preferred the name Tropis, given by Hedwig to Pian's Monograph, i. 1. It seems, however, that there ought to be a Georgia after Georgi the Russian traveller and botanist. See GEORGIA.

GEORGIA, in Geography, a country of Asia, between the Caspian and Black Seas, and particularly appropriated to the territory that lies between the Caspian Sea and Mingrelia, anciently known by the name of "Iberia." The ancient

Iberia, which lies to the west, is now chiefly the "Immeritia" of European Turkey, on the other side of a branch of the Caucuses. Georgia, or more properly "Gurgia," including Daghelitan and Schirvan, may be considered as constituting the Albania of the ancients; a name, however, that has been applied in different quarters to mountainous regions.

The whole country, which is known by the name of Georgia or Gruzinia, is divided into two considerable Christian states. One of these, bounded by the Black sea, contains the kingdom of "Immeritia," and the principalities of "Mingrelia" and "Guriel," (which see respectively,) and is now governed by a common prince, who bears the title of tsar or czar. Each of these states had formerly its own ruler, all acknowledging the supremacy of the Grand Sultan, to czar Solomon united them under his authority, and freed them from the paramount Ottomans. Solomon, having upon his accession forbidden the scandalous traffic practiced by the nobles of selling their peafants, greatly offended the Turks, who gained by that species of commerce. Being by their intrigues driven from his throne, and compelled to find an asylum in the woods and mountains, he lived like a wild man for sixteen years, in caverns and holes, and frequently, by his personal courage, escaped affaifination, until he was re-instated in his dominions by the Russians. This prince, on ordinary occasions, was distinguished from his subjects by riding on an ass, perhaps the only one in Immeritia, and by wearing boots. He had no regular troops, but collected a defultory army of 6000 men, without artillery. These troops were drawn together by the found of the trumpet; in other respects the prince's orders were infribed at the markets, which are held every Friday. One of his fervants ascended a tree near the place of meeting, and proclaimed the edict with a loud voice. His subjects were of the Greek religion. Solomon died of the plague in 1784, and was succeeded by his nephew David, who threw himself under the protection of Russia. In 1783 his embassadors were introduced to the empress at Peterburg, and, in the eastern style of homage, threw themselves on the ground at her feet.

The second Georgian state consists of the principalities of "Kardelia" or "Cardelia," (Kartalnia) and "Kakhetty," which have been long governed by Christian princes, in submition to the Persian empire, but, since the shock sustained by the throne of the Sophis, have rendered themselves independent. Each of these two provinces formerly composed a distinct state; but they have both lately been reduced under the sole sovereignty of prince Heraclius of the Kakhetian dynasty. The state of Karducla and Kakhett borders northwards on the Karda, eastwards on Daghelitan and Schirvan, (which see respectively,) southwards on the Persian Armenia, and westwards on Immeritia. The capital is Tiflis (which see). The czar, or prince Heraclius, who is celebrated for his bravery and other great qualities, as well as by the important part which he acted during the disturbances that agitated Persia after the death of Tamas Kulian, submitted in the year 1783 to the Russian empire, thus voluntarily sacrificing an independence which he seemed to have secured by his exploits; but the advantages of which were richly compensated in the protection he procured by this submission. However, notwithstanding this close alliance with Russia, he was compelled in 1786, in order to escape the connection with it, and to acknowledge himself tributary to the Porte; but he died soon afterwards. Within a few years past the Russian interests revived, and prevailed; and in February 1801, Georgia was by a public ukase united to that empire. The Georgians or Gruzinians, as they are sometim
GEORGIA.

times called, avoided all communion with the Tartars, and have distinguished themselves as the most numerous and powerful body of the mountaineers of Caucasus, now for the greatest part subject to the protecting authority of Russia. The inhabitants of Georgia, when it was one kingdom, were Christians; but since the year 1639, they were blended with Mahometans; the king of Persia having conquered and divided the country into two provinces or kingdoms, and having obliged the people to embrace the Mahometan religion. But since they have been under the protection of Russia, they have again avowed themselves Christians, following in part the rights of the Armenian, and in part those of the Greek church. They are represented as the most tractable Christians of the East. The Georgians excel in the use of the bow, and are reputed to be the best soldiers in Asia. The women are celebrated for their beauty, but though they are very handsome they love to adorn themselves with paint, and are not in high estimation for their modesty. As the country produces strong wine, the Georgians are addicted to intoxication, and the women, as well as the men, indulge freely in the use of brandy. The men are fine, handsome, virtuous, and courage; fathers sell their children, and sometimes their wives. According to the laws of war in Turkey, any province which revolts is given up to pillage, and the inhabitants are reduced to slavery. In consequence of this custom, which prevails throughout Asia, Georgia and Circassia supply the market of Constantinople with slaves; though it is said, that the Circassians alone have the honour of being admitted into the bed of the sultan. This supply of female slaves is continually furnished by the Leagues Tartars, who, situated between the Caspian and Black seas, between Georgia and Circassia, are perpetually at war with these two provinces. They carry over to the eastern coast of the Black sea the slaves they have taken, and sell them to the Turfik merchants, who come thither at stated times for this traffic. The inhabitants of this same coast, likewise, seize on their countrymen in the neighbouring villages, and sell them; and children have been sometimes sold by their parents. See Circassia.

The air of Georgia is dry, very warm in summer, and very cold in winter. Fine weather commences in the month of May, and continues till the end of November. The soil is extremely fertile, provided the ground be watered. The bread and fruits are excellent; and the pastures feed a great number of cattle, fat and lean. The game is of excellent flavour, and the wild hogs are delicate. The inhabitants make wine, which they sell into Armenia and Persia, especially to Isphahen, for the king's table. Silk forms a considerable branch of trade to Erzerum; though the inhabitants are unacquainted with the best method of winding it. In this province there are only four considerable towns; viz. Tiflis, Gori, Suren and Al. See Persia.

Georgia, one of the United States of America, situated between 31° and 35° N. lat. and between 5° and 16° W. long.; extending in length about 600 miles, and in breadth 250; and bounded on the east by the Atlantic ocean; S. by Earl and West Florida; W. by the river Missippis; N.E. and N. by South Carolina, the Tennesse state, or by lands ceded to the United States by South Carolina. Its population is estimated, by the census of 1790, at 85,528 persons; of whom 29,264 were slaves; but the number has since been much augmented. The settlement of a colony between the rivers Savannah and Altamaha became the subject of contemplation in England in the year 1732, with a view to the accommodation of poor people in Great Britain and Ireland, and for the farther security of Carolina. The benevolent and humane proposed to raise a fund for conveyingligrant emigrants to this part of America, free of expence. Their generous project was encouraged by letters patent obtained from his majesty George II. in June 1732; and, in honour of the king, the new province was called "Georgia." A corporation was established for settling the colony, which was to be separated from Carolina by the Savannah; and a large sum of money was raised for the purpose of carrying the liberal and humane design into execution. General Oglethorpe was selected for conducting the emigrants, about 116 in number, to their new abode; and soon after their arrival, in the commencement of the year 1733, they marked the spot, on which Savannah now stands, as the most proper for the foundation of their settlement. Accordingly they proceeded to erect a fort, and a number of small huts, for their defence and accommodation. A treaty of amity was concluded between the settlers and their neighbours, the Creek Indians; and various regulations were framed, for their future government. The number of new settlers from the Highlands of Scotland and from Germany gradually increased; so that in the course of three years, Georgia received above 400 British subjects, and about 170 foreigners. Afterward, adventurers from Scotland, Germany, and Switzerland followed the colonymen, and contributed to encourage the hopes of the proprietors as to the permanence and prosperity of the colony. Several towns were built, and, in 1739, more than 600 people were employed in trading with the Indians for furs and skins. Nevertheless, in 1741, the English government received information that scarcely a sixth part remained of the number of persons who had migrated to Georgia; and those that continued were so much discouraged, that they seemed to be desirous of fixing in a more favourable situation. It was thus found that the system of government, which had been formed for this colony, was highly injudicious and altogether inconsistent with its prosperity. The first use which the proprietors of Georgia made of the unlimited powers with which they were invested, was to establish a system of legislation that made them absolute masters, not only of the police, justice, and finances of the country, but even of the lives and estates of the inhabitants. As great inconveniences had been found to arise in other colonies from large possessions, it was thought proper in Georgia to allow each family only 50 acres of land; which they were not permitted to mortgage, or to dispose of by will to their female issue. This last regulation, however, which made the males only capable of inheritance, was soon abolished; but other restrictions of a discouraging nature still remained. No man was permitted to leave the province without a licence. If any of the lands granted by the trustees were not cultivated, cleared, and fenced round with a wooden fence, or pales fix feet high, within 18 years from the date of the grant, such part was to revert to the trustees for the benefit of the colony. It was forbidden to purchase, or export rum, and to trade with the Indians without a special licence obtained for this purpose. Under these restraints the province languished, and the people complained; till at length the trustees, in the year 1752, surrendered their charter to the king, and it was made a royal government. From this time, till the peace of Paris in 1763, the province struggled under many difficulties; arising from the want of credit with friends, and from the frequent molestation of enemies. The good effects of this peace were sensibly felt, and its annual exports, which in 1752 amounted to no more than about 10,000l. sterling, were very much augmented; and its population and agriculture proportionally increased; though under some checks and interruptions from disputes and wars with the Creek Indians. But since a treaty of peace and friendship with the Creek nation was concluded in 1790, the state of Georgia has been rapidly advancing in every kind of improvement.

Since
GEORGIA.

Since the revolution, Georgia has been divided into counties, comprehended under two districts, viz. the Upper and the Lower; the former includes 15 counties, viz. Montgomery, Wallingford, Hancock, Greene, Franklin, Oglethorpe, Elbert, Wilkes, Lincoln, Warren, Jefferson, Jackson, Bullock, Columbia, and Richmond; the latter contains nine counties, viz. Camden, Glynn, Liberty, Chatham, Bryan, McIntosh, Effingham, Screven, and Burke. The principal towns are Augusta, formerly the seat of government, Savannah, the former capital of the state, Sumbry, Brunswick, Frederica, Wathington, and Louisville, which is the metropolis of the state, and where its records are deposited. The principal rivers which water Georgia, are Savannah, which separates it from South Carolina, Ogeechee, which runs parallel with the former, and Altamaha, which runs parallel with the others. Besides these and their numerous branches, we might mention Turtle river, Little Stitilla, Great Stitilla, Crooked river, and St. Mary's, which forms a part of the southern boundary of the United States. The rivers in the middle and western parts, belonging to the "Georgia Wester territory," will be noticed in another place. All these rivers contain a plentiful supply of various sorts of fish, as rock, mullet, whiting, shad, trout, drum, baf, cat fish, whiting, brim and flounder; and the bays and lagoons afford oysters, and other shell fish. The chief lake, or marsh, in this state, is Ekananoka, called by some Ouaquaphenogaw, which is 300 miles in circumference. The eastern part of the state, between the mountains and the ocean, and the rivers Savannah and St. Mary's, comprehending a tract of country more than 120 miles from N. to S., and from 50 to 80 E. and W., is level without a hill or furnace. At the distance of about 40 or 50 miles from the sea-board, or salt-marsh, the land gradually rises to mountains. The vall chain of the Alleghany or Appalachian mountains terminates in Georgia, 60 miles S. of its northern boundary. From the base of this mountain spreads a widely extended plain, of the richest foil, and in a latitude and climate well adapted to the culture of most productions either of the south of Europe or of the East Indies. In the low country, near the rice swamps, bilious complaints and fevers are very general during the months of July, August, and September; and at the approach of this lively febrile, the rich planters, with their families, remove either to the sea-islands or to a more elevated situation, for the benefit of the air. In the winter and spring, pleuridies, peripneumonies, and other inflammatory disorders, produced by colds, are common, and frequently fatal. The winters in Georgia, however, are mild and pleasant; snow is seldom seen, nor is vegetation interrupted by severe frosts. In the hilly country, commencing about 50 miles in some parts, and in others about 100 miles from the sea, the air is pure and luscious, and the water good and abundant. From June to September the mercury in Fahrenheit's thermometer fluctuates from 70° to 90°; and in winter from 40° to 60°. The most prevailing winds are S. W. and E.; and in winter N. W. The E. wind is warmest in winter and coolest in summer; the S. wind in summer and autumn is damp, fullery, and infalburious. In the S. E. parts of the state, the trade winds impart their agitation to the atmosphere, and serve to purify and mollify it. In the lowlands rice is cultivated; and in the interior and hilly parts, wheat and Indian corn, and the other productions common to the northern states, are the objects of agricultural attention. Rice is at present the staple commodity of this state; and the other chief articles of produce are tobacco, wheat and indigo. Georgia also yields cotton, flax, silk, corn, potatoes, oranges, figs, grapes, pomegranates, &c. The four woods of oak, hickory, mulberry, pine, cedar, &c. The whole state is bordered with islands, of which the principal are Skidaway, Wadsaw, Ossabaw, St. Catharine, Sapelo, Frederica, Jekyll, Cumberland, &c. These islands are surrounded by navigable creeks, between which and the main land is a large extent of fall-march at a medium four or five miles broad, fronting the whole state, and intersected with creeks, which admit a general inland navigation, between the islands and the main land, from the N. E. to the S. E. corners of the state. The entrances of rivers flowing between these islands, form capacious harbours from three to eight miles broad; communicating with each other by parallel fall creeks. The islands in their natural state are covered with pine, oak, hickory, live oak, and red cedar. The soil is grey, formed by a mixture of sand and black earth, which renders it very fertile and yields, by cultivation, good crops of indigo, corn, cotton, and potatoes. The soil of the main land, adjoining the marshes and creeks, resembles that of the islands; except that, which borders on the creeks and river that penetrate far into the interior of the country, and which furnishes the valuable rice swamps. The soil between the rivers, at a greater distance, changes from a grey to red colour; and still more remotely, into the mulatto kind, confiding of a black and red earth. This fort of land is generally strong, and yields large crops of wheat, tobacco, corn, &c. This soil is succeeded by another, nearly black, and very rich. This succession of different soils is uniform and regular, intermixed with occasional veins of different sorts; and stretches, in the order above-mentioned, across this state nearly parallel with the sea-coast, and extends through the several states, nearly in the same direction, to the banks of Hudson river. The culture of cotton is now so much an object of attention in this state as to afford a reasonable expectation, that the states of South Carolina and Georgia may, in a few years, be able to raise more than 10 millions of pounds annually for exportation. With proper attention, most of the tropical fruits would flourish in this state. The south-western part of this state, and the adjoining parts of E. and W. Florida, will, it is conjectured, at some future period, become the vineyard of America. The chief articles of export are rice, tobacco, indigo, figo, limber, naval flowers, leather, deer skins, snake root, myrtle and bees wax, corn, and live flock. The value, in sterling money, of the exports of Georgia, in the year 1755, was 15,744; in 1762, 121,677; in 1791, value in dollars, 491,472; in 1792, 456,973; in 1793, 501,383; in 1794, 676,154; in 1795, 950,158; and in 1801, 1,854,495. In 1795, the tonnage employed in this state was 28,450, and the number of American vessels was 11,225. In return for her exports, Georgia receives West India goods, teas, wines, clothing, and dry goods of all kinds: from the northern states, chee, fish, potatoes, apples, cyder, and horses. The imports and exports are principally to and from Savannah, which has a fine harbour, and is the chief emporium of the state.

The disposition and character of the inhabitants, collected from various parts of the world, are very much diversified; they are charged with indolence, which is attributed partly to the relaxing heat of the climate, and partly to the want of motives, necessary for exerting industry; they are prised for their freckledns and hospitality to strangers. Their diversions are dancing, horse-racing, cock-fighting, and chiefly hunting. They are reproached with an addictedness to gaming.

The different religious sects of this state are Baptist, Methodists, Presbyterians, Episcopalian, Roman Catholics, Quakers, and Jews. The two first are the most numerous; the third, fourth, and fifth are about equal in number; and the Catholics and Jews have each of them one church. The civil
Constitution of Georgia was adopted and ratified by a convention of delegates from the people, on the 6th of May, 1777, and is formed upon a plan similar to the federal constitution of the United States. All legislative power is vested in two distinct branches, a Senate and House of Representatives, both chosen by the people at large, and is held at the General Assembly. The members of the Senate are chosen for the term of three years, and those of the House of Representatives are chosen annually. The Senate consists of one member from each county, and the House of Representatives of thirty-four members. The executive power is vested in the hands of a governor, who holds his office during two years. Freedom of the press and trial by jury shall remain inviolate, and all persons shall be entitled to the writ of habeas corpus. All persons shall have the free exercise of their religion, without being obliged to contribute to the support of any religious profession but their own. In each county a superior court is held twice in every year, in which all causes, civil and criminal, shall be tried, those excepted, which may be subject to the federal court, or such as may by law be referred to inferior jurisdictions. The judges of the supreme court and the attorney-general, shall have a salary established by law; and hold their commissions for three years. In the administration of justice, this state is divided into two districts, called the upper and lower circuit; and there are only two judges appointed to sit in the superior court; each of these judges being appointed to try causes in each circuit. Besides the superior court, there is an inferior court, a court of common pleas established in each county, which sits twice in a year, with five judges, appointed by the legislatures. The county courts have a jurisdiction of criminal causes, which can be tried only in the superior court. Besides these there are the sheriff's court, and courts held by the justices of the peace, in every part of the state. The literature of this state, which is yet in its infancy, is generally advancing towards higher degrees of improvement. For this purpose a college is established at Louisville, with liberal endowments; and in subordination to this it is propounded to found academies in every county of the state. This institution is denominated the "University of Georgia." The funds for its support consist of about 35,000 acres of valuable land, together with nearly 6666 acres of land in bonds, houses, and town lots in Augusta. Other property also, to the amount of 6666 acres, has been set apart in each county for erecting and furnishing their respective academies. The fund originally designed to support the literary orphan school, founded by the Rev. George Whitfield, a few miles south of Savannah, consists chiefly of rice plantations and negroes. On the death of the countess of Huntingdon, to whom Mr. Whitfield bequeathed this property as trustee, the legislature, in the year 1792, passed a law, vesting it in thirteen commissioners, with power to carry Mr. Whitfield's original design into execution; and in compliment to the countess, the feminary is denominated "Huntingdon college." The middle parts of this state are inhabited by the Muscogee or Creek Indians, the most numerous tribe of Indians within the United States. See Creeks. The Georgia Western Territory consists of an extensive tract of land, a principal part of which belongs to, and is inhabited by the Creek, Chickasaw, Chickasaw, and Cherokee nations of Indians. It is washed by the Mississippi river on the west, and may be considered as extending eastward as far as the Appalachian and Flint rivers. It is intersected by a great number of streams, which run in every direction; the principal are the Yazoo, and Loofa Chitto, which discharge themselves into the Mississippi, Pearl, Pascagoula, Mobile, Alabama, Tombalbeeke, Escambia, and Chatta Hatta, which fall into the gulf of Mexico; and the Tennessee Bend, with Chucquamaga river, which falls into it from the south-east, water its northern part. Twenty millions of acres of this territory was sold in consequence of an act of the legislature, passed in 1793, to certain companies; and the purchase money, amounting to $5,000,000, was paid into the state treasury. This land was afterwards sold at an advanced price, by the original purchasers, to various persons, principally of the middle and eastern states. This transaction produced a great degree of discontent; but the ferment has since subsided; and the termination of the dispute has been a general satisfaction on the part of the purchasers, that the discordant proceedings of the legislature cannot affect their title, which they conceive to be good against all claims on the part of Georgia. More. Georgia, New, or South Georgia, an island in the South Atlantic ocean, discovered by La Roche in 1675, seen by Mr. Guyot, in the ship Lion, in 1756, and more particularly described by captain Cook, who explored it with attention in 1775, described its extent and true position, and named it Georgia, in honour of his majesty. It is situated between 53° 57' and 54° 37' S. lat., and between 33° 13' and 35° 34' W. long. It extends S. E. by E. and N. W. by W., and in that direction is 31 leagues long, and its greatest breadth is about 10 leagues. It seems to abound with bays and harbours, especially on the N. E. coast; but they are rendered inaccessible for the greatest part of the year by the vast quantity of ice; or, at least, it must be dangerous lying in them, on account of the breaking up of the ice-bergs, by which the coast is bounded, and which rise up perpendicularly in masts of very considerable elevation. When the fall they float about in the sea like detached islands, and in falling make a noise like that of a discharged cannon. The inner parts of the country exhibit an appearance not savage and horrid than the coast. The rocks raised their lofty summits, till they were lost in the clouds, and the valleys lay covered with everlasting snow. The lands, or rather rocks, bordering on the sea coast, were not covered with snow like the inland parts. The rocks seemed to contain iron. They are of blackish horizontal slates, probably approaching to hornblende. Not a tree was to be seen, nor a shrub even big enough to make a toothpick. The only vegetation that could be seen was that of a coarse strong-bladed grass-growing in tufts, wild burnet, and a plant like masts, which spring from the rocks. Seals or sea-lions were numerous, but smaller than those at Staten Land. Several flocks of penguins of a large size were observed, and besides these, the oceanic birds were albatrosses, common gulls, and that fort called by Cook Port Egmont lans, terns, frigate birds, divers, the new white bird, and a small bird like those of the Cape of Good Hope, called yellow birds, which were found to be most delicious food. All the land birds that were seen consisted of a few small hawks; but our navigators found no quadrupeds. The dung of one was seen, suppos'd to have belonged to a fox or an animal of that kind. On the whole coast our voyagers observed neither a river nor a stream of fresh water. They thought it highly probable that the country has no perennial springs; and that the interior parts, as being much elevated, never enjoy heat enough to melt the snow in such quantities as to produce a river or stream of water. The coast alone receives warmth sufficient to melt the snow, and this only on the N. E. side; for the other, besides being exposed to the cold south winds, is in a great degree deprived of the sun's rays by the uncommon height of the mountains. On the approach of our navigators to Georgia, they first discovered an island in S. lat. 54° and W. long. 38° 23'; which was called "Willis's island," which was a high rock of no great extent: call of this, between it and the main, they observ'd...
ed another island, to which, on account of the number of birds they saw on it, they gave the name of "Bird Island." This island is of larger extent than the former, lies close to the N. E. point of the main land, which was called "Cape North." After having cleared the passages between these two islands, they pursed their coasting voyage to "Cape Buller," and at length arrived at a bay, which they denominated "Pojeeion bay," situated in S. lat. 54° 5'. W. long. 37° 18', 11 leagues E. of Cape North. The land in which this bay lies, was at first judged to be part of a great continent; but upon coasting round the whole country, it was found to be an island, about 70 leagues in circuit. Between this bay and Cape Buller lies the "Bay of islands," so named on account of several small islands lying in and before it. The next projecting point was called "Cape Saunders," and beyond this is a large bay, which was named "Cumberland Bay." The next projecting land, which was an island appearing to be the extremity of the coast to the east, was called "Cape Charlotte," and on the west side of it lay a bay, which was named the "Royal Bay," the W. point of it being called "Cape George." These two capes are distant from each other six leagues. The island above mentioned, distant in the direction of S. by E. eight leagues from Cape Charlotte, was denominated "Cooper's Isle," which is a rock of considerable height, about five miles in circuit, and one mile from the main. The coast between them forms a large bay, named "Sandwich Bay." At Cooper's Isle the main coast takes a S. W. direction for the space of four or five leagues to a point which Capt. Cook called Cape Disappointment. Off this are three small islands, the southernmost of which is green, low, and flat, and lying one league from the Cape. Advancing towards the S. W., land opened beyond the Cape, which proved to be an island, and was called "Pickering island." In failing round this island, our navigators were almost continually involved in a thick mist, which led them to apprehend that they might be surrounded with dangerous rocks.—Cook's Second Voyage, vol. ii.

**GEORGIA.** A township of America, in the state of Vermont and county of Franklin, containing 1068 inhabitants. It is situated on lake Champlain, opposite to the north end of South Hero island, and joins Milton on the south and St. Albans on the north. The river La Moille traverses the S. E. corner of this township.

**GEORGIA, Gulf of,** a large gulf of the North Pacific ocean, between the continent of North America and Quendra and Vancouver's island; about 120 miles in length from north to south; the breadth varying from 6 to 20 miles. It contains several clusters of islands, and branches off into a great number of canals, most or all which were examined by Capt. Vancouver and his officers.

**GEORGIAN PLANET, or GEORGIIUM SIDUS, in Astronomy, the name given by Dr. Herchel, the discoverer, to the seventh primary planet of the solar system. It is now generally known, particularly on the continent, by the name of Uranus.**

This planet was discovered by Dr. Herchel on the 13th March, 1781. It is supposed that other astronomers have observed it, and inferred it in their catalogues as a fixed star. But Dr. Herchel, when he first saw it, was struck with its appearance, which seemed to differ from that of the neighbouring small stars. He happened to be accidentally engaged in examining the small stars near the feet of Gemini, and he observed one considerably larger than the rest, but not being so brilliant, he suspected that it might be a comet; in consequence of which he observed it with different magnifying powers, from 227, with which he discovered it, to 200, and found that its apparent magnitude increased in proportion, contrary to what takes place in the fixed stars. He therefore measured its distance from one of the neighbouring fixed stars, and comparing its distance for several nights he found that it moved at the rate of about 41" in an hour. Dr. Herchel wrote immediately to the Royal Society, that other astronomers might join in observing it; upon which it was found and observed by Dr. Maldeley, who at once immediately declared that he suspected it to be a planet; and on April 1, he wrote an account of this discovery to the astronomers at Paris, so that it was soon observed by all the astronomers in Europe. Mr. Lexell was then in England, and applied himself to compute the orbit upon the supposition that it was a comet; he therefore, according to the usual manner in such a case, supposed the orbit to be a parabola, and ascertained several parabolic distances, 6, 8, 10, 11, 12, 14, 16, and 18 times the earth's distance from the sun, and found that any parabolical distance between 14 and 18, would answer very well to the observations. Boscovich printed a memoir on the subject, in which he showed that there were four different parabolas in which a body might move, and yet the computed places would agree with the observations which had then been made. Other astronomers, however, found that a circular orbit, whose radius was about 18 times the distance of the sun from the earth, would agree better with the observations; and confirmed Dr. Maldeley's opinion that it was a planet. Upon the supposition, therefore, of a circular orbit, M. de la Lande proceeded to investigate its magnitude from the following observations. Mem. de l'Acad. Roy. des Sci. 1779.

GEORGUM SIDUS.

From these data, M. de la Lande calculated the elements of a circular orbit; but it having been found that the motion did not agree with any possible circle, it became necessary to calculate the elements of an elliptic orbit. When a sufficient number of oppositions had been observed for this purpose, professor Robison of Edinburgh undertook this investigation, a full account of which is given in Edin. Trans. vol. i. 1788. The observations on which this investigation is founded are as follows:

<table>

From which the following elements were obtained:

- Mean distance
- Eccentricity
- Periodic time
- Mean anomaly at the 5th opposition
- Long. of apogee
- Long. of the node
- Inclination of the orbit
- Equation of the centre

The elements, as given by La Place, are as follows:

</table>

From which the following elements were obtained:

- Mean distance
- Long. of apogee
- Long. of the node
- Inclination of the orbit
- Equation of the centre

The diameter of this planet is about 4 times that of the earth, or 35,112 English miles nearly. When seen from the earth, its apparent diameter, or the angle which it subtends at the eye, is 3° 5', and its mean diameter, as seen from the sun, is 4'. As the distance of the Georgian from the sun is twice as great as that of Saturn, it can scarcely be distinguished by the naked eye. When the sky however is serene, it appears like a fixed star of the seventh magnitude with a blueish white light, and a brilliancy between that of Venus and the Moon; but with a power of 200 or 300, its disc is visible and well defined. Its arc of retrogradation is 3° 36', and the duration of its retrograde motion 151 days.

This planet is accompanied by six satellites, all of them discovered likewise by Dr. Herichel. The two first, which he saw for the first time in the month of Jan. 1787, proved afterwards to be the second and fourth, the others were discovered some years later.

The most remarkable circumstance attending these satellites is, that they move in a retrograde direction, and revolve in orbits nearly perpendicular to the ecliptic, contrary to the analogy of the other satellites, which phenomenon is extremely discouraging when we attempt to form any hypotheses relative to the original cause of the planetary motions.

According to La Place, if we take for unity the semidiameter of the planet, equal to 1° 39', supposed feet at the mean distance of the planet from the sun, the distance of its satellites will be as follows:

- I. 13:120
- II. 17:022
- III. 19:845
- IV. 22:752
- V. 45:507
- VI. 91:008

And the duration of their sidereal revolutions:

<table>
<thead>

</tr>
</tbody>
</table>

La Place concludes that the first five satellites of the Georgian may be retained in their orbits by the action of its equator, and the sixth by the action of the interior satellites; hence he concludes that the planet revolves about an axis very little inclined to the ecliptic, and that the time of its diurnal rotation cannot be much less than that of Jupiter and Saturn.

Use of the Tables.—The general construction of this kind of tables will be explained under Planet. The manner of calculating the mean longitude of the planet is as follows. Vince's Astronomy, vol. iii. From Table I. take out the mean longitude, the apogee, and node, together with the arguments II., III., IV., VI., VII., VIII., and place them in an horizontal line. But if the given year be not found in that table, take the nearest year preceding the given year as an epoch, and take out as before.

Under which, from Table II. place the mean motion in longitude of the apogee and node, with the arguments answering to the number of years elapsed since the epoch, to the given year.

Under these write down (Table III.) the mean motions of the same, for the given day of the month.

Under these write down (Table IV.) the mean motions of the same, for the given hour of the day.

Under these write down (Table V.) the mean motions of the same, for the given hours and minutes.

Add together the numbers in the several columns, rejecting twelve signs, or any multiples thereof, if they occur; and in the arguments, rejecting 10,000 in the arguments IV., VI., and 100 in the arguments II., III., V., VII., VIII., or any multiples thereof, and you get the mean longitude, the apogee, and node, for the arguments for the given time.

From the mean longitude of the Georgian subtract the longitude of the aphelion, and you have argument I., or mean anomaly.

With argument I. take out the equation of the orbit in Table VI., together with the secular variation, with their proper signs, except the time be before 1780, in which case the secular variation is to be taken out with a contrary sign, making a proportion for the minutes and seconds of the argument, and you first get the equation; and doing the same for the secular variation, you get the secular variation; then say, 100 : the number of years from 1780 to the given time
GEORGIUM SIDUS.

Before 1789 the secular variation must be taken with a sign opposite to that found in the table. With argument II. take out the equation in Table VII., making a proportion in this and in the following equations, for the intermediate numbers of the arguments. With argument III., take out the equation in Table VIII. With argument IV. take out the equation in Table IX. With argument V. take out the equation in Table X. With argument VI. take out the equation in Table XI. With argument VII. take out the equation in Table XII. Take the sum of all these equations, regard being had to the signs of the first equation, and of the secular variation, the signs of the others being positive; and from it subtract $7'20''$, and you get the value of these eight equations; and this applied with its proper sign to the mean longitude already found gives the longitude of the Georgian in his orbit.

From the longitude thus found, subtract the longitude of the node, and you have argument IX.

With argument IX. enter Table XVII. and take out the reduction to the ecliptic, with its proper sign, making a proportion for the minutes and seconds of the argument; and this applied to the longitude of the Georgian in his orbit, gives his true heliocentric longitude on the ecliptic, reckoned from the mean equinox.

With argument IX. enter Table XVI. and take out the latitude, making a proportion for the minutes and seconds of the argument, and you have the true heliocentric latitude of the planet.

With the mean anomaly enter Table XIV., and take out the radius vector; and correct it by the following Table XV., and you have the true distance of the planet from the sun, that of the Earth being unity.

**Example.**—To find the heliocentric Latitude and Longitude of the Georgian, on Nov. 26, 1789, at 16° 14', mean Time at Greenwich.

</table>

This is the true heliocentric longitude from the mean equinox; and if we want it from the true equinox, we must apply the equation of the equinoxes.

In this operation the first five lines are taken out immediately from the table, and the sums of all the columns give the mean longitude of the aphelion, the node, and the arguments for the given time. Argument I. is immediately found according to the rule, the equation to which is thus found. The equation (Table VI.) for $422^\circ$ is $3 26 59.6$, and the variation or $60^\circ$ is $431.1$; hence $60^\circ: 54 15' : 1 31.1 : 35'.1$, which (as the equation is decreasing) subtracted from $-32659.6$ gives $-23254.5$, the equation required. And to find the secular variation, that variation is $+7.44$ for $42^0$, and it decreases $0.16$ for $60^\circ$, hence $60^\circ: 54 15' : 0.16 : 0.15$, which taken from $+744$ leaves $+729$, the secular variation corresponding to the given argument. Now this secular variation is reckoned from 1780, and from thence to November 26, 1789, there has elapsed 99 years; hence $100: 9.9 : +729 : +0.7$ the secular variation for 99 years. With argument II, 628, take the equation from Table VII. Now the equation for 628 is $4.7$, and it changes $0.7$ for 10; hence $10: 8 : 0.7 : 0.6$, which as the equatio
rion decreases, subtracted from 4°.7 leaves 4°.1, the equation required. By proceeding thus to argument VIII, we get all the equations, and by taking the difference of the positive and negative parts, we get 3° 21' 45".5 for the value of the first eight equations; which applied to 4° 10" 6' 11".4 gives 4° 6' 47" 25'.9 the longitude of the Georgian in his orbit. From this longitude subtract 2° 12' 48" 19" the longitude of the node, and we get 1° 23' 56" 7", which is argument IX; with which enter Table XVII. and take out the reduction, which is 8°.9, and this applied to 4° 44' 25".9 gives 4° 6' 47" 17", the heliocentric longitude of the Georgian on the ecliptic from the mean equinox. Also with argument IX, enter Table XVI. and take out the latitude. Now for 1° 23' the latitude is 36° 57", and it increases 28°.8 for 60°; hence 60° : 56° 7° : 28° 8° : 26° 9°, which added to 36° 57" gives 37° 23".9, the heliocentric latitude of the Georgian.

Table I.

Epochs of the mean Longitude of the Planet, with the Arguments of the Equations.

In the Bif textiles day must be subtracted for the months of January and February.
### Table VI.

Equation of the Orbit for 1780, with the secular variation to be applied to the longitude.—Before 1780, this secular variation must be applied with a contrary sign.

**Arg. I = (Mean long. — aphelion) or mean anomaly.**

GEORGIAN Bible. See Bible.

GEORGIAN Monks and Nuns, are religious of Georgia, in Alia, who follow the rule of St. Basil.

GEORGIANA, in Geography, a name originally given to a tract of country in the province of Maine, in North America.

gEOGR, something that relates to the culture or tillage of the ground.
The word is borrowed from the Latin geographus; and that of the Greek γεογραφικός, of γη, earth, and γραφή, a book, I work, labour, of γράφω, to write. The Geographies of Virgil are four books composed by that poet on the subject of agriculture.

GEORGEV, in Geography, a town of Rufia, in the government of Caucausus; 22 miles W.N.W. of Ekaterinograd.

GEORGIA, in History, so named by Willemow in honour of Professor Georgi; see Georgia, and DAHLIA.

GEORGITZ, in Geography, a town of Walachia; 18 miles N.N.E. of Bucharest.

GEOSCOPY, a kind of geography, or knowledge of the nature and qualities of the ground or soil, gained by viewing and considering it.
The word is formed of the Greek γθ, earth, and σκόπεω, to view.

GEOSTATICS. See Statics.

GEOPHRUS, in Ancient Geography, a town of Syria, according to Polybius, which surrendered to Antiochus.

GEOPHYRA, a town of Syria, in the Seleucide territory, according to Ptolemy; 22 miles from Antioch.—Allo, a town of Africa, according to Polybius, in the vicinity of Carthage, situated on the bank of the river Macros.

GEOPHYRAEI, a people mentioned by Herodotus, who were probably natives of Gephyra in Syria; they migrated with Cadmus into Boeotia, where they occupied the territory of Tanagra; but on being driven from thence by the Bectos, they took refuge in Attica.

GEOPIDE, a people of Scandinavian origin, of whom the Gothic extraction Jornandes gives the following account: the Goths, leaving Scandinavia under the conduct of King Barth, put to sea with only three ships. One of these, falling short of the other two, was thence called "Geopanta," signifying in the Gothic tongue: and hence the name of Gepantia and Gepide, which was at first given them as an appellation of reproach. Procopius likewise expressly affirms, that the Goths, the Vandals, the Visigoths and the Gepides, were originally the same nation; and that they had the same customs, manners, religion, and language; and that they only differed in names, borrowed, perhaps, by them from their different leaders. They entered Scythia with the other Goths, and settled in the neighbourhood of the Tanais and Pulas Meritis. There they continued till the reign of Arcadius and Honorius, when, their number being greatly increased, they approached the Danube, and having afterwards crossed that river, dwelt in the neighbourhood of Singidunum and Sirmium, about the year 450, when they still were when Procopius wrote his history. They had kings of their own, and formed a distinct nation, separate from both the Ostrogoths and Visigoths; but perhaps not one from the Lombards, who were afterwards masters of Italy. Under their king Fafid, they gained a complete victory over the Burgundians about the year 245; and Fafida, elated with this victory, laid waste the territories of the Goths, whose sovereign Olrogotha refused to grant them land for their accommodation. Being defeated by the Goths, they afterwards joined them, and other northern nations, in the irritation which they made with their united forces into the empire in the second year of the reign of Claudius; but they were defeated by that prince with great slaughter. In the year 279 Probus granted them lands in Thrace, upon promise of their quiet submission; but whilst the emperor was engaged in war in the East, they seized the neighbouring provinces, and were cut off in great numbers by Probus after his return. St. Jerome mentions the Gepidi among the other nations of Barbarians, who, in 407, invaded Gaul, and overran its provinces. Attila afterwards subdued them, and in 451 they served under him in his famous expedition into Gaul. Upon the death of Attila, the Gepids shook off the yoke under the conduct of their king Ardari, who obtained a complete victory over the Huns; in consequence of which the Gepids not only recovered their ancient liberty, but gained possession of ancient Dacia, N. of the Danube, from which they had been driven by Attila. They then entered into an alliance with the Romans, who agreed to pay them an annual pension. Having obtained possession of part of Illyricum, with the city of Sirmium, they continued quiet till the year 537, when, on account of them joining the Heruli, and plundering the neighbouring provinces, they were compelled by Justinian, after several encounters, to abandon Illyricum, and to content themselves with Dacia beyond the Danube. In the year 550, a quarrel arose between the Gepid and the Lombards; but the latter, having obtained a reinforcement from Justinian, attacked the former, and gave them a total overthrow. This defeat was followed by a peace between the two nations, which was brought about by the mediation of Justinian. The peace, however, was of short duration. Under their respective sovereigns, viz. Cumidius, king of the Gepide, and Alboinus, king of the Lombards, they commenced mutual hostilities; and determined to abide by the issue of a single battle. The contest was very severe, and remained for some time very doubtful; but at last, the Gepids were put to flight, and pursued by the victorious Lombards with such slaughter, that scarcely one was left alive of the numerous multitude that had engaged. After this victory the Lombards seized the whole of Dacia, and obliged the Gepids either to submit, or to retire. Henceforth they had no king of their own, but lived in subjection either to the Lombards, who were masters of their country, or to the princes of the neighbouring nations, especially the Huns, settled in Pannonia. Thus their kingdom terminated in the year 572, Justin, the successor of Justinian, being then emperor.

GEPE, in Geography, a river of Germany, which rises near Neustadt in the county of Mark, and runs into the Bigge, two miles N. of Olpe, in Westphalia.

GER. CAPE. See Auch.

GERA, a town of Saxony, in the Vogtland, on the Elbe; 30 miles S.S.W. of Leipzig. N. lat. 50° 49'. E. long. 12° 6'.—Allo, a town of Italy, in the department of the Upper Po.—Allo, a river of Germany, which runs into the Unfrull, six miles N. of Erfurt.

GERA, in Ancient Geography, a town of Arabia.

GERT. A, a town of Lusitania. Portus.

GERÉS.
GERÆSTIUM, a country of the Peloponnesus, in Arcadia.

GERÆSTUS, a town and port of the island of Euboea, upon the S.W. coast, about 15 miles from Carythus; now Erecho.

GERALFINGEN, in Geography, a town of Switzerland; four miles S.E. of Soleure.

GERANDRUM, in Ancient Geography, a town of the island of Cyprus.

GERANGER, in Geography, a town of Norway, in the diocese of Drostenheim; 22 miles S.S.W. of Romildal.

GERANIA, in Botany, the 73d natural order in Jussieu's system, or the 13th of his 15th classes. The following is his definition of this, one of his most important and extensive classes. Cotyledons two. Petals many. Staminens inferred below the germien. — The Calyx is of one or many leaves, very rarely deficient. Petals hypogynous, or inferted below the pistil, definite in number, very rarely indefinite, for the most part distinct, but sometimes connected at the base, into a sort of scale monopetalous corolla; they are rarely wanting. Stamens inferred below the pistil, definite or indefinite, the filamenta often distinct, sometimes united all together into one tube, more rarely collected into several bundles; anthers distinct, or united only in Vilia and Impatiens (called Balsamina by Jussieu). German superior, in manyimple, in some multiplied; style simple, or multiplied, or deficient; stigma one, or several. Fruit superior, sometimes simple, of one or many cells; sometimes, but more rarely, multiplied, each pericarp of one cell. The order of Gerania is thus defined by Jussieu. Calyx simple, either of five leaves, or of one deeply five-leafed, permanent. Petals five. Stamens definite, their filaments united at the base, sometimes all fertile, sometimes part of them abortive. German simple; style one; stigmas five, oblong. Fruit either of five cells, or of five capsules, each cell or capsule containing one or two seeds. Capsules without a peri camb, (or albumen). Stem either somewhat flabby, or hercaceous. Leaves with stipules, opposite or alternate. Flowers, in the former cafe, opposite to each leaf; in the latter, axillary.

Jussieu enumerates only two genera as properly belonging to this order, Geranium, which includes Eroditum and Pelargonium jullly separated from that genus by the late M. L'Héritier; see Eroditum; and Monfonia, which is but too nearly akin to Geranium. He subjoins three genera as related to this order; Tropaeolum, whose affinitie is very obscure; Impatiens (his Balsamina), which is perhaps still less akin to it; and Oxalis, which last we would rather refer to the Rutaceæ, an order which Jussieu sees but imperfectly to have studied. He indeed, like Linnaeus, hints some relation between Oxalis and Tribulus or Zygoophyllum, both which last he fixations in the first section of his Rutaceæ; but we presume to think they are there misplaced, and that Oxalis is not so much allied to them as to the real Rutaceæ, so many of which are found in New Holland. In all such doubtful cases however, which form the difficulty and the pedantry of the study of natural orders, and in which our chief guide being conjecture, humility and candour are most becoming, we merely aim at collecting observations. The unnatural combinations complained of in a systen professedly artificial, cannot be half so hurtful as error masked in authority in the details of a pretended natural one. The doubts and lents of the excellent Jussieu are in themselves instructive, but how few are content like him to confede their doubts! He has at length acquired a pupil worthy of himself in this country, Mr. R. Brown, whose opportunities of observation, among the paradoxical novelty of New Holland, have given ample scope to his intelligence and affility.

GERANIA, in Ancient Geography, a town of Thrace. — Allo, a town of Phrygia. — Allo, an ancient town of the Peloponnesus, in Laconia, on the confines of Messenia. — Allo, a mountain of Greece, in the territory of Megariss, towards the illims of the Peloponnesus.

GERANIS, or GERANIUM, in Surgery, a bandage formerly applied to fractured collar-bones, and dislocated shouldcrs. The word is derived from γέρανος, a crane, because the shape of the bandage was thought to resemble an extended crane.

GERANITES, γέρανιτες, a crane, in Natural History, a name given by some authors to such pieces of agate, or any other of the semi-precious gems, as have round spots in them, resembling in clothe the eye of a crane.

Gen. Ch. Cal. Periathan inferior, of five ovate, acute, concave, permanent leaves. Cor. regular, of five large, obovate or obcordate, equal, spreading petals. Nectary five glands at the base of the germin, alternate with the petals. Stam. Filaments 10, awl-shaped, recurved, united at the base into a small cup, five alternate ones longer, all shorter than the petals; anthers oblong, ventive, five of them occasionally abortive. Pet. Germin superior, with five furrows, beaked; style central, awl-shaped, longer than the filaments, permanent; stigmas five, oblong, reflexed. Pet. Capsules five, aggregate, membranous, globose, separating at the mide, each attached upwards to a long, linear, flat, pointed, rigid, smooth awn, at length elastically recurved, adhering by its point to the summit of the style. Seed solitary, lateral, roundish, their surface smooth or dotted.

Eff. Ch. Calyx of five leaves. Petals five. Nectariferous glands five. Fruit beaked, of five aggregate capsules, each tipped with a long, recurved, naked aven.

Obf. This genus, as above defined, contains only the Geraniana columna of Linnaeus, or what are commonly called European Geraniaus, or Crane's-bills, bearing but one or two flowers on a stalk. (See Eroditum.) Thus it is adopted by Willkdnov, who has 39 species, 13 of which are natives of Britain. They are tlerably naturally distributed into three fections.

* Flower-flalks single-flowered; 4 species.

G. singuineum, Engli. Bot. t. 272, a hardy inhabitant of rocky woods and abrupt gravelly ground, is an example of this section, though the late Mr. Davall once found in Switzerland an occasionally two-flowered variety. See Pl. Brit. 739. A variety found on the Laneshire coast, of humble depreived growth, with white red-veined petals, is frequent in gardens.

G. fllirium, Jacq. Hort. Vind. v. 1. t. 19, an inconsistent species, is, we believe, commonly single-flowered.

** Flower-flalks two-flowered. Root perennial, 24 species. Most of the Crane's-bills usually cultivated for ornamen are of this division, as

G. anonyunfolium of L'Héritier. Curt. Mag. t. 266. This shovly species, discovered by Mr. Maffon in Madiera, was, as Mr. Curtis records, long known in our gardens by the name hvegetum, admirably expressive of its smoothness, and the French botanist changed it for the work. We could have
no redress, as the original name had not been printed. It is a hardy greenhouse plant, throwing out, from its short knotty stem, a profusion of spreading, long-stalked, hissing, palmate, pinnatifid leaves, and many spreading, leafy branches, forked upwards. The flowers are large, of a fine crimson, broader than a half-crown.

G. macrorhizum, Linn. Sp. Pl. 953. Jacq. Hort. Rar. t. 154. native of Italy, is a very common hardy perennial in our gardens, remarkable for the roundness of its red petals, and the strong, but aromatic, cedar-like, scent of its herbaceous. The plant is of humble growth, with a short knotty stem, like the leaf. Leaves soft and downy.

G. phaeum, Linn. Sp. Pl. 953. Engl. Bot. t. 132; and G. fusca, Linn. Mant. 97, two species very nearly akin, are remarkable for the dark brown colour of their flowers; as G. reflexum, ibid. 257. Cavan Dift. t. 81. f. 1, is for its reflexed petals, and G. lividum, I. Hort. Geran. t. 39, first well determined by Haller at his No. 935, though he was not for some time attended to, for its flat, round, serrated petals, of a pale livid dove-colour. These four leaves are often seen in gardens about London.

G. nodosum, Linn. Sp. Pl. 953. Engl. Bot. t. 1091, is the most rare British species, and scarcely found elsewhere but on the mountains of Providence and Dauphinny, in shady places.

G. fliratianum, Linn. Sp. Pl. 953. Curt. Mag. t. 551, a native of Italy, very hardy with us, is generally admired for its delicately pencilled blossoms.

G. angustissimum, Curt. Mag. t. 203, now frequent in gardens about London, but from what country imported is not known, was first ascertained as a distinct species by the late Mr. Curtis. Its flowers are prettily veined with reddish-purple on a pale ground.

G. britannicum, Linn. Sp. Pl. 954. Engl. Bot. t. 404, a very handsome blue-flowered species, common in pastures in the north, is extremely remarkable, and almost singular in this natural order, for having sometimes double flowers, in which state it was found near Athol house, Scotland, by lady Charlotte Murray in 1793. It is often seen with white petals.

G. virginicum, Linn. Sp. Pl. 954. Curt. Mag. t. 504, a native of Mount Baldus, was introduced into England by the indefatigable and intelligent Mr. Lod lige, whose zeal and liberality as a cultivator are above all praise. Its leaves are beautifully flat, the plant dwarf, but the flowers peculiarly large, bluish-coloured, veined with red.

G. pyrenicum, Linn. Mant. 97. Sm. Fl. Brit. 735. Engl. Bot. t. 405. Curt. Lond. fac. 5, t. 42, common about London and Edinburgh, has not been well understood, even by Mr. Curtis, who undertook to illustrate it. Linnaeus originally confounded it with molle hereafter mentioned, from which its even capsules, perennial root, and greater magnitude, keep it very distinct.

**Flower-stalks two-flowered. Root annual; 11 species.**

G. boveocum, Linn. Sp. Pl. 955. placed first in this section, well drawn in Dilleniis Hort. Eth. t. 133. f. 169, is remarkable for its very black hairy seed-vessels, and villos leaves.

G. molle, Engl. Bot. t. 778, ought to follow immediately; with dijeficum, t. 7533; rotundifolium, t. 157; and pajritis, t. 385. These four, long confounded, and inaccurately understood by any botanist, are beautifully distinguished, in every degree of luxuriance, by their capsules, which are corrugated and naked in the first, more slightly corrugated, but hairy, with reticulated seeds, in the second; carinated, even and hairy, with reticulated seeds, in the third, with much more entire leaves; even and hairy, with smooth seeds, in the last, whole hairs on the part in question are; moreover, close-packed, not spreading as in the preceding. We were obliged to the late Mr. Davall for first calling our attention to this part, and thus leading to one of the most satisfactory discoveries in European botany.

G. carolinianum, Linn. Sp. Pl. 956. Jacq. Hort. Schonbr. v. 2. t. 148, where it is mistaken for a new plant, and called 

Germania, in Gardening, comprehends plants of the herbaceous perennial kind, of which the species cultivated are, the dark flowered crane's-bill (G. phaeum); the knotty crane's-bill (G. nodosum); the streaked crane's-bill (G. fritatum); the Siberian crane's-bill (G. leucanthes); the bloody crane's-bill (G. fanguineum); and the long-rooted crane's-bill (G. macrorhizum); but there are other sorts that may be cultivated with propriety.

The fifth species has several varieties, with short spreading stems and small leaves and flowers; with large leaves deeply divided, and with variegated or striped flowers.

**Method of Culture.**—Each of these species of plants is capable of being increased in two ways; either by lifting the seeds or parting the roots. Where the first method is adopted, the seeds should be sown in the autumn as soon as they have become perfectly ripened, either in pots or in a shady border in the garden ground where the mould is light and fine. As soon as the plants have acquired a few inches in growth, they should be pricked out into other pots, or beds of similar earth, at the distance of five or six inches in the latter case; but where this cannot be done, they may be transplanted elsewhere until the following autumn or spring, and be then put out into other pots or borders, where they are to continue, being occasionally watered in a moderate manner.

In cases where the parting of the roots is practicable, care should be taken not to divide them too much; planting them out in the early part of the autumn, either in pots or other vessels, where they are to continue.

Most of these sorts of plants are of rather hardy growth, and succeed in most kinds of ground, demanding but little attention in their cultivation, besides that of their being kept clear from all sorts of weeds and rubbish.

All of them are capable of affording variety in the borders, clumps, and other parts of pleasure gardens, and the potted kinds produce a fine effect in situations about the houses in mixture with those of other sorts.

**GERANOS, Figae, in Antiquity, a remarkable dance performed in the festival called Dilia.**

**GERANZAGO, in Geography, a town of Italy; nine miles E.N.E. of Pavia.**

**GERAR, or Geras, or Gerasum, in Scripture Geography, a city of the Philistines, S. of Judah. The Abimelechs were kings of this city in the time of Abraham and Isaac. At this time it was the boundary of the Canaanites, situated on the river Bezon, about seven miles S.W. of Debir, and six E. of Beeriheba. It afterwards belonged to the tribe of Simeon. Gerar extended far into Arabia Petraea, being 25 miles from Edathorpe, beyond Daram, the south of Gudah. Motes lays, that it lay between Kedesh and Shur; and he mentions the Jordan or valley of Gerar. (Gen. xxvi. 26.) Sozomen speaks of a little town, called Gera, 50 stadia from Phalasum.**
Gerard is confounded with Beerheba, Ashkelon, Alluah, and Arad.

GERARD, Herr, in Botany. See Aegopodium.

Gerard, in Biography, who flourished about the end of the eleventh, and commencement of the twelfth centuries, founder and first grand-master of the order of St. John of Jerusalem, was a native of the isle of Marigues, on the coast of Provence. While Jerusalem was in the hands of the Saracens, some Neapolitan merchants obtained permission from the sultan of Egypt and Syria, in the year 1059, to erect a Benedictine monastery, near the holy sepulchre, for the convenience of the pilgrims who came to visit it. Among others Gerard came to pay his devotions at the holy city, where he obtained a high character for piety and prudence. The monastery soon became rich, and in conformity with the spirit of the times the abbot built, with the wealth poured in by the rich devotees, an hospital for the reception of the poorer claths, and with proper accommodation for the aged and the sick. The management of this he gave to Gerard. A part of the building was separated for a chapel dedicated to St. John, because it was said that Zacharias, the father of St. John, had lived on the spot where it was built. Gerard, after the conquest of Jerusalem, by Godfrey of Bouillon, projected the foundation of a new religious order, in which the ecclesiastical and military character should be blended. He began about the year 1170, to carry his design into execution, when numbers of persons associated with him under the denomination of the Hospitallers of St. John of Jerusalem, "who, besides the three usual vows of chastity, poverty, and obedience, took a particular vow to devote themselves to the relief of all Christians in distress. The order was recognized, and privileges granted to it by pope Piacul II. Gerard was the first grand-master, and Fitch was the commencement of that order which has been so frequently and so long celebrated in history: the members of it were first demoted knights of Rhodes, and afterwards knights of Malta. Morei.

Gerard, John, a learned German Lutheran divine, was born at Jenae in the year 1551, where he was educated, but at the age of nineteen he went to Altdorf for the sake of greater progress in the oriental languages; and in 1643 the university conferred on him the degree of M.A. He was appointed professor of philosophy at Wittenberg in 1646, and in 1652 he was nominated professor of history at Jenae. After this he was created doctor of divinity, and made professor in that faculty, having devoted much of his time to biblical and theological learning. He was likewise appointed rector of the university of Jenae. He died in the year 1688, and left behind him, as memorials of his great learning, many works of very deep erudition: among these were "Harmonia Linguarum Orientalium;" "Dissertationum theologiarum Fideiculis;" "De Ecclesiae Copiae Ortu, Progrefu, et Doctrina."

Gerard, Alexander, was born at Garioch, in the county of Aberdeenshire in the year 1552; he was educated at the grammar-school at Aberdeen, and so great was his progress, that he was entered a student in Marischal college when he was but twelve years of age. Here he devoted his first four years to the study of Greek, Latin, the mathematices, and philosophy, and was, at the close of the course, admitted to the degree of M.A. He now commenced his theological studies, which he prosecuted at the universities of Aberdeen and Edinburgh. Immediately on the completion of his twentieth year, he was licenced to preach in the church of Scotland, and in the year 1570 was chosen fellow to the University of Edinburgh. Dr. Gerard was ordained a minister of the church of Scotland, and in the following year he was appointed professor of divinity in the Marischal college, and about the same period he took his degree of doctor of divinity. He continued to perform the several duties attached to his office till 1771, when he resigned the professorship, together with the church living, and was preferred to the theological chair in the university of King's college, a situation which he held till his death in 1775. Dr. Gerard's attainments were full rather than brilliant, the effect of close and almost incessant study, and a fine judgment. He had improved his memory to such a degree, that he could, in little more than an hour, get by heart a sermon of ordinary length. He was author of "An Essay on the Theory of the World" published in 1750, and which obtained for him the prize of a gold medal, from the Society of Edinburgh. This work was afterwards much enlarged and reprinted in 1780. His "Dissertations on the Genius and evidences of Christianity," published in 1766, are well known and highly appreciated; so also are his "Essay on Genius," and his sermons in two volumes. In the year 1799 his sons gave the world a posthumous work of much merit, which had been left among the papers of his father, entitled "The Pastor's Care," which made a part of his theological course of lectures. As a clergyman the conduct of Dr. Gerard was marked with prudence, exemplary manners, and the most punctual and diligent discharge of his ministerial duties; his sermons were simple and plain, adapted to the common chafs of hearers, but so accurate as to secure the approbation of the ablest judges. As a professor of divinity, his great aim was not to impose by his authority upon his pupils any favourite system of opinions; but to impress them with a sense of the importance of the ministerial office; to teach them the proper manner of discharging all its duties; and to enable them, by the knowledge of the scriptures, to form a just and impartial judgment on controverted subjects. Possessing large stores of theological knowledge, he was judicious in selecting his subjects, happy and successful in his manner of communicating instruction. He had the merit of introducing a new, and in many respects a better, plan of theological education, than those on which it had formerly been conducted. Having a constant regard to whatever was practically useful, rather than to unmeaning speculations, he enjoined no duty which he was unwilling to exemplify in his own conduct. In domestic life he was amiable and exemplary: in his friendships steady and disinterested, and in his intercourse with society hospitable, benevolent, and unassuming; uniting to the decorum of the Christian pastor, the good breeding of a gentleman, and the cheerfulness, affability, and ease of an agreeable companion.

GERARD, John, a surgeon and famous herbalist of the time of queen Elizabeth, was born at Nantwich, Cheshire, in 1547. He practised surgery in London, and rose to eminence in that profession. Mr. Granger says "he was very many years retained as chief gardener to lord Burleigh, who was himself a great lover of plants, and had the best collection..."
Gerarde lived in Holborn, and had there a large botanical garden of his own, of which he published a catalogue in 1556 and again in 1599. Of this work scarcely an impression is known to exist, except one in the British Museum, which proved of great use in preparing the Hortus Kesaris of Mr. Atman, as serving to ascertain the time when many old plants were first cultivated. Holborn was then in the outskirts of the town on that side. The reader of English herbal history will recollect that the hypocritical Richard Hill, asked the bishop of Ely to fend for "some of the good strawberries which he heard the bishop had in his garden in Holborn," by way of shewing himself in good humour at the council, while, in fact, he was in fact meditating the future removal of Lord Harrowden's catalogue. The catalogue of Gerarde's contains, according to Dr. Pulteney, 1333 species, or at least supposed such, though many doubters were varieties, and there is an attestation of Lobel falsified, ascertaining his having seen nearly all of them growing and flowering. This was one of the earliest botanical gardens in Europe.

The great work of our author is his Herbal, or General History of Plants, printed in folio in 1597, by John Norton, who procured the wooden cuts from Frankfurt, originally done for the German herbal of Tabernaemontanus. The basis of the text was the work of Dodonaeus entitled Pompates, for which also we believe the same cuts had been used; see Donoxenex. Lobel affirms that a translation of the Pompates had been made by a Dr. Priefft, at the expense of Mr. Norton, but the translator dying soon after, the manuscript was used by Gerarde, indeed without acknowledgment. The intelligent reader of the Herbal will observe that most of the remarks relative to the places in which certain plants are found, their common nanes, &c., belong to the original work, and refer to the county in which Dodonaeus wrote, not to England. Gerarde is also accused of having been no Latin scholar, and of having made many mistakes in the additional matter which he translated from the works of Clusius, Lobel, &c. He also certainly misapplied many of the cuts. Notwithstanding such faults, Gerarde had the great merit of a practical knowledge of plants, with unbounded zeal, and indefatigable perseverance. Dr. Pulteney judiciously observes that notwithstanding his manifest inferiority to Lobel in point of learning, it must yet be owned that Gerarde contributed greatly to bring forward the knowledge of plants in England. His connection with the great, and his situation in London, favoured an extensive correspondence, both with foreigners and his own countrymen; and his success in procuring new exotics, as well as scarce indigenous plants, was equal to his diligence and affability. In fact, we owe to Gerarde and his friends the discovery of many new English plants, and his name will be remembered by botanists with esteem, even after the utility of his Herbal is superseded." Among the persons to whom we are indebted for the communication of exotic plants and seeds, are recorded Sir Walter Raleigh, Edward Lord Zouch, and Lord Hunsdon, with many of the elevated rank.

A second edition of Gerarde's Herbal was published by Dr. Thomas Johnson in 1636, which has ever since been a very popular book, and indeed, as Haller remarks, Gerarde was the classical author of the English, almost to the time of Ray. Johnson, like many other editors, enlarged his author with great freedom, and undoubtedly made many essential corrections. He has prefixed a list of his additions, which are very numerous, and a learned historical preface. He was a man of far more learning than Gerarde, but by no means so good a botanist. Among the most valuable of his additions are the communications of Mr. John Goodyer of Maple-Durham, Hampshire, a man of singular penetration and accuracy in practical botany. Johnson added many excellent figures, either of new plants, or in the place of such as were badly executed in the first edition. Among the latter is Gratiosa lauenfa, which Haller complains he could make nothing of. It proved to be Scutellaria minor, and is well reprinted in Johnson's edition, p. 581.

Mr. Granger, in his Biographical History of England, ed. 4. v. 1. 275, mentions only two engraved portraits of Gerarde.

"John Gerard;" engraved by William Rogers, for the first edition of his Herbal.

Ditto engraved by Paine, for Johnson's edition of the same book.

The latter, dated 1636, is a small copy of the former. These is a spring of the potato plant in the left hand.

The writer of the present article is pleased of the copper-plate itself, very much worn, of an octavo portrait of Gerarde, without age or date, holding a spring of Cyphus, with his arms and the Italian motto, "O genti, bene!" In one corner below is a branch of Jasmine, in the other the Bugloe. The name of the engraver seems to be Hall.

Gen. Ch. Calyx five-cleft: Corolla two-lipped; the lower lip in three deep emarginate lobes, the middlemost deeply divided. Capule of two cells, opening at the base.

This
pany with six other persons, members of the same society. On his arrival he remained at Pekin, studying the language, and during this period, being admitted frequently into the presence of the emperor, he ho ingratiated himself with him, as to obtain an appointment to join an embassy sent to regulate the boundaries with the court of Muscovy. He contributed much to the facility of this business, and on his return to China was treated with great honour by the emperor, who chose him his instructor in mathematics and philosophy. Gerbillon is supposed to have enjoyed more advantages than almost any other person, for studying the manners of the Chinese court, and for making observations on the neighbouring country. He obtained permission to preach the Christian religion in China, and had the direction of the French college in Pekin, and was in the end made superior-general of all the missionaries sent from France. He died at Pekin in the year 1727, leaving behind him curious accounts of his eight journeys into Tartary, which have been printed in Du Halde’s Description de la Chine. He was the author of the “Elements of Geometry,” and of a work on Perspective, both printed in a very handsome manner at Pekin. Moreri.

GERBOA, in Zoology. See Dirus.

GERBSTADT, in Geography, a town of Germany, in the county of Mansfeld; 30 miles S.W. of Dessel. N. lat. 51° 40'. E. long. 11° 47'.

GERDAU, a river of Luneberg, which runs into the elmenau, at Oldenbrandt.

GERDAVEN, a town of Prussia, in the province of Natangen, situated on the Omet, near a considerable lake, which is called the “Calendur of Gerdaiven,” from its prognosticating the weather; 30 miles S.E. of Königsberg. N. lat. 54° 16'. E. long. 21° 27'.

GERDEN, a town of Germany, in the bishopric of Paderborn; 14 miles E. of Paderborn.

GERDES, DANIEL, in Biography, was born at Bremen in 1608, where his father was engaged in a commercial life. Great care was taken of the education of Daniel, who made a rapid progress in the classics. At first it was intended he should pursue the law as a profession, but the plan was changed, and he devoted himself to the study of theology. In 1722 he was admitted into holy orders, and immediately afterwards made a tour on the continent, and formed an acquaintance with the most learned men of that period. In 1726 he was admitted to the degree of doctor, and in 1735 he was chosen professor of theology at Groningen, and upon his entrance on the office he delivered an oration “De uen-tione quae Fides ex omnis doclar.” The same year he was elected a member of the royal academy of sciences at Berlin. He died in the year 1765, leaving behind him many works that bear ample testimony to his learning and zeal in the cause of literature. His writings are mostly theological, and tend to the elucidation of the difficult parts of the Old and New Testament. Gen. Biog.

GERDIN, in Geography, a town of Russia, in the government of Perm, situated on the Wolga; 152 miles N. of Perm. N. lat. 59° 40'. E. long. 56° 14'.

GERDOSA, a mountain of Africa; 80 miles E. of Angus.

GEREKEK, a town of Hindooistan, in Bahar; 12 miles S. of Bahar.

GEREM, a town of Grand Bavaria; 15 miles S.S.W. of Badakshan.

GEREMISCHANGKAIA, a town of Russia, in the government of Upha; 36 miles W. N.W. of Bagul-ná.

GEREN, a town of Prussia, in Pomerelia, on the Vlunla; 9 miles W.S.W. of Marienburg.

GERENLIO, or GERMANNUS, in Ancient Geography, a town of Italy.—Alfo, a town of the Peloponnesus, in Laconia. Ptolomy.—Alfo, a town of Meffinia, on an eminence, S.W. of Aba-gonia. Pausanias says that this town was the same with the “Meta” of Homer. It was consecrated to Machaon, an ingenious physician, slain by Eryphlius, whose bones were collected by Nestor, and deposited at Rhodon, near this town. It had a temple dedicated to Machaon. East of it was a mountain called “Calathion,” on which was a temple consecrated to Calathica, with a grotto, having a street entrance, and containing in its interior many curiosities.

GERENNA, or JERENNA, in Geography, a town of Spain, in the province of Seville, surrounded by large Doros, supposed to have been the effect of an earthquake; 12 miles N.N.W. of Seville.

GERENSCHANSKOLI, a forterey of Russian Siberia, in the government of Kolivan; 240 miles S.S.W. of Kolivan. N. lat. 50° 15'. E. long. 79° 14'.

GERESHEIM, a town of the duchy of Berg; 5 miles E. of Duffeldorf.

GERE SOL, in Mufi, one of the chiefs.

GERESPA, in Ancient Geography, a town of Asia, in the interior of Media, sometimes called Geripa, and Geripa.

GERESTADT, in Geography, a town of Norway, in the bishopric of Aggerhus; 32 miles S.W. of Tonberg.

GERESTO, a town of the island of Negropan; 16 miles S. of Carito.

GEREUTH, a town of the principality of Wurzburg; 5 miles N. of Ebers.

GERFALCON, GERFALCON, or Gerfalcon, (for Falco). This is naturally a very bold, wild and fierce bird, and is therefore very difficult to be reclaimed; but when that is done it proves one of the very bold kinds, and will fly at almost any thing. The beak of the gersalcon is always blue, and the claws are remarkably long and strong.

In going up to the gate, as the sportmen express it, these birds do not hold the same fort of course that others do, but immediately climb up upon the train on flight of the bird, and as soon as they have reached her, they immediately make the attack, and generally pull her down at the first encounter; but if not, always at the second or third.

This fort of hawk is to be fed and rewarded like the others. It is of a very fly and crafty nature, and is so flightful, that it loves to keep the calling a long time; therefore, instead of cotton, it is proper to give them sometimes a calling of tow, and to keep them sharp fast. As to the reclaiming this fort of hawk, it is only to be done by gentlefins and kindnes; and when the has been taught to be turned loose, she is not to be taught to come to the pets of hens or other fowl. But the must never be suffered to taste any living flesh, for that will be apt to draw away her love from the hand and voice. Whenever she eats, the falconer must be close to her, and must make her eat the choicest pieces out of his hand. There is great care to be taken in the making of these birds, for as they are made at first, so they are for ever; and it is a necessary caution, with birds of this bold and fierce nature, not to hurry over the business, but to repeat the same thing very often till it is perfectly fixed. See Falconry.

GERGAR, in Geography, a town of Spain, in the province of Grenada; 10 miles S.W. of Parchena.

GERGARALVA, a town of Tranilvania; 16 miles W. N.W. of Hermenfadt.

GERESA. See Gersasa.
GER

GERSENESES, or Gersemites, in *Ancient Geography*, an ancient people, who inhabited the land of Canaan, before the Israelites took possession of it. Their territory lay next above that of the Amorites, on the east side of the sea of Tiberias; and it was afterwards possessed by the half-tribe of Manasseh. [See Geography.]

GERGETHI, or Gergheta, a town situated in the Troad, E. of Rhetium, Ophrynum, and Dardanus, in the vicinity of the site of Troy or Ilium, near mount Ida. This town appears to have been inland from some distance from the sea.

GERGINA, a town of Asia, in Phrygia, at the foot of mount Ida, seeming to be the same with Gergetha.

GERGIS, the name given by Steph. Byz. to the Gergetha of Strabo.

GERGOS, in *Geography*, a town of Africa; 30 miles W. of Tripoli.

GERGOVIA, in *Ancient Geography*, a strongly fortified place of Gaul, belonging to the Arvernii. According to Caesar (I. vii. 36.) it was situated on a very high mountain, and every access to it was extremely difficult. At length it was obliged to submit to the victorious arms of Rome, and it was probably so completely destroyed, that no trace remains from which we may ascertain its situation. It has been conjectured, however, that its situation was in the vicinity of Clermont.

GERHARDSBRON, in *Geography*, a town of Germany, in the principality of Anspach; 28 miles W. of Anspach. N. lat. 49° 17'. E. long. 10°.—Also, a town of Wurttemberg; 28 miles E. of Haibron.

GERINES, a sea-port of the island of Cyprus, anciently called "Cerynia." The walls, which are about half a mile in circumference, appear to be erected on the foundation of the ancient walls. This place has one entire church, and two or three in ruins. Its chief trade is with Caramania, whether it exports rice and coffee brought from Egypt, and whence it brings back florax, and a great number of passengers. Gerines is the residence of an Aga and Cadi: 16 miles N.N.W. of Nicofia.

GERINGSWALDA, a town of Saxony, in the circle of Leipzig; 20 miles S.E. of Leipzig. N. lat. 51° 5'. E. long. 12° 46'.

GERIS, a town of Egypt, on the left bank of the Nile; 8 miles N. of Aphonin.

GERISA, in *Ancient Geography*, a town of Africa Propr. situated between the two Syrtis. Potomny.

GERISAU. See GERISA.

GERKOW, Jorkow, or Barka, a town of Bohemia, in the circle of Saaz; 22 miles N. E. of Saaz.

GERLACH, Stephen, in *Biography*, was born at a village in Swabia in the year 1546. He laid the foundation of a learned education at Stuttgart, and became distinguished for his diligence at the university of Tubingen, where, in 1566, he took his degree of B. A. with great applause. Shortly after this he withdrew from the university on account of the plague. He was admitted to the degree of doctor in philosophy in 1567 at Ellingen, and in 1573 he accompanied an embassy from the emperor Maximilian II. to the Turkish court. He continued at Constantinople about five years, acquainting himself with the manners and religion of the Turks and Greeks, and cultivating an acquaintance with the most eminent men in the latter communion. Upon his return to Tubingen he obtained other preferment, and engaged in the duties of his profession with so much zeal and fidelity, as to injure his health. He died in 1612 in the 66th year of his age. He was author of "An Epitome of Ecclesiastical History," of "A Journal of the embassy sent to the Porte by the emperors Maximilian II. and Rudolf II." abounding in curious and interesting particulars, historical, ecclesiastical, and theological: and numerous theological "Differtations," &c. More.

GERLATZKOI, in *Geography*, a fortress of Russia, on the E. side of the Iritich, in the government of Kolyvan; 212 miles W. of Kolyvan. N. lat. 54° 20'. E. long. 75° 24'.

GERM, in *Vegetable Philosophy*. See Embryo.

GERM, in *Navigation and Commerce*, the name given in Egypt to small vessels which serve to carry European merchandise from Alexandria to Rosetta, and to bring back to Alexandria the commodities of Egypt and Arabia. These vessels are of strong barks, tolerably constructed; without decks, drawing little water; and, according to their size, having two or three masts with very large latine sails, the yards of which are fixed to the heads of the masts, and cannot be lowered, so that, however bad the weather may be, the sailors are obliged to climb up the whole length of them, in order to furl the sails. They are, in general, of about five or six tons burden. Goods are often damaged in these uncovered vessels, and the navigation of them is dangerous in a rough sea. Although the distance which they have to sail is scarcely more than 12 leagues, and though the bay of Aboukir, which is in the middle of their passage, affords them some shelter, this coasting trade is not free from danger, especially at the mouth of the western branch of the Nile, formerly called the "Bolhitic," now the "branch of Rosetta;" where is a bar formed by the sand, upon which the waves, driven by the wind from the offing, and opposed by the stream of the river, break with great fury. A small island, dividing the entrance of this branch, leaves on each hand a narrow passage, called in the language of the country "Boghas," a canal or strait. But there is only a narrow channel of this passage which is securely navigable; for it is continually shifting, on account of the shallowness of the bottom and the agitation of the sea. A pilot, "Reis," or master of the "Boghas," is continually employed in fouding this changeable passage, and indicating it to the "germs." In spite of all these precautions, they often get on shore; and, being soon overwhelmed with water and sand, perish with their crews and cargoes.

GERMA, or GERSE, in *Ancient Geography*, a town of Asia, upon the Hellespont; which, according to Ptolemy, was a colony founded by the Gauls, named Tolotiboians, in Galatia.

GERMAIN, COUNT ST., in *Biography*, a conspicuous person of a mysterious character, who resided in England a considerable time, and of whom nothing was certainly known, but that he was a fine performer on the violin and an elegant, though not a learned or original, composer. Being here at the same time as prince Lobkowitz, they were inseparable. He printed a book of violin solos to present to his friends and admirers, which he called "La Matheque raidonnée," in which there were elegant passages, singular movements, and amusing canons. In his songs, the melody was Italian, and in good taste; but the accompaniments were thin, and without carrying on any ingenious design. It was reported, that when examined before the privy council, during the rebellion, he was obliged to dissemble, "fut figilto confusionis," that he was originally a musician by profession; but that by his obvious fortune he had realized an independent fortune; but this, like newspaper reports, merita confirmation.

GERMAIN, ST. in *Geography*. See ST. GERMAIN.

GERMAIN, ST. A. town of France, in the department of the Creuse, 15 miles N. W. of Guzeret.—Also, a town of France, in the department of the Aube; three miles S. W. of Troyes.
GERMany, in Matters of Genealogy, signifies whole, entire, or own.

"German, quasi cadem filipre genitii." Feil. Hence,

German, Brother, denotes a brother both by the father's and mother's side, in contradistinction to utterine brothers, &c. who are only so by the mother's side.

German, Confrat., are those in the first or nearest degree, being the children of brothers or sisters.

Among the Romans we have no instance of marriage between confins german before the time of the emperor Claudius, when they were very frequent.

Theodorus prohibited them under very severe penalties, even fine and proscription. See Consanguinity.

German acacias, bezoar, bible, black, coins, compafaei, emperor, empire, flute, language, measure, monics. See the several fabulatives.

German School of Engraving. Germany was probably the birth-place, and Italy the cradle, of that art of engraving which is performed with a view to its being afterward printed on paper. Engraving itself, as performed on metals, and with the instrument which is still in use for that purpose, which in the English language is termed a graver, and in French a burin, is of very remote antiquity; the Greeks of the early ages having employed it in the decorations of their shields, pateras, and other implements of war and sacrifice; and the Hebrews, and perhaps the Chaldeans and Egyptians, at a still earlier period; but miliefs we suppose (which is by no means improbable) that the art of engraving and printing from tablets of wood travelled from China to Europe, it was reserved for the artists of Germany or Italy, and most probably the former, first to perceive that ink might be delivered, and impressions thus multiplied to an indefinite amount, both from the incisions and surfaces, of engraved plates of metal, and blocks of wood.

The precise time of the discovery has not been ascertained. The baron Heinemckin, who had excellent opportunities of acquiring information, and pursued his enquiries with zeal and accuracy, has clearly shown that the fabrication of cards for games of chance was first practised in Germany, by means of the art of engraving, and was in use so early as the year 1376. Not long afterward, the same art that had been subservient to amusement, was employed to gratify and disseminate superstition, and extremely rude outlines of saints and legendary tales, which were cut on tablets of wood, and were printed in the cities of Mentz, Strasburgh, and Haerlen, toward the close of the fourteenth, and beginning of the fifteenth centuries, are not uncommon in the port-folios and bibliographical collections of the curious.

Of these engravings, the earliest that is known, whose inscription contains a date, and which may therefore be esteemed a great curiosity, is now in the library of Earl Spencer. It was discovered by Heinemckin in the library of a convent at Basel, near Memmingen: its subject is the legendary tale of St. Christopher carrying the infant Jesus across the sea; it bears the date of 1423, and is inscribed "Christioper faciunt, quia haec eis fuerit usus: nulla nomen benedicat vir."

This rude but curious engraving is of the folio size, and was found carefully pasted within the cover of an old book, with a view, no doubt, to its preservation.

The same magnificent collection of Earl Spencer contains also one of the original engraved blocks which were used in the very infancy of printing, before movable types were invented. It appears to be of the wood of the pear tree, and in the course of the three centuries and a half since it
GERMAN SCHOOL OF ENGRAVING.

It was engraved, is here and there perforated by worms. It may be necessary to observe, that the earliest printed books were impressed from engraved blocks or tablets of this kind. To the rude representations of saints and miracles, their names and legends, cut in the Gothic character, or German text, on a scroll or label, were added, for the better information of the unlearned spectator, and in aid of the labours of the artist, if such he might be termed; and from these explanatory scrolls, the idea was first caught of printing books, to which the works of imitative art became in their turn merely illustrative. Some of these prints are simply outlines, and in others, which were produced somewhat later, shadowing, with a single course of lines, is feebly attempted.

The tablet in the collection of Earl Spencer, is of the former kind, and originally constituted the second leaf of the second edition (of which there is a complete copy in his majesty's library) of the history and visions of St. John the Divine.

It is, probably, therefore, one of the earliest engravings on wood that was ever performed, excepting the prototypes for the playing cards, which have been before-mentioned, and perhaps the oldest of which the original tablet itself is still extant. Hence it appears that the art of engraving is the parent of that of printing, and that at least branch of printing which delivers the ink from the surface of the engraving; and which is now termed letter-press printing, originated in Germany.

The present writer conceives that a great deal too much of juicy importance has been attached to the invention, as it has been termed, of printing; that the traffickers in its productions, by diverting the attention of those who might else have become men of taste, from its true mark, have falsified or intercepted much of the pleasure which the engravers' art is capable of imparting; and that the philosophy of degrading has buried alive under a heap of rarity and early rubbish which has been piled, and is still piling, on it without mercy, from the novel of dealers, collectors, and those who have, unfortunately for society, nothing better to do than to labour under them.

A knowledge of the era, and of the author of a great work, or an useful invention, is certainly desirable. Bedefe that it is necessary to the truth of history, it seems to us in indulging the amiable sentiment of gratitude. It would call forth our sincere regret, if the name of the author of Paradise Lost, or the Cartoons, or Principia, had sunk in oblivion. But at the time which we are considering, paper and ink were in constant and daily use; and impressions from dies and from seals had for ages been taken, and were under hourly observation; it therefore required no protracted train of thought; no long connected chain of causes and effects; no mighty genius, like that of Homer, Michael Angelo, or Newton, to perceive that impressions might also be taken either from the surfaces or incisions of engraved blocks or plates. The art of printing, as I conceive, originated in a concurrence of circumstances entirely independent of the minds or studies of its reputed inventors. We have seen that at first, when it was coarsely performed, and (like the tops of ballads, and the drolling speeches of criminals at present) grossly addressed itself to the lower classes of the community, it was regarded as of very little consequence; and though Keffer, Guttenburg, and Faust, cannot be ranked in the class of inventors, the inferior merit of perceiving that the arts of engraving and printing might be applied to purposes of greater magnitude and importance than had hitherto been observed, may be justly claimed for them. It is the important consequences gradually resulting from the discovery, that have made us attach a degree of credit to the name, and entertain an unmerited respect for the supposed researches, of the discovery to which, in point of real ingenuity, the maker of the first pair of spectacles or stockings, or the first sheet of paper, would be far more justly entitled.

In tracing effects to their true causes, it ought not to be forgotten that the great benefits we have derived, and continue to derive, from engraving and printing, ought, in fairness, to be partly ascribed to the discovery of the means of converting rags into paper: this probably helped to fngulate the idea of printing, and perhaps two centuries and a half had scarcely more than brought this invention to the degree of perfection necessary for the reception of impressions from printing types and engravings. Had the modern art of making paper been known to the ancients, we had probably never heard the names of Faust and Finiguerra, for with the same kind of flamps which the Roman tradesmen used for their pottery and packages, books might also have been printed; and the fame engraving which adorned the flicks and pateras of the remote ages, with the addition of paper, might have spread the rays of Greek and Etrurian intelligence over the world of antiquity. The process of printing is indeed so simple in itself, and was so nearly obvious in the state of things we have just attended to, that a child at play, who wanted to multiply a given form, might almost be ashamed not to have perceived it: and we ought rather to wonder it was not discovered sooner, than that it was discovered so soon.

The art of engraving and printing from tablets of wood, then, may be said to have been rather discovered than invened in Germany, and rather seen than discovered. That it was little thought of at the time, may be inferred from the number of wood cuts, the production of this period, which appear without either dates or the names of their authors, who were at once the designers, engravers, and printers of their own works, but who deemed those works of too little importance to claim for themselves distinction on account of having performed them.

For the accommodation of those persons who could not afford to pur chase manuscript copies of the Old and New Testaments, beside the apocryphal visions of St. John the Divine, which has been already mentioned, a small folio volume, entitled "Historia Veteris et Novi Testamenti," (commonly known by the name of "The Poor Man's Bible," and published about this time, or soon after. In the same manner as the former, each leaf, printed from a single engraved block of wood, consisted of a mixture of reading with pictorial representation, such as it was; to which colour was in some instances afterwards added with the hair pencil, or some such implement. The printing was performed only on one side the paper, and two of these leaves being pasted together have the appearance of a single leaf printed on both sides. Copies of these early wood cuts, sufficiently faithful, may be seen in Strutt's Biographical Dictionary of Engravers.

As the title of this anonymous and undated book (the Poor Man's Bible) imports, its publication was regarded merely as a cheap contrivance for disseminating the knowledge of holy scripture. Other books of engravings, printed in the same manner, were soon afterward produced, among which are "Histo ria beatae Mariae Virginis," "Ars Memorandi," "Ars Moriendi," and "Speculum Humanae Salvationis," but we pass over, as of minor importance, all particular mention of these and various other engravings on wood by unknown workmen, which were apparently executed in Germany, about the time now under our observation. The next work which bears a date after the print of St. Christopher and the infant Jesus, and the first engraving book which bears date at all, is called "The Chiromancy of Doctor Hartlieb." It consists of twenty-four small folio leaves, printed on both sides.
GERMAN SCHOOL OF ENGRAVING.

At the beginning of this curious book," says Strutt, "is a large vignette, representing Dr. Hartleib kneeling and presenting it to the princess Anne, who is seated upon her throne; and the names of these two personages are engraved at the bottom of their portraits. The prints in this book are exceedingly rude; but have not, as far as one can judge from the copy of one of them, given in the "Lide generale d'une Collection complete d'etampes," the appearance of being so ancient as those in the Apocalypse, or Poor Man's Bible. This curious compilation is dated 1448, and the name of Jorg Schaeff, the artist, who is supposed to have performed the engravings, appears upon the fourth page."

Of Hans Sporer and Johann von Paderborn, who are mentioned among the earlie German engravers on wood, we know nothing more than their names. They may perhaps be the authors of some of the works we have enumerated. Johnl Schnitzer executed the geographical charts for the edition of Ptolemy, printed at Ulm in 1486. His map of the world is ornamented with ten rude heads, which are intended to represent the winds, and is inscribed, "Inlucum per Johanne Schnitzer de Arnhem." Sandrait indeed mentions and copies a print, which he believes to bear the date of 1455, and which is marked with a cypher, such as the reader will find in our first plate of the monograms, &c., of the German school of engravers. As this cypher is composed of the initials of Hans Sporer, it may possibly be from his graver; yet neither Sandrait, nor the author of "The little chronological Series of Engravers," which was printed at Cambridge, ascribe it to him; the latter afferts in his Preface, that the two lives in the date, or what Sandrait supposes to be such, are intended for fevens; which makes a difference of twenty-two years in the age of the print, and brings it down to the time when the elder Schauflein is believed to have flourished.

The subject of the above print is a young woman caring for an elderly man while the steals his purse; a subject which has often been repeated by other masters, both on copper and on wood. In what part of Germany, Hans or John Schauflein was born does not appear. Strutt says, "his prints are executed in a bold spirited style, and the compositions shew him to have been a man of genius, though the fluff manner which characterized the early German masters obliterates much of their merit. Besides which they are incorrectly drawn; the extremities of the figures, in particular, are very defective. Schauflein usually marked his prints with an H and an S, or an I and an S joined together, without the ped; "The Life of Christ," a set of middling-sized upright prints, in quarto; another set of "The Life of Christ," in an octavo volume, consisting of 37 prints, entitled "Vite et Passo Jefu Chritii," &c. published at Francefort by Christiaen Egonius, A. D. 1537. To these are added, "Hillorie Evangelii," containing the miracles, parables, &c. of Christ, in thirty-six prints, the same size as the above, and printed on both fides. These are marked with the I and S joined together upon the peol.

This artif sunk by Strutt to have also engraved on copper; but perhaps "the very free etching of a landscape," if not the plate executed with the graver, of "Soldiers converting," of which this author treats, may be the work of a third engraver of the same name. The date of the latter is 1551, and Strutt has previously recorded of the third Schauflein, that he has been, by himself a print of two men fighting, cut on wood, in a coarse but spirited manner, and a very fine mannerly etching in the style of a painter, representing a large company at an entertainment in a garden, of which prints prove him to have been a man of great abilities. He was probably of the same family with the former two.

In the year 1493, appeared the celebrated Chronicle of Nuremberg, which was compiled by Hermann Schadel, a folio work, ornamented with a considerable number of engravings on wood by Wilhelm Pleydenwerff and Michael Wolgemut. These engravings are greatly superior to all that had previously appeared in Europe, and consist, for the most part, of figures of various kinds, and landscapes which, though professedly views of certain cities, towns, &c. bear so little resemblance to those places respectively, that they are probably altogether the work of fancy. They are, however, cut in a bold and spirited style, and the characters of the heads are in some instances far from being badly delineated, though that meagre fifteenth is everywhere prevalent, which so strongly marks the early art of Germany.

Pleydenwerff was a native of Germany, and perhaps of Nuremberg, but it does not appear that he ever engraved on copper, or used any monogram or other mark by which to distinguish his engravings from those of his associate.

Michael Wolgemut, or Wolgemuth, was born at Nuremberg in the year 1434. He is said to have been instructed in engraving by a certain Jacob Walsh, but both Strutt and Huber doubt this fact, grounding their doubt on the want of resemblance between the styles of design and engraving of these two masters. Walsh does not appear to have engraved at all upon wood, whereas Wolgemut did little else. The engravings on copper attributed to Wolgemut do not bear even a distant resemblance to those of Walsh. The latter was a tame artist, or rather workman, and his work characterized by labour and care, which is generally ill bestowed; whereas Wolgemut may even be termed an artist of genius, a word, by the bye, which seems to batter down the argument of Strutt and Huber, since if a man of genius flutters under a mere manual workman, as by chance he may, he will certainly emerge from the style, or want of style of his master.

Wolgemut did occasionally engrave on copper, but his works on wood are far more numerous, and more generally known. In Strutt's account of this artist, he says, "we have some few excellent engravings on copper, executed about this time: these have much of that spirited style in them which appears in the wooden cuts of Wolgemut; they are marked with a W surmounted by a small o, and these prints, I verily believe, are the productions of his graver."
He proceeds to describe one of the rarest and best of these prints which he found in the collection of the late Dr. Monroe. It is ten inches and a half high, by seven and a half in width, and represents an old man seated in a praying posture. He has a standard resting upon his left shoulder, and a book before him. Behind him is an armorial shield, with three different bearings; and, at the bottom, a cave with a gate before it. Above the figure is a scroll, upon which is written, “See Wilhelmine Dux Aquitaine et Comes Picata- rienus.” The head of this figure is well drawn; the hands are marked in a spirited manner, the folds of the drapery are broad, and boldly expressed, and the whole is composed in a style which does much honour to the artist. With respect to the mechanical part, it is executed with the graver only, in a dark, clear style, yet without formality, so as to have the effect of a neat etching.

It is no small addition to the honour of Waghemut, that he was the tutor of Albert Durer, a name so greatly celebrated in the annals of engraving.

Arrived at the period when engraving both on wood and on copper began to shine forth with superior lustre in Germany, it is necessary to look back a few years in order to note the introduction of the latter branch of the art, into that part of Europe.

The reader will find under the article Italian school of Engraving, the popular and perhaps the true account of the discovery of the mode of printing from the incisions of the graver, which, soon after the middle of the fifteenth century, was introduced into Germany. As the first engravers on wood were the manufacturers of playing-cards, (called Formelbilder and Briefbilder in Germany and in France,) so the earliest modern engravers on metal, both in Germany and Italy, were goldsmiths, and the first artist who eminently distinguished himself in the former country was Martin Schöen.

Yet having already mentioned Jacob Walsh of doubtful chronology, it may not be improper in this place to add, that this engraver was particularly fond of introducing Gothic architecture into his prints, in the delineation of which he took no small pains; but, from a want of knowledge in perspective, his delights of this kind are sadly confounded. He drew very incorrectly, and his compositions are in the extreme of that stiff and meagre taste which characterizes the early productions of the German school. His mark, confounding of the initial letter of his surname and a kind of lozenge crofs, may be seen in our first plate of monograms, &c. of the German school of engravers; but it is to be observed, that there are some few prints marked with the crofs only, which have the appearance of being more ancient than those which are marked with the W and crofs.

Of the former kind are, “a hairy, wild, Man fighting with a Bear,” and “a Woman fented, carrelling a Unicorn,” both small, and of the upright form.

Of the latter kind (marked with the W and crofs,) a Gothic ornament for a crozier, a large upright; “The inside of a Gothic Edifice,” a middle-sized circular plate, “A Ship striking against a Rock,” with the inscription, “Herdz” in German text, a small plate; a set of military subjects, small, and another of saints standing in Gothic niches, small uprights; “Three Skulls in an Arch, ornamented with Gothic work;” and “The Genealogy of Jesus Christ,” wherein saint Elizabeth appears on a throne, reading, with the Virgin Mary and infant Christ below. On the right hand is David with his harp, and on the left Aaron. Behind the throne arises a genealogical stem of the lineage of Christ from David to Joseph, represented (as usual) by half figures. This last is a large upright print.

Martin Schöen, or Schön, or Schöengauer, called by the foreign writers on art, Le Beau Martin, or Hübfe Martin, and mistakenly called by Vafani Martin of Antwerp, was born at Cœmbach, a small city in the circle of Franconia, in the year 1426. He was educated a goldsmith, and a certain Lüprecht Ruit, and Francis Van Stofs, or Stolhirs, have been mentioned as his tutors. At the age of forty, and probably before, he distinguished himself by his extraordinary powers in the arts of painting and engraving, particularly the latter, and died at Colmar in 1486. His prints are without dates, but he, rather than any other man, may claim the honour of having been the first to practice the art of engraving on plates of metal, with a view to their being afterward printed on paper.

Schöen engraved from his own compositions, some of his plates are numerous, and shew that his mind was fertile and vigorous. If it was not sufficiently vigorous to burst the Gothic fetters which at that time manseled the taste of Germany, his admirers may solace themselves by doubting whether the unfilled powers of any individual whatever would have been found adequate to so difficult an occasion. The tyranny of established custom is probably not less firm and unyielding in the arts of design than in those of education.

How the stiff and meagre manner,—the angular draperies and emaciated forms which characterize the early productions of the Germans, came to prevail among the Gothic and Celtic nations, from whom they derived them, is a curious, and perhaps not an unimportant, question. By comparing the early efforts in art of all nations of which we have any memorials, we may be led to infer, that man has gradually learned to see objects as they really exist in nature; the images pictured on the retina of the eye appear to be refracted in their transmision to the intellectual retina, and in every country continue to be so refracted, until, as the fun of science slowly ascends, the morning dentity of the mental medium is gradually rarefied; it is not less observable, nor a less curious fact, that a similar haggard lankness in the attempts of man in an uncivilized state, to imitate the human form, has almost universally prevailed, even in ages and climates the most distant from each other. The early art of Egypt, Perfa, and Hindoostan, agrees in meagreness with the rude efforts of the Mexicans and South-sea Islanders, and with the German art, derived from the Gothic and Celtic nations, which is now under our observation.

In the time of Martin Schöen, and Albert Durer, German art was much in the same state with European ethics: theory was separated from practice; and both art and philosophy remained perplexed with false analogies, metaphysical jargon, and occult nonsense; till Bacon, and the resurrection of the antique, referred them to the results of experience, as a criterion of principle.

Neither lord Orford then, nor any other man, should have dispraised either Schöen or Durer, for not having done, what no artift of any other school has of himself been able to perform: for, not only neither of these founders of the German school, but none of the early Italian masters, has shown that he possessed the penetration to see beyond this gloomy exhalation from the barbaric ages, till the great examples of classic art began to re-appear, and reflect back on nature the light they had received from her.

The works of Schöen evince a strong mind operating on the co-existing state of things, brooding over the abyss from whence the future elements of his art were to be created; and using with considerable success the materials by which it was surrounded; and it may be regarded as fortunate for
his claims, that in the infancy of his St. Anthony he has
adopted a subject that in its nature fet him free, or nearly so,
from the Gothic bondage with which, on other occasions,
his genius was shackled: he has been the first boldly to
venture into the regions of Chimera, and by the potency
of his art has compelled thence the demons that Callot and
Teniers were afterward solicitous to invoke and proud to
embody; while the expression of undisturbed faith and pious
reignation in the countenance of the holy man whom they
are hurrying into the air, shews that he saw and copied that
portion of Nature which the devil vouchsafe to reveal to him,
with clear definition, and delicate, though determined, hand. If
his demons are more fantastic and left terrible than modern
art would deem it proper to introduce, we should recollect
that the age of Schöen was that of Ariosto, and that two
centuries slipped between the grotesque mollons of Ariosto,
and the sublime demonology of Milton.

It is consonant to the progressive improvement of critical
observation, that more should be known of the human counte-
enance at an early period, (or indeed at any period,) than of
the rest of the figure, because it is the kind of study and observa-
tion in which men are most interested. Accordingly, Schöen's
heads are in general by far the best parts of his performances.
The few of his single figures of St. Martin and St. John have
considerable merit; the divine character and expression of
that of his Christ bearing his crofs, as it appears in the
good impressions, have rarely been surpassed; and several
other heads in this extensive composition posses a propor-
tional share of excellence.

In this, as well as in several other of Schöen's prints, may
be traced a latent feeling existing in the mind of their
author, that the engraver's art might be rendered subservient
to the expression of the various textures of fabrics. Nay
more; this elementary principle strongiy discovers itself in
the manner in which he has treated the grain of the wooden
crofs; in the various modes he has invented of describing the
different materials of draves in which the figures are habited,
and in the facility of the ground; perhaps the latter is as
much the result of the necessary operation of the unedu-
cated graver, as of study. Yet, is it in such full concord with the
barrenness of the scene, and the barbarism of the subject,
as to be not unworthy of favourable notice; while the
whole together seems to shew that a sentiment has subsisted
from the very commencement of engraving, that it was
susceptible of this particular merit, and which may therefor
be fairly presumed to be not founded in the fallacious
reinements of modern fashion, (though perhaps sometimes
run after with too much of fashionable avidity,) but one of
the primary elements of the art.

The mark which Martin Schöen affixed to his works may
be seen in our first plate of the monograms, &c. of the German
school of engravers. Heinmeken has enumerated an hundred
and fifty of his engravings, molt of which are much and de-
servedly fought alter by connoisseurs. We shall begin our
select hit with the mention of those of which the subjects
are taken from faced history.

A Nativity, where the Virgin Mary is in the act of ador-
ning the infant Saviour, who is laying on a straw pallet; behind
the Virgin appears a bull and an afe; and in the distance
St. Joseph. Three angels appear in the air, holding a
scroll.

Another Nativity, where Joseph is seen in profile, holding a
lamp. The bull and afe are here looking at the infant
Christ; the scene in a vaulted stable, where, through an
opening, are seen three shepherds in conversation, and three
angels hymning in dulcetly above.

On the same plate of copper, which is still kept as a cu-
tiosity, and may be seen in the chapel of the hospital at Col-
mor, is likewise engraved "The Adoration of the eastern
Kings." The scene here is also in a stable, where the kings
are kneeling and offering presents to the infant Saviour, who
is held by the Virgin Mary. This plate is very skillfully
executed, and is of a small folio size.

"The Flight into Egypt," in which angels are represented
after St. Joseph to gather dates, and lizards are intro-
duced with both local and allegorical propriety, one on
the ground, and two others climbing up a tree. This also
is in small folio.

A set of ten plates of "The wife Virginis," and "The
foolish Virginis," small uprights. The former bear their
lighted lamps in their hands, and are crowned with garlands
of flowers; the latter are trampling on their garlands, while
their lamps also are on the ground.

A set of twelve small quartos from the life of Christ.
In the first he is represented in prayer on the mount of Olives;
in the second, arrested by the government; in the third,
before the high priest; in the fourth, soldiers are scourging him;
in the fifth, he is crowned with thorns; in the sixth, Pilate
is washing his hands; in the seventh, he is exhibited to the
multitude; in the eighth, bearing the crofs; the ninth is the
crucifixion; the tenth the holy Euphrasis; the eleventh the
defence into hell, and the twelfth the Resurrection.

A large folio of "Christ bearing his Crofs," one of the
most celebrated of the engravings of Schöen, and on
which we have commented above.

A Crucifixion, also in folio, and which has been copied by
Israel van Mechelin. The Virgin Mary and St. John are
in this print represented at the foot of the crofs, and angels
in great affection: "The last Judgment;" a set of twelve
middle-sized uprights, of which the subjects are taken from
the life of the Virgin; "The Death of the Virgin,"
also, which has also been copied by Van Mechelin and
other contemporary artists, and is a composition of con-
derable merit, and one of the most carefully finished en-
gravings of the matter; "St. Anthony hurrying into the
Air by Dammon," a very capital work, of which we have
already spoken, an upright folio, but not very large. A set
of the apostles, very small.

Of miscellaneous subjects, Schöen has engraved "The
Alchemists fighting;" "A Bishop's Crozier," in folio, in
the spiral volute of which is the Virgin Mary with the infant
Christ, and an angel playing on a lute; an incense-cup or
center with a chain, ditto. Twelve small plates of goldsmiths'
ornaments, conflating of armorial bearings with their appropriate supporters, &c. cloathing with an
ecutcheon, bearing the cypher of the artifal himself, sup-
ported by a female; and "The Battle against the Saracens,"
in which St. James appears on the part of the Christophians;
a large folio plate, prefumed to have been the last of Schöen's
engravings, from the circumstance of certain dilater figures
toward the left hand corner being left in an unfinished
plate.

Bartholomew Schöen is said, by professor Chrilt, to have
been the brother of Martin, but of the dates of his birth
and death we find no account. His apparently very an-
cient engravings are known by his initials, having between
them a mark of separation exactly resembling that which
separates the initials of Martin Schöen, which confirms the
probability of their having been the same person.

The engravings of Bartholomew bear that fort of resem-
blance to those of Martin, that a bad copy does to a good
original, and in neatness and feeling are exceedingly defective.
They are partly original, but the greater number are copies
from the very superior prints of his brother.

His
His original works consist chiefly of grotesque figures, of which some are by no means destitute of humour. It may suffice to mention the few following, which are all engraved on small plates.

A beggar man, with an old woman in a wheelbarrow; a man playing on a lute, with an old woman holding a lade and jar; two grotesque heads of an old man and woman, marked in a better style than the former; and a lover and his mistress, a small circle.

He copied the best from the life of Christ, the large folio of Christ bearing the cross, and various other of the prints of Martin, but the copies may be known from the originals, by their inferiority as well as by the difference between the two signatures.

When a man of original genius, or one who may claim that noblest of human distinctions, the title of inventor, shines forth on the world, a swarm of busy flatterers round his glory are kindled into exultation, buss in his rays, and think to share his fame. Such was Bartholomew Schöen, when compared with reference to his brother; such probably were Paul and George Schöen, who have been mentioned as goldsmiths and engravers of this early period, and such were those other contemporary imitators and immediate successors of Martin, who now claim some small portion of our notice.

Of talents far inferior to those of Martin Schöen, yet engravers to whose works the virtuosi are by no means indifferent, were the Israel von Mechelns, father and son, whom Strutt has mistakenly inclined to identify, as having been one and the same individual. Both were natives of Mecheln or Mekenin, a village near Bocholt, in the bishopric of Munster, in Westphalia.

The elder Israel von Mecheln (or Mekenin) was born in the year 1424, and, like Schöen, he was by trade a goldsmith.

The year of the nativity of the younger Israel has not been mentioned. The latest of his engravings is dated in the year 1522, and he died in 1525. It has been conjectured, that he studied under Martin Schöen, from the number he has copied of that master’s works, but this seems very insufficient evidence of the fact. It rather seems to show that the baron’s inventions corresponded with the dryness and infidelity of his style as an engraver.

The works of the Von Mechelns (if the father engraved) are numerous. That he did engrave, is inferred by the baron Heinrich from the following circumstance. "An attentive examination (he says) will make it appear that all these prints are not by the same hand. I am almost certain that Israel, the father, engraved several, those especially which have the greatest marks of antiquity, and are executed in a rude style, approaching nearest to the work of the goldsmith. Nor, do I deny, that the son may have commenced originally as a goldsmith, by engraving armorial bearings, flowers, foliage, crofies, and other ornaments; but he was a painter as well as an engraver, and a man of tolerable ability, considering the time in which he lived." Strutt, on the other hand, can see no reason for dividing the works which pass under this name, nor can he find any other difference in the prints that might reasonably be expected in the works of an individual artist, who performed so many; his most early productions being of course the rudest, but all equally defective where he has attempted to express the naked parts of the human figure.

The difficulty, and the importance also, of the question, ceases, when we reflect that it was part of the professional business of the goldsmiths of that day, in which every apprentice was instructed, to ornament their productions with engraving.

Of these engravings, so little worthy of learned controversy, the principal are; the portrait of the tenor Mecheln, an elderly nun with a long beard, his head dressed with a turban. The plate is in quarto, and bears the inscription "Israel von Mecheln, Goldschmidt." Ditto of Mechelin, junior, and his wife, inscribed " Figuare faciatur in Maria, et in Animam, I. V. M." in quo.

These are among the prints which Heinrich supposes to be the work of Mechelin the father, and Strutt, the early productions of the son. They bear the evident marks of being the attempt of a novice, being wretchedly engraved and quite as ill drawn.

"Judith and Holofernes," of the folio size. In the back ground is an army, where cannon and other modern implements of war are ignorantly introduced. "The Banquet of Herodias." This also is a folio plate, twelve inches in length, and marked Israel V. M. At one end is seen the decollation of St. John the baptist; and at the other, Herodias and her father appear seated at table. "Herod’s Cruelty," is a middle-sized upright.

Of holy families, the Israel’s engraved several, the chief of which may be known from each other by the following peculiarities. In one, the Virgin Mary, habituated in a long robe, is fitting with the infant Christ, while beyond an enclofure appears St. Joseph reposeing. Toward the bottom, at the right hand corner, is a small griffon, from which it has obtained the name of the Virgin of the Grifhopper. It is in quarto, and inscribed Israel V. M. (This plate has been copied, with improvements, both by Albert Durer and Mark Antonio.) In another, the Virgin Mary, seated in a landscape, is about to kiss the infant Saviour; the Deity appears in the clouds above; and St. Joseph sleeping. (This is a middle-sized upright, and is partly finished by means of etchings, which are apparently made with the point of the engraver, somewhat in the manner of Rembrandt.) In another, which is dated 1485, the Virgin and Child are surrounded by four angels. This is also a middle-sized upright.

In other sacred subjects, we shall mention "The Annunciation," in quo., where an angel appears holding a scroll, on which is the motto "Ave, Gra.;" and the Virgin is kneeling before a praying deff, on which is inscribed I. V. M. "The Death of the Virgin Mary," copied from Schoen. "The Virgin crowned by Angels, and standing on a Crucifix, while the fall of Satan is represented below," an upright folio. "The Scourging of Christ," ditto. "The Bearing of the Cross," a large folio, copied from Schöen, and the large folio of the "Crucifixion of our Saviour," which are distinguishable from each other by the following peculiarities: in the one, angels are receiving the blood from the wound of the dying Saviour, while the Madonna and St. John appear below; in the other, which is esteemed the superior work, St. John holds a book in one hand, while the other is lifted, and the hands of the Madonna are clasped; and the ground in the latter is almost left white, whereas in the former it is nearly covered with engraving.

From the legends of the Roman Catholic rubrics, the younger Israel has engraved, "St. George and the Dragon," in quo., inscribed I. V. M. Schöen’s "St. Anthony tormented by Demons," and "St. Jerome," in which the saint appears seated in a room and painting a scroll.
On the right hand corner is the lion's head. The latter has been copied by Lucas of Leyden, and in the opinion of Strutt is Israel's master-piece, though perhaps that distinction ought rather to be granted to his moral print of "A Cavalier and Lady, walking in amorous talk, while Death from behind a Tree is threading an Hour-glass," a design which, whoever was its original author, had previously been engraved by Sporer or Schaffelen, and has been subsequently copied by Albert Durer and several others.

Of the angular design consisting of three naked women, with a globe hanging above, which is inscribed 153, there is also an engraving by Israel.

A folio plate of "The Death of Lucretia;" a pair in quarto, of "A Woman finging, while a Man accompanies her on the Lute;" and "A Man playing the Organ, which a Woman blows the Bellows," both marked I. M.; Schöen's richly ornamented incunabula, and several plates of grotesque foliage and other goldsmiths' ornaments, are all that we shall mention of the two hundred and fifty engravings by the Izraels which are enumerated by Heinemarch. Neither of them appears to have had any settled monogram, but marked his engravings variously, as we have stated in the course of our life, sometimes adding to his name and residence the word "Goldschmit," and at others "Tzni Brockholdt," in the German character. The best of their works, as has been before intimated, are copies from the superior productions of Martin Schöen.

Matthew, or Martin Zagal, Zalinger, or Zinck, goldsmith and engraver, was born in the year 1430, but in what part of Germany is not known, though from the subjects of two of his engravings, it may be guessed that he was of Munich: neither is the year of his death certain, though, that he lived to the beginning of the sixteenth century, and engraved till the age of seventy-five, may be inferred from the circumstance of one of his prints being dated in the year 1505.

The extreme of Gothic stiffness appears in his works. His composition is bad, and his drawing full worse: the mechanical part of his engraving, indeed, poisselles a certain degree of neatness, but is without the fainted ray of taste. It is proper, however, to observe, that from the decay of the art, or rather from the stiffness of Zagal's manner of engraving, his plates would not lend many good impressions; that many of the retouched prints, which are exceedingly bad, are abroad in the world, and it is also probable, that the author of the edition, in which he printed, it is necessary to see the early impressions of his plates; nor should be left unmentioned, that in his latter engravings he displays a more intimate knowledge of perspective than we find among his predecessors in Germany. Zagal marked some of his prints simply with the initials M. Z.; and others, as will be found in our first plate of the monograms, &c. of the engravers of Germany. Among his best engravings may be reckoned "Solomon's Idolatry," a muddling-sized upright, dated 1501. "A Holy Family," in which the Virgin Mary is receiving water from a fountain, in a cup, in the same date with the preceding. "The legendary Story of St. Christopher bringing the Infant Jesus across an Arm of the Sea," a small upright. "A Lover seated in a Landscape, entertaining his Mirthful," and "Two Lovers Embracing," ditto. Two large and very rare folio engravings of "The Grand Ball and Tournament at Munich:" in the former of which is represented a dance and card party, in which the duke of Bavaria is engaged at play, and in the latter a tournament, at which the duke is present. "The Martyrs St. Catherine and St. Ursula," both in 8vo. "The Martyrdom of St. Sebastian," in 4to. "A Lover to War," ditto, and "Ariflotie the Philosopher," a subject often repeated, and called by some Socrates and Xantippa. The last is a very rare print, in 4to.

Albert Glockenton was a native of Nuremberg, born in the year 1432, and who flourished as an engraver at the commencement of the sixteenth century; but the time and place of his death are uncertain. Strutt says of him, that if he did learn his art from Schöen, he not only imitated his manner, but copied a great number of his prints; which copies constitute the greater part of the works of Glockenton. He executed his plates with the graver in a neat but servile manner, by no means improving the drawing of his originals. He marked his engravings with a little half Gothic initials of his name, as may be seen in our first plate of the monograms of the German engravers, and sometimes added the date.

The principal works of Glockenton, after the original of Martin Schöen, are "Christ bearing his Cross," and "Christ crucified," both rare and of the folio size; "The Death of the Virgin." The set of the wife and foolish virgins, ten plates; the passion of our Saviour, a set of ten others, both of which are more particularly mentioned in our account of Schöen, and the "Virgin and Child at an Altar," in 4to. The latter is superior, in point of composition, to the German art of that period, is marked with only a Gothic G, and bears the very early date of 1466; which is perhaps the most ancient that is to be found on any copper-plate print whatever. Of this engraving particular mention is made under the article Glockenton, in the "Catalogue Raifonnée du Cabinet d'éblampe de Brumès."

Contemporary and co-equal with Zagal and Glockenton, was an engraver for whom Strutt claims a sort of doubtful existence, by the name of Wenceslaus of Olmuts, in Bohemia. He found a copy of Martin Schöen's "Death of the Virgin" in the Museo collection, which had not only the name of this artist inscribed upon it, but the date of the year in which it was engraved, namely 1481. He adds, "there is no doubt of its being a copy from Schöen, because it bears the evident marks of a servile imitation. It is highly probable that Wenceslaus was the disciple of Schöen,"—another observation arises from a strict examination of this print, upon comparing it with the ancient German engravings marked with the W only; which is, that they are evidently the work of the same artist as the preceding, though they have usually been attributed to Michael Wolgemut, the master of Durer. The name is perfectly plain," but the words that follow are far less legible, and in the opinion of the present writer are much more like Olmuts Holten than Olmuts in Bohemia.

Of these prints marked with the letter W only, Strutt mentions the following:

The "Annunciation," where the Deity appears above and a pot of flowers is introduced on the fore-ground; a small upright. "The Cavalier and Lady heedless of Death." "The Lail Supper;" "The Crucifixion of St. Anthony;" small and nearly square; and the set of small uprights from the "Life and Passion of Christ."

The above are all from Schöen; those which follow are from the Izraels of Mekenin.

An old Man leading a little Boy, with a Woman following carrying a Girl at her back; and "A Lover entertaining his Mirthful;" two small uprights; and "The naked Women with a Globe suspended from above."

We are now again arrived at the time when the Nuremberg Chronicle was published, and those extraordinary works both on copper and on wood began to appear, which are known to the world under the highly respected name of Albert Durer.
GERMAN SCHOOL OF ENGRAVING.

Of the various powers of Albert; his reputation as the father of the German school of painting; and his general merits as an artist, we have already treated pretty much at large; (see Durer, Albert.) It remains to add our list of his principal engravings, and to comment more particularly on those of which are, and deserve to be, most conspicuous. Though the defects of the artist are pointed out in the critical remarks which follow, and which are chiefly extracted from lectures delivered at the Royal Institution in the years 1805 and 1806, yet are they calculated to lead the attentive observer to a more intimate acquaintance with the merits of this extraordinary engraver, and to confirm the general and justly merited praise which has now, for three centuries, been bestowed on Albert Durer.

The resemblances between the several objects which this master has introduced into his engravings, and their archetypes in nature, proceed, for the most part, too much upon the sublime principles for the generalized dignity of his subjects; and his powers of imitation are too prodigiously lavished upon subordinate and unessential parts.

The expression of his figure of "Melancholy," which would else have approached sublimity, is considerably injured by the introduction of a multitude of objects, most of which the mind does not readily affiliate with the sentiment of melancholy. It must first be perceived or discovered, that these objects are allusions to astrology, alchemy, and the occult sciences, as they are called. The performance addresses itself, therefore, to the curious and inquisitive part of mankind, and not to men; and as neither the eye nor the mind can at once dilate with greatness and descend to little-ness, it is evident that the research it requires must be the destruction of sublimity.

Though there is nothing of the "holy calm," with which Collins has surrounded his figure of melancholy, this composition may still be thought interesting on another account, namely, as a true picture of the times in which it was engraved; for precisely thus was attention perplexed and distracted on most philosophical subjects in the age of Albert Durer; and as he is author of seven treatises, most of which are on the metaphysics of art, he had probably experienced much of that species of melancholy which proceeds from the mental exhaustion and dissatisfaction in which such studies often terminate. Regarded in this view, it is no inapt verification of the old adage, "The painter paints himself." It might have alluded to reconcile us to the defects of this performance, if Albert Durer had named it his "Study"; or, if we could fancy the figure out of the picture, we might be content to let our attention dwell awhile on the skill with which he has represented most of the other objects, when abstractedly and severally considered. This talent, however, of representing the characters and textures of individual objects, is still more conspicuous, and somewhat less objectionable, in the print of "St. Jerome in the Room," wherein all the objects are rendered with a fidelity little short of the camera oblique. Regarding the art as in its infancy, we may look at this engraving with the same kind of pleasure, and should at all the works of art of this period, with the same candid indulgence; which with Reynolds contemplated in "The Virgin and Child" by Van Eyck, in the cathedral church of Bruges the "artific," says Sir Joshua, "having accomplished the purpose he had in view."

Another of the most celebrated, though not the best, of Durer's engravings, is his "Adam and Eve." He has, in this instance, had recourse to nature for his models, but his Eve is not "the fairest of her daughters," nor his "Adam the goodliest of men born;" yet we may perceive that he selected from nature with which he was acquainted; and though we do not behold the symmetry and superfluous grace of Greek beauty, we probably feel the felt and acknowledged beauty of Nuremberg. It will, it is believed, that the Paradise they must shortly quit, does not seem very desirable to inhabit; here is no gentle light, no luxuriants of vegetation, and no abundance of animal life. To use more of the words of Milton, nature is so far from wanting as in her prime,—so far from playing at will her virgin fancies, that she appears, in those of Shakespeare, "bald with dry antiquity;" yet if Raphael has violated this cardinal principle of propriety, by erecting a church, and houses two stories high in his Paradise, who shall throw the first stone at Albert Durer? The boles of his trees, though among the first, if not the very first that were ever engraved, have much of the truth of individual nature, and their foliage, and the fur of the cat, are expressed with a degree of freedom that must surprise those who reflect that no etching has been employed, and how comparatively ill calculated are the flack and stiff lines of the unfinished graver to the expression of such objects. The introduction of the cat and mouse in Paradise could not fail to be understood, from its familiarity; but though ingenious, this very familiarity render it unfit for the occasion. The prophet Idris has far more nobly expressed the primeval harmony and happiness of the brute creation.

The Eve of Albert Durer is apparently of the same family that Otho Venius, and Rubens, afterwards adopted for their models; and in the engraving which collectors call "The Death's Head," is a female figure, which still more evidently shows the sneeze in which Rubens must have held the works, or at least the women, of Albert Durer. It is not easy to conceive the occasion that could have given birth to this mysterious print of Death's head. It presents us without the ordinary routine of human life, with either allegory, or perhaps a sort of poetic armorial bearing. The crest is a winged helmet, richly ornamented, and beautifully executed; and though a skull, which one should think could not fail to be an awful monitor, is highly embossed on the shield, the female supporter, headlesse of her charge, headless of the moral leonin, and of the moral character she has to sustain, is obviously listening to the very suspicious suggestions of a fort of savage man. It appears to be one of the night thoughts of Albert Durer, and perhaps, like those of Dr. Young, may be intended to mark the lamentable influence of the grosser passions. Whatever its author may have intended to inculcate by this print, its execution as an engraving is admirable. The helmet, with all its pomp of heraldic appendage, and the actual and reflex lights on its polished surface, are characteristically, though minutely, expressed; the skull is accurately drawn, and its bony substance is described with a masterly hand; the author has even splendidly attended to the finer enamel of its two remaining teeth. The head of the Savage, with its beard and wild rudiment of snaky tangled hair, has considerable and well-managed breadth of light and flanks, though its character is far less savage than should seem to belong to the rest of the figure: its expression is, doubtless, meant to be affumed and inflating. The countenance of the female has seldom been surpassed for that faceless mixture of character and expression that lends a willing ear to a delusive promise; and the heads and hands of both figures are far better drawn than we have hitherto seen among the productions of the German school: the drapery also, which we have been accustomed to see stiff, flarished, and complicated, is here relaxed into freedom and simplicity, and is so remarkable for its texture: approaches so near to what is now termed picturesque composition of forms and light and shade; and
GERMAN SCHOOL OF ENGRAVING.

is, on the whole, so inferior to that of his Melancholy, and some other of his infrequent works, as leaves us either to wonder that Albert Durer, having once attained, should ever lose sight of the excellence of its principles; or to infer that he did not perceive their excellence, or that the science he deduced from his own observation of nature prevailed but occasionally over the prejudices of his education.

In his small prints of the life of Christ, of which Marc Antonio is said to have pirated the copy-right, other infinances occur of this style of superior simplicity in the drapery, and some of broad and captivating effects of light and shade. His Jesus Christ suffers greatly, or beams with God-like benevolence; his Magdalen and Madonnas are sometimes divinely pathetic; and many other of the heroes in these interesting and often grand compositions, are exquisitely finished miniatures, remarkable for that fort of accordance and conciseness of parts which we deem the internal evidence of truth and nature. The principal portraits of Durer, engraved on copper, are those of the elector Frederic of Saxony, dated MDXXXIII. Albert, elector of Mayence, dated 1523. Bilibald Pirkheimer, dated 1524. Melanthon, dated 1525. These are all of the quarto size.

In folio he has engraved his friend Erasmus, good impressions of which are now become very rare, dated 1526, and two figures of himself, on the same plate, one being his portrait in the year 1509, and the other in 1517. They stand on either side of a piece of architecture.

Of the portraits of Durer, it may with truth be said, that, in point of drawing, they posse the fame internal evidence of correctness which distinguishes the best of his historical heads: in Kyl; they are laboured; but the labour is not ill-betted; and the chiaro-uro is frequently comprehensive and clear. His compositions from holy writ, and those legends which in his day were thought to be nearly of equal authority, are numerous. The principal of those on copper are "The Adam and Eve in Paradise, or Sin of our first Parents," which has already been the subject of detailed comment, a very elaborate work in folio, dated 1524. Another "Adam and Eve," which represents them after their expulsion from Paradise. "Adam crawling, and Eve sitting with an Infant at the Entrance of a Cavern," in quarto. "A Man with a Beard, seated on the Ground (his Horse fastened to a Tree) caressing a Young Woman," a small quarto plate, known by the name of "Judah and Tamar," and believed to be the earliest of Albert Durer's engravings. "The Nativity," where the Virgin Mary is adoring the Infant Christ, while St. Joseph is drawing water from a well. "A Holy Family," known, among connoisseurs, by the title of "The Virgin of the Butterfly," where the Madonna is seated in a landscape, with the infant in her arms, and St. Joseph asleep near her. Another, known by the title of "The Virgin of the Apple," where the Infant Christ, kneeling, is playing with a bird, and an apple is tied near the group. Another, known by the title of "The Virgin of the Pear," which is dated 1511, where the Infant Christ, holding a pear, is sitting with his mother at the foot of a tree. Another, known by the name of "The Virgin of the Apple," which is dated 1514. All of them are of the 4to. dimensions. An etching of the "Holy Family," in folio, wherein the Virgin Mary is standing and holding the Infant Christ in her arms, and a girl is introduced at prayers, dated in the year 1519. A set of fifteen, including the frontispiece, entitled "The small Paffion," very rare, and dated from 1507 to 1512. "Christ Crucified, with the Holy Women at the Foot of the Cross," a small circle, without the artist's mark, and said to have been done for the sword-belt of Charles V. "The Saviour prostrate in the Garden of Olives," very rare, and dated 1517. "A Group of Angels bearing the Instruments of Crucifixion, &c." engraved on tin, or iron turned over, and dated 1516. "The grand Ecco Homo," in large 4to, with a Latin inscription, and dated in 1512, a very rare print, much sought after by connoisseurs. "The Entombing of Christ by the Holy Women," in small folio, a print dated 1507, and in which several cats are strangely introduced, but which some think is not by Albert Durer. "The Infant Prodigy," a kneeling figure, in folio: some pretend that this is a portrait of Durer himself. "St. Hubert at the Chase," a folio print, in which the Saint is represented kneeling before a crucifix, which appears upon the head of a stag! the scene is a wood, with a cascade at some distance.

Albert Durer has been analogously compared with our poet Spenser, and it has been remarked, that if any one of his performances were to be pointed out as more particularly resembling Spenser, it should be that of the Legendary Tale of St. Hubert. They are characterized by the romantic heights of extravagance; the fame abundance of ideas; the fame unremitting and successful attention to minute excellence; the fame general air of incoherency rendered credible, and, if we should say now, if the works of the poet and engraver were now produced for the first time; the fame want of concentration, brevity, and general effect; but a temporary adoption of the sympathies of the sixteenth century, as far as art is concerned, reconciles us to these.

Of the subject of St. Jerome, Durer has engraved two plates in small folio, on one of which, where the Saint is sitting in a chamber, we have already commented; in the other he is kneeling before a crucifix, in a rocky defile, and the engraving is far less elaborately finished than the former.

"A naked winged Woman standing on a small Globe suspended in the Clouds, holding in one Hand an elaborately wrought Cup, and in the other a Bridle," a folio print, known among dealers by the name of the Larger Fortune. According to Vahrn, it should be called Temperance, according to others. Prudence; but, perhaps, Albert Durer meant it for the Guardian Genius of Nuremberg, of which city a bird's eye view appears beneath.

Another "Naked Woman on a Globe," in 4to, called the Lesser Fortune. She holds a long derrick and a thistle. The figure of "Melancholy," on which we have already commented. She is sitting, her head reposing on her hand, surrounded by various emblems, a folio plate, of exquisiter workmanship, dated 1514. "The Dream of M. Wolgemut," where he is represented asleep near a lying pen: the devil is behind with a large pair of bellows, and on the side Venus, with Cupid walking on fleeks. "The great Satan," who is attacked by a fawn whilst reposing with a nymph, a small folio, the work of the graver, and performed with admirable skill. "The Sortes," four asked women in a room: a globe, with the letters O. G. H. is enamelled from above, and in an adjoining chamber appears the devil surrounded by flames: it is dated 1497. Baldiniuoli thinks it is the earliest of Durer's engravings. It is copied from Wolgemut, and is a rare print. "A Chaste on Horseback, and in complete Armour, pursued by Death on Horseback, (who is holding forth an Hour-Glass,) and another Spectre:" this is a very highly finished and exquisite engraving, in small folio, of which good impressions are rare. It is by some termed "Death's Horrors," and by others, with more propriety, "The Worldly Man:" it is dated
GERMAN SCHOOL OF ENGRAVING.

dated 1513, and the impressions which were taken before this date was inscribed, are much valued. "The Death’s Head," of which we have already given a particular description, in small folio, dated 1525. Another heraldic subject of the same dimensions, displaying a lion rampant on a field, and a helmet surmounted by a cock perching on its wings. "A Large Horse," behind which marches an armed man with boots, bearing a halbert, and another bore of more beautiful form, behind which marches another armed man with a halberd, giving a griffin on his helmet: both in 5to, and dated 1507. A dishevelled Scorsers, mounted on a Lie-Goat, and flying through the Air, with a Ditaff in her Right-Hand. "The Prodigal Son," a small upright folio, of which the impressions, before the date 1513 was added, are held in most esteem.

Under the article Etching we have ascribed the invention of this mode of art to Albert Durer. The earliest of his etchings, which bears a date, is called "The Rape of Proserpine," a folio print, dated 1516, and in two years afterwards appeared his more celebrated etching of the march of an army, which has been called "The Cannon," from a large piece of ordnance forming the principal object on the fore-ground; the scene represented is the entrance of a village, with a bird's eye view over an extensive country, and three Turks are introduced near the fore-ground. Both these etchings are reported to have been performed on plates of iron or steel; and the latter, which is now become rare, is among the largest of the works of Albert Durer.

The principal of those works of our artist which are commonly supposed to have been engraved on wood, are as follow:—The portraits, in folio, of Albert Durer, inscribed "Albert Durer counterfeitt in seinem Alter des L.VI." without the engraver's cypher; another with his cypher; the emperor Maximilian I; a bust with numerous ornaments, inscribed "Imperator Caesar Divus Maximilhanus Pius Felix Augustus 1519." Ulrichs Varnbuler, a rare print, with the following inscription on a shield, "Albertus Durer Noricus redire quod notatur 1502.

From the numerous historical works which Durer performed in this manner, we select the following: A set of twelve folio prints, including the frontispiece, from the life and passion of Jesus Christ, inscribed "Pablo Domini, &c." dated 1510. A set of twenty-two small uprights, known by the name of the Smaller Passion, and inscribed, "Histoia Crucifitului Domini According to St. John, 1510." An "Ecce Homo," in folio, engraved in a bold and broad style, and with great freedom. The "Holy Trinity," surmounted by the Angic Hoff," and dated 1511. Another "Ecce Homo," known by the title of "The Mystery of the Mafs." A set of sixteen folio pieces, inclusive of the frontispiece, of which the subjects are taken from the Apocalypse, and the text printed on the reverse of every leaf. A set of twenty-two small folio prints from the life of the Virgin Mary, dated 1509, 1511: seventeen of this beautiful set of engravings were copied by Marc Antonio at Venice, to all of which copies, except one, the Italian artist added the cypher of Albert Durer. "The Holy Family," of the folio dimensions, where St. Anne holds the infant Saviour, and the Virgin Mary is in the act of adoration. "The Rhinoceros," a rare print, in folio, with a German inscription, dated 1515.

In chiaroscuro (or chiaroreuso) printed from a succession of blocks, the following are ascribed to Albert Durer: "A Holy Family in a Landscape:" two angels are crowning the VirglinMary, and on the fore-ground are three rabbits; in large folio. Two, of legendary stories from the lives of St. Augustin and St. Christopher, in large folio, the latter of which is scarce. A sort of apostles of the emperor Maximilian, where, accompanied by the Virgin Mary and numerous saints, he is adoring the Saviour. (Of this piece HUBLER produced an impression in which very richly colored.) A pair, which are scarce, of "A Portrait in a Glove of Sepia," generally called the Siege of Vienna, dated 1527. A set of six ornamental designs for tapestry, of architectural subjects. The whole number of engravings by Albert Durer, and after his death, are listed to amount to 1214: but Marritte's collection amounted to no more than 420, which were sold at his death for 1830 livres. See the article Durer in the Catalogue Raifonnee of the Brueghel cabinet.

The triumphs of the emperors Maximilian, which, when palled together, form two very large and long prints of the frieze form, have been generally ascribed to Albert Durer, but the refearches of Mr. Dacre of the British Museum, and Mr. Edwards of Pall-Mall, have determined that they are the performances of various other artists, though perhaps executed under the general superintendence of Albert Durer.

Lucas Cranach, of Kranach, was born at Cranach, in Weilplath, in the year 1472 or 1474, and died at Weymar in 1553. He was educated a painter; yet whether he studied under any other master than his father has not been recorded. He lived several years in the service of the elector of Saxony as an artist, distinguishing himself by his engravings on copper and wood, and in that manner which is technically called chiaro-fure. His fertility of invention far outran his judgment: led away by the livelihood of his fancy and talent for composition, he took such forms as were before him, following the stiff Gothic taste which prevailed in his country at the time, without attempting to improve it. His manner of drawing is rather dry and tawdry, than absolutely incorrect, but his heads have a moderate portion both of character and expression, though they are not marked with precision or in a pleasing style: his hands and feet are very defective, and a total ignorance of the art of distributing light and shade confuses his effects.

Cranach sometimes marked his plates with the initial letters of his name: and sometimes with the cypher, but more frequently with the dragon holding a ring in his mouth, which will be found in our first plate of German marks and monograms. The dragon is the emblem of the elector of Saxony, to which, on some occasions, Cranach added the electoral fire.

The following will probably be found among the best of his engravings, beginning with those which are executed on copper: Portraits of Jean Frederic elector of Saxony, where an angel appears on high with a crown of laurel, in large folio, and very rare. The two electors of Saxony, Frederic and Jean, the former of whom is holding a chaplet, in folio, dated 1510, and almost square. Christinian II. king of Denmark and Norway, surrounded by ornamental architecture, armorial bearings, &c. in large folio. A portrait of Martin Luther in the habit of a monk of St. Augustin, inscribed "Des Luter geblatt," in folio and dated 1525. The chief of his historical works are: "Adam and Eve after their Fall," (called by some the Penitence of St. Chry- folium) the scene is a defart, where a naked woman and child appear on the fore-ground, and in the back-ground a man is crawling, a folio plate, dated 1569. marked with the cypher and little dragon of Cranach, and executed quite in his Gothic manner. "The Temptation of our Saviour in the Desert," where the Christ has somewhat better pretensions to merit, than generally belongs to the figures of Cranach, but the tempter is as grotesque and entertaining a devil as you would wish to see: the print is in small folio, and marked L. C. W. the latter denoting Wittenburgh; it
GERMAN SCHOOL OF ENGRAVING.

is very rare and bad. A whimsical composition, of "Jesu Christ in the Clouds," surrounded by angels, and inspiring the editor of Saxon, a half length of whom appears below; a small print, almost square.

In chiarofuro, that is, on two blocks of wood, the one for the outline and darker shades, and the other for the demitints and lights, Cranach has engraved "St. Christopher carrying the Infant Christ over an Arm of the Sea," a folio print, dated 1507. "St. George and the Dragon," a large 4to. "St. John preaching in the Deserts," in folio, dated 1576. And, "A Naked Venus" (of judicious beauty) accompanied by Cupid, who is trying his bow, in folio.

The letter-prefs engravings of Cranach, commonly supposed to have been performed on wood, are as follow: But of Jean Frederic, elector of Saxony; ditto of Martin Luther in the costume of a monk of the order of St. Augustin, dated 1520; both in folio.

Whole length portraits of Martin Luther; Philip Melanthon; the emperor Charles V.; the emperor Ferdinand; Jean Frederic, elector of Saxony; and Jean Guillaume, duke of Saxony, all of the folio size.

A half length of the elector of Saxony, holding a book open before a crucifix, a rare print, marked with the little dragon, dated in 1552, and inscribed with a Latin sentence.

Of his historical works, the following are held in most request among collectors. "Adam and Eve in Paradise, or the Sin of our First Parents," dated 1509. "The Annunciation." "St. John preaching in the Deserts," which has been called a grand composition, and is dated 1516, and the "Decollation of St. John," all of the folio size.

A set of twelve in small folio from the life and passion of Jesus Christ, inscribed on the title page "Paffio D. N. Jesu Chrifti veniullfimis imaginibus," &c. and dated 1509.; the set is highly esteemed among connoisseurs. A smaller set of twelve, of the Martyrdoms of the Apostles, in 4to, and which are held in still more request for rich composition and the expression of the heads, and are on the whole superior to the preceding: they are dated in the year 1549.

It is curious to reflect, with how frequent infallibility, the Goths-german artists of the age of Cranach selected subjects that called for the introduction of beauty even of the highest kind, and drew out their virgin Miracles and Venemins in all the most graceful of their age and country. Paris visited by the three Goddesses on Mount Ida, is a rare piece in large folio, dated 1508. "Curtius leaping into the fiery Gulph" is also in folio, and dated 1508. Three plates of tournaments, of which two are called the great, and the other the little tournament, dated 1569; and a pair of park scenes with flags in the rutting time, and which are very rare, conclude our list of the engravings of Lucas Cranach.

Hans or John Burgkmair painter, and engraver on wood, was born at Augsburg in the year 1474. He studied under Albert Durer, and some of his engravings are dated so early as 1510, but the time and place of his death are unknown. He engraved chiefly, if not entirely on wood, and his prints possess much of the fire and spirit which distinguished his work. Professor Chrift attributes to him some small spirited wooden cuts which are made for the ancient editions of the works of Geyer de Keiferberg, which bear the above date (of 1510), and are marked I. B. Many of the works of this artist bear his name at length, the rest are marked with one or other of the two cyphers which will be found in our plate of the monograms, &c. of the German school.

The following are the engravings by Burgkmair, which are most sought after by collectors: "The Emperor Maximilian I. on Horseback;" of which design there is a dupli- cate engraving in clare obscure, which bears the name of Joht de Nagker, but which is partly the work of Burgkmair. It is a very rare print, dated in the year 1508, both of the folio size. "St. George on Horseback," also bears the name of Nagker, and is of the folio size, and in clare obscure. "Jesuf and the wife of Potiphar," is of a square form, and in 4to. "St. Thomas," "St. Bartholomew," and "St. Sebastian," dated 1515, are all in folio. "A young Woman mourning the loss of a Hero that Death has overcome," is a rare print in folio; by Burgkmair and Nagker.

The remainder of the letter press cuts of this artist are, a set of two hundred and thirty-seven for a folio work, of which the manuscript by Marc Treitz Sweurwein is in the Imperial library at Vienna: its title is "Der weif{Kong} (the wise king), and it confides the distinguised acts of the emperor Maximilian.

"The triumphant Entry of Maximilian," consisting of one hundred and thirty-five blocks or plates, have remained for a long period of time unknown at the castle of Ambras, but within these few years have been removed to the Imperial library at Vienna, since which, impressions have been taken, and several sets have been brought to England. Many of these engravings are the work of Burgkmair, and are marked at the back with his name or initials, though the whole generally passes under the name of Albert Durer, and were probably executed under his direction. Another work, executed by these artists conjointly with Hans Schauflein, is called the "Tewdruck;" but the greater number of the prints contained in it are from the graver of Burgkmair.

Johnsen, or Hans Baldung, named Grien or Grun, painted and engraved for the letter press and in clare obscure. He was a native of Gemund in Swabia, and was born in the year 1476. He flourished as an engraver through the earlier part of the sixteenth century, and the latest of his works is dated in the year 1534, but the time of his death is uncertain.

His engravings are executed in a bold style, and with considerable power over the instruments of his art. Strutt says of him, that "his figures are rather expressive than correct; the naked parts of them are poorly drawn; and the extremities, though free and spirited, are often heavy, and not well marked:" yet considering the period and place at which Baldung lived, he may be regarded as a meritorious artist. His engravings are sometimes marked with his name at length, and at others with the cyphers which we have in our plate of German monograms. His principal works are "Adam and Eve in Paradise," "The Fall of Adam," in the latter, a tablet is suspended from a tree, bearing the motto "Lapsus humani generis," and the date 1511. Both are of the folio size, and the Fall of Adam is a performance of merit in clare obscure.

A set of thirteen figures in small folio of the Saviour and twelve apostles, dated in 1514, and marked with the artist's cypher. "The Crucifixion," with the holy women and St. John at the foot of the Cross, in clare obscure. A set of four small uprights representing the Effects of Love, or Influence of Women, exemplified in the stories of Samson and Dalilah, Solomon's Idolatry, David and Bathsheba, and Xantippe and Socrates, (called by some Aristotle and Phryne), dated 1515. "A drunken Bacchus lying at the mouth of a Caft," in 4to. "The Sorceres," who is mounted on a he-goat, holding a cauldron. A pair, cut in a matterly style, of wild horaces in a forest, with the name of Baldung at length, and the date 1534. Another pair of small landscapes, which are said to be etched on plates of iron, and are very rare.
GERMAN SCHOOL OF ENGRAVING.

Of Hans Brüng, a designer and engraver for the letter press, very little more is known than that he was contemporary with Baldung, and has sometimes been mistaken for him from the similarity of their cyphers, and their taste in designing and engraving. Misleading the numeral 5, in the dates of his engravings, for a 6, Strutt has placed him a century too late.

Thole of his works which are best known, are "Adam and Eve in Paradise," of the folio size; bearing the cypher of Brüng, and the date 1519. A set of three of the 4to. dimensions, dated 1524; viz. "Christ on the Cross," "Christ lamented by the holy Women," and "A dead Christ," with angels bearing him away. Another set of thirteen, of the Saviour and twelve apostles, also in small 4to. and the three Delinities in a landscape, dated 1515, a very rare print in 4to.

Lucas or Louis Krug, or Krugen, painter, goldsmith, and engraver, was born at Nuremberg in the year 1490, and died in the same city in 1535. He formed his taste, in designing and engraving, from studying the works of Lucas of Leyden, and drew the human figure better than many of his contemporaries, though his attitudes are ill chosen, and his draperies flipp. His mark was a small pot or jug placed between his initials on a tablet, as represented in our first plate of the monograms, &c. of the German engravers, to which the date was in some instances added. His principal engravings are as follow:

Hans Schauflein, the third engraver of that name, was born at Nuremberg some time about the year 1487, and died at Nordlingen, a town in Swabia, in 1550. He studied under Albert Durer, and imitated his style with considerable success.

But few libraries have the honour ofpossessing a complete copy of this celebrated work, of which Melchior Pantzing says, in the dedication to Charles king of Spain, that he had seen no less of the actions that are therein engraved and defcribed, which in fact are those of the emperor Maximilian I. under the fictitious name of Tewerdanks.

Albert Altdorfer, whom some have mistakenly supposed to have been of Altdorf in Switzerland, was a native of Altdorf in Bavaria, born in the year 1488. His name is found in the regifter of the citizens of Ratibon in the year 1511, where, having passed the routine of preparatory civil offices, he was made a member of the interior senate, and architect of the city of Ratibon, and where, in 1538, he died without issue.

Some of his pictures may yet be seen at Ratibon, and at the town house is preserved a complete collection of his engravings. The French call him "le petit Albert," prematurely in contradistinction to the great Albert Durer, and because his engravings are small, for which reason all he is usually ranked with "the little masters."

His merit was however not inconsiderable. He engraved both for the rolling-press and letter-press; but those which he did for the latter are his best performances. He polished a lively fancy, a free hand, and great facility of invention. Yet his style is German, and his drawings, though spirited, is incorrect. He marked his plates and blocks with the two forts of monograms which appear in our plate of the cyphers, &c. of the German school. One of these marks has been attributed to Altdorfer; but the evident superiority of the latter master is of itself sufficient (independent of the cypher) to correct the mistake.

From the spirited wooden cuts of Altdorfer, Holbein, of whom we shall presently speak, is said, and probably with truth, to have derived great assistance in the progress of his studies.

Altdorfer's principal engravings on copper are the portrait of himself; and that of Martin Luther, in an oval, surrounded by foliage; the head of an infant, one of his earliest works, dated in 1507; "Adam and Eve in Paradise;" "Solomon's Idolatry;" "Dalfah and Samson;" "Judith and Holofernes;" several small prints of the Madonna and infant Christ; a Crucifixion, with numerous figures; another with the Virgin Mary and St. John, both small uprights; "St. Jerome reading in a Cavern," where is an altar, book, crucifix, and a table, with the monogram of the artist; another St. Jerome among buildings, accompanied by a lion; "St. George combating the Dragon:" two etchings of the death of Dido, and that of Lucretia; a pair copied from Marc Antonio, of "Venus accompanied by Cupid entering the Bath," and "Venus leaving the Bath:" there are small uprights and in a neat style. "Cupid Sporting with Satyrs," "Amphion faved by Dolphins," dated 1525. A pair of "Laercionknecht," and "Chastity," represented by a female sitting on an altar, and holding a sceptre, with numerous attendants bearing lanterns. "A Warrior precipitating himself into the Sea." A pair of small landscapes lengthways, one with rocks and the other with trees, which are touched with considerable freedom. The "Symagogue," with a Latin inscription; and two plates of ornamented vases in 4to.

The number of engravings by this master, which are supposed to have been performed on wood, is considerable, probably exceeding a hundred, of which the following are most valued — A set of forty of "The Fall and Redemption of Man" small uprights, executed in Altdorfer's best manner, and much valued; but collectors should be careful not to admit into their portfolios, instead of these, a set of which all but two are copies from Altdorfer, and which were published at Zuric A.D. 1604, under the forged name of Albert Durer. "The Sacrifice of Abraham," and "Joshua and Caleb," both small. "The Annunciation," ditto, dated 1513.

The four following are in 4to. "The Purification;" "The Massacre of the Innocents," dated 1511; "The Decollation of St. John the Baptist," and "The Resurrection of Christ," both dated 1512, and the latter esteemed one of the most spirited works of the master.

The
GERMAN SCHOOL OF ENGRAVING.

The beautiful virgin of Ratibof, engraved from her statue in Ratibof cathedral, is engraved in chiaro-scuro, though these few impressions were printed without the half tint; this is a rare print.

Of the often repeated subject of St. Jerome, Altdorfer has engraved two blocks, in one of which the holy man is kneeling before a crucifix in a cavern, and the other may be distinguished by its very romantic background, both are small, but both held in esteem. "St. George and the Dragon," and "The Judgment of Paris," both dated in 1511, and "St. Christopher and the infant Christ," are in all four. A mountainous landscape with buildings, and a large tree on the right hand, another of a gateway, and a grand baptismal procession, a fort of allegory, where, inside of a church, the virgin and child, some angels, and a pilgrim, appear in the procession, are all of the folio size.

Hans Holbein the elder flourished towards the close of the fifteenth century, and was of Augsburg, but afterwards removed to Basel in Switzerland. According to professor Chiril, he engraved on wood, and certain prints marked with an H., or the cypher H.B., the B being joined to the first perpendicular stroke of the H., are attributed to him; but Strutt doubts whether they ought not rather to be ascribed to Burgkmair or Baldung.

The great celebrity of his son has reflected a reflected light upon his name. Hans, or John Holbein the younger, was born at Augsburg in the year 1495 or 1498, and died of the plague in London A.D. 1543. He was the pupil of his father, and gave earnest of his very extraordinary powers, at a very early age.

About the time of his father's removal to Basel, the genius of Holbein began to dawn on the arts of Europe. At this time, before engraving, as has been said by various authors, for the letter-press in a very superior style, he painted portraits, and occasionally historical subjects in dittemper and in oil, and Erasmus, who was then superintending the printing of his works at Basel, came to fit for his likeness to young Holbein.

Being charmed with his portrait, Erasmus soon formed a friendship for the artist, and at his persuasion Holbein soon after travelled to England. He brought with him the portrait of his friend, and letters of warm recommendation to the great Sir Thomas More, who was at that time lord chancellor, and high in the favour of Henry VIII.

Hollin was received by the chancellor in the most friendly and flattering manner, and the family of the Morees, besides several other persons of distinction, and finally the king himself, honoured our artist byfitting to him for their portraits. Patronized by Sir Thomas, and poikelf of high talent in the arts as had not appeared in England before, he was easily received into the royal service upon very liberal terms, and to our pride was Henry of the abilities of his protege, drawing to the claims of his genius, that he frequently sat to him for his portrait, and the story which we have related of the condensation of the emperor Maximilian to Albert Durer has been often repeated of king Henry and our artist.

After the death of Henry, Holbein still continued to enjoy the royal favour, and several portraits of Edward VI. from his hand are still extant.

The career of Holbein was but short, but as the poet on a leaf interesting occasion has beautifully said," the funds of his hours-glass were diamond-sparks," which, as they fell, glittered in the radiance of his reputation. He died, as we have before mentioned, of the plague, in his apartments at Whitehall.

For an account of his merits as a painter the reader is referred to the article HOLBEIN. He began engraving when he was about sixteen years of age, and very numerous and of extraordinary merit are the letter-press cuts which are said to be from his hand, and after his own designs, which adorn the books that were printed about this time at Bafle, Zutic, Lyon, Leyden, and London.

Holbein appears to have formed his style, probably under the direction of his father, from studying the works of his contemporary Altdorfer, who was now rising in reputation, though not more than ten years older than our artist, and it seems highly probable that the whole of whatever letter-press engravings are from the hand of Holbein himself, are the production of those fifteen years of his life which elapsed between the years 1511 and 1526, when he came to England, for it is not very likely that he would be led aside from the advantages of the royal and noble patronage which he enjoyed in England as a painter, by any inducements which the printers and booksellers of the continent might offer. Engaged in inferior pursuits, the present writer is inclined to think that he did no more than design the little wood-cuts which are ascribed to him during his residence in our island.

The foreign writers on art, however, call him "the glory of wood engraving," and the "phenomenon of his age," adding that in order duly to appreciate his merit as an engraver, the connoisseur should not look at the hastily printed and worn impressions which are common, but should have before him, early proofs, printed only on one side the paper, such as were lately in the collection of M. Otto, an amateur of Leipzig, which, in point of delicacy, exceed all that had previously been exhibited.

His most esteemed production in this way bears the Latin inscription

"Cernere vis Holpese simulacra finmillina vivis?\nHoc opus Holbini nobilis carne manus;"

and consists of a series of ninety small letter-press cuts, of unequal merit, of which the subjects are taken from the Old Testament. The encomiums that have been repeatedly passed on the whole, namely, that "boldness, spirit, and decision are united in their execution," are only applicable to the best of these cuts: the rest are scarcely, if at all, superior to the common place of the day.

The first edition of this work, which is commonly termed Holbein's Bible, is said to have been printed (at Lyons, by the brothers Malchior and Gafpar Trechsel) in the year 1539, and as this was thirteen years after his departure for England, it is not easy to believe that these cuts are really engraved by Holbein, notwithstanding what is asserted in the inscription: and they are on the whole inferior both in design and engraving to the "Dance of Death," of which we shall presently speak.

That the craft of publishers on such an occasion should have outstripped the skill of truth, and that a name which had refounded through Europe should be used as the trumpet of popularity and the means of profit, would be the very extraordinary occurrence. The work was for the multitude, and the multitude, on such a point, were easily deceived; nor could Holbein, if he were really the author of the fictitious, easily contradict the complimentary inscription:

"The Dance of Peasants," engraved from a picture which he painted in the fish-market at Bafle, and evidently before his departure for England, of which fine impressions are now become rare and valuable.

The cuts for "The Praise of Folly," of his friend Erasmus, have also been ascribed to Holbein, besides several detached frontispieces, jewellery ornaments, and vignettes, and, lastly, we shall mention the "Imagines Mortis," or "Dance of Death."
GERMAN SCHOOL OF ENGRAVING.

Death," over Holbein's claims to which the accurate research of M. Douce of the British Museum has thrown a shade of doubt that may not easily be dispelled.

It consists of forty-fix small upright prints, each surround-

ed by a double line border, wherein Death, in the skeleton

form, is pathetically represented as beating off an individual
from every flation and condition of life, from the emperor
in his imperial state, down to the meanest peasant; and the

general moral which combines the whole is, that Death pays no

regard to age, sex, or condition.

It seems proper here to observe that these engravings are

not taken, as Papillon, Strutt, and others have mistakenly

supposed, from an ancient painting on the walls of a ceme-
ytery at Bafiil, and that this painting is not from the hand of
Holbein, but is of much older date. The originals are
drawings or small pictures which have been sup posed to be
by Holbein, between which and the large picture in the

cemetery there is this material difference, that the former forms
one long and connected procession of single figures, each led
by a skeleton, whereas the latter is composed of separate
groups, in which one or more living figures or skeletons are
occasionally introduced, as the views of the artist, and
altogether forming a series, the idea of which was no doubt
suggested by the walls of the cemetery, and by the dances
of death that were sometimes found painted in the crypts of
ancient cathedrals, and of which there was one at Lubec,
another in the church of the Innocents at Paris, and

another in our old cathedral of St. Paul.

The cypier formed of an H and an L, which appears to

cut in the Imagines Mortis, of which the subject is
called "The Duchess," is certainly not that of either of
Holbeins, and is very likely to have belonged to some
German wood engraver, whose initials might be thus conjoin-
ed, who was the real engraver of the whole set of the Dance
of Death, and who might perhaps be Hans Lederer, as is

conjectured by Mr. Douce.

Bartolomeo Beham was born at Nuremberg some time

about the year 1496, and, according to Sandrart, ended his

days in Italy, a short time before the middle of the succeed-

ing century. He travelled thither with Duke William of

Bavaria, and became the disciple of Marc Antonio, under

whose instruction he advanced rapidly in his profession, and

whose style he imitated without implicit following. He
remained several years at Rome and Bologna, working chief-
yly in the excellent school of Marc Antonio, and incorpora-
ing with the careful and patient manual execution of Ger-

many, the accurate drawing of his master, and the fine taste
of Italy and Raphael. Strutt accordingly lays of him, that "his
drawing is correct and masterly; his heads characteristic,
and the other extremities of his figures well marked."

Sandrart states of this master, that in his time a great many

of his engravings (presumptively engraved plates, and not
impressions from them) might be seen in the gallery of the elec-
tor of Bavaria at Munich, and in the cabinet of the prince of
Neubourg.

The collection of the works of Bartolomeo Beham is

however attended with considerable uncertainty, from the
circumstance of many of them having been published with-

out his name, monogram, or other mark. Strutt attributes to
him the engravings that are marked with a small die, on
which sometimes appears the letter B, whilst the abbe Ma-
rolles, Huber and Roux, contend that these prints are the
production of Balthasar.

Of the works generally attributed to this master the fol-
lowing are the principal:—the portraits of William, duke of
Bavaria; Erasmus Baderman, at the age of 30, and Leo-
nard van Eck, a counsellor of Bavaria, all in octavo. The
emperor Charles V., at the age of 30, with the Latin in-
ferior "Progenies divar quis quid for Carolus ille imperii
Cesar et ora tulit," and the emperor Ferdinand I. with the in-
ferior "Proximus a summo Ferdinando Rex
Romanorum fecit tulit ora genas," both in quarto, and marked
B.B. There are a finely engraved pair of portraits, and so
much in the style of Marc Antonio, that Vafieri thinks the
portrait of Charles V. is really engraved by that master.

The best historical works of Beham are "Adam and Eve,
with the figure of Death introduced into Paradise." "Judit
beheading Holofernes," dated 1525, and in the tale of
Marc Antonio. "The Madonna suckling the Infant
Christ at a Window," (without the mark of the artist.) "A Sybil reading, and having before her a boy holding a
Flameaux," (marked B. B. but apparently after Raphael.)
"Susannah and the Elders," after Julio Romano. The
data of Lucretia and Cleopatra, both without the engraver's
mark. "The Judgment of Paris," with a back ground,
a small frieze, representing a combat, and marked
"Titus Graecus," and another small plate of a combat,
wherein soldiers are fighting with clubs, comparison to the
above. "An Infant carefiling a Dog," a small circle, dated
1523. Another Child, with a skull near him, marked
B. B. and dated 1523. An emblematical piece, inscribed
"Der Weif Lauf," in which appears a half naked woman
fettered, and asleep under a tree, an infant at her side, and
a lamb at her feet; and an indelicate subject from Ecclesiaster.

Hans Sebald Beham, the cousin or nephew of Bartholomew,
was born at Nuremberg in the year 1500, and died at
Frankfort on the Maine in 1550. He is said by Sandrart
to have studied under his relative, but Bartholomew went
early to Rome, and, it must be remembered, was but four
years older than Sebald; perhaps he merely learned of him
the rudiments, and afterwards studied with Aldegrovius, of
whom we shall presently speak, the works of Albert Durer.

He was obliged to quit Nuremberg on account of his
libertinism, but settled soon after at Frankfort; where, how-
ever, he relapsed into his former courses, and after engraving
for some years, in the course of which the number of plates
and tablets which he produced is surprising, he became the
landlord of a tavern.

The German biographers of Sebald maintain, that when
he established himself at Frankfort, he altered his monogram,
by substituting the letter B for the P which he used
at Nuremberg; they do not say he did it for the sake of con-
cealment, and it may in some degree account for this varia-
tion, when we recollect that these letters are often orally
confounded among the people of that nation. The Abbé
Marolles, Le Comte, and the French writers, on the other
hand, often call him Hlbens, and Sebald de Bohemen, for
which we cannot so readily account.

Sebald Beham ranks deservedly high among the little
master; he engraved chiefly from his own compositions,
which shew a lively and vigorous invention, though some-
what hampered by the Gothic-german taste, which was
then prevalent, and which chiefly appears in the hatched
and inelegant folios with which he loaded his draperies. His
drawing of the naked, on which he seems to have justly,
prided himself, though not free from manner, is often

Vol. XVI.
correct, and sometimes masterly; his heads are expressive, and his other extremities carefully determined. The manual part of his engraving on copper, executed with the graver only, is clear and delicate. The prints which he has cut on wood are light, but spirited and free, as wood engraving ought to be; for wood engraving ought not to emulate the delicacies and difficulties of the art of engraving on copper.

His two monograms will be found among those of the first plate of the German school. From these which he engraved between the years 1539 and 1549, with the Nuremberg cypher, we select the following: 1539, the portraits of Sebald Beham and his wife Anna, where his cypher appears encircled by buds. Two small plates of "Adam and Eve in the terrestrial paradise," dated 1540. "St. Jerome with his Lion holding the cardinal’s hat." "The Madonna suckling the infant Christ." "The Virgin of Ratibon," where the feet is represented flanding on a crescent, and surrounded by radiance, and "The Death of Dido," all dated 1540. "St. Anthony writing in the desert," and "St. Sebald, (the patron saint of Nuremberg)," sitting among trunks of Trees, and holding in his right hand the Model of his Church," both dated 1524. "Two Peasants marching and playing on the flute and bag-pipes, and a male and female Peasant Dancing," dated 1528. "A Triton supporting a Nereid," dated 1532. "Force, allegrovised by a Woman sitting on a Lion," dated 1534. "A young Man sitting under an Arbour embracing a young Woman," dated 1526. "The Death of Cleopatra," dated 1529. An ornamented vase with an inscription. "A combat between the Greeks and Trojans," inscribed "Krichen und Dreetjen," and another combat, inscribed "Achilles and Hector," both small friezes.

Of those which S. Beham engraved at Frankfurt, between the years 1531 and 1549, and which are marked with his second cypher, the following are held in most esteem.

A vase enriched with sculptured ornaments, at the base of which are two fayrens, dated 1531. "Adam and Eve carelessly each other." "Adam and Eve in Paradise," between whom is Death, with a serpent wound round him, presenting the fatal apple; a high finished plate, dated 1543. "The emperor Trajan arrested at the head of his Army." "Melancholy and Patience," two female figures, the former copied from the celebrated engraving of the same subject by Albert Durer, dated 1539; the latter figured on a column, which is inscribed "Patience," and dated 1540. Another pair, of Good Fortune and Evil Fortune, the former figure flandering and holding a wheel, the latter arrested in her course by an evil genius, who is presenting her with a lobster or crawfish. An etching of a buffoon presenting flowers to a young woman. A set of the four evangelists, dated 1541. Another set of twelve of the labours of Hercules, dated from 1542 to 1548. "Ein Einzig beating a Drum," inscribed "Im Bauer Kreig," small, and dated 1525. "A Roman Charity," very finely engraved, dated 1544. The arms of Beham, as granted to the family by the emperor Maximilian, a hexagonal print, inscribed "Sebalt Beham, von Nurnberg, malt, jükt wohnhafter Burgker in Frankfort," dated 1544. Both of Domitian in the manner of an antique medal. A set of six, and a title-page of the months represented by male and female peacants dancing, the first dated 1545. "The Judgment of Paris," dated 1546. "Death seized from behind by a naked female," a beautifully finished plate, dated 1547, with the following words inscribed on a stone, "Omnes in homine venalium mors absit." "A Man endeavouring to root up a Tree," dated 1549, and inscribed "Impedibilis, &c," and a virgin and child copied from Bartholomew Belian, dated 1549.

The letter-press cuts of S. Beham have not been thus carefully arranged and separated. We select from them the following. His own portrait in a bonnet and without a beard. A set of eight from the Passion of our Lord, two of which are marked with his former, and two with his latter cypher. An "Holy Family," in which St. Joseph is plucking fruit. "The Virgin and Child." "A Penitent." "St. Jerome with a Bible and Crucifix." "Immortality," represented by a female crowned with stars, and trampling on a skeleton, dated 1548. A public bath of Anabaptists, of both sexes and all ages, of the circular form. Another public bath, a large print on four leaves. "A village Fair" of the frieze form, and "A March of Soldiers," also of the frieze form, and large; the four last-mentioned engravings are very rare; a set of three hundred and forty-eight, engraved for "Biblique Historique Artificiosime depictum," printed at Frankfurt in 1537. But it is to be observed that there are two editions of this hible, of which the former is in Latin, and the latter, dated 1539, is in the German language.

Gregory Peins, or George Pentz, was also a native of Nuremberg, born in the year 1500. He first studied in the school of Albert Durer, and profited much by the instructions of that distinguished master, but it was in Italy, and under Marc Antonio, that he finished his taste, formed his style of engraving, and acquired that correctness of drawing which we regard with so much admiration in his best works. His plates are executed entirely with the graver, which he handled with much skill, uniting with great precision a degree of freedom which was unexampled. He appears to have worked on some of the best plates that pass under the name of Marc Antonio.

The far greater number of the engravings of Peins are of small dimensions; wherefore he is usually classed among "the little masters;" but he has produced some few large prints; one especially of great merit, of "An Army passing a Ditch, and scaling the Walls of a fortified City," after Julio Romano; which, as Strutt has said, is "an admirable specimen of the artist's superior abilities."

Peins died at the age of fifty-six, but where, his biographers have not mentioned: his monogram will be found in our plate of those of the German school; and the most esteemed of his numerous works are those which follow: Portraits of Gregory Peins and his wife on the same plate, with the inscription "Imago Gregori Peins Imago Duxore Gregori Peins." From this engraving it should appear, that the name it bears was the true name of our artist, and that the name Georgius Pentz, which appears under his large plate after Julio Romano, is probably an error of the publisher Van Aelst. Portrait of Jean Frederic, doctor of Saxony, a rare print, dated 1535.

The belt of the historical works of Peins are, a pair of "Either before Ablution," and "The Temptation of Job;" another small pair of "Judith in the Tent of Holofemes, and Judith appearing afterwards with his Head;" another pair, finely executed, of "Solomon's Idolatry," and "The Judgment of Solomon."

Peins appears to have professed some judgment, at least some humour, in pairing his prints; the next companions which we have to notice, are "Susannah solicited by the Two old Men," and "Lot intoxicated by the Two young Women, his Daughters."

From the history of the patriarch Joseph, we find a set consisting of four plates; another set from the history of Tobit of seven, including the title-page. A pair of "The Good Samaritan, and the Conversion of St. Paul." A set of the Four Evangelists after Aldegrever, which bear the cyphers of both artists. Another set of the Seven Works of Mercy, of the circular form, and with German inscriptions. Another set, very highly finished, consisting of twenty-five, from the Life of Christ. "Hedelia receiving

But his principal and largest work, of which we have already spoken, is "The taking of Carthage by the Romans," after Julio Romano.

Among that class of the ancient engravers of the continent who are called the "Little Masters," from the small dimensions of their works, Henry Aldegrever stands in the very first rank. He was born at Zontl in Welfphalia, A. D. 1502, but of his ancestors we find no account. Both his baptismal and family names have been mistaken, for, by some authors, he is called Aldergraft; while others, perhaps, mistaking some of the smaller works of Albert Altdorfer for his, lay that his christian name was Albert; but professor Christ affurés his readers that the name of this artist was Henry, and not Albert; and upon his own portrait his name is written, at full length, "Aldegrever."

Nuremberg was at that time the head-quarters of German art; and thither young Aldegrever was sent to study under Albert Durer. He imitated the style of his master with great success, and gradually learned to blend with it a certain small portion of the elegance and simplicity which Italy first caught from the resurrection of Grecian art; and Germany from the engraving, which were brought thither from Italy. Aldegrever is a lofty object, which receives the first faint rays of a rising sun, and is universally allowed by his critics, that had been refuted in Italy, "the genius and ability which displayed itself so conspicuously in his own country, would have shone with double luster."

The manual part of his engraving, executed entirely with the graver, is extremely neat, and in a style evidently founded upon that of Durer. He is among the first who gave texture to the light parts of flesh by the admixture of small long dots, which has since been carried to such admirable perfection by Naenteil and others. His drawing of the naked, which he seems fond of introducing, is more correct than is found among his predecessors of Germany, and his men more correct than his women. His heads are, in general, expressive, and his other extremities well marked, though occasionally somewhat heavy.

The time of the decease of Aldegrever is not accurately known, but the latest of his prints is dated in the year 1558. The Abbe Marolles had seen at least three hundred and fifty different prints from his graver, of which the following list contains the names of the principal: but the great demand for his works has occasioned his plates to be much worn, and often re touched; and Strutt, with becoming solicitude for his fame, advises the collector to be circumstant as to the impressions he admits into his portfolios. His monograms may be seen in six plates of those of the German school.

The principal portraits of Aldegrever, are those of himself without a beard, aged 28, and dated 1530. Another of himself, aged 35, in which he appears with a long beard: Martin Luther, dated 1549; Philip Melarchon, of the same date; and Albert Vander Helst, aged 28, and dated 1558; all in quarto.

His folio portraits are those of William Duc de Julius; John of Leyden, king of the Anabaptists, and Bernard Knipperdolling, another fanatic.

Of his historical engravings, the most celebrated are: A set of six, from the History of Adam and Eve, dated 1540. A set of four, from the History of Lot, dated 1555. A set of four, from the History of the patriarch Joseph, dated 1528 and 1532; all in quarto.

The only etching from the hand of Aldegrever is now become very scarce; its subject is Orpheus and Eurydice, dated in 1526, and in 12mo.

James, or Jacob Bincck, was also of Nuremberg, or, according to some authors, was born at Cologne, in the year 1504, and died at Rome in 1560. His style of engraving greatly resembles that of Aldegrever, under whom, or Albert Durer, he probably learned the rudiments of his art, and improved himself afterward in the school of Marc Antonio; yet his style is not always the same; it often behoves more feeming facility than that of Aldegrever, and when at the hot, more of Italian taste. He apparently studied also, and imitated, that of Marc de Ravenna.

His cypher, composed of the initial letters of his name, is that of many other artists who lived about the same period; but he sometimes added a little bird, and at others used the monogram, which will be found on our second plate.

The chief works of Jacob Bincck are, "A young Man drest in a Bonnet, holding a Skull under his Cloak, and a Cup in his Right-Hand." This, according to Sandart, is his own portrait; but, though the face may possibly resemble him, the rest of the composition is copied from an engraving of the same size by Israel von Mechenin.

The portraits of Francis I, Christianus II, surrounded by ornamental architecture; a young prince, dated 1526; Luke Gaffeo, dated 1529; the archduchess Elizabeth of Denmark; a pair, of Martin Luther, inscribed "In sentio Vela," and Philip Melanchthon, inscribed "Si Deus pro nobis quis contra nos." His principal historical engravings are, a small plate of St. Jerome. "Marcus Curtius precipitating himself into the fiery Gulf," marked 15 I. B. 29. A pair, of the frieze proportions, of "Infant Bacchanales gathering grapes," &c, and "The Triumph of Bacchus," wherein his car is drawn by fayirs, and attendant nymphs are playing on musical
GERMAN SCHOOL OF ENGRAVING.

musical instruments, dated 1528, 1529. A set of the Seven Planets personified. Another of the Seven Cardinal Virtues. An emblematic piece on medallion, in which a flaming heart, i.e., an heart of ardent virtue, is beaten on an anvil, by four allegorical females: figures, as we are informed in Bihlaib Pirkheimer's emblems, are Experience, Easy, Tribulation, and Intolerance, marked 15. L. B. 29. "History," a female figure with wings, writing. A pair of "Peacocks marketting with People of Superior Condition." A set of twenty, of Divinities standing in Niches, copied from Curalicus, who copied them from Rosso.

"A Woman besatting the Devil with a Dilaff;" "A Woman advancing with Surprises towards a Man who is seated near a Pedestal, on which is a Child," after Raphael, and engraved under the direction of Marc Antonio. "A Male and Female Peafant Dancing." "The Blind Child." A vignette, with Cupids mounted on dolphins.

Strutt begs leave to add, a figure of "Saturn standing in a Niche devouring One of his Children," a small upright, which differs in the style of engraving from the foregoing, being more bold, spirited, and correct. The real meaning of this allegory must be, that Time is swallowed up by Eternity. On a tablet which is introduced is "Jacobus Buinck Colonienis, fecit 1530."

Another of the "little masters" of Germany was Hans or John Brosamer, born at Fulda, in the circle of the Upper Rhine, in the year 1506. His manner of engraving often bears resemblance to that of Aldegrever, but the school in which he studied is not known; sometimes, however, he differs from that distinguished master by interworking the lines of his draperies and backgrounds with flapping. His drawing of the naked is however very deficient; and in manual execution he by no means equalled the Behams. He died at the age of fifty-four, and his cypher, composed of the letters H and B, will be found in our first plate of those of the German school.

His principal engravings are, the portraits of Martin Luther, and the abbot of Fulda, dated in 1541.

And in history; "Samson and Dalilah;" "David and Bathsheba;" and "Solomon's Idolatry;" dated 1543, all small uprights. "Xystippe and Socrates;" "Laeocoon and his Sons," dated 1538; "The Rape of Helen;" of the frieze form, dated 1540; "Marcus Curtius leaping into the Gulf;" a small circular plate; "The Judgment of Paris;" "A Crucifixion, with Angels, the Virgin Mary, and St. John;" the grand procession of Christian Heroes;" a rare print, engraved on wood, and sometimes attributed to Burgmair; and "Biblia Veteris Testamento artificialis picturis effigie," printed at Frankfort in the year 1552, and consisting of a set of engravings on wood, chiefly, but not entirely, copied from those of Holbein, which were published at Leyden in 1547; but by no means equal to the originals, either in spirit, nature, or truth.

Augustin Hirchfogel was born at Nuremberg A. D. 1526, and died in the same city in 1560. He was probably educated a painter, but produced several etchings, of which the landscapes possess considerable merit, being etched with some taste and the touch of a master, but when he introduced the human figure it is very incorrectly drawn.

The singular monogram of Hirchfogel, surmounted by a little crofs, will be found in our first plate of those of the German school, and his principal productions are as follow:

The "Raphael's slaughter of the Innocents," from a sketch by that master, which differs from the print by Marc Antonio, dated 1545. A set of four, and another set of six landscapes, from his own compositions of castle and mountain scenery, in 4to., dated 1546. A folio landscape, in which is introduced an ill-drawn female intended for Cleopatra, dated 1547. An ornamented vase in 4to. dated the same year, and two small views of fca-ports, with flippings, &c. dated 1549.

Henry, whom Strutt has mistakenly confounded with Hans or John Lautenfack, was also of Nuremberg, or, according to some authors, was of Doppelmair, and born in the same year with the preceding artist. He was the son of a painter, and learned the principles of design in his father's house, which he probably continued to inhabit, for we find that he died in his native city in the year 1596.

The elder Lautenfack employed much of his time in engraving on the precious metals for the sideboards and personal ornaments of the opulent and the great, but in the year 1567 he published at Frankfort on the Main the "Geometrical proportions and perspective of the Man and Horse;" in small folio; "The Martyrdom of St. Catherine;" two ornamental plates of boys, &c.; "The decollation of St. John the Baptist;" "Christ expiring on the Cross," and a boy standing on a globe with a bow in his hand, and below whom is a deluge, with many small figures, are also engraved by Henry Lautenfack, whose marks will be found in our second plate of German monograms.

Of the same place and family with the preceding, was Hans Sebald Lautenfack, who was born in the year 1508, but of the principal events of whose life, and the time of whose death, we are ignorant.

His portraits are held in esteem among connoisseurs for their truth of resemblance; and his landscapes, which are chiefly etchings, for their wild, or beautiful, or grand effects; but the figures which he has introduced are generally disproportionate.

His landscapes are of an historical character, and are commonly denominated after the figures they contain. Of these the following will probably be found most worthy of the collector's attention: "The little David combating the Great Goliath," dated 1551. "The Blind Man of Jericho, restored by our Saviour," and another miracle of "The Devil cast out from the Canaanite," both dated 1550. "Balak and his As," in a very mountainous landscape, and a very rich scene of "The Labours of the Vintage," are also dated in 1550, all of the folio size. An upright landscape with a large farm, dated 1551. A pair of interesting and extensive scenes in 4to. dated 1552 and 1555. A grand tournament, of large folio dimensions, entitled "Equitria pedeslirique pinguiscon." 1560; and another grand joust, entitled "Secundum Circumenv Ludorum, etque certamen continentis," 1560, both of which are now become very rare. A pair of views of the imperial city of Nuremberg, in large folio, each engraved on three plates, and dated 1552 and 1555.

The principal portraits by Hans Sebald, are those of his father Paul Lautenfack, painter of Nuremberg, in folio, himself, in small folio, dated 1552. Heroumnius Steurtab. Georgius.
GERMAN SCHOOL OF ENGRAVING.

Georgius Roggenbach, and two other half-lengths, all in folio.

The brothers David, Jerome, and Lambert Hopfer appear to have been the sons of a goldsmith, and flourished at Nuremberg within the first fifty years of the sixteenth century. They produced a great many spirited engravings, which Holzer afterwards made the foundation of his style. David was the most industrious of the three, but deflected in the vicious taste of his age and country; yet his freedom of handling is very pleasing, and displays itself to advantage in buildings and ornaments. He usually marked his plates with the initials of his name, between which he introduced what the Abbé Marolles appears to have mistaken for a candlestick, for he emphatically calls the Hopfers "le Maîtres du Chandelier," but what is really intended for a hop-plant, in allusion to their name, which in the German language signifies hop-plant. These letters, with the plant, sometimes appear on a tablet, for which see our plate of German monograms.

The principal works of David, are the portraits of Nero and Galba, of the 400 size, as medallions. Carolus Rex Catholicus, the fame. Martin Luther, dated 1523, and Claude Sturzbecher, a rare print in folio.

Of his historical engravings, we shall mention, "David beheading Goliath," in 400, and "David Playing on the Harp before Saul," in folio, dated 1537. "The Adulterous Woman;" "The Presentation in the Temple;" "The Last Judgment;" and "A Grand Altar;" with the figures of Jesus Christ, the Virgin Mary, St. John the Baptist, and others, all in folio. A fort of ridiculous "Morice Dance of Grotesque Figures," "The Monopolier of Grain, excrated by the People," inscribed, "die Sprich Solomo, Das Inhalts." A subject from the 10th chapter of Solomon's Proverbs, dated 1534, both in folio. "The Three Great Jewels, Jews, David, and Judas Maccabeus, on horseback." "The Three Christian Heroes, Charlemagne, King Arthur, and Godfrey of Boulogne," companion to the above, both in 400, and after Hans Burgmaier. "A Grand Village," of figure form and folio dimensions. "Two Females Surveying themselves in a Mirror, behind whom are Death and the Devil." Two very grotesque figures, inscribed "Bolhka, Markela," in folio. "The Crucifixion between the Two Thieves." Another "Crucifixion," in which St. John and the Virgin Mary are introduced, the latter pierced by a sword, in allusion to her excessive grief; and a small copy of a celebrated work of Andrea Mantegna, of "A Combat of Marine Monitors." "Jerome Hopfer etched much in the same style with his brother, but was somewhat inferior in merit. He made several copies from celebrated works of Albert Durer, and sometimes engraved from his own compositions, marking his prints as did his brother.

His best works after Durer are, "St. Hubert," "St. Jerome," and "The Grand Cannon." "Hercules Combating the Hydra," is from Andrea Mantegna; and the best from his own designs are "Lucina holding a Moon in her right Hand, and a Flaneau in her left." "Minerva holding a small Figure of Victory." A rare print of "The English and French drawn up in battle array, previous to the Fight at Agincourt." And a battle, after Julio Romano.

Of still less merit than his brethren, was Lambert Hopfer, who composed in etching a great number of the wood cuts of Durer, but his works display little taste and less correctness. Among them are a set of fifteen of "The Life and Passion of Christ," "The Conversion of St. Paul," "The Fall of our First Parents," Several plates of arabesque ornaments, and four beautiful candelabra, with an arabesque border, which is esteemed the best of his engravings.

Strutt has added to these another Hopfer, for whom he claims equal merit with the first. The initial letter of his christname was an N. He worked with the graver, but imparted to his lines somewhat of the roundness of etchings, and drew more correctly than David or any other of the family. To this artist he ascribes "The Call of Jeremiah," a small upright, dated 1525. "A female Saint, holding a Palm Branch, and several Figures sleeping with the Deity appearing above," which, he says, is "a line spirited etching."

David Funck, a printseller of Nuremberg, towards the beginning of the last century, collected and published all the plates of these artists, amounting to two hundred and thirty, under the title of "Opera Hopferiana:" some of which were found to be executed on plates of iron or tin.

Virgile Solis engraved both on copper and on wood, chiefly from his own designs; was born at Nuremberg in the year 1514, and died in the same city in 1570. Under what matter he studied does not appear. His early works resemble those of Beham, but when he came to engrave after Raphael, and other Italian masters, he adopted a style more open and spirited. His prints on wood bear great resemblance to those of Jott Ammon, both in design and execution.

Virgile Solis was a man of ability. His compositions are often judicious, but his drawing of the naked is not equally correct. He is classed among the little masters, and used occasionally three cyphers, which will be found in our second plate of the monograms of the German engravers.

Mr. Evelyn says, that for "imitating the vile pollutants of Aretin, he had his eye put out by the sentence of the magistrate." Strutt presumes, that if this story be true, the engravings of Solis must have been copies from those which Marc Antonio did after the design of Julio Romano, (and which had nearly coilt him his life,) to which the poet Aretin did but supply verses.

The engravings of Solis amount to upwards of eight hundred, of which it may suffice to specify the following: "The Marriage of Cupid and Psyche;" "The Assembly of the Gods;" and "Mount Parnassus," all after Raphael. "The Bath of the Anabaptists," a small plate, after Aldegrove. A set of four plates of fragments of ancient architecture. A set of six heads of Roman emperors, small. A pair of small frises, in which are numerous parquequets. A set of portraits of the kings of France, from Pharamond to Henry III. The above are on copper, with some few etchings, which are inferior to the rest of his works.

His principal engravings on wood, are a set of one hundred and seventy from Ovid's Metamorphoses, small, and dated 1563. A set for the emblems of Nicolas Reusner, dated 1581. And, another set for those of Andrea Anglicus, both of which books were printed at Frankfort in the year 1581.

Melchior Lorich, or Lorich, was born at Flensburg, in the duchy of Slefwic, in the year 1527, and died at Rome in 1586. He was distinguished both as an artist and an antiquary: some time about the middle period of his life, he made a voyage to Constantinople, where he painted and engraved the portraits of the grand seignior and his favourites, which are now become very rare, and where he formed a collection of Turkish dresses, which were afterwards engraved on wood, and published in the year 1576, in a folio volume. His engravings are decidedly those of a man of talent: he drew with considerable spirit, and a tolerable degree of correctness. His works on wood are executed with much freedom and boldness, while in those on copper they
GERMAN SCHOOL OF ENGRAVING.

qualities are in some degree lost in the neatness to which he laboured his finishing. Strutt speaks of a crucified figure, (which is designed so much in the style of Michael Angelo, that he supposes it to be engraved after some work of that great master) as a very extraordinary production. It is executed entirely with the graver, and the left leg and arms are much more short-handed. He says, "if this figure be not quite correct in all its parts, it is however well drawn upon the whole, notwithstanding the difficulty of the short-handings, and is finished in a style of neatness equal to that of Jerome or Anthony Vicrius, while it is superior to them in point of taste." His monograms, which he sometimes surmounted by the date of his work, will be found in our second plate of those of the German School.

The works of Lorich, which are held in most request among connoisseurs, are: the portrait of Martin Luther, dated 1528. That of Albert Durer, with four Latin verses, dated 1559, a very rare print, done in imitation of a Cameo, and those which we have mentioned above of the grand seignior and his favourite fulta, very neatly executed on copper, and very scarce. Ariosto, the Staggryrite, dated 1561. "St. Jerome in the Desert," dated 1556; and a small upright of a female head, beautifully executed, are also on copper.

His best engravings on wood, are a set mentioned above, of the costume of Turk, in small folio, dated from 1570 to 1581. "The Tiburtine Sybil," dated 1571, executed in his best style. "A Woman preening her Breast, with numerous Animals below," and inscribed "Ops Saturni conjux materque Deorum," a very spirited engraving in folio, dated 1565. And "The Deluge," a large folio, engraving on two blocks, the impressions from which are afterward pasted together.

Theodore de Bry, or de Brie, the elder, was born at Liege in the year 1528, and died at Frankfort on the Maine in 1598; at which latter place he chiefly resided, but to whom he owed his early initiation to art is not known. He appears to have formed his taste by copying the works of Sebad Beham. He worked almost entirely with the graver, and acquired a neat and free style, which was well adapted to small subjects, in which numerous figures were required to be introduced, such as plate, and funeral, porcelaneous. He drew correctly: his heads in general are spirited and expressive, and his other extremities well marked, and his back grounds, though frequently light, are touched with a masterly hand.

About twenty years before his death he visited England, and engraved at least two large and laborious plates, of which we shall presently speak, in the city of London. He died, as his sons in the 3d part of Boissard's collection of portraits inform us, March 27, 1598. De Brie marked his plates with the cypher T. B. F., and at other times with that of Rene Boisson, and his principal engravings are those which follow: an etching of "St. John in the Desert," a rare print. A pair of "The Fountain of Youth," and the "Little Village Fair," copied from Sebad Beham. "A Bacchanalian Procession," from Julio Romano. Three mixtures of the grotesque with the allegorical, of the circular form. "The Golden Age," a small circle, after Abraham Bloemaert. A pair of portraits in medals of Scanderbeg and Donice his wife. A set of nine figures of the mutes, in folio. The plates for the four first volumes of Boissard's Roman Antiquities (of which the two last volumes were completed by the sons of our artist). The plates of the manners and customs of the Virginians, published in "The brief true Report of the New-foundland of Virginia, by Thomas Harriot, servant to Sir Walter Raleigh," from drawings by J. White, printed at Frankfort by J. Wechlerius, A. D. 1599, which were afterwards copied by Picart, for his "Religious Ceremonies, &c." The plates to the Latin narrative of Spaniard cruelties in America, published 1598.

His largest work appeared in the same year, and is entitled "Descriptio Indicis Orientalis et Occidentalis," in nineteen tracts, which are contained in five folio volumes.

De Brie is also the author of a work which may be thought still more interesting to British feelings, because connected with British history. It is the procession of the knights of the garter in the 18th year of the reign of Elizabeth, of which Strutt gives a very particular description: "The procession is represented as moving along a portico quite open on the side next the observer, but supported by thirty-three pillars of the Ionic order, on the side from him. Over each knight companion of the order, are his arms within the garter, and, in a compartment below, his name, titles, &c. are written in French. The last stall was vacant, and there is only a fancy portrait given, without name or arms. There are sixty portraits in the procession, each of them between four and five inches in height! Under the arches of the portico is a delightful view of a hilly country, (too hilly for an English prospect,) interspersed with castles, churches, houses, rivers, woods, &c. and an exact view of Windsor castle as it appeared in that reign. The roll is fifteen feet three inches long, and was engraved on twelve plates."

Hollar to his plate of the procession, copied in small from this engraving, in Ashmole's order of the garter, says, "the original was designed by Marc Garrard, who could be then only fifteen years old." Wherefore Strutt concludes this to be a mistake, but perhaps Garrard made a reduced copy from this print, from which copy Hollar's plate was engraved, which would reconcile the accounts; for Lord Orford dates Garrard's drawing in the year 1584, whereas De Brie's plate was finished in the year 1578; and Strutt, reasoning from the dedication being made in the name of Thomas Dawes, Rouge-Croix, concludes that it was designed by him.

Strutt says he never heard of any other imitations from this plate than the proof, which, after belonging to the Norroy king at arms, came finally into the possession of John Penn, esq. of Earl Durham in the county of Norfolk; but the engraving is mentioned by Huber, and presumably therefore, is not unknown on the continent. To this detailed account of this very curious historical engraving, Strutt adds the order of procession, and the names of the sixty portraits of the knights companions and officers of plate; and the reader who wishes to be informed on these points, is therefore referred to his biographical dictionary.

The other plate which our artist is known to have engraved in London, is "The Funeral Procession of Sir Philip Sydney," on thirty-four plates, forming, when pasted together, a very long roll, but more frequently forming a book. In the inscription beneath, it is said to be "contrived and invented by Thomas Lant, gent. servant of the honourable knight, and graven on copper by Derick, or Theodore de Brie, in the city of London 1578;" and prefixed is the portrait of Mr. Lant, aged 32.

Jean Theodore de Brie the younger was the eldest son of Theodore, of whom we have just concluded our account. He was born at Liege in the year 1561, and died at Frankfort on the Maine in 1623.

The engravings of Jean Theodore are on the whole superior to those of his father both in taste and precision, and he united his father's literary parts to those works in which
which he engaged, as well as in the engravings; but Jean Israel, the second son of Theodore, who also afflicted, and succeeded him, was far less successful.

The brothers John, Theodore, and Israel, completed the plates for Boissard's Roman Antiquities, and added several to the collection of portraits of illustrious persons, which their father had begun to form.

Among other portraits, we find those of Gerard Mercator the celebrated geographer, and Daniel Specklin, both in 1450.

Jean Keleti was born at Dresden in the year 1530; under whom he studied is not known, but he continued engraving in his native city, until some time about the close of the sixteenth century. He engraved some plates after Jean Marie Losienni, who was sculptor and architect to the electors of Saxony, of which the following are those of most importance.

"Nimrod building the Tower of Babel;" "The Destruction of the Babylonian Empire;" "The Empire of Rome," in the back ground of which is the death of Cæsar. "The Empire of the Church," where the Pope is represented receiving the homage of Charlemagne; and "An Allegory," where a winged figure of Death, with two trumpets, is supporting a globe, all of the 4to. size.

Tobias Stimmer was born at Schaffhausen towards the close of the sixteenth century, but resided chiefly at Strasbourg, where he was patronized by the margrave of Baden, and became both a painter and engraver of eminence. His engravings are chiefly on wood, and from his own compositions; the engravings in the "Novissimo Tobias Stimmeri sculterum Bibliothecarum figurarum verissimi Latinis et Germaniae expolterem," are from compositions by Stimmer, though he was as diligent in the engraving by his brother Christophor, and his pupil Christophor Maurer. Stimmer understood the human figure very well, and composed with so much taste and judgment, that Rubens has been heard to declare, that he had studied Stimmer's bible with attention and with great benefit, and Sandrart, who relates this anecdote, calls the book, "A Treasury of Science for the art of Painting."

In the earlier part of his career, Stimmer was unfortunate, and passed some of his best days in painting the façades of houses at Frankfort on the Main, and at Strasbourg. But let no man of talent, who poises the means of shewing his talent, despair; it was the pleasure he received from some of these, which accidentally caught his notice, that occasioned the margrave to engage Stimmer in his service, and became the foundation of his fortune. For him our artist painted the history of his ancestors, and the margrave's own portrait to this day affords the superior powers of Stimmer in this department of art.

We have given his monograms in our second plate, and his principal work, excepting his bible, is "The Annunciation," in folio.

Jean Christophor Stimmer was born at Schaffhausen in the year 1552, and died at Paris some time about the commencement of the succeeding century. He was the brother and disciple of Tobias, and engraved on wood a great number of his compositions with considerable success, for he drew with ability, and hatched his engravings in a bold, but mellow style.

After the death of his brother, Christophor travelled to Paris, where he performed some engravings, and was commonly known by the name of "the Swiss," and where he died, leaving behind him a son, who also engraved on wood a considerable number of plates after Francis Chauveau.

Christophor used the complicated cypher which will be found among those of our monograms of the Schaffhausen school, and his bell engravings are those which follow. — A set for the New Testament, with the Apocalypse, printed at Strasburg in the year 1588. A collection of portraits of the scholars and theologians of the German nation, printed also at Strasburg by Bernard Jobio, in 1591. "Icones Affrare," a collection of emblems printed in the same year, all of the 4to. size; and a capital print of an historical portrait of a kneeling figure, inscribed "Contrasta pictus Bildnus des Hermann Lusarar von Schwende," &c.

Joel or Jodocus Amman or Ammon, designer and engraver on wood and on copper, was born at Zurich in 1539, and died at Nuremberg in 1591. Not meeting with encouragement in his youth at Zurich, he travelled to Nuremberg, a city where the arts were reported to be in a flourishing state, the year he became of age, and in 1577 renounced the rights of a citizen of Zurich, in order the more firmly to attach himself to his adopted country. Strutt says of him, that if patience and industry of themselves could constitute an artist, Amman would well deserve that character, from the multitude of deligns which he made, and the great number of plates which he engraved, amounting, according to Huber, to more than five hundred and fifty. But though a great genius may be improved by cultivation, yet it is equally certain that neither patience nor industry can create a great genius. Much merit, however, was certainly poiffed by our artist; who lived at a time when almost every book which appeared was ornamented with prints, and was employed by many of the great booksellers, especially Siegmund Feyeranbandt of Frankfort.

The engravings of Joel Amman upon copper are not equal to those which he performed for the letter press. His invention was not very copious; his figures are tolerably proportioned, and the detail of his drawing is careful and moderately correct; animals in particular he touched with great spirit. His style of engraving is neat and decided, yet if his lines are more regular, they are less free than those of many of his predecessors. He affixed various marks to his performances, as may be seen in our second plate of the monograms, &c. of the German school of engraving.

His principal works on copper are, a set of twelve illustrious women, beginning with Eve, under the title of "Eva die Gebererin?" a set of figures of warriors, small uprights, marked Joel Amman inventor 1590; the set consists of eight, and there is a set of eight others, fighting with swords and flails. The four feaons, and the four elements, dated 1569. A set of the twelve months, perfonified, and a set of fifteen friezes of hunting subjects; a considerable number of etchings of subjects of piety, after Winckelmann Jamitzer; the bombardment of a city, dated 1570, in folio, and the portrait of Carparis di Colignon, D. Caillidone, marked Joel Ammon Figurinum, 1573. His best engravings on wood are, "The Creation of Man?" "The New of the Empire," both in folio, the latter an oval. "The Marriage at Cana," in quarto; a set of one hundred and fifteen, entitled, "De omnium liberum mechanicum et fedentarium artium genera continens, &c. Edit. per Hollmann Beoperum Francof. 1564." This work
work consists of articles and artificers, represented in their respective employments: among them are some excellent figures, and in that which represents the engraver, Amman has given his own portrait. A second edition was printed A.D. 1574, and a third in 1588, but the first is now become very scarce. The book is a large octavo.

A set of one hundred and two, besides the portrait of Feyerabendt, for a Latin edition of Livy, printed at Frankfort A.D. 1572, in oblong quarto.

Another set for a folio edition of Pliny, printed also at Frankfort A.D. 1584. Another set for a quarto book of hunting, printed at Frankfort in 1582, which book was considerably augmented after the death of Amman, and reprinted in 1617. Another set of one hundred and three of ecclesiastical habits, dated 1564, and another of one hundred and twenty, for "Gynaecium, Sive Theatrum Mulierum, in quorum praecipuarum omnium per Europam, &c." in oblong quarto, printed at Frankfort, 1586.

Christopher Maurer engraved from his own compositions, and from those of T. Stimmer, both on copper and on wood. He was born at Zurich A.D. 1558, and died at Wintertour in 1614. His father Joffannu was an artist, and under the paternal roof he learned the rudiments of art, but was afterwards removed to Strasbourg, and placed under Tobias Stimmer, where both the master and scholar were close students, and soon began to be distinguished by the number of interesting and beautiful works which they produced.

The cypher of Maurer will be found in our second plate of German monograms. After passing some years in the school of Stimmer, he returned to his native city, and added to his reputation by his fresco pictures which adorn the façades of distinguished houses, and by the just likenesses he displayed in his portraits; with the true spirit of a Swiss artist, he always preferred patriotic subjects, and has often painted the origin of the Helvetic confederacy.

Of his engravings, those on copper are most sought after by connoisseurs, particularly a set of bible cuts, and four emblematical etchings relative to proceedings in the courts of law, which, after the death of the artist, were introduced into a Latin book.

Of his letter-pref engraving, which are neatly executed, the belt are probably the first of animals of the chase, which he executed in conjunction with his master, and which were published at Strasbourg in the year 1605. And a set of the Bible under the title of "Historische Vorlesungen über die ganze Bibel," which do honour to his inventive talent, as well as to his manual powers as an engraver.

Christopher Jamitzer, or Jamnitser, was born at Nuremberg in the year 1560, and died in the same city in 1617. He performed several etchings which are marked with the cypher which the reader will find among our monograms of the German engravers, but they are far from being of flirt rate merit.

Of the same family were Bartholomew and Wenceslaus Jamitzer, whom we pafs as unimportant persons.

The best works of Christopher consist of groups of boys variously occupied, and the best of these groups are those which follow: A set of twelve, in 12mo.; another set of twelve, mounted on marine animals; another set of four combined with swans, flowers, &c.; four children dancing in an arbour. A set of grotesque chimeras, in quarto; Christopher Jamitzer also engraved a portrait of himself fitting in a perspective machine, in the act of drawing or meaffuring.

Matthew Greuter was born at Strasbourg A.D. 1564. He travelled more than once to Lyons and Avignon, and from thence to Rome for professional improvement, in which latter city, in the year 1639, he died.

Strutt describes him as a man of genius, but so much praise as is implied in this word, cannot justly be allowed him. He worked partly from his own compositions, but his drawing is by no means correct; his extremities in particular being sadly neglected. He sometimes executed his plates with the graver only, in a neat style, and in other instances has employed etching. His principal productions are, the portraits of the popes Innocent X., and Sixtus V., the latter surrounded with an ornamental border in which the papal coinage is introduced. Cardinal Seraphinus Olivarius Razzaliius; all in quarto.

Of his historical works we shall only mention "The Virgin and Child," lasted in a landscape, after Baroccio. Mary Magdalen leaning her hand upon a skull, after S. Gaetano, dated 1584; both in quarto. An emblematical print of Venus standing on a globe, with various virtues and vices personified, very neatly etched, and marked M. Greuter inv. et fec. 1587, in small folio. "The Fall of Phaeton," after Windel Dieterlin, in large folio, dated 1588. "The Destruction of Troy," after Lanfranc, and the magnificent cavalcade of the emperor Charles V. engraved by Greuter in concert with Lucas Vorlermann, a large print of the frieze form, engraved on several plates.

As to Jean Frederic, the son of Matthew Greuter, was born at Rome, and bred, and died in Italy, our account of him will be found under Italian School of Engravers.

Matthias Kager was born at Munich in the year 1566, and died at Augsburg in 1634. He studied in Italy, and beside ranking high among the historical painters of his time, was an engraver of merit. His style is neat, and performed chiefly with the graver, though sometimes with the admixture of etching. His attachment to liberty, and aversion to the manners of a German court, induced him to quit that of Bavaria, and he became a citizen and finally a burgomaster of Augsburg.

Of Adam Ellheimer, furnamed Adam of Frankfort, who should else have been mentioned in this place, we have already spoken. See Elheimer.

Theodore Kruger, or Cruger, was born in the city of Munich A.D. 1576. He travelled to Italy for improvement, where he formed his style of engraving on that of Francisco Villamena. He handled the graver, which was the sole instrument of his art, with boldnefs, freedom, and facility, but his chiaro-curo is very defective, and his outlines incorrect and hard.

His principal engravings are: "The Life of St. John the Baptist," on twelve upright folio plates, after Andrea del Sarto, with the portrait of the painter prefixed, and dedicated to Colmo de Medicis, dated 1618. "The Lail Supper," in large folio, after the fame. "The return of the Holy Family from Egypt," where the infant is embracing Jesus Chrift, after F. Bigio, also in folio. "The infant Saviour blefing the little St. John," after the fame painter. And "A Prince on a Tribunal, surrounded by divers Statesmen," after Lanfranco, and inscribed "Vox mibi."

Cruger has also engraved some portraits after Gabriel Waver, to which he signs his name Ditrich Cruger, by which Chriftian name he is yet known in Italy.

Theodore
GERMAN SCHOOL OF ENGRAVING.

Theodore Cruger, the younger, was born in the year 1618, and was the son of the preceding artist. The Italians call him Della Croce, the Flemings Verorens, and the German Kruger. In the year 1710, he engraved, in concert with two others, the Florentine gallery. He also engraved "St. Francis at Prayer," after Carlo Maratti, and a couchant Venus, both in folio, before several portraits, among which is the daughter of Georgione, after that master; and Ludovico Asdmar, after P. Dandini.

Dominic Culfos, otherwise called Balten, was the son of Pierre Balhan, a painter and poet, who had some pretensions also to knowledge in the art of engraving. He was born some time about the year 1560 at Anvers, and died at Augsburg in 1612. His real family name appears to have been Balten, but he settled at the last named city, at an early age, under the name of Dominique Culfos, and married there the widow of Barthelmy Kilian, the elder, who was enabled to establish a lucrative print trade, which continued to flourish for a long period of time.

Culfos had several daughters, of whom some were educated to the art of engraving, and succeeded tolerably well. He worked in a neat style, entirely with the graver, but his prints are laudable, smallsized, and without harmony of effect. Florent le Comte says he engraved portraits in the taste of Vandyke, but as Strutt properly remarks of this mistaken assertion, there is not the least resemblance between the fine portraits of Culfos, and those so highly and justly esteemed by Vandyke.

The principal engravings of this artist, are: the effigies of the German emperors, large whole length figures, in folio, dated 1601.

The portraits of the Fuggera family, of which the first edition, which is now become very rare, and is dated 1593, contains but sixty-four portraits: in the second the number of portraits is increased to sixty-seven: the third contains a hundred and twenty-seven, besides the arms of Fugger, and an ornamental title, but the names are added, of Lucas and Wolfgang Kilian. Another set of portraits of heroes, &c. entitled "Atriurn Heroicum, Zafarum, Regum, aliorum famulatum ac principium, &c."

The chief of his engravings of separate portraits are thofe of pope Sixtus V, prince Sigismund in the costume of Moldavia, after J. ab. Aeh, and from the same painter Marcus Bragadino, dated 1591. Christianus II. duke of Saxony, Henry bishop of Augsburg, in an oval, Johan Philipp, bishop of Bamberg, ditto, Maximilian, duke of Bavaria, and Elizabeth Laffaringen his wife, a pair of ovals, dated 1598, all of the folio dimensions.

The most esteemed of the historical works of this artist, are a set of "Female Saints," half length, after Franz Apspruck. A set of four in folio, of "L'Histoire de l'Enfant prodigue," and "Judith beheading Holophernes," after John Von Auchen, of the folio size.

Lucas Kilian, the patriarch of a numerous progeny of engravers, was born at Augsburg in the year 1579. Under whose direction he studied, is not known, but the works of Hevely Goltzis and Muller appear to have been his school. He appears, however, that he went to Italy, in order to complete his studies, where he engraved several plates from the pictures of the great Italian masters: but returned, and died in his native city in the year 1637.

Few artists have manifested a greater command of the graver than Kilian; whether we consider the apparent facility with which his strokes are turned over each other, or the firmness with which they are executed, one cannot help admiring the author, though it evidently strikes us that by paying too close attention to this part of his art, he neglected the correctness of his outlines, and fatigued the lights with unnecessary work." Such is the opinion of our countryman Strutt: to which should be added, that his drawing is not accurate, nor his chiaroscuro broad and impressive.

Of the numerous works of Kilian, the following are held in most esteem: "The Adoration of the Shepherds," a middling-sized plate, from the younger Palm. The same subject, a large upright, after Springer. Another of the same subject, after Rotenhamer. And another (a large upright) from J. Heinie. "A Holy Family," from Cornelius de Haelroem, and "The Miracle of the Loaves and Fishes," from Tinoretto: both large uprights. "Christ Praying in the Garden," a small upright, arched at the top, from Frederic Sutius. "A dead Child," from Michael Angelo. And "A Nymph and Satyr," from J. Heinie, both small uprights. "The Rape of Proserpine," a large folio plate, from the same master. "The Entombment of Christ," an upright, without the painter's name, dated 1602, which perhaps, with many other of the engravings of Lucas Kilian, is from his own design.

The best portraits by this master, are those of himself, aged 55, a rare print in 4to. "Petrus Culfos, vulgo Balten, Pictor et Poeta Antverpianus," dated 1609. Nicholas Chriophe, Prince de Rudzivil, both in 4to. The emperor Chriilian II, dated 1615. Maria Eleonora Suevorum Gothorum Regina. Aulavus Adolphus Suevorum Gothorum Rex. And Albert Durer, a half-length; all of the folio size; but whether the latter is from a picture by Rotenhamer, or after Albert Durer himself, the present writer is uncertain.

Wolfgang, the brother of Lucas Kilian, was also of Augsburg, and born in the year 1581. He studied under Dominique Culfos, and, after his return from Italy, under his brother Lucas, whose style he imitated without attaining to the same degree of excellence: his prints are somewhat neater, but more fliff and formal.

Wolfgang employed the greater part of his time in engraving portraits, of which the following are those of most importance. Ernst Count Mansfield. Maximilian of Walenfein, dated 1622. Jean Major, mathematician of Augsburg. Frederic Baron de Tuffenbach. Jean Goden, Bishop of Wurzburg. Ferdinand III, king of the Romans, all in 4to. Of the folio size: the archbishops of Mayence, Cologne, and Treves; his own portrait, inscribed "Labor impessus omnis vincit," and a set of twenty-seven of the emperors and archbishops of the house of Austria, from 1229 to 1625, with their lives and eulogiums, published at Augsburg in 1629.

The most esteemed of his historical works, are the "Baptism of Jesus Christ," after Paolo Veronese. "The Assumption of the Virgin Mary," after Tinoretto; "The Descent from the Cross," after Paolo Farinato, and the "Good Samaritan," after Giacomo Bassano, all in folio. "The Resurrection of Christ," arched at the top, after F. Basso. The four Evangelists, in upright ovals, from his own design; and the "Festival of the Peace of Weilphalia," after Joab Sandrart, in large folio, engraved on two plates, and which is now become a rare print.

Bartholomew Kilian, the third son of Wolfgang, was born at Augsburg in the year 1639, and died in the same city in the year 1666. He distinguished himself at a period of life so early, that Sandrart emphatically says, "he was born an artist." At the age of eighteen he engraved a Magdalen after M. Gondelach, which induced his father to place him under M. Merian of Frankfort, after studying with whom two years and a half, he travelled to Paris for further improvement. Here he remained more than three years, availing himself of the instructions of different artists, and

A 2
work consists of artifices and artificians, represented in their respective employments: among them are some excellent figures, and in that which represents the engraver, Amman has given his own portrait. A second edition was printed A.D. 1574, and a third in 1588, but the first is now become very scarce. The book is a large octavo.

A set of one hundred and two, besides the portraits of Feyerabandt, for a Latin edition of Livy, printed at Frankfurt A.D. 1572-3, in oblong quarto.

Another set for a folio edition of Pliny, printed also at Frankfurt A.D. 1584. Another set for a quarto book of hunting, printed at Frankfurt in 1593, which book was considerably augmented after the death of Amman, and reprinted in 1617. Another set of one hundred and three of ecclesiastical habits, dated 1564, and another of one hundred and twenty, for "Gynaecium, vix Theatrum Mulierum, in quorum prenecum omnium per Europam, &c." in oblong quarto, printed at Frankfurt, 1586.

Christopher Maurer engraved from his own compositions, and from those of T. Stimmer, both on copper and on wood. He was born at Zurich A.D. 1558, and died at Winterthur in 1614. His father Johina was an artist, and under the paternal roof he learned the rudiments of art, but was afterwards removed to Strasbourg, and placed under Tobias Stimmer, where both the master and scholar were close students, and soon began to be distinguished by the number of interesting and beautiful works which they produced.

The cyprian of Maurer will be found in our second plate of German monograms. After passing some years in the school of Stimmer, he returned to his native city, and added to his reputation by his rare pictures which adorn the fassades of distinguished houses, and by the just likenesses he displayed in his portraits; with the true spirit of a Swiss artist, he always preferred patriotic subjects, and has often painted the origin of the Helvetic confederacy.

Of his engravings, those on copper are most sought after by connoisseurs, particularly a set of bible cuts, and four emblematical etchings relative to proceedings in the courts of law, which, after the death of the artist, were introduced into a Latin book.

Of his letter-prest engravings, which are neatly executed, the best are probably the set of animals of the chase, which he executed in conjunction with his master, and which were published at Strasbourg in the year 1605. And a set of the bible under the title of "Hilfskrafte Vorstellung über die ganze Bibel," which do honour to his inventive talent, as well as to his manual powers as an engraver.

Christopher Jamitzer, or Jannitzer, was born at Nuremberg in the year 1560, and died in the same city in 1617. He performed several etchings which are marked with the cypher which the reader will find among our monograms of the German engravers, but they are far from being of first-rate merit.

Of the same family were Bartholomew and Wenceslaus Jamitzer, whom we pass as unimportant persons.

The best works of Christopher consist of groups of boys variously occupied, and the best of these groups are those which follow: A set of twelve, in 1200; another set of twelve, mounted on marine animals; another set of four combined with fawns, bowers, &c.; four children dancing in an arbore. A set of grotesque chimeras, in quarto; Christopher Jamitzer also engraved a portrait of himself fitting in a perspective machine, in the act of drawing or measuring.

Matthew Greuter was born at Strasbourg A.D. 1564. He travelled more than once to Lyons and Avignon, and from thence to Rome for professional improvement, in which latter city, in the year 1638, he died.

Strutt describes him as a man of genius, but so much praise as is implied in this word, cannot justly be allowed him. He worked partly from his own compositions, but his drawing is by no means correct; his execution in particular being badly neglected. He sometimes executed his plates with the graver only, in a neat style; and in other instances has employed etching. His principal productions are, the portraits of the popes Innocent X, and Sixtus V., the latter surrounded with an ornamental border in which the papal crown is introduced. Cardinal Seraphimus Olivarius Razzalins; all in quarto.

Of his historical works we shall only mention "The Virgin and Child," seated in a landscape, after Baroccio. Mary Magdalene leaning her right hand upon a skull, after S. Gac- tano, dated 1684; both in quarto. An emblematical print of Venus standing on a globe, with various virtues and vices personified, very neatly finished, and marked M. Greuter inv. et fec. 1587, in small folio. "The Fall of Phaeton," after Windel Dieterlin, in large folio, dated 1588. "The Destruction of Troy," after Laurence, and the magnificent cavelade of the emperor Charles V. engraved by Greuter in concert with Marcus Vorderman, a large print of the frieze form, engraved on several plates.

As Jean Frederic, the son of Matthew Greuter, was born at Rome, and lived and died in Italy, our account of him will be found under Italian School of Engravers. Matthias Kager was born at Munich in the year 1566, and died at Augsburg in 1634. He studied in Italy, and before ranking high among the historical painters of his time, was an engraver of merit. His style is neat, and performed chiefly with the graver, though sometimes with the adixture of etching. His attachment to liberty, and aversion to the manners of a German court, induced him to quit that of Bavaria, and he became a citizen and finally a burgomaster of Augsburg.

S. Kilian engraved a portrait of him in 1626. The best of his own prints are: "The Adoration of the Shepherd," dated 1610. "St. John Baptizing Christ in the river Jordan," both of the folio size, and from compositions by himself: "The Holy Family," in an oval, also from his own picture, and in 4to. and "St. Francis surrounded by the Monks of his Order, to whom Christ and the Virgin Mary are appearing in the Clouds," a middling-sized upright from P. Remigius Bozzolo.

Of Adam Elsheimer, furname Adam of Frankfort, who should else have been mentioned in this place, we have already spoken. See Elsheimer.

Theodore Kruger, or Cruger, was born in the city of Munich A.D. 1576. He travelled to Italy for improvement, where he formed his style of engraving on that of Francesco Villamena. He handled the graver, which was the sole instrument of his art, with boldness, freedom, and facility, but his chiaroscuro is very defective, and his outlines incorrect and hard.

His principal engravings are: "The Life of St. John the Baptist," on twelve upright folio plates, after Andrea del Sarto, with the portrait of the painter prefixed, and dedicated to Colmo de Medicis, dated 1618. "The Last Supper," in large folio, after the same. "The Return of the Holy Family from Egypt," where the infant is embracing Jesus Christ, after F. Bigio, also in folio. "The infant Saviour bleeding the little St. John," after the same painter. And "A Prince on a Tribunal, surrounded by divers Statesmen," after Laurence, and inscribed "Vox mildi.

Cruger has also engraved some portraits after Gabriel Wayer, to which he signs his name Ditrich Cruger, by which Christian name he is best known in Italy.

Theodore
GERMAN SCHOOL OF ENGRAVING.

Theodore Croger, the younger, was born in the year 1648, and was the son of the preceding artist. The Italians call him Della Croce, the Flemings Vercruys, and the German Kruger. In the year 1710, he engraved, in concert with two others, the Florentine gallery. He also engraved "St. Francis at Prayer," after Carlo Maratti, and a coauntich Venus, both in folio, beside several portraits, among which is the daughter of Georgione, after that master; and Ludovicus Adimari, after P. Dandini.

Dominic Culfos, otherwise called Balzans, was the son of Pierre Baithafar Baltens, a painter and poet, who had some pretensions also to knowledge in the art of engraving. He was born some time about the year 1560 at Anvers, and died at Augsburg in 1612. His real family name appears to have been Balzens, but he settled at the last named city, at an early age, under the name of Dominique Culfos, and marrying there the widow of Barthelemy Kilian, the elder, was enabled to establish a lucrative print trade, which continued to flourish for a long period of time.

Culfos had several daughters, of whom some were educated to the art of engraving, and succeeded tolerably well. He worked in a neat style, entirely with the graver, but his prints are laboured, taillefs, and without harmony of effect. Florent le Comte says he engraved portraits in the style of Vandyke, but as Strutt properly remarks of this mistaken assertion, there is not the least resemblance between the fluff portraits of Culfos, and those so highly and justly esteemed by Vandyke.

The principal engravings by this artist, are: the effigies of the German emperors, large whole length figures, in folio, dated 1594.

The portraits of the Fugger family, of which the first edition, which is now become very rare, and is dated 1593, contains but sixty-four portraits: in the second the number of portraits is increased to sixty-seven; the third contains a hundred and twenty-seven, besides the arms of Fugger, and an ornamented title, but the names are added, of Lucas and Wolfgang Kilian. Another set of portraits of heroes, &c. entitled "Atrium Heroicum, Cæfarum, Regum, aliorumque summatum ac principium, &c."

The chief of his engravings of separate portraits are those of pope Sixtus V. prince Sigismund in the costume of Moldavia, after J. ab. Aeh, and from the same painter Marcus Bragadino, dated 1601. Christianus II. duke of Saxony, Henry bishop of Augsburg, (in an oval) Johan Philipp, bishop of Bamberg, ditto. Maximilian, duke of Bavaria, and Elisabeth Lotharingea his wife, a pair of ovals, dated 1598, all of the folio dimensions.

The most esteemed of the historical works of this artist, are a set of "Female Saints," half lengths, after Frez. Aipruck. A set of four in folio, of "L'Histoire de l'Enfant prodigue," and "Judith beheading Holofemes," after John Von Auchen, of the folio size.

Lucas Kilian, the patriarch of a numerous progeny of engravers, was born at Augsburg in the year 1579. Under whose direction he studied, is not known, but the works of Heury Goltzuis and Muller appear to have been his school. It appears, however, that he went to Italy, in order to complete his studies, where he engraved several plates from the pictures of the great Italian masters: but returned, and died in his native city in the year 1617.

"Few artists have manifested a greater command of the graver than Kilian; whether we consider the apparent facility with which his strokes are turned over each other, or the firmness with which they are executed, one cannot help admiring the author, though it evidently strikes us that by paying too close attention to this part of his art, he neglected the correctness of his outlines, and fatigued the lights with unnecessary work." Such is the opinion of our countryman Strutt; to which should be added, that his drawing is not accurate, nor his chiaroscuro broad and impressive.

Of the numerous works of Kilian, the following are held in most esteem: "The Adoration of the Shepherds," a middle-sized plate, from the younger Palma. The same subject, a large upright, after Spranger. Another of the same subject, after Rotenhamer. And another (a large upright) from J. Heintz. "A Holy Family," from Corneinits de Haerlem, and "The Miracle of the Loaves and Fishes," from Tintoret: both large uprights. "Christ Praying in the Garden," a small upright, arrows, at the top, from Frederic Suffolk. "A dead Christ," from Michael Angelo. And "A Nymph and Satyr," from J. Heintz, both small uprights. "The Rape of Proserpine," a large folio plate, from the same master. "The Entombing of Christ," an upright, without the painter's name, dated 1600, which perhaps, with many other of the engravings of Lucas Kilian, is from his own design.

The belt portraits by this master, are those of himself, aged 55, a rare print in folio. "Petrus Culfos, vulgo Baltens, Pictor et Poeta Antwerpianus," dated 1620. Nicholas Chriolopez, Prince de Rudzivill, both in folio. The emperor Christian II. dated 1615. Maria Eleonora Suevorum Gothorum Regina. Gualtavus Adolphus Suevorum Gothorum Rex. And Albert Durer, a half-length; all of the folio size: but whether the latter is from a picture by Rotenhamer, or after Albert Durer himself, the present writer is uncertain.

Wolfgang, the brother of Lucas Kilian, was also of Augsburg, and born in the year 1581. He studied under Dominic Culfos, and, after his return from Italy, under his brother Lucas, whose style he imitated without attaining to the same degree of excellence: his prints are somewhat neater, but more still and formal.

Wolfgang employed the greater part of his time in engraving portraits, of which the following are those of most importance. Ernest Count Mansfield. Maximilian of Wallenstein, dated 1542. Jean Major, mathematician of Augsburg. Frederic Baron de Teufflenbach. Jean Gedeon, bishop of Wurzburg, and Ferdinand III. king of the Romans, all in folio. Of the folio size; the archbishops of Mayence, Cologne, and Treves: his own portrait, inscribed "Labor incipiens omnia vincit," and a set of twenty-seven of the emperors and archdukes of the house of Austria, from 1229 to 1625, with their lives and eulogiums, published at Augsburg, in 1629.

The most esteemed of his historical works, are the "Baptism of Jesus Christ," after Paolo Veronese. "The Assumption of the Virgin Mary," after Titiorcetto; "The Departure from the Cross," after Paolo Parniato, and the "Good Samaritan," after Giacomo Baffano, all in folio. "The Resurrection of Christ," (arched at the top), after F. Baffano. The four Evangelists, in upright ovals, from his own designs; and the "Festival of the Peace of Westphalia," after Joab Sandrart, in large folio, engraved on two plates, and which is now become a rare print.

Bartholomeu Kilian, the third son of Wolfgang, was born at Augsburg in the year 1612, and died in the same city in the year 1696. He distinguished himself at a period of life so early, that Sandrart emphatically says, "he was born an artist." At the age of eighteen he engraved a Magdalen after M. Gondolbach, which induced his father to place him under M. Morian of Frankfort, after studying with whom two years and a half, he travelled to Paris for further improvement. Here he remained more than three years, availing himself of the instructions of different artists, and

Returning to his native city, he continued to cultivate his art, and produced a great many excellent portraits, with some few historical subjects. Strutt is mistaken in saying he worked entirely with the graver, but is right in what he affirms of the originality of Bartholomew's style. He worked in a manner entirely different from those of the Kilians, who had preceded him; sometimes, in order to make a striking distinction between the flesh and the draperies of his figures, he finished the former with dots only; and at other times expressed the darker shades of his flesh by lines, which he blended with dots in the lighter parts. Mariette and Barthelemy talk of him as an example for a painter, but these writers are warmer in their praise than an inspection of his work will fully warrant.

B. Kilian generally marked his engravings, of which the following list contains the principal, with his name at length, but sometimes used only his initials, and at others, according to Huber, a cypher which does not appear to belong to him, but which we have copied, with others of the Kilian family, in the second plate of our German monograms.

Six half length portraits, in folio, of celebrated protestant preachers at Augsburg, after B. Hopfer. Three medallions of archbishops of Salzburg, with allegorical accompaniments, after Henry Schoenfeld. Johannes III. king of Poland, after Bleemart, dated 1681; a large built of learned execution. Maximilian Emanuel, electoral prince of Bavaria, with historical accessories, a celebrated work, and the subject of a thesis. The emperor Joseph as king of the Romans, on horseback, the subject of another academical thesis, da'd. 1694; which Huber pronounces one of the finest prints existing for natural grandeur; all these are in large folio. The portrait of Augustus II. Abbas Eimildenius, is a large upright folio, dated 1686.

The best historical production of Bartholomew is a "Madonna and Child," a beautiful engraving in large folio, after Caspar Sing.

Philippe Kilian was a younger brother of Bartholomew, imitated his style, and confined his talents almost entirely to portraits. He engraved, among many others, the portrait of his elder brother, whom he never equalled, though many of his works possess no small portion of merit. Strutt mentions another engraver of this family of the name of Wolfgang Philip, who flourished in the next century, and who executed a great number of portraits, which however have too little merit for our particular notice.

Yet to show that nature had not exhausted the Kilian stock of talent, we shall here mention a little out of his chronological place, Philippe Andrea Kilian, great nephew of Bartholomew, who was born at Augsburg A.D. 1714, and died in that city in the year 1759.

Descended from a family of artists, he imbibed, in early life, what may perhaps be termed an hereditary taste for fine art. He first studied drawing and engraving under Frederick of Augsburg, and afterwards became the pupil of G. M. Prieder of Nuremberg, where he distinguished himself by engraving some plates for the "Physica Sacra of Schuchzer," and laid the foundation of his future fame.

Some years after, while engaged in engraving from the Dresden gallery, the reputation of our artist flogged so high, that Augustus III. of Poland emphatically called him "the Magnet of Dresden," and when any other engraver produced an inferior plate from the collection, was used to say, in the way of delicate reproof, that it ought to be re-engraved by Kilian.

But his art was withstanding these honours, felt so much satisfaction, while residing at the court of Dresden, or such passionate desire to return to his native city, that he sought an occasion to make such arrangements as enabled him to quit Bavaria after a residence of four years.

P. A. Kilian is usually reckoned among the most meritorious historical engravers of Germany. On a basis of good drawing, he erected rather a singular style of execution; he interworked his principal or first course of lines with very delicate strokes, which he crossed with a course of lines exceedingly loose, upon the first, and sometimes added a third course, somewhat more square; at other times he interworked his shadows with long slender tacks, as they are technically termed among engravers. But the characters of his heads are not equal to his general knowledge of the human figure.

His best historical engravings are, "Jesus Christ at prayers in the Garden of Olives," an upright plate of the folio size, from a design of his own, "The Adoration of the Kings," after Paolo Veronese; "The Woman taken in Adultery," after Titorets; and "The Family of a noble Venetian," after Paolo Veronese, are all large folio plates, executed for the Dresden gallery, "Mary Magdalene washing the Feet of Christ," is from Nicholas Grali; "The Baptism of St. Augustine," from J. B. Pittoni; and "Herodias with the Head of John the Baptist," from Carlo Dolce, are all of folio dimensions, "Regina Angelorum," where the Virgin appears surrounded by Angels in Glory, after Bergmüller, and another from the life of the Virgin, after C. T. Schelther, are a large and highly esteemed pair of engravings. But perhaps his most jubilantly celebrated work is a very large plate of "St. Cosmo and St. Damian," after J. Wolfgang Baumgartner.

The best portraits from the graver of Philippe Andrea, are those of Francis I. emperor of Germany, in a coat of armour, after Meitens. And Clemens Rezzonics Venetus, Pontif Max, after G. D. Porta, a pair in large folio. Maria Therezi, queen of Austria, an upright folio. Johan Martin Crillfell, from a picture by P. A. Kilian, himself, Christoph Henry Andre Geret, after J. Romelli. Field marshall Curtius Christopel Graff von Schederen, after Stranz. Ferdinand, duke of Brunswick, general in chief of the allied army, after Ant. Pefne; and Godofredus Schurzefius, marked P. A. Kilian, pinx. et sculp. 1750, of all the dimensions.

George Christophor Kilian, another engraver of the same family, was living at Augsburg when Heineken published his "Idee generale d'une Collection complete d'Estampes," and perhaps may be living still.

Ifase Major was born at Frankfort on the Maine in the year 1718, and died in 1749. Discovering an early inclination for the arts of design, he was placed with Roland Savery, under whom he studied landscape painting for a time, but desirous of becoming an engraver, he placed himself, for instruction in that art, with Giles Sadler. He united etching with the work of the graver, but his works want energy, though they were held in some estimation at the time in which he lived. His principal productions are, a set of six middling sized landscapes, wild scenes in Bohemia, from Pietro Stephani. A very large landscape from Rowland Savery, in which St. Jerome is introduced. Another set of eight mountainous and savage landscapes in Bohemia, in large folio, after J. St. Wolf, and an allegorical portrait of the emperor in a car of triumph drawn by eagles and swans.

Christopher Jegher was a justly celebrated engraver on wood, as was born some time about the year 1590, but the incidents of whose life are but little known. He established himself at Antwerp when he was about thirty years of age, where his extraordinary merit so strongly recommended.
moved him to Rubens, that he was engaged by that great master to engrave: a considerable number of his compositions, and it is no small praise to add that he succeeded to the perfect satisfaction of the painter.

After the death of Rubens, Jegher re-purchased most of these engravings, and published them on his own account. Collectors should therefore bear in mind, that those impressions, from which the name of Rubens as the publisher is taken away, and that of Jegher fabricated, are of the second edition, and consequently of inferior value to the first.

There is a degree of freedom and vigour in the style of Jegher that is perfectly homogeneous with that of Rubens; his hatching is broad and powerful, and the imitation of the engravings is so well expressed, that his belt prints very much resemble drawings made with the pen and ink. He drew with masterly correctness; the extremities of his figures are well marked; and his heads, though flight, are full of expression.

His belt, and by far the greater of Jegher's productions, are after Rubens, but he has engraved a Crucifixion after F. Franck, which is dated 1637, and some few more from other masters.

The following are after P. P. Rubens: "Susannah surprized by the Elders." "A Repose in Egypt," both in large folio. Some of the latter are printed in chiarofauco, i.e. with an additional block or two to add the dimittins, and are now become scarce. "The infant Christ and St. John playing with a Lamb." "The Coronation of the Virgin Mary," and "The Temptation of Christ in the Desert," all middling-sized folios. "Hercules destroying Envy and Difcord," is from the etching at Whitehall. "The Conversation of Lovers," is a very large garden-scene, engraved on two blocks. "A drunken Silenus supported by Satyrs," is of the upright form, and a very fine composition of the matter, which was also engraved on copper by Bolfwert.

Matthew Merian, the elder, was born at Basle in the year 1593. His first studies were under the direction of Theodore Meyer, who instructed him in drawing. He afterwards became the disciple of Theodore de Brie. He was a man of talent, and his principal engravings are landscapes, which he etched in a flight free style, and finished with the graver. His views have much of that rare and valuable topographical quality, the appearance of having been really copied from the places of which they bear the names, and which quality Merian had the skill and the honour of imparting to his disciple Wenceslaus Hollar, of whom we have given an account in our progress of English engraving, but whose monograms will be found in our third plate of those of the German school.

Merian married the daughter of his tutor de Brie, by whom he had issue: he died in the year 1657, aged 58, at Frankfort, or, according to some of his biographers, at Schwabebach.

His works, according to Le Compte, amount to upwards of five hundred plates. They are well known, and there is not so much disparity in their merits as to make a selection here either easy or necessary. His works and monograms are five in number, as will be found in our third plate.

Of Matthew Merian the younger, who was for a short time in London, we have made but slight mention in a former place.

His daughter, Maria Sybilla Merian, was a much more distinguished character. She was born at Frankfort on the Main in the year 1647. At the age of four years she lost her father, which in most cases is a great misfortune, but not so here, for her mother found in her second husband, Jacques Morell, a kind and indulgent protector, who fostered the infant genius of Maria.

Morell, as is well known, was a distinguished painter of fruits, flowers, and insects; and under his instruction our young artist soon distinguished herself as a painter and natural philosopher, to which attainments she afterwards added the art of etching.

In the year 1665 she married Jean André Graf, a meritorious painter of Nuremberg, who studied in the school of Morell. In 1679 she published the first volume of her "Histoire des Insectes de l'Europe définies d'après nature, et expliquées par Marie-Sybille Merian; ou l'on traite de la génération et des différentes métamorphoses des insectes et des plantes dont ils se nourrissent," and in 1683, she published the second volume of the same work, in the execution of which the paid attention to the engravings as well as the designs, it being the first work wherein is displayed the minia which is so important in the eye of the connoisseur, and that she used the etching needle with the dexterity she had before evinced in the management of her pencil.

In the course of the next year, she returned to Frankfort with her family, and, from a mistaken zeal in religion, separated from her husband; retired with her mother and two daughters to Wefl Friedland, and became a member of the fraternity of Labadistes. The fraternal society of Labadistes, (who called themselves brothers and sisters,) had then assembled under Peter Yrond, and their head-quarters were the castle of Den Bofch, situated between Franker and Lezard, of which the possessor's name was Sommerdyck. Here she remained a considerable time, and here she had opportunity to inspect at leisure a fine collection of the insects of America, of which she made very exact drawings, and from hence forth after professional knowledge led her to make occasional excursions to Amsterdam and other parts of Holland, which at that time abounded with cabinets both of pictures and natural history.

Her enthusiasm now took a new turn, and coinciding with the wishes of the Dutch naturalists, she was induced, in the year 1699, to undertake a voyage to Surinam. On her arrival, after an agreeable passage, a wide field opened to her professional ambition. She painted the insects and reptiles of the country on vellum, and examined with philosophical care their various habits and changes: but the heat of the climate, and her intense application, having injured her health, it became necessary for her to return to Europe in the following year.

She brought home an ample collection, not only of drawings, but of shells, dried insects, &c. She now settled at Amsterdam, and immediately set about publishing the fruits of a voyage, than which none had ever been performed more truly interesting to the naturalists of Europe.

Of the sixty large folio plates contained in her "Metamorphoses Insectorum Surinamensis, &c." several were executed by herself, and the rest supplied the descriptions. It was published at Amsterdam in the year 1705.

In the second edition, which was published by the physician Jean Marret, in the French language, more plates and explanations were added by the author, who confirmed the rest of her days to delineations and researches of this nature.

Too far advanced in life to venture on a second voyage, yet knowing that much had been left unaccomplished at Surinam, Maria Sybille now formed the design of sending thither her eldest daughter, who had accompanied and assisted her in her former voyage. Jeanne Helene cheerfully undertook the commission, landed at Surinam, painted with hereditary skill all the remaining subjects of natural history that she could find interesting in the country, added her remarks, and transmitted them to Amsterdam; but death had now interposed to prevent this consummation of the pleasures of Maria Sybille.
Sybille. The supplement was however published by her second daughter Dorothia Maria, who was born in 1678, and herself painted flowers and insects with great ability.

The curious, who would form an adequate idea of the knowledge and talent of this extraordinary artist, should visit the principal cabinets of Holland. Yet in our own national collection at the British museum, are some volumes of her paintings on vellum, which are almost daily turned over with wonder by its numerous visitants.

John William Baur was a very meritorious painter and engraver of landscape and history. He was born at Strafbourg in the year 1600, studied under Frederic Bredel, and afterwards in Italy, where he resided a considerable time, and where he was patronized by the duke of Bracciano and prince Guilielmini. In the year 1627 he removed to Venice, and from thence to Vienna, and died there three years afterwards, at the age of forty.

The landscapes which he painted with water colours on vellum are particularly celebrated, and he engraved a vast number of plates from his own designs, some of which are in a style resembling that of his contemporary Callott, to which he affixed the cypher which the reader will find in the third plate of our monograms, &c. of the German school of engravers.

Melchior Kuffel completed the volume of his works, which contains not less than five hundred engravings, after the death of Baur, whose "deligans," in the language of Strutt, "manifest great marks of a superior genius, but without cultivation." The cypher with which he usually marked his engravings, of which the following are the names of the principals, will be found in our plate of monograms.

Portrait of Don Paolo Geordino II; Orsino, duke de Bracciano, an oval, dated 1646, a rare print; a set of eighteen, of the costume of different nations; a set of fifteen of the battles of various nations, entitled "Caprici di varie Battallie," in quarto; another set of fourteen battles; a set of eight landscapes, and another of four, entitled "The Elements." A set of twenty of a superior character, of the battles of "La Guerre Belgeique," and his principal work, consisting of one hundred and fifty plates in quarto, from Ovid's metamorphoses, published at Vienna in 1644. These are chiefly etched, and finished with the graver. The figures introduced are generally small and incorrect in the drawing, the back-gounds rather dark, and the trees deficient in lightness and freedom. The architecture, which Baur is fond of introducing, is well designed, and correct in the perspective.

Hans or Jean Ulfic Franck was a native of Kaufbeuren, an imperial city of Suabia, born in 1603, and was particularly excellent in painting and etching small figures. He settled at Augsburg, where he died in the year 1682.

In conjunction with Suan Sandrart, A. Zelt and J. Meyer, Franck engraved a set of the Fountains in Rome and its environs. The bell of his other engravings are four combat in quarto, dated 1643: "David and Abigail," and "Alexander defeating Darius," dated 1644, and both in folio.

Joachim Sandrart was born at Frankfort on the Maine in the year 1606, and began his career of art by studying under Theodore de Brie and Matthew Merian, of whom we have spoken. At the age of fifteen he went on foot to Prague, to visit and obtain instruction from Giles Sadedler, after which he placed himself under Gerard Honthorst, of Utrecht, to learn the principles of painting, with whom he travelled to England. He afterwards visited Venice, Bologna, Naples, and Rome, and received instructions from Titian, Paul Veronese, Guido, Guercino, Poussin, and others; in short, if instruction and example alone could have produced a great artist, Joachim should have been the first of his time. He returned however to Germany, and finally settled at Nuremberg, where he established an academy of art, and where he died ten years afterwards, at the age of 77.

Sandrart was rather an artist of acquirement than of genius, and hence his works are deficient in vivdness and warmth. He painted and engraved history and portrait; he was also a man of letters, and his "Academy of Architecture, Sculpture, and Painting," which was first published at Nuremberg in the year 1679, though prolix, is still celebrated through Europe.

This book, which contains much historical information, and the biography of the most distinguished artists, is enriched with a considerable number of engraved portraits, beside other prints. It was first published in the German language, but an edition in Latin was printed in the year 1683, and it has since received various additions from the succессors of Joachim Sandrart.

His own engravings are performed chiefly with the point, and the bét of them will probably be found to be a half length figure of the goddess Flora, after Titian; an elderly couple contemplating a Cupid in a very delicate action; and "The Death of Cleopatra," from his own composition, all in quarto.

Jacques Sandrart, the nephew of Joachim, was born at Frankfort in the year 1632, and died at Nuremberg in 1688. He studied engraving at Amsterdam under Cornelius Dantierte, and afterwards at Dantzic under W. Hondius.

He settled finally at Nuremberg, where he pursued his art with singular industry, the number of his portraits alone being not fewer than four hundred, some of them of the folio dimensions, and executed with the graver alone, in a clear and neat style, beside which he published a number of geographical charts and other engravings.

His portraits are not uncommon, and among the most meritorious will be found to be those of his uncle Joachim Sandrart, a half length figure, inscribed "Seculi Notiff Apelles." The bulls of Rodolphius II., Ferdinand II., Ferdinand III., and Frederic, prince of Norwega and duke of Slesvici; a half length of Hohannes Michael Délherrus, after R. Wernfels; Ernuth Sophia, electoral princess of Saxony, &c. Johannes Paulus Auer, painter of Nuremberg; Joachim Sandrart, junior, dated 1688; all in folio.

Jean Jacques Sandrart, the son of Joachim, whom we have just dismissed, was born at Ratifon A.D. 1655, and died at Nuremberg in 1698. He studied the arts of design under his father and his great uncle Joachim; his works prove the facility of his invention. He enriched the volumes of Joachim with several tasteful and spirited etchings, and his portraits, which are etched, and finished afterwards with the graver, are deftly held in esteem. His best works are, the portraits of Elizabeth Henrietta, princes of Brandenburg, surrounded by emblems; and Silvius Jacob de Dunkelmann, both in folio, after Adam le Clerck; "The Holy Family," after Joachim Sandrart; "Aeneas saving his Father from the Flames of Troy," after Raphael, dated 1682. "Marphorus, or the Statue of the Rhine," among ruined edifices; "The Nile" among ruined monuments of antiquity, all in folio, and the latter pair, with many others after Joachim, are introduced into his "Academy, &c."

Jean Jacques also engraved several plates of merit for a folio work, entitled "Suecia Antiqua et Hodierna."

Suan Marie Sandrart was the father of Jean Jacques, and was born at Nuremberg in the year 1658. She studied under the direction of her father, and engraved with some ability a considerable number of plates of ornaments. She engraved also a Bacchus, with the inscription "Im-
German School of Engraving.

Of Hollar, who flourished about this time at Prague, we have already spoken. See Origin and Progress of English Engraving.

That extraordinary artist, Adrian van Ostade, for an account of whose merits as a painter, see the article Oostade, performed about this time some etchings, which are very justly admired for their freedom and spirit. They are not all executed in the same style, though the fame mind be everywhere evident. Some are dark and coarse, and were printed just as the aquafortis left them, while others are more neatly executed, and appear to have been subsequently worked upon with the triangular point, as was the custom of Rembrandt and Worlidge. The two marks with which Ostade occasionally subscribed his etchings, will be found in our third plate of the monograms of the German school.

The whole of his etchings consist of at least fifty-two plates of various dimensions, all from his own designs, of which the following are perhaps most worthy of being specified: Several Peasants at the door of a Cottage, with a fair in the back ground, a middling-sized upright plate, "A Dutch Wake," the plate, "Several Peasants Fighting with Knives," a small plate, lengthways, dated 1658. "The Cottage Dinner," the plate, dated 1653. All these are in his bold style of etching. Those which follow are such as he finished with more care. "The Painter," with an inscription beginning in this manner: "Pictor Apellis, pingar," and the first impressions of these plates are with the cap considerably above the eyes of the figure; in the second impressions, the cap nearly touches the eyes. "A Mountebank," a small upright plate, arched at the top. "The Spectacle Seller," a small upright plate. "A Man, Woman, and Child, at the Door of a Cottage," a middling-sized plate, lengthways, dated 1652. Several peasants, half figures, at a window, one of them is fingering a ballad, and another holds the candle, a small upright plate. "A Man Leaning over a Hatch, blowing a Horn," the plate. "A Cottage Entertainment," with figures dancing, a middling-sized plate, lengthways.

The biographers of lieutenant-colonel de Siegen, (an officer in the service of the landgrave of Hesse,) have contended with the friends of prince Rupert for the honour of the invention of mezzotinto. The lieutenant-colonel was born in the year 1620, and, according to the baron Heinneckin, executed in that manner a portrait of the princess Amelia Elizabeth of Hesse Cauffel, in 1643.

For an account of prince Rupert's pretensions to the discovery, see the article Origin and progress of English Engraving. "An Holy Family," after Caracci, in folio, is also mentioned (but without a date) as a mezzotinto production of Siegen.

Jean Francois Ermelo, who possessed considerable talents in the art of painting and engraving landscapes and cattle, was born in the environs of Cologne in the year 1621, and died at Nuremberg in 1693. He studied under J. Holzmann and Jean Bot, and the following plates, consisting chiefly of landscape scenery, adorned with ruined edifices and animals, were etched by him with great spirit and freedom. A pair of upright landscapes, "A Rocky Scene, and a composition of Ancient Architecture," in 4to. "A Landscape," in which the figures introduced are a faun and bacchante. Another, with monumens of antiquity. And a pair of "Pastoral Scenes," with shepherds, cattle, and ruined edifices, all of the 4to size.

Matthew Keefell, or Kyfell, was born at Augsburg in 1621, and died there in the year 1682. He successfully mingled the work of the graver with that of the point, and his best prints, which are named in the following list, possess a large share of merit. The portraits of Christopher Benden, in 4to. Carolus Sulzer, Adolphus Zobellius, Andreas Winkler Johannes Michael Dillierus, after Ulricus Mayr (an highlyfinished head in an octagon border). Leonarius Weilhins, after Jos. Werner, all in folio. A set of forty-two after Ludovico Burnacini, entitled "Il Pomo d'oro," and consisting of scenic decorations, &c. dated 1668, are folio etchings; and the only historical work from his hand, with which we are acquainted, is "The Virgin and Child," apparently from a composition by himself.

Melchior Keefell, the brother of Matthew, was born at Augsburg in the year 1622, and died in the same city in 1683. Here he acquired the rudiments of his art, but perfected his studies under Merian of Frankfurt, from whence, after residing some few years, he returned to Augsburg, and began to engrave the "Iconographia," of Wilhelm Baur, a folio work, which consists of one hundred and forty-eight prints of various sizes, consisting partly of the "Life and Miracles of Jesus Christ," and partly of views of the "Seaports and Gardens of Italy," which work was published at Augsburg, A. D. 1682.

Strutt says of this artist, that "there is something very agreeable in his manner of engraving, especially when he confined himself to subjects where the figures are small, for as he drew but incorrectly, his figures appear defective, as they increase in size." Baur was fond of ornamenting the back-grounds of his compositions with superb buildings, which Keefell has executed with much spirit; his rocks also, and mountainous inflances, have great merit; but his trees want freedom, lightness, and characteristical determination of their foliage; his chiaro-fuco is also pretty and fattiguing to the eye, if this be not rather the fault of Baur.

Melchior engraved other plates besides those for the Iconographia of Baur, of which the principal are, "The History of Ulysses," from Theodore van Telden; some antique statues, executed entirely with the graver; and the portraits of Sebatianus Kirchmairus, public professor at Ratisbon, after Benj. Block, in 4to. Johannes Hoxius, Maximilanus Curz, dated 1658; and Antonius Schottius, dated 1680, all of the folio size.

Jeanne Sibelle Keefell, born at Augsburg in the year 1646, was the third daughter of Melchior, married Jean Ulrich Kraus, engraved, among other plates, a set of four, of the Satyr and Villagers, Juno Venus, and Pallas, after Elthommer, and died in her native city in 1717.

Jonas Umbach was also of Augsburg, born in the year 1624, and merits an high rank among the artists of Germany. His prints consist chiefly of etchings after his own designs, executed with spirit and an appearance of facility. He engraved one hundred and eleven plates, of which the following are the subjects of the principal, and died in his native city about the commencement of the seventeenth century. "A Madonna and Child." "An Holy Family." "A Penitent Magdalen," and "St. Peter," all of small dimensions. Four plates from "The Parable of the Good Samaritan." Four etchings of "Infanticide Sports." A pair of "Triumphs of Marine Deities." "A Family of Satyrs," all of small sizes; and a set of four landscapes, adorned with ruins of ancient monuments and pastoral figures, dated 1678, in 4to. highly esteemed engravings.

Langel
Lingelbach, Backhuysen, and Jean Henry Roos, also performed some meritorious etchings in Germany about this time. The animals of the latter are much celebrated, and among his best plates may be reckoned a set of twelve, of "Domestic Animals," in 1704. A pair of "Grand Landscapes," adorned with cattle and ruined buildings, and "Un Berger endormi au pied, &c." He was born at Otterdorff, in the Palatinate, in 1671, and died at Frankfort in 1681, and his matters were Julian Jardyn and Adrian de Bie.

The family of the Wolfgangos contributed but little to the advancement of engraving; we therefore pass them briefly. George Andrea Wolfgang was originally a goldsmith and engraver on the precious metals, but afterwards studied engraving on copper under Matthew Keefell, and skimped some few mezzotintos. He was born at Chemnitz, in Saxony, A. D. 1631, and died at Augsburg in 1716. The best engravings of George Andrea are the portraits of George Frederic, margrave of Brandenberg, after C. Zieli, in folio, and Pierre Muller, Jurienfult, in 4to. And, in history, "A Grand Sacrifice to Diana," after A. Schoenfeld, and "Saul consulting the Ghost of Samuel," after Jof. Werner, both of the folio size.

Andreas Matthew, the son of George Andrea Wolfgang, was born at Augsburg in the year 1662, and died in the same city in 1735. He studied the elements of design under the direction of his father; but embarking for England with his brother, precipitously at some point in the Mediterranean Sea, they were intercepted by an Algerine corsair, and carried into captivity. On their liberation, which was in consequence of a ransom paid by their father, they both returned to Augsburg, where Andre Matthew settled, and began to engrave portraits; he also engraved a print of "The Court of Algiers," in which he has represented himself as a slave.

His best portraits are those of George Andre, his father, and Nicolaus Nuremberger, both in 4to., and in folio, John George Buttner, bishop of Frankfort, and Christophor Rad. In mezzotinto he has engraved Charles VI., king of the Romans. But, perhaps, his very best performance is a portrait of the margrave of Anfach.

His younger brother, Jean George Wolfgang, was born in 1664, received the same instructions as Andrea Matthias, and soon after their release from captivity travelled to Berlin, and in 1704 became engraver to the court. He engraved and published there a great number of portraits, among which that of the elector Frederick William, after Jacobi's equestrian statue in bronze, is deftensively held in most esteem, though, in most of his portraits, the figure is executed with delicacy, and Jean George is, on the whole, as an artist, the flower of the Wolfgang family. He died at Berlin in the year 1704.

Guillauus Andrea Wolfgang was the son of Andrea Matthias. He was born at Augsburg in the year 1692, and, after studying portrait engraving and miniature painting under his father for a time, followed his uncle to Berlin, where he remained for many years, but returned finally to his native country, where he died in the year 1766.

His best portraits, of which the figure is engraved chiefly in dots, are those of M. Francois Reyter, admiral pour l'Armee navale Angloise en Afrique. Wolfgang Jacobs Sulzer, Reipublice Augustae Decemvir, after G. Eichler, and Carl Freyher von Stien in small folio.

Jean Jacques Thurneis, or Thurneisen, was born in the year 1736 at Basle, in Switzerland, and died in the same city in 1718. After having learned to draw in his own country, he went to Strasbourg to study engraving under Pierre Aubry, where he remained about three years, and removed successively to Lyons, and to the court of Turin.

In 1695, he returned to Vienna, accompanied by his sons; and his great merit, which was called by his rivals his superior fortune, obtained for him the patronage of the emperor Leopold. He was now the object of envy to the artists of Augsburg, where he continued to reside for some years; but as age approached, he wished to see again his native land, and departed for Bale in the year 1699, where, as we have already said, he finished his career.

Thurneisen was a man of a robust frame, vigorous mental powers, and extreme professed audacity. His monument will be found in our third plate of those of the German school. Among the engravings he performed, those which are executed with a single stroke or spiral, in imitation of Mellan, have been most admired, though, perhaps, not most justly. He also occasionally imitated the square croffings of F. de Poilly.

His son, Jean the younger, worked in imitation of his father, but was less successful. The best engravings by Thurneisen the elder are, the portraits of Laurentius Scotus, after Luc Damarat, dated 1661. Francois Tur-utein, after P. Haud. Petrus Weronfus, prefect in the academy of Bale, after L. F. Wettelin, engraved of the folio size, (by the Thurneisens, father and son,) in 1702.

Of his historical works, our allotted space only allows us to mention "The Virgin Mary, Infant Christ, and St. John," in a circle, after Carl Dauphin, a folio plate, engraved in the fashionable style of Mellan. "An Infant Christ," after Blanchet, in 4to. "La Bilancia Politica del Boccacini." Two large folio plates of "Grand Theses in Philosophy," in which whole length portraits of the princes palatine of Neubourg are introduced, and the statues of Laocoon, Antinous, and Latona, in the style of Melan, for Sandreit's academy.

Francois Ertinger was born at Wyl, in Swabia, A. D. 1640, travelled to Italy for improvement, but died at Paris in the year 1700. As an engraver, neither his judgment nor his taste ranks very high; but the following lift of his best works will shew that the subjects of his prints at least were sometimes wisely chosen.

A set of eight plates, after Rubens, from the History of Achilles. "The Marriage of Cana in Galilee," a large folio, after Raymond le Paget. A set of ten, from the fac-simile of the History of the Counts of Thoulouse. A large folio, of a Boccaccian subject, after N. Poutlin; and the portraits of Nicholas Machiavel of Florence, the celebrated political philosopher, in 8vo. Gabriel de Pinaco, Jurconfult; and Jean Ferdinand de Boucham, bishop of Anvers, after F. de Cock; both in folio.

Gerard Lairesse was born at Liège in the year 1640, and died at Amsterdam in 1711. He was instructed by his father, Regnier, in the rudiments of art. For an account of his merit as a painter, see the article Lairesse. He etched a vast number of plates, from his own compositions with great freedom, and the fearlesss hand of a painter who has other objects in view than the graces or blandishments of manual execution. His chiaroscuro is broad and powerful, and so contrived as to conduct the eye of a spectator at once to the principal objects in the composition.

The major part of his designs were engraved by himself; and, as Ballan observes, are highly esteemed by connoisseurs, and exceedingly useful to students in art.

The portrait of Lairesse, in folio, surrounded by emblematical ornaments, has been engraved by N. Vilicher.

The most esteemed of his own engravings are, "The Sin of our first Parents," and "Adam and Eve expelled from Paradise," a pair in folio. A rich composition of the design of Joseph
GERMAN SCHOOL OF ENGRAVING.

The prints of Lairetse are generally inscribed with one or other of the four monograms which the reader will find in our third plate of those of the German engravers.

Samuel Bottschild was born at Sangerhausen, in Thuringia, A.D. 1640, and died at Dresden in 1707. He was an artist of taste; and, being possessed of elevated habits of thinking on professional subjects, he was appointed director of the Dresden academy, and inspector of the electoral gallery. His excellence in freece painting is attested by his picture of "The Defecent from the Crofs," in the church of St. Martin at Halberstadt, and by several paintings which adorn the castle gardens near Dresden; and his etchings are performed with much picturesque freedom: the general character of his art partaking much more of the grand than the graceful. His principal engravings are, "The Army of Sennacherib defeated by the exterminating Angel," in folio. A set of four, entitled "Le Don de l'Entendance!" "Le Don de la Science!" "Le Don de la Sagefle!" "Le Don de la Force!" in 4to. A set of the four parts of the day, with Latin inscriptions. A pair of emblematical subjects, intituled "La Foi et la Paix!" "La Foi et la Charite!" ovals, in 4to. "Ulyses and Epius," and a subject from the Life of Hercules, both of the folio size.

Elias Hainzelmann was born at Augsburg in the year 1640, and died in the same city in 1693. He studied engraving at Paris in the school of Francois de Poilly, whose style of manual execution he imitated with great success; and Strutt has well observed, that had his drawing been equally correct, his works would have ranked with those of the greatest masters. They possess, however, especially his portraits, a considerable share of merit.

From Hainzelmann's historical works, the following will probably be found most worthy of selection: "The Silence," after Annibal Caracci; so called, because, while the infant Christ is sleeping, the Madonna holds up her finger to St. John, as he approaches, to prevent his disturbing the Saviour. This picture has since been engraved by others, but particularly by Bartolozzi in a very superior style. A large upright plate of an Holy Family, after Sebastian Bourdon; and two others of the same subjects, from the same painting, in one of which the infant St. John presents a lamb, and in the other an apple, to Jesus Christ. St. Francis, after Domini- ciniano. "The Noli me tangere!" or Christ in the garden, approached by Mary Magdalen, after Albano. "The Madonna and Child!" after Raphael. "Jesus Amabilis!" Mater Amabilis; St. Regard; all of the folio size.

His belt portraits are those of Francis Xavier, of the fraternity of Jefuits; George Philip Rits, after Ulric Mayr; Marcus Habern, and Juliana Benedicta Winkelrin, after the same. David Thomas ab Hagelsein, after de Neve; Agnes van Schoenbergen; Godfried Eggerus; Gabriel Willet; John Jacob Hailer, after D. Savoy, all in folio, and Johann Christoph ab Aedelmannsehlen, after C. C. Kretzschmann, in very large folio; the head, the size of real life.

Jean Ulric Kraus, or Kraffef, was born at Augsburg A.D. 1645, and died in the same city in 1719. He was the disciple of Melchior Kufell, and married Jean Sybille his daughter, and became a close imitator of the works of his contemporary Le Clerc. But all followers are meedily behind. Though Kraus copied Le Clerc's life of Chrift, which consists of fifty subjects, it is sufficiently obvious that they are not copies.

His engravings are numerous, chiefly from his own compositions, and the subjects of them, for the most part, views of buildings, or taken from the Old and New Testaments. In imitation of his model Le Clerc, he generally introduced a vast multitude of figures into his compositions, but they are less graceful, and far less well drawn. He frequently enriched his back grounds with architecture, which he appears to have well understood, and his chiaro-curo is often judiciously disposed, and his general effects good.

The cypher with which Kraus uniformly marked his prints will be found in our third plate of German monograms, and the list of his principal works is as follows: a set of fifty subjects copied from Le Clerc's life of Christ, in small folio plates, two subjects on each, printed at Augsburg 1705. The history of the Old and New Testaments, in 4to, containing four small subjects on each plate, and apparently designed to be bound in 8vo. So as to have two subjects only on a leaf. The number of leaves would then amount to one hundred and eighty-eight, and they are so numbered. The four feaons, and the four elements, desiged for the royal tapestries. A set of twelve interesting views of the city of Nuremberg, after Andrea Graf, in folio, and a very large and capital view of St. Peter's church at Rome, after the same master.

Carl Guillaume d'Amling, or ab Ambling, was born at Nu- remberg A.D. 1654, and died at Munich in the year 1702. He studied under F. de Poilly at Paris, and imitated his style, but with no very great success. He was a painter as well as an engraver, but was chiefly engaged in engraving portraits. When he attempted history, neither his drawing of the naked, nor the expression of his head is correct, and the general appearance of his prints is cold and metallic.

Yet the race is not always to the swift, nor the battle to the strong, and Ambling, notwithstanding these defects, obtained court patronage, and became engraver to the duke of Bavaria.

Of his numerous portraits, we shall only mention those of Maximilian Emanuel, electoral prince of Bavaria, after T. Macolinus Muficus, dated 1670, a rare print. Maximilian Emanuel, elector of Bavaria, after J. B. Champigne, both in folio, and the latter esteemed one of his very best performances. An equestrian figure, also of his patron, and Henrietta Maria Adelaide, duchess of Bavaria, after Dela- monce, dated 1675, in an oval, and also of folio dimensions.

Of his historical works the principal are, a set of thirteen plates of different sizes, of the histories of the emperor Otto and Louis of Bavaria, from the tapestries in the castle of Munich, which were executed after P. Candido. Another set of nine in folio, from the same tapestries, representing perforinations of the months September, October, and No- vember, the four Seasons, Morning, and Night.

The family of Meyer Baurifeld as artists, and chiefly as engravers, through two centuries. Joachim was born at Strakburg early in the sixteenth, and distingifhined himself by engraving a set of sixty-two prints of combats with the sword.

Andre was a native of Zurich, and engraved several views of

Jean Meyer reigned about the fame time, or a little earlier,
at Nuremberg, but is premature by Strutt to have been of the fame family as the preceding. He etched, among other
plates, a fet of battles in a flight but spirited fyle, from his own compositions.

Felix Meyer was more celebrated. He was born at
Winterhull, in Switzerland, in the year 1623, and died at Weyden in 1733; his genius developed itefelf at Nuremberg,
whilet fudyng under F. Zermel, a celebrated painter of landscape, to which he afterwards added the fludy of nature. His etchings are defervedly held in esteem among connoif-
leurs, for the freedom and intelligence which they display, combined with effective chiarofuro. The moft important
of thefe are, a fet of twelve, ornamented with ruined edifices and rocks, &c. Another fet of four of the fceenery of Swit-
zerland, with ancient monuments and figures, dated 1701. Another fet of four of the fame kind of fubjects, and an-
other fet of the fame number, of a more wild, mountainous, and rocky character, all of the 4to. dimensions.
Joachim François Beich, or Beich, was born at Munich in
the year 1655, and died in the fame city in 1748. He
studied the principles of defign under his father, who was a painter of Zurnberg, but domiciliated at Munich. They
both painted landscafe and battles, and Joachim travelled to Italy for improvement, where he refided for feveral years,
contemplating the fceenery of that claffical landscafe country, and the works of Gafpar Pouflin and Salvator Rofa.

On his return to Munich, he took up the etching point with succefs, and produced several fets of plates of landscafe fce-
enery in a grandftyle, among which the principal are, a fet of eight mountainous landscafe from his own compositions, in
4to. Another fet of fix. Another fet of fix with rocks,
cataracts, and banditti, in the style of Salvator Rofa, of the folo size.

George Philip Rugendas of Augsburt was born in the
year 1666. He learned drawing of Isaac Etcher, but
afterwards studied with more advantage from the works of 
Pietro Tempella, and Bourgognone. He travelled to
Vienna, from thence to Venice, and from thence to Rome, 
where he remained a long time, and refided Augsburt in the
year 1695. At this time the war of the Spanish suc-
cellion was raging in Germany, and our artift had oppor-
tunity to contemplate its effects, and draw battles, skirmilhes,
and fages, from nature. Among thefe the bombardment and
taking of his native city by the French and Bavarians, formed
an infterting fubject for his pencil and etching needle, and
he published in fix prints, their military operations in that
neighbourhood during the years 1703 and 1704.

Rugendas defervedly holds a diffinguifhcd rank among
batttle painters. His defigns are at once bold and correct,
his composition orderly, his pencil facile, and his colouring
performed on principle; above all, the varied attitudes and
graces of his cavalry are jufly admired.

Besides the pictures from his hands, which are not uncommon in the galleries and cabinets of Germany, Rugendas has performed a confiderable number of etchings and plates in mezzozinto, of which the fubjects are chiefly hunting and battles; fome by himfelf, and others in conjunction with his fons, of whom he had three that were educated to the arts.

We begin our lift with a fec tion from his etchings; a fet of fix of "Capricie de Giorgio Filippo Rugendas," dated
1698. Three fets of "Cavilers Marching, in Action, &c."
contifling of twenty-two plates, in 8vo. A fet of very
capital etchings, in folio, of "Les Operations militaires
de Francois et des Bavaros a Augbourg et a Bes Environ," dated 1704.

His belt mezzozintos are, "A Colonel of Huffars on
Horfeback." A fet of four, of "Combats between Hun-
garian and Prufian Huffars." A fet of four, "Hunting
Pieces." A fet of four, "Battles, &c. in the Turkift
Campaign." Another fet of fix, entitled "Les Operations
et les Occupations militaires," &c. all in folio.

The following were produced in conjunction with his fons:
A pair of "Mountainous Landscafe," in 4to. A pair of
"Combats between Cavalry." A fet of four, of "Marches
and Halts." Another fet of four, of "Camps and Skir-
milhes," all in 4to. A fet of fix, of "The Amufements of
the Camp." Two fets of Battles, confifling of fix
in each. A fet eight, of "Marches, Halts, and Combats
of Cavalry," all in folio; and a fet of twenty of various
military fubjects, in 4to.

Jaques Chrifophle le Blond, or Blon, an engraver in mezz-
zinto, was born at Frankfort in 1670. He travelled to
Rome in the year 1696, in the suite of the imperial ambaff-
dor, where he fudyed painting under Carlo Maratti,
but having been of a mechanical turn, he entered with
warmth into various [precautions; at length he learned to
perform mezzozinto, and difcovered a method of printing mezz-
zinto plates in colours. The Dutch painter Overbeck
perfuadcd him to bring his new discovery to Amsterdam, from
whence he emigrated to England.

Eagerly bent on the execution of his new project, he ex-
cuted in London feveral large plates in mezzozinto, from
pictures by the greateft masters, and difpofed of the prints
by lottery; but thofe who obtained the prizes appear not
to have held them in any very great estimation. He made
known the manner in which he performed and printed thefe
plates, in a book entitled "Colorito, or the Harmony
of Colours in Painting, reduced to mechanical practice,
under eafy precepts and infallible rules," which were printed both
in Engliih and French: but nothing is more common than
the failure of infallible pretenfions, and the spirit of fine art
has always evaporated in the various attempts to reduce
it to mechanical practice. le Blond's project did not suc-
cceed.

He afterward let on foot a fcheme for copying the Car-
toons of Raphael in tapeftiy, and made drawings for that
purpofe; but though money was fubfcribed, houfes built,
and looms erectcd at the Mulberry-ground, near Chelsea,
this project alfo failed, and poor le Blond, to the no small

dif-
artift of no other description could find subsistence. Among
the petty courts of the German electors, there was probably
at this time very little taste, yet obfervation enough to
discriminate between two or more fets of features; and perfons
vanity and courfily pomp enough, to court at the means of
attaining a certain fpecies of perifhable popularity.

We have paffed lightly over engravers of this inferior de-
scription, and fome we have entirely omitted, as they con-
tributed nothing toward the advancement of art, but rather
perhaps retarded its advancement.

From these men of mediocritv, attention turns with plea-
sure to the contemplation of the extraordinary powers of
Jacob, or Giacomo Frey. Frey was born at Lucerne in
Switzerland, in the year 1681, and his life presents a curious
instance of the infalphatibility of genius, which it should
seem that no rigour of adverse fortune can fubdue, and
no ftre of intermperate affections can conftume.

He was apprentifed to the trade of a cartwright, and in
fpite of his propenfities towards the fine arts, was obliged
to follow that trade till he attained the age of two and twenty,
when he fomehow or other made his way to Rome; but in
quitting the pefculian and placid valle of Lucerne, he feems
to have taken leave of all fober restraint, and on his ar-
ival in Italy, his paffions, which had hitherto been held in
check, hurfied him into every dangerous excefs. Yet, as
the fame Po, which roars and rifs in the Alps, winds
afterward a flaty river, through the plains of Italy, fo it
was with our artift: when the ebullition of paffion was
over, he fent with delight to the advice of Arnold van
Witlenhout, and the inftructions of Carlo Maratti, and from
that period began to make furprifing prorogres in the art
of engraving.

A speech of Maratti to Giacomo Frey, which fo strongly
marks his good fenfe and obfervation, has been recorded:—
"The engravers of history (fai this) make too much ufe of the
burin, and hence afford a certain hardnefs in the contours,
from which, however, the beft prints of Doriy are com-
paratively free. I would advise you to familiarize yourfelf with
the etching point, becaufe it operates in a far more picturesque
manner than the graver."

Frey followed this advice. Robert van Audenarde was
at this time his fellow-difcipline and liberal rival, but the rapid
 strides of our artift foon left him at an immens diftance,
thana man of ability. He drew with superior taste; had
a fine eye for the harmony both of colours and chiarofcur;
etched with a degree of spirit and freedom, which have very
rarely been attained; worked over and refined his etchings
with the graver, at once with Minute and facility; incor-
porating the whole by means of fuch exquisite feeling of the
merits of his original, that it has been emphatically faid of his
prints, that they appear rather printed than engraved. He
was the Gerard Audrain of Italy, and femeied only to dif-
fer from Audrain himfelf, as Raphael, Guido, Dominichino,
and Guercino, (after whom his principal works are engraved,) differ from Le Brun. In fhort, his feeling for the pecu-
lar excellencies of the fpiritual mifters of the Italian fchools was
of the highest and pureft kind; fo that it may be faid, almost
without a metaphor, that in his engravings their forms ap-
pear revivified by the spirit of Giacomo Frey. He died at
Rome in the year 1752, the adoration of every intelligent
artift, yet before he had received more than an earn of the
prizes that were juftly his due.

It is to be regretted, that when his plates, which were
published by his son Philip, began to wear, they were in-
judiciously retouched, perhaps by Philip himfelf, who de-
stroyed all his father's fweetnefs and harmonious mellownefs;
fo that good impressions of the prints of Frey, in their ori-
Vol. XVI.
Bernard Vogel was the conducer of Heifs, some of these very large plates being engraved by them in conjunction. He was a native of Nuremberg, born in 1663, but resided chiefly at Augsburg, where he espoused the daughter of Heifs. In the earlier part of his career, he produced some tolerably good portraits with the graver, but latterly engraved only in mezzotinto. He retired from Augsburg to his native city, probably after the death of his father-in-law, and died there in the year 1737, leaving behind him a son, Jean Christophe, who engraved several plates in mezzotinto, after Kupetzky.

The best works of Bernard Vogel are the portraits, performed with the graver, of Johann Michiel Weckmann, after L. C. Eichler; Augustan Hermann Frankius, professor of theology; and Johannes Michael Welfer, senator of Nuremberg, after J. C. Hirchelmann, all in folio.

The chief of his portraits in mezzotinto, are those of Johannes Kupetzky, painter, dated the year of our artist's death; Michael Gottfried Wittber, a celebrated surgeon, after Kupetzky; and George Bledinger, the painter, all in folio.

Christopher Vogel engraved, in the same manner, the portrait of his father, inscribed "Chalcographus Norib." Jean George Bergmuller was born at Dircheim, in Bavaria, A. D. 1687, and died at Augsburg in 1752. He learned the rudiments of art under Andrea Wolf, of Munich, but afterwards studied with more advantage under Carlo Maratti. He painted successfully, both in oil and in fresco, and etched a great number of plates, in an able and masterly style, which he afterwards finished with the graver. He was likewise the author of two works; one on the growth of man, which he called "Antropometria: the other on mensuration and architecture, published 1752, and became director of the Academy of Arts, which was established at Augsburg. His son, Jean Baptiste, also followed the art of engraving with some success.

Jean Daniel Herz, draughtsman and engraver in aquafortis, was born at Augsburg A. D. 1693, and died in the same city in 1754.

Herz was an artist of original powers, rich in composition, bold and rough in execution, but deficient in grace and harmony of parts. He was appointed director of the imperial academy of arts at Augsburg, and filled the office with credit; but an hereditary director of an academy, nature, and science, will not endure, and his son Daniel, to whom the directorship unfortunately devolved, soon made himself appear ridiculous in this situation, though he was a tolerably good knight of the holy Roman empire.

The style of execution of Herz the elder bears marks of great rapidity, and rapid he must have been, for his plates are numerous, and some of them of very large dimensions.

We have selected the following, as those which, on the whole, are most worthy of the portfolio of the connoisseur. "The Annunciation," richly composed, and in very large folio. "The Raising of the Cross." "The Assumption of the Virgin." "The Adoration of the Kings." "An Ecce Homo." "The Crucifixion." "The Death of Amasis." "The Dispute between St. Paul and the Philosopher s.
fophers of Athens." And "The Judgment of Solomon;" all in very large folio. "The Coronation Procession of Queen Maria Theresa at Pr€ubourg;" also of very large dimensions.

Jean Edme Ridinger, a very distinguished engraver of animals, was born at Ulm in the year 1695, and died at Augsburg in 1757. His father was a reputable drawing master, and from him our artist received his earliest instructions in the art. He afterwards studied painting under Christopher Reisch, but as an engraver studied nature alone, and was one of her successful votaries. He formed a style of engraving animals for himself, which consists chiefly of etching, which is performed with characteristic freedom and firmness, tempered and harmonized, without being over laboured, with the graver. He appears to have studied in the wilds and most unfrequented recesses of the forests of Germany, and the back grounds of his savage animals are conceived and executed in a grand and masterly style, occasionally displaying all the wild vigour of luxuriant and uncontrolled vegetation, which can only be contemplated in the depths of untrodden forests, and occasionally in his dens of bears, tygers, lynxes, &c. the most barren and desolate rocky solitude, insomuch that the reflecting spectator is led to wonder, either at the bold truths and fertility of a daring imagination, or, if he believes that Ridinger has really visited such scenes, at the dangers he must have escaped.

Nor are his portraits of wild and ferocious animals, less than his landscape scenery, the result of vigorous observation, and extensive power over the instruments of his art. In tracing their habits and manners, he combined the exactitude of a naturalist with the talents of a consummate artist.

Several of Ridinger's prints may be called historiall, being representations of chases which really took place in his time, and at which he must have been present, in the forests of Germany, with portraits of the animals that were killed or taken, and beneath these engravings there is generally a particular description, or history, of the chase, in the German language. He did not, however, draw the human figure, nor that of the horses, with equal ability; though his chirotonsos are often effective, yet in many instances his lights are too much scattered. He worked from his own compositions, and sometimes painted, as well as engraved, a favourite subject, but his pictures are not common. The most esteemed of his numerous engravings are those which follow:

"The Terrestrial Paradise," a set of twelve large folio plates, in which are introduced, in an appropriate manner, all the various animals; the subjects are connected by means of the history of Adam and Eve. These are grand compositions, finely executed, and in England but rarely seen. A set of sixteen fables. A set of heads of wolves and foxes, finely executed. A set of four large upright folios, which by some are esteemed the masterpieces of Ridinger, and two of which, representing "Beasts feeding on a Stag," and a haunted "Wild Boar in a Forest," are of especial value to connoisseurs. A pair of "Stag-hunting" and "Bear-hunting," in large folio, both designed from nature. Another pair of hunting pieces, of "The large Wild Boar with double Tusk," and "The Stag in Rutting-time," dated 1755 and 1757, taken by the duke and duchess of Wurtemberg. A set of sixteen hunting pieces of the larger and smaller game, as practised in the different states of Germany, with German and French explanations beneath, rich and interreling compositions. A set of twelve plates of savage and carnivorous animals, all in large folio, and after his own designs.

Ridinger also engraved, with his usual ability, a lion-hunt, after Rubens.

The Preillers were a numerous family of engravers, whom we shall pass with brief notices, as they rarely rose above mediocrity.

Jean Daniel Preiller, an engraver of portraits, was of Nuremberg, and lived at the close of the seventeenth and beginning of the eighteenth centuries. His son Jean Justin was born in the same city in the year 1698, and died there in 1775. He resided in Italy a considerable time, and became director of the Imperial Academy of Augsburg. His most distinguished works are "The Apotheosis of Eneas," a set of the four elements, after Edmond Bouchardon; and another set of the four parts of the day, all in folio. A set of fifty plates of the antique statues, first engraved in Rome, from drawings by Bouchardon; small uprights. The etchings of the Jesuits' church at Antwerp, after Rubens, consisting of twenty small plates, exclusive of the portraits of Rubens and Vandyke.

George Martin Preiller, a younger brother of Jean Justin, was also of Nuremberg; he engraved, in the family style, a considerable number of portraits, and a set of twenty-one plates of statues, at Rome and at Florence, from drawings by his brother Jean Martin.

The engraving of Valentine Daniel, another son of Jean Daniel Preiller, was chiefly confined to book plates and portraits.

Jean Martin Preiller, the fourth son of Jean Daniel, travelled from Nuremberg to Rome for improvement, and became, on the whole, perhaps, the best engraver of the family. He accepted an invitation to Denmark, and was living in good repute at Copenhagen in the year 1770. His style is clear and neat, but deficient in vigour, and his bell prints are "Chrift bearing his Cross," a large folio, from Paolo Veronese. "Samson, placed on the Crown of Ninox upon the Pyramis Head," by Guido, a large folio, engraved with the former, for the Dresden gallery. "A Battle," from Parrocio, and a Bacchusian subject, from Pierre, both in large folio.

Jean Alexander Thiele was born at Ehrfurth in the year 1695, and from the rank of a common soderer rose to be a distinguished engraver and painter of landscapes. A decided taste for this art, and some pictures of Agriculture, which it was his good fortune to see and copy in Dilemmer, introduced him to the notice of that artist, by whose instructions he failed not to profit. He is believed to have been the first in Germany who attempted to paint landscape in crayons, which, though an ineligible mode of art, is a proof of his ingenuity; he afterwards acquired a knowledge of oil-painting under Menyky, in which he gloried, and in which he excelled. His industry was the romantic part of Saxony, and more especially the banks of the Elbe and the Saale. His etchings, of which the subjects of the principal are named below, are rude but masterly. The celebrated Dietrich studied under him at Dresden, where he left a son, and where he died in the year 1752.

A pair of mountainous landscapes, adorned with ruins of ancient buildings, dated 1725, in folio, and very rare; a pair of smaller landscapes, of more rude character; a set of three mountainous landscapes; a landscape of grander character; a pair adorned with ruined monuments of antiquity, in the form of "The ancient Port or Mouth of the Elbe," drawn from nature, and dated 1742; a pair of views at Naumburg, all in quarto; a set of five of superior execution, from nature, including views of Pilnitz, Konigstein, Muffen, and Dresden, dated 1726, in large folio.

Paul Troger was born at Zell, in the bishopric of Brixen, in the year 1693, and died at Vienna in 1777. He studied the rudiments of his profession in his birth-place, and afterwards
travelled for improvement to Fium, in the bishopric of Trent, in order to avail himself of the instructions of D. J. Alberti, after which he went to Vienna, and soon became known by his prints, and by the pictures with which he adorned some of the churches of Austria. In etching, the touch of Truger is firm and precise, his figures are well designed, and his expression just. He became director of the Imperial academy of Vienna, and engraved in a good taste both historical subjects and landscapes, the latter of which he ornamented with figures, ruins, &c.

His best prints are two small Holy Families; "The Virgin and Child;" "St. Joseph carrying the Infant Christ;" "The Virgin in Grief, comforted by Angels;" in folio. Five small landscapes. And a pair of landscapes, in which ancient monuments are introduced, in quarto, dated 1724.

Jacob Maenli was born at Vienna in the year 1695, and died in the same city at an advanced age; and, according to the baron Heinmeck, was a mezzotinto engraver of considerable ability. He was employed by C. Luech, inspector of the Imperial gallery at Vienna, to theft the celebrated collection in mezzotinto, and had executed thirty-one of the plates, when the death of both the engraver and employer put an end to the completion of their project. Maenli, of these thirty-one prints, only eleven were ever made public; the rest are preserved to have been sold by the heirs of Maenli, and are now missing. At the head of the work is a portrait of the emperor Charles VI., and Heinmeck and Strutt have given life of the subjects engraved.

Antoine Joseph Prener, or Von Prener, after the death of Luech and Maenli, undertook, in concert with Stempart, Altomonte, Schmutzer, and others, to recomplete the work from the Imperial gallery, and after a considerable lapse of time produced "Theatrum Artis pictorice, quo tabula depicta quae in Caesarea Vindobonensi Pinacotheca servatur," &c. in four folio parts, or volumes, of which part one was published in 1728, part two in 1729, part three in 1731, and part four in 1733.

These four parts contain one hundred and sixty prints, which are surrounded by borders in a bad taste, and the work altogether is but of mediocrib character. The best portraits by this artist are those of Jean Gottfried Auerbach, painter to the emperor Charles VI., and count d'Ourt, governor of Vienna, both of the folio size.

Gaspard von Prener, the son of Antoine Joseph, was also an engraver, who travelled to Italy for improvement, and was engaged in engraving the "Museum Florentinum." He also produced a set of fifty-four etchings, neatly finished with the graver, of historical subjects from Taddeo Zucchetto, and other distinguished painters, dated 1746.

G. A. Muller was born at Vienna some time about the commencement of the eighteenth century, worked in a delicate style, and, in concert with the Schmutzers, produced Rubens's series of the history of Decius, of which Muller engraved two.

His other principal works are the portraits of Philippe Louis, count de Sintzendorf, after M. Altomonte; Jacob van Schuppen, member of the academies of Paris and Vienna, after a picture by himself. "The two Children of Rubens at the age of adolescence," from a celebrated picture by that painter, in the Lichtenfein gallery.

The brothers, Jean Adam, Joseph, and Andrea Schmutzer, were natives of Vienna, and born about the close of the seventeenth, and beginning of the eighteenth centuries. They died, the former in the year 1739, the two latter in 1742.

Their grandfather, a general in the Imperial service, lost much of his property by the accidents of war; and the infidelity of the tutor to whom he had entrusted the education of his son, reduced that son to grievous extremities, but his sufferings struck out a talent with which it now appeared that nature had endowed him. He acquired the art of engraving on iron and steel, and ornamented locks and firearms with much taste.

He brought up his sons, the brothers of whom we treat, to the profession of gun-engraving, which they quitted for the more elegant art of engraving on copper. Jean Adam was the elder, but, in spite of application, could never attain to the eminence of Joseph and Andrea. He engraved, however, for the gallery of Vienna under Altomonte, and his best prints are the portraits of the three empresses Elenora, Amelia, and Elisabeth.

Joseph and Andrea generally, if not always, worked in concert, and affixed their names, sometimes Joseph and Andrea, and at others Andrea, and Joseph Schmutzer, with brotherly alternation. Josephpossessed dexterity both in etching and engraving, and Andrea possessed great facility in managing the tool, which was the necessary result of his being educated to engrave on steel, and to which he added a careful study of the works of Borel, and Van Dalen. The best prints from the gravers of these brothers are the portraits of the emperor Charles VI. on foot, after M. de Meyten; the empress Elizabeth Christina, after J. G. Auerbach; Gustavius Adolphus, baron de Gotter, Prussian minister of state; and Leymann, a librarian, or bookfeller, of Vienna, all in folio, and the two latter, also after Auerbach. A pair of ancient temples, in large folio, decorated with statues and trophies, after Joseph Galli Bibiena.

But their most distinguished work is three folio plates, from Rubens's life of Decius, in the gallery of the prince of Lichtenfein.

Jacques Schmutzer was the son of Andrea, and had the misfortune to lose his father when he was seventeen years of age. By what further misfortune he came now to be so very poor as to be employed partly as a butcher and partly as a shepherd is not known, but he was employed to watch sheep, sometimes in the fields, but more frequently when penned up for slaughter. The public drawing-school, however, was in the neighbourhood of the sheep-pen, and his love for art often induced him to confide his flock to some indolent country lad, whilst he flew away to draw with the students of the academy.

The celebrated medalist Matthew Donner, apprized of these circumstances, took some notice of the lad, and invited him home, but by some new accident or impulse, he now began to study architecture; which pursuit he did not afterwards renounce for the arts of design. He was employed for three years as an architect in Hungary, during which time he designed and painted and engraved historical subjects at his leisure hours, and on his return to Vienna, continued occasionally to practice architecture.

He had now the good fortune to become known to the baron de Kettler, a great patron and protector of art and artists, who, charmed with his effays in engraving, solicited the prince Kaunitz, and the empress queen, to send the young Schmutzer to Paris; his solicitations were attended to, and our young engraver was placed under the guidance of Wille; here he perfected himself in the art, and in the course of the four years he remained in that celebrated metropolis, learned to use the graver with masterly intelligence.

He was now recalled to Vienna, with high rank in his profession, and was named by Maria Therefa a Director of the academy.
academy. He superintended the education of a great number of students in his mature age, and at the close of the last century, was as great at Vienna, as Wille in Paris.

The best of Schmutzer's engravings are the portraits of Don Emanuel, of the illustrious family of Delfains, and Joseph von Sonnenfelst, both small; Martin de Meyens, the celebrated painter, after a picture by himself, dated 1756; C. G. E. Detvcry, another celebrated artist, after the same, dated 1765; Joseph Wenceslaus, prince of Lichtenfleins, after V. Fanti; the emperor Francis I., after von Lichtard, dated 1769; the companion to which is the engraver Maria Theresa, and two portraits of prince Kaunitz, one after J. Steiner, and the other after Hagenauer, dated 1786, in a circle; a much esteemed and rare piece of engraving.

The above are all in folio. We now proceed to select from his historical engravings, "Ulysses discovering Alcyone and Andromache," after the prince of Saxe Tefchen, dedicated to madame the archduchess; "Mutius Saxov before Porteum," from a picture by Rubens in the cabinet of the prince Kaunitz, dated 1758; "St. Gregory refusing to admit the emperor Theodolus into the Church," after the same master, both plates in folio, and of learned execution; "Venus rising from the Sea," from a picture by Rubens, in the gallery of count Schoenborn at Vienna, beautifully finished, and four large and interesting landscape views at Neulawde and Dornbach, in which occurs the tomb of Roffenc, and the statues of the Gladiator and the god Mars.

George Frederic Schmidt was born at Berlin A. D. 1712, and died in the same city in 1775. Schmidt was defined by Fortune to be a tradesman, but the voice of Talle, (fays Huber,) proclaimed him an artist. His perseverance, after various strugles, at length, surmounted the obstacles that opposed themselves to the gratification of his natural propensities, and he was admitted a student in the school of George Patel Bucbing at Berlin, from whence his ambition was furthered, rather than his purvue, in the year 1736, carried him to Paris, where he frequented the school of Nicholas de Larmeflin, who honestly and earnestly seconded the professional wishes of Schmidt, by imparting to his disciple all that was possible to him, to communicate of his knowledge of the art of engraving.

In the year 1742 he was admitted a member of the French academy of Arts, although (which at that time was an important exception) he was of the Protestant religion. At this time Schmidt, Prieler, and Ville (of whom the reader will find an account under French School of Engravers) were distinguished at Paris by their superior merit in engraving, and were bound together by the ties of friendship, while they reigned between them a noble professional emulation. Schmidt had recommended himself to the friendly regard of the celebrated Rigaud by the very fine portrait of F. Mignard, which he engraved for his reception into the Royal Academy, and Rigaud contributed to his spreading reputation, by seeking and obtaining for him such engagements as were analogous to his wishes and talents.

In two years, however, or a little more, he was summoned to Berlin, and nominated engraver royal, and in the year 1757 he was sent for to Petersburg by the empress Elizabeth, to engrave her portrait, which he executed (with many others, while he remained in Russia) to the great satisfaction, not only of the connoisseurs of the court, but of the best judges throughout the Russian empire.

On his return to Berlin, in 1752, he began to delineate himself in a new career of engraving, by etching in a picturesque style after the works of Rembrandt, in which he imitated Rembrandt's own mode of execution, but generally bit into his plates to deeper tones.

The engravings of Schmidt amount in number to nearly two-hundred, beside the vignettes which he did for the works of the king of Prussia. Count Craven published a catalogue raionné of the whole, from which we have thought the following most worthy of selection, as specimens of the various powers of our artist.

Portraits performed chiefly with the Graver, and of folio dimensions.—Confinante Scarlatti, prince of Moldavia, a rare and fine print, dated 1738; Charles Gabriel de Tubieres de Caylus, bishop of Auxerre, after Fontaine; Louis de la Tour d'Auvergne, count de Evreux, after H. Rigaud, dated 1742; Johannes Baptista Rosseau, after J. Aved, dated 1749; Charles de St. Alvin, archbishop of Cambrai, after H. Rigaud, dated 1743; Maurice Quinten de la Tour, from a picture by himself, dated 1743; Jean Baptiste Silva, a celebrated physician, after Rigaud, dated 1743; Pierre Mignard, first painter to the French king, after his friend Hyacinthe Rigaud, engraved in 1744, for Schmidt's reception into the academy, a piece regarded by connoisseurs as a chef d'œuvre of the masters, and the finish of which is engraved in a style so soft and mellow, that it has been emphatically said to be rather painted than engraved. The four last are in large folio.

After his return from Paris to his native city, Schmidt engraved the portraits of Antonio Peine, first painter to the king of Prussia, and Samuel Baro liber de Cocceii, both in folio, dated 1751 and 1752, and reckoned among the best portraits from the graver of Schmidt.

Johannes Theodore Eller, auflie-councilor, &e. after Peine; and Louis Albertene de Brandt haron de Grapendorf, after le Sucur, are a very rare and beautiful pair of portraits of the folio size.

Among the best portraits which our artifll engraved at Petersburg, are those of Michel de Woronzow, count of the Holy Roman empire, and Nicholas Elterhazy de Galantha, both in large folio, after L. Toque, and dated 1758; Pierre Comte de Schuallow, grand-master of the Prussian artillery, from the life, and dated 1760; the engravings of Elisabeth of Ruffia, a whole length figure, with accompaniments of the imperial costume, after L. Toque, which Huber calls a superb print, more especially for the execution of the accessories parts, it is dated in 1758; Count Cyrilus de Rafumovizky, after L. Toque, and Jacobus Mounney, from a picture by Schmidt himself, dated 1760, are rare and beautiful, and M. de Katt, field marshal and minister of ficate to the king of Prussia; the last portrait from the graver of Schmidt, the head in which is by himself, but the rest finished by Berger the elder.

Among his historical and fancy works, may be distinguished a pair of "The fair Greek," and "The amorous Turk," the two first plates which Schmidt engraved under Larmeflin at Paris; "Tahage Flamande," &c. in folio, after Oladie, engraved in a style resembling that of Viffcher, and dated 1757; "The Virgin Mary fitting with the Infant Christ and St. John," after Vandyke, dated 1753; "The Virgin at Prayers," after S. Ferrata; "The Presentation in the Temple," after Pietro Teila, for the Imperial gallery at Petersburg; "Alexander and Philip the Phycian," after Ananbail Carracci, engraved in imitation of the historical style of Gerard Audran, at Berlin 1769, and "Timoleon justified by Alexander," companion to the above, and after the same painter, both in large folio.

In imitation of the Style of Rembrandt.—A half length of a bearded old man with a feathered bonnet, designed by the engraver, and an old woman in profile, after Rembrandt, companion to the above; built of an Oriental in the style of Castiglione, dated 1753; built of a young man in a Rem-
German School of Engraving.

Among the most esteemed of his historical works are: "The Infant Christ asleep in a Landscape," a beautiful print, "The Education of the Virgin," "The Prophet Jeremiah," "Tirielas" and "The Holy Family," which are among the finest achievements of the artist.

Joseph Wagner was born on the 17th of September 1756, at Thalendorf, on the lake of Constance, and died at Venice some time about the year 1793. He was the pupil of J. Amiconi, to whom the print is dedicated, and the funeral monument of Sir Andrew Mitchell, knight of the Bath, and ambassador from the king of Great Britain, who died in Berlin in 1771, is a fine work of his hand.

Wagner was a pupil of J. Amiconi, whom he accompanied to England and to Italy, and, obedient to the advice of this master, he afterwards travelled to Paris, and studied engraving with very considerable success. In 1756 he settled at Venice, and published there the engravings of himself and pupils, and finally established a successful commerce with several parts of Europe. Among his disciples were Flipart, Berardi, and, above all, Bartolozzi, whose talents have been reduced to his master, to him, to Italy, and to England, and who still live in engraving in Portugal amid the din of arms.

Wagner's engravings are particularly easy and engaging, and in this sense, what we term admirable. It is built on the firm foundation of sound drawing, and partakes highly of the merits of Gerard Audran and Giacomo Faro. Like them he harmoniously mingled etching with the work of the graver and dry needle, and, like them, he evinced a high feeling of the merits of those masters after whom it was his fortune to engrave.

The elements of his style are vigour tempered with mildness andfacility; hence he is celibately bold, and, without the least appearance of labour, produces, in his best works, an effect of finishing, which others labour after in vain, and which is more particularly observable and appropriate in infantile subjects, or where he has to touch the imagination with indefinite grace. In his figures of the Infant Saviour and St. John, where the characters in his original allowed him to be so, he is, indeed, the Flamingo of his art; though if living artists had found a place in our Cyclopaedia, that honour must rather have been awarded to the most distinguished of his pupils.

Wagner's first attempts in engraving are said to have been the portraits of the English princesses Anne, Amelia, and Caroline, daughters of George II. Of his other portraits, the most remarkable are a pair in folio, whole length figures of the empresses Anna of Russia, and Peter the Great, executed by Minerva. The empress Elizabeth Petrovna, with a Russian inscription, and Farinelli crowned by the Muse of Harmony; all in folio, and after his first master, Amiconi.

Among the most esteemed of his historical works are: "The Infant Christ asleep in a Landscape," a beautiful print, "The Education of the Virgin," "The Prophet Jeremiah," "Tirielas" and "The Holy Family," which are among the finest achievements of the artist.
ployed, but that the melo-drama, to render it interesting, should never admit an air superior to an elegant ballad, is what lovers of dramatic music, and judges of good composition and good singing, will never subscribe to.

But though M. Suard is so determined a foe to all opera music but that of Gluck, and singing, except that of the natives of his own country, when he speaks of the instrumental music of Germany, he is very just, and celebrates the schools of Vienna, Coblenz, Mannheim, Munich, and Stuttgart; which have produced the Stamitzes, the Tounich, Canabichs, Schreeters, Haydn, and innumerable other symphonists, whose compositions are known to all lovers of music. All these different symphonists (says with great truth M. Suard) have a peculiar character and style of their own; yet, continues he, "it must be allowed that all give way to the inexhaustible Haydn for invention and originality. He unites all the resources of science to the charms of good taste: he is noble and gay, full of grace and force; simple with infinite variety; and unites to movements the most sweet and captivating in melody, the greatest orchestral effects."

This character is written with such truth, intelligence, and feeling, that we forgive the elegant and refined writer much of his bigotry for Gluck, and intolerance for all dramatic music, except that of France.

No praise is too strong for the instrumental music of Germany, in general by the composers so justly celebrated by M. Suard; but when to these we join Emanuel Bach, and the admirable Mozart, and his scholar Beethoven, it seems as if instrumental music, at least, was arrived at its acme of perfection. This extensive empire has likewise produced masters who have equally equalled the most eminent Italian dramatic composers of the last century; such as Hasel, Taffi, Graun, J. C. Bach, Millesseweeck, Gluck, Naumann, &c., without mentioning the orators, and maestres of Haydn, and the dramatic music of Mozart, perhaps the best of its kind. So that Germany may be said frequently to vie with Italy itself in its own best style of composition.

GERMAN, in Geography, a township of America, in Fayette county, Pennsylvania; containing 1855 inhabitants.

GERMAN Flats, the chief and post-town of Herkemer county, in the state of New York, situated on the N. side of Mohawk river, opposite to Herkemer, and 22 miles E. of Whitesville; and containing 1637 inhabitants.

GERMAN Town, a town of New York, in Columbia county, containing 516 inhabitants. — Also, a town of Philadelphia county, in the state of Pennsylvania, seven miles N. of the city of Philadelphia. It is a corporation, containing chiefly of High and Low Dutch, and contains about 200 houses, chiefly of stone, some of which are large and elegant, forming one street about two miles in length. The public buildings are a Presbyterian, German-Calvinist and Lutheran church, a Friends' meeting-house, and an academy. Here is a considerable manufacture of flockings, made of cotton, thread, and worsted. This is an ancient town, pleasantly situated, and by its vicinity to the metropolis, well adapted for manufactures. The principal congregation of the Methodists, and the parent of that in America, subsists in this place. A severe battle was fought here between the English and Americans in October 1777. — Also, a post-town, and capital of Stokes county, N. Carolina, situated near the town fork of Dan river, and containing a court-house, gaol, and about 100 houses; 528 miles S.W. by S. of Philadelphia. — Also, the chief town of Hyde county, in Newbern district, N. Carolina. — Also, a town of

Bracken county, in Kentucky, containing 81 inhabitants — to, a town of the state of New Jersey; 17 miles W.S.W. of Morristown.

GERMANTOWN, in Botany. See TUSCERUS.

GERMAMER, in the Materia Medica. The common germander, teucrium chamissoi, of the chamerdy minor genus, is a native of England, and flowers in June and July. The leaves and tops have a moderately bitter taste, accompanied with a weak aromatic flavour, diminished by drying the plant. They give out their virtues both to water and spirituous酒tinctures. The chamerdy has been chiefly esteemed in the character of a mild aperient and corroboration; it is recommended in uterine obstructions, interrupting fevers, and in the rheumatism and gout. The good effects of the chamerdy in the latter disorder are recorded by different authors who have employed it in various forms and combinations, of which the celebrated antispirite, or Portland powder, is an instance. According to Murray the virtues of this plant should be nearly allied to those of Marrubium; and therefore it promises to be useful in anaphylactic affections, coughs, and infarctions of the lungs. The virtues, however, are somewhat problematical.

The Marum germander, or Syrian herb mastic, teucrium marum, flowers from July till September. It is a native of Spain, and is said to grow plentifully also in Greece, Egypt, Crete, and Syria. It was first cultivated in England by Parkinson in 1649, and is now to be found in many of our gardens. The leaves and younger branches of marum, when recent, emit, on being rubbed between the fingers, a volatile aromatic smell, which excites sneezing, but to the taste they are bitterish, with a sensation of heat and acrimony. According to Lewis (Med. Hort.) it loses but little of its pungency by being dried and serves out its active matter partially to water, and completely to rectified spirits. Dried with the former, it yields a highly pungent, subtile, volatile, essential oil, similar to that of coryn-gratia, but stronger and of less perfidious pungency. Rectified spirit carries off, in the impregnation of the spirituous tincture, a considerable share of the smell and pungency of the marum, but leaves much the greatest part concentrated in the extract; which, on being tailed, fills the mouth with a durable, penetrating, glowing warmth. Wedelius strongly recommends this plant as an important remedy in many diseases requiring medicines of a stimulant, aromatic, and deodrant quality; and instances of its efficacious use have been adduced by Linneus, Rofenlein, and Borgius. At present, however, marum is here chiefly used as an orrhine, and is an ingredient in the "publis cactiv compositus" of the London Pharmacopoeia. The dose of the powdered leaves is from a scruple to half a dram, which Murray advises to be given in wine.

The water germander, teucrium foerdium, is a native of England, in marshy situations, and flowers in July and August. The leaves of foerdium have a smell resembling that of garlick, whence its name; and to the taste they are bitter, and slightly pungent. When moderately and newly dried, they give out, says Lewis (Med. Hort.) their smell and taste both to water and to rectified spirits. In dilution their peculiar flavour abides, with weak, but the impression of the distilled fluid is not strong, nor could any essential oil be obtained onsubmitting to the operation of several pounds of the herb. The ancients attributed to foerdium a peculiar antispirent and alephaphrnic power, and it had for many ages the character of being remarkably efficacious in all putridal and putrid diseases. With this view it entered into the composition of several official medicines, that were supposed to be antidotes to various kinds of poisons and infecccions;
fections. But, notwithstanding this celebrity, it appears to be a very insignificant article of the Materia Medica, and is therefore very justly fallen into disuse. Bergius, however, states its virtue to be "antiputredinosa, tonica, diuretica, diuretica, relutens," and some others recommend it to be employed externally in antipticc eataplasms and fomentations. Woodville Mat. Bot.

**GERMANDER, Rock.** See *Veronica.*

**GERMANEA, in Botany,* named by Lamark after Mont. de Saint-Germain, a great admirer and cultivator of plants. Lamark Díct. v. 2. 499. Illuftr. t 514. Jufl. 116. 449. See *Plectranthius,* which latter appellation, given by L. Heritier, who was partial tother to M. de Saint-Germain nor his admirers, has been universally adopted.

**GERMANIA, in Geography,* a polls-town of Culpepper county, in Virginia; 82 miles from Washington.

**GERMANICIA, in Ancient Geography,* a town of Afa, situated on a plain between mount Taurus and mount Amansos, on the bank of a small river which ran into the Tyrannus, W. of the town.

**GERMANICOPOLIS,* a town of Ethunya, near the Propontide, called by Pliny Helgas and Boos-Cate — Alfo, a town of Paphlagonia, called Gangra. — Alfo, a town of Hauria.

**GERMANICUS, Caesar,* in Biography, grand-nephew of Augustus, nephew of Tiberius, and grandson of Livia. When Augustus adopted Tiberius, he obliged him to adopt Germanicus, who thus, according to the Roman law, stood in the filial relation to them both. Germanicus married Agrippina, grand-daughter of Augustus, a lady not more illustrious for her rank than her virtues, and he himself grew up in the general affection of the public, on account of the excellence of his temper, and the mildness of his disposition, and was denominated the "delight of the Roman people." Germanicus was very learned and eloquent, and, at an early age, he became illustrious in warfare, and was raised to the most important offices of the state. When Augustus died, he was engaged in a war in Germany, and the affection of the soldiers unanimously saluted him emperor. He refused the honour, and then appeased the tumult which his indifference to the rank had occasioned. He continued his exploits in Germany, and defeated the celebrated Arminius, and upon his return was rewarded with a triumph. The Germans fought with the greatest bravery, but were at length obliged to yield to superior discipline and generalship. The concluding battle was attended with great slaughter to the Germans, and gave the Roman commander occasion to raise a trophy with this inscription, "The nations between the Rhine and the Elbe subdued by the army of Tiberius Caesar," but this subjugation was only a temporary cessation of the contest, and, upon some defeat experienced by the Romans from the elements, the Germans renewed their attack, which afforded Germanicus an opportunity of acquiring new laurels, and he expected to have made an entire conquest of Germany, but the emperor, jealous of his successes, recalled him, with many compliments upon his past conduct, and the prospect of a second confute. On his return he was honored with another triumph, which was celebrated with extraordinary magnificence. That part of the spectacle which was most affecting to the Roman people, was the harangue of the victor, filled with his three sons and two daughters. Germanicus was soon sent into the East to quell some disturbances there; the powers entrusted to him on this occasion were very extensive, but the auspicious Tiberius had placed Pife as a spy and check on the illustrious general. Germanicus entered upon his second confutehip, having the emperor for his colleague; he visited Athens, and was received in that city with all the adulation usually practised by the inhabitants. He then failed to Euboea and Lesbos, thence he touched upon Thrace, and crowning into Asia, viewed the ruins of Troy, and consoluted the oracle at Colophon. Pife hastily followed him, and after terrifying the Athenians with a severe harangue, and throwing out inflations against Germanicus, embarked for Rhodes, where he would have perished had he not have been favored by the humane affiffance of the prince, whom he overtook there. Germanicus now proceeded to execute his commission. He placed the banner on the head of Zeno, son of the king of Pontus, an ally of the Romans. He then reduced Cappadocia and other places to the state of Roman provinces, and in the ensuing year he made a progress into Egypt, and viewed every thing that was deserving of notice in the country, at the same time opening the public granaries to the people, who were suffering under a scarcity. Upon his return from Egypt to Syria, he found that Pife had abrogated every regulation which he had established among the legions, and in the cities, and his indignation at this behaviour widened the breach between them. At this time Germanicus was attacked with a disease which afterwards proved fatal, and which was imputed to the effects of poison, but some of our best historians, having impartially examined the collateral facts, do not think the evidence sufficient to justify the allegation. Germanicus himself had no doubt that he was the victim of the malignity of Pifo, and, in his last moments, conjured his friends to prosecute with the utmost vigour the authors of his death. He died at Ephesius, near Antioch, in the year 19, in the thirty-fourth year of his age. His death was the subject of universal lamentation at Rome. Every other concern was forgotten, and the people, without waiting for an order from the magistrates, forsook the forum, flung up their houses, and affirmed every token of universal sorrow. A profusion of honours was decreed to his memory, and even foreign princes and nations joined their testimonies of esteem and regret. He had been highly esteemed not only for his military accomplishments, but also for his learning, humanity, and extensive benevolence. In the midst of war he devoted some moments to study, and he favoured the world with two Greek comedies, some epigrams, and a translation of Aratus in Latin verse. Tacitus, Suetonius, and Univer. Hist.

**GERMANO,** in Geography, a town of Naples, in La- vora, containing four parishes, four convents, and about 800 perions. Near this place are the ruins of "Custium," destroyed by Theodoric, king of the Goths. The town is situated 43 miles N. N. W. of Naples. N. lat. 41° 33'. E. long. 13° 45'. — Alfo, a town of the duchy of Urbino; 13 miles E. N. E. of Urbino. — Alfo, a town of France, in the department of the Sefa, late in the lordship of Verelli; four miles E. of St. Ina. — Alfo, a town on the W. coast of the island of Porto Rico. N. lat. 18° 20'. W. long. 67° 40'.

**GERMANS,** so called from the name of their country, in Ecclesiastical History, one of the sects of rigid anabaptists into which the Flemingians were divided; the other two being denominated Flandrians and Friedlanders. See Flemingians.

**GERMANS, St. or Germanus,* in Geography, a borough town of Cornwall, England, was, during the Anglo-Saxon era, a bishop's see. In 981, the Cornish bishop removed his see from Bodmin to this place; but bishop Levisius translated it to Crediton, in Devonshire, in 1049. King Athelstan founded a priory for secular canons here; to which the cathedral buildings were annexed. Of these nothing remains
In ancient times Germany was inhabited by various nations, which the Romans, with whom they waged war for some centuries, considered as Gauls. Of these the Helvetii, Boii, Tecteophagi, and Gothi (see Gorbits, &c.), and the Teutones, who dwelt in the Simus-Godanum near the Cimbri, were among the first that crossed the Rhine, and applied to themselves the name of Germani, probably from the Teutonic word Gier or Guer, a sword, alliterating, as it were, their quality of warriors. The word Guer or Gier, in the Italian and French, which is not of Latin origin, appears to confirm this etymology. (See the history of the ancient Germans in the sequel of this article.) It is also from the Teutones that, in the German language, the country is called Teufeland, and latterly Deutschland. (See Teutones.) The French gave it the name of Allemagne from the Allemanni, one of the German nations. (See Alemani.)

In the middle age the northern and north-eastern regions of Germany got an accession of population from the Vandals and Slavonians; and towards the end of the seventeenth century, some parts of Germany received an inconsiderable increase of inhabitants, by some thousands of French protestant refugees, who left France after the revocation of the edict of Nantes.

Buoching states the extent of Germany at 13,724 German square miles, 15 to a degree; but professor Crome of Gieffen, including Silesia, states it at 12,796 German square miles, and its circumference at 500 German miles.

Germany is bounded on the north by the river Eider, and the canal of Holstein, which separate it from Denmark, and by the Baltic sea; on the east by Prussia, Poland, Hungary, Slavonia, and Croatia; on the south by the gulf of Venice, Italy, and Switzerland; and on the west by the Rhine and the North sea.

Maximilian, grandfather to Charles V., divided Germany into ten circles, and this division was confirmed in the diet of Nuremberg in 1552; but the circle of Burgundy, which contained the seventeen provinces of the Low Countries, having been detached from the empire, it latterly contained only nine circles, viz.

1. The Circle of Austria, which comprised, 1, the arch-duchy of Austria proper; 2, the duchy of Silesia; 3, the duchy of Carinthia; 4, the duchy of Carniola; 5, the Austrian Frioul; 6, the Lithuanian; 7, the territory of Triest and Tiume; 8, the county of Tyrol; 9, the bishopric of Trent; 10, the bishopric of Brixen; 11, the commandaries of the Teutonic order in Austria, and on the Etzch; and 12, the lordship of Trapez, belonging to the prince of Dietrichstein.

II. The Circle of Westphalia, which comprised, 1, the bishopric of Munster; 2, the bishopric of Osnabruck; 3, the bishopric of Paderborn; 4, the bishopric of Liége; 5, the abbot of Corvey; 6, that of Stablo and Münster; 7, that of Werden; 8, that of Cornelius Muller; 9, that of Essen; 10, that of Thorn; 11, that of Havelburg; 12, the duchy of Cleves; 13, the duchy of Juliers; 14, the duchy of Berg; 15, the principality of Münster; 16, the principality of Verden; 17, the principality of Nisian; 18, the principality of East Friedland; 19, the principality of More; 20, the duchy of Oldenburg; 21, the county of Mark; 22, the county of Ravensburg; 23, the county of Schauenburg; 24, the county of Lippe; 25, the county of Steinfurt; 26, the counties of Tecklenburg and Lingern; 27, the county of Bentheim; 28, the counties of Münster and Liége; 29, the county of Hoya; 30, the county of Diepholz; 31, the county of Wieda.
111. The Circle of the Lower Rhine, or the electoral circle of the Rhine, which comprised, 1, the electorate of Mayence or Mentz; 2, the electorate of Trèves; 3, the electorate of Cologne; 4, the palatinate of the Rhine; 5, the principality of Aremberg; 6, the county of Lower Lorraine; 7, the burggrave of Reineck; 8, the county or lordship of Heidelberg; 9, the commandry of the Teutonic order Coblenze. The prince of Thurn and Taxis was a member of this circle, without having any territorial possessions in it.

114. The Circle of the Upper Rhine, which comprised, 1, the bishopric of Worms; 2, the bishopric of Speyer; 3, that of Strasbourg; 4, that of Bale or Basel; 5, that of Fulda; 6, the principality of Heiligenheim; 7, the abbey of Prüm; 8, the abbey of Weißenburg; 9, that of Odenheim; 10, the landgrave of Heidelberg; 11, the principality of Hersfeld; 12, the county of Katzenellenbogen; 13, the county of Hanau-Münzenberg; 14, that of Hanau-Lichtenberg; 15, the principality of Simmern; 16, the principality of Lautern; 17, that of Veldenz; 18, the principality of Deux Ponts; 19, the county of Spornheim; 20, the principality of Salm; 21, the principality of Naiffau; 22, the principality of Waldeck; 23, the county of Solms; 24, the county of Königstein; 25, the county of Upper Hohenheim; 26, the possession of the Wald or Wild, or Rau Graven and Rhine Graves, (in Latin, Comites Saltuarii, Forclhari, Silicetres et Hirtifici, counts of Grumbach, Stein, and Dunaun; 27, the county of Leiningen; 28, the county of Wittgenstein; 29, the county of Falkenstein; 30, that of Kirchhingen; 31, that of Wartenberg; 32, the lordships of Biebrich, Dachtul, and Ohllbrück; 33, the free imperial cities of Worms, Speyer, Frankfort on the Maine, Friedberg, and Wetzlar; 34, the imperial borough of Friedberg; 35, the imperial villages of Münzfelden, Soltitzbach, and Soden.

115. The Circle of Swabia, which comprised, 1, the bishopric of Constance; 2, the bishopric of Augsburg; 3, the abbey of Eichstät; 4, the abbey of Kempen; 5, the county of Wirtemberg and Teck; 6, the margraviate of Baden; 7, the principality of Hohenzollern; 8, the abbey of Landau; 9, that of Buchau; 10, the principality of Fürstenberg; 11, the county of Oettingen; 12, the principality of Klettgau; 13, the principality of Lichtenheim; 14, that of Friedberg-Schellenberg; 15, the abbey of Salm-Aulich; 16, the abbey of Wemgarten; 17, that of Offenhauen; 18, that of Eichlingen; 19, that of Yrlce; 20, that of Urfach; 21, that of Raitersheim; 22, that of Königstein; 23, that of Rott; 24, the abbey of Weißenburg; 25, that of Schaffenrod; 26, that of Marchtal; 27, the abbey of Peterhausen; 28, the abbey of Wetterhausen; 29, that of Zwingelte; 30, that of Gengenbach; 31, the county of Hohenlohe; 32, that of Guttenzell; 33, that of Rotunfen; 34, the county of Windisch; 35, that of Bödeheim; 36, the commandery of Alschhausen; 37, the

landgrave of Stühlingen; 38, the landgrave of Baar; 39, the county of Truchseß-Waldburg; 40, the county of Königlieg; 41, that of Eberlein; 42, that of Fugger; 43, that of Hohen-embge; 44, that of Hohen-Gerlofs; 45, the county of Neipperg; 46, the county of Bondorf; 47, the lordships of Wiibenburg, Hadun, Moekirch, Tannenberg and Argen, Mindelheim and Schwabach, Gündelingen, Julingen, Eglolf, Thannhausen, Ettlingen; 48, the free imperial cities of Augsburg, Ulm, Eningen, Reutlingen, Nördlingen, Halle, Ueberlingen, Rothweil, Heilbronn, Günzburg, Mönningingen, Linzai, Dürkheim, Biberach, Ravensburg, Kempen, Kaffeburen, Welt, Wangaug, Ynsl, Leutkirch, Wimpfen, Gengen, Pfalzendorf, Buchhorn, Aalen, Bopfigen Dietrich, Offenburg, Gengenbach, Zell on the Hammerbach; 49, the imperial village of Alschhausen.

116. The Circle of Bavaria, which comprised, 1, the archbishopric of Salzburg; 2, the bishopric of Friesingen; 3, the bishopric of Ratisbon; 4, the bishopric of Paffau; 5, the principality of Berchtesgaden; 6, the abbey of St. Emmeram in Ratibon; 7, that of Halberstadt; 8, the lordships of Upper Mühlberg in the same place; 9, the duchy of Bavaria; 10, the Upper Palatinate; 11, the principality of Neuburg; 12, the principality of Sultzbach; 13, the landgrave of Leuchtenberg; 14, the principality of Steinheim; 15, the county of Ingel; 16, the county of Ortenburg; 17, the lordships of Einfelden, Salzburg, Pfyrbaum, Hofen, and Bieteck; 18, the free imperial city of Ratibon.

117. The Circle of Franconia, which comprised, 1, the bishopric of Würzburg; 2, the bishopric of Würzburg; 3, the bishopric of Eichstät; 4, the commandery of the Teutonic order of Mergentheim; 5, the principality of Coblenz, or Bayreuth; 6, the principality of Onolfschaff; 7, the archbishopric of Spire, of the duchy of Coblenz; 8, that of Würzburg; 9, the county of Hohenlohe; 10, the county of Caull; 11, the county of Wertheim; 12, that of Rieneck; 13, that of Erbach; 14, the lordships of Lorrain, Seinfheim, Reichellberg, Württemberg, and Hauen; 15, the free imperial cities of Nuremberg, Rothenburg, Windheim, Schwaben, and Würzburg; 16, the imperial villages of Goethein and Schaffau.

118. The Circle of Upper Saxe, which comprised, 1, the duchy of Pomerania; 2, the electorate of Brandenburg; 3, the electorate of Saxony; 4, the duchy of Saxe-Weimar; 5, the duchy of Saxe-Gotha; 6, that of Saxe-Coburg; 7, that of Saxe-Meiningen; 8, that of Saxe-Hildburghhausen; 9, the abbey of Meissen; 10, that of Naumburg-Zeitz; 11, the principality of Altenburg; 12, the principality of Querfurt; 13, the principality of Anhalt; 14, the abbey of Quedlinburg; 15, the abbey of Walkenried; 16, the principality of Schwartzbich; 17, the county of Mansfeld; 18, the county of Stolberg and Wernigerode; 19, the county of Darby; 20, that of Hofstein; 21, the principality of Hatzfeld; 22, the county of Reus; 23, the county of Schönburg.

119. The Circle of Lower Saxony, which comprised, 1, the bishopric of Halberstadt; 2, that of Lubeck; 3, the abbey of Ganderheim; 4, the duchy of Magdeburg; 5, the principality of Halberstadt; 6, the duchy of Bremen; 7, the principality of Celle; 8, the principality of Götzenhagen; 9, the principality of Calenberg; 10, the duchy of Saxe-Lauenburg; 11, the duchy of Wolfsbitter; 12, the principality of Blankenburg; 13, the duchy of Holstein; 14, the duchy of Mecklenburg; 15, the
the principality of Schwerin; 16, the principality of Ratzeburg; 17, the county of Ranzau; 18, the free imperial cities of Luebeck, Goslar, Muhlhausen, Nordhauen, Hamburg, and Bremen.

The following countries, without forming part of any of the nine circles, were likewise considered as belonging to the German empire; viz., 1, the kingdom of Bohemia; 2, the margravate of Moravia; 3, the margravate of Upper Lusatia; 4, that of Lower Lusatia; 5, the duchy of Silesia; 6, the county of Montbellard; 7, the three circles of the immediate Knights of the Empire, in Szuibia, Franconia, and on the Rhine; 8, the lordships of Aich and Wafflerburg, the convent of Schollenthal, the burggraviate of Freudenberg, the barony of Hordgen, the abbey of Cappenberg, that of Elten, the lordship of Rheda, the abbey of Burcheid, the lordship of Jever, the barony of Kniphauzen, the lordships of Dyk, Meckernich, Schuamn, Wylre, Richold, Stein, Dreyfs, Landkron, Rhade, Saffenberg, Schaumburg, Oberstein, the county of Homburgh, and the barony of Schauen. The German empire had also several fiefs in Italy.

The climate and temperature of Germany must in general be acknowledged to be temperate, yet it is considerably milder in the southern than in the northern parts, where the winter is sometimes extremely severe, and of long duration. The air, however, is everywhere serene and healthy, except in a few low marshy places towards the North sea. The wine thrives, and yields excellent wine, in all the southern parts. The falsity of the climate may likewise be inferred from the longevity of the inhabitants, some of whom arrive to a very great age.

There is perhaps no country in Europe in which the soil varies more than in Germany. Sandy plains and barren heaths predominate in the north-east, and swamps and marshes in the north-west; but some of the interior and southern parts have an uncommonly fertile soil, and great attention is generally paid to its improvement. The south and the south-east side is the most mountainous. Bohemia is separated from Szuibia by the Rieben Geburgh, or the Giants' mountains. Towards Hungary are the Carpathian mountains; towards Italy the Alps. In the interior parts are the Schwarzwald, (black forest,) the Rauhe Alb, the Erzgebirge, the Fichtelberg, the Harz, or Hereymian forest, whose highest summit, the Brocken, is only 3,580 feet above the level of the Mediterranean sea. In ancient times Germany was covered with forests, chiefly of oak, birch, pine, fir, larch, and ash trees. Though they have been considerably thinned, and immense tracts of them converted into tillage, there are yet some very large woods, as the Speilart, the Schwarzwald, the Hartzwald, and the Thuringerwald.

The extent of sea-coal on the North sea is not much above 150 English miles, and on the Baltic about 500 English miles. The principal lakes are the Boden see, or lake of Constance, in Szuibia, which forms one of the boundaries towards Switzerland; the Chiem see, in Bavaria; the Grafler see, in Austria; the lakes of Damascus, Neuwarp, Madsen, and Wilm, in Pomerania; those of Werbelrus, Uckersee, Pareklin, Schwiiduch and Rappin, in Brandenburg; the Dammer see, in the county of Diepholz, besides several smaller ones in Mecklenburg and other parts of the country.

But it is chiefly the great number of rivers, by which Germany is intersected in various directions, that give it immense advantages for trade. It counts five hundred and twenty rivers in all; sixty navigable to a great length, and six, viz. the Danube, the Rhine, the Mayne, the Weser, the Elbe, and the Oder, ranking among the largest and most noble rivers of Europe.

The number of mineral springs and baths exceeds one thousand; the most famous are Carlsbad and Egra, in Bohemia; Wimbachbrunn, in Szuibia; Toplitz, in Austria; Heilbron, in Bavaria; Witten and Salters, in the circle of the Upper Rhine; Freyenwalde, in Brandenburg; Dobbe- ran, in Mecklenburg; Laukhedt, in Saxony; and Pymont, in Westphalia.

As almost all climates, or at least all temperatures and foils, are to be met with in Germany, it abounds in almost all productions of nature and their varieties, and chiefly in all kinds of corn; such as excellent quality, hemp, hops, tobacco, madders, saffron, rape-seed, rhabar, excellent garden vegetables and orchard fruits; wine, in greatest perfection on the banks of the Rhine, Mayne, Moselle, and Neckar. The agriculture of Germany has been considerably improved of late by the efforts of Mr. Thaer and other patriotic writers. In the rearing of cattle and sheep Germany is, however, greatly deficient. The breed of horses, except in Mecklenburg, East Friesland, Oldenburg, Holstein, and some parts of Hanover and Wittenberg, is very indifferent. The number of oxen is not sufficient either for agricultural purposes or for consumption. The best breed is in East Friesland, Oldenburg, and Holstein. The number of sheep does not exceed thirteen or fourteen millions. The Spanish breed has been naturalized in some parts of the Prussian and Saxon dominions. The breed of hogs is much neglected; that of goats is encouraged in the mountainous parts, where they also rear ailes and mules. The forests are cleared with wild boars, hogs, deer, and hares. Poultry is abundant. Salted and smoked goole, and goose-quills, are exported from Mecklenburg and Pomerania. Some parts of Germany are remarkable for fine larks and thrushes, of a delicious flavour. Others abound with flogging birds, particularly Canary birds and goldencheeks, which are exported to almost every country of Europe. Bees are less attended to than in ancient times. Silkworms are reared with particular care in some of the southern, and even northern districts.

Of the mineral productions of Germany, gold forms the most inconsiderable part, small particles of it are found in the Rhine, the Danube, the Elbe, and the Saale. Silver is more plentiful; its annual produce exceeds 200,000 marks, that of copper amounts to 100,000 cwt. The supply of tin from the mines is sufficient for home consumption. Iron of a very good quality, lead, quicksilver, coal, salt, asphalt, and mountainous parts, where they also rear ailes and mules. The forests are cleared with wild boars, hogs, deer, and hares. Poultry is abundant. Salted and smoked goole, and goose-quills, are exported from Mecklenburg and Pomerania. Some parts of Germany are remarkable for fine larks and thrushes, of a delicious flavour. Others abound with flogging birds, particularly Canary birds and goldencheeks, which are exported to almost every country of Europe. Bees are less attended to than in ancient times. Silkworms are reared with particular care in some of the southern, and even northern districts.

Silkworms are reared with particular care in some of the southern, and even northern districts.

The principal manufactures of Germany are those of linen and woollen cloth, cotton, thread, lace, china, hardware, inferior to none but the English, gials, tobacco and snuff, writing paper, soap, wax, toys and trinkets, and silks, but not equal to the French. Manufactures flourish most in the Austrian and Prussian dominions, in Saxony, in the present kingdom of Westphalia, in the grand duchy of Berg, &c. The towns most remarkable for extensive manufactures are Altona, Augsburg, Berlin, Bronsvick, Bremen, Caffel, Cet. Cc 2 Chemnitz.
Chernitz, Deflau, Dresden, Eisenach, Erfurt, Erlangen,
Francfort on the Mayne, Göttingen, Gottha, Hamburg,
Hanau, Hanover, Harrenforth, Hof, Leipsic,
Lubeck, Magdeburg, Meissen, Neufstadt on the Dicke, Newfeld,
Nurnberg, Offenbach, Plauen, Quedlinburgh, Stuttgart,
Ulm, and Zwickau.

Situated almost in the centre of Europe, bounded by the
Baltic and North sea, and intersected by many large rivers,
Germany has enjoyed, till very lately, a most extensive com-
merce. Its principal ports are Hamburgh, Altona, Kiel,
Lubeck, Wismar, Roflock, Stralsund, Stettin, Emden,
Bremen. Inland towns of great trade are Brunswick, Mag-
deburg, Leipsic, Naumburg, Francfort on the Mayne, and
Francfort on the Oder, Vienna, Augsburg, Nurnberg,
Breslau, and Ulm. The principal articles of exportation are
timber, corn, fruit, wine, tobacco, madders, coal, flax, al-
potash, horses, oxen, salt and smoked meat, butter, cheese,
honey, wax, leather, wool, cotton yarn, linen cloth to the
amount of six millions flerling, linen yarn, thread lace, cotton
fluffs, hardware, lead, copper, brass, quicksilver, china,
carthen-ware, mirrors, glass, wooden toys and trinkets, &c.
Germany imports corn, oxen, and horses chiefly from Hun-
gary, Poland, and Denmark, hops from Hungary, those
from Ireland and Holland, flax and cotton, all sorts of co-
lonial produce, wine and fruit, silk and cotton fluffs,
paper, jewellery and trinkets. It carries on a most important
trade with European Turkey, from whence it gets by land
as far as Semlin, and from thence upon the Danube by way
of Vienna, an immense quantity of raw cotton, which is
distributed all over the north of Europe, Germany and
Switzerland. As it has to pay annually from three to four
millions of piasters in hard cash to the Turks, these money
transactions are carried on by means of the bankers of Vienna.
The principal insurance companies are at Hamburgh, Lu-
beck, and Bremen. Weights, measures, and coins differed in
every petty principality of Germany, and this circumstance
was one of the disadvantages which travellers at least
experienced from that number of free cities and small states for
which Germany was particularly remarkable. It is true,
as has been justly observed by the intelligent author of an
essay on the Reformation of Luther, that all these cities and
principalties of moderate extent had their principle of life
active, peculiar, and independent. Each prided itself on making
industry, sciences and arts flourish in its little capital.

By the treaties of Passau in 1552, of Augsburg in 1555,
and of Mantsl in 1548, the Roman Catholic, Lutheran, and
reformed religion, were acknowledged as dominant in Ger-
many: but all other sects enjoyed a complete toleration, and
the number of Jews in some parts is very considerable.

According to Mr. Charles Villier's view of the present
state of ancient literature and history in Germany, in his re-
port to the third clafs of the French institute, the German
literati possess a great facility in entering into the spirit of
nations and of ages, different from those of the present day,
and are eminently successful in archeological researches, and
in the interpretation and translation of the ancients, par-
cularly of the Greeks, perhaps on account of some secret affinity
between the two nations, as the analogy of the two languages
seems to indicate. But if any species of literary production
can be said to belong to Germany, almost exclusively, it is
the history of literature. The German literary and critical
journals, especially those published at Jena, Halle, Leipzick,
and Göttingen, rank among the best in Europe. Before
the revolutionary wars, the number of authors exceeded
7000. Their literary productions found a ready market at
the two fairs of Leipzick in the spring and autumn of every
year. The number of new books published at those fairs
was rarely under 4000: but since the fall of Prussia, in 1807,
it has never exceeded 1500. Two hundred German, and
about thirty foreign book-sellers, used to meet at Leipzick,
to barter their respective publications; the amount of these
exchanges was generally above 200,000 flerling. Anciently
German authors wrote most of their works in Latin.
In the beginning of the seventeenth century, there were at
least 400 out of 700 written in that language; towards the
end of the eighteenth century the proportion was only 200
in 2000. Before that period the literary labours of the
Germans were confined to theology, jurisprudence, and bib-
ilical and classical criticism: but during the latter half of the last
century they have been extended to every branch of science
and literature; mineralogy, natural history in general, chemic-
istry, alchemy, and geometry have been cultivated with an
intelligent ardour and perseverance that have been rewarded
with many brilliant discoveries. Statitics, which elucidates
the theoretical tenets of political economy, and furnishes
important materials to the historian and the geographer,
is indebted alike for its origin and its improvement to
the literary industry of the Germans. In metaphysics they
have incurred the reproach of dogmatical obscurity,
and in their dramas and novels they are justly accused
of a delirious affection of morbid sentimentality. But
their epic and tragic poets, and their moral philosophers,
have immortalized themselves by works, which have been
eagerly translated into all the idioms of modern Europe.
The great names of Luther, Kepler, Leibnitz, Haller,
Euler, Moebius, Puffendorf, Pott, Marggraf, Hagedorn,
Lessing, Gleim, Kleist, Heyne, Rahener, Kleopock, Ram-
ler, Gellner, who live in the records of literary fame, must
be added those of Bernoulli, Lambert, Klaflner, Wieland,
Schiller, Gottle, Herder, Zollkoffer, Spalding, Bloch,
Mof, Mendelsohn, Klapproth, von Humboldt, Vols, Holty,
Michaelis, J. A. Eberhard, Von Zach, and many others,
whose merits are as conspicuous as they are generally ac-
knowledged.

The German language is of Teutonic origin, and may be
regarded as a primitive one, as it is the mother tongue of the
Dutch, Flemish, Danish, Swedish, and English languages.
Its dominion extends from the boundaries of Lapland and
Finland, to those of France and Italy. In the middle ages,
the similarity between the idioms derived from the German
was so great, that the German and English millionaries
that went to Sweden, Denmark, and Norway, had no difficulty
in making themselves understood in those countries. The
learned Hume, in his introduction to his Sueo-Gothic Glos-
sary, has also discovered a startling conformity between the old
Teutonic and Persian languages. That which it bears to the
Greek in its construction is not less striking. The dialect
known by the name of Low German, or Low Dutch, is
now diffused in writing, and wholly confined to the vulgar
in the kingdom of Westphalia, in the dukedoms of Mecklen-
brug and Holstein, and in Pomerania: it comes very near the
Dutch. The High German, or High Dutch, has been con-
 siderably improved since Luther's time: it is remarkable
for strength, richness, bold invention, and compound words,
which renders it admirably fit for the higher strains of epic
poetry. The learned dictionaries of Adelung, Eberhard,
and Campe, have served to elucidate the meaning of every
one of its terms, so that it may now be considered as fixed.
It is spoken in its greatest purity in Upper Saxon, part
of Lower Saxon, and on the banks of the Neckar and the
Maine. There are still some traces of the Slavonian lan-
guage left on the shores of the Baltic, in some districts of
Pomerania, in Silesia, Bohemia, and Moravia: but it is dis-
appearing very fast.
No country can boast of more and better institutions for the acquisition of knowledge and science than Germany. Notwithstanding the great extent of territory ceded to France, there are still 30 universities, of which 17 are Protestant, 11 Catholic, and two mixed, viz.: Greifswalde, Jena, Leiden, Wittenberg, Gottingen, Halle, Helmstedt, Kiel, Rostock, Altdorf, Erlangen, Rinteln, Giesenh, Marburg, Stuttgart, Tubingen, Frankfurt on the Oder, are Protestant universities; Bamberg, Witzzburg, Paderborn, Fulda, Dillingen, Freyburg, Inpruck, Vienna, Ingolstadt, Salzburg, and Prague, are Catholic universities; and the two mixed ones are Erfurt and Heidelberg. The oldest of them is that of Prague, which was founded in 1348, and the most modern that of Erlangen, founded in 1743. Most of these learned seminaries, which have furnished the northern regions of Europe with able teachers, are provided with extensive libraries, anatomical theatres, museums of natural history, botanical gardens, and astronomical observatories. The professors are animated with the noble ambition of extending the fame of the university in which they teach by their writings, and as the students pay a liberal fee for their lectures, this opens an honourable and useful competition among the teachers. Every student is at liberty to select what lectures he chooses to hear, and may employ his time as he likes. He has only a severe examination to undergo when he offers himself as a candidate for any situation in the law, administration, or church, or when he wants to take his degree as a doctor in medicine, without which degree he cannot be admitted into any college of physicians. All the other useless scholastic formalities have long since been abrogated.

Besides these universities there is a great number of public or free grammar schools, lyceums, and other learned schools in Germany. The methods of teaching have been considerably improved within the latter half of the eighteenth century, when Bapfelow, profiting by the hints thrown out by J. J. Rousseau, opened the Philanthropinum at Delfau, and set an example of liberal and scientific education, which was soon imitated by men of enlightened views and extensive information. Campe, Villaume, Saltzmann, Trapp, and latterly Pfalzlozzi, have eminently contributed to introduce better modes of instruction. There are also many establishments destined to train young men for particular employments, such as military, mineral, commercial, and even agricultural schools. Females are most educated at home under the eyes of their mothers, who are particularly anxious to guard their daughters against the baneful influence of ladies boarding schools.

The numerous literary societies of all kinds, public libraries, reading clubs, circulating libraries, critical journals, and other means of disseminating and preferring knowledge, afford another proof of the high state of civilization to which most countries of Germany are arrived. The most distinguished of its learned societies are the imperial academy of natural philosophy at Vienna, the royal academy at Berlin, the academies at Cadiz, Erfurt, Gottingen, Hanover, Manheim, Munchen; the agricultural societies at Halle, Leiden, and Holstein. The best public libraries are those of Berlin, Delfau, Gottingen, Gottha, Hanover, Leiden, Manheim, Stuttgart, Weimar, Vienna, and Wolfenbuttel. Though Germany may boast of being the cradle of the art of printing, England and France bear the palm. The generality of German books are printed without titles, with bad types, and on bad paper. A few splendid editions have, however, been attempted at Leiden, and met with merited success. The liberty of the press, which was never general all over Germany, has received its death-blown from the fury which the French government exerceses in every one of its counties, since the peace of Tilsit.

Of the fine arts, music is that in which the Germans excel. They vie with the Italians, and the names of Handel, Bach, Haydn, and Mozart are revered by their rivals. Germany has also produced some good painters and engravers, but few statues and architects. With respect to dancing, it is far behind Italy and France. The principal academies for the encouragement of the fine arts are at Berlin, Delfau, Leiden, Manheim, and Vienna. The most celebrated galleries of pictures are at Delfau, Vienna, Sans Souci, near Potsdam, Dassel, Manheim, and Caffel.

The influence of the arts on the manners of a people is no where more striking than in Germany, where concerts and musical parties, together with dancing, form the chief amusement, and the manners of the middle orders are polite and affable.

Before the peace of Luneville in 1801, the population of Germany was rated at 27 millions of inhabitants; but as it lost 3,795,000 individuals, though the cession of the countries situated on the left shore of the Rhine, its present population is very little above 23 millions.

The history of Germany in its ancient state, its gradual advancement towards extent of territory and dominion, and its recent decline and fall, presents to our notice a subject that is in a variety of respects peculiarly interesting. The western monarchy of Rome was first refounded, then invaded, and at length overturned by the warlike inhabitants of Germany; and it was from the woods of this country that the most civilized nations of Europe issued; and we may still distinguish in the rude institutions of these barbarians the original principles of our laws and manners. Ancient Germany, excluding from its independent limits the provinces westward of the Rhine which had submitted to the Roman yoke, extended itself over a third part of Europe. Almost the whole of modern Germany, Denmark, Norway, Sweden, Prussia, Livonia, Prussia, and the greater part of Poland, were peopled by the various tribes of one great nation, whose complexion, manners, and language denoted a common origin, and preferred a flinking resemblance. On the west, ancient Germany was divided by the Rhine from the Gallic, and on the south by the Danube, from the Illyrian provinces of the empire. A ridge of hills, rising from the Danube, and called the Carpathian mountains, covered Germany on the side of Dacia or Hungary. The eastern frontier was faintly marked by the mutual fears of the Germans and the Sarmatians, and was often confounded by the mixture of warriors and confederating tribes of the two nations. Such was also the case with respect to the Gauls on the west, where it is still more difficult to fix their boundaries on account of their constant fluctuation. In the remote darkness of the north, the ancients imperfectly descried a frozen ocean, that lay beyond the Baltic sea, and beyond the peninsula, or islands of Sarmatia. But their nearest northern limit was the Hercynian forest, at that time supposed to be impenetrable. It appears from authentic documents that the climate of ancient Germany was much colder than that of the country in its more modern state. For the evidence of the fact, and the explanation of it, we refer to the article CLIMATE, where the reader will also find some reflections on the influence which variety of climates is supposed to have on the minds and bodies of the different inhabitants of the globe. The keen air of Germany contributed, without doubt, towards forming the large and masculine limbs of the natives, who were, in general, of a more lofty stature than the people of the south, gave them a kind of strength better adapted to violent exertions than to patient labour, and inspired them with
with constitutional bravery, which is the result of nerves and spirits. "In hos artus, (fays Tacitus, Germania, iii. 20.) in his corpore, qua manumur, excemens." The severity of a winter campaign, that chilled the courage of the Roman troops, was fearfully felt by those hardy children of the north, who, in their turn, were unable to resist the summer heats, and disdosed away in languor and ficknifs, under the beams of an Italian sun.

As to the origin of the Germans, although we cannot allow with Tacitus, that they were "Indigena," or natives of the feil, yet we must admit that ancient Germany was not peopled by any foreign colonies, already formed into a political society; but the name and nation received their existence, as we have already observed in the preceding of this article, from the gradual union of some wandering barbarians, probably of the same nation with the Celts and Gauls, and both, perhaps, defended from the ancient Goths, or descendants of Homer, the eldest son of Japhet. (See Dispersion of Mankind.) The Germans, however, were very much intermixed with the old Scythians and Sarmatians, on that side which joined their territories, and particularly between the two great rivers, Rhine and Danube; and they, without doubt, had adopted many of their customs, as well as intermingled some portion of their language with their own; but in all other parts of Germany, we find such an exact conformity in their religion, laws, customs and languages, as affords a very strong presumption that they were defcaled from the same ancient stock with the Celts or Gauls, and that they came by gradual and successive migrations from Asia. (See Celtica.)

How this country came to be denominate Germany, and whence its inhabitants derived the appellation of Germans, it is not easy to determine. The most probable conjecture is, that they were so called, either from their affinity to the Celts, or from the Celtic words "ghar man," a warrior like man; but this was not their original name, any more than the appellations of "Tentones" or "Allemanii," by which, as we have already observed, they were occasionally denominate. This name was of a more modern date, and seems to have had its rise on the other side of the Rhine, when the Cernufts, Eburonese, Carabin, and Pannonian crossed that river, after the example of some others of their countrymen, and settled in Gaul. Thence, it seems, were the first to whom the appellation of Germans was given, and which, therefore, extended no farther than the Rhinenth here on the Gallic side, but soon after passed over to the other, and became common to other people of the same language and customs, till at length it became the general name of the whole nation, and the country was called from them, Germania or Germany.

Whatever may be supposed to be the remote origin of the German tribes, they appear to have been in a savage and uncivilized state on their first settlement in this country. The account given of the country itself by Cæsar and Tacitus is so unfavorable, that it seems to be almost incredible, that a brave nation, for such we must allow the ancient Germans to have been, would have been contented to remain in it, when they were destitute of neither strength nor courage to have forced their way into others more pleasant and fruitful. These ancient historians describe it as wholly barren and uncultivated; and even its variety of soil and climate added to the horror of it, from the dreadful forests, putrid and insalubrious bogs, the inclemency of its winds, dampness of its seas, lakes, and rivers, and flaterity of its foil. The uncivilized state of the ancient Germans may be inferred from the account given of them by Tacitus; for in his time they were unacquainted with the use of letters (German, ii. 19); and the use of letters is the principal circumstance that distinguishes civilized people from a herd of Savages incapable of knowledge or reflection.

Of the useful and agreeable arts of life the ancient Germans were wretchedly destitute. Modern Germany is said to contain about 2,350 walled towns, whereas, in a much wider extent of country, the geographer Ptolemy could discover no more than ninety places, which he describes with the name of cities, though, according to our ideas, they would not deserve that splendid title. We can only suppose them to have been rude fortifications, constructed in the centre of the woods, and designed to secure the women, children, and cattle, whilst the warriors of the tribe marched out to repel a sudden invasion. Such is the account given of them by Cæsar; and Tacitus affirms that the ancient Germans had no cities. Even in their hamlets or villages they did not build their houses contiguous to each other. They considered it as a badge of servitude to be obliged to dwell in a city surrounded with walls. Each barbarian fixed his independent dwelling on the spot to which a plain, a wood, or a stream of fresh water had induced him to give the preference. Neither stone, nor brick, nor tiles, were employed in these slight habitations. They were, indeed, no more than low huts of a circular figure, built of rough timber, thatchted with straw, and placed at the top to leave a free passage for the smoke. That these confidered cities as places of confinement rather than of security, appears from the following circumstance: when one of their tribes had shaken off the Roman yoke, their countrymen required of them, as an evidence of their having recovered liberty, to demolish the walls of the towns which the Romans had built in their country.

In the most inclement winter, the hardy German was satisfied with a scanty garment made of the skin of some animal. The natives, who dwelt towards the north, clothed themselves with furs; and the women manufactured for their own use a coarse kind of linen. The game of various forts, with which the forests of Germany were plentifully stocked, supplied its inhabitants with food and exercise. Their numerous herds of cattle, left remarkable for their beauty than for their utility, formed the principal article of their wealth. A small quantity of corn was the only produce exacted from the earth. The use of orchards, or artificial meadows, was unknown to the Germans; nor can we expect any improvements in agriculture from a people, whose property every year experienced a general change by a new division of the arable lands, and who, in that strange operation, avoided disputes, by suffering a great part of their territory to lie waste, and without tillage. Gold, silver, and iron, were extremely scarce in Germany. Its barbarous inhabitants wasted both skill and patience to investigate those rich veins of silver, which have so liberally rewarded the attention of the princes of Brunswick and Saxony. Although the various transactions of peace and war had introduced some Roman coins (chiefly silver) among the borderers of the Rhine and Danube; yet the more distant tribes were absolutely unacquainted with the use of money, carried on their limited traffic by the exchange of commodities, and prized their rude earthen vessels as of equal value with the silver vases, the presents of Rome to their princes and ambassadors. If we contemplate a savage nation in any part of the globe, a supine indolence and a carelessness of futurity will be found to constitute their general character. This was decidedly the case with respect to the ancient Germans. The care of the house and family, the management
of the land and cattle, were delegated to the old and infirm, to women and slaves. The lazy warrior, defirous of every art that might employ his leisure hours, consumed his days and nights in the animal gratifications of sleep and food. Nevertheless, the found that summoned the German to arms was grateful to his ear. It raised him from his uncomfortable lethargy, gave him an active pursuit, and, by strong exercise of the body, and violent emotions of the mind, restored him to a more lively sense of his existence. In the dull intervals of peace, these barbarians were immediately addicted to deep gaming and excessive drinking; both of which, by different means, the one by infaming their passions, the other by extirpating their reason, alike relieved them from the pain of thinking. They gloried in passing whole days and nights at table; and the blood of friends and relations often stained their numerous and drunken assemblies. The possession and enjoyment of property are the pledges which bind a civilized people to an improved country. But the Germans, who carried with them what they most valued, their arms, their cattle, and their women, cheerfully submitted to the invariable silence of their woods for the unbounded hopes of plunder and conquest. The innumerable swarms that invaded, or seem'd to infest, from the great flour-bowl of nations, were multiplied by the terrors of the vanquished, and by the credulity of succeeding ages. And from facts thus exaggerated, an opinion was gradually established, and has been supported by writers of disingenuous reputation, that in the age of Cæsar and Tacitus the inhabitants of the north were far more numerous than they are in our days. On this subject sir William Temple and Montesquieu have indulged the usual licence of their fancy. A more serious inquiry into the causes of population, seems to have convinced modern philosophers of the falsehood, and indeed the impossibility, of the supposition. To the names of Marmion and of Machiavel, we can oppose the equal names of Robertson and Hume.

A warlike nation like the Germans, without cities, letters, arts, or money, found some compensation for this savage state in the enjoyment of liberty. Their poverty secured their freedom, since, says Gibbon, our definies and our possessions are the strongest fetlers of despotism. Cæsar and Tacitus inform us, that the state of society among the ancient Germans was of the rudest and most simple form. They lived entirely by hunting or pasturage. They neglected agriculture, as we have already seen; their chief food was milk, cheese, and flesh. While society remains in this simple state, men, by uniting together, scarcely relinquish any portion of their natural independence. The authority of civil government was extremely limited among the Germans. In times of peace they had no common or fixed magistrate; but the chief men of every district differed justice and accommodated differences. In the far greater part of Germany, the form of government was democracy, tempered indeed, and controlled, not so much by general and positive laws, as by the occasional ascendant of birth and value, of eloquence and superstition. Some tribes, however, on the coast of the Baltic, acknowledged the rights of kings; but their kings had not absolute or unbounded power; their authority consisted rather in the privilege of advising than in the power of commanding. Matters of small consequence were determined by the chief men; affairs of importance, by the whole community. As soon as a youth, born of free parents, had attained the age of manhood, he was introduced into the general council of his countrymen, solemnly invested with a shield and a spear, and adopted as an equal and worthy member of the military commonwealth. The assembly of the tribe was convened at stated seasons, or on sudden emergencies. The trial of public offences, the election of magistrates, and the great bufiness of peace and war, were determined by its independent voices. Sometimes these important questions were previously considered, and prepared in a more select council of the principal chiefmen. The magistrates might deliberate and peruse; the people only could resolve and execute. When timid, though just and prudent, counsels were proposed, they expressed their dislike by a hollow murmurm. But whenever a popular orator proposed to vindicate the meanest citizen from either foreign or domestic injury, whenever he called upon his fellow-countrymen to avert the national honour, or to pursue some enterprise full of danger and glory, a loud clashing of shields and spears expressed the eager applause of the assembly; for the Germans always met in arms. On occasions of danger a general of the tribe was elected; and in circumstances of pressmg and extensive danger, several tribes concurred in the choice of the same general. The bravest warrior was named to lead his countrymen into the field, by his example rather than his commands. His power expired with the war, and in time of peace the German tribes acknowledged not any suprême chief. Princes were, however, appointed, in the general assembly, to administer justice, or rather to compose differences (minor controversias, Caesar) in their respective districts. To the choice of these magistrates, birth was regarded as much as merit. To each was assigned, by the public, a guard, and a council of 100 persons; and the first of the princes appears to have enjoyed a pre-eminence of rank and honour, which sometimes tempted the Romans to compliment him with the regal title. The Germans respected only those duties which they imposed on themselves. The most obscure picker refitted with disdain the authority of the magistrates. Every individual among the ancient Germans was left at liberty to chuse whether he would take part in any military enterprise which was proposed; it became, of consequence, the great object of every person, who aimed at being a leader, to gain adherents and to attach them to his person and interest. Caesar calls these adherents Ambacti and Cosentes, i.e., retainers or clients. Tacitus calls them Comites, or companions. The chief distinction and power of the leaders consisted in being attended by a numerous band of chosen youth. This was their pride as well as ornament during peace, and their defence in war. The leaders gained, or preferred, the favour of these retainers by presents of armour and of horses, or by the profuse though inelegant hospitality with which they entertained them. But even after they united in society, the Germans circumscribed the criminal jurisdiction of the magistrate within very narrow limits, and exercised almost all the rights of private refection and revenge. Their magistrates had the absolute disposition of the landed property within their district, and they distributed it every year according to a new division; but they had not the power of imprisonment, or of inflicting any corporal punishment on a private citizen. Every individual was obliged to avenge the wrongs which his parents or friends had sustained. Their enemies were hereditary, but not irreconcilable. Even murder was compensated by paying a certain number of cattle. A part of the fine went to the king or sate, a part to the person who had been injured, or to his kindred.

Chastity is admired, almost without exception, to the wives of the ancient Germans. Polygamy was not in use, except among the princes, and among them only for the sake of multiplying their alliances. Divorces were prohibited by custom rather than by law. Adulteries were punished as rare and insupportable crimes; nor was seduction justified by example.
example and fashion. Tacitus evidently indulges an honest pleasure in the contrast of barbarian virtue with the dilatory conduct of the Roman ladies; yet there are some striking circumstances that give an air of truth, at least of probability, to the conjugal faith and chastity of the Germans. The German huts, open on every side to the eye of indiscretion or jealousy, were a better safeguard of conjugal fidelity than the walls, the bolts, and the eunuchs of a Persian harem. Besides, the Germans treated their women with esteem and confidence, confided them on every occasion of importance, and fondly believed that in their breasts reposed a sanctity and wisdom more than human. Some of these interpreters of fate, such as Valleda, in the Batavian war, governed, in the name of the Deity, the fierce nations of Germany. The rest of the sex, without being adored as goddesses, were respected as the free and equal companions of soldiers; associated, even by the marriage ceremony, to a life of toil, of danger, and of glory. In their great invasions, the camps of the barbarians were filled with a multitude of women, who remained firm and undaunted amidst the found of arms, the various forms of destruction, and the honourable wounds of their sons and husbands. The women dreaded death much less than the foe. If the day was irrecoverably lost they well knew how to deliver themselves and their children, with their own hands, from an inflicting victor. Heroines of such a cast may claim our admiration; but they were most assuredly neither lovely, nor very susceptible of love.

Conscious pride taught the German females to supplant every tender emotion that floated in competition with honour, and the first honour of the sex has ever been that of chastity.

The religious fylem of the Germans was dictated by their wants, their fears, and their ignorance. They adored the great visible objects and agents of nature, the sun and the moon, the fire and the earth; together with those imaginary deities who were supposed to preside over the most important occupations of human life. They were persuaded that by some ridiculous arts of divination, they could discover the will of the superior beings, and that human sacrifices were the most precious and acceptable offering on their altars. If there was any difference between the Gauls and Germans in point of religion, it consisted only in this, that the latter, being more fierce and untractable, were not only more tenacious of their superstitious rites, but likewise more cruel and inhuman in them. It appears, from the testimonies of Caesar, Tacitus, Dio Cassius, Strabo, Athenaeus, and other ancient authors, that the Germans had no temples, but performed their religious rites in groves erected for that purpose, or in woods, forests, and defert places. Temples were not introduced in Germany till long after the Gauls had erected them; and the inferior divinities introduced among the Gauls, such as Love or Jupiter, Mars, Apollo, Mercury, Venus, Diana, &c. were also adopted by the Germans, though some of them were represented under different names and attributes. Jupiter was worshipped under the name of Thor or Taran, i. e. the Thunderer; this name was given by the Gauls to Mars; and the Germans bestowed it on their Odin or Woden; but the name of Jupiter was never adopted by the Gauls, nor by the Germans. Both Gauls and Germans agreed in worshipping the supreme deity under the name of Hefas or Efus, and under the emblem of an oak, which was consecrated to him. The goddess Hertha was one of their ancient deities, and her idol was preferred in a wood or grove, "Caellum nemus," upon a covered cart, and she had but one priest to minister to her, who was the only person that was allowed to approach her. The worship of this goddess corresponded with that which the Romans and others paid to the "Earth," under the name of "Magna Deorum Mater." A solemn procession was occasionally celebrated in the preceding countries of Mecklenburg and Pomerania. The unknown symbol of the "Earth," covered with a thick veil, was placed on a carriage drawn by cows; and in this manner the goddess, whose common residence was in the isle of Rugen, visited several adjacent tribes of her worshippers. During her progress, the found of war was hushed, quarrels were suspended, arms laid aside, and the reliefs Germans had an opportunity of taining the blessings of peace and harmony. The "Truce of God," so often and so ineffectually proclaimed by the clergy of the 11th century, was an obvious imitation of this ancient custom.

The influence of religion on the minds of the ancient Germans was far more powerful to inflame than to moderate their fierce passions. The consecrated standards, long revered in the groves of superstition, were placed in the front of the battle; and the hostile army was devoted with dire execrations to the gods of war and of thunder. A brave man was the worthy favourite of their martial deities; and the wretch who had lost his shield was banished alike from the religious and the civil assemblies of his countrymen. Some tribes of the north seem to have embraced the doctrine of transmigration; others imagined a gross paradise of immortal drunkenness. (See the Edda, p. 25.) All agreed, that a life spent in arms, and a glorious death in battle, were the best preparations for a happy futurity, either in this or in another world.

It is said that the Germans, as well as Gauls, were early taught by their Druids, as fundamental truths, an overruling providence, and the immortality of the soul; but these noble principles of religion and virtue were soon corrupted as instruments of divination and superstition. Caesar says, indeed, (Com. i. vi. c. 21.) that the Germans had no druids, as the Celts had; but Tacitus, who was better acquainted with the Germans, speaks frequently of their priests, whose office and authority, as he states them, were similar to those of the Gaulish druids, and they seem to have been of the same order of men, though perhaps they did not bear the same name. As to the immortality promised by their priests, it was in some degree conferred by the bards, who by their military songs kindled in the breasts of their audience the enthusiasm of arms and glory. The view of arms and of danger heightened the ardor of those songs; and the passions which they tended to excite, the desire of fame, and the contempt of death, were the habitual sentiments of a German mind. A contempt of danger and of death was one of the principles which they instilled into the minds of their youth, and a regard to which their priests inculcated as the first means of reputation and wealth, and also of happiness in a future life. Under the influence of this principle their armies, which consisted more of infantry than cavalry, were easily raised and maintained. Like the Gauls and Britons, the Germans fought in separate cantons or tribes; and thus they were induced to exert themselves with the greater firmness and vigour in defence of their relations, neighbours, and friends, and for the honour of their respective communities. We are told, indeed, that some of them, especially the Cimbri, formed their whole infantry into one square battalion, and placed their wives, children, and baggage behind a fence made of their wagons; and when they were prepared for an attack, a signal was given, which was re-echoed by an universal shout, and repeated till the engagement commenced. They used no art or stratagem in fighting, but wholly confided in a furious untet...
GERMANY.

The ancient Germans were a brave and independent race of men, and peculiarly distinguished by their love of liberty and arms. They opposed the Roman power, after it had arrived at maturity. After their contest with Caesar, who was provoked by the Treviri to invade their country, and yield themselves prisoners. The military weapons of the cavalry among the Germans were shields and spears, which they used in common with the foot, but the latter kind, besides their darts, bows and slings, and seldom had recourse to their pikes and swords. Their arms were adorned with their favourite furniture and chief ornament; so that they never appeared in public without them. The sword was so sacred, that the most solemn and obligatory oaths were those which they took upon a naked blade. Nor did they affix in any solemn rite, without their sword, shield, or spear. They even wore them at their familiar visits, banquets, and religious dances; and they were frequently to be burnt or buried with them, when they died. The sports, games, and exercises of the Germans, were of the masculine kind, and such as seemed to them to the operations of war. It was a long time before they acquired any knowledge of the liberal arts, or even that of writing; and we are told, that Charles the Great caused some of their barbarous poems, which they had been accustomed to sing from memory, and which celebrated the illustrious actions of their ancient kings and heroes, to be committed to writing for us, and by way of encouraging them to learn to read. The Saxons, it is said, had such a contempt for letters, that they refused to learn to read the gospels till they were put into verse, and let to such tunes as they could easily sing. Even their laws were not reduced to writing till about the 12th or 13th centuries.

The native disposition of the ancient Germans displayed itself chiefly in their martial genius, and in their singular facility. In some cases their love of liberty, and hatred of tyranny and oppression, precipitated them to acts of treachery and even of murder; for in such cases they were easily incensed, and extremely vindictive. On other occasions, Tacitus says, they were noble, magnanimous, and beneficent, without ambition to aggrandize their dominions, or to invade those from whom they received no injury; rather choosing to employ their strength or valour defensively, than offensively; to preserve their own, than to revenge their neighbours. In their own houses, furniture and diet, they were distinguished by their plainness and simplicity; but at the same time, they were no less distinguished by their hospitality to strangers, and by their readiness to succour those that were in distress. Although in most of their customs the Germans very much resembled the Gauls, yet, with regard to their funeral rites, they were very different. The latter performed these obsequies with pomp and profusion; whereas the Germans discharged their last offices to the dead with plainness and simplicity; the only grandeur they affected, was to burn the bodies of their great men with some peculiar kinds of wood; and afterwards they flung each man’s armour into the funeral pile, and sometimes his riding dree. They then deposited their ashes in urns, like the Gauls, Romans, and other nations. It may be observed in general, that the sacrifices they offered for their dead, the presents made to them at their funerals, and the other superstitious rites performed on those occasions, were all the while, and the evidence of an established belief, that the soul was immortal.

Their revolt against Augustus, which was suppressed by Agrippa, and the insurrection which commenced among the Roman legions in Pannonia, quelled partly by Drusus, and finally by Germanicus; their other more considerable wars with the Romans were waged against the emperors M. Aurelius, Alexander, Maximian, Valerian, Aurelian, Probus, Constantius, Julian, Valentinian, and some of his successors. Some hints are taken of these conflicts under the names of the Alamanni, Gepidae, Franks, Suevi, Heruli, and Burgundians. Their country was divided into a number of petty dukedoms, independent of each other, though occasionally connected by a military union, until it was reduced to the condition of a Roman province; and when the Roman empire was shattered by the Northern barbarians, Germany was again run over by the Franks about the year 480, and continued in subjection to chieftains of that nation, who governed over the Batavians, Alemani, Frisians, Saxons, Thuringians, and Bavarians, until the end of the eighth century, when Charlemagne united all Germany into one kingdom, as part of the Frankish monarchy. The conquered German nations had hereditary dukes of their own at first, and were governed by their own laws; but Charlemagne put an end to the former, and governed the different German provinces by counts and royal delegates, and in the year 800 he assumed the title and dignity of emperor. But the empire of Charlemagne was a structure erected in so short a time, that it could not be of long duration. Under his immediate successor it began to totter, and soon after fell to pieces. The crown of Germany was separated from that of France, and the descendants of Charlemagne established two great monarchies, so fortified, as to give rise to a perpetual rivalry between them. But the princes of the race of Charlemagne, who were placed on the imperial throne, were not altogether fo degenerate as those of the same family who reigned in France. In the hands of the former, the royal authority retained some vigour; the nobles of Germany, though possessed of extensive privileges and ample territories, did not so early attain independence. The great offices of the crown continued at the disposal of the sovereign, and during a long period, they remained in their original state without becoming hereditary in the families of the persons to whom they had been granted.

At length, the German branch of the family of Charlemagne became extinct upon the death of Louis IV. His feeble descendants who reigned in France had sunk into such contempt, that the Germans, without looking towards them, exercised the right inherent in a free people; and in a general assembly of the nation at Worms, in the year 911, offered the imperial crown to Otho, duke of Saxony, who declined it on account of his great age, and recommended Conrad, count of Franconia. The latter was unanimously elected emperor. His reign was disturbed by the disobedience of some nobles whom he subdued, and by the pretensions of Henry, son of the duke of Saxony, his benefactor. Their quarrels, however, did not prevent Conrad from acknowledging the merit of that prince in the same manner as Otho had done his. He recommended Henry as the fittest prince to be his successor, and his proposal being approved by the nation, he sent to Henry, without waiting for the hour of death, the crown, the sceptre, the lances, the sword, and other imperial ornaments.

Henry I. ascended the imperial throne of Germany in 919. He was surmounted the Fosider, because he was passionately fond of hawking. To confirm his authority, he made more use of persuasion than of arms. His descendants, the three Othos, were placed in succession on the imperial throne by the suffrages of their countrymen. The extensive terri-
tories of the Saxon emperors, their eminent abilities, and enterprising genius, not only added new vigour to the imperial dignity, but raised it to higher power and pre-eminence. Otto the Great marched at the head of a numerous army into Italy, and, after the example of Charlemagne, gave law to that country. On his arrival at Rome, he was consecrated by the pope, and crowned emperor of the Romans. He created popes and deposed them by his sovereign will. He annexed the kingdom of Italy to the German empire. Elated with his successes, he assumed the title of Caesar Augustus. A prince, born in the heart of Germany, pretended to be the successor of the emperors of ancient Rome, and claimed a right to the same power and prerogative. See the biographical article Otto.

But while the emperor, by means of these new titles and new dominions, gradually acquired additional authority and splendour, the nobility of Germany had gone on at the same time extending their privileges and jurisdiction. The situation of affairs was favourable to their attempts. The vigour which Charlemagne had given to government quickly relaxed. The incapacity of some of his successors was such, as would have encouraged vassals, left enterprising than the nobles of that age, to have claimed new rights, and to have assumed new powers. The civil wars in which other emperors were engaged, obliged them to pay perpetual court to their subjects, whose support they depended, and not only to connive at their usurpations, but to permit and even to authorize them. Fiefs gradually became hereditary. They were transmitted not only in the direct, but also in the collateral line. The investiture of them was demanded not only by male but by female heirs. Every baron began to exercise sovereign jurisdiction within his own dominions, and the dukes and counts of Germany took wide steps towards reclaiming their territories distinct and independent states. The Saxon emperors observed their progress, and were aware of its tendency. But as they could not hope to humble vassals already grown too potent, unless they had turned their whole force and attention to that enterprise, and as they were extremely intent on their expeditions into Italy, which they could not undertake without the concurrence of their nobles, they were obstinate not to alarm them by any direct attack on their privileges. They aimed, however, at undermining their power. With this view, they inconsiderately bestowed additional territories, and accumulated new honours on the clergy, in hopes that this order might serve as a counterpoise to that of the nobility in any future struggle.

The unhappy effects of this fatal error in policy were quickly felt. Under the emperors of the Francorian and Swabian lines, whom the Germans, by their voluntary election, placed on the imperial throne, a new face of things appeared, and a scene was exhibited in Germany which astonished all Christendom at that time. The popes, hitherto dependent on the emperors, and indebted for power as well as dignity to their beneficence and protection, began to claim a superior jurisdiction, and in virtue of authority, which they pretended to derive from heaven, tried, condemned, excommunicated, and deposed their former masters. These pretensions gave rise to the factions of the Guelphs and Ghibellines, of which the former was attached to the popes, and the latter to the emperors. Pope Gregory VII. had observed that the princes and nobles of Germany had acquired such considerable territories and such extensive jurisdiction, as rendered them not only formidable to the emperors, but disposed them to favour any attempt to circumscribe their power. He forewarned that the ecclesiastics of Germany, raised almost to a level with its princes, were ready to support any person who would stand forth as the protector of their privileges and independence. With both of these Gregory negotiated, and had secured many devoted adherents among them, before he ventured to enter the lists against the head of the empire. He began his rupture with Henry IV., upon a pretext that was popular and plausible. He complained of the vileness and corruption with which the emperor had granted the investiture of benefices to ecclesiastics. He contend- ed that this right belonged to him, as the head of the church; he required Henry to confine himself within the bounds of the civil jurisdiction, and to abstain for the future from such sacrilegious encroachments on the spiritual domain. All the confines of the church were denounced against Henry, because he refused to relinquish those powers which his predecessors had uniformly exercised. The most considerable of the German princes and ecclesiastics were ex cited to take arms against him. His mother, his wife, his sons, were threatened to be distrusted all the ties of blood and duty, and to join the party of his enemies. At length, the emperor was even obliged to appear as a supplicant at the gate of the captive in which the pope refused, and to fling there three days barefooted in the depth of winter, imploring a pardon, which he obtained with difficulty.

This act of humiliation degraded the imperial dignity. The two factions kept Germany and Italy in perpetual agitation during three centuries, and, notwithstanding the return of some short intervals of vigour, under the administration of a few able emperors, the imperial authority continued to decline. During the anarchy of a long interregnum, subsequent to the death of William of Holland, it dwindled down almost to nothing.

In the year 1273, Rodolphus of Hapsburgh, the founder of the house of Austria, was elected emperor, not that he might re-establish and extend the imperial authority, but because his territories and influence were so inconsiderable as to excite no jealousy in the German princes, who were willing to preserve the forms of a constitution, the power of which they had destroyed. Several of Rodolph's successors were placed on the imperial throne from the same motive, and almost every remaining prerogative was wrested out of the hands of feeble princes, unable to exercise or to defend them.

During this period of turbulence and confusion, the constitution of the German empire underwent a total change. The princes, the great nobility, the dignified ecclesiastics, and the free cities extended their usurpations. They claimed and exercised the right of governing their respective territories with full sovereignty. They acknowledged no superior with respect to any point relative to the interior administration and police of their domains. They exacted taxes, imposed taxes, coined money, declared war, concluded peace, and exercised every prerogative peculiar to independent states. The forms of feudal subordination formed the only connection among the various members of the community. This bond of union, however, was extremely feeble.

From the accession of Rodolph of Hapsburgh, to the reign of Maximilian, the empire felt every calamity which a state must endure, when the authority of government is so much relaxed. The divisions among its members gave rise to perpetual private wars, which were carried on with all the violence that accompanies refluxment when unrestrained by superior authority. Rapine, outrage, executions, became universal. The variety of expedients employed to restore order and tranquillity, prove that the grievances occasioned by this state of anarchy had become intolerable. Arbiters were appointed to terminate the differences among the several states. The cities united in a league to check the extortions of the nobility, and the latter formed confederacies to main-
in tranquility among their own order. Germany was divided into ten circles, in each of which a provincial jurisdiction was established. But all these remedies proved inefficient. At length Maximilian instituted the imperial chamber, a tribunal composed of judges named partly by the emperor, partly by the several states, and vested with authority to decide finally concerning all differences among the members of the Germanic body, and thus restored some degree of vigour to the imperial authority.

But notwithstanding the salutary effects of these regulations, the political constitution of the German empire, at the beginning of the sixteenth century, was of a species peculiar as not to resemble perfectly any form of government known either in the ancient or modern world. It was complex body, formed by the association of several states, electors, princes, dignitaries of the church, counts, barons, and free cities, each of which possessed sovereignty and independent jurisdiction within its own territories. Of all the members which composed this united body, the emperor was the head. In his name all decrees and regulations, with respect to points of common concern, were issued; and to him the power of carrying them into execution was committed. But this appearance of monarchical power in the emperor was more than counterbalanced by the influence of the princes and states of the empire in every act of administration. No law extending to the whole body could pass, no resolution that affected the general interest could be taken without the approbation of the diet of the empire held at Ratisbon. In this assembly every sovereignty and state of the Germanic body had a right to be present, to deliberate and to vote. The decrees or resolutions of the diet were the laws of the empire, which the emperor was bound to ratify, and to enforce. In this respect the German empire was similar to the Achaeian league in ancient Greece, or to that of the United Provinces of the Netherlands, and of the Swiss cantons in modern times. But, as the acute historian of the emperor Charles V. observes, the Germanic body was not formed by the union of members altogether distinct and independent. All the princes and states, joined in this association, were originally subject to the emperors, and acknowledged them as overlords. They originally held their lands as imperial fiefs, and owed the emperor all those services which feudal vassals are bound to perform to their liege lord. But though this political subjection was entirely at an end, the ancient forms introduced while the emperors governed Germany with authority not inferior to that which the other monarchs of Europe possessed, still remained. Thus an opposition was established between the genius of the government and the forms of administration in the German empire. The former considered the emperor only as the head of a confederacy, the members of which, by their voluntary choice, raised him to that dignity; the latter seemed to imply that he is really invested with sovereignty power. The emperors were distinguished by the most pompous titles, and by marks of dignity as intimated their authority to be superior to that of all other monarchs. The greatest princes of the empire attended and served them, on some occasions, as officers of their household. They exercised prerogatives which no other sovereigns ever claimed. They retained pretensions to all the extensive powers which their predecessors had enjoyed in a former age. But, at the same time, instead of possessing that ample domain which had belonged to the ancient emperors of Germany, and which stretched from Belf to Cologne, along both banks of the Rhine, they were stripped of all territorial property, and had not a foot of land that belonged to them as heads of the empire. Their revenues were reduced almost to nothing, and the extraordinary aids which, on a few occasions, they obtained, were granted sparingly, and paid with reluctance. The consequence of this ill-constructed frame of government was, that the emperors imagined themselves to be the real overlords of Germany, and aimed at simultaneously recovering the exercise of those powers which the forms of the constitution seemed to vest in them, and which their predecessors Charlemagne and the Osias had actually enjoyed. But, the princes and states, aware of these pretensions, watched the decisions of the imperial court to circumscribe its power within limits still more narrow. This jealousy of the imperial authority increased considerably from the time that the elective power was vested in a few princes of chief dignity.

During a long period, all the members of the Germanic body had a right to assemble, and to make a choice of the person whom they appointed to be their head. But amid the violence and anarchy which prevailed for several centuries in the empire, seven princes, who possessed the most extensive territories, and who had obtained an hereditary title to the great offices of the state, acquired the exclusive privilege of nominating the emperor. This right was confirmed to them by the golden bull (See Bull.; the mode of exercising it was uncertain, and they were dignified with the appellation of Electors. (See Elector.) The nobility and free cities, being thus deprived of a privilege which they had once enjoyed, were left connected with a prince, towards whose elevation they had not contributed by their suffrages, and came to be more apprehensive of his authority. The electors, by their extensive power, and the distinguishing privileges which they possessed, became formidable to the emperors, with whom they were placed almost on a level in several acts of jurisdiction. Thus, the introduction of the electoral college into the empire strengthened the principles of discord in the Germanic constitution, which were continually alimented by the various and repugnant forms of civil policy in the several states. The free cities were small republics, in which the maxims and spirit peculiar to that species of government prevailed. The princes and nobles to whom supreme jurisdiction belonged possessed a sort of monarchical power within their own territories. Their common deliberations could not be carried on with the same spirit while the love of liberty and attention to commerce were the reigning principles in the cities; and the desire of power, and ardour for military glory, the governing passions of the princes and nobility. The secular and ecclesiastical members of the empire were as little fitted for union as the free cities and the nobility. Considerable territories had been granted to several of the German bishops and abbots, and some of the highest offices of the empire, having been annexed to them unequally, were held by the ecclesiastics raised to those dignities. The younger sons of noblemen of the second order, who had devoted themselves to the church, were commonly promoted to these stations of eminence and power; and it was no small mortification to the princes and great nobility, to see persons raised from an inferior rank to the same level with themselves, or even exalted to superior dignity. The education of these churchmen, the genius of their profession, and their connection with the court of Rome, rendered their character, as well as their interest, different from that of the other members of the Germanic body, with whom they were called to act in concert. Thus another source of variance was opened.

To all these causes of dissension must be added another, arising from the unequal distribution of power and wealth among the states of the empire. The electors and other nobles of the highest rank not only possessed sovereign jurisdiction, but governed such extensive, populous, and rich countries,
countries, as rendered them great princes. Many of the other members, though they enjoyed all the rights of sovereignty, ruled over such petty domains, that their real power bore no proportion to this high prerogative. The electors and emperors, by turns, endeavored to extend their own authority, by encroaching on those feeble members of the Germanic body, who sometimes defended their rights with much spirit, but more frequently, being overawed or corrupted, tamely surrendered their privileges, or meanly favored the defigns formed against them.

But the empire of Germany comprehended countries of such vast extent, and was inhabited by such a martial and hardy race of men, that when the abilities of an emperor, or zeal for any common cause could rouse this unwieldy body, it was still able to act with force. Charles V. grand son of Maximilian, and heir to the kingdom of Spain, in right of his mother, was elected emperor in the year 1519. In his reign happened the reformation of religion caused by Luther, which occasioned incessant wars till 1648. (See Luther and Reformation.) There were moments when Charles V. flattered himself with the hope of being able to hold the balance between the Roman Catholics and the Lutherans. But the contending parties were too much inflamed with animosity, and in addition to his wars against Francis I. of France, he was forced to sustain a violent one in the heart of the empire. Fortune, which smiled upon him in the beginning of his reign, forsook him towards its end. He abdicated the imperial throne, in 1558, in favor of his brother Ferdinand I., who had the address of getting his son Maximilian II. declared king of the Romans, or successor to the imperial crown in his life-time. This precaution became familiar to the house of Austria, and kept the imperial sceptre in that family, until the extinction of the German empire. By his last will Ferdinand ordered that if either his own male issue, or that of his brother Charles should fail, his Austrian estates should revert to his second daughter Anne, wife to the elector of Bavaria. This circumstance is the origin of the opposition made by the house of Bavaria, in later times, to the Pragmatic sanction in favor of Maria Theresa, mother of Joseph the second.

The reign of Maximilian II. was disturbed by internal commotions, and an invasion from the Turks. He died in 1576, and was succeeded by his son Rodolph, who was involved in wars with the Hungarians, and in differences with his brother Matthias, to whom the empire devolved at his death. Having no children, Matthias conferred the crown of Hungary on his cousin Ferdinand arch-duke of Austria, and caused him to be elected king of Bohemia, which election proved the source of a long war. Ferdinand perfected the numerous sects in Bohemia. They took up arms; the brave Mansfeld fought at their head, and Matthias, who came to the assistance of his kinman, died of vexation, for not having been able to obtain a complete triumph over the Bohemians. A tender of the imperial crown was made to Maximilian, duke of Bavaria, who prudently declined the offer. Ferdinand was therefore proclaimed emperor in 1619, but the Bohemians, maintaining that the same individual could not wear the crown of Germany together with that of Bohemia, conferred the latter on Frederick, the elector palatine. Yielding to the intrigues of his spouse Elizabeth, daughter of James I. of England, against his own conviction, Frederick made a splendid triumphal entry into Prague; but a few days after, his army was attacked on the heights near the town, and completely routed. He was obliged to fly with his wife and children, and found at last an asylum in Holland. His defeat was the beginning of the thirty years' war which ravaged Germany from the Danube and the Rhine to the shores of the Baltic, without little interruption from the battle of Prague to the peace of Westphalia. The unfortunate Frederick, who had been put under the ban of the empire, died broken-hearted. Ferdinand's arms were almost constantly victorious against the Protestant princes for the space of ten years. He was on the point of crushing their party when Gustavus Adolphus of Sweden rushed upon him. In vain did the Imperialists commanded by Tilly endeavour to check his career; they were defeated and dispersed. Ferdinand was going to sue for peace when the fall of the Swedish monarch at Lutzen re-animated his hopes; Wallensteins's defection did not arrest his arm. He continued fighting against his Protestant vassals to the hour of his death, which happened in 1637. The war raged with unabated fury under his son Ferdinand III. who was appointed his successor on the imperial throne. The Protestant cause was ably defended by the heroes brought up under the great Gustavus Adolphus. History will never forget the names of the duke of Saxe Weimar, of Bannier, Torlenton, Piccolominini, Mercy, Wrangel, and many others who shook the Austrian power, till at length a general peace was concluded at Westphalia in 1648, which brought tranquility to Sweden and Germany. France, has been considered for a century and a half as forming the basis of the political system of Europe, under the name of the peace of Munster or peace of Westphalia.

Leopold I. who was elected emperor of Germany, after the death of his father Ferdinand III. in the year 1652, had to combat the French on one side, and the Turks on the other. The latter advanced to the walls of Vienna, but were compelled to raise the siege by the valor of John Sobieski, king of Poland. The fertile province of Alace was conquered by France, but the Turks, having been repeatedly defeated by prince Eugene of Savoy, were forced to cede Transylvania by the peace of Carlowitz in 1699. During Leopold's long reign, the duke of Hanover was admitted into the electoral college, the elector of Saxony obtained the elefive royal crown of Poland, the elector of Brandenburg was acknowledged hereditary king of Prussia, and a prince of the Bourbon family was seated on the Spanish throne. Leopold died in 1705. The reign of his son Joseph I. lasted but six years, and is remarkable only for the victories which the great duke of Marlborough gained in his cause over the French. As he left no male issue, the elector of Mayence exerted all his influence to procure the imperial crown to his brother the archduke Charles, who was at that time in Spain, disputing the crown of that kingdom with Philip IV. of Anjou, grandson to Louis XIV. The elevation of Charles to the empire terminated the contelations which had harassed Spain and Germany. The peace of Utrecht, concluded in 1713, was followed by that of Baden with France in 1714, and that of Passarowitz with the Turks in 1717.

Charles VI. intent upon securing his hereditary dominions to the archduchess Maria Theresa his daughter, framed that famous Pragmatic sanction which was soon to disturb again the peace of Germany. Happily for him the crown of Great Britain devolved to the house of Hanover, which circumstance drew the connection of Austria and England against their common enemy more close. Charles VI. married his daughter to Francis duke of Lorraine, and died in 1740. No sooner was he in the grave than the Pragmatic sanction was attacked on all sides. The great Frederick of Prussia conquered Silesia, and Spain and Bavaria preferred their claims on several provinces. The intrigues of France caused the imperial throne to be filled, after an interregnum of two years, by the elector of Bavaria, who took the name of Charles VII., and was proclaimed emperor in 1742.
But after five years of disastrous warfare, he died deprived nearly of all his states. Maria Theresa had sufficient influence to place her husband on the throne of the empire in 1745. Francis I. was acknowledged as emperor of Germany by the king of Prussia at the peace of Dresden, signed on the 27th of December 1745, and by the French, at the peace of Aix-la-Chapelle in 1748.

The interval of peace which Germany enjoyed was not of long duration. Frederick the Great of Prussia having discovered the plots which were formed against him by the emperor, the elector of Saxony, Ruffia and France, and being subsidized by England, occupied Saxony, and refitted the attacks of his numerous enemies with alternate succeses, for the space of seven years. Peace was at length signed once more at Hubertusburgh on the 15th of February 1763. Francis I. died two years after. His son Joseph II., who had been declared king of the Romans in 1764, was proclaimed emperor after his death. His attempt to profess himself of part of the dominions of Charles Theodore, the last elector of Bavaria, who died in December 1777, disturbed the peace of Germany for a short time. No battle of any consequence was fought between the Austrian and Prussian armies; but the severe winter campaign of the latter end of 1778, and the beginning of 1779, having thinned the ranks of both, the treaty of Teschen was concluded on the 13th of April 1779, and the peace of Wiltphalia appealed to, and confirmed for the last time. Maria Theresa left her hereditary dominions to her son Joseph II. at her death, which happened in 1780. Frederick the Great of Prussia, who was the last pillar of the Germanic constitution, died in 1786. Ambitious of imitating the example of his illustrious opponent, Joseph II. introduced many futile reforms in the administration of his dominions, proclaimed an unbounded religious toleration, suppressed a number of useless empires, abolished the use of the rack in criminal inquisitions, and extinguished the remains of servitude and villainage which oppressed the peasants of his dominions. But his well-intended innovations were too sudden. Difcontent broke out in the Netherlands, which he vainly attempted to still by force instead of adopting conciliatory measures. The rebellion of his Flemish subjects broke his heart. He died childlesse, though he had been married twice; and his brother Leopold, grand duke of Tuscany, succeeded him on the imperial throne in 1790. His unfortunate engagement with the king of Prussia and the elector of Saxony, to oppose the French revolution with all their might, and to affright the emigrants in their attempts to re-enter France by force, hallowed the violent measures of the war party in France, which ultimately led to the extinction of the German empire. He died on the 1st of March 1792. His son Francis II. was raised to the imperial throne in the middle of July following. He embarked in the confederacy formed against France, left the Austrian Netherlands, the Brittan, and all his posessions in Italy, and was at length obliged to abdicate the imperial throne of Germany, and to be contented with the title of emperor of Austria. See Confederation of the Rhine.

The peace of Wiltphalia, which had been regarded as the basis of the political system of Europe, had, in fact, fown the seeds of the dissolution of the German empire, by conferring on each prince and state of the German confederacy the privilege of contracting alliances in their own names. Their interests were continually clashing with each other. The irresistible force of revolutionary France has only accelerated a disorganization which would infallibly have taken place, through the rivalship of the Austrian and Prussian monarchs, supported, one by the Catholic, and the other by the Protestant states. Composed of such discordant materials, it is rather a matter of surprize that its existence as a state should have been protracted to the length of one thousand years.

The Germans never formed a nation united by the ties of similar habits, laws and religion. These differed in almost every petty principality, and the tie of language, from its many idioms and different pronunciation, was so weak, that the national hatred of the inhabitants of the Prussian dominions against those of the Austrian states was as great as that which prevails between the English and the French. The difference between the Protestant and Catholic countries was also so considerable, that Whiff farmers in the former envied their livelihood by study, the clergymen in the latter were even ignorant of the first four rules of arithmetic. Palitzsch, a Saxox farmer, who was a fellow of the Royal Society of London, died in 1788, and six months before his death a clergyman was wanted, in the gazette of Cologne, capable of teaching the rudiments of common arithmetic. The only feature which may be marked as a national one in the Germans of all persuasions and places, is the industry and perseverance of the middle and lower ranks, and the pride and haughtinefs of the nobility. As soldiers, the Germans, when ably commanded, have always shewn themselves endowed with steady courage and persevering strength. But the name of German is extinct. Henceforth the traveller must inquire into the peculiar character and disposition of the Austrian, Prussian, Saxon, Bavarian, Württemburg, and the inhabitant of Wurttemberg, Baden, Berg, Hesse Darmstadt, Naflus, and the other smaller states of the confederacy of the Rhine. GERMANY, Upper and Lower, in Ancient Geography, divisions of Gaul; which see.

Germans, in Geography, a town of America, in Adams' county, Pennsylvania, containing 1012 inhabitants.

GERMEN, or GER, see Embryo.

Germes, in Botany and Vegetable Physiology, the rudiments of the fruit, constituting one of the two essential parts of the pistil of a flower, the stigma being the other; the style, which usually elevates the latter, not being indispensable, nor always present. The Latin word germen properly means a bud, or sprout (see Gemma); which latter, in scientific language, is now universally used in its stead. Linnæus therefore applied germen technically, and very happily, to the bud, or origin of the future offspring, which had as yet no appropriate name. In this he is generally followed, even by the only person who could officially have contended with him in such a point, the celebrated Jullien. Nevertheless, Gertner, assuring some well-founded authority on account of his valuable labours respecting fruits and seeds, prefers the word ovarium, borrowed from anatomists, for it is not classical Latin. The only reason for this innovation is, as he is pleased to express it, that Linnæus "recte impropreo" calls this part germen. The authority of Gertner has unfortunately milled one excellent writer of late to adopt the term ovarium, to which we object, not so much for its want of classical authority, as it might well be defended on the ground of analogy, but because it is not appropriate, and is not used by Gertner in the original anatomical sense, but in a new and arbitrary one. Vegetables have no such organ as the ovarium of animals. Malpighi, much more correctly, calls the germen the "uterus"; by this is meant the same organ used by plants with naked seeds; whereas germen is applicable in all cases to the rudiment of the fruit, whenever its nature may
may be. Such a comprehensive term is of the more value, as not having any respect to the disputable point of whether any seeds are really naked or no. We agree with Gartner that they cannot in their origin be naked, but must have some integument through which they are impregnated; see 

"Persionation of Plants." In an advanced state the family as a whole cannot but be the presence of fused inflorescences in a certain sense, that is, such as have only their own carinal elements, but no real perianthus or seed-covert.

Gartner very successfully combats the Linnaean hypothesis, that the germ originates from the path of the plant, as the flammers from the woody part. This idea was purely hypothetical, and is unsupported by any anatomical fact, however ingenious the theory of germination deduced from it by the illustrious Swedes.

The germ is formed as early as any part of the flower, of which indeed it frequently constitutes the base. Before the stigma is ripe for impregnation, all the internal parts of the germ, especially the young seeds, receive their due shape and structure, except only the embryo, the rudiments of which can scarcely be detected at that period. If no impregnation takes place, the germ, and even the seeds sometimes continue to grow, but a cavity only in such case will be found in the place of the embryo, which has at least proved abortive and withered away, if it ever had any existence. More frequently indeed only the hafts or withered rudiments of seeds are found in an advanced impregnated germ; and still more generally the whole germ withers if the flammers and stigma have not performed their office.

Germens are either solitary or numerous, simple or aggregate, in different genera of plants. With respect to situation, it is important to note whether the germ be superior, that is, above the bases of the calyx and corolla, or inferior, below them. Such a difference commonly marks a very essential generic distinction, yet in that monotypic genus Sarracena, some species have a superior and others an inferior germen. This proves, on a careful anatomical investigation, to depend merely on a greater or less degree of elevation of the organ in question within the cavity of the calyx. Indeed such an investigation of flowers in general will show that there is perhaps no such thing as an inferior germen, strictly speaking, because there must necessarily be a continuation of the integuments of the flower and their velvets, in some form or other, along the outer part of what is commonly deemed an inferior germen, to the stamens whatever their nourishment is derived. But this "were to consider too curiously." The line is in almost every case drawn with sufficient distinction for all useful purposes, and is generally indicated in due time by a spontaneous separation of parts. Sarracena is erroneously judged by Linnaeus to have the germ below the corolla though above the calyx, a strange and unexampled circumstance indeed! He was misled by the close adherence of the thin pellucid tube of the corolla to the germ. In Abies, however, there is an approach towards such a singularity of structure, the calyx being inferred half way down, while the corolla crowns the germ, for this plant, being akin to Sarracena, particles of that irregularity of position in the germ which we have already described naked eye.

Nothing is more wonderful than that difference of vascular constitution in the germens of different genera or natural orders, by which, though in all cases nearly equally juicy while young and growing, in some it becomes coriaceous, or woody, and dry, as it ripens, while in others it attains a soft pulpy consistence, which obliterate its all its original internal structure. The wife ends nourished by these differences are indeed apparent, but the means by which they are accomplished are, if not ineradicable, at least unexplained.

GERMEN, Str., in Geography, a town of France, in the department of the Oise; 12 miles W. of Beauvais.

GERMERSHEIM, a town of France in the department of Mont SEMEUR, and chief place of a canton, in the district of Sancey, 5 miles S. of Sancey. The place contains 1,251, and the canton 11,383 inhabitants; in 16 communities. It is situated at the confluence of the Oise and the Rhine, and was erected into a town by Rudolph, I., who died here in 1290. It was taken by the French in 1794. N. lat. 49 12. E. long. 25°.

GERMINATION, in Vegetable Physiology, the first beginning of vegetation in seeds, is accomplished by moisture, heat, and air, acting mechanically and chemically on the substance and component parts of the seed, as well as simulating its vital principle. These agents must perform their functions together, in order to produce a salutary effect, otherwise the vital principle, or the chemical properties of the seed, may be imitated or spoilt, nor must their application, generally speaking, be longer delayed than usually happens in the ordinary course of nature. Some seeds, indeed, may be kept out of the ground for years, or may remain buried far beneath its surface, we know not how long, without losing their vegetative power; while others must scatter themselves in their own way, immediately from the seed-velvet, in order to succeed with certainty. A seed absorbs, through the vessels of its base, or feet, any moisture that comes in its way, and it soon meets with such a supply when committed to the ground, at the same time receiving, throughout its whole substance, a definite portion of heat, some seeds requiring more than others. Atmospheric air is also necessary to the germination of seeds, on account of the oxygen gas which makes a part of its composition, and which modern chemists have found to be adsorbed by seeds, in the moments of incipient germination, from air or through the surrounding foil. This appears from their being incapable of vegetation while buried deep in the earth, or while under the exhausted receiver of an air-pump; though such as have been so situated immediately grow, when the atmosphere has access to that part of the foil in which they lie. By the above agents the bulk of the seed is increased, and its vital principle stimulated. The integuments burst, and the radicle, or young root, protrudes, which being most susceptible of the stimulus of moisture, for that reason (as Dr. Darwin ingeniously judged,) elongates itself in the direction where it meets with this stimulus, increasing chiefly at the extremity, and descending into the earth. It is a well-known fact that the radicle takes this direction, in whatever position the seed may happen to lie. Dr. Darwin’s seems to us the best explanation of this curious law of the vegetable constitution, and preferable to any one founded on principles of mechanics or of gravitation. Accordingly, the rudiments of the young plant, confiding of the cotyledons and plumula or bud, being most imitated by air, raise themselves out of the ground, entirely for the most part, in pursuit of it. If some few cotyledons do remain and wither under ground, it is only because they have already met with a sufficiency of air or oxygen to answer their destination. See Cotyledons.

During the process of incipient germination, the immediately necessary function of nourishment, till the young root can derive any from the soil, are furnished by the albumen, a substance either constituting a separate body of itself, as in grapes, corn, palms, etc., which, from a hard, dry, and tailed effect, changes, by the action of water and oxygen, into a milky or fuscaceous fluid, wets the opera-
GERNSHEIM, or GERNSHHEIM, a town of Germany given, in 802, to the landgrave of Hesse Darmstadt; 81 miles E.S.E. of Mann.

GERNYOSZEG, a town of Transylvania, on the river Maras; 10 miles S.W. of Kerestur.

GEROSCOMIA, of 765; aged, and 5000, I chrisi; a term used by the ancients for that sort of medical practice which treated of the proper regimen to be observed in old age.

GEROD, in Geography, a town of Germany, in the territory of Liebfeld, with a rich Benedictine abbey; eight miles N.E. of Duderstadt.

GERODOT, a town of France, in the department of the Aube; nine miles E. of Troyes.

GEROLDSHOFEN, a town of Germany, in the bishopric of Wurzburg; 20 miles N.E. of Wurzburg.

GEROLDSTEIN, a town of Germany, in the county of Katzenelnbogen; seven miles S. of Naufeld.

GEROLSTEIN, a town of France, in the department of the Sarre, and chief place of a canton, in the district of Prum; 24 miles N. of Troyes. The town contains 350, and the canton 2892 inhabitants, in 29 communes. N. lat. 50° 16'. E. long. 6° 38'.

GERON POINT, a cape of Ireland, in the county of Antrim, on the east coast. W. long. 5° 52'. N. lat. 52° 3'.

GERONA, or GIRONDE, Lat. Gerundia, a town of Spain, in the province of Catalonia, the see of a bishop, suffragan of Tarragona. This is a fortified town, of nearly a triangular form, situated on the side and at the foot of a steep mountain; the river Tar runs through it. The streets are narrow and crowded, but the houses are tolerably well built. It has several churches and convents; and its population amounts to about 12,600 persons, a fourth of which number consists of priests, monks and nuns, scholars and students. Several provincial councils have been held in this place, one in 517, another in 1668, &c. The trade of this town is inconsiderable, and its only manufactures consist of a few looms for stockings, coarse cloths, and woollen and cotton stuffs. The cathedral and collegiate churches are the two most remarkable edifices in Gerona. The treasury of the cathedral is richly furnished with chalices, crosses, shrines, relics, &c. of gold and silver set with jewels. In the Capuchin convent there is an Arabian bath, constructed in the most elegant style, and consisting of columns standing on an octagon stylobate, or low-baths, encircling a reservoir to contain water. The university of Gerona, founded in 1521 by Philip II., was abolished in 1715 by Philip V. After the suppression of the Jesuits, public instruction was concentrated in one college, accommodating 800 students, who are taught the Latin grammar, rhetoric, philosophy, and theology. The library is select and extensive. Schools are kept by the community of the Beguines for the gratuitous instruction of poor girls; 47 miles N.E. of aecston. N. lat. 42° 10'. E. long. 2° 35'.

GERONIMO, St., a town of Mexico, in New Biscay; 90 miles N. of Parral.

GERONTE, a small island in the Mediterranean, near the coast of Naphza. N. lat. 36° 25'. E. long. 30° 4'.

GERONTE, in Antiquity, a kind of judges, or magistrates, in ancient Sparta; answering to what the Areopagites were at Athens. See Areopagites.

The word is formed of Greek, gerontes, which signifies old men. Whence also the words germen,something belonging to an old man; and geranium, a famous book among the modern Greeks, containing the lives of the ancient men.
The Senate of gerontes were called germen, that is, assembly or council of old men. The gerontes were originally instituted by Lycurgus: their number, according to Ione, was twenty-eight; and, according to others, thirty-two. They governed in conjunction with the kins, whose authority they were intended to balance, and to watch over the interests of the people. Polybios defines their office in few words, when he says, "per ipso et cum ipsi omnia administravit." None were to be admitted into this office under sixty years of age, and they held it for life. They were succeeded by the Ephebi.

GERONTASSA, in Geography, a small island in the gulf of Engia; four miles south of Engia.

GERONTAXON, in Surgery, a little ulcer, shaped like the head of a dart, and making its appearance occasionally on the cornea of old persons. The term is derived from ρηχος, an old person, and ωτος, a dart.

Gen. Ch. Germon calyx simple, of numerous upright, lanceolate, somewhat awl-shaped, keeled leaves, longer than the corolla. Cor. compound, somewhat imbricated, uniform; each floret hermaphrodite, with a corolla of one petal, ligulate, abrupt, five-toothed; the outer ones equal in number to the calyx-leaves, inner ones fewer and shorter. Stam. Filaments live, very short; anthers united into a cylindrical tube. Fil. Germin oblong, five-angled, the length of the filaments; ligmas two, thread-shaped, recurved. Petio none, except the permanent, oblong, upright, gaping calyx. Seeds of the circumference awl-shaped, as long as the calyx; their crown stalked, of five spreading rough bristles; those of the disk awl-shaped, but shorter, their crown feathery. Recept. naked.

Eff. Ch. Receptacle naked. Calyx simple, of many leaves. Seeds of the disk with a feathery crown; those of the circumference with one of five naked rays.

Obi. Linn. has originally described the receptacle as naked, which is confirmed by Gertner, Willdenow, and Jacquin. Afterwards he attributed chaffy scales to this part, which is adopted by Schrober, but, as we believe, without foundation. Jacquin, in consideration of the etymology, properly makes this genus, as well as Tragopogon and Andropogon, of the masculine gender.

Two certain species of Geropagon only are known. They have the cloflest natural affinity to Tragopogon, but differ in the bristles, not feathery, crown of their external row of seeds. The genus is merely artificial, as not at all supported by habit, nor is the difference in the crown of the seeds greater than what occurs among indistinguishable species of one genus in others of this natural order.

1. G. albus. Linn. Sp. Pl. 1109. Jacq. Hort. Vind v. 1. t. 33. — "Leaves smooth." — Native of Italy and the Levant; sometimes kept in botanic gardens for curiosity only. It is annual, with a branched stem, 12 or 18 inches high, clothed with many alternate, clasping, long, grapy, smooth leaves, each branch terminated by a small, inconspicuous, pale pink flower, like the pink hawkweed, but far less hardy. The seeds are larger and more remarkable. The herb abounds with milky bitterish juice. Nothing can be more closely allied than this plant to Tragopogon porrifolius of Linnaeus: see Engl. Bot. t. 408.

2. G. hirsutus. Linn. Sp. Pl. 1109. (Tragopogon graminifolius, floridante flore; Colon. Echpr. t. 231.) — "Leaves hairy." — Found by Colonius, who alone of all botanists seems actually to have seen this species in a wood of wild pear-trees near Cirinola in Italy, flowering in May. It appears to differ from the preceding, chiefly in the roughness of its leaves, which neverthelss is so precisely and forcibly indicated by Colonius, that we dare not presume it not to be a sufficient distinction. All authors have adopted this plant from Colonius, nor had Linnaeus a specimen.

A third species occurs in recent writers, G. calciatus; Linn. Syll. Veg. ed. 13. 395. (Tragopogon calciatus; Jacq. Hort. Vind. v. 1. t. 165.) This was received by Jacquin from Italy, and he sent a specimen to Linumaes, who referred it to Geropagon. The habit is that of a Scorzonera. Root perennial. Flower, tall, calyx, and upper leaves hairy. Calyx of a double row of scales, shorter than the corolla, which is yellow. Crown of the seed slightly hairy, and, as far as we can perceive, uniform. — This is certainly no genuine Geropagon, and we are convinced it is the identical Scorzonera hirsuta of Linnaeus, well figured in Colonius’s Ephedras, t. 233, though unfortunately we cannot prove it to demonstration, there being no specimen of the latter in the Linnaean herbarium. The plant in question is however the Geropagon hirsutus of Allioni, Fl Pedem. v. 1. 229, as his fynonym was read, though he took it to be annual. S. GERRARD, in Geography, a county of Kentucky, in America, containing 6083 inhabitants, of whom 1254 are slaves.

GERRARDS, Peter van Zyl, in Biography, a painter, born at Amsterdam in 1607. He came to England and lived in the same house with Vandyke on terms of friendship and intimacy. He studied his manner successfully, and on his return to Amsterdam was so highly thought of, as to bear the name of the second Vandyke.

GERENS, GERUL or GIRONI, in Ichthyology, names given by the Venetians to a fish common in that part of the world. It is the smaris, or marna alba of authors. Artedi very judiciously makes it a species of the sparus, and distinguishes it from others, by its having a black spot on each Ede, and the nectar and tail-tins red.

GERRHA, Eijes, among the Greeks, wicker hurdles, resembling the Roman vinca, which the Romans held over their heads to shelter themselves.

GERRHE, or GERHON, in Ancient Geography, a people of Sceuthia, in Europe, S. of the Danube.—Allo, a people of Asiatic Sarmatia, not far from the Caucasian sea.

GERRHUS, a river of Sarmatia, which runs into the Palus Misodictis.—Allo, a river of Asia, in Albania.

GERRI, in Geography, a town of Spain, in Catalonia; 27 miles N. of Balangner.—Allo, a town of Africa, in Nubia, situated on the Nile; containing about 140 houses. 150 miles N.N.E. of Semaur, N. lat. 16 15. E. long. 33°.

GERISH, a small island, near Cape Neddock, close to the main land of the district of Maine, in America.

GERRY, a township of America, in the state of the Massachusetts, and county of Worcester; incorporated in 1786, and containing 14,000 acres of land, in which are 802 inhabitants; 30 miles N.W. of Worchester.

GERS, a river of France, which rises near La Barthe de Nelles, in the department of the Upper Pyrenees, traveries the department of the Gers, and runs into the Garonne, about three miles S.E. of Agen.

Gers, one of the nine departments of the south-west, or Garonne, region of France, bounded on the N. by the department of the Landes and the Lot and Garonne, on the E. by the department of the Upper Garonne, on the S. by the
the departments of the Upper and Lower Pyrenees, and on the W. by the department of Landes. This department is composed of Condominois, Armagnac, and Conmingues, and takes its name from the river which crosses it from south to north. Its capital is Auch. It is situated in N. lat. 43° 40'; its territorial extent is 7,474,764 square leagues, or about 539 square miles, and the number of its inhabitants is estimated at 291,845. As it is divided into five districts, viz. Condour, containing 67,103 inhabitants, La Noville, with 57,445, Auch, having 58,285, Lombras, with 37,593, and Miranda, with 79,579 inhabitants. The number of its cantons is 50, and of its communes 700. The total of its contributions, personal, stump-tary, and on movables and immovables, &c., is 5,563,310 francs, and the expense of administration, justice, and public instruction, is 278,498 francs. The soil of this hilly department is indifferently fertile, yielding moderate crops of grain, wine, fruits, and good pastures.

GERSA, or GAIRSA, an island of Scotland, five miles E. of Enhallo, two S. of Weir, and one E. of Mainland, is two miles long and one broad, and contains 50 inhabitants. The greatest part consists of a conical hill; steep on the W. side, and towards the E. more plain and fertile. The only harbour is that of Millburn on the E. coast. See GAIRSA.

GERSAU, or GERSAT, a village or town of Switzerland, at the foot of the Rigi, and the smallest republic in Europe. Its territory is about a league in breadth, and two leagues in length; situated partly on a small neck of land at the edge of the lake of Switzerland, and partly lying upon the rapid declivity of the Rigi. It contains about 1,500 inhabitants, having their general assembly of burgesses, their landmanns, their council of regency, their courts of justice, and their militia. In the whole republic there is not a single horse; and the only way of arriving at the town is by water, excepting a narrow path down the steep sides of the mountain, which is almost impassable. Gersia is entirely composed of scattered hovels and cottages of a very neat and picturesque appearance; each dwelling is provided with a field or small garden. The inhabitants are much employed in preparing silk for the manufactures of Basle. This little republic is under the protection of the four cantons, Lucerne, Uri, Switzerland, and Unterwalden; and in case of war furnishes its quota of men.

The town is six miles distant S.W. from Switzerland. N. lat. 46° 55', E. long. 8° 20'.

GERICHTZ, a town of Bohemia, in the circle of Konigingratz; nine miles N.W. of Konigingratz.

GERGISCHNITZ, a town of Germany, in the principality of Bayreuth; six miles E. of Bayreuth.

GERSDORF, a town of Germany, in the principality of Querfurt; four miles N.E. of Juterbog.

GERSON, in Biography, chancellor of the church and university of Paris at the beginning of the fifteenth century; according to whom the groundwork of all difcant was the plain chant; and in his treatise on the education of children for the choir of Notre Dame, he enjoins a particular attention to chanting, counterpoint, and discent, as the three most essential branches of their instruction and study. (Magister cantus flatatis horis docet pueros planum canum principaliter, et contrapunctum, et aliquos discentes honos.—decent and sober melodies.) He likewise tells us, that in this cathedral, during his time, the choirsisters were only allowed, by the statutes, to practise discent till their voices broke. (Nec faciet eos tantum incolere in talibus, quod per dam in grammatica profectum; attento maximse quod in ecclesia sofra discentus non est in ufu, fed per flatataa prorn supporter, solum quod voces quae mutare dicuntur.) The Abbé Lebeuf understands these last words as we have translated them: (Le débâc qui est point au long dans l'Eglise de Vals. XVI.)

Paris, et qu'an contraire il étoit défendu par les flétats, au moins à l'égard des voix qui avoient pafté le temps de la mutation. Traité Hift. sur le Chant. Eccles. p. 92.) The indefatigable Abbé Lebeuf found in the king of France's library the statutes here alluded to, which had been framed in the 13th century, and from which the chancellor had been ordered to make extracts in 1428. He concludes the fourth article of his tracts, which relates to psalmody, by informing us that no written discent was allowed in church missals or graduals, except for the exercise and improvement of the singing boys. (Nec debet in cantu notulato regulariter impleari discentus, propter exercitationem fum.) Gerson, to. iv. ult. edit. p. 717.

GERSFACH, in Geography, a town of Germany, in the county of Eberbach, on the Murg; taken by the French in 1794; three miles S.E. of Baden. N. lat. 48° 48'. E. long. 8° 20'.

GERSFINTZ, a town of Germany, in the county of Erbach; seven miles N.W. of Erbach.

GERSTE, CHRISTIAN LUDWIG, in Biography, was born at Giesen in 1701; here he was educated, and in the year 1733 he was appointed professor of mathematics and the mechanical sciences in that city. On account of some dispute he was dismissed from his office, and left Giesen in 1744; he went first to Altona, and from thence to Peterburgh; but meeting with no encouragement, he returned and attempted to get reinstated in his office, but failing in his design, he inflicted the landgrave, was arrested at Frankfort in 1748, and doomed to perpetual imprisonment in the castle of Marburg, with an annual allowance of 200 florins. Here he employed himself in teaching the mathematics to those young persons who came to his prison for instruction, and his leisure moments were occupied in studying the phenomena of the atmosphere, and the changes which take place in it, in order to become very expert in the science of meteorology. In the year 1766 he was liberated from his confinement, but his freedom was not complete; he was admitted at large for a time by way of proving whether he was entitled to a general discharge; escaping however from his shackles he went privately to Frankfort, where he kept himself concealed, or at least quiet, till he died in 1768. His works were numerous, and written in the Latin language: they chiefly relate to meteorology, to the methods of calculating eclipses, and to the structure of astronomical instruments. He was esteemed by his contemporaries for his integrity and his learning. He sent some papers to the Royal Society of London, of which several were inserted in the volumes of their Transactions. Moretti.

GERSTEN, in Geography, a town of Germany, in the principality of Eilenach, on the Werra; eight miles W. of Eilenach.

GERSTWALD, a town of Germany, in the Ucker Mark of Brandenburg; nine miles S. of Prenzlau.

GERTHAUSEN, a town of Germany, in the county of Hennberg; ten miles N.W. of Meiningen.

GERTRUDENBERG, a town of Germany, in the bishopric of Osnabrig; one mile E. of Osnabrig.

GERTRUDENBERG, St., a town of Brabant, but in later times subject to Holland, with a good harbour, formed by the Merwe, which here extends to a considerable lake, called "Bies Bosch," over which is a passage of two hours to Dort. It is built in the form of a crecent, with regular fortifications, good buildings, and forts with sluices, by means of which they can lay the adjacent country under water. In ancient charters it is called "Mons Latinos," the mountain of the shore. In 1645, Pepin de Landen, duke of Brabant, gave it to his daughter Gertrude, who
built a church dedicated to St. Amand, bishop of Tongres; but the place afterwards becoming celebrated by the death and pretended miracles of St. Gertrude, it has since been called "Mout de St. Gertrude," or Gertrudenberg. The castle was built in 1231. After passing through many vicissitudes, it was ceded by the French in February 1793, and taken; but soon after evacuated. The French took it again in 1795. It is distant 10 miles S.E. of Durt, and 7 N.E. of Breda. N. lat. 51° 40'. E. long. 4° 44'.

GERTZ, a town of Germany, in the principality of Wurzburg; 5 miles W.S.W. of Mannfrist.

GERVAIS, ARMAND FRANCIS, in Biography, was born at Paris about the year 1660; he was educated at the Jesuits, and at fifteen years of age he entered among the bare-footed Carmelites. At the age of twenty-two he was appointed by his superiors to teach theology to the younger members of the order; and he was at the same time distinguished as a pulpit orator. Some years after this he withdrew into the monastery of La Trappe, where he successively filled very important offices belonging to that order. The changes which he introduced, and the reforms which he mediated, created an alarm; and in 1698 he resigned his offices, and quitted his residence in the monastery. From this period he wandered, from solitude to solitude, following the same ascetic course of life which he had followed in the habit of practising in the college. Having, in 1744, published the first volume of an interesting "General History of the Cistercian Order in France," in which was a severe attack upon the Bernardins, he was arrested and imprisoned in the Abbey of Notre Dame de Reclus, in the diocese of Troyes, where he died in 1751, at the age of ninety-one. He published, besides the work alluded to, "The Life of St. Cyprian," with an abridgment of his works, including notes and dissertations: "The Lives of Peter Abard and of his wife Helen;" "The History of St. Peter, Abbot of St. Denis;" in three volumes, 12mo. "The Life of St. Irenaeus," in two vols. 12mo. Also lives of St. Paul, Epiphanias, Rufinus, and other eminent persons. He was distinguished as a controversialist, and was the opponent of Father Courayer on the subject of English ordinations. He is characterized as a man of great learning and inglorious virtues, but his manners were austere, impetuous, and forbidding. Moret.

GERVAIS, Sr. in Geography, a town of France, in the department of the Puy de Dome, and chief place of a canton, in the district of Riom; 15 miles N.W. of Riom. The place contains 2182, and the canton 9262 inhabitants, on a territory of 2825 kilometres, in 11 communes.

GERVAIS-de-Maffey, St. a town of France, in the department of the Orne, and chief place of a canton, in the district of Domfront; 9 miles N. N.E. of Domfront. The place contains 1628, and the canton 17,228 inhabitants, on a territory of 1321 kilometres, in 14 communes.

GERVAIS-la-Ville, St. a town of France, in the department of Herault, and chief place of a canton, in the district of Beziers. The place contains 1263, and the canton 8641 inhabitants, on a territory of 1772 kilometres, in 10 communes.

GERVAIS of Tilbury, in Biography, an historian of the thirteenth century, a native of Tilbury, in Essex, and nephew to King Henry II. He was, through the interced of Otho IV. made marshall of the kingdom of Arles. He wrote a commentary on Geoffrey of Monmouth's British History, and also a trilingual History of England. His other works are "A History of the Holy Land;" "Origines Bur- gundionum;" "Mirabilia Orbis," and a Chronicle; entitled "Imperialium Otiorum." The compilation of the ex-

GERVASIO GATH, the nephew of Bernard; was also a painter of considerable merit in the same style of colouring, as is evident in a picture of St. Schallian, in the church of St. Agatha at Cremona, where it is united to the design of the antique; and also in the Martyrdom of St. Cecilia, at St. Pietro, in the same city.

GERVASO, Sr. in Geography, a town of Italy, in the department of the Mela; 15 miles S. of Brescia.

GERUMA, in Botany, barbarously corrupted by Fork hall from an Arabic name Djerum. Fork. /Egyptiaco-

Arab. 62. Jull. 264. Lamark. Dict. v. 2. 702.—

Gen. Ch. Cal. Persiant inferior, of one leaf, flat, five-toothed, small, green, permanent. Cor. Petals five, lanceolate, abrupt, spreading, three as long as the calyx, white. Nectary, a thick ring surrounding the germen, bearing the filaments on its outer edge. Stam. Filaments five, erect, half the length of the corolla; anthers erect, triangular. Fil. Germen globulo, deeply immersed in the nectary; style thread-shaped, small; stigmas three, widely, spreading, red, wedge-shaped, emarginate at the extremity. Peric. Capsule superior, oval, of four, or perhaps five, cells, and as many valves. Stalk, two, in each cell, oval, inserted into a triangular white pulp; one of them often abortive.

Eff. Ch. Calyx with five teeth. Petals five, abrupt, Nectary, a ring round the germen. Stigmas three, emarginate. Capsule superior, ovate, of four or five cells. Seeds two, allied to a pulp receptacle.

G. alba. Leaves alternate, oval-oblong, somewhat serrated.

This is all that can be gathered from Forkhall's account, and it forms a botanical enigma. Some circumstances indicate an affinity to Jussieu's Euphorbe. The accounts of the stigmas and of the fruit are the most remarkable. Nothing is said of the habit, duration, or sensible qualities.

GERUND, in Grammar, a sort of tense, or time, of the infinitive mood: very like to the participle, but indeclinable.

The word is formed of the Latin gerundius; and that from the verb gerere, to bear.

The gerund expresses not only the time, but also the manner of an action; as, he fell in running.

It differs from the participle, in that it expresses the time, which the participle does not. And from the tense properly so called, in that it expresses the manner, which the tense does not.

Grammarians are much embarrassed to settle the nature and character of the gerunds: it is certain they are no verbs, because they do not mark any judgment or affirmation of the mind, which is supposed to be the essence of a verb; and besides, they have their several cases, which verbs have not.

Some, therefore, will have them to be adjectives passive, whose subjunctive is the infinitive of the verb: on this footing they denominate them verbal nouns, or names formed of verbs, and retaining the ordinary regimen thereof.

Thus, say they, tempus est legii librorum, or librorum, is as much as to say, tempus est iuris legii librorum, vel librorum. But others dispute this decision.

The Greeks have neither gerunds nor supines; but instead
of them they make use of the infinitive, in the same manner as the French; 

They insert it thus, "to boire." When the article happens to be made ufe of, then its genitive is put for the gerund in de, as viro, faciendi, of doing; the dative or ablative is put for the gerund in do, and the neuter for the gerund in dum. But the infinitive in this fene is often expressed without the article, as "Apergo aliqui, faculando petitus, an excellent archer; 

Γάμος, fecondum didit, he gave it to carry. In Greek, however, the termination εν corresponds to the Latin gerunds; thus, from λέγειν, to say, is deduced λέγειν, διετούπτω, it must be faid. These verbal adjectives, as they may be called, sometimes denominated gerunds, are ufed occasionally either in an active or a passive fene; τον άνθρώπον, it is for thee to cultivate the ground; τον ανθρώπον, and the body should be accustomed to obey the understanding, and be disciplined with toils and sweat. Xenophen.

An ingenious grammerian oberves, that the Latin gerunds in de, do, and dum, are but the participle in dui in the oblique fenes; and as this is taken from the prefent participle, they have its feme, namely, an active fene. On the fame principle that participles exprefs powers or habits in action, and their tendency is to dignify those powers, and not their operation, i.e. to become abfolute nouns; the oblique fenes of the participle in dui, when alone, become in their naure abfolute nouns. Hence gerunds, being thus nouns in reality, are governed like other nouns in the genitive, dative, accufative, and ablative, either with or without a prepoftion; as ratio folidi, the art of writing; charta utilis, folido, paper is ufeful for writing; promptus ad audietium, ready for hearing, or to hear; memoria excellendo auguriae, the memory is increased by cultivating. Gerunds also, having the nature of nouns, may govern a genitive; as facultas aquarum; ficut lactum connamandum, the power of the beflowing of his lands on his fefcendants. The gerunds, however, as retaining in a degree their verbal character, govern the feme of their repective verbs, as uifendi domum potius, veni ad recipiendum pecuniam, parceando victis. As adjectives affume the nature of nouns when ufed alone in the neuter termination, fo the gerunds in dum, the neuter of participles in dui, become fubftantives, denominating, with is, necefulty or obligation, as vivedum is mihi recte, living well must be to me, or I must live well. Jones's Grammar of the Latin Tongue, 1800.

GERY, Sr. in Geography, a town of France, in the department of the Lot, and chief place of a canton, in the district of Cahors; 5 miles N. W. of Cahors. The place contains 1250, and the canton 6335 inhabitants, on a territory of 180 kilometres, in 9 communes.

GERYON, a name given by some of the affected chemical writers to quickilver.

GERSAT, in Geography, a town of France, in the department of the Puy de Dôme; 4 miles N. E. of Clermont.

GERZEN, a town of Bavaria; 11 miles E. of Landshut.

GESAN, a town of the Arabian Iraik; 8 miles S. E. of Mendall.

GESAS, a town of Sileia, in the principality of Neiff; 3 miles S. E. of Patchcan.

GESEKE, a town of Germany, in the kingdom of Weftphalia; 9 miles E. S. E. of Lipbladt.

GESERICH, a lake of Pruifia, in Oberland, near Dutch Erlan.

GESERVAGHERD, a town of Peruca, in Chorofan; 30 miles S. of Esfeman.

GESHEN, Rocks and rivers of. See AMARUA.

GESHURITES, in Scripture Geography, a people who dwelt beyond Jordan, in the half tribe of Manufiah.

GESIS, in Geography, a town of Germany, in the county of Feldkirch; 4 miles E. of Feldkirch.

GESKENDORF, a town of Pruifia, in Oberland; 7 miles S. S. E. of Safald.

GEMSOLD, a town of Germany, in the bishooip of Ofnabruk; 12 miles S. E. of Vorden.

GESNER, Conrad, in Biography, "the greatest naturalift the world had ever seen since Aristotle," the first who ever collected a museum of natural history, and the discoverer of the true principles of botanical arrangement in the flower and fruit, "to which the very existence of botany as a science is owing," was born at Zurich in 1516. Like most of those who have rendered the most eminent services to science or their fellow-creatures, he had to contend with the greatest difficulties, especially with poverty in his youth, and with a feeble and sickly constitution to the day of his death. He very early imbued an ardent love of plants from his mother's brother, named Friccius, and this seems to have led him to the study of animals, and even of fossils. He was educated for the medical profession, which he subfsequently practifed in his native town, and to the emoluments of which he was indebted for the means of pursuing and promoting, by various expenfes means, his darling studies. He founded and supported a botanical garden; kept a painter and an engraver in wood ceftantly in his service, and acquired a very extensive library. He exercised the general habit of reading, with great success, to which the excellence of the botanical cuts he has left us, with respect to the habit as well as ftructure of plants, is owing. Many of these appear in the Epitome of Cкаменiус, and a large collection of the whole has been published in more recent times by Trew and Bömècle, printed from the original blocks. Gefer undertook various laborious journeys in pursuit of plants, especially on the Alps; and while he was, perhaps, the most learned naturalift of his own or any age, he rivalled the best experiences of his contemporaries in practical observation. He united to the investigation of the external characters of plants, the most affiduous attention to their medical properties, and his own health and life were frequently endangered by the experiments he made for the good of others. He was reported to have killed himself with a dose of two drams of the root of Dorsium, but though his stomach was at first debilitated, he speedily recovered, and amused his friends with a narrative of his cafe. At length this great man fell a victim to the more immediate duties of his profefion, having caught the plague, of which he died on the 13th of December, 1565, aged 49. When he found his end approaching, he requested to be carried into his museum, where he expired amid the monuments of his labours, thankful for what he had been able to accomplish, and supported by all the pious hopes and confolations of a Christian philosopher. His piety and benevolence were no lefs eminent than his talents. He was the general peacemaker among fuch of his literary acquaintances as were more inefible or lefs candid, and he laid aside, for a while, his own immediate employements, to devote his services to the family of a deceased friend, Moihan, whose work on Dioscorides he superintended, and published for their emolument. He was much attached, by fimilarity of talent to Valere Cordus, who died in 1541, at the age of 30, on his travels, at the early age of 29, and whose "Historia Plantarum" was fubsequently edited by Gefer. These able botanists had never had a personal interview, and Gefer was much more intimately acquainted with a young man named David Kyber, who died, at nearly the same age, of the plague at Stralsburgh in 1555; and whose "Lexicon Rei Herbariae Trilingue" (Latin, Greek, and German) he pub...
Gesner

Lived the same year, with a very affectionate and consolatory epistle to the father of the author.

The principal works of Conrad Gesner are the following, not to mention various little treatises relating to Botany, or to the Materia Medica, which from time to time came from his ready and prolific pen, of some of them accompanying the books he edited for other people.

"Bibliotheca universalis," or a catalogue of Latin, Greek, and Hebrew books, printed at Zurich, 1545, in one volume folio, with criticisms, and often specimens of each. This seems to have given Haller the idea of his own "Bibliotheca Botanica," and "Bibl. Anatomica."

"Historiae Animalium," comprised in five books, making three great folio volumes in a very small type, with numerous wooden cuts. The first was published at Zurich in 1551, the last in 1587, after the decease of the author. There is also an edition in German. This is a vast compilation, and critical review of all that had been done before him in Zoology, with every thing that he could lay of his own knowledge to illustrate the subject, and many incidental botanical, as well as medical remarks. Instead of being the work of a physician, who raised and maintained himself by his practice, and who was cut off in the middle of a most active and useful life, one would suppose it the labour of a recluse, shut up for an age in his study, and never diverted from his object by any other cares. This work is arranged according to the plan of Aristotle, only the viviparous quadrupeds are separated from the viviparous. It does not extend to insects or shells. The former however had not escaped the attention of Gesner, for his labours respecting them make a part of the work of Moutet, entitled "Insectorum sex Minorum Animalium Theatrum," published at London in 1634, the earliest book on entomology.

The "Icones Animalium," with their nomenclature, form a separate publication from the above, confining the wooden cuts and names only.

"Aquarium Animantium Enumeratio juxta Plinii," a little 8vo. printed at Zurich in 1556. A list of the German and English names is subjoined.

A little work in Latin, "De Lacute," treating of milk and its preparations, from various authors. Zurich, 1541, in 8vo.

"De Secretis Remedia Theofuris," a Pharmacopoeia, which has gone through a number of editions in various languages.

"De rari et admirandis herbis, quae fiv quod notce luceant, fie alias ob causs, Lamarce nominatur." A curious and learned little work, with wooden cuts, in 4to. Zurich, 1555. It is accompanied with a description of the celebrated mount Pilay, or Mons Prado, the northern extremity of the Alps, which Gesner visited in 1555. Several alpine plants are here, for the first time, noticed.

"De omnium Fossilium gener." Zurich, 1565, 8vo. Also "De rera Fossilium, Ladipum et Geranarium maxime figuris," with wooden cuts, more curious than useful.

The botanical remarks relative to the scientific arrangement of plants, on which the supereminence merits of this great man are founded, are chiefly to be gathered from his letters, which were published after his death. From the number of wooden cuts, and of drawings, which he had prepared, it is probable he meditated a general botanical work, the future arrangement of which frequently occupied his thoughts, and prompted many of these letters.

Gesner married at the early age of 20, for which he was accused of imprudence, but it does not appear that he had any reason to repent. His wife survived him, and notwithstanding the dangerous nature of his disease, which was accompanied with a pestilential carbuncle, she did not desert his death-bed, for he expired in her arms. He left no offspring. His remains were honourably interred, the day after his decease, in the cloister of the great church at Zurich, near those of his intimate friend, Fryius, who died the preceding year. Abundance of Latin, and some Greek verses, were composed to his honour, and his life, written by his countryman Jonas Simler, was published in the ensuing year. From this work, and Haller's Biblioth. Bot., much of the above information is derived. Haller mentions Gesner as probably the first person who, being short-sighted, found the advantage of concave glassies. S.

We have received the following additional account of C. Gesner, in relation to his medical profession.

His father, who was a worker in hides, was killed in the Swiss civil war, and left him in such poverty, that he went to Stralsburg, and entered into a situation as a servant. His master, having observed his great inclination to reading, allowed him to employ the time, which was not absolutely necessary to his service; in study; and he made such progress while at Stralsburg, that, having acquired a little money, he went to Paris, where he first attained an ample knowledge of the Latin and Greek languages, and of rhetoric, and afterwards applied to the study of philosophy and medicine: but as he soon found the means of subsistence fail, he was under the necessity of returning to his native country, and of teaching the languages and philosophy for a livelihood. This expedition was successful, and even procured him the means of visiting Montpellier, where he refined the study of medicine, which he completed, by taking the degree of doctor at Basle in the year 1540. He then determined to settle at Zurich, where his merit procured him the appointment of professor of philosophy, and he discharged the duties of that office, with universal reputation and esteem, during twenty-four years. These duties, and his studies in the closet, prevented him from entering largely into the practice of medicine; in which, however, his extensive knowledge furnished him with such numerous resources, that his practice was extremely successful, and he rose superior to the prejudices of his contemporaries. Gesner had always a decided predilection for the study of botany, which he early conceived and retained through life, as we have already mentioned in the former part of this article. It was not without great trouble and difficulty that he became a scientific man; for he was of a delicate and sickly constitution; but his spirit and courage gave him strength to support the fatigues of body and mind. Notwithstanding the delicacy of his habit, he traversed the Alps in search of plants; and among other journeys over those mountains, he made one with Jean Bublin in 1561. He even cut plants from the waters, and has been known to plunge into the lake of Zurich to procure those which grew there. Ever animated by the same spirit, he visited Paris again, travelled through the southern provinces of France, and thence pulled into Italy. In order to study the nature of fishes, he went to Venice with a view to investigate those of the Adriatic, and sometime afterwards he repaired to Stralsburg to examine those of the Rhine. From these sources of information, from a constant personal observation, conjoined with the study of the writings of the ancients, he obtained the means of accomplishing that immensity of treasures, which a man, who only attained to 49 years of age, could hardly be supposed capable of producing.

Gesner, John Matthias, was born at Roth, in Anspach, in 1691, where his father was a clergyman. He received the first part of his education at the gymnasia of Anspach, and...
and was quickly distinguished by his progress in the ancient and oriental languages. From Ansbach he went to Jens, where he exhibited his learning and talents in several publications. In 1715 he was appointed co-rector of the gymnasium of Weimar, and keeper of the public library. In 1730 he accepted the rectorship of Thomas's school at Leipzig, and on the establishment of the university of Gottingen he was invited to be the professor of rhetoric, an office in which he was so greatly distinguished, as to acquire the reputation of being the most able philologus of the age. He was at the same time made librarian and president of the German Society, and to his inspection all the schools of Gottingen were given. On the appointment of the Royal Society at Gottingen he was the first member of the historical class, and was afterwards appointed a councillor of state, and perpetual director. He died in 1761. His works are much too numerous to be named in this place, but they were such as to entitle him to almost the highest rank in the literary world. Among others may be noted his "Index etymologicus Latinatatis," and his "Thesaurus Latinus Lingue et Eruditionis Romanae," 4 vols. fol. Geffreys's elaborate work, followed the order of Stephanus, but added such notes and other improvements as appeared necessary. These additions confute chiefly in the number of remarkable phrases and passages from the Roman classics with illustrations. Gen. Biog.

GESNER, Solomon, was born at Basel, in Switzerland, in the year 1559. Having received the early part of his education at his native place, he was sent to Breflaw to pursue the studies necessary to his future profession. From this place he went to Strasbourg, where he was so fortunate as to obtain an academic exhibition for five years, which he employed in the study of philosophy, the mathematics, and the learned languages, as well the Hebrew, Chaldee, and Syriac, as those of Greece and Rome. He now became private tutor to a noble Livonian, and when he was 24 years of age he was admitted to the degree of M.A. In 1592, he was invited to fill the theological chair in the university of Wittemberg, and almost immediately entered upon the duties of his office, and was at the same time admitted to the degree of D.D. He also occupied the important posts of dean and rector of the university, afeessor in the ecclesiastical consistory, and first preacher in the church. His close application to businefs injured his health, and he fell a sacrifice to a complication of disorders in 1605, when only in the 46th year of his age. His works are a Latin translation of "The Prophecy of Hosea," "Disquisitions on the Pfalms," treating of the dignity, the use, the argument, and the connection of the Psalms, and many other works of a theological and controversial nature. Gen. Biog.

GESNEB, John, a canon of Zurich, and professor of natural philosophy and mathematics in that university, probably belonged to the same family as the great Conrad. He was the intimate friend of Haller, in whose society he studied at Leyden and Bafle, and with whom he maintained a close correspondence during the life of that distinguished man. Their tale for botany was the same, and their characters similar. His letters make an interesting part of the "Epistolae ad Hallerum," and abound with solid and curious botanical criticism and information. He paid much attention to the cryptogamic clafs, and other difficult branches of the science, as well as to the anatomy and physiology of plants. He survived his learned friend 12 years, dying in 1793, at the age of 81.

This author published two physiological dissertations on plants in 1749 and 1751, reprinted at Leyden in 1753, along with Linnaeus's "Oratio de pergaminatis intra patriam." In these he treats of the life and structure of vegetables, their propagation, fettes, chaitic motion of some of their fflans, and their methodical classification. He reviews the experiments and observations of Leeuwenhoek, Malpighi, Grew, Hales, &c. announces the new system of Linnaeus, whom, with a kind of prophetic spirit, he calls a man destined to reform all natural history. These disftinctions are the most magnificent epitome possible of all the botanical science of that day, in which the improvements of each writer are set in the most just and instructive point of view for their mutual illustration.

With all his knowledge, the subject of our present article, and even his friend Haller, were imposed on by one of the grosseft deceptions. A perfon prefented him with a common meadow Crowfoot, on some branches of which were flack flowers of the common Daily. He immediately published, in 1753, a learned dissertation on vegetable monstres, entitled "De Ranauculo bellidiforo," in which he exhibits a figure of this flrange anomoly. As Haller had given his function to the discovery, botanifs could scarcely fuppose it was an evident mistake, till Dr Joseph Banks obtained the original fpecimen after Geffer's death. On its being fent to with boiling water, in the presence of several botanifs, amongst whom was the writer of this, the flam of the Ranauculo came out of the base of the daily, as from a feaf; and indeed the different pubfhefts of each was very diftinguifhable before their separation. A history of the whole is given by Mr. Kofig, in his Annals of Botany, v. i. 308, with a plate drawn for him by Joseph Banks by Mr. Bauer, and signed by all the witnefses.

Geffer published at different times eleven disftinctions in quarto, from 1750 to 1773, under the general title of "Phytographia Sacra." One of the latter ones are illuftrative of the plants of fcripture, the refl being of natural nature, containing various anatomical and phyfiological, as well as botanical and economical matter. He adopts the Linnaean fystem, and furnifhes many remarks concerning the sexual doctrine.

He meditated a very extensive work on the characters of plants, for which he had prepared a coniderable number of exquisifely engraved, though too much crowded, plates, some of which are in our hands; but this publication never took place.

He wrote also on extraneous foldil, and composed an index to Weimann's "Phytophragia," printed in 1761 in 8vo. A catalogue of his library for which he was published in 1759, by which it appears to have been one of the best collections of botanical books ever offered to the public. S.

Gen. Ch. Cal. Perianth of one leaf, superior, in five deep, acute segments, permanent. Cor. of one petal, incurved and recurved; tube thickish, with a contraction at the neck and a funnel-shaped throat; limb five-cleft, obvue, its upper segments conoeo, or crested, the three lower flat and spreading. Stam. Filaments four, mostly shorter than the corolla, two longer than the others; anthers arrow-shaped, simple. Pyl. German inferior, depressed, roundish; style thread-shaped, parallel to the filaments; stigma capitate. Peric. Capsule roundish, crowned with the spreading calyx, imperfectly two-celled, the partition being longitudinally interrupted.
interrupted in the middle. Seeds very numerous, minute.

**Geit** attached to the partition at each side.

Ohf. We prefer, with Linnaeus, the name Geoforia to Geforia, as the most correct in its construction, and supported by the best analogies, though Plamier originally wrote the latter. In such cases it is needless to baffle the reader with precise quotations, and we merely adopt the orthography that appears the best, except where there do any difference worth commemorating.

Linnaeus has given but three species of this genus, to which Swartz has added seven new ones, besides the Linnan Crambpera fructifica, in his Prodromus Fl. Ind. Occ. where he also made the Cyvilia of L. Heritier a Geoforia; see Cyvilia. But in his Fl. Ind. Oce. 1032 he submits to the opinion of those who reckon it distinct. All the Geoforia are of Weil Indian origin, and very little known in Europe, except the tanentofa, kept in botanic gardens for its rarity rather than beauty. Several of the species first described by Swartz are eminently handsome, and well deserve to be introduced into our flowers, especially his varietas, which bears tubular curved scarlet flowers, with projecting lamens, like some of the finest Erica. All the species are shrubby, except G. panula of Swartz, whose leaves resemble a Frizula or Arjuna, and G. acutilis of Linnaeus, Sp. Pl. 870. (Rapuncklo affinis, &c, Sloane Jan. v. 1. 102. f. 1.) both which are herbageous, and fearely rise above the ground. The leaves in all are simple, alternate, softly, thick, more or less crenate, toothed, or serrated, rough or smooth. Flowers corymbifer, mostly on a long common stalk. Corolla variously shaped in different species, but always more or less curved, from above one to two inches long. They chiefly grow in rocky, shady, mountainous places, in Jamaica, or in Hifpania. Full descriptions of all that Dr. Swartz has observed may be found in his Fl. Ind. Occ. v. 2. 1015—1031.

**Gesoriacum**, in Ancient Geography, a town of Gaul, belonging to the Morini; now Boulogne.

**Gesene**, in Geography, a town of Boeheim, in the circle of Boletus; nine miles N. E. of Turna.

**Gesserit**, Quamh. See Quamh. f. lew gersitis.

**Gesses** is the furniture belonging to a hawk. See **Jesses**.

**Gesti**: Francesco, in Biography, a favourite disciple and imitator of Guido Reni in the art of painting, some of whose works are little inferior to those of his master, and are often sold for his. He is generally known by a want of fulness of execution, and of energy in his actions.

**Gessico Point**, in Geography, a cape of Ireland, in the county of Sligo, at the northern extremity of Sligo bay. N. lat. 54° 22'. W. long. 8° 33'.

**Gesso**, a town of Naples, in Abruzzo Citra; 15 miles N. E. of Civera Borela.

**Gessofs**, a town of the state of Maryland, in America; eight miles E. E. of Fort William.

**Gessor**, a name used by some of the Arabian writers for galbanum.

**Gesta**, in Geography, a town of Sweden, in Weil Gotland; 23 miles N. E. of Uddevalla.

**Gestation**, Uterine, or utero-gestation, in Med. Wifery, the bearing or containing a fetus in the womb. See Inception.

**Gestation** is also a term in the Ancient Medicine, used for a fort of exercise, by us called carriage.

It consisted in making the patient ride on horseback, or in a chariot, or a boat; or even in rocking him in his bed, if he could not endure a more violent agitation.

Acelepiades first brought frictions and gestation into practice. The design of gestation was to recover strength, after a fever, &c. was gone.

**Geste**, in Geography, a town of France, in the department of the Mayen and Lorraine; 12 miles N. W. of Chollet.

Allo, a river of Germany, which runs into the Weser, near its mouth; called also Geife.

**Gesticulation**, the making of affected, indecent, or unfitting gestures, or even of proper ones in too great number. Gesticulation is a grievous fault in an orator.

**Gesten**, in Geography, a town of Switzerland, in the canton of Uri; 15 miles S. of Altorti.

**Gestrada**, a province of Sweden, about 51 miles long and 10 wide; bounded on the N. by Helsingland, on the E. by the Gulf of Bothnia, on the S. by Upland, Weifland, and Dalecarlia, and on the W. by Dalecarlia. The inhabitants do not concern themselves with agriculture, but derive their chief support and wealth from mines, forests, lakes, and rivers. The capital of this province is Geife, which sea.

**Gestu et Fana**, in Laws, an ancient writ, where a person's good behaviour was impeached; now out of use.

**Gestungshausen**, or Gesellung in Geography, a town of Germany, in the principality of Coburg; seven miles E. of Coburg.

**Gesture**, a motion of the body, intended to signify some idea or passion of the mind.

Quintilian defines gesture, totius corporis motus & conformitatis. Gestures are a kind of natural language, which supplies the use of speech in those naturally dumb. The mimic and pantomimes were very great proficients in the style of gesture.

Gesture consists principally in the action of the hands and face; and may be defined, a suitable conformity of the motion of the countenance, and of several parts of the body, in speaking of the subject matter of the discourse. (See **Action**.) With regard to oratory, gesture may properly be called the second part of pronunciation; in which, at the voice should be suited to the impressions it receives from the mind, so the several motions of the body ought to be accommodated to the various tones and inflections of the voice. When the voice is even and moderate, little gesture is required; and nothing is more unnatural and disfiguring than violent motion, in discoursing upon ordinary and familiar subjects. The motions of the body should, therefore, rise in proportion to the vehemence and energy of the expression, as the natural and genuine effect of it.

Gesture is either natural, or from imitation. The former denotes such actions and motions, either of the whole body, or of some particular part of it, as naturally accompany our words, just as these result from the impressions of our minds.

As to the whole body, it should not continue long in the same passion, but be constantly changing, with a gentle and moderate motion. As to the several parts of the body, the head is the most considerable; to lift it up too high, has the air of arrogance and pride; to stretch it out too far, or throw it back; appears clownish and unmanly; to hang it downwards on the breast, shews an unmannerly bashfulness and want of spirit; and to fix it on either shoulder, argues both and insolence; in calm and sedate discourses, the head should keep its natural state and upright posture, occasionally moving, and turning gently, sometimes on one side, and sometimes on the other, as occasion requires, and then returning back to its natural position. It should always accompany the other actions of the body, except in aversion.
aversion, which is expressed by stretching out the right hand, and turning the head to the left. But nothing is more indecent than violent motions and agitations of the head.

The passions are principally represented by the countenance; and the several parts of the face contribute to the proper and decent gesture of the whole. In a calm and sedate discourse, all the features retain their natural situation. In sorrow, the forehead and eye-brows lower; and the cheeks hang down; but in expressions of joy and cheerfulness, the forehead and eye-brows are expanded, the cheeks contracted, and the corners of the mouth turned upwards. Anger and resentment contract the forehead, draw the brows together, and thrust out the lips; and terror elevates both the brows and forehead. To these natural signs of the passions, the orator should endeavour to conform.

The motions of the eyes require the most careful management; because, as Cicero observes, (De Orat. lib. iii. cap. 59.) other parts of the countenance have but few motions; whereas all the passions of the soul are expressed in the eyes by so many different actions, that cannot possibly be represented by any gestures of the body, if the eye be kept in a fixed posture. Thus, in speaking on pleasant and delightful subjects, the eyes are bright and cheerful; but if they frown and are languid in delivering any thing melancholy and sorrowful. In anger, the eyes discover a certain vehemence and intenfeness; in expressions of hatred and detestation, the eyes are turned either aside or downwards; thus Virgil has expressed Dido's resentment and disdain of Æneas:

"Illa solis occulos avera tenerat."

And lib. vi. ver. 469.

The eyes are also sometimes turned downwards, to express-modesty; and they should be always turned towards the object which is addressed. A gentle and moderate motion of the eyes is commonly most suitable, whereby they may be directed to some of the audience with an air of respect and modesty; but their motions ought to vary, according to the different nature of the passions which they are designed to discover in the speaker, and convey to his hearers.

The shoulders should neither be elevated nor depressed: a continued motion of the arms should be avoided; their action should be very moderate, and follow that of the hands, which need never be idle. Quintilian says, great fires on the action of the hands, when he says, "The hands, without which all gesture is lame and weak, have a greater variety of motions than can well be expressed: for they are almost equal to our words. Do we not desire with them, promise, call, dismiss, threaten, beseech, deter, fear, inquire, deny? Do not they express joy, sorrow, doubt, confidence, petition, menace, pleasure, number, and time? Do not they excite restraint, prove, admire, and blame? That in so great a variety of speech among all nations and countries, this seems to me the common language of mankind." (De Orat. lib. xi. cap. 3).

As all bodily motion is either upward or downward, to the right or left, forward or backward, or circular, the hands are employed by the orator in all these, except the last; and as they should correspond with our expressions, they ought to begin and end with them. In admiration, and addresses to heaven, they must be elevated, but never raised above the eyes; and in speaking of things below us, they are directed downwards. Side motion should generally begin from the left, and terminate gently on the right: in demonstrating, addressing, and on several other occasions, they are moved forward; and in threatening, sometimes thrown back: when the orator speaks of himself, his right-hand should be gently laid on his breast. When no other motion is necessary, the hands should be kept about as high as the breast, to as to make nearly a right angle with the arm. They should never be suffered to hang down, nor to roll upon the cushion or bar. The left-hand should never move alone, but accommodate itself to the motions of the right: in motions to the left, the right-hand should not be carried beyond the left shoulder; in promises and explications of compliment, the motion of the hands should be gentle and slow; but in exhortations and applause, more swift. The hands should be generally open; but in expressions of composure and anger, they may be closed. Neither the breast nor the belly should be thruf out; the trunk should be easy and flexible, fitting itself to the motions of the head and hands; and the feet should be kept steady.

There are other gestures, which arise from imitation, as when the orator describes some action, or perforates another speaking: but here he should be careful not to exceed his part, by running into any ludicrous or theatrical mimicry, or changing his action or voice in a manner unsuitable to his own character. See farther on this subject, Ward's Oratory, vol. vi. p. 344. & c. p. 369. & c. Sheridan's Lect. on Elocution, lect. vii. p. 113. & c. See also Action, Imitation, Pronunciation, and Voice.

Gestus Bonus, in Lati. See Good a-bearing.

Getal, Septimius, in Geography, second son of the emperor Severus, and brother and partner of Caracalla, was born at Milan in 189, and was raised to the title of Augustus. In the eighth year of his age he was moved with compassion at the fate of some of the partisans of Niger and Albinus, who had been ordered to be executed, and his father, struck with the humane feelings of his child, remitted the sentences. Though he was not free from the vices of an heir to the empire, yet the mildness of his disposition made him a greater favourite with the people than his brother, and this circumstance inflamed their mutual hatred. On the death of Severus both princes succeeded to a joint sovereignty, but their union was of short duration. Caracalla, jealous of his brother's popularity, ordered him to be poisoned, and when he found the infamous act could not be effected, he murdered him with his own hands in the presence of his mother Julia, who, in the attempt to defend her favourite son, was severely wounded in the arm by Caracalla. Getal had not reached the twenty-third year of his age when he fell a victim to the brutality of his brother. Before his death, Severus had, in the anguish of a disappointed father, intimated that the weaker of his sons would fall a sacrifice to the stronger, who, in his turn, would be ruined by his own vice. (Herod. i. 20. 1.) See also the article Caracalla.

Getal, in Geography, a town of Sweden, on the N. coast of the island of Alan. N. lat. 60° 25'. E. long. 9° 50'.

Gete, or Geet, a tribe of Scythians, who, according to Herodotus (I. iv.), inhabited that part of Thrace which is near the Iler or Danube. Strabo says (I. vii.) that they had the same language with the Thracians, and he represents them as occupying those arid uncultivated plains which lie along the sea-coast between the mouths of the
GET

the Iber and that of the Tyrrhens, in which the army of Dar- 
rus, in its march against the Scythians, was in danger of per-
rishing for want of water. Pliny (i. iv. c. ii.) says, that
they inhabited that declivity of Mount Helmus which is
turned towards the Danube. Under the empire of Trajan,
the Getes were subjected to the Roman dominion. Herodotus
speaks of Zamolxis as the legislator of the Getes; and he
says that from him they derived the dogma of the soul's im-
nortality; and Trajan attributed to this principle the inter-
pidity with which they encountered death in the perils of war.

The Getes possessed only a small space along the coast, but
their territory extended to a considerable distance in the in-
terior of the country. Those who inhabited the western part
in ascending the Danube, were called "Dacians," but those
who were more appropriately denominated Getes, occupied
the eastern parts near the Exulian sea; and those who in-
habited the banks of the river Tyrrh, were called "Tyri-
getes." They had all the same language. These people
were continually intermixing themselves with the Scythians,
Balkarians, Sarmatians, Medians, and Thracians. The Getes
were without doubt the same people with those who were
called Gothis, and whose migrations were so extensive. See
Gothis.

GETTCHAO, a town of China, of the third rank, in
Chang-tong; 27 miles E.S.E. of Lu.

GETE, part of the country of the Eluts, in Chinefe
Tartary, so called even to the time of Timur, is regarded
by some geographers as the country of the ancient Maffa-
getas, towards the lakes of Palkati, Balkash or Tengis, and
Zaizan. The contafth, or great Khan, used chiefly to re-
side at Harcas, or Erga, on the river Il, which flows from
the S.E. into the lake of Balkash. See Jats.

GETHSEMAME, in Scripture Geography, a village in
the mount of Olives, whither Jesus sometimes retired,
and in a garden of which he endowed his agony, and was
taken by Judas. Matt. xxvi. 36, &c.

GETHYLIS, in Botany, (γήθυλις), an ancient
Greek name for some sort of pot-herb of the onion-tribe,
and is therefore well enough applied to this bulbous plant,
as it appears to be derived from γήθυλις, guity or jep, and
may allude to the beauty of its blossoms.) Thoub. Nov.
Sp. Pl. v. 2. 104, Mart. Mill. Diét. v. 2. 275, (Papi-
ria; Thoub. Act. Lund. p. 1. sect. 2. 117.—Chals and or-
Narceæ, Jaff.

Gen. Ch. Cal. none, except an obliquely truncated cylin-
дрical sheath. Car. of one petal, superior; tube very long,
thread-shaped; limb widely spreading, regular, in six deep,
elliptic-oblong, equal segments. Stamps. Filaments six, in-
ferred into the mouth of the tube, shorter than the limb,
often divided; anthers linear, vertical, rolled inwards, often
two to each filament. Pét. Germen inferior; style simple,
capillary, longer than the stamens; stigma capitate. Peric.
Berry club-shaped, obtuse, radical, sessile on the bulb itself,
several filiform, of one cell. Seeds imbedded in pulp, glo-
bose, smooth, lying over each other in a triple series.

Eff. Ch. Corolla with a very long thread-shaped tube;
limb in six deep segments. Berry radical, club-shaped, of
one cell. Seeds numerous.

Obf. Linnaeus, mifled by the occasional luxuriante of the
stamens, placed this genus in the clafs Decandria.

Four species are defined in Willdenow, besides his and
Jacquin's G. plicata, Hort. Schoenbr. v. 1. 42. t. 80,
which is Hypoxis plicata of Linnaeus, and we are at a loss
to discover why it is removed to Galbiya, for which no rea-
nion is given, nor does the description in Jacquin suggest any,
except the length of the tube. The fruit, when known
must decide this question.

41. t. 79, is a good example of the genus. The bulb is glo-
fuse, with a very strong tuberous base, and thick fibres.

Stamina. Lecyth, several, three or four inches high, linear,
obtuse, fringed, spirally twisted. Flower the height of the
heaven, green-white, the size of a daffodil.

G. fijlula, Gawler in Curt. Mag. t. 188, has a white
flower, externally purplish, and very narrow, flat, smooth
leaves. It is distinguished in that work from the original
G. offa, Linn. Sp. Pl. 639, 1753, as having an authority
of some specimens and drawings of the late excellent
Mr. Maffon, in the hands of Mefia Lee and Kennedy,
in which both plants are well defined. According to this
authority, G. offa is said to have properly twelve flaments.

Thunberg certainly confounded these two.

All the species of Galbiya have the habit of a Calceium;
but the berry, said to be very pleasantly scented and well-
tasted, is their striking characteristic. They are natives of
the Cape of Good Hope, rarely seen in our gardens, where
they do not easily blossom.

GETONIA, a name given by Dr. Solander, and, as we
presume, derived from γετονία, a yifecycle, but of its applica-
tion in the present instance we have no information. Roxb.
Coromand. v. 1, 61. (Calycoperis; Lamarck Illust. t. 357.)
—Chals and order, Decandria Monogynia. Nat. Ord. Holo-
baces, Linn. Eleagni, Jaff.

Gen. Ch. Cal. Perianth of one leaf, superior, deeply di-
vided into five equal, elliptical, obtuse, spreading segments,
permanent. Car. none. Stam. Filaments ten, shorter than
the calyx, inserted in two rows into the lower part of its seg-
ments, capillary, erect; anthers incumbent, roundish. Pét.
Germen inferior, ovate, furrowed; style thread-shaped,
shorter than the stamens; stigma simple. Peric. none, ex-
cept the cruf of the field, which is ovate, furrowed, crowned
with the larger withered calyx. Seed solitary, ovate.

Eff. Ch. Calyx in five deep segments, superior. Corolla
none. Seed coated, crowned with the enlarged withered
calyx.

1. G. floribunda. Roxb. Corom. v. 1, 61. t. 87.—Native
of forefists on the coast of Coromandel, where it was first
noticed by Kenné, flowering in February and March. The
flower is woody and climbing, with long, leafy branches,
downy like the whole plant. Leaves opposite, 
filament, ovate, acute, entire, about two inches long. Flowers
in axillary and terminal, compound leafy clusters, with op-
posite filaments, inodorous, greenish-white. Seed and perma-
nent calyx of a rusty hue.—The natives call this shrub Band-
mooroodoodoo.

We have no doubt of the propriety of Lamark's synonym,
which our lamented predecessor, the Rev. Mr. Wood, not
knowing the Getonia, could scarcely ascertain. (See Ca-
lycopera.) If we be right, the main branch in La-
mark's plate is diminished, the separate fruits only, and
permanent flaments, being of the natural size.

GETTYSBURGH, in Geography, a small poft-town of
America, in the State of Pennsylvania and Adams county,
situated at the head of Rock creek, one of the head-waters
of the Monocacy; containing about 300 houses; 9 miles N.
of the Maryland line, and 118 W. by S. from Philadel-
phia.

GETZENDORFF, a town of Austria, seated on the
river Raisenpach; 12 miles S.E. of Vienna.

GEVASI, a town of the Arabian Trak, on the Tigris;
95 miles S.E. of Bagdad.

GEVAUDAN, a mountainous country of France, so-
called
called before the revolution, situated in Languedoc; of which Mende was the capital.

GEVES, a town of Africa, situated on a river of the same name, S. of the river St. Domingo.

GEUL, a river of France, which runs into the Meuse, about 5 miles below Maerdrich. — Allo, a town of France, in the department of the Lower Meuse; 5 miles N. of Wyck.

GEUM, in Botany, is mentioned by Pliny, though we learn nothing from that author respecting the derivation of its name. Ambrosius confectures that it comes from rras, to be spangled, because its beautiful flowers and seeds are the boast and glory of the Alps. — Avens, or Herb-bennet.— Linn. Gen. 256. Schreb. 543. Willd. Sp. Pl. v. 2. 1113. Lamarck. Illust. t. 413. Mart. Mill. Dict. v. 2. Sm. Pl. Brit. 554. Jut. 358. Gaertn. t. 74. (Caryophyllata; Tour. t. 151. Lamarck. Dict. v. 1. 396.) Chaff and order, Neu- fandria Polygynia. Nat. Ord. Simifera, Linn. Juss. Jaff. Gen. Ch. Col. Perianth of one leaf, in ten segments, rather upright; the alternate segments very small, acute. Petals five, rounded; claws narrow, of the length of the calyx, into which they are inserted. Stem. Filaments numerous, ovate, of an equal length with the calyx, and inserted into it; anthers short, broad, obtuse. Petals yellow, numerous, collected into a head; filaments into the side of each gamer, hairy, long; stigmas simple. Parent none; common receptacle of the seeds oblong, hairy, placed on the reflexed calyx. Seeds numerous, compressed, rough; each tipped with the long gigantic style.

Seeds with a jointed awn. Receptacle columnar.

Only five species of Geum are described by Linnæus in the last edition of his Species Plantarum, though in Willdenow's edition we meet with eleven of this genus, of which number G. urbannum and ricola are the only British ones, and to which we are enabled, by the assistance of Dr. Smith, to add two or three others from his herbarium.

2. G. ricola Water Avens. Linn. Sp. Pl. 717. Eng. Bot. t. 1566.— "Radical leaves lyrate. Stipulas ovate, acute, cut. Flowers drooping. Seeds twinned and feathery. - Found in meadows and moist woods more commonly than is usually imagined, perennial, flowering in June and July. Rest spreading, woody, aromatic, sometimes of use in intermittent fevers. Stem about a foot high, drooping at the top. Leaves lyrate, or confundly pinnate, serrated, hairy. Petals erect, never fully expanding. The general appearance of this elegant species, an universal favourite amongst botanists, is thus truly described in English Botany, "the rich combination of the dark-green wrinkled leaves, with the glowing red-brown of the flower, and calyx, and singularly delicate colour of the petals, added to the graceful position of the flowers, render this one of the most picturesque of our native plants."

3. G. virginianum. American Avens. Linn. Sp. Pl. 716. (G. camadene; Jacq. Hort. v. 2. 82. t. 175.) — "Stems Vol. XVI. leaves ternate; the upper ones lanceolate. Stipulas oblanceolate. Flowers erect. Seeds of the seeds hooked. — Native of North America, from whence it was introduced by Mr. P. Miller in 1753. It is nearly allied to habit in G. urbannum, but the petals, which are shorter than in calyx, are white, and the whole plant is of a greener hue. Its leaves are also more attenuated towards the base. It flowers in June, and is a hardy perennial. Roat inodorous. Radical-leaves generally bipinnate. Seeds smooth.

6. G. montana. Pyrenean Avens. Willd. Sp. Pl. v. 2. 1115. (Caryophyllata pyreniae, amplexica et rotundicri folio, mutantes flore; Tour. Linn. 295.) — "Flowers drooping. Petals shorter than the calyx. Seeds hairy, twined at the base." — This is taken up by Willdenow from Tournefort, and is perennial, found on the Pyrenees. Its appearance is similar to G. ricola, but differs in the large size of its radical leaves, and shape of its awn, which are thinly covered with hairs, and naked at the top. Stem erect, about a foot and half high. Seeds very woolly.

9. G. montana. Great Mountain Avens. Linn. Sp. Pl. 717. Jacq. Auffr. v. 3. t. 575. — "Leaves pinnate, hairy; the outer leaflet very large; round; the lower ones regularly decreasing. Stem single-flowered. Awns upright, hairy. — This, and the following species (G. reptans) are found most abundantly on the highest alps of Austria and Switzerland, where they are extremely ornamented during the months of July and August. Mount Cenis is described by travellers as a favourite habitat of these beautiful plants. The root of G. montana is fibrous, aromatic, and somewhat aromatic. Stem round, leathery, from three to four inches to a foot in height, erect, generally single-flowered, simple. Petals roundish, yellow, longer than the calyx. Seeds oval, brown, with a long feathered awn.

G. aurantiaca. Species with broad, fleshy leaves. Stem single-flowered. Axils of leaves, hairy. —Hawaii, where it is native.

11. G. aemoneoides. A. & C. Arvensis. Wild. Sp. Pl. v. 2. 1177. — "Leaves pinnate, smooth; leaflets wedge-shaped, toothed at the top. Stem single-flowered. Axils of leaves, hairy. —There is no figure of this rare species extant. Willdenow has very properly reduced it to Geum, though the plant was previously known as Dryas pentapetala. (Linn. Sp. Pl. 717.) Native of Kamtschatka. Root perennial, throwing out filiform, fleshy creeping. Stipulas narrow. Petals five, large, round, white, spreading. Seed numerous, tipped with an hairy awn, and longer than the flower. It appears by the Linnean Herbarium to be a very elegant species.

13. G. calvijjum. Marsh-marigold-leaved Avens. —Radical leaves kidney-shaped, almost circular, sharply crenate; on slightly leafy stalks. Calyx turbinate, with lanceolate segments. Axils hairy. —Gathered by Mr. Meezies on the west coast of North America. This is remarkable for the resemblance of its radical leaves in shape and size to those of Caltha palustris, except their being slightly hairy, and their long foot-stalks being furnished with a few small oblong or three-lobed leaflets, indicating an approach to a lyrate leaf altogether. Stem above a foot high, erect, bearing three or four smaller, fleshy rounded leaves, more deeply crenate or cut, and terminating in about three flowers, on slender stalks. Calyx hairy at its base, turbinate; its segments oblong-lanceolate, obtuse, at length crenate, the larger ones equal in length to the petals which are yellow and broad, like those of a common Crowfoot. Axils straight, bluish, hairy in the lower part, possibly becoming hooked at an advanced period.

Geum urbanum, in the Materia Medica, is a common British plant, called Avens, in woods and hedges, flowering from May till August. The root, which is the part medicinally employed, has an aromatic and somewhat astringent taste, and a pleasant smell of the clove kind, especially when it is produced in dry and warm soils. It gives out its astringent matter equally to water and spirituous menstrua; but its aromatic part most perfectly to the latter. In distillation with water it yields a small quantity of a bituminous oily matter, of a very grateful fragrance. This plant, though little used in Britain, is held in great esteem for various virtues on the continent; but the character, under which it has been received since the year 1760, is that of a febrifuge; many infancies having been assuaged by its efficacy in obstinate intermitments, after the Bovian bark had failed. It is said that a tincture of the root, made in the proportion of four ounces of the root digested with a quart of brandy in a sand heat, and given in the quantity of half an ounce or more, two, three, or four times a day, seldom fails to cure agues. Others have given it with equal success in decoction, powder, or electuary, in the proportion in which the Cinchona bark is commonly employed. This root has also been found useful in several chronic disorders, as a general tonic and astringent; and experiments made by Buhlehave evince its antiscptic power to exceed that of Peuvian bark. Woodville, Med. Bot.

GEVOLLING, in Geography, a town of Austria; eight miles S. of St. Polten.

GEVREY, a town of France, in the department of the Côte d'Or, and chief place of a canton, in the district of Dijon; 7 miles S. of Dijon. The place contains 1128, and the canton 7894 inhabitants, on a territory of 260 kilometres, in 46 communes.

GEUSS, JOHN MICHAEL, in Biography, was born in Holstein in 1745. His father undertook the care of his education, and found in his son a turn for mathematical and philosophical pursuits, which he encouraged, and by which he became distinguished, and was chosen professor of the mathematics in the university of Copenhagen. His principal work was the "Theory of the Art of Contracting Mines," in the composition of which he was assisted by the MSS. of Behlor, which he had the good fortune to obtain, though they had been suppressed in France, after the death of that able engineer. He published also a "Treatise on the Art of Contracting Mines." He gave a translation in the German language, from the Danish, of Olufsen and Povelsen's voyage to Iceland, which was printed in two volumes 4to. He lent several valuable papers to Bretin's, Ingenieur-und-Artillerie Magazin, and published a set of logarithmic tables.

GEUTZ, in Geography, a town of Austria, in the duchy of Anhalt-Coten, near Cotten.

GEWICZE, GEWITZ, or Gzwiff, a town of Moravia, in the circle of Olmutz; 24 miles west of Olmutz. N. lat. 49 45. E. long. 16 35.

GEWOLD, CHRISTOPHER, in Biography, flourished in the seventeenth century. He was one of the acute counselors of Maximilian, first elector of Bavaria, who confided to his care the archives of the duchy, in order that he might make use of them as an historian. His works relate chiefly to the history of his own country; of these we may mention "Genealogia Serenissimorum Bohemorum Ducum, 1605," "Chronicon Monasterii Reicherspergen.", "Delivatio Norici veteris, ejusque Confiniun," and "Commentarius de Septem virutu Romanorum Imperii." Morelli.

GEX, in Geography, a small territory of France, in the cidental province of Burgundy, extending from Port d'Echalde to the village of Croissy, and from the town of Gex to Geneva, being seven leagues in length and three in breadth.
breadth, watered by the Rhine and other streams, and bounded on the west by mount Jura, which yields excellent pastures. The principal articles of trade are cheese, wine, and coal. It now forms a part of the department of Lake Leman.

Gex, a town of France, in the department of Leman and chief place of a canton, in the district of Geneva, situated at the foot of mount St. Claude; 9 miles N. N. W. of Geneva. The place contains 2,401, and the canton 9,209 inhabitants, on a territory of 212½ square miles, in 14 communes. N. lat. 46° 20'. E. long. 6° 8'.

GEYER, a town of Germany, in the circle of Erzgebirg, situated in the midst of mines, and having manufactures of vitriol, sulphur, alum, and arsenic; 6 miles W. S. W. of Wolkenstein.

GEYERSBERG, a town of Bohemia, in the circle of Königigratz; 28 miles E. N. E. of Chrudim.

GEYRACH, a town of the duchy of Styria; 9 miles S. S. W. of Cilley.

GEYS, or GEYS, a town of Germany, in the bishopric of Fulda, situated on the Ulster; 15 miles N. E. of Fulda. N. lat. 50° 43'. E. long. 10°.

GEYSS Rucken Jaffelick, a mountain of Germany, which separates Upper Carniola from the county of Cilley; 6 miles N. E. of Stein.

GEYSZING, New, a town of Saxony, in the margraviate of Meissen; 12 miles S. E. of Plzinzt.

GEZAEL, a town of the Arabian Irak, on the Ephrathas; 120 miles W. N. W. of Basfora.

GEZAN, or DESAN, a sea-port town of Arabia Felix, in the principality of Abu-Arifch (see Abu-Arinfch); 23 miles W. of Abu-Arifs, the capital of the principality. This province of Gezan, situated on the Arabic gulf, and in a fertile country, carries on a considerable trade in fennas, of which great plenty is furnished by the circumjacent territory, and also in coffee, which is brought hither from the mountains of Hafchid-u-Bakil. It has a trade likewise with the ports on the opposite side of the Arabic gulf; but has no intercourse with the inhabitants of the Inam.

GEZEID, a town of Egypt, on the right bank of the Nile; 72 miles N. N. W. of Cairo.

GEZIRA, or JASSEERA, a town of Asiatic Turkey, and capital of a pashalic, in the province of Diarbekir, on the right bank of the Tigris. The whole province of Diarbekir is also called "Al-Gezira;" 75 miles S. E. of Diarbekir. N. lat. 37° 16'. E. long. 42° 42'.

GEZIRA CUBROS, in the Medin Medica of the Ancients, a name given to tale by Avicenna, Serapion, and others. These authors do not give any explication of what sort of substance they mean by this name, but seem to suppose it a thing universally known, and only give a lift of its qualities.

GEZIRAT AL DAIHB, or GEZIRAT IDDEHAB, or the Golden Island, in Geography, an island in Lower Egypt, formed by canals cut from the left bank of the Nile, opposite to Finsa.

GEZIRAT AL TEB, or Island of Birds, an island in the Red sea. N. lat. 22° 18'. E. long. 47° 56'.

GEZULAT, or GEZULA, an inland province of the empire of Morocco, E. of the province of Sus, and N. of the coast of N.; this, together with the province of Draa, lies in the vicinity of mount Atlas which, in this southern part of the country, extends almost to the sea. The inhabitants of this province are considered as the most ancient people of Africa. The country produces a great quantity of barley, and affords pasture for cattle; it has mines of iron and copper, of which are made various utensils, that are exchanged for cloth, spicery, horses, and other necessaries. It has every year a fair, which lasts two months, for the sale and exchange of cattle and merchandise in general. The people are free, being allies rather than subjects of Morocco. Their arms consist of sabres, large hoop two-edged swords and lances. They are numerous, but have no towns, and they generally live in camps and villages.

GFOLL, a town of Austria; 8 miles W. N. W. of Graz.

GHALESA, a town of Arabia Felix, which was once a famous city and sea-port, but now sunk into decay, about 20 cottages only remaining to shew the place where it stood, and the inhabitants are only provided with dates, and the milk and flesh of a few sheep; 20 miles S. of Hodeida.

GHALCHULIVA, in Zoology, the Ceylonese name of a species of East Indian serpent, a snake of a pale brown, variegated with transverse breaks of white, and found among rocks and stones.

GHAN is a name given in Meccosy to caravanserais.

GHANA, as Edri or Abuflada call it, or Ghinar, in Geography, a city and capital of a kingdom in Africa, situated nearly midway between the Indian sea and the Atlantic ocean, or the E. and W.; and between the Mediterranean and the Ethopic seas on the N. and S.; and, therefore, considered as major Renell as the point on which the central and eastern positions depend. This country lies on the borders of the Nile-Abled, or Guin river, and is bounded on the N. by Caufina or Kaffina, on the E. by Wangara, on the S. by Melli or Lamement, and on the W. by Mezkara and Kaffina. The city is placed in Renell's map on the north bank of the river. According to Edri, Ghana is distant 37 journeys (each day's journey of Edri being about 19.60 geographical miles) from "Gerna," through Agadez, or Agadoff. Ghana is an ancient and ruined city of Fezzan, as much, about four journeys E. S. E. of Mommrik, in N. lat. 27° 25'. E. long. 16° 20'. Agadez is 25 of Edri's journeys from Gerna, bearing S. by W. or S. S. W. from the capital of Fezzan. Ghana is 12 days of Edri's foot to the southward of Agadez, or about 229 geographical miles. It appears that Ghana lies somewhat to the eait of the line which passes through Agadoff from Genna to Ghana, and Mr. Rennell has taken 700 as the general line of distance from Genna to Ghana. Mr. Matia was told, at Morocco, that Ghinny (Ghana) was 40 journeys from Kabra, the port of Tumbidto, along the bank of the Niger. These, taken at the caravan rate when traversing the desert between Fezzan and Egypt, Morocco and Jarma, &c. that is, at 163 per day, produce 657 geographical miles. The interjection of this line with that from Genna places Ghinny in N. lat. 16° 10'. E. long. 15° 23'; in which position it stands at 760 miles from the city of Benin, on the coast of Guinea. For the further settlement of this important point in adjusting the map of Africa, see Rennell's Proceedings of the African Association, p. 119, &c.

GHANARA, a city of Africa, the capital of Wangara, situated on a river, which runs into the Niger, or rather into a lake (the Lybia Palus of Ptolemy) formed by the Niger. N. lat. 15° 40'. E. long. 15° 40'.

GHAASSA, or GASSA, capital of a district in the northern part of Boten, in the East Indies, and the residence of a zamoon, or provincial governor. The highest mountain in its neighbourhood, whole head is eternally covered with snow, sends forth a spring of water at its base of great degree of heat, that few are found capable of bearing, even for a short time, any part of the body immersed in it. It is situated near the spring-head of Pa-chenu river. N. lat. 27° 53'. E. long. 89° 19'.

GHAT,
GHEAT, a small island in the river St. Lawrence. N. lat. 45° 20'. W. long. 93° 20'.

GHAHARI, a town of Persia, in the province of Iracl: 27 miles E. of Ispahan.

GHEBARABA, a town of Persia, in the province of Iracl: 5 miles N.W. of Ispahan.

GHEBAN. See Gihan.

GHEBAN, a town of Persia, in the province of Iracl: 7 miles N.W. of Ispahan.

GHEBAI, a town of Italy, in the department of the Mela: 10 miles S. of Brescia.

GHEDEMIS. See Gadamis.

GHEDEL, a town of Asiatic Turkey, in the government of Sivas: 15 miles S. of Amaceh.

GHEDEMAN, a town of Persia, in Chorasan; 18 miles S. of Herat.

GHEIRA, a town of Asiatic Turkey, in Natolia; 38 miles N.N.E. of Mogha.

GHEIVE, a town of Asiatic Turkey, in Natolia; 20 miles E.N.E. of Hnik.

GHEL, a town of Arabia, on the coast of the Red Sea, anciently called " Ocilius": 48 miles S.S.E. of Mocha.

GHELEN, Salaryn, in Biography, was born of a respectable family at Prague. When he had attained to a proper age for improvement by foreign travel, he went into France and Italy; and acquired an accurate knowledge of the languages of those countries. On his return he published, through Laud, and made himself known to Erasmus, at whose recommendation Froben engaged him as his corrector of the press, by which he gained a small but competent maintenance. He soon attained a higher office than that of corrector of proof-sheets, and joined to it the duties of a critic and translator. He published a dictionary of the Greek, Latin, German and Dalmatian languages; and annotations upon Pliny and Livy. He translated from the Greek into Latin the Antiquities of Jofephus, some Homilies of Chrysolom, and many other learned works. Just before his death, which happened in 1554, he had employed his talents on, and nearly finished, a version of Jullin Martyr's works. Besides those already mentioned he was editor of many other works. He was acute and ingenious, and wrote with elegance and fluency. In his private character he was mild and placid, simple and sincere. Moretti.

GHEMARA. See Gemara.

GHEMA. In Geography, a town of Italy, in the department of the Cegna: 13 miles N.N.W. of Novara.

GHEMISH, a town of Asiatic Turkey, in the government of Sivas: 24 miles W. of Amaceh.

GHENNA. See Ghinna.

GHEGNT, a city of France and chief place of a district, in the department of the Scheldt, formerly capital of Audirand Flanders, situated on the conflux of the rivers Scheldt, Lys, Moeze, and Lieve, which, together with a number of canals, intersect it in a variety of directions, and divide the town into 26 small islands. It is encompassed by walls about 15 miles in circumference, and includes gardens and corn-fields. Since the French revolution it has been divided into four quarters, viz. North, South, East, and West, and as many cantons. The former contains 15,000, and the corresponding canton 17,454 inhabitants, on a territory of 225 square kilometres, in two communes; the second, or south, contains 15,000, and its canton 16,469 inhabitants, on a territory of 35 square kilometres, in two communes; the third, or east, includes 13,000, and its canton 16,073 inhabitants, on a territory of 35 square kilometres, in three communes; and the fourth, or west, contains 13,000, and its canton 18,319 inhabitants, on a territory of fifteen kilometres, in three communes. This city was first chos for their habitation by the Nortiv, and afterwards occupied by the Vandals, who gave it the name of Wanda, whence the present appellation of Gand, or Ghent, is supposed to be derived. It was encompassed with walls by Odowec, grand-terror of Flanders, and has since been frequently enlarged, particularly in the year 1297, by order of Philip the Bold, 25th count of Flanders. The inhabitants were always warlike, and often engaged in military contests with their own princes, and with their neighbours, which were conducted in many instances with savage cruelty, and terminated in extensive and fangurious slaughter. Ghent was the birthplace of Charles V., of whose nativity in their town the inhabitants had little reason to boast, as he loaded them with frequent and heavy impositions, chastised them with rigour for their occasional revolts, and subjected the magistrates and several of the chief citizens to the most humiliating treatment. This conduct on their part inflamed their disposition to revolt, and the consequence was, that one of the small cities in Europe was reduced to a state of perfect solitude. However, it afterwards regained some small portion of its ancient splendour, and became, at least previously to times of recent confusion, considerable. In November 1676, was concluded in this city the famous treaty called the "Treaty of Ghent," containing 25 articles, and amongst others some of them stipulating that the Spanish and foreign troops should leave the country, that the provinces of Holland and Zeeland should remain united with the others, that the Catholic religion should be maintained, and that the ancient privileges of the country should be secure; and this treaty was approved and ratified by Philip III., King of Spain. In 1678, Ghent was taken by Louis XIV., king of France, but restored to Spain at the treaty of Nimeguen in the same year; and it remained in their possession till it was taken by the allies in 1706, after the battle of Ramillies. It was seized by the French in 1708, but recaptured by the allies under prince Eugene and the duke of Marlborough, in the same year. Ghent was erected into a bishopric in 1559 by Pope Paul IV., at the solicitation of Philip II., king of Spain, subject to the archbishop of Malines. It had, besides the cathedral, six parish churches, and many religious houses; some of the streets are broad and well-paved, and the market places spacious, in the midst of one of which is a statue of Charles V., in his imperial habit. Ghent carries on a considerable trade in cloth, linen, lace, and silk manufactures, and is much aisiected, in favourable times, by two navigable canals; one to Sas-de-Ghent, and another to Bruges, Oostend, &c. The magistracy consists of burgomasters, echelons, and common-council. John, the third son of Edward II., King of England, was born in this city, and from this circumstance called John of Ghent. In November 1792, the French took possession of this city, but evacuated it on the retreat of Dumourier; however, they afterwards regained it in their progress through the country: 58 miles S.W. of Antwerp. N. lat. 51° 15'. W. long. 3° 45'.

GHER, a town of Africa, in the country of Sugulmeffa, or Sigulmeha, on the Ziv, near mount Atlas; 90 miles N.W. of Sugulmeffa.

GERANGOL, a town of Africa, in the country of the Foulahs, on the S. side of the river Senegal. N. lat. 16° 40'. W. long. 14°.

GERÈDE, a town of Asiatic Turkey, in Natolia; 28 miles E. of Boli.

GERHISTEN MOUNTAINS, a chain of mountains of Aifa, situated on the N. of the country of Candahar, 15 miles N. of Candahar.

GERHONG, or KIRKANU, a town of Aifa, and capital of the country, on the Degoo, 150 geographical miles.
GHEZ, a town of Grand Bucharistan; 24 miles S.S.W. of Balk, N. lat. 36° 16'. E. long. 65° 42'.

GHEZAN. See GEZAN.

GHEZERI. Pier Leone, called Cavalier Geszi, in Biography, a painter who was a pupil and imitator of Pietro Corriva. He was selected with Luigi Trevianni, and other artists of the same style, to paint the prophets in St. John Lateran; and executed many other works of less consequence; but he obtained most celebrity by his skill in caricature, which he freely indulged.

GHEIUND, in Geography, a town of Bengal; 25 miles S.S.W. of Goragut.

GHEIMINS. See GEIMINS.

GHEKERS, an appellation given to those who inhabited the northern and largest division of the hilly tract situated between the Bhum, the Sindre, and Cusimere, in Hindostan, by way of contrast to the Jondis, who occupied the southern and least division.

GHIDORE, in Geography, a province of Bengal, bounded on the N. by Bahar, on the N.E. and E. by Curruckpore, on the S. by Burboom, and on the S.W. by Curruckdeel and Moy. The chief place is Ghidore; which is 70 miles S.E. of Patna. N. lat. 24° 53'. E. long. 86° 23'.

GHEIZ, a fortress of Peria, in the province of Irak, taken by the Afghans in 1723.

GHILAN, or KILAN, synonymous with the ancient Gelb, a province of Western Persia, bounded on the N. by the provinces of Aderbijian or Aderbeiztan and Schirvan, on the N.E. by the Caspien sea, on the E. by the Caspien sea and the province of Mazanderan, on the S. by the Perisan Irak, and on the W. by the provinces of Aderbijian and Curdistan; about 200 miles from E. to W., and 150 from N. to S. This is one of the most beautiful and fertile provinces of Peria, producing silk, olives, rice, tobacco, and most excellent fruits of all kinds, and in such abundance, as not only supply the wants of its inhabitants, but sufficient to provide for a great part of Peria and Armenia. The manufactures and silk of Ghilan are esteemed the best in Peria, and have been in such repute for many years, that Roshd, its capital, is become one of the first commercial towns in this part of Asia. The inland fort is usually white, and chiefly built into the interior cities of Peria, or fold to the Turks; the inferior kind is yellow, and principally disposed of to the Russians. Roshd supplies the bordering provinces of Persia, and the independent neighbouring states, as far as Georgia, with European merchandise, except the goods which are transported immediately from Atarak, through Kilar and Moffok, to the nearest part of Georgia, and of the neighbouring mountains; and those sent from Shanakoo to the League Tartars, and other independent tribes. In this province are seen whole forests of mulberry, box, and walnut trees. Every peasant has a garden to his cottage, planted with orange-trees, citrons, figs, and vines. For a further account of the trade and government of this province, we refer to the articles Caspien Sea and Persia.

We shall here only add, that in the year 1792 Akau, called by Dr. Pallas Aga Mamet, collected an army, and purposed his conquests in the vicinity of Gilian, till at length he had...
no rival, except Hidast, khan of Ghilan, whom he forced to fly from Rashid or Rashid, his place of residence, and who was killed near the port of Saleh. In consequence of these events Akin became monarch of the whole of Western Persia; and having been made a eunuch in his infancy by order of Naser Shah, he nominated for his successor his nephew Baber Serdar.

GHILDJ, a town of Africa, on the Senegal; 30 miles N.W. of Gallam.

GHILON, a town of CurdiJian; 50 miles S.S.W. of Erbil.

GHINNA, a town and territory of Africa, on the river Rio Grande, near its mouth. N. lat. 11° 15'. W. long. 14° 15'.

Gen. Ch. Cal. Perianth of one leaf, tubular, permanent, inferior, itsSorice with five pointed spreading teeth. Cor. of one petal, irregular; tube long, narrow; limb of two lips, the upper one large, rounded, concave, ascending; lower in three deep roundish segments, the middle-mottl longer, deflected, emarginate. Stam. Filaments four, inserted into the tube above its base, two of them longer than the rest; anthers each of two separated oblong cells, one of them terminal, fertile in the longer filaments only, the other like a little scale in the middle of each filament. Pod. Germen roundish, superior; style thread-shaped, the length of the tube; stigma four-lobed. Peric. Drupe turbinate, angular, dry, projecting beyond the permanent calyx. Nut angular, of four or five cells. Seeds solitary. Eff. Ch. Calyx with five sharp spreading teeth. Corolla ringent, two-dipped; the lower lip three lobed. Nut coated, four-celled, involuted with the calyx. Seeds solitary. Anthers of two dilate lobes.

Obs. We think this genus ought to be placed in Diilynaia, along with Verbena, to which it is nearly akin, though only the larger flowers appear to be perfect; but this may be variable, and cannot well be determined without repeated examinations of wild specimens.

1. G. spicata. Wildl. n. 1. Ait. Hort. Kew. ed. 2. v. 1. 459. (G. verbena; Sw. Ind. Occ. v. 2. 1869. Verbena curassavica; Linn. Sp. Pl. 28. Veronica fimus, &c. Herm. Parad. t. 240.)—"Fruit with four thorns. Leaves smooth."—Native of several parts of the West Indies, where Houkton and Swartz have gathered and examined it. This is an annual and rather humble herbaceous plant, with a branched stem, ovate deeply serrated leaves, and long loose spikes of small whith flowers.

2. G. mutica. Wildl. n. 2. Sw. Ind. Occ. v. 2. 1900. (Tamonea spicata; Aulb. Guian. 650. t. 268.)—"Fruit without thorns. Leaves downy."—Native of Guiana and Cayenne. Much like the former, but with downy leaves, and an unarmed fruit, and the middle segment of the lower lip of the corolla, according to Swartz, is emarginate in this, entire in the preceding. Neither of them have much beauty, nor any other qualities to recommend them for cultivation with us in the Nove, though perhaps they might be planted out for the summer, if desirable, like other tender annuuals.

GHINNA, or GHENNE, in Geography, a town of Egypt, on the E. side of the Nile, opposite to Kufa, or Koptos, on the other side, and distant from Cairo, on the Red Sea, about 90 geographical miles. N. lat. 26° 11'. E. long. 32° 45'.

GHINE, a town of Asiatic Turkey, in Notoria; 24 miles N.W. of Sinob.

GHO. See KEMLINK.

GHO, a town of Africa, belonging to the Foulahs, on the Senegal; 12 miles S.W. of Goumel.

GHIR. See GIRL.

GHIRGUNG. See Ghirguin.

GHIRLANDAIO, DOMENICO, in Biography, a painter, of whom Vafar speaks as being of the first rank in his time. His real name was Corradini. He at first was employed by his father, in his own profession of goldsmith, at Florence, who obtained the name of Ghirlandaio, by having been the first to make little metallic garlands (Ghirlandi) for children to wear. Domenico continued to paint, after he had adopted painting as his profession, for the churches and convents in Florence, both in fresco and in oil. He, like other artists of the time, introduced into his pictures the portraits of his friends, but gave them more characteristic appertaining to the subject, than had hitherto been done there; and he was the first who left off gilt ing pictures, and attempted to imitate its effects by colours. He was called to Rome by Sixtus IV. to affix other masters employed in painting his chapel. His works there were afterwards spoiled to make room for those of M. Angelo. He was highly honoured, and employed nobly; but his greatest glory is, having had the great hero of the art, M. Angelo, for a pupil. He died in 1493. at the age of 44. His brothers, David and Benedetto, finished many of his works, and educated his son Ridolfo to the art, who afterwards made great progres, and obtained efeem from Raphael himself, who invited him, but not successfully, to work in the Vatican. In Ridolfo's pictures, Mr. Fuseli says, "there is something analogous to the genius of Raphael; the composition, the vivacity of the face, the choice of colours, something ideal in the use of nature, betray similar maxims, with inferior powers." He died in 1565, aged 75.

GHIRNAH, in Geography, a river of Hindoostan, which runs into the Taptus; 36 miles S.W. of Burhanpur.

GHISCOLA, a town of Italy, in the department of the Upper Po; 15 miles E. of Cremona.

GHISTELLES, a town of France, in the department of the Ais, and chief place of a canton, in the district of Bruges; 11 miles S.W. of Bruges. The place contains 2500, and the canton 11,754 inhabitants, on a territory of 1821 kilometres, in 18 communes.

GHIVIRA, a town of Italy, in the department of the Orona; 30 miles N.W. of Milan.

GHIZNI, or GIMNA, an ancient empire of Hindoostan, founded by Abulfajr, son of Korfan, A. D. 960, who revolted from the king of Buharistan. Ghizni confirmed chiefly of the tract which composed the kingdom of Bactria, after the division of Alexander's empire; that is, the countries lying between Parthia and the Indus, and south of the Oxus. The Ghizni empire, subject to the fame causes of decay with other unwieldy fates of rapid growth, was, in 1153, forcibly divided; the wether and largest part, and which held retained the ancient name of the empire, being feized on by the family of the Gauries, (so demoted...
Lahore. 

G I A

GHIZNI, or GAZNA, a city of Candahar, once the reputed capital of the Ghiznian empire, and placed among the western Sources of the Indus, and not far from the Indian Caspian. The position of Ghizni is erroneously fixed by M. D'Anville in the N.W. extreme of Cabul; whereas it appears to be almost in the very heart of that province. It is termed the "Second Medina," on account of the great number of illustrious personages whose remains have been interred there. Wonderful stories are related concerning its extent and population in ancient times; nevertheless, Baber expresses his surprize at its having ever been pitched on for the seat of any empire. Ghizni is distant about 56° geographical miles S. by W. from Cabul, about 1679 miles from Candahar, and about 88 miles from Bannian.

N. lat. 33° 55'. E. long. 68° 22'.

GHOBAN. See GORBAN. 

GHOER, a town of Holland, in Overijssel, on the 
Rigge; 10 miles N. E. of Berkelo.

GHIR. See GAUR.

ghORAB, a town of Arabia, in the country of Ye-
men; 15 miles E. of Tarno.

GHOUP, a mountain of Southern Africa. This, and
also Nieuweld, are a continuation of the Roggeveld moun-
tain, and join the divisions bearing the same name in the
district of Graaf Reynet. They have lately been defeated, on
account of the number of Boisfretman hotentots, who
dwell-chief behind them.

GHOUBUND, a town, and district of Cabul; 42
miles N.W. of Cabul. N. lat. 34° 55'. E. long. 67° 52'.

GHOURLI, a town of the kingdom of Balk. N. lat. 35°
40'. E. long. 66° 36'.

GHIULE EL ALIAH, a town of Arabia Felix; 10 miles
NNE of Chaimir.

GHIULPAYGAN, a town of Persia, in the province of
Iraque, taken by the Afghans in 1723; 100 miles N.W. of
Ispahan. N. lat. 35° 45'. E. long. 50° 40'.

GHUMISCHAN, a town of Asiatic Turkey, in the
government of Trebifond; 50 miles S.S.W. of Trebif-
ond.

GHUNFEDE, a sea-port of Arabia, on the Red Sea,
belonging to the shereff of Mecca. All vessels which carry
coffee to Jidda are compelled to anchor here, and pay a duty;
145 miles S. of Mecca. N. lat. 20° 7'.

GHUN, one of the smaller Cape Verd islands, being
little more than a rock.

GHURMAN, a town of Persia, in Segellian; 30 miles
N.E. of Perah.

GHYASPOUR, a town of Hindostan, in Bagh; 20
miles W.S.W. of Chuprah.

GIA, an Italian adverb, used in Music for already,
formerly, andante; as "Gia maestro di cappella del Duomo
di Milano," former maestro di cappella, or composer, to
the cathedral of Milan.

GIABBAR, in Geography, a fortress of Asiatic Turkey, in
the province of Diharibekir; 120 miles S.S.W. of Diarbekir.

GIACOMI, in Geography, of Parma, compassed for the theatres of Venice, between the years 1704
and 1726, seven or eight different dramas, written chiefly by Apostolo Zeno and Metastasio. He was the scholar of Cappelli, but adopted a more high and flighty style, with which the Venetians were much captivated, before they heard the more graceful and expressive airs of Vini and Haifi.

GIACOMO, St., in Geography, a town of Italy; three
miles S. of Verona.—Alto, a town of the Valtelin; two
miles N.W. of Chiavenna.

GIACOMO, St., a valley of, a valley of Switzerland, which
is part of the county of Chiavenna. It is narrow, and
watered by the torrent Lira, contains about 10 parishes, is under
the jurisdiction of the commissary, and possesses several
important privileges that prefer the inhabitants from the oppre-
sion which their neighbours endure. All smokes are tried in
the valley. The criminal statutes are those of Chiavenna, with
this difference, that instead of the assessor, the valley chooses
four personas, who are always present at the examination;
and without whose concurrence, torture cannot be inflicted,
or sentence passed. The valley has its own code of juri-
prudence, and courts independent of the commissary, from
the decision of which an appeal lies to the diet.

The lower part of the valley produces vines and corn;
the upper, rye, barley, and patura, mixed with large groves of
fir and pine.

GIACOMO, St. AEGIS, in Geography, a mountaineer, and a disciple of Julquin, enumerated by Adam among
the fingers and composers of the pontifical chapel in the 16th
century. He was maestro di cappella some time to the
princely of Lorrain, and had acquired great fame by his madri-
gals, of which he published at Venice, between the years
1339 and 1375, five books. In one of which the celebrated
madrigal, "Il bianco e dolce Cigio cantando moare," which was
in high favour all over Europe.

GIADEN, in Geography, a town of Arabia, 60 miles W.
S.W. of Mecca.

GIADILA, a town of Arabia, in the province of
Neda-ed, 90 miles S.W. of Karbistan.

GIADRI, a town of Albania, on the Drino; 86
miles N. of Alege.

GIAGAS of Africa. See JAGAN.

GIAGH, or JEHUG, a cycle of twelve years, in use
among the Turks and Cathayans.

Each year of the gagh bears the name of some animal;
the first that of a mouse; the second, that of a bull; the
third, of a lynx or leopard; the fourth, of a hare; the fifth,
of a crocodile; the sixth, of a serpent; the seventh, of a horse;
the eighth, of a hawk; the ninth, of a monkey; the tenth,
of a hen; the eleventh, of a dog; and the twelfth, of a hog.
The are divided the day into twelve parts, which they
call gaghls, and distinguish them by the name of the same
animals. Each gagh contains two of our hours, and is di-
vided into eight Kats, as many as there are quarters of hours
in our day.

GIALAKOVA, in Geography, a town of European
Turkey, in Romania; 60 miles N.E. of Filippopoli.

GIALLOLINO, in Natural History. See NAPLES.

GIAMANI,
GIAMANI, in Geography, a town of Perse, in the province of Chufilian; 28 miles S.S.W. of Suffer.
GIAMBASH, a town of Affiaci Turkey, in Natalia; 22 miles S.S.E. of Smyrna.
GIANAH, a town of Perse, in the province of Kerman; 55 miles E. of Simgan.
GIANCABIO, Sr. a town of Naples, in the province of Otranto; 12 miles S.W. of Brindii.
GIANNONE, Petron, in Geography, was born at or near Naples about the year 1607. He was educated for, and practiced in, the law, but was much more distinguished as an historian. In 1722, he wrote a "History of Naples," in four volumes. The style is pure, but the freedom with which he discussed several topics relating to the origin of the papal power gave too much offence to the court of Rome, that he was obliged to emigrate from his native country. He found an asylum in the court of Sardinia, which, however, dared not to allow himself his protector, but chose rather to represent his situation as that of a prisoner. Giannone died in Piedmont in 1745. Extracts from his history were afterwards printed in Holland under the title of "Aneideses Ecclesiasticæ." His posthumous works were given to the world in a quarto volume, containing, among other miscellaneous matters, his profession of faith, and a justification of his history.

GIANOTTI, a performer on the double-bass, in the opera at Paris, from the year 1739 to 1767, who published, in 1759, a treatise on the principles of Ramas, entitled "Guide du Compositeur," the Composcr's Guide; a work much esteemed by the followers of Ramas. The author of this treatise having been long in the practice of explaining the fyltem of the fundamental base to his scholars, has drawn up his own work in a clear and intelligible manner.

GIANNUTTI, in Geography, a small island in the Mediterranean sea, near the coast of Italy. N. lat. 43° 24', E. long. 11° 20'.

GIANT, a man of extraordinary, enormous stature and bulk.

The reality of giants, and of nations of giants, is much controverted among the learned. Travellers, historians, and relations, both faced and profane, furnish various instances of them; a great part of which naturaflis and antiquaries find absurd.

Thee among the ancients who spoke of giants, as historians, and affirms there were seven beings, are Caesar, de Bello Gallico, lib. i. Tacitus, de Morib. Germanor, and Annal. lib. ii. Florus, lib. iii. cap. 3. St. Augustine, de Civit. Dei. lib. xv cap. 9 and Saxo-Grammaticus, at the end of his life: among the moderns, Hiera, Magnes, Mifcalan, de Gigantibus; Chaffagonus, de Gigantibus; Kircher, Mund. Subterr. lib. viii. feé. ii. cap. 4, and to many others, that Stephenus, in his notes on Saxo-Grammaticus, affirms, nothing can be more extravagant than to deny or allegorize the authorities we have concerning them.

Dr. Derham observes, that though we read of giants before the flood, Gen. vi. 4, and more plainly after it, Numb. xiii. 33, yet it is highly probable the size of man has always been the same from the creation: for as to the Nephilim, Gen. vi. the ancients vary about them, some taking them for monsters of impiety, atheism, rapine, tyranny: as to thefe, Numb. xiii, who were evidently spoken of as men of a gigantic size, it is probable the fables which may add to their bulk.

Be this as it will, it is manifested, that in both these places giants are spoken of as rarities and wonders of the age, not of common nature; and such instances we have had in all ages. But it is not at all improbable, that the first men were of a strength and stature superior to that of mankind at present, since they lived a much longer time; long life being commonly the effect of a strong constitution. There are many fabulous relations, such as we take to be the work of Thesibocules, who is said to have lived up from 1615, and to have been higher than the trophies, and twenty-six feet in height, and even more. But no better we suppose the giants to have been, of whom Solomon gives an account in his fifth book; such as Harthen and Starchater, among the men; and among the women, "reporta eift (faith he) puella, in capite vulnerata, corrupta, induta chlamys aurea, longitundinibus cubitum 50, latitudinis inter humeros quantor," Old. Mag. Hift. lib. v. cap. 2.

But, as for the more credible relations of Gellius (whose height was six cubits and a span, i. Sara xv. 4.), which, according to bishop Cumberland, is somewhat above eleven feet, English, of Or, king of Bahan, (Deut. iii. 11.) whose head was nine cubits long and four wide, of Maximinus the emperor (who was nine feet high), and others in the reign of Augustus and other Roman emperors, of about the same height; to which might be added the dimensions of a Skelton, dug up in the place of a Roman camp, near St. Alban's, by a man inherited Marcus Antoninus, of which an account is given by Mr. Cheeselden, who judged, by the dimensions of the bones, that the person was eight feet high, Phil. Trans. N. 334; these antique examples and relations, we say, may be mistaken, may exist, with modern ones; of which we have divers in J. Ludolph. Comment. in Hist. Zeith. lib. ii. cap. 2, Magnus, Corningus, D. Hakewel, and others; the last mentioned writer speaks from names, of porters, and archers belonging to the emperor of China, fifteen feet high, and of others from Purchas, of ten and twelve feet high, and more. See that learned author's Apol. p. 258. The existence of a race of men above the common stature, on the coast of Patagonia in South America, has been the subject of dispute for the last centuries. In one century almost all navigators, of every country, affirmed that there were such persons; and in the next the fact is denied by the greater number, and their predecessors are treated as timid or boasting fabulists. The Yena Garecillo de la Vega, in his history of Peru, relates, that according to a tradition universally received, a number of vessels or junks came to St. Helena with a company of giants on board, of a stature so enormous, that the natives of the country were not higher than their knees; that their eyes were as broad as the bottom of a plate, and their limbs proportionally large. But these are fables, similar to those relative to the same subject in other parts of the world. See GIANT'S homes.

Turner, the naturalist, reports, that he had seen, near the river Plata, on the coast of Brazil, a race of giants, who went dark naked, one of whom was twelve feet high; but he acknowledges that he saw no others to talk. The ocular witnesses on the affirmative side of the question are, Magellan, Lisboa, Sarmento, and Noddal, among the Spaniards; Cavendish, Hawkins, and Knivet, among the English; Sebald, De Noort, Le Maire, and Spilborn, among the Dutch; and among the French, those who went in the expedition from Marseilles and St. Mabes, in the year 1704.

Knivet affirms that he measured several dead bodies, which he found buried at Port Deire, which were from fourteen to sixteen spans high; and that he had frequently seen at Brazil one of the Patagonians, who, though a youth, measured no less than thirteen spans; and that the English prisoners at Brazil allowed him, that they had seen many men of the same gigantic stature upon the coasts of the Irait; this account is also confirmed by Sebald de Weel, and Oliver de Noort. Ari: Chas.
GIANT.

Clifz, a commissary on board Le Maire's fleet, declares that he found, in the sepulchres on the coast of Patagonia, the bones of men who were between ten and eleven feet long. Nodal and sir Richard Hawkins merely relate, that these savages were a head taller than the inhabitants of Europe, and of such a stature, that the people on board their vessels called them giants.

Those who bear testimony to the contrary, are Winter, the Dutch admiral Hermitz, Froger in De Gennes's Narrative, and sir John Narborough. Sir Francis Drake also is silent with respect to the stature of the inhabitants of Patagonia; but Winter positively affirms, that the accounts of their being giants are falsehoods invented by the Spaniards. Narborough measured the skulls and the print of the feet of the savages on the coast of the Strait of Magellan, which, he says, were of the common size: and he had often seen companies of them at Port St. Julian, who were neither taller nor bigger than other men. However, it may be observed in general, that the greater part of those who hold the affirmative in this question, speak of people that inhabited the desert coasts of Patagonia to the east and west; and that, on the contrary, those who hold the negative, speak of those who inhabit the Strait upon the sides of the utmost point of America to the north and south. Prevost relates, not from his own knowledge, but from the testimony of eye-witnesses, that there was, at a considerable distance within the country from the coast of Chili, an Indian nation, called by their neighbours Cauchois, who some illnes came down to the Spanish settlements, that were more than nine feet high, and were the same race with the Patagonians who live on the eastern coast. It appears from various relations, that the inhabitants of the two borders of the Strait are of the common stature, and that the race, distinguished by the name of Patagonians, make their constant residence upon the desert coasts, fearfully inaccessible to any but themselves; and when European ships frequented the Strait, they removed and settled in the interior part of the country; however, the current testimony of late navigators, particularly commodore Byron, captain Wallis, and captain Carteret, will put an end to the doubts that have been hitherto entertained of the existence of such persons. Commodore Byron, who visited the coast of Patagonia, in 1764, speaks of the inhabitants as of a gigantic stature; but he did not measure any of them, and only concluded, by the proportion of their stature to his own and that of his companions, that they could not be less than five and a half, or seven feet in height, and proportionably strong and bulky. Captain Wallis had an interview with these people in 1766, and found, by measuring them, that the stature of the greater part of them was from five feet ten inches to six feet, though there were some who were fix feet five and fix feet six inches, and one who was fix feet seven inches. Captain Carteret, who attended captain Wallis on this occasion, confirms the above account in his letter to Dr. Marty. See Phil. Trans. vol. 18. art. 2. p. 26, &c. See Hawkinsworth's Voyage, vol. ii. Intro. and p. 28. 154.

GIANTS, in Ancient Mythology, were the sons of Terra, or the Earth, by Cetus, who made war against Jupiter and the celestial deities, to avenge the defeat of the Titans. These giants are represented as of an enormous height and size, having a wild and dreadful aspect, and polished of strength proportioned to their bulk: each of them had a hundred hands, and serpents instead of legs. Being determined to dethrone Jupiter, they reversed Mount Ossa upon Pelion, and Olympus upon Ossa, and from thence attacked the gods with huge rocks, some of which fell into the sea and became islands, and others fell on the earth and formed mountains. Jupiter summoned a council of the gods, and being informed that it was necessary to obtain the affiance of some mortal, with the advice of Pallas he called up Hercules, and with the aid of this hero, extirpated the giants Enceladus, Polybotes, Alecton, Porphyryon, the two sons of Alcides, Ephialtes, Ophius, Eurytus, Clytus, Ty- thybus, Pallas, Hippolitus, Agram, Thoas, and Typhon, the last of whom it was more difficult to vanquish than all the others. Jupiter having thus gained a complete victory, cast the rebels down to Tartarus, where they were to receive the full punishment of their enormous crimes: according to the account of some of the poets, he buried them alive under Mol Etna and different islands.

For the explication of this table, some have supposed that Jupiter (for whose history, see JUPITER) destroyed the robbers that infested Thesaly, and that these are the pretended giants; for we have already observed (in the preceding article) that the appellation "Nephtian," occurring in scripture, and translated giants, signifies people addicted to all kinds of licentiousness and violence, or robbers and ruffians. Jupiter, when he left Crete to visit the other parts of Greece, usually relied on Mount Olympus, where he had probably built a strong citadel. This mount Olympus, highly elevated, was afterwards taken for heaven itself, and the most ancient poets, especially Homer, so describe it. The banditti now mentioned, determined in their attack on that prince, besiege him in his citadel, which afterwards gave rise to the fiction of their having attempted to scale heaven, and of their having made an assault upon it. It is added, that with this view they piled Ossa upon Pelion, importing, as it is conjectured, that they had fortified these two mountains, which are also in Thesaly, and at no great distance from Olympus, whether they retired after their excursions, and kept Jupiter's garrison in awe. For other particulars, see Bailer's Mythology, vol. iii. See also TITANS.

GIANTS' BONES, a name too hastily given by the vulgar to certain bones and parts of skeletons, of an enormous size, found in England and other places. Of all the numbers of these, which have been publicly shewn about as wonders in nature, not one but has proved, on examination, a bone of an elephant, or else of a whale, or of some other terrestrial or aquatic animal now perhaps extinct; the first, however, is usually the case, as the bones of elephants are much more frequently found buried in the earth than those of the whale.

Sir Hans Sloane mentions a vertebra of the loin of a whale sent him from Oxfordshire, where it was dug up under ground, and afterwards used as a stool to sit upon, and vulgarly suppos'd part of a human back-bone. Now, if the whole size of the body had been calculated from this piece, the account would have presented such a size as would have far exceeded all the fabulous stories of giants' skeletons extant in the world.

Many skeletons of this kind have been found which have been called the skeletons of giants: such are those of Phylloratus, which are said to be the bones of men of twelve, twenty, and even thirty cubits high; that found in a mountain of Crete, and mentioned by Plato and Pliny, forty-six cubits high; another of sixty cubits, found near Tangier in Mauritania, mentioned by Plutarch and Strabo, and supposed to be the skeleton of Anteus; the skeleton of Pelas, the son of Evander, found in Rome, and said to be taller than the walls of that city; another, found in England in 1171, fifty feet long. St. Aulins alleges, in proof of the existence of giants before the flood, a grider tooth, which he saw on the shores of Utica, which was in reality that of a
GIANT.

The tooth in the church of St. Christopher, at Hirpilla, and the shoulder bone of St. Christopher, preserved in a church at Venice, are of the same kind. The tooth, preferred and shown at Antwerp, is only the grinner of an elephant; and another, belonging to a skeleton which was dug up near Tunis in 1635, was sent to the learned Pierref, who took the imprecision of it in wax, and comparing it with the tooth of an elephant shown near the place, found it to be of the same shape and size. Sir Hans Sloane has given an accurate and learned account of several other mistakes on this subject, for which we must refer to the Philof. Transact. N. 494. However, Montf. Le Curt, in a memoir read before the Academy of Sciences at Rouen, received a number of inferences, in which skeletons, or parts of skeletons, of an uncommon magnitude, have been found; these have been examined by anatomists, he says, and have been by them reputed real bones; and hence he infers the existence of giants.

GIANTS CAUSEWAYS, a name given in the county of Antrim, on the north coast of Ireland, to a vast quantity of that kind of basaltes, (see BASALTES) which stands in columns, and runs out a great way into the sea.

The ignorance of the vulgar as to the nature of this stone, has occasioned this great pile of it to be supposed artificial and the work of giants, since inhabitants there. But whoever considers this amazing series of columns, will be soon convinced no human hands could have formed them, and will find an accuracy in their figures greater than could have been expected from the most curious hand. The length of the several columns, and their joints so regularly placed in rows, and the niches of their articulations, by which no space or vacancy is left between, are wonderful.

This causeway forms a kind of mole, or quay, projecting from the base of a heap promontory some hundred feet into the sea; and the perpendicular columns of which it is formed exhibit an appearance not unlike a solid honey-comb. The angle columns are irregular prisms of from four to eight sides; but the pentagonal and hexagonal are by far the most numerous, and, when examined, they are found full half as much necessarily required in the places where they stand to fill up between others, so as to leave no vacancy. Each of these columns is separable into a series of joints, each of which is so well fitted to the place, that the joining appears only a crack or crevice in the flone: yet these are regularly articulated, there being always a convexity on one part, and a socket in the other to receive it, so that the joints cannot slip off from one another; besides which, the angles of one frequently shoot over those of the other, so that they are completely locked together, and can rarely be separated without a fracture of some of their parts. The depth of the concavity is generally about three or four inches. These hollows are of great use to the neighbouring poor, for they make a kind of salt pans of them, and thus very easily procure themselves a kind of bay-fall in summer. They fill these little basins with sea-water at high tides, and the heat of the sun and of the flone contributing greatly to the evaporation, as well as the shallowness of the basin, the whole humidity is found evaporated in the time of four tides, and they take out the salt ready for use. The length of these joints is various: they are from eight to four and twenty inches long, and for the most part longer towards the bottom of the column; they are generally from fifteen to twenty inches in diameter.

The triangular and square columns are fewer in number than the others, but they stand principally in the inner part of the large series, and are seldom seen, unless searched for by a curious eye.

The regular figure of the flone, composing this causeway, is not more wonderful than its quantity. The whole country for many miles being full of it, and a vast mass running far into the sea: for, besides what vulgarly goes by the name of the Giants Causeway, which is itself of vast extent, there are great numbers of the same pillars at distances in other places.

There are two other smaller and imperfect causeways to the left hand of the great one, and farther in the sea, a great number of rocks shew themselves at low water, which appear plainly all to consist of the same sort of columns. In going up the hill from the causeway there are found, in different places, a vast number of the same columns; but these do not stand erect, but are laid flantly upwards in different angles and directions. Beyond this hill, eafilward, also, at several distances, there stand a great number of the same pillars, placed slanting erect, and in clusters of different sizes. These are seen scattered, as it were, over the several parts of the hills.

One parcel of them is much admired, and called by the country people the looms of the organs. It stands in an elegant form, and faces the bottom of the hill. The columns, of which this cluster consists, are about fifty in number, and they are so nicely put together, that the tallest fland in the middle, and the shortest gradually on each side of it to the end, so that they look like the pipes of a church organ viewed from the front. The tallest one of all these, which stands exactly in the centre, is forty feet high, and consists of forty-four distinct joints.

What is eminently called the Giants Causeway is, in fact, a small portion of that vast basaltic area, of which the promontories of Bengalore and Fairhead confit, and which extends over a great part of the neighbouring country. These two great promontories, which have been examined by Hamilton and lately by Dr. Richardson, stand at the distance of eight miles from each other, and are the leading features of the whole coast of Antrim. The former of them, situated about seven miles Well of Ballycastle, represents itself at a distance, and in profile, as an extensive headland, running out from the coast a considerable length into the sea; but, strictly speaking, it is made up of a number of leffer capes and bays, the whole of which forms what the foremen denominate the headland of Bengalore. These capes are composed of a variety of different ranges of pillars and a great number of strata, which, from the abruptness of the coast, are very conspicuous, and form an unrivalled pile of natural architecture, in which all the neat regularity and elegance of art is united to the wild magnificence of nature. The promontory of Fairhead raises its lofty summit more than 500 feet above the sea, forming the eastern terminations of Ballycastle bay. It pretends to view a vast compact mass of rude columnar flones, the forms of which are extremely grofs, many of them being near 150 feet in length, and of a coarse texture. At the base of these gigantic columns lies a wild waste of natural ruins, of an enormous size, which, in the course of successive ages, have been tumbled down from their foundation by storms, or some more powerful operations of nature. The massive bodies have sometimes withstood the shock of their fall, and often lie in groups and clumps of pillars, resembling many of the varieties of artificial ruins, and forming a very novel and striking landscape. Besides these two promontories, there are several other parts of the county of Antrim which exhibit a similar columnar basaltic structure. Thus the mountain of Dunmull, between Coleraine and the river Buth, abounds in such basalt, particularly at the crags of Illamore, where two different ranges of columns may be discovered; they may be seen
GIANT.

also at Dunluce-hill, near the castle of Dunluce; in the bed of the river Bush, near the bridge of Buff-mills; on the summit of the mountain of Croaghmore; in many parts of the high land over Ballintoy; in the island of Raggery, opposite Ballycastle, and various other places, through an extent of coast about fifteen miles in length and two in breadth. Beyond this tract, which abounds in perfect pillars, an attentive observer will be able to trace the same materials and stratification in very dilant parts of the country, as far as the northern shore of Loughaneagh, and the mountains of the county of Derry; in many places of which imperfect columnar forms may be observed; so that the great cauze which generated this species of flow has been exerted through a space of more than forty miles in length and twenty in breadth; that is, through above eight hundred square miles.

Of the different varieties observable in the columns that compose the Giants Caufeway and thofe of the other parts of the coast, the following comparative view has been given by Mr. Hamilton. 1. With respect to form and magnitude: the pillars of the caufeway are comparatively small, not very much exceeding one foot in breadth and thirty in length; sharply defined, neat in their articulation, with convex or concave terminations to each joint. In many of the capes and hills they are of larger size, more imperfect and irregular in their figure and articulations, having often flat terminations to their joints. At Fairhead they are of a gigantic magnitude, sometimes exceeding five feet in breadth and a hundred in length; often apparently delirious of joints altogether. 2. With respect to situation: the pillars of the Giants Caufeway fand on the level of the beach, from where they may be traced, through all degrees of elevation, to the summit of the highest grounds in the neighbourhood, as at the old fort of Dummull, and on the top of Croaghmore, fix hundred feet at leaft above the level of the sea. 3. With respect to diposition and arrangement: at the caufeway, and in most other places, they fand perpendicular to the horizon; in fome of the capes, and particularly near Uthet harbour in the ifle of Raggery, they lie in an oblique position; at Doon-point, in the fame ifland, and along the Ballintoy shore, they form a variety of regular curves. 4. With regard to colour and grain; the Giants Caufeway basalt is blackish, close, and uniform; its varieties of colour are blue, reddish, grey; and of grain, all that can be fuppofed from extreme fineneef to the coarfe granulated appearance of a flow, which refembles imperfect granite abounding in cryftals of fhorn, chiefly black, though fometimes of various colours. 5. With repect to texture: though the Giants Caufeway basalt be in general compact and homogeneous, yet the upper joint of each pillar, where it can with certainty be ascertained, is always rudeiy formed and cellular. The grofs pillars alfo, in the capes and mountains frequently abound in these air-holes through all their parts, which fometimes contain fine clay and other apparently foreign bodies: and the irregular basalt beginning where the pillars ceafe, or lying over them, is, in general, extremely honey-combed, containing in its cells cryftals of zeolite, little morfels of fine brown clay, fometimes very pure fteatite, and in a few infamces bits of agate.

The inland pillars, upon the whole, differ from thofe which run into the fcn, and are called the caufeway, only in the following particulars: fome of the inland pillars are much larger than thofe of the caufeway, being two feet and a half in diameter, and among thofe there are only found fuch as have three, four, five, and fix fides, none of them having yet been found to have five or eight fides, as many of thofe of the caufeway fcth have. And, finally these taller pillars, though compofed of as many joints as thofe of the caufeway, yet have not that curious articulation of the ball and focket, but are only joined by the laying one smooth surface on another; fo that a joint of a single column may be dropped off from the rem, by a confiderable force pressing against it. There is nothing like this observable fuch in fome of the columns of the caufeway itself: for among the numbers which are jointed by the ball and focket, there are fome which only adhere by being applied furface to surface. This is found only in a few of the columns, however, and they always fland within the clufiers, and are compofed of few thin fides. In thofe alfo the joint is not made by the application of two horizontal planes, but by fuch as flant, so that it looks very like the breaking of an entrochus or aferia.

The joints, as we fee the pillars above the furface, are usually as many in number as the pillar is feet high; but they are not regularly each of a foot long, for they are fhortest at the upper part of the columns, and run gradually longer and longer as they approach the sea. This is obferved both in the inland columns, and in thofe of the caufeway; but though the length of the joints differs, their convexities and hollows are much the fame in all parts of the column.

There are other basaltic columns, similar to thofe above defcribed, in our own island; particularly at Staffa, one of the western iflands of Scotland; in the mountain of Cader-dris, near Dolgelly, in Merionethshire; where they probably form a group as in other places. Mr Strange has given an account of two groups of prismatic basaltic columns, which he difcovered in the Venetian flate in Italy; one in Monte Roffo, about feven miles narrowly from Padua, and the other in Monte del Diano, near San Giovanni Allarme, about ten miles north-west of Vicenza. The form of the latter is nearly circular, refeembling that of the Giants' Caufeway; that of the former approaching more to an oblong or oval figure: the columns of San Giovanni are much about the fame size, and mafter about a foot in diameter; thofe of Monte Roffo are very unequal, some being a few inches, while others scarcely exceed three inches in diameter; thofe of both thefe Venetian groups manifest all the varieties of prismatic forms obfervable in the Giants' Caufeway, and other fuch groups; but they are commonly of five, fix, or seven fides, and the hexagonal form seems mostly to prevail.

The texture of the former ftrict is folid and uniform; the furface smooth, and the internal parts of a dark iron-grey colour; thofe of Monte Roffo have a rough and knotty furface; and, when broken, manifest a variegated colour, and unequal texture of parts; refeembling an inferior ftrict of granite, of which the mountain is formed, and which ferves as a bafe for this range of columns. Other groups of artifiicial basaltic columns have alfo been obferved in the province of Velay and Auvergne in France; particularly by M. De Varennes, at Blaud near Langens, and M. Dalmart, near le Mont d'Or; and M. Sage mentions another near St. Alcon, in the fame province. Kircher has long ago defcribed a group of the fame columns near Viterbo in Italy. Mundus Subterr., lib. viii. cap. 9, &c. And Mr. Strange mentions another at Caffel Nuovo, in the Euganean hills, about four miles south-west of that of Monte Roffo.

For the various controversies with regard to the origin of these basaltic columns, and of the meta-tray-ruccs in general, see Trufp.

GIANTS' HEAD, in Geography. a cape on the eait coaft.
of the island of St. Christopher, a little to the east of Ragged Point.

GIAR, a town of Peria, in the province of Farilban; 70 miles E. of Schiras.

GIAR, Al. See Djar.

GIAR Anahar, in Botany, a name given by Avicenna, Scarpian, and the rest of the Arabian writers, to the potamo-phon of those times. This is translated from the water-rush, but that is founded on an error: it is certain that the plant thus called by the Arabians was very different from the potamo-phon of our times. Avicenna tells us, it had flowers resembling those of the water-lily; and it seems either to have been the ignota aquatica or water arrow-head, or else the butomus, or some of the smaller species of nymphæa.

GIARAF, Cape, in Geography, a cape on the coast of Tripoli. N. lat. 34° E. long. 12°.

GIARDINI, Felice, in Biography, in many respects the greatest performer on the violin during the last century. He was a native of Piedmont; and when a boy was a choi-rifer in the Duomo at Milan, under Palesini, of whom he learned figuration, the harpsichord, and composition; but having personally manifested a disposition and partiality for the violin, his father recalled him to Turin, in order to receive instructions on that instrument of the famous Sonini. But though his preference of the violin, upon which he soon became the greatest performer in Europe, seems a lucky circumstance, yet he had talents which would have made him a superior harpsichord player, had he continued to practise that instrument; but he used to say, that he was perforce cured of that vanity at Paris, by the performance of Madame de S. Maur, a helicar of Rameau, who played in such a manner, as not only made him ashamed of his own performance, but determined him never to touch the instru-ment again in serious practice. He went to Rome early in his life, and afterwards to Naples, where, having obtained a place among ripienos in the opera orchestra, he used to flourish and change passages much more frequently than he ought to have done. "However," says Giardini, of whom we had this account, "I acquired great reputation among the ignorant for my impertinence; yet one night, during the opera, Jonelli, who had composed it, came into the orchestra, and lecting himself close by me, I determined to give the maestro di cappella a touch of my taste and exaction; and in the symphony of the next song, which was in a pathetic style, I gave loose to my fingers and fancy; for which I was rewarded by the composer with a violent slap in the face; which," adds Giardini, "was the first time I ever received from a great master in my life." Jonelli, after this, was however very kind, in a different way, to this young and wonderful musician.

Giardini came to England in the spring of 1750. His first public performance in London, at which we were present, was at a benefit concert for old Cuzzoni, who sung in it with a thin cracked voice, which almost frightened out of the little theatre in the Hay-market the fan of those who had perhaps heard her at the great theatre in the same street, with extasy. But when Giardini played a solo and concertos, though there was very little company, the applause was loud, long, and furious, as nothing but that bestowed on Garrick had ever equalled. We had met him the night before at a private concert, with Gardiner and Trifi, at the house of Nothrab. Franks, esq., who was himself one of the last dilettanti performers on the violin in that time; and we were all equally surprised and delighted with the various powers of Giardini at so early a period of his life; when, besides, it is of his own composition of the most brilliant kind, he played several of Tartini's, in manuscript, at sight, and at five or six feet distance from the notes, as well as if he had never practised any thing else. His tone; bow; execution; graceful carriage of himself and his instrument; performing a M.S. piece of a young composer in the room, he declared that Giardini had so improved it as to make it better than he intended, or had imagined it to be in the warm moment's of conception; and lastly, playing variations extempore, during half an hour, upon a new but extra-ordinary kind of birth-day minuet, which accidentally lay on the harpsichord—all this threw into the utmost astonishment the whole company, who had never been accustomed to hear better performers than Feodric, Brown, and Collet! By the academy, scholars, manner of leading the opera and oratorio; performance in private concerts, compositions vocal and instrumental, we shall lay nothing here, lest our praise should be too much for others, and too little for ourselves.

He soon got possession of all the posts of honour in this country. He was engaged and cared for at most of the private concerts of the principal nobility, gentry, and foreign musicians; at the Castle and King's-Arms concert in the city; and in 1754, he was placed at the head of the opera band; in which he introduced a new discipline, and a new style of playing, much superior in itself, and more con-genial with the poetry and music of Italy, than the languid manner of his predecessor Feodric; who, except one or two seasons, when Veracini was at the head of the orchestra, had led the opera band from the time that Caffraniu was diffi-ciliated, till the arrival of Mingotti.

In 1756, on the failure and flight of the Imperatorio or undertaker of the opera, Vanefchi, the Mingotti, and Giardini joined their interests, and acquired for a while the sovereignty of the opera kingdom, by which gratification of their ambition, these two great performers were soon brought to the brink of ruin, as others had been before them. But though great applause was acquired, and appearances were favourable, yet the profits to the managers were so far from solid, that they found themselves involved at the end of the season in such difficulties, that they were glad to resign their slippery honours, and thrink into a private station.

Giardini, while in the opera management, besides arranging paticioses, set several entire dramas; but though he had so great a hand on his instrument, so much fancy in his compositions, and so liberal a flank for the audience, yet he had not sufficient force or variety to supply a whole evening's entertainment at the Lyric theatre. Yet after he had resigned his throne in the orchestra, he frequently threw in a lively air or romance into the operas of other masters, which was more applauded than all the rest of the drama; of which kind were the favourite airs of "Voci amanti," and "Ah non fi perde tu fiii," &c.

In 1762, on Mattei quitting the management of the opera, in spite of former unfriendliness, Giardini and Mingotti again regained the reins of opera government. But after struggling two years against the storm, during the decline of Mingotti's favour, and after an inauspicious season, at the end of 1763, Giardini and his partner again abdicated their thrones. From this period, Giardini, always hovering over his former Lyric kingdom, without the power of invading it, or bringing about a resperation, was forced to content himself with teaching ladies of rank and fashion to sing, and the produce of a great annual benefit. He continued here, unrivalled, as a leader, a solo player, and a composer for his instrument, still augmenting the importance of his instrument and our national partidity for the tale of his country, till the admirable productions and great performers of Germany began.
began to form a Teutonic interest and Germanic body here, which, before Giardini’s departure from London, became very formidable rivals to him and his Roman legions.

At the end of 1784, he went to Italy, and resided a considerable time at Naples, with Sir William Hamilton, one of his first scholars on the violin after his arrival in England.

Remaining on the continent till the summer of 1789, Giardini returned to this country, bringing with him a female pupil and her whole family, attempting a burletta opera at the little theatre in the Haymarket, while the great opera-house, which had been burned down, was rebuilding; but his prima donna not being approved, their speculation failed, and he had her and her whole family on his hands. During his absence the public had learned to do without him, and reconciled themselves to his loss; his health, hand and eyes were impaired; he was dropical, his legs were of an enormous size, and little of his former superiority on his instrument remained, but his fine tone. He composed quartets that pleased very much, but in which he never played any other part in public than the tenor. The style of music was changed; he printed many of his old compositions which used to please; but now could gain neither purchasers nor hearers, so that about the year 1793, he went to Petersburg with his burletta troop; which seems to have pleased as little there as at Moscow, as in London; and he is said to have died in this last city in great wretchedness and poverty!

But before we try to account for this melancholy termination of so brilliant a career, let us endeavour to do justice to his professional abilities.

It is the business of every artist to endeavour to arrive at the head of his profession during the age in which he lives, but no one can be expected to aspire at superiority over all mankind, past, present, and to come. Homer, our own Shakespeare, and Milton, have, perhaps, succeeded in that with, if ever they formed it, and Dryden and Pope have gained two out of three of these ages. If Giardini has been surpassed by a few in taste, expression, and execution, his tone and graceful manner of playing are still unrivalled, nor does any one, of all the admirable and great performers on the violin, surpass all others so much at present, as Giardini did, when at his best, all the violinists in Europe.

That a man with such talents and intellects as art and nature fearlessly ever allowed to the same individual, who might have realized 40 or 50,000l., should, by extravagance, caprice, and a total want of benevolence and rectitude of heart, die a beggar, unfriended and unpitied, is fiercely credible! It is painful to probe the private character of such a man; yet it should not be concealed. Truth and morality require it to be recorded. The kings of Egypt used to be tried after their decease.

And if young musicians of great talents, who are prone to deviate from propriety of conduct, should chance to read this article, it may serve as a beacon, and remind them of the possibility of surviving favour and talents, however great, and terminating their existence in misery and mortification.

A respectable professor, who, from Giardini’s first arrival in England, was constantly attached to him, and a sincere admirer of his talents, his wit, and even the immensity of his spleen and spite; before he quitted this country in 1784, delineated his character in the following manner, a copy of which came lately to our hands, accidentally.

*Sketch of the private character of a great musician.*—There exists a man who would rather gain half a crown by superior facility and cunning, than be gashed by usual and fair means; who is so difficult a commerce, that the utmost circum-
and distinguished by its agreeable situation and fabulous air; 15 miles W. of Turin.

GIAUF, Aa, a district of Egypt, in the S.E. part of the Delta.

GIAVI, a town of the island of Sardinia; 21 miles E.S.E. of Algheri.

GIAUKIRI, a town of Asiatic Turkey, in Natolia, anciently "Sigeum," chiefly inhabited by Greeks.

GIAZA, a town of Italy, in the Veroné; 14 miles N.N.E. of Verona.

GIB, in Agriculture, a sort of stick with a hook at the end, which is sometimes useful in making and repairing hedges, and for various other purposes.

Gib, in Mechanic. See Crane.

Gibbs, or Tidings. In Minerva, are pieces of wood from two to four or more feet long, with a bird's-mouth or notch cut in each end, that are placed as slats between the four upright poles, at the corners of square or rectangular shafts, which are supported with wood, instead of being girded or bricked.

GIBAU, in Geography, a town of Moravia, in the circle of Olmutz; eight miles N.E. of Olmutz.

GIBBAWAYS, an Indian tribe residing in Upper Canada, on the E. side of Detroit river, opposite to fort Gibraltar.

GIBBEN, a town of the duchy of Courland; 32 miles N.E. of Piltyn.

GIBBETHON, in Scripture Geography, a city of Dan, allotted to the Levites (Josh. xxi. 23.); probably the same as Gubbata; 12 miles from Eleutheropolis. Here they shared the tomb of the prophet Habakkuk.

GIBBON, Edward, in Biography, was born at Putney in 1737. His father was a gentleman of fortune, and some years member of parliament. The subject of this article was a very delicate and sickly child, informed that his parents had but little hope of rearing him. From nine years of age to twelve, he was under the tuition of Dr. Woodfon at Kingston-upon-Thames. Here he acquired the elements of classical learning, and he mentions his twelfth year as particularly "propitious to the growth of his intellectual faculties," because at this period he read a variety of English works of poetry, romance, history and travels.

He then went to Weitsmantle school, but his ill state of health prevented him from making a regular progress in the studies of the place. For several years he was chiefly the object of medical care, till at length, and, as it were, very suddenly, his constitution acquired firmness, and his father immediately sent him, as gentleman-commoner, to Magdalen college, Oxford. He was probably ill prepared to receive the benefits of an university education, and he signified the fourteen months that he spent there as the most idle and unprofitable of his whole life. To a total neglect of religious instruction he has attributed a very remarkable incident which took place at this time. He had from an early age been addicted to disputation on topics of divinity. His leisure from other pursuits induced him to turn his attention to the controversies between the Papists and Protestants. His mind was overfed by the arguments of the former, and in 1755 he had an interview with a popish priest in London, when he solemnly abjured the errors of Protestantism. He immediately wrote an elaborate letter to his father, in which he avowed the change in his sentiments, and justified the measure which he had taken. With all the zeal of a new convert he has since declared, "I am proud of an honest sacrifice of interest to conscience; I can never blith if my tender mind was entangled in the sophistry that seduced and many misunderstandings of Chillingworth and Bayle." He was sent by his father to Lausanne, and placed with a Calvinist minister, by whose judicious efforts, aided by his own found reason and mature reflections, his faith in the Romish articles gradually gave way, and on Christmas day 1754, he received the sacrament in the Protestant church. During the time he spent at Lausanne, he laid the foundation of that knowledge in the languages, and in the art of logic, which enabled him to make him a figure in the literary world. To the "History of the Decline and Fall of the Roman empire," we have had occasion frequently to recur for an elucidation of facts, we may therefore be allowed to speak somewhat at large of the author of that work. His ruling passion, that of reading, completely developed itself in Switzerland, and he wanted no excitements to industry, from a tutor. Belles lettres, and the history of man, and the human mind, were his favourite objects of study; for the mathematics he had no inclination, and what he did not, and perhaps could not pursue, he was ready to condemn, and congratulated himself that he escaped from them "before his mind was hardened by the habit of rigid demonstration, so destructive of the finer feelings of moral evidence." That this view of the effect of mathematical studies was unjust, might be proved from a variety of instances in which the ablest mathematicians have been equally celebrated for their fine taste and excellent judgment in other branches of literature. In the year 1758 he returned from Lausanne to London, where he was kindly received by his father, and he found in a mother-in-law, a new relative, who in time conciliated his good will and confidence. He now began laying the foundation of a copious library, and soon set about preparations for appearing before the public as an author. In 1761, he printed his "L'éloge fur l'Étude de la Littérature," in one volume 12mo. It was a very respectable juvenile performance, and was highly praised in the foreign journals. At home it obtained but a small share of public notice. While he was composing this work, at last before it was published, he was engaged in the military profession, which was but ill calculated for a person of his turn. The peace, in 1763, set him free from a commision which he had held in the militia, and he immediately paid a visit to Paris, and during some months in that capital, he went to Lausanne, where he passed a year in cultivating society, and in collecting materials for a profitable journey into Italy. This he undertook in 1765, and it was, as he fat amusing amid the ruins of the capital, while the fairs were singing vespers in the temple of Jupiter, that the idea of writing his great work, viz. "The History of the Decline and Fall of this City," rushed into his mind. He had, previously to this, proceeded some way in another intereting design, and composed, in the French language, the first book of a History of the Swiss liberty; but this, perhaps on account of its style, was condemned by a literary society of foreigners in London, to whom it was read, and he committed it to the flames. In 1767, he allided in compiling a critical work, entitled "Mémoires Littéraires de la Grande Bretagne," the successe of which was but trifling. In 1770 he published, in his native tongue, a pamphlet, entitled "Critical Observations on the sixth book of the Aeneid," which was intended as a refutation of Dr. Warburton's hypothesis concerning the meaning of the defeat of Æneas; and in the same year, by the death of his father, he succeed to an estate considerably involved, and from the perplexities of which he scarcely ever extricated himself. His circumstances were, however, well suited to the talk he had undertaken as an author: for he thought himself, that had he been either much poorer or much richer, he should never have accomplished it. Leisure and books were necessary on
the one hand; on the other, the stimulus of a handsome increase of property. His acquaintance was large, but he compensated the hours devoted to them by early rising and close application. In 1774, he was, through the interest of Mr. Elliot, introduced to a seat in parliament, which he occupied during eight years, and gave, says he, many a silent vote in support of the rights, though not, perhaps, the interest of the mother country. Early in 1776 the first volume of his "History" made its appearance; its success was very great, and far surpassed the most sanguine expectations of the author: "The first impression," says he, "was exhausted in a few days; a second and a third edition were fearfully adequate to the demand, and the book-seller's property was twice invaded by the pirates of Dublin." It was received with general applause, but the praises of none were so keenly relished by Gibbon, as those of the two celebrated historians, Hume and Robertson, who, instead of viewing his rising fame with jealousy, promoted it with liberal commendation. In the midst of his triumphs, his two chapters, concerning the growth and progress of Christianity, raised a storm against him, which, as he had foreseen, he regarded with some alarm. He was attacked on all sides, but as he professed to have written only as a historian, he declined entering the lists as a controversialist. In one instance his fidelity, as an historian, was attacked; here he felt that he was called on for a "Vindication," in which he admitted that he successfully repelled the principal charges, and returned them on his antagonist. It was suggested, in the two chapters referred to, that the progress of Christianity was peculiarly favoured by secondary causes, and, of course that its origin was not divine; though this theory had not been delineate of advocates among sincere believers in the truth of the Christian syllem, yet there is little doubt that Gibbon was an unbeliever, and he wrote in this part of his work under the mask of a friend. His pretensions were unveiled by many excellent writers, who ranked high in the established church, and by others who were not in the church, but who were equally alive to the spread of sceptical principles, and active in opposing their propagation. After he had resumed his work, he was solicited by ministers to write an answer to the manifeste of the court of France, on its declaration of hostilities. On this occasion he published his "Memoire Justificatif," which was written in French, and much admired for its style and its reasoning, and was delivered, as a state paper, to the courts of Europe. For this service he was rewarded with the appointment of one of the Lords of Trade, by which a handsome addition was made to his income, and little to his engagements. In 1781 the second and third volumes of his History appeared, which supported the reputation which he had already acquired. Upon the dissolution of Lord North's ministry, the board of Trade was abolished; as occasioning only an useless expense to the state. The defalcation in Mr. Gibbon's income no longer permitted him to support the same style of living in his own country, and he removed his residence to Lausanne: here, in an elegant retreat, he finished his History, in three other quarto volumes, which were published in 1788. It was with real regret that he diminished an occupation, which had given to many years of his life that zeal which an interesting object of pursuit can alone impart. He came to England to superintend the printing of his work, and then returned to Lausanne, to spend, as he hoped, the remainder of his days; but the horrors of the French revolution, which menaced the quiet and happy regions of Switzerland, gradually loosened his attachment to Lausanne, and he began to look towards England for a refuge. He regarded the events that were taking place in France with the utmost abhorrence, and he either was, or had become so from the occurrences of the times, a decided enemy to every species of public reform. He avowed his assent to Mr. Burke's creed, which he had vindicated in his "Reflections:" "I admit," says he, "his eloquence, I approve his politics, I adore his chivalry, and I can almost excuse his reverence for church establishments." Mr. Gibbon returned to England in 1792, but after a few months residence his attention was forcibly called to the progress of a disease, which had subsisted in a small degree for thirty years, and which now terminated his existence, Jan. 16, 1794. He has characterized himself in the following words: "I am endowed with a cheerful temper, a moderate sensibility, and a natural disposition to repose rather than activity; some mischievous appetites and habits have, perhaps, been corrected by philosophy or time. The love of study supplies each day, each hour, with a perpetual source of independent and rational pleasure." "He was," says his biographer, "easy in society, and fond of it; he was beloved by his friends, and had, in an eminent degree, the manners and habits of a gentleman. Early indulgence and habit had made the conveniences and elegances of cultured life effectual to his comfort, and he was not one, who could have been content with the consolefiances of mental superiority in an humble state. His great work, which will long be a monument to his fame, is a performance of vail and accurate research, and of enlarged and philosophical thinking: it abounds in splendid passages, and its style displays a thorough mastery of the whole compass of the English language." After his death two quarto volumes of his miscellaneous works were published by lord Sheffield, containing, among other things, memoirs of his life and writings, composed by himself; to which the reader is referred for more particulars relating to this celebrated man.

GIBBONS, ORLANDO, without exception, the best composer for the church during the reign of King James I. and though not blemished with longevity, yet, during his short life, he contributed amply to the music of the church, which he enriched with numerous compositions, that are still fresh and in constant use among the best productions within its pale.

This excellent musician, a native of Cambridge, was brother of Edward Gibbons, bachelor of Music, organist of Brifol, gentleman of the Chapel Royal, and master of Mathew Lock; and of Ellis Gibbons, author of two madrigals in "the Triumphs of Oriana," who is filled by Ant. Wood, "the admirable organist of Salisbury." In 1604, at the age of twenty-one, Orlando was appointed organist of the Chapel Royal, in the room of Arthur Cock. In 1622, he was honoured at Oxford with a doctor's degree in music, at the same time as his friend Dr. Heyther, when both were countenanced and favoured with indulgencies in the university in consequence of letters from the learned Camden, who recommended them with friendly zeal to its notice. According to Ant. Wood, the academical exercise in his or more parts, performed at this time for Heyther's degree, was composed by Orlando Gibbons, "as one or more eminent musicians then living had several times told him." So that green-sentiment, as well as boys, through idleness or ignorance, are sometimes reduced to the humiliating necessity of having recourse to the charity of friends, before they can exhibit an exercise.

A manuscript copy of the exercise performed for Dr. Heyther's degree, is said to have been found, signed with the name of Orlando Gibbons. It is an anthem for eight voices, taken from the forty-seventh psalm; and appears to be the very same composition as the anthem of Orlando Gibbons.

The harmony in Gibbons's service in P, printed by Dr. Boyce, is pure, clear, and grateful; and the melody more accented and flowing than we have found in any choral music of equal antiquity.

The two parts in one, of the Gloria Patri, though they may be the cause of some confusion in the words, discover no restraint or trifling in the melody, which continues to move with the same freedom, as if no composer had exultation. And though the parts, on account of the confusion arising from all the parts singing different words at the same time, pronounced in the style, in which his full anthems are composed, to be vicious; yet the lovers of fugue, ingenious contrivance, and rich, simple, and pleasing harmony, must regard them as admirable productions, alla Palestrina, a style in which Tallis and Bird acquired so much renown.

Besides his admirable choral compositions, O. Gibbons was author of melodies in two parts to the hymns and spiritual songs of the church, translated by George Withers, and of several other works which are mentioned elsewhere. See Fantasia and Parthemia.

Dr. Tudway, in the dedication of the first volume of his manuscript "Collection of the most celebrated Services and Anthems used in the Church of England," addressed to Lord Harley, for whom it was made; after a just and warm eulogium on the abilities of Tallis and Bird, says that "none of the later composers could ever make appear so exalted a faculty in compositions for the church, except that most excellent artist, Orlando Gibbons, organist and servant to king Charles I. whose whole service, with several anthems, are the most perfect pieces of church compositions which have appeared since the time of Tallis and Bird; the air to solemn, the fugues and other embellishments so just and naturally taken, as must warm the heart of any one, who is endowed with a soul fitted for divine raptures." To this encomium every candid judge of harmony will readily subscribe; but when the doctor tells us, that the celebrated service in F was composed by Orlando Gibbons in 1635, he furnishes not very favourable proof of his knowledge in chronology; as it is recorded on the monument erected to his memory by his widow, that he died ten years before that period. For in 1625, being commanded, ex officio, to attend the solemnity of the marriage of his royal master, Charles I. with the princess Henrietta of France, at Canterbury, for which occasion he had composed the music, he was seized with the small-pox, and dying on Whitunday, in the same year, was buried in that cathedral.

GIBBON, Dr. CHRIStOPHER, was the son of Orlando Gibbons, and scholar of his uncle Ellis Gibbons, organist of Bristol. He had been honored with the notice of Charles I. and was of his chapel. At the reformation, besides being appointed principal organist of the Chapel Royal, private organist to his majesty, and organist of Westminster Abbey, he obtained his doctor's degree in music at Oxford, in consequence of a letter written by his majesty Charles II. himself, in his behalf, which is inserted by Ant. Wood in the Pall Oxon, vol. ii. col. 158; who says, that he completed his degree in an act celebrated in St. Mary's church, July 11, 1664.

The compositions of this man, which were not numerous, seem never to have enjoyed a great degree of favour; and though some of them are preferred in the Museum collection, they have long ceased to be performed in our cathedrals. His abilities on the organ, however, must have been considerable, to entitle him to the honours he filled, at a time when the style of playing that instrument was so much more complicated and elaborate than at present. Dr. Blow, who, in singing and composition, was educated by Captain Cook, is said to have been a scholar on the organ of Dr. Christopher Gibbons, who died 1676.

Orlando Gibbons had two brothers, Edward and Ellis, the one organist of Brilrot, and the other of Salisbury. Edward was a Cambridge bachelor of music, and incorporated at Oxford, 1592. Besides being organist of Brilrot, he was priest-over, sub-choirer, and master of the choir-boys in that cathedral. He was sworn a gentleman of the chapel, March 21, 1663, and was the master of Matthew Lock. In the Triumphs of Oriana, there are two madrigals, the one in five, and the other in six parts, composed by Ellis Gibbons. Wood styles him the admired organist of Salisbury. Of Edward Gibbons, it is said, that in the time of the rebellion he assisted king Charles I. with the sum of one thousand pounds; for which in token of his loyalty, he was afterwards very severely treated by those in power, who deprived him of a considerate estate, and thrust him and three grand children out of his house, though he was more than four score years of age.

GIBBOUS, in Astronomy, is used in reference to the enlightened parts of the moon, while the is moving from full to the first quarter, and from the left quarter to full again; for all that time the dark part appears horned, or eulogised, and the light one bunched out, convex, or gibbosus.

GIBBOSIUS fil. ghibbianus p. t. in Ichthyology, a name given by Mr. Ray to the fish called by the Dutch brui. It is a smooth fish without scales, its belly is white, its fins and tail black. It grows to a considerable size, sometimes to four feet. It is caught all over the East Indies, near the sea shores, and is very firm, and much esteemed at table. It has its name from the remarkable rind of its back, which is like that of the perch, but much thicker. Ray's ichthyolog. Append. p. 4.

GIBBY, in Geography, a cluster of small islands, in the East Indian sea, about twelve leagues in circumference, well inhabited, situated on the equator. E. long. 126° 5'.

GIBE, a town of Arabia, in the province of Nodin; 130 miles E. N. E. of Hajar.

GIBEAH, in Scripture Geography, a city of Benjamin, the birth-place of Saul, the first king of Israel. Josh. xiii. 24. Ezra ii. 26. Nehem. vii. 36. Gibeah was about two leagues N. from Jericho. In Jerome's time it was entirely destroyed.

GIBEL-EL-TOR, a mountain of Palestine, anciently called Mount Tabor, which see.

GIBELLET, or GARBLE, a sea-port of Syria, anciently called "Gabala" and "Gabulon." Situated on the coast of the Mediterranean, at the mouth of the river Jabbok; 12 miles S. S. W. of Tripoli.

GIBELIN, a town of Palestine; eight miles E. of Gaza.

GIBELINS, Gibelins, Gibellins, or Gibellines, a famous faction in Italy, opposite to another called the Guelphs.

The Guelphs and Gibellins ravaged and laid waste Italy for a long series of years; so that the history of that country, for the space of three centuries, is only a detail of their mutual conflicts and mortal wars.

The Guelphs frequently offered the power of the see of Rome, as the Gibellins did the emperor's right of fore-
GIBELINO, in Geography, a town of the duchy of Parma, on the right bank of the Po; 16 miles N.W. of Parma. N. lat. 45° 1'. E. long. 10° 7'.

GIBEON, in Scripture Geography, the capital city of the Gibeonites, which awaited themselves of the oaths of Joshua, and of the elders of Israel, in an artful representation which they made of their belonging to a remote country. (Josh. ix.) Joshua and the elders made an unadvised league with them; but upon a discovery of their mistake, they spared their lives, and condemned them to the servile office of carrying wood and water to the tabernacle, and other work of a similar kind, in token of their puerility and duplicity, as slaves and captives. In this state of servitude they remained till the entire dispersion of the Jewish nation, A. M. 2553. The Gibeonites were defended from the Hivites, the old inhabitants of the country, and poissed four cities, viz. Cepherah, Beeroth, Kirjath-jearim, and Gideon, the capital, afterwards given to Benjamin, excepting Kirjath-jearim, which was assigned to Judah. The Gibeonites submitted to the burdens imposed upon them by Joshua, and continued faithful to the Ishmaelites. Nevertheless Saul destroyed a very great number of them (2 Sam. xxi. 1, 2, 3, &c.); but God, as a punishment of his cruelty, in the reign of David, caused a great famine, which lasted three years (A. M. 2582; B. C. 1017); and David was informed by the prophets, that this calamity would continue as long as that cruelty, which Saul had exercised against the Gibeonites, remained unrelented. The Gibeonites, being asked what satisfaction they required, answered, "Seven of Saul's sons will we put to death, to avenge the blood of our brethren." Accordingly the Gibeonites cursed them in the beginning of spring, when, in Paelin, the barley-harvest commenced. From this time we find no mention of the Gibeonites, as forming a separate people. But they were probably included among the "Ne-Thinim," who were public slaves appointed for the service of the temple. (1 Chron. ix. 2.)

Gideon was seated on an eminence, as appears by its name, denoting a hill; it was 40 furlongs N. from Jericho, according to Josephus. It is called "Gaba'a" (see 2 Sam. v. 25, compared with 1 Chron. xiv. 16.) We find mention of the fountain and pool of Gideon. (2 Sam. ii. 13.) The tabernacle and altar of burnt offerings, made by Moses in the wilderness, were removed to Gideon. (1 Chron. xxv. 29, 30.) When Solomon was seated on the throne, he went to sacrifice at Gideon, because this was the most considerable of all the high places where sacrifices were then tolerated, the temple not being yet built. (1 Kings, iii. 4.)

GIBERT, BALDIANUS, in Biographia, was born at six in 1062. He was educated partly at Paris and partly at Soissons. At the age of twenty-two he was appointed to teach philosophy at the college of Beauvais, and in 1688 he
obtained the professorship of rhetoric in the college of Mazarin at Paris, which office he filled with great reputation more than fifty years. He was a zealous defender of the privileges of the university, of which he was several times chosen rector. He obtained other preferments connected with the university, but on account of his opposition to the revocation of an appeal made by the university against the bull Unigenitus, the court, in 1740, exiled him to Auvergne. He died in the following year at the age of seventy-nine. He was author of many works, in which are displayed much erudition and solidity of judgment, but the style is somewhat involved. Among his publications are "De la véritable Eloquence," "Réflexions sur la Rhetorique;" "Judgement iitriles Geography," "Histoire des Savans sur les Auteurs qui ont traité de la Rhetorique," in three volumes 12mo. Moretti.

GIBERTI, Giambattista, a very learned prelate of the church of Rome, was born at Palermo towards the close of the fifteenth century. He visited Rome when he was but twelve years of age, where he was distinguished for the brilliancy of his talents. He was introduced to pope Leo X. who entertained a great regard for him. He had a thirst for polite literature, but was, at an early age, taken from the pursuit, and placed in the service of a person of high rank. By pope Clement VII. he was employed in some very important legations to the king of France and other potentates. In 1523 he obtained from his patron the government of Tivoli, and in the following year he was created bishop of Verona; he was not, however, allowed to take possession of his fee, but was kept at Rome as the adviser and friend of the pope. In 1527 Giberti was given as one of the hostages by the pope to the Imperial army, on which occasion he underwent much ill treatment, and was more than once threatened with a shameful death. He was, at length, through the interposition of his friend, Cardinal Pompeo Colonna, restored to his liberty, and retired to his bishopprie, on which he continued to reside till his death, except when occasionally summoned to Rome by Paul III. He died in 1543, and his works, which were numerous, have been published collectively; they chiefly consist of his constitutions and regulations for the government of his church, which under his direction became a model of ecclesiastical discipline. He eradicated many abuses, and was profuse in alms to the poor. He was the patron of learned men who resorted to his palace, among whom was the celebrated poet Flaminio. He printed at his own expense, and under his own superintendence, several works of the fathers, and in order to render his editions correct, he entertained several Greek copyists. Moretti.

GIBET, or Gibet, a machine in manner of a gallows where notorious criminals, after execution, are hung in irons, or chains: as spectacles, in terrærem.

The word in French, gibet, properly denotes what we call gallows: it is suppos'd to come originally from the Arabic gabet, mount, elevation of ground; by reason gibets are usually placed on hills, or eminences.

GIBETS, the offals or entrails of a goose; including the heart and liver, with the feet, gizzard, &c.

The word is suppos'd to be formed of goble, from the French gobeau, mouthful.

Giblets make a considerable article in cookery: they boil giblets, fry giblets, make ragouts of giblets, giblet-pies, &c.

GIBLIEN, in Geography, a town of Egypt, on the left bank of the Nile; 13 miles N. of Afn.

GIBLOS, a city on the coast of Phœnicia, between Tripoli and Beræta; called also Byblus, which fee.

GIBON, a town of the island of Cuba; 22 miles N.N.E. of Bayamo.

GIBRÁLTER, a town of Spain, in the province of Seville, on the river Odicel, with a harbour for small fishing vessels; containing about 150 houes in two parishes, and situated about 10 miles from the Atlantic; 44 miles W. of Seville. N. lat. 37° 20'. W. long. 7° 1'.

GIBRALTAR, derived from Gibel, an arabic word signifying mountain, and Tarle, the name of a Moorish general, who conquered Spain and disembarked here in the year 712, is a town of Spain, in the province of Andalusia, but belonging to Great Britain, situated on a rock, at the southern extremity of Europe, and reckoned one of the keys of Spain. This rock forms a promontory from Spain into the sea, opposite another promontory extending from Africa, bounding a narrow sea, which unites the Atlantic and the Mediterranean, called in Latin "Fretum Herculanum, or Gadjtanum," and in English the Strait of Gibraltar. The length is about eight leagues, and the breadth, in the narrowest parts, nearly five. On these two promontories are placed the famous mountains of Calpe in Europe, and Abila in Africa, known to the ancients by the name of the pillars of Hercules. From the top of the promontory of Calpe, the eye commands an extent of 40 leagues, two seas, and five kingdoms, viz. Seville and Granada, in Spain, and Barbary, Fez, and Morecco, in Africa. In endeavouring to trace the town mentioned by Melas, Strabo, and Phinius, under the names of Calpe, Carthaya, Melaria, Belo, and Belipo, and also the promontory of Juno, situated from east to west on the shore of the straits, no vellige is perceived, except the mountain and seite of Carthaya; which latter city passed from the possession of the Phœcicians to that of the Carthaginians, and is now reduced to a mere heap of ruins, scarcely discernible in the bay of Gibraltar, where the Carthaginian tower was also situated. This ground is now occupied by a meadow farm. On calling your eyes over the kingdoms of Granada and Seville, you see the lofty ridges of the defert del Cuerro, as well as the mountains of Hogen and Sanorin, and towards the east, opposite to Gibraltar, the new town of Algiers. In the middle of this immense expanse of waters the ruins of Great Carthaya; at a short distance, on a little hill, the town of St. Roch is situated; on the east you perceive the chain of mountains, called the Sierra de Ronda, abounding in fruits and aromatic plants. Near these is said to be the town of Munda, so celebrated in Roman history as the scene of the battle between the forces of Pompey and Augustus, when they were disputing the empire of the world. The objects which bound the horizon on the right are the Sierra Nevada, and the Alpajuras; on which the snow lies all the year. The mountains supply a number of fountains and rivulets of clear water, forming the fountains of the Xenil and the Darro; rivers which water the city of Granada and give fertility to the rich province of Andalusia.

The promontory on the European side is joined to Spain by an isthmus, or neck of land, so narrow, that from some aspects the rock has the appearance of an island. The length of the isthmus is about 200 paces; across which the Spaniards have drawn a line and fortified it, to prevent the garrion from having any communication with the country.

The form of the rocky mountain, on which the fortresses of Gibraltar is built, is oblong; its summit is a sharp craggy ridge, extending nearly from N. to S., almost three miles, and in breadth no where exceeding 1/2 of a mile. The line of its ridge is undulated, and the two extremes are somewhat higher than the centre. The summit of the Sugar-loaf, which is the highest point towards the south, is elevated
the height of 1439 feet; the Rock-mortar, which is the highest eminence to the north, is 1350 feet; and the Signal-houses, which is nearly the central point between these two, is 1276 feet above the level of the sea. The western side of the mountain forms a series of rugged slopes, intersected with abrupt precipices. Its northern extremity is perfectly perpendicular, except towards the N.W., where what are called the Lines intervene, and a narrow passage of ground that leads to the iikums, and is entirely covered with fortification. The eastern side of the mountain mostly consists of a range of precipices; but a bank of sand, rising from the Mediterranean in a rapid acclivity, covers a third of its perpendicular height. Its southern extremity falls in a rapid slope from the summit of the Sugar-loaf into a rocky flat of considerable extent, called Windmill Hill. The principal masts of the mountain rock consists of a grey, dense marble; the different beds of which present to Spain a face of 1350 feet of perpendicular height, in a conical form. These beds, or strata, are of various thicknesses, from 20 to upwards of 40 feet, dipping in a direction from east to west, nearly at an angle of 35 degrees. In some parts of the solid masts of this rock, we find tesselated bodies entirely transmuted into the constituent matter of the rock, and their interior hollows filled up with calcareous spar; but these do not occur often in its composition, and its beds are not separated by any intermediate strata. This rock is suffering a flow, but constant deposition; and the uncovered parts of its present holes of various sizes, hollowed out of the solid rock, and apparently formed by the attrition of gravel or pebble, set in motion by the rapidity of rivers or currents in the sea; whence it is presumed, that, however high the surface of this rock may now be elevated above the level of the sea, it has once been the bed of agitated waters. On the west side of the mountain, towards its base, strata occur, which are of a different kind from the mountain rock. (See Major Imrie's mineralogical Description of Gibraltar in the Transactions of the Royal Society of Edinburgh, vol. iv.)

The first, or highest, forms the segment of a circle, its convex side being towards the mountain, and its slope being in that direction. This stratum consists of a number of thin beds; the outward one, which is the thinnest, is in a state of decomposition, and is mouldering down into a blackish-brown or ferruginous coloured earth. The beds below this increase progressively in breadth to 17 inches, where the stratification reappears upon a rock of an argillaceous nature. This last bed, which is 17 inches thick, consists of quartz of a blackish-blue colour, in the septa or cracks of which are found quartz crystals, colourless and perfectly transparent. These crystals are composed of 18 planes, disposed in hexagonal columns, terminated at both extremities by hexagonal pyramids. The largest seen by major Imrie, did not exceed one-fourth of an inch in length; they generally adhere to the rock by the sides of the column, but are detached without difficulty. Their great degree of transparency has obtained for them the name of "Gibraltar diamonds." The rock is completely fretted with batteries, thrown up at all points, where the ascent could not be rendered completely inaccessible; so that from Europa Point, which advances farthest into the sea on the south side, to the highest part of the rock, which is that of the north (at about two miles distance from the other), there is not a single point, which is not put into a defensible condition. On the side nearest Spain, the internal fortifications, made since the time Gibraltar was besieged by the combined armies of France and Spain, are astonishing. These improvements are principally owing to general O'Hara, the late governor; a great number of workmen having been employed about it, for eight years, at an immense expense. In order to form some idea of the labour expended on these fortifications, it will be sufficient to observe, that the excavation was effected by the force of gunpowder, in the centre of the mountain, and in the solid rock, form vaults of such height and extent, that during a siege they are capable of containing the whole garrison. These caverns, of which the most considerable is the hall of St. George, communicate with the other batteries, established along the mountains by a winding road, passable on horse-back. On returning towards Europa Point, as you enter the town, your attention is engaged by considerable fortifications, barracks, magazines, and batteries, placed wherever the nature of the ground would admit. On the highest point of land the tower of St. George was built, under the directions of general O'Hara, who intended to raise it to a sufficient height for commanding the whole of Cadiz, and observing all that passed in that port; but the undertaking, being disapproved by the British government, was left in an unfinished state. Along the mountain are several grottos, or natural excavations, the most famous of which is that of St. Michael; the height of the entrance being 437 feet (varas) yards above the level of the sea. The cavern below is at least 70 feet, and contains columns of crystallizations and stalactites, resembling all the orders of architecture. About 100 paces from its gate is another beautiful cavern, 65 varas square, and the vault 21 varas high. On the right is a second excavation, adorned with caprices of nature similar to those of the former, but so regularly disposed, that it has the appearance of a temple. Perhaps this was formerly used for consulting some oracle, probably that of Hercules, who was the principal divinity of the place, as well as of the cave in the promontory of Ampelus, on the coast of Africa. From the entry of this cavern you discover the whole of the bay of Gibraltar, two leagues across from east to west, and three from north to south. You also command a view of the country-houses, the flower and kitchen gardens, which the inhabitants have formed one above the other, on the side of the mountain, up to the royal road, and the public walk, extending for about half a mile from the town of Gibraltar to the new town on the fort. The English have spared no pains in covering the rock with trees and flowers, in supporting the earth with walls and props, in cutting a number of roads through the solid rock, and in making them passable on horse-back and in carriages up to the very summit. They have even some artificial meadows for their flocks. From the grotto of St. Michael, situated on the southern part of the mountain, at an almost equal distance, the Signal tower and the Sugar-loaf, the entrance of which is 5000 feet above the level of the sea, you discover the magazines, the batteries, the new town; on the south, the marine hospital, which is a handsome and convenient building. The view extends over a number of country-houses, to some of which beautiful gardens are attached; in time these new buildings will form a town as considerable as that of Gibraltar. Near them are eight magnificent ciphers, large enough to contain 50,000 tons of water, and bomb-proof; they receive all the water which flows down the side of the mountain, previously purified in copper vessels erected for the purpose. On the south side you perceive a number of mountains, called Tarfes; and near them formerly stood a very ancient tower, with a cistern and well. In a cove not far distant several flutes have been found with human bones above the common size, to strongly incut them as to form one solid mass. (See Pollard's Regnums.) From Europa Point to the gate on the land-side
are several moles, which facilitate the unloading of ships, and enable them to cast anchor in security. Before you arrive at the south gate you observe a handsome, large, square, surrounded with trees, now called the Field of Mars, formerly the Red Sand; of such a size, that the 6000 men, usually comprising the garrison, can perform their manoeuvres without inconvenience. Here the guard always mutters, and on Sundays and holidays they make it the grand parade.

The prevailing forms of religion in this promontory are the Catholic, that of the church of England, and the Jewish, each of which has its own burying ground, among the shaky earth of the mountain.

The town of Gibraltar is on the west side at the foot of the mountain; it is large, well built, fortified with strong walls, battlements, and works to cover them; a large fort protects and marks the mole, built in the form of a bridge, 300 feet long; a church is built near it; and on the land side is another mole, which covers the part fortified by a fort with a tower, and two or three breast-works, thrown up in front. On entering the town by the south gate, you perceive on the left an edifice, containing the library of the officers of the garrison; consisting chiefly of the works of modern authors. The governor's house is built on the ground formerly occupied by the convent of Franciscans; to which is attached a beautiful garden, which, on Thursday and Sunday evenings, during the summer, is the promenade of the officers of the garrison and inhabitants of the city. The principal street into which you enter on leaving the governor's house, is the residence of the merchants, and on the right is the Catholic chapel, rebuilt in an excellent style of architecture; this street extends almost through the whole length of the city, being more than half a mile long, and on each side it has handsome flat pavements, and a number of shops from one end to the other. All the houses are built in the English style, with small doors, flat roofs, and numerous bow windows, behind which the prime goods of all ports are exposed to sale. The inhabitants are chiefly military; the commerce with Africa is neither constant nor regular; and although the contraband trade with Spain, both in money and goods, is one of the principal branches of trade, that cannot be sufficient (says La Borda) to indemnify England for a million and a half of plate, which on an average it sells annually, to maintain this point in the Mediterranean, where in other respects the duties collected are very small. This place is advantageously situated for victualing the fleets, and the protection of the coast of Africa, from whence the English procure their corn, and as a place of refuge for their privateers and fleets of war. The port is a key to the Mediterranean and to the Atlantic; confus from all the isles of Europe and North America usually reside there. The Americans, as well as the Swedes, Danes, and Dutch, in time of peace, carry on a direct commerce with Gibraltar, by supplying themselves with the articles they want, and leaving in exchange flour, cod, pitch, and tar, masts, rum, maize, rice, flour, sugar, pepper, ginger, cotton, aniseed, and the other articles of commerce, which they procure from Abyssinia, Africa, and Europe. The coasts of Granada, Seville, and Catalonia, furnish wine, and Africa wax and fresh meat in great quantities; they also import from Spain brandy, raisins, almonds, oranges, lemons, figs, salt, &c., which the merchants from the north carry back in exchange. Gibraltar contains altogether 9000 inhabitants, including eight regiments, amounting to 6000 men; so that this place is rather a military colony than a commercial establishment. The population of Gibraltar extends one mile to the south, and nearly as much towards the top of the mountain; and if we may judge from the new buildings lately erected, it is certainly increasing. All the houses are painted black on the outside, with white borders or ledges, showing the number of stories, which are generally two or three. This mode is well suited to a country where the reflection of the sun is very violent. The police is well conducted; no beggars are to be found here; the streets are preferred clean and plentiful; and though they are all well lighted at night, no one is allowed to walk without a lantern, and a permission from the general of sentinels requiring answers to their challenges being stationed in the town, as well as patrols and watchmen. All forms of religion are tolerated without inconvenience, and the number of Jews, who live here more securely than in any other part of Europe, is very considerable. Gibraltar has a theatre, which, though small, is well laid out and adorned with tape. For want of regular actors, the officers of the garrison perform, during the greater part of the year, a number of English plays.

On the opposite side of the straits of Gibraltar is the town of Ceuta. The traveller, who wishes to cross over into Africa, may take advantage of the N.W. winds, and of the small vessels which are continually plying and replying.

The origin and foundation of this town are lost in the obscurity of time. It is certain, however, that the Phenicians, the Egyptians, and other ancient people, landed at Gibraltar; and the name of the pillars of Hercules, by which this place was known, is nothing more than a tradition preserved among the Phenicians, who peopled this coast, and brought their gods and religious worship with them. But it is not known whether the straits or columns existed in the remotest antiquity, and if the inscription "non plus ultra" meant that nothing was more wonderful than the separation of the two continents, or not more probable, that no one had dared to navigate beyond this point. However this be, it is probable that the first navigators of the Mediterranean landed at Gibraltar, or its environs. This opinion is supported by the authority of Pomponius Mela, who, being born at Cadiz, may be supposed to feel more interest than others in whatever related to this coast. The Moors seized on Gibraltar in the eighth century, and held it without interruption till the fourteenth, when, in the year 1316, it was taken from them by Perez de Guzman; but they took it in the year 1333, and held it till the year 1462, when it was retaken by the Spaniards, and it has continued in the hands of the Christians from that time. The English took it from the Spaniards during the war of the succession in Spain; the fort surrendered to the united fleet of England and Holland under Sir George Rooke, in 1704; and the allies took possession of it in the name of Charles III. The place was ceded to the English by the treaties of Utrecht and Seville; it was besieged at several times without success. Since the English have been masters of the place it has been so much improved and strengthened, as probably to bid defiance to the utmost efforts of an enemy. In the course of the American war, the Spaniards again besieged it; but their memorable attack with floating batteries of upwards of 200 cannon, in ships of all sizes, terminated only in disappointment, in the destruction of the ships and men employed, and in the immortal honour of the brave defenders: 16 miles N. of Ceuta; 76 S. of Seville. N. lat. 36° 44'. W. long. 5° 19' 46'.

Gibraltar, an ancient town of South America, in the government of Caracara, and province of Venezuela, is situated on the E. coast of the lake Maracaibo. The country in its vicinity is well watered with rivers, and furnishes all kinds of the most quality, and very large-reeds. The bell Spanish tobacco is produced here, called Tobago de Maracaibo, from which is made the valuable snuff, vulgarly called "Meekeba" snuff. The air is very innoxious in the rainy season, and therefore
the merchants and planters retire at that time to Maracaybo, or Merida; 100 miles S.S.E. of Maracaybo. N. lat. 10° 4’ W. long. 67° 36’.

GIBRALTAR Point, is the western extremity of a sandbank, in Upper Canada, which forms the harbour of York, and upon which block-houses are erected for its defence. There is another place of this name on the fide of lake Memphia-
magog, in the town of Bolton, in Upper Canada.

GIBRIN, a town of Syria; 10 miles S.E. of Aleppo.

GIBSON, RICHARD, in Biography, the Dwarf, was placed by a lady at Mortlake, to whom he was page, with Francis de Clyne to learn to paint, both in water and in oil; but he informed himself more by studying the works of Lely, and gained considerable reputation.

GIBSON, EDWARD, in Biography, was born at Bampton, in Welford-more, in the year 1666. He received the early part of his education at the free-school in his native town, and at the age of seventeen he was sent to Queen’s college, Oxford. In 1681 he was admitted to the degree of B.A., and in the same year, having already applied himself most diligently to the study of the northern languages, he published a new edition of William Drummond’s Polyceni-Mudiana, and James V. of Scotland’s Catinica Rubfica, quartos, illustrated with notes. In 1692, he gave a translation in the Latin language, together with the original, of the “Chronicon Saxonicum”; likewise a work entitled “Liberum Manuscriptorum in duabus insignibus Bibliothecis, altera Dugaldiana Osnoni, Catalogus,” with a dedication to Dr. Temnion, afterwards archbishop of Canterbury, which proved the foundation of the author’s subsequent fortune under the auspices of that prelate. He next published a correct edition of Quintilian “De arte Oratoria;” and a new edition of Somner’s treatise on the Roman ports and forts in Kent. In 1694 Mr. Gibbon commenced A.M., and shortly afterwards was elected fellow of his college, and admitted into deacon’s and priest’s orders. In 1695 he published an English translation of “Cæsem’s Britannia.” This work was patronized by lord Somers, who offered Mr. Gibbon a living in the Isle of Thanet, which he declined, on account of ill-health, and in the following year he was appointed librarian at Lambeth, by the archbishop, Dr. Temnion, who received him into his family, and who appointed him morning preacher at Lambeth church. His publications about this period were, “Vita Thomæ Bodleii, Equitis Aurati,” together with “Hitoria Bibliothecæ Bodliæanae;” also, “Reliquiae Spelmannianæ;” being the posthumous works of sir Henry Spelman, relating to the Laws and Antiquities of England, together with the Life of the Author.” He was now appointed domestic chaplain to the archbishop, through whose interest he obtained the lecturership of St. Martin’s in the Fields, and was presented to the rectory of Stitled in Essex. His promotion in the church went on rapidly, but it did not render him indifferent to the cause of literature, and in 1713 he published his celebrated work, entitled “Codex Juris Ecclesiastici Anglicae; or the statutes, constitution, canons, rubrics, and articles of the church of England, methodically digested under their proper Heads, &c.” The scheme of church power vindicated in this volume was excepted against, not only by dissenters, but by the founders and most constitutional lawyers within the pale of the church; who maintained that the principles and claims advanced in it would be sufficient, if acted upon, in their utmost extent, to establish a sacerdotal empire, which must draw all power to itself, and render the civil magistrate its minister and dependent. In 1715 our author, who had taken his degree of D.D., was consecrated bishop of Lincoln, and in 1723 he was translated to the see of Lon-
don. In this situation, on account of the weak health of Dr. Wake, then archbishop of Canterbury, almost every thing relating to the affairs of the church was confided to him. His great zeal for the established religion, and his opposition to the dissenters, who were endeavouring to obtain the repeal of the Corporation and Test acts, kindled him in the effusion of the prime minister, sir Robert Walpole; and he was, about the same time, rendered obnoxious to men in power, by several attacks on the principles in his “Codex,” which the authors contended were inimical to the civil constitutions of this country, and favourable to a spirit of intolerance and persecution. Of these attacks, one of the most able was conducted by the recorder of Bristol, afterwards Mr. Justice Foller, at the desire of lord Hardwick, lord-justice of the court of king’s bench. Bishop Gibbon’s constitution was naturally strong and vigorous, but he exercised it with almost incomparably, to that, at length, it might be said to be fairly worn out by his labours and exertions. For some time before he died, he became sensible that his end was approaching, and in 1748 he breathed his last at Bath, being in his seventy-third year. Besides the works already enumerated, the bishop was author of several others, highly esteemed by the learned. He wrote and published many pastoral letters, addressed to the clergy and laity of his diocese, intended to oppose the growth of inanity and enthusiasm; some vitiation charges, occasional sermons, and small tracts against the prevailing vices of the age. These smaller pieces have been frequently reprinted, and it is said that the bishop received more real satisfaction on account of the repeated demand for his practical works, than from the honours conferred on him by his larger and more learned treatises. He polished the social principles in an eminent degree, and his beneficence and charity were very extensively, though privately, exercised. An instance of liberality is recorded, which redounds greatly to his honour: Dr. Crow had left him by his will 2500l. which bishop Gibbon freely gave to Dr. Crow’s own relations, who were in indigent circumstances. Biog. Brit.

GID, or GIDDY, in Rural Economy, a morbid condition occurring in sheep and some other animals, in which there is a confluent vertigo or turning round. The affection is generally considered as a kind of hydrocephalus, or encysted collection of watery matter in the head, between the dura and pia mater.

It has, however, been suggested by some as depending upon a worm or maggot under the horn on either side of the head; in support of which Mr. Collins has been informed of cows having the disease, and being cured by having a perforation made near the horn, and the worm or maggot taken out; but this is no doubt another sort of disorder.

Some farmers consider this complaint as the most common among sheep that are richly fed, and know it by the name of the fluidy evil, the cure being attempted by the use of small bleeding and affaetides; and in order to guard against a relapse, the sheep should be put into a hilly or elevated pasturage.

Among the graziers in the county of Lincoln the disease is known by the terms fluidy, and bladder on the brains, and in its remedy a fort of trepanning proceds is had recourse to, by which great numbers of sheep are supposed to be saved. The person who performs the operation raises the scalp with a strong hooked knife jut over the part affected, to the extent of about half a crown piece, after which, nearly the same extent of the skull-bone is elevated, letting it hang by a hinge on one side; then by means of a quill, cut flaring to a point, in the form of a spear, and hacked on each side, the bladder is sought for and brought out whole, the
bone being immediately put down again, and covered with a platter.

The South Down sheep farmers, when the animals are affected in this way, say they are *paterfis*.

Various other modes of cure have been proposed, but they do not seem worthy of much attention. See *Sheep*.

*Gidda*, in *Ancient Geography*, See *India*.

*Giddiness*, in *Medicine*, a sensation as if the objects surrounding the person were in a state of circumjacent, or whirling motion, accompanied with an inability to maintain the erect posture, or to move forward in a straight line; in technical language this is designated *Vertigo*; which see.

*Gidrno*, in *Geography*, a town of Albania; 8 miles N. of Alessio.

*Gida*, a river of Sweden, which rises in the Lappmark of Åsele, and traversing Angermanland, runs into the gulf of Bothnia. N. lat. 16° 20', E. long. 18° 54'.

*Gidel*, a town of Candahar; 50 miles S.E. of Kabul.

*Gidid*, a town of Africa, in Dar-fur, nearly S.E. and about 22 miles from Cobbi, on the road from Cobbi to Kil. This town has a competent supply of water; and yet the Fukkara, who poiffs it, are supposed to be so destitute of hospitality, that they will hardly furnish a traveller sufficient to allay his thirst. In this town are many huts, and some of them belong to merchants who derive their origin from the eastward. — *Alfo*, a town of Nubia; 35 miles S. of Gerri.

*Gid,-shehir*, a town of Asiatic Turkey, in Nato- lia; 8 miles S. of Biebehiri.

*Gidola*, a town of Russia, in the government of Wil- burg; 20 miles N. of Wilburg.

*Gieg*, a town of Germany, in the bishopric of Bamberg; 7 miles N. of Bamberg.

*Giedkuliszi*, a town of Samogitia; 24 miles S. of Rorene.

*Giedroyce*, a town of Lithuania, in the palatinate of Wilna; 24 miles N.W. of Wilna.

*Giedungen*, a town of Norway, in the diocese of Christiania; 18 miles N.W. of Stavanger.

*Gieguzin*, a town of Lithuania; 15 miles S. of Wilkomiers.

*Gie.*, in *Botany*, the Ceylon name of a small fruit, described by *Gartner* v. 2. 486. t. 180, of which nothing more is known. The nucleus is singularly pitted, like a *Rutus*, but if the figure be in all points correct, it cannot be a grain of the fruit of that genus. The internal parts, being decayed, might have afforded something decisive, especially the situation of the embryo.

*Gillum*, in *Geography*, a town of Norway, in the diocese of Aggerhus; 53 miles N. of Christiania.

*Gien*, a town of France, and principal place of a dis- trict, in the department of the Loire, seated on the Loire; 32 miles S.E. of Orleans. The place contains 5117, and the canton 11,366 inhabitants, on a territory of 410 kilomet- res, in 11 communes. N. lat. 49° 45'. E. long. 0° 13'.

*Giene*. See *Ken*. A

*Giersor*, a town of Africa; 10 miles S. of Tripoli.

*Gier*, a river of France, which runs into the Rhone, 12 miles below Lyons.

*Gierace*, a town of Naples, in Calabria Ultra, the see of a bishop, suffragan of Reggio; containing 13 churches, and 4 monasteries. Near it are some sulphureous baths; 34 miles N. of Reggio. N. lat. 38° 6'. E. long. 12° 35'. — *Alfo*, a town of Sicily, in the valley of Demes- na; 30 miles S.W. of Milletta. N. lat. 37° 48'. E. long. 14° 22'.

*Gieranonly*, a town of Lithuania, in the palatinate of Wilna; 20 miles N.E. of Lida.

*Gierga*, a town of Bengal; 48 miles S.E. of Doee.

*Giesim*, a town of Nubia, between Senmaar and Abyssinia; 100 miles E.S.E. of Senmaar. N. lat. 13° 16'. E. long. 35° 15'.

*Giessen*, a strong town of Germany, in the princi- pality of Upper Hesse, situated in a fertile country, on the Lahn. It is defended by a good citadel and arsenal. An university was founded here in the year 1605; 36 miles N.E. of Mentz. N. lat. 50° 35'. E. long. 8° 43'.

*Giezina*, a town of Samogitia; 22 miles E.S.E. of Roe- fienne.

*Giffa*, a town in *Surger*, signifying dwellings behind the ears.

*Giffen*, Herbert, in *Biography*, a lawyer and philo- logist, was a native of Gueldres in France. He studied at various universities, as those at Louvain, Paris, and Or- lens, and in 1567, he took his degrees in the law. He went to Venice in the train of the French ambassadour, and from thence to Germany, and taught philosophy and juris- prudence at Strauburg, Altdorf, and Ingolstadt. He was educated in the principles of Protestantism, which he renounced for the Catholic religion previously to his being in- vited to the imperial court, where the emperor Rodolph be- folowed upon him some important offices. Being sent into Bohemia, he died at Prague in the year 1604, being about seventy years of age. His principal works are "*Comment. de Imp. Juliano*;" "*Index Hlitt. Rerum Romanorum*"; and notes and comments upon Aristotle's politics, ethics; also upon Lucertins, Moror, Baylo. *Giffth-Meleh*, the name given by the German chen- mists and metallurgists to the first appearance of arsenic, or the grey flowers arising from the roasting of cobalt, and flicking to the long wooden funnel, which they carry from the furnaces. The word giffth-mehl is German, and signifies poisonous meal or flour.

*Gifhorn*, in *Geography*, a town of Germany, in the principality of Luneburg-Zell, seated on the Allier; 19 miles E. of Zell.

*Gifoni*, a town of Naples, in Principato Citera; 7 miles E. N. E. of Salerno.

*Gift*, or *Grant*, in *Law*, a method of transferring personal property, answering in some measure to the convey- ances of real estates. Gifts and grants are thus to be dis- guised from each other, that gifts are always gratuitous, whereas grants are upon some consideration or equivalent. With regard to their subject-matter, they may be divided into gifts or grants of chattels *real*, and gifts or grants of chattels *personam*. Under the former class may be included all leaves for years of land, assignments, and surrenders of these leaves; and all the other methods of conveying an estate less than freehold; though these very seldom carry the out- ward appearance of a gift, however freely bestowed; being usually expressed to be made in consideration of blood, or natural attachment, or of five or ten shillings nominally paid to the grantor; and in case of leases, always reserving a rent, though it be but a peppercorn: any of which considerations will, in the eye of the law, convert the gift, if executed, into a grant; if not executed, into a contract.
Grants or gifts of chattels personal are the act of transferring the right and possession of them; whereby one man renounces, and another man immediately acquires, all titles and interest therein, which may be done either in writing or by word of mouth, attested by sufficient evidence (Park. § 57), of which the delivery of possession is the strongest and the most essential. But this conveyance, when merely voluntary, is somewhat suspicious; and is usually confined to be fraudulent, if creditors or others become sufferers thereby. And, particularly, by statute 3 Hen. VII. c. 4, all deeds of gift of goods, made in trust to the use of the donor, shall be void; because otherwise pernons might be tempted to commit treason or felony, without danger of forfeiture; and the creditors of the donor might also be defrauded of their right. And by statute 13 Eliz. c. 5, every grant or gift of chattels, as well as lands, with an intent to defraud creditors or others (3 Rep. 82), shall be void, as against such persons to whom such fraud would be prejudicial; but, as against the grantor himself, shall stand good and effectual; and all persons partakers in, or privy to, such fraudulent grants, shall forfeit the whole value of the goods, one moiety to the king, and another moiety to the party grieved; and also, upon conviction, shall suffer imprisonment for half a year.

A true and proper gift or grant is always accompanied with delivery of possession, and takes effect immediately; as if A., gives to B. 100l. or a flock of sheep, and puts him in possession of them directly; it is then a gift executed in the donee; and it is not in the donor's power to retract it, though he did it without any consideration or recompense (Jenk. 109): unless it be prejudicial to creditors; or the donor were under any legal incapacity, as infancy, coverture, durefs, or the like; or if he were drawn in, circumvented, or imposed upon by false pretences, obesity, or surprize. But if the gift does not take effect, by delivery of immediate possession, it is then not properly a gift, but a contract; and this a man cannot be compelled to perform, but upon good and sufficient consideration. See Contract.

The conveyance by gift, "donatio," is properly applied to the creation of an estate-tail, as feoffment is to an estate in fee, and lease to that of an estate for life or years. It differs in nothing from a feoffment, but in the nature of the estate passing by it; for the operative words of conveyance in this case are do or dedit (Weit. Symbol. 256); and gifts in tail are equally imperfect without delivery of seisin, as feoffments in fee-simple. (Litt. § 50). See Feoffment. This is the only distinction which Littleton seems to make, when he says (§ 57), "it is to be understood, that there is seffor and feoffor, donor and donee, lessor and lesee;" viz., feoffor is applied to a seffor in fee-simple, donor to a gift in tail, and lessor to a lease for life, or for years, or at will. In common acceptance gifts are frequently confounded with grants. (See Grant.) Blackl. Com. B. ii.

Gift-day, in Rural Economy, is a term implying a boon-day, or a day's work given from the tenant to the lord, or from neighbour to neighbour.

Gifts, New Year's. See STRENE.

GIG, Fish. See Fish-gig.

GIGA, ItaL. GIGUE. Fr. a jig, the name of a gay dance, and of its tune. The Crufa Dict. defines this word from Dante, par. 14, "fiumeno mosfale di corvo"; a musical instrument with strings. The Crufa, likewise, says, that it is an intrumental movement, to called.—Walther's derivation from Stige, Germ. a violin, or fiddle, comprehends both the tune and the instrument upon which, originally, it was most frequently played. The time of the gig, or jig, is always quick, and in triplets of 3, 5, or 7.

Carelli's jigs were long in favour; but, being in the fashion, as most of our old country-dances, they are almost all become vulgar, except the gighe in his 5th folio, and 15th sonatas, op. 11.

Rouleau says that jigs are now wholly out of fashion in Italy and France; but the movement is only improved by new and more elegant passages: for, whatever is played quick, in triplets of 3, 5, or 12 quavers in a bar, is still a gighe, or jig.

GIGAIA, GIGHA, GIG, or GIGA, in Geography, one of the smaller western islands of Scotland, about 7 miles long and one breadth, partly rocky and partly arable, situated in N. lat. 55° 56'. W. long. 5° 43'. and separated from the peninsula of Cantyre, or Kintyre, by a channel 3½ miles broad. There are no trees in this island; but oaks are sometimes dug up in the morasses. Near its centre is Dun-cliffs, a high steep rock, flat at top, which appears to have been a strong fortification. At Kilchattan is a rude column, 16 feet high, 4 broad, and 8 inches thick, and near it is a cairn. On the western shore, which is bold and rocky, there are some remarkable caves; and on the S. coast is a subterraneous passage 133 feet in length. Between the projecting points and rocky rocks on the E. coast are creeks, in which vessels may be safely moored. This island contains 592 inhabitants.

About 1½ miles S. from Gigha, is the isle of Caray, or Cara, near a mile long and half a mile broad, containing 22 inhabitants. The shores are everywhere high and rocky, except at the N. E. end, where is the only landing place. The Mull of Cara, at the S. end, is a perpendicular rock 167 feet high. At the N. E. end, the land is a mixture of fields, sand, and common mould; the rest of the island, the surface, is a stratum of peat earth. Between Gigha and Cara is Gighalum, a small uninhabited island.

GIGANTES, a cluster of small islands among the Philippines, N. W. of Sibu. N. lat. 11° 42'. E. long. 121° 20'.

GIGANTIC. See GIANT.

Gigantic Order, in Architecture, a name given by Scamozzi and others to the Tuscan order.

Gigantomachia, the battle of the giants against the fabulous gods of the ancient heathens. See Giant.

The word is Greek, γίγαντομαχία, formed of γίγαντης, (gigante, giant; and μάχη, combat, of μάχομαι, μάχη, I fight.

Several of the poets have composed gigantomachias: that of Scarron is the finest of all his pieces.

Gigantophontes, is a name given to Minerva, on account of the asilence which she gave to Jupiter in his content with the giants.

Gigay, in Geography, a small island of the Hebrides, on the E. coast of Barra, yielding tolerable pasture, but difficult of access.

Gigeri, See JIEL.

Gigeri, a term used by some writers to express the offals of poultry of any kind, including the intestines, extremities, and whatever else is thrown away before the dressing. See Giblets.

Gigg, Giga, or Jig, in Music and Dancing. See Giga.

Giges, among Farriers, small bladders or blisters on the inside of a horse's lips. They must be laid open, and cleansed with salt and vinegar, or alum-water.

Gige, in the Manufacture of Flax, denotes a hole made in the earth, where fire is made to dry the flax laid over it.

Gigge, Anthony, in Biography, a learned Italian, who flourished in the early part of the seventeenth century, and was admitted to the degree of doctor by the Ambro-
flan college at Milan. He was author of many learned works, but that on which his reputation is chiefly established, was entitled "Theaetetus Linguae Arabeæ, seu Lexicon Arabico-Latinum," published in four volumes folio, in 1632. As a resource for the learning and industry which it exhibited, pope Urban VIII. nominated the author to an honourable post in a college at Rome; but he died before he could enter upon its functions, or enjoy its emoluments. Gen. Biog.

GIGLIO, or ISOLE DEL GIGLIO, in Geography, a small island in the Mediterranean, near the coast of Italy, anciently called Algilia, or Iglion. N. lat. 42° 28'. E. long. 10° 53'.

GIGMILLS, a kind of fulling mills, for fulling and burling of woollen cloth, prohibited, anno 5 and 6 Ed. VI. c. 22.

GIGNEE, in Geography, a town of France, in the department of the Herault, and chief place of a canton, in the district of Lodève, seated on the Herault; 10 miles S. E. of Lodève. The place contains 2785 inhabitants, and the canton 13,632 inhabitants, on a territory of 290 kilometres, in 21 commune. N. lat. 43° 39'. E. long. 3° 38'.

GIGNY, a town of France, in the department of the Yonne, on the Surin; 7 miles S. W. of Orgelet.

GIGOT. See Gioia.

GIGOT, in the Munage, a branch after the form of a gigot, or leg, is a branch, the lower part of which is round, and called in French gargouille.

GIL, in Geography. See Jhox and Anu.

GILJON, in Scripture Geography, a fountain, well of Je-rufalem, where Solomon was anointed king by Zadok and Nathan. The upper channel of Gilon was ordered, by Horeckia, to be conveyed into Jerufalem, for the advantage of the waters; 1 Kings, i. 55. 2 Chron. xxviii. 30. - Alto, the name of one of the four rivers, whose sources were in Paradise, Gen. ii. 13. The Arabsians believed this to be the Ouxus, a river which rifes in the mountains of Imaus, and runs from east to west; and after winding much, returns, and discharges itself into the Caffian sea, westward. This river separates the provinces of the Turks and Persians. Modern geographers call the Ouxus, Anu; which see. The Arabians name it Gehon, and Neher-Bakh, the river of Balk, because it passes through that city. Calvin, Scaliger, and others, think that Gilon is the most western channel of the two made by the Tigris and Euphrates, when, after their confluence, they separate again to enter the sea. Others again maintain that Pifon is the western channel, and that Gilton is the eastern. This is the opinion of Dobo- chart and Huetius. (See Eden.) Others suppose the Gilton to be the Araxes which see.

GILON, Juxta of the Romans, a considerable sea-port town of Spain, in Alturias, formerly the capital of this province, with an old castle, containing about 800 families, 18 miles N. of Oviedo. This infertile port, contracted and maintained at a great expense, is referred to by the English for shanters and cachifts. N. lat. 43° 32'. W. long. 5° 42'.

GIKRI, a town of Hindoofland, in the circur of Nagore; 15 miles S. E. of Catchwe.

GIL, Island of, an island of the North Pacific ocean, so called by lignor Caamano, about 14 miles long and 6 broad, between Princes Royal’s island and Pitt’s Archipelago.

GILA, a river of New Mexico. See Colorado.

GILACAN, a small island in the North Pacific ocean, N. of the Catanduanes. N. lat. 14° 26'. E. long. 124° 27'.

GILARZA, a town of the island of Sardonia; 15 miles S. E. of Doha.

GILATTELKE, a town of Transylvania, 14 miles N. of Chuenenburg.

GILBERG, a town of Sweden, in Warmeland; 24 miles W. of Carslait.

GILBERT, Humphrey, in Biography, descended from an ancient family in Devonshire, was born about the year 1539. His mother, after becoming a widow, married Mr. Raleigh, by whom she had Sir Walter; of course, Humphrey Gilbert and Sir Walter were half brothers, and, as we shall see, both became distinguished in the annals of their country. The subject of the present article was educated at Eton, and from hence was sent to Oxford to complete his studies. He soon exhibited a turn of mind better adapted to an active than a literary life. He was early introduced to the court of Elizabeth, and there acquired that arduous of loyalty which seemed to be the ruling passion of those who approached the queen. His first expedition as a warrior was at Havre, in 1563, after which he was sent over to Ireland, to affilit in quelling the disorders in that country, and role to the chief command in the province of Munster. In 1570 he received the honour of knighthood as a reward for his services. In the following year sir Humphrey Gilbert served, as a burgess, in parliament, for Plymouth; and in 1572 he failed with a reinforcement to colonel Morgan, then acting in Flanders. He, about this period, became anxious for the advancement of maritime discovery, and the improvement and extension of trade and commerce; with these views, in 1576 he published "A Discourse, to prove a passage by the north-west to the East Indies." He probably designed to make attempts for the discovery of this passage, but an anterior project was that of settling some of the countries in the northern part of the New World. In 1578 he obtained a patent from the crown for making settlements in the unoccupied lands of North America, and fitted out an expedition with which he failed for Newfoundland, where he continued a short time, and returned without having effected any thing of import- ance. He, however, perished in his design, and in 1583, in company with his brother, sir Walter Raleigh, returned to Newfoundland, and took possession, in the queen’s name, of the harbour of St. John, and granted leaves of the circumjacent country to those of his company who chose to take them. He carried out with him a Saxon miner, in hopes, no doubt, of finding gold, more than sufficient to repay them for all their trouble and labour. This man pretended to have discovered a rich silver mine on the coast, and dug up some ore, which satisfied sir Humphrey that the means of wealth were within their reach. He now fully expected that he could obtain from the queen the loan of ten thousand pounds, to enable them to prosecute their discoveries, but his voyage was truly disastrous; the largest ship was lost in a storm, with all the crew except twelve men, and the miner and the ore perished at the same time. He himself had fortunately gone on board a small slop, for the purpose of exploring the coast. After this he refused to shift his station to his larger remaining vessel, being resol- ved not to desert the little crew with whom he had encountered so many dangers. He steered homeward, in the midst of a tempestuous sea, and on the ninth of September, when his small bark was in the utmost danger of foundering, he was seen, by the crew of the other ship, sitting in the stern of the vessel, with a book in his hand, and he was heard to cry out, "Courage, my lad! we are as near heaven at sea as at land." About midnight the bark was swallowed up by the sea; the gallant knight and all his men perished with her. Though sir Humphrey Gilbert did not effect a settlement at Newfoundland, yet the pro
ject was soon after realized under his patent, so far as to be of great advantage to the fishery from this country. Biog.

Gilbert, of Gilberts, William, a physician, was born, in the year 1540, at Colchester, of which borough his father had been recorder. After studying some time at Cambridge, he travelled abroad for farther improvement in those branches of science to which he was particularly addicted; and took the degree of doctor of physic in some foreign university. He returned to his own country with a high character for philosophical and chemical knowledge, and was made a member of the College of Physicians in London, where he settled for the rest of his life. He was an intimate friend of famous men and with his much reputation and success, that he at length became first physician to queen Elizabeth, in which office he continued during the life of that prince. The vacancies from the duties of his profession he employed in the pursuit of philosophical experiments, particularly relative to the magnet, and in these he was assisted by a pension from Queen Elizabeth. We are informed of no other circumstances concerning the life of this learned man, who died, unmarried, November 20, 1603, aged 63, and was buried in his native place, where a handsome monument was erected to his memory by his brothers. He left all his books, globes, mathematical instruments, and cabinet of minerals, to the College of Physicians. His picture, which represents him as of a tall figure and cheerful countenance, is in the gallery over the schools at Oxford.

The capital work of Dr. Gilbert, entitled "De Magnet, Magneticisque Corporibus et Magnis Magnetis Tellure, Physiologia nova, plurium et argumentis et experimentis demonstrata," was first published at London in 1600, and has been reprinted in Germany. This is not only the earliest complete system of magnetism, but also one of the first specimens of a philosophical system built upon experiments, after the manner so much infallted on afterwards by the great lord Bacon. Aikin, Biog. Mem. of Med. Eley.

Gilbert, John, the son of Mr. Thomas Gilbert, a gentleman possessing an estate of about 300l. a year, was born in the year 1724. His eldest brother had a liberal education, with a view to the bar, and became afterwards a member of parliament for Newcastle and Litchfield: but the subject of this article had only such instruction as the obscure village of Farley, in the neighbourhood of his father's house, could afford. At the age of twelve or thirteen years, he was bound apprentice to Mr. Bolton, father of the well-known and justly celebrated Matthew Bolton, of Soho, near Birmingham; between whom and Mr. Gilbert an intimacy subsisted, as long as the latter lived. At the age of 19 he left his father; and as he died possessed of extensive lime-works, they required attention. Accordingly Mr. Gilbert, in order to undertake the superintendence of them, quitted his connection with Mr. Bolton, who very reluctantly parted with him, and devoted himself to the management of his own family concerns. Notwithstanding the disadvantages under which Mr. G. had laboured in early life, he possessed talents, which, matured by age and experience, could not fail of recommending him to notice. But the most remarkable circumstance in the history of this ingenious person, and that indeed which has induced us to give a brief account of him, was his introduction to the duke of Bridgewater, at the time when he was prosecuting improvements of his collieries, in the neighbourhood of Manchester. Mr. Gilbert's brother was then fled to the duke; and defirèd him to inspect and examine his Grace's collieries at Worlsey. After viewing the works, it immediately occurred to him, that if the coals on that part of the duke's estate could be brought to market in such a populous town as Manchester, and for the supply of the numerous works in its vicinity, the colliery, which, in the state it was at the time of his inspection, yielded little profit, would become extremely valuable. It is said, that he persuaded himself altogether from company for two days, at the Bull inn at Manchester, to consider how this might be done by water-carriages, as that by land was very expensive, and, on account of the badness of the roads, very inconvenient, and almost impracticable. Having digested his scheme, he communicated it to the duke, who was no less struck with the proposition suggested by Mr. G. than the projector himself. Accordingly the work was soon after begun. Mr. G.'s name was seldom occurred in connection with this very important and lucrative undertaking; and as he proceeded Mr. Brindley in this business, of which we have ample and satisfactory evidence, we thought that justice required a candid and impartial statement of the case. Mr. G. was so fortunate, in the prosecution of this work, as to find time upon the duke's estate, which, until otherwise have been brought by land from Buxton, at the distance of near 30 miles; and in a work of this great extent, this was no inconsiderable saving. The tunnel was entirely executed, as well as planned, by Mr. G.: who, being acquainted with Mr. Brindley as a neighbour, and knowing him to be a very ingenious and elegant workman, engaged his assistance in the conduct and completion of this arduous undertaking, and introduced him to the duke for this purpose. The duke was so well satisfied with his agent and projector, that at first they lived together for two or three months in the year, and for several of the last years of Mr. Gilbert's life, he spent half his time with him. In June, 1757, he removed with his family to Worlsey, that he might, with greater convenience, attend the prosecution of the business he had undertaken. As a farther evidence of the duke's regard for Mr. G. we may here add, that he gave his son, who was educated for the church, the second bell preferment at his disposal, to the amount of about 1500l. per annum. We might mention many other concerns in which Mr. G. was engaged, and in which he had an opportunity of manifesting his skill and judgment, in the conduct of canals, mines, and other improvements relating to rural economy. We shall merely add, that he is said to have been the first person who suggested the use of gun-power in obtaining rock-fall. Mr. G. was probably too modest and unassuming, that he did not, during his life-time, lay claim to the honour which belonged to him, with respect to the duke of Bridgewater's canals and collieries; and we have introduced his name into the Cyclopaedia, in order to do him justice, without meaning to detract from the merit of his coadjutor and successor, Mr. Brindley, to whom we have already paid ample and deserved respect under his biographical article. Mr. Gilbert's general character commanded the esteem of all who knew him, and his death, even after a prolonged life of about 73 years, which happened at Worlsey, on the 4th of August, 1757, was, without doubt, regretted by his friends, and especially by the noble duke, who was in the house at the time.

Gilbert's Island, in Geography, an island near the S.W. coast of Terra del Fuego, N. lat. 55° 15', W. long. 71° 5'.

Gilbert's Town, a town of America, in the state of Virginia, seated on the Shenando, 30 miles N. of Charlotteville.

Gilbertines, in Ecclesiastical History, an order of religious, thus called from St. Gilbert, of Sempringham, in the county of Lincoln, who founded the name about the year 1148: the monks of which observed the rule of St. Augustine, and were accounted canons; and the nuns that of St. Benedict.
The founder of this order erected a double monastery, or rather two different ones, contiguous to each other, the one for men, the other for women, but parted by a very high wall.

St. Gilbert himself founded thirteen monasteries of this order, viz. four for men alone, and nine for men and women together, which had in them seven hundred brethren, and fifteen hundred sisters. At the dissolution there were about twenty-five houses of this order in England and Wales.

GILBERTUS Angelicus, in Biography, the first practical writer on medicine, whom this country produced, places by Bale, (who calls him Gilbertus Lugdun. and says he was physician to Hubert, archbishop of Canterbury,) in the reign of king John, about the year 1210. But Lehnard, without stating the grounds of his opinion, makes him more modern. Dr. Freind observes, that it is obvious, from the work by which he is principally known, a "Compendium of Physic,"(?) that he must have lived several years later in the thirteenth century, very probably in the beginning of the reign of Edward I: "For he quotes Averroes," Dr. Freind remarks, "who reached to the close of the twelfth century; and whose works could not have been translated to early, and indeed were not translated till the middle, at least, of the thirteenth, as Bacon, a good voucher, informs us; and the mention he makes of a book, "de Speculis," which, without doubt, is that written by Bacon, and what he transcribes from Theodorick, concerning a leprosy, evidently shows that he lived low in this century, &c." (Hist. of Physic, vol. ii. p. 267.) According to Lehnard, he maintained a high character for his knowledge in philosophy and physic, which he had acquired by great study and much travelling; and he was very successful in his practice. His writings are principally compiled from those of the Arabian physicians, like the works of his contemporaries in other nations; sometimes, indeed, he transcribes whole chapters word for word, especially from Razes. He is represented as the first English physician who ventured to expound the absurd practices of the superstitious monks, who, at that time engrossed much of the treatment of diseases, and is said to have contrived with them the methods recommended by the ancients. The principal work of Gilbert, entitled "Compendium Medicina tam morborum universalium quam particularium," was corrected by Michael Capella, and printed at Lyons in 1510: and afterwards at Geneva, in 1612, under the title of "Laurus Anglicana, seu Compendium totius Medicinae." His other treatises were, "De viribus Aquarum;" "De Re Hierbaria;" "Thefaurus Puerorum;" and "De tundae valutudine." Elov. Dict. Hist. Freind, loc cit.

GILBING, in Geography, a town of Prussia, in Ermland; 12 miles W. of Allenstein.

GILBOA, in Scripture Geography, a mountain of Pa- laistine, celebrated on account of the defeat and death of Saul, and his son Jonathan. (1 Sam. xxxi. 1, 2, 3.) Ezech. and Jerom place this mountain six miles from Bathfin, otherwise Scythopolis.

GILD, or GUILD, originally signifies a fraternity, or company.

The word is formed from the Saxon gildan, to pay, because every man was gildar, i.e. to pay something towards the charge and support of the company. Hence also our Guildhall, q. d. the hall of the fraternity or fraternity, where they meet, and make orders and laws among themselves.

The origin of gilds, or guilds, is thus related: it being a law among the Saxons, that every Freeman of fourteen years old should fix sureties to keep the peace, or be committed; cert in neighbours, confining of ten families, entered into an association, and became bound for each other, either to produce him who committed an offence, or to make satisfaction to the injured party: that they might the better do this, they raised a sum of money among themselves, which they put into a common fock; and when one of their pledges had committed an offence, and was fined, then the other nine made satisfaction out of this fock, by payment of money, according to the offence.

Because this association consisted of ten families, it was called a dencurnery; and from hence came out later kinds of fraternities.

But, as to the precise time when these guilds had their origin in England, there is nothing of certainty to be found; since they were in use long before any formal licence was granted them for such meetings.

It seems to have been about the close of the eleventh century, says Anderson, in his History of Commerce, vol. i. p. 76, that merchant-guilds, or fraternities, which were afterwards styled corporations, came first into general use in many parts of Europe. Mr. Madox, in his annals, chap. i. § 9, thinks, they were hardly known to our Saxon progenitors, and that they might be probably brought into England by the Normans; although they do not seem to have been very numerous in those days. The French and Normans might probably borrow them from the free cities of Italy, where trade and manufactures were much earlier propagated, and where possibly such communities were first in use. See CHARTERS OF COMMUNITY, CITY, AND CORPORATION.

Edward the Third, in the fourteenth year of his reign, granted licence to the men of Coventry to erect a merchant's guild and fraternity, of brethren and sisters, with a master, or warden; and that they might found chapteires, below alms, do other works of piety, and constitute ordinances touching the same.

So Henry the Fourth, in his reign, granted a licence to found a guild of the Holy Cross, at Stratford-upon-Avon.

GILD, in the royal boroughs of Scotland, is still used for a company of merchants, who are free men of the borough.

Every royal borough has a dean of gild, who is the next magistrat below the bailiff. He judges of controversies among men concerning trade; disputes between inhabitants touching buildings, lights, watercourses, and other nuisances; calls courts, at which his brethren of the gild are bound to attend; manages the common fock of the gild; and amerce, and collects fines.

GILD, or GUILD, according to Camden, also signifies a tribute, or tax. See GILD.

GILD, according to Crompton, also signifies an amercement. As in foot-gild, which he interprets a prelation within the forest.

Hence, to be quit of all manner of gild, is to be discharged of all manner of prelations to be made for gathering leaves of corn, lamb, and wool, to the use of folellers.

GILD, or GUILD, is also used among our ancient writers for a compenation, or mulct, for a fault committed. See UN-GILD.

Hence, sergeld is the price of a man; osgei'd is the price of a cattle; angeld, the single value of a thing; rengeld, the double value, &c.

There are divers other words which end with gild, and shew the several kinds of payments; as dangeld, vanegild, fornegild, bobergild, fortgild, punigild, &c. which fee.

GILD, or GUILD-rents, are rents payable to the crown by any
any gild, or fraternity; or such rents as formerly belonged to religious gilds, and came to the crown at the general dissolution: being ordered for sale by the flat.

GILDABLE, or Gildable, denotes a person tributary, that is liable to pay tax, or tribute.
Camen, dividing Suffolk into three parts, calls the first gildable, because liable to tax; from which the two other parts were exempted, because ecclesiastical domestes.
Gildable is also explained in an ancient MS. to be that land or lordship which is subjunctio curie vicem.

GILDAS, in Biography, surnamed the Wise, a British monk, and the most ancient British writer now extant, was born in the year 520. He is known among many authors by the name of Badonius, by which he is distinguished from Gildas Albanus, who is said to have lived at an earlier period. His surname Badonius is derived from a memorable victory gained by the Britons over the Saxons, at the hill of Badon, now Bath, about the time of his birth. Having been carefully educated according to the manners of the times he became monk of Bangor, where he diligently applied himself to the learning of that period, and particularly to the study of the scriptures, with a view of qualifying himself for the duties of a public preacher. He is said to have visited Ireland at the request of Americus, afterwards king of the country, where he distinguished himself by his zeal and success in converting Pagans, confuting the heresies of the age, establishing monasteries, and in reforming the corrupt state of principles and manners which had become prevalent among the Christians in that island. Upon his return to his native country he visited the monastery of Llan-carvan, lately founded by a pious nobleman of South Wales, and endeavoured, by all the means in his power, to engage other persons, eminent for rank and fortune, to follow his example. He spent some time in the northern parts of Britain; visited France and Italy, and then returned home, where he acquired a high reputation as a most indefatigable preacher who never hesitated to confute the prevailing vices of the age. He is supposed to have died at the abbey of Bangor in the year 590; though, according to some writers, this event happened at Cliftonbury, full twenty years prior to this. The chief work of this author is: "Epitome de Excidio Britanniae, et Cafligatione Ordinis Ecclesiastici," containing lamentations over the miseries and almost total ruin of his countrymen, and very severe reproofs of the corruption and profiriolity of manners in which all ranks were sharers, and of which he drew a most alarming picture. This curious remains of British ecclesiastical antiquities was first printed by Polydore Virgil in 1525, from an imperfect copy. It was afterwards published in 1568 by John Jofleline from another, and a more perfect manuscript copy, but the best edition was published by Dr. Thomas Gale, in the first volume of his "Histoire Britannica, Saxonica, &c." Gildas wrote several "Letters," in which there are numerous fragments in an old collection of canons preferred among the MSS. in the Cottonian library. Other pieces have been ascribed to him, but these are considered by the best judges, as not really his, among them is the "Histoire de Gelles Brittonum." Moreri.

GILDAN-Da-Bais, St. in Geography, a town of France, in the department of the Lower Loire, and chief place of 2 cantons, in the district of Savay. The place contains 659, and the canton 5527 inhabitants, on a territory of 255 kilometres, in five communes.

GILDER. See Gilder.

GILDHALDA TEUTONICORUM was used for the fraternity of Easterling merchants in London; called also the Stileyard.

GILD-HALL, q. d. Gilda asta, the chief hall in the city of London. See Gild-hall.

GILD-MERCHANT, Gilda Mercatorum, was a certain privilege, or liberty, granted to merchants, whereby they were enabled, among other things, to hold certain pleas of land within their own precincts.

King John granted gildam mercatorum to the burgesses of Nottingham.

It is held, that if the king grants to a set of men to have "gildam mercatorum," a mercantile meeting or assembly, this is alone sufficient to incorporate and endue them for ever. 10 Rep. 30. 1 Roll. Abr. 515.

GILDING, or GULDING, the art, or act, of spreading or covering certain substances with gold, either in leaf or powder, or in amalgam with quicksilver. See an account of these preparations of gold under Gold.

The art of gilding was not unknown among the ancients, though it never arrived among them at the perfection to which the moderns have carried it. For this purpose the gold was beat into plates, with which the walls of apartments, dishes, and other vessels were covered. In early ages these plates were thick, so that this mode of gilding was very expensive. (See the process employed for gilding in this manner, the horns of the ram brought by Neffer, as an offering to Minerva, in Homer’s Odyssey, i. iii. v. 492.) In process of time, however, the expense was much lessened, because the art was discovered of making these plates thinner, and of laying them on with a fire.

Pliny affords us, that the first gilding seen at Rome was after the destruction of Carthage, under the censorship of Lucius Mummius, when they began to gild the ceilings of their temples and palaces; the Capitol being the first place on which this enrichment was bestowed. But he adds, that luxury advanced on them so hastily, that in a little time you might see all, even private and poor persons, gild the very walls, vaults, &c. of their houses. "When we cover our houses with gold," says Seneca, (Ep. 115.) "what else do we than rejoice in deception? for we know, that coarse wood is concealed under that gold." We need not doubt but that they had the same method with us, of beating gold, and reducing it into leaves; though, it should seem, they did not carry it to the same height: if it be true, which Pliny relates, that they only made seven hundred and fifty leaves, four fingers square, of a whole ounce. Indeed, he adds, that they could make more; that the thickest were called brattac Primflata, an account of a statue of the goddess Fortune at Frantide, gilt with such leaves; and that those of the thinner sort were called brattac quaeterie.

The modern gilders also make use of gold leaves of divers thicknesses; but there are some so fine, that a thousand do not weigh above four or five drachms. The thickest leaves are used for gilding on iron, and other metals; and the thinnest on wood. But we have another advantage above the ancients, in the manner of using and applying the gold; the secret of painting in oil, discovered of late ages, furnishes us with means of gilding works that shall endure all the injuries of time and weather, which to the ancients was impracticable. They had no way to lay the gold on bodies that would not endure the fire but with whites of eggs, or size; neither of which will endure the water: so that they could only gild such places as were sheltered from the moisture of the weather.

The Greeks called the composition on which they applied their gilding on wood, leucophrey, or leucophrex;
which is described as a fort of glutinous compound earth, serving, in all probability, to make the gold flake, and bear polishing. But as to the particulars of this earth, its colour, ingredients, &c. the antiquaries and naturalists are not agreed.

There are several methods of gilding in use among us; viz. gilding on an aline fire; gilding on a water fire; gilding by the fire, which is peculiar to metals; gilding of books, &c.

We may distinguish, in general, two kinds of gilding, one with, and the other without, the application of heat. The first method is practised on those substances, such as wood, paper, leather, flax, gilded and japaned ware, &c. which would be injured, and even destroyed at the temperature requisite for the other sort of gilding, which is employed on substances that are not liable to alteration by exposure to a moderate heat, such as metals, and sometimes glass and porcelain.

There are two methods of gilding on wood, viz. oil-gilding, and burnished gilding.

Gilding in oil, or on an oil fire, is performed by cementing the gold to the ground by means of fat oil. Linseed oil may be prepared for this purpose, by putting such a quantity of it into a broad vessel as may cover the bottom about an inch deep, and adding to it as much water as will rife six inches or more above the bottom. Let the vessel be exposed to the sun and rain, and the contents be occasionally stirred for five or six weeks, till the oil appear of the consistence of treacle. Then separate the oil from the water, and place it in a long bottle, or separating-funnel, used by the chemists, in such heat as will render it perfectly fluid; pour off the clear part, and strain the remainder through a funnel, and the whole will be fit for use. The water helps to clear and bleach the oil, and improve it in other respects.

In order to prepare the wood for gilding, it must first be covered or primed with two or three coatings of boiled linseed oil and white lead, in order to fill up the pores, and conceal the irregularities of the surface, occasioned by the veins in the wood. If greater neatness and perfection in the work be required, the wood should be first rubbed with fift-skin, and then with Dutch rufhes.

When the priming is dry, the next operation is that of fixing the work, or laying upon it, by means of a brush, or a large pencil, a thin coat of gold fize; care being taken that the brush or pencil be made to pass into all the cavities and projecting parts, if the subject be carved. This gold fize is prepared by grinding calcined red ochre with a due proportion of the fat, or thickest drying oil that can be procured; (the older the better); and this fize, in order to fit it for working more freely, is to be mixed, previously to its being used, with a small quantity of oil of turpentine, till it acquires a proper consistence. Sometimes the work is fixed with fat oil, and the Japanese gold fize (see Gold Fize), ground also with ochre. If a high degree of perfection be required, the work should be fixed a second time, and some add a third fixing, before the gold is laid on. In order to ascertain its fitness for this purpose, it is touched with the finger; and if it feel somewhat adhesive or clammy, or, as the gilders call it, “stuck,” but not so as to be brought off by the finger, it is in a fit state for gilding. But if it be too clammy as to daub, or come off on being touched, it is not sufficiently dry; or, if it has no clannyness or sticking quality, it is too dry, and must be fixed over again before it is gilt. When the gold fize is good, it will be sufficiently dry in about twelve hours for the application of the gold. In this process, when the surface is sufficiently large and plain to contain them, the gold leaves may be laid on entirely, either by means of a squirrel’s tail, or immediately from the paper which originally contained them, which last method, practised by those who have acquired the necessary dexterity, is the simplest and most expeditious, as well as the best, for the perfection of the work. The leaves, being laid on the proper parts of the work, must be settled to the ground, by gently compripling those, which seem to want it, with the squirrel’s tail on a cotton ball; and if any part of the gold has flown off, or has been dis placed, so as to leave any part uncovered, a piece of another leaf, of a corresponding size and figure, must be laid upon it. When the parts are too small to admit of laying on whole leaves, or when vacancies are left, after laying on whole leaves, which require to be covered with the lips or fragments of leaves, those that are to be used are turned from the paper upon a cushion. (See Gilding Cushion and Cushion.) They are then cut into lips, of a proper size, by a blunt pallet-knife (see Gilding Knife); and each slip is taken up on the point of a fine brush, or by an instrument called the “tip,” (see Gilding Tips), which being moistened by breathing upon it, will take up the leaves, or any fragments of them from the cushion. When these are thus applied to the parts of the work that were to be covered, they are gently pressed down by the cotton ball, till they lie every where evenly upon the ground; and the gold will immediately adhere to the flaky surface of the fize. Where the work is very hollow, and small pieces are wanted to cover parts that lie deep, they may be taken up, by the tip already mentioned, or the point of a fitch pencil, first breathed upon, and thus conveyed to, and settled in, their proper places. The whole of the work, being thus covered, should be suffered to remain till it be dry, and it may then be brushed over by a camel’s hair pencil, or soft hog’s hair brush, in order to clear away any loose particles of the gold leaf. If, after bruishing, any defective parts appear, such parts must be again sized; and treated as before. The squirrel’s tail used in gilding is cut short, and sometimes spread in the fan-fashion, by means of a piece of wood formed like a pencil-hick, but broad at both ends, and split to receive the tail; but it will equally serve in its own form, when the hair is cut to a proper length. The cotton should also be formed into a ball, by tying it up in a piece of fine linen rag; for if it be used without the rag, the fibres adhere to the gold fize, and embarrass the work.

This sort of gilding is chiefly used for domes, and the roofs of churches, courts, banqueting-houses, &c. and for figures of plaster, lead, &c. that are to stand exposed to the weather.

This oil-gilding is the most simple and easy, least expensive, and most durable, as it will not be readily injured when exposed to the open air; and it may be also cleaned with a little warm water and a soft brush; but, as it cannot be burnished, it wants the high lustre which is produced by the method we shall next describe.

Gilding, Burnished, or in Stipple, or on Water-fire, is that kind of gilding which is generally used for picture frames, mouldings, tafaces, and such wooden works as are sheltered from the weather, and not subject to dampness. In order to prepare the wood for this sort of gilding, those parts that admit of it should be first well rubbed with fift-skin, and then with Dutch rufhes. It should then be carefully covered with strong fize, made of shreds, &c. of white leather, such as that used by glowers, or clippings of parchment boiled in water, in the proportion of about a pound of the
the fards or clippings, to fix quarts of water, to the con- 
sistency of a jelly, and then strained through flannel while 
hot. When this coating is dry, eight or ten more must be 
applied, confining of the fame fize, mixed with fine fluter 
of Paris, or washed chalk, or powdered whitening; which 
mixture must be made by melting the fize, and flow- 
ing the whitening, &c. gradually into it, tarring them well 
together, that they may be thoroughly incorporated. This is 
laid on with a fift brush, and often or seldom repeated, 
according to the nature of the work; for pieces of sculp- 
ture, seven or eight layers suffice; for flat, or smooth works, 
they use ten or twelve. In the latter case they are applied 
by drawing the brush or pencil over the work; in the 
former, by dubbing it finely on, that the fize may enter all 
The dents of the carving.

After the falt coat is laid on, and before it be quite dry, 
a brush pencil, dipped in water, should be passed over the 
whole, to smooth it, and take away any inequalities that 
may have been formed; and when it is dry, the parts that 
admit of it should be again brushed over till they are per- 
efcntly even. The work should then be repaired, by freeing 
all the cavities from the priming; after which a water polifh 
should be given to the parts designed to be burnifhcd, by 
rubbing them gently with a fine linen rag moistened with 
water.

When the whole work is become quite dry, a moderately 

thick layer must be applied, composed of fize and bole, 
or yellow ochre. Doffic, in the Handmaid to the Arts, gives 
the following recipe for the fimpflef compositions, used as 
the proper cement or gilding fize in this kind of gilding: 
"Take any quantity of bole arseniac, and add some 
water to it, that it may ftoak till it grow fowt. Levigate it 
then on the flone, but not with more water than will pre- 
vent its being of a flift confidence, and add to it a little 
 purified fuet or tallow scraped; and grind them together. 
When this is wanted for use, dilute it to the confidence 
of cream, by parchment or glovers' fize, mixed with double 
its quantity of water, and made warm. Some melt the 
flut or tallow, and mix it previously with five or six times 
its weight of chalk before it is put to the bole, to facilitate their 
commixture, to which in this wet state they are somewhat 
repugnant. It is alfo fometimes prefufed to put foap fuds 
to the bole; which will contribute to its unifying with the 
tallow." (See Gold Size.) Let this composition be diluted with warm fize mixed with two-thirds of water, and 
let it be spread with a brush over the whole of the work, and 
then fuffered to dry; and then let the fame mixture be ap- 
piled in the fame manner, at least once more. After the faft 
coat, it should be rubbed in the parts to be burnifhed with a 
soft cloth, till it be perfectly even. Some add a little ver- 
milion to the gilding fize, and others colour the work, if 
carved, before it be laid on, with yellow and the glovers' 
fize; to which a little vermilion, or red lead, fould be added. 
This laft method is designed to give the appearance of gilding 
to the deeper and obscure parts of the carving, where the 
gold cannot, or is not thought neceffary to be laid on. But 
this practice is much difputed; and instead of it fuch parts 
of the work are coloured after gilding; which operation is 
called "Matting."

The work being thus prepared should be laid in a position 
somewhat declining from the operator; who, having at hand 
a cup of clean water, and some hair pencils, moistens a part 
of the work, and then applies the gold leaf to the part so 
moiftened in the manner already directed under the article 
Oil-Gilding, till it be completely covered, or till it be 
too dry to take the gold. This will immediately adhere on 
being pressed with the cotton ball. The operator proceeds 
to moiften the next part of the work, and apply the gold as 
before, repeating the operation till the whole is completed. 
It, in examining the work, any parts should appear to need 
being repaired, they should be moiftened as before, and 
covered with the gold; but care should be taken that no 
part be milled in the first operation, as it is not fo easily 
mended as in oil-gilding; nor fhould any drops of water be 
fusfured to fall on the perfect part of the gilding, as the gold 
is very apt to turn black in this fate. The work being 
thus far gilt, when dry, and fit for the purpofe, which it 
will ufually be in about twenty-four hours, remains, either 
to be burnifhed, or matted.

The proper period for this purpofe can only be afcer- 
tained by experience, and varies at different seasons. The 
mode of diftinguifhing the fitnefs of the work to take the 
burnifh, is to try two or three particular parts at a distance 
from each other; and if these take the polifh well, the whole 
may be concluded to be in a fit flate. But if the gold peel 
off, or be disordered by the rubbing, the work must be 
deemed not sufficiently dry; and if the gold bear the rub- 
ing well, and yet receives the polifh favourably, it is a proof 
of its being too dry, which should be prevented by watching 
the proper time. For the work, when too dry, both re- 
quires much more labour to burnifh it, and fails at laft of 
taking fo fine a polifh.

To burnifh it, is to smooth and polifh it with a burnifher, 
which is ufually a dog's or wolf's tooth, or a blood-flone, 
as agate, or a pebble, or something else very smooth, fitted 
in a handle for that purpofe.

To mat, is to give it a light fick in the places not burn- 
ifhed, with a pencil dipped in fize, wherein a little ver- 
milion sometimes has been mixed. This helps to prefev- 
er it, and prevent its flawing, when handled. Or, it is to cover 
the hollow parts with a colour the nearest in appearance to 
gold.

Some recommend for this purpofe red lead, with a little 
vermilion ground with the white of an egg; but yellow 
ochre, or Dutch pink, with red lead, would better an- 
swer the end; or the terra di Siena, very flightily burnt, or mixed 
with a little red lead, would have a much better effect, and 
be more durable than any other mixture to near the colour 
of gold in shade. Flints fize will likewifesupply the 
place of the whites of eggs. This operation of matting 
impofitcs the neceffity of yellowing, which is intended to 
give the appearance of gilding to the deeper and obscure 
parts of the carving where the gold cannot, nor is thought 
necelTary to be laid on.

The laft thing is to apply a vermeil, or lacquer, in all the 
little lines and cavities; and to flop and amend any little 
fauls with shell-gold.

The composition here called "vermeil," is made of gum 
gutta, vermilion, and a little of some ruddy brown colour, 
ground together with Venice varnish and oil of turpentine. 
Some gilders, in lieu of this, content themselves with fine 
lacca, or dragon's-blood, with gum-water.

Sometimes, instead of burnifhing the gold, they burn- 
ifh the ground or composition laid on laft before it; and 
content themselves afterwards to wash the part over with fize. 
This method is chiefly practifed for the hands, face, and 
other nuditites in relievo; which, by this means, do not ap- 
pear so very brilliant as the parts burnifhed; though much 
more so than the parts perfectly flat, or matted.

To gild a work, and yet preferve white grounds, they 
apply a layer of Spanish white mixed with a weak flin-glue, 
on all the parts of the ground where-on the yellow, or the layer next under the gold, might 
run.
GILDING.

Gilding, Japanese, is performed by means of gold powder, or imitations of it, cemented to the ground by a kind of gold size; for the method of preparing which, see Gold size. This kind of gilding may be practiced on almost any substance whatever, whether wood, metal, leather, or paper; nor is there any preparation necessary, besides making the surface on which the size is to be laid, even, and perfectly clean. Then spread the chosen size, mixed with a due proportion of oil of turpentine and varnish, with a brush over the work, if the whole surface is to be gilt; or draw with it, by means of a pencil, the proper figure defined, avoiding carefully any other parts; when it is almost dry, to as to be capable, by its camminias, of receiving the gold, dip a piece of washe-leather wrapped round the finger in the gold powder, described under Skill-Gold, and rub it lightly over the sized work; or spread the powder with a soft camel's hair pencil; and with a camel's hair brush clear away the loose powder, after the gilded surface is dry. When leaf gold is used, the method of sizing must be the same as for the powders; but great care is necessary in laying them on, while the size is in a proper state of dryness.

There is a false kind of gilding, in which a colour of gold is given by painting and varnishes, without employing gold. Thus a very fine golden colour is given to brass and to silver, by applying on these metals a gold coloured varnish, which, being transparent, shews all the brilliancy of the metals underneath. Many ornaments of brass are varnished in this manner, which is called gold lacquering, to distinguish them from those that are really gilt. Silver leaves, thus varnished, are put upon leather, which is then called gilt leather; and many picture-frames have no other than this counterfeit gilding, which may be discovered by washing it with a little rectified spirit of wine; for the spirit will dissolve the varnish, and leave the silver leaf of its own weight. For plain picture frames, thick tin-foil may be used instead of silver; the tin leaf fixed on with glue is to be burned off, then polished with emery and a fine linen cloth; and afterwards with putty applied in the same manner; being then lacquered over with the varnish five or six times, it looks like burnished gold. (See Lacquer.) Among the false gildings may also be reckoned those which are made with thin leaves of copper or brass, called Dutch leaf. In this manner are made all the kinds of what is called gilt paper. See Gilding of Paper.

Gilding of Books. There are various methods, with respect to the cement used, by which the edges of books or paper may be gilt. Strong gum-water or定义false size, or glover's-size may be employed; but as the gum-water, and weaker sizes are apt to run beyond the edge, and thus cause the leaves to flick together, the false size, melted with the addition of some common proof spirit of wine, and thus a part of honey or sugar-candy is much to be preferred; to which must be added a third of bole armeniac well powdered.

The following composition may be used for this purpose: Take bole armeniac, and sugar-candy well powdered; mix them with the whites of eggs, beaten to an oily consistence; and the cement will be fit for use. In applying any of these cements, the paper, inquires or in books, should be well cut and polished on the edges to be gilt; and well screwed down by a press; in this state it is to be brushed over, first with a little of the cement without the sugar-candy and the bole; and when that is dry, either with the cement above given, or any other solution of gum or size with the proper proportion of the bole; after which it may be suffered to dry; and then water-polished, by rubbing it with a fine linen rag lightly moistened. It is then fit for receiving the gold, provided it be moistened at that time; and the leaves may be then laid on, being cut according to the breadth which they are to cover, and pressed closely down by a cotton ball; and after the gilding is thoroughly dry and firm, it may be polished. See Book-binding, and Gilding of Paper.

Gilding on china-ware. The gold is very much valued on china-ware, and would be much liked in a wafer not that it is very liable to get its lustre, and to rub off. The Chinese have at present a method of preventing both these accidents, in a great measure, by means of a sort of polishing, which they give it after it is laid on. They prepare for this purpose a fine piece of agate, which they polish on one surface in as perfect a manner as possible. With this they rub over the gold, as it lies on the porcelain, several times, when it first comes from the baking. This gives the gold a lustre which it would not otherwise have, and fixes it down to the ware in such a manner, that it cannot easily be got off. The principal mischief to which gold thus laid on is subject, is the tarnishing, or growing dull; this is remedied by the same sort of means. They wet the vessel, upon which they would revive the lustre of the gold, in common clean water; and while it is wet, they rub it with the same polished agate, adding a little fair water at times to keep it moist. If the gold has not been well laid on at first, this may possibly raise it or take it off in some places; but if it was originally put on with the help of this stone, as all the gold on porcelain now is, the rubbing it with it a second time never gives it any new fretches, but recovers its primifine lustre and beauty. It must be observed, that the rubbing with this stone must be all done one way, both in the first laying on the gold, and in the brightening of it up afterwards. This may serve as a method for us as well as the Chinese, not only to recover the beauty of our tarnished gilt china-ware, but also to lay gold upon some of our home manufactures of this kind. Observe, for les Costumes de l'An. See Porcelain.

Gilding on enamel and glasses, is performed by burning or annealing, i.e. by producing a cohesion of the gold with the glaze or enamel, by the intermediate action of a flux, or by producing the like effect without any. In both these methods, the gold is made to adhere to the enamel or glaze, in consequence of the fusion or annealing to that state, either of the flux used, or of the body of the enamel or glaze itself, by which the gold is cemented to such body. The flux, when any is used, may be either simple glasses of borax, or any of the preparations of fluxes powdered (see Flux); and the gold is used, either in the form of leaf gold, or in that of powder made mechanically, or by precipitation. (See Gold powder.) When leaf gold is employed without any flux, the enamel or glaze may be moistened with a very weak solution of gum arabic, and again dried. After being thus prepared, it should be breathed upon till it becomes a little adhesive or sticky, and then laid upon a sufficient number of leaves of gold: when the gold is thus united to the enamel or glasses by the cementing quality of the gum arabic, the work is ready for burning. If a flux be used, it should be finely levigated, tempered with a very weak solution of gum arabic, and very thinly spread on the part of the work to be gilded; and when the gum water is almost dry, the leaf gold should be laid on that part thus prepared for it, which is then in a state proper for burning. In the present practice, the aurum fuliginosum, or precipitation of gold by alkaline salts, is made by those who gild plates in the greatest perfection; and the volatile alkali is employed for the precipitation by the chemist, who prepares it for this purpose. But when this kind of precipitate is chosen, the use of any flux must be avoided, and a very considerable degree of heat
Gilding.

Heat applied. The manner of using the precipitate powders of gold; the aurum fulminans excepted, as well as the leaf gold, may be varied, by adding to it or omitting any flux; but in what way forever the powder is used, it is to be tempered with the oil of spike, and worked as the enamel colours; and the quantity of flux, when any is used, may be a third of the weight of the gold. In casks where the glaes is very hard, or where the opportunity of a strong heat cannot be conveniently obtained, the expedient of using a flux in the following manner may be adopted with great advantage. Grind glaes of borax to a fine powder; and having tempered it with oil of spike, lay it on the glaes where the gilding is to be made; then burn the glaes with a degree of heat, that will cause the borax to run; and when it is cold, apply the precipitate or leaf gold, and burn it again, as in other casks. After the work is burnt, if it be intended to be burnished, a proper luttre may be given to it, by rubbing the gilded part with a dog's tooth, or with a fine agate, or iron burnishers. Handmaid to the Arts, vol. 1 p. 374, &c. See Ruby Glass.

Gold may be laid upon white earthenware or glaes, by drawing your design upon the vessel to begin, with japanners' gold size, moistening the size, as you find necessary, with oil of turpentine. Set the work in a clean place to dry for about an hour, and then place it so near the fire that you could but just bear the heat of it with your hand for a few seconds. Let it remain there till it feels quite tacky or clammy; then, having procured a cushion and home leaf-gold, cut it into flakes of the proper size, and lay it on with a little cotton wool. When the gold is all on, put the work into an oven to be baked for two or three hours.

Drinking glases, with gilt edges, have been much admired in this country; the best of these are brought from Germany: those that are made in England, though equal in beauty to the foreign, being greatly inferior in the durability of the gilding. Dr Lewis made several experiments with a view of discovering this art; from which he concludes, that the gold is cemented to them by means of an intervening matter, which will adhere to glaes so as not easily to be rubbed off. He tried maltish, and other golden bodies rubbed warm on the glases, and several spirituous varnishes; but none of these were found to adhere sufficiently to the glases. He recommends to the trial of the artists in this way the harder oil varnishes; and glases have been since prepared in England, probably on the principles which he has pointed out, with as durable gilding as those brought from Bohemia and Thuringia.

M. Zeigler, in a German translation of the "Commercial Philosophico-Technicum," describes a varnish for this purpose, with the method of using it, which appeared from his experiments to be the best. This varnish is prepared by boiling fine transparent amber, reduced to powder, in a braze vessel, to the cover of which a valve is fitted, with as much drying oil as will just cover it; and by diluting the above solution with four or five times its quantity of oil of turpentine. This varnish may be made to dry sooner, and acquires greater firmness by grinding it with a little white lead, or rather with a mixture of white lead and minium.

It is to be applied very thin on the glass, and the gold leaf laid lightly on the varnished part; when the varnish is thoroughly hardened, the gold may be burnished, by laying a piece of smooth paper between the tooth or file burnisher, and the gold. This gilding, M. Zeigler observes, is durable, and of a fine lustre. Com. Phil. Techn. p. 65, and 614.

Gilding of figures and letters on paper, and for the embellishment of manuscripts, is performed with shell-gold, tempered with gum-water; or the characters may be drawn with a milky solution of gum-ammoniac made in water, and gold-leaf applied upon them when almost dry, or if all or any part of them is become quite dry, they may be again sufficiently moistened for receiving the gold by breathing on them. Letters raised from the surface of paper or parchment, in the manner of embossed work, such as are seen on ancient manuscripts, may be formed either by friction on a proper body with a solid piece of gold, or by leaf-gold. The former method is procured by tempering pulverized crystalline with strong gum-water, and with this paste forming the letters; when they are dry, they are rubbed with a piece of solid gold, as in polishing, and the letters will appear as if gilt with burnished gold. The letters are formed with an embossed figure, either of the separate letters, or of whole words, cut in steel; and each letter of these flakes, when they are used, is anointed evenly with a feather dipped in oil. Then fill these concave letters with the above paste, and strike the flakes in a perpendicular direction on the paper or vellum, laid over some sheets of paper.

When the embossed letters are formed with leaf gold, the following, or a similar composition must be used. Thicken beaten whites of eggs with as much verminum as is necessary to give them the consistence of paste; use the flakes as before; and when the letters are dry, moisten them by a small pencil with strong gum-water; and when this is almost dry, cover the letters with leaf gold, pressing it close to every part of them with cotton or soft leather; after the gilding is dry, polish it with proper burnishers. Com. Phil. Techn. p. 64 and Handmaid to the Arts, p. 453 &c.

Gilding of fitch-fitch, as craw-fish, carps, &c. may be performed without injuring the fish, by means of a current which Mr. Hooker, in his pithumous papers, directs to be prepared in the following manner: Put some Burgundy pitch into a new earthen pot, and warm the vessel till it receives so much of the pitch as will fill it; mix and stir it; then draw some finely powdered amber over the pitch when growing cold; add a mixture of three pounds of linseed oil, and one of oil of turpentine; cover the vessel, and boil the contained ingredients over a gentle fire; grind the mixture as it is wanted, with so much pomice-stone in fine powder as will reduce it to the consistence of paste. When the fish has been wiped dry, this mixture is spread upon it, and the gold leaf laid over it, and gently pressed down; after which, the fish may be immediately put into water, and the cement will harden, and be in no danger of falling off.

Gilding on leather. See Lacquering.

Gilding of metals may be done by cleaning the surface of the metal, and applying gold leaves to it, which, by means of rubbing with a polished blood-stone, and a certain degree of heat, are made to adhere perfectly well. In this manner silver leaf is fixed and burnished upon brass, in making French plate; and sometimes also gold leaf is burnished upon copper and upon iron. For this purpose, the metal, being previously polished and quite clean, is heated to about the temperature of melted lead, and covered with a double layer of gold leaf; then a blood-stone burnisher, applied gently at first, and gradually increasing the pressure, will cause the surfaces of gold and copper to touch each other in almost every point, and then adhere with a force proportioned to the completeness of the contact. The first layer being thus burnished, a second is made to adhere in the same manner, and sometimes a third, if the gilding is intended to be very solid. This method of gilding is tedious, and is subject to the almost impossibility of using a sufficient pressure without injuring the evenness of the gilded surface. In casks where these objections do not apply, there cannot be a more effectual
GILDING.

Effectual mode of gilding, as we perceive in the manufacture of gilt silver and copper wire. The first, before it is committed to the wire-drawer, is plated with gold, by having several leaves of gold successively burnished down upon it, and being then subjected to the strong compresion that takes place in wire-drawing, the gold and the other metal become so perfectly united, as to form, in a manner, one substance. See Gold Wire.

Some metals, and particularly silver, may be gilt in the following manner: dip pieces of linen in the solution of gold by aqua regia, and then burn them to ashes; rub these ashes on the surface of the silver, well cleansed from any minute matter, with a wet linen rag, dipped in salt water, and the particles of gold contained in them will thus be applied to the silver, and adhere to it, without the application of heat, or intervention of any other body. Burnish the silver with a blood-lime, till it acquires the colour of gold. Most gilt ornaments on fans, manuscript-boxes, and other toys of much value, and silver gilt in this manner.

Beckmann (Hist. of Inventions, vol. 1) tells us that this method of gilding, sometimes called dry, and sometimes cold gilding, is a German invention; and that foreigners, at least the English, were first made acquainted with it about the end of the 17th century; for Robert Southwell describes it in the Phil. Trans. for 1698, and says, that it was known to very few goldsmiths in Germany. See Gilding of Metals by the fire.

Gilding on Paper, Parchment, and Vellum. There are various methods used for this purpose, according to the several ends which the gilding is designed to answer. For the most part, size, properly so called, and gum-water, are used as the emulsions, and the powders are more generally employed than the leaf gold. See the three first articles in Gilding.

The gilding proper to be used with water-colours may be either with the leaf-gold or powder; the leaf-gold may be laid on the designed ground by means either of gum-water, or spirit of lamp oil; observing, that the gum-water or size be of the weaker kind, and laid sparingly on the ground, and that proper time be allowed for it to be dry; and then the gold is applied to it, as in the articles above recited; and it may be polished, if necessary, by the dog's tooth, or other kind of burnisher. In gilding larger surfaces, it will be found useful to colour the ground with the gall-lime, and when colours are to be laid on the gilding, the gall of any beast bruised over the gold will adapt it for receiving the colours. When the gold powders are used along with paintings in water-colours, they are previously formed into shell-gold. The gilding proper for the coloured paper used in binding books, and for other such purposes, is performed much in the same manner; only that the gum-water and size may be much stronger, and that they are generally conveyed to the ground by means of a wooden plate or print, or by an engraved roller, which make a impression of the intended figure or design. In this kind of gilding, the japanner's gold-size may be also commodiously employed; and this should be always used when the embossed appearance is wanted in the greatest degree; and for this purpose it should be thickened with yellow ochre, mixed with as much red-lead as the proper working of the print will admit. Instead of the genuine leaf-gold, or gold powder, the German powder, formed of the leaves called Dutch gold, is commonly used in this kind of gilding. The edges of books or paper are gilt in the manner directed under the article Book-binding and Gilding of Books.

Gilding on Thread and Wire. See Gold-thread, and Gold-wire.

Gilding on Wood. See the three first articles in Gilding.

Gilding on Metals by the Fire. There are two ways of gilding by fire; viz. that with liquid gold, and that with leaf gold. For the latter, see Gilding of Metals, supra.

The former, technically called "water-gilding," is performed with gold amalgamated with mercury, in the proportion of about six or eight parts of mercury to one of gold.

In order to this operation, they heat some pure quicksilver in a clean crucible; and, when it is nearly boiling, put about a fifth of its weight of fine gold in thin plates heated red-hot, and stir them gently about, till the gold be found dissolved, and is incorporated into a mass with the mercury. It is then allowed to cool; and when cold, it is to be put in a piece of soft leather; and by gradual pressure, the fluid part of the amalgam, consisting almost wholly of mercury, may be forced through the pores of the leather, while the gold, combined with about twice its weight of mercury, will remain behind, forming a yellowish silvery mass, of the con-"fiuence of soft butter. This, after having been bruised in a mortar, or shaken in a strong phial with repeated portions of salt and water, till the water ceases to be fouled by it, is fit for use; and may be kept for any length of time, without injury, in a corked phial. It is of inestimable importance that the materials of this amalgam should be perfectly pure; and therefore, the mercury employed in the preparation of it should be procured from the distillation of the red precipitate (nitrous red oxyd of mercury), either alone, or mixed with a little charcoal powder.

When silver is the metal to be gilt, it is prepared for the operation by soaking it in warm dilute amnatic acid, so that the surface may be rendered perfectly clean; it is next washed in clean water, which should be two or three times changed, in order to free it from the whole of the acid; and being afterwards dried, and made moderately warm, a little gold amalgam, also warm, is to be evenly spread upon the silver, to which it will immediately adhere. In applying the amalgam, the operator uses a little knife, or a brush made of hairs or wires, for the purpose; and giving the work a gentle heat before the fire, he dabbs or spreads the amalgam with the brush farther and more evenly upon it.

Thus far advanced, the metal is set over the fire, upon a grate, or in a fort of cag, under which is a pan of charcoal, yielding a heat just sufficient for evaporating the mercury; by which means the mercury, dissipated in fumes, and leaves the goldople adhering to the work, in proportion as the mercury, evaporating and flying off, discovers places where gold is wanting, they take care to supply them, by adding new pieces of amalgam with the knife or brush.

If a thicker gilding is required than can result from so much of the amalgam as is applied at once, the metal, after the first quantity has left its gold fixed on the surface, has more of the amalgam spread upon it. After the evaporation of the mercury from this, another quantity may be applied in the same manner. When the mercury is evaporated, so that the surface becomes uniformly of a pale yellow colour, the metal is made to undergo other operations, by which its colour and luster are heightened. For this purpose, it is first rubbed with a scratch brush, composed of fine brass wire, till its surface is made clean and smooth, but the pale yellow colour still remains; then it is covered over with a composition called gilding wax, and again exposed to the fire till the wax be burnt off; and this application is repeated till the gold appears of a proper colour. This gilding wax is composed of bees' wax, mixed with the following substances;
GILDING.

The colour of the gilding is heightened by a perfect dilatation of some mercury remaining after the former operation. The gilt surface is then covered over with a saline composition consisting of equal quantities of nitre, sal ammoniac, green vitriol, and verdigris, finely powdered, and mixed up into a paste with water or urine; or, this is used instead of the gilding wax. The piece of metal thus covered is heated till the mixture smokes, and quenched in water or urine. This effect seems to be produced by the acid of nitre, which is diversified by the vitriolic acid of the alun, or other vitriolic salt, during the exposure to heat, acting upon any particles of copper which may happen to lie on the gilted surface. If the colour of the gilding be not sufficiently heightened by the first application, a succeeding one will complete the desired effect. Some artists think they give an additional lustre to their gilt work, by dipping it in a liquor prepared by boiling some yellow materials, as sulphur, orpiment, or turmeric. The only advantage of this operation is, that a part of the yellow matter remains in some of the hollows of the carved work, in which the gilding is apt to be more imperfect, and to which it gives a rich and fold appearance.

Copper, and the alloys formed by its combinations with zinc, are gilded much in the same manner as silver; but their affinity for mercury being considerably less than that of silver, it is not easy to produce a complete adhesion of the amalgam of gold to the burnished surface of these metals by the same means, and with the same success as in the former case. Advantage is here taken of the nitric acid for facilitating the adhesion of the copper and mercury in the following manner. The piece of copper, e. g. a button, is first cleaned by steeping it in acid and frequent washing, and it is then burnished in a lathe, or by other means: after this, it is dipped in a neutralized solution of nitrat of mercury, and in a few seconds, on account of the strong affinity of nitric acid for copper, the mercuial salt is decomposed. The copper takes the place of the mercury, and at the same time the mercury is deposited in the metallic state, on the surface of the copper, covering it entirely, and strongly adhering to it. The gold amalgam is now applied, and the result of the process is the same with that which has already been described. Thus a given quantity of gold may be made to cover a larger surface than in any other way of gilding on metals; five grains of gold completely gilding both the upper and under surfaces of 144 copper buttons, each of them an inch in diameter. (Phil. Mag. ix. 20.)

Iron cannot be gilt by amalgamation, unless it be previously coated with copper, by dipping it in a solution of blue vitriol, or rubbed with the vitriol itself a little moistened. Iron may also receive a golden coat from a saturated solution of gold in aqua regia, mixed with spirit of wine; because the iron, having a greater affinity for the acid, precipitates the gold from it.

In the gilding of iron, or rather steel, by means of an amalgam, peculiar difficulties occur. If recourse be had to the method of simple burnishing down, the heat requisite for this purpose will, in many cases, bring the temper of the steel too low; on such occasions the mode already described of gilding copper is sometimes practised; that is, the parts of the steel to be gilded are pickled over with nitrat of mercury, by which they are covered with a slightly adhering coating of mercury; then the amalgam is applied, and the gilding finished in the usual way. The objections to this process are, firstly, that a con siderable heat is required, though inferior to that requisite for burnishing down; and, secondly, that even with all possible care, the gilding is apt to be rough and to scale off. A very considerable improvement on this method is to trace the figure of the gilding on the steel first of all with a brush charged with a strong solution of sulphated copper, in consequence of which a pretty thick coat of metallic copper is deposited on the steel to which it may be made to adhere with considerable firmness by means of the burnisher; thus the gilding is, in part, performed upon the copper.

A new method of gold gilding upon steel has lately been published (see Phil. Mag. x. p. 144), possessing many advantages over the others, and capable of ultimately attaining a very high degree of perfection. This method depends upon the well-known fact, that sulphuric ether and nitro-muriat of gold are mixed together, the ether will, by degrees, separate from the acid nearly the whole of the gold, and retain it for some time in solution in nearly a metallic state. If either, thus charged with gold, is spread, by means of a pen or fine brush, on the surface of highly polished steel, the ether preternaturally evaporates, leaving the gold behind in close contact with the steel, and the adhesion is considerably improved by the subsequent application of the burnisher. The dermaids, and especially the rapid volatility of ether, are objections of some moment, but may be got over by using the burnish oil of turpentine instead of the ether, which has nearly the same efficacy in decomposing the nitro-muriat of gold, and is both cheaper, and not so very quickly evaporable.

On the subject of gilding by amalgamation, Dr. Lewis has the following remarks: "There are two principal inconveniences in this business; one, that the workmen are exposed to the fumes of the mercury, and generally, sooner or later, have their health greatly impaired by them; the other, the loss of the mercury; for though part of it is said to be retained in the cavities made in the chimneys for that purpose, yet the greatest part of it is lost. From some trials I have made, it appeared that both these inconveniences, particularly the first and most considerable one, might be in a good measure avoided, by means of a furnace of a due construction." If the communication of a furnace with its chimney, instead of being over the fire, is made under the grate, the ash-pit door, or other apertures beneath the grate, closed, and the mouth of the furnace left open, the current of air, which otherwise would have entered beneath, enters now at the top, and passing down through the grate to the chimney, carries with it completely both the vapour of the fuel, and the fumes of fuel matters as are placed upon it. The back part of the furnace should be raised a little higher above the fire than the fore-part, and an iron plate laid over it, that the air may enter only at the front, where the workman stands, who will be thus effectually secured from the fumes, and from being incommoded by the heat, and at the same time have full liberty of introducing, inspecting, and removing the work.

If such a furnace is made of strong forged (not milled) iron plate, it will be sufficiently durable. The upper end of the chimney may reach above a foot and a half higher than the level of the fire; over this is to be placed a larger tube, leaving an interval of an inch, or more, all round between it and the chimney, and reaching to the height of ten or twelve feet; the higher the better. The external air, passing up between the chimney and the outer pipe, prevents the latter from being much heated, so that the mercurial fumes will condense against its sides into running quicksilver, which falling down to the bottom, is there caught in a hollow ring, formed by turning inwards a portion of the lower part, and conveyed by a pipe at one side into a proper receiver.

Another method is mentioned by authors of gilding upon metals, and also upon earthenware and glass, which is, to fuse gold with regnium of antimony, to pulverize this mass, and
and spread the powder upon the piece to be gilt; afterwards to expose it to such a fire that the regulus may be evaporated while the gold remains fixed. But Dr. Lewis mentions the following inconveniences to which this method is subject: the powder does not adhere to the piece, and cannot be equally spread; part of the gold is disintegrated along with the regulus; glass is liable to the heat necessary for the evaporation of regulus of antiquity; and copper is liable to be corroded by the regulus, and to have its surface rendered uneven. Lewis’s Com. Phil. Techn. p. 77, &c. p. 81. 88. and 165. Macquere’s Dict. Chem. Eng. edit. 1777; and Aikin’s Dict. of Chemistry, art. Gilding.

Gilding Cufflink, is formed by a few folds of flannel, or a quantity of tow or wool, secured on a piece of wood of any size from eight to fourteen inches square by a light covering of leather, and fastened tight round the edges. The surface should be perfectly flat and even, and it is usually furnished with a handle. See Cushion.

Gilding Knife, a slip of the hollow Spanish cane, cut up to a smooth and sharp edge, with a good penknife; this cane knife cuts the gold leaf better than one of steel, as it is apt to stick to this last. This knife may in all respects be the fame as those used in painting, called “pallet knives;” the blade of which may be four or six inches long, and somewhat more than half an inch in breadth, with a proportionable handle.

Gilding Pallet, a flat piece of wood, about three inches long, and an inch broad, covered with a piece of fine woollen cloth. By breathing upon this pallet, to moisten the cloth a little, and then clapping it gently down upon the gold leaf, this may be raised from the cushion, and conveyed to the work to be gilded.

Gilding Tcep. a tool made by fastening the long hairs of a squirrel's tail between two cards, and used for taking up the gold leaf after it is cut, and applying it to the article to be gilded.

Gilding Wax. See Gilding of Metals.

Gildo, in Biography, a powerful lord in Mauritian, served the emperor Theodotus, in his brother’s revolt in 573, with so much fidelity, that he was raised to the chief command in Africa. During the reigns of Arcadius and Honorius he maintained a kind of independence, and ruled, at his pleasure, the provinces under his command, which he oppressed by every species of tyranny. In the diffusions between the eastern and western empires, he was persuaded by the minister Eutropius to acknowledge Arcadius: for this he was condemned as a public enemy by the Roman senate. About the same time a deadly quarrel had arisen between Gildo and his younger brother Maufezel, in which the latter had taken refuge in the court of Honorius. Gildo, with a brutality that can never be sufficiently excoriated, fattated his disappointed vengeance upon the two children of his brother, whom he barbarously murdered. Massezel, anxious for revenge, landed a body of troops in Africa, and encamped in the face of a numerous army of Moors collected by Gildo. Thence, intimidated by the superior discipline of the Europeans, fled almost without a blow. Gildo escaped to the sea-shore, where he embarked for a foreign country, but being driven back by adverse winds, he was seized by the inhabitants and thrown into a dungeon. There a voluntary death saved him from the cruel fate, which his conscience told him he might expect from his injured brother. The revolt of Gildo, says the historian, was considered as an event of so much importance to the empire, that the poet Claudian made the “Gildonic war” the subject of one of his panegyrics, to the honour of Stilocho, who was the commander in it, against the subject of this article. Gibbon. Univer. Hist.

Gilead, in Scripture Geography, mountains of Palestine, which lay E. of Jordan, and separated the lands of Ammon, Moab, Reuben, Gad, and Manasseh from Arabia Deserta. According to Eusebius mount Gilead reached from Libanus northerly toward the kingdom of the Amorites, which was ceded to the tribe of Reuben; so that it must have extended above 70 leagues from north to south. This mountain, or rather chain of hills, was much celebrated for its excellent balm. Jer. viii. 22. xlvii. 11. xii. 8. Gen. xxxviii. 25. See Balsam. Gilead derived its name from Gael-hard, g. d. the heap of witwes, in reference to the heap of stones raised as a monument of the covenant between Jacob and Laban. Gen. xxxvi. 21.

Giles, in Biography, a learned Italian prelate, and cardinal of the sixteenth century, distinguished himself by the progress which he made in different branches of literature; and was appointed professor of philosophy, and then of theology, in his order, that of the hermits of Augustina. In 1507, he was raised to the post of general of his order, and was employed by pope Julius H. to open the council assembled at the Lateran in the year 1512; and, in 1517, was sent legate into Germany by Leo X., on which occasion he was promoted to the office of cardinal. After this he was sent into Spain, and employed in many difficult negotiations. He was nominated bishop of several important sees at different periods, and also patriarch of Conflatantinople. He died at Rome in 1532, and left behind him a very high character for learning. He was, during his life, perpetually confounded in difficulties that occurred to the literature in the Oriental as well as the Latin and Greek languages. He was the author of many works that bear testimony to his reputation, among these are, Remarks on the early Chapters of the Book of Genesis, Commentaries on some of the Psalms of David; Dialogues, Epistles, Poems, &c. In the third volume of “Amphithea Collectio veterum Monumentorum,” many letters of this prelate and his correspondents are inserted, which contain numerous facts as well relating to his own history, as to that of the period in which he flourished. Moreri.

Gilmor, in Geography, a small poit and market town of the county of Down, Ireland. The river Bann runs through the centre of it, over which there is a very handsome bridge, highly ornamented with hewn stone, of twenty-two arches. It is a handsome neat town, and the country about it is highly improved; the housetops are good, and chiefly inhabited by wealthy and reputable linen-drapers. The linen trade is carried on very extensively here, and the cloth is so remarkable for the fineness of its texture, as the river is for giving it an excellent bleach. Nothing can exceed in beauty the vale from Banbridge to Moyall. Through Gilford, on the borders of the Bann, for a continuance of fix miles; the river in delightful meanders, the rising grounds surrounding it adorned with woods, and the bottoms variegated with bleached greens, afford views the most beautiful and picturesque. Gilford is 622 miles N. from Dublin, and 11 miles from Armagh.

GILCAL, in Scripture Geography, a celebrated place, W. of Jordan, where the Israelites encamped after their passage of this river, and where a considerable city, famous for many events, was afterwards built. It was about a league from Jordan and from Jericho.

GILCE, in Geography, a town of Thrullin, in the circle of Sandland;
2. G. heterophylla. (Quivicia ovata; Cav. n. 553, t. 214.)—Leaves oblong, undivided, sinuated, or pinnatifid. Flowers four-leafed, ovoid, somewhat umbellate.—Gathered by Commerçon in the islands of Bourbon and Mauritius. The leaves are rather smaller than in the last, and remarkable for their variety of shapes, being either oblongate and blunt, or somewhat pointed, and either undivided, or more or less finely waved or sinuated, or deeply and accurately pinnatifid like an oak-leaf; all these varieties are found on the same specmen, nor can we separate Quivicia ovata, though all the leaves of one plant happened to be undivided, for the original specimens accord in every other particular. The flowers are much smaller than in the first species, and grow from two to four together in rather an umbel, than a cluster. 

Capul the size of a pea, pointed, slightly silky.

3. G. oppositifolia. (Quivicia oppositifolia; Cav. n. 534, t. 214.)—Leaves opposite, elliptical, undivided. Flowers somewhat umbellate.—Native of the Mauritius. Leaves broadly elliptical, obtuse, uniform, two inches long, all nearly opposite, as well as the branches. We have not few the flowers. The fruit is rather umbellate than racemose, the size of a large pea, furrowed, depressed, clothed with shining waxly down, and opening into four or five parts on the same branch.

GILMER, or GILMARI, in Biographie, half king of the Vandals in Africa, a descendant of Gereric, succeeded to the throne of his deceased cousin Hilderic. The emperor Justinian joined the cause of the dethroned sovereign, and determined to annex the African provinces once more to the Roman dominions. Belisarius was chosen to execute the design, who failed in 533. Zano, the brother of Gilimer, was, at this time, engaged in the conquest of Sardina, by which circumstance the force of the Vandals was divided, while a considerable party at home still adhered to the late king Hilderic. Gilimer assembled his troops to redress the invaded, but being defeated with great slaughter he was glad to re-
tire to the Numidian defects, having first exercised the tyrant's policy, by commanding the execution of Hileric and his captive friends. Carthage submitted to the victorious Belharis; but Gillimer collected his scattered forces, and being joined by Zano, who had returned from Sardinia, a second action ensued, in which Zano lost his life, and Gillimer again retreated. The loss of the African provinces succeeded, and the defeated king was forced to take refuge in the inaccessible mountains of the interior of Numidia. Even here, he was surrounded by a part of the Roman army under Pharus, and reduced to the utmost distress, which to him was peculiarly afflicting by its contrast with the luxury and effeminacy in which he had been accustomed to live. So deplorable was his situation, that he is reported to have applied to Pharus for a lyre, a siphon, and a loaf of bread; the first he said was to soothe his sorrows; the second to dry up his tears; the third he asked as an humble delicacy, of which he had not tasted for a long time. His distresses at length obliged him to submit to the conqueror; he defended to the mountains, and followed Belharis to Conflantinople, marching in the train of his triumph; on which occasion, he suffered neither tear nor sigh to escape, but frequently exclaimed, in the language of Solomon, "Vanity of vanities, all is vanity!" The emperor received him with respect, and showed him much attention and kindness; he would have raised the fallen monarch to the dignity of patrician, could he have been persuaded to renounce the Arian doctrine, in which he had been educated. He was put in possession of a large estate in Galata, where, in the bosom of his family, he ended his days in peace. The extinction of the Vandal kingdom in the person of Gillimer is to be dated from the year 534. Gibbon. Univ. Hist.

GILLION, in Geography, an island in the East-Indian sea, about 36 miles in circumference. S. lat. 7° 6'. E. long. 114° 37'.

GILLS, St., a town of France, in the department of the Schelkt, and chief place of a canton, in the district of Ternonde. The place contains 3228, and the canton 16,770 inhabitants, on a territory of 95 kilometres, in 65 communes.

GILTZSTAIN, a town of the duchy of Carinthia; 10 miles E.N.E. of St. Veit.

GILL, in Agriculture, a term sometimes applied provincially to the pair of wheels and frame on which timber is conveyed.

GILL, John, in Biography, was born at Kettering, in Northamptonshire, in 1697, and discovering, when very young, an uncommon capacity for learning, his father, who was a dissenter of the Baptist persuasion, sent him to a grammar-school in the neighbourhood, where he soon out-kinpt his companions in classical attainments. When he was but eleven years of age he had read several of the common school books in Latin, and made a considerable proficiency in the Greek. Owing to the narrow circumstances of his parents he was put to business, but he did not fail to improve his leisure moments by an attention to classical literature, so that by the time when he had attained his nineteenth year he had read all the Greek and Latin authors that had fallen in his way, and had diligently studied logic, rhetoric, moral and natural philosophy. He had likewise studied Hebrew so as to be able to read the Old Testament in the original with pleasure. In 1716 he was baptized, and soon after commenced preaching in private. He now removed to Higham Ferrers to prosecute a regular course of studies under Mr. Daws, a man of considerable learning, and pastor of a baptist church in that place. His stay here was short, and after about a year he returned to his native town, and became assistant preacher to the congregation there; and in 1719 he received and accepted an invitation to become pastor of a baptist congregation in Southwark. The duties of this situation he discharged with great fidelity and usefulness more than half a century. He died in 1774 in the seventy-fourth year of his age. His sentiments in religion were strictly Calvinistic; and his moral conduct was unimpeachable and truly exemplary. He was author of many works, particularly of "An Exposition of the Old and New Testament;" in nine volumes folio; "A Body of Divinity," in three volumes 4to.; "A Supplement to Mr. Whilton's Essay towards restoring the true text of the Old Testament." In the year 1738, when he had published the third volume of his "Exposition of the New Testament," the degree of doctor of divinity was conferred upon him by the university of Aberdeen without his solicitation or knowledge; information of the fact was communicated to him by two of the learned professors, who declared that his diploma was presented to him, "on account of his great knowledge of the scriptures, of the oriental languages, and of Jewish antiquities, of his learned defence of the scriptures against Deists and infidels, and the reputation gained by his other works." Dr. Gill had, indeed, from the time of his settling in the metropolis, paid a most unwearying attention to the oriental languages: he had studied the writings of the fathers, ecclesiastical history, the accounts of the rites and customs of the eastern nations, all which he knew were adapted to enrich his stores of biblical learning, and to qualify him for the duties of his profession. Gen. Biol.

GILL, in Botany. See GLECHOMA.

GILL, in Geography, a township of America, in the state of Massachusetts and county of Hampshire, situated on the W. bank of Connecticut river, 90 miles from Boston; containing 700 inhabitants.

GILL, or Bich, is a name in several English counties for a brook, rivulet, or small stream of water.

Gill, a measure of ale or beer, is 1-4th of an ale pint = 8.8125 cubic English inches = 1.220779 wine gills = .0160984 cubic links.

Gill of wine, cider, oil, &c. = 1-4th of a wine pint = 7.21875 cubic English inches = 8.91490 ale gills = .0145307 cubic links.

Gill, Scotch measure, = 1-4th of a mucklekin = 1-16th of a Scotch pint, the cubic content of which varies much in different places. See Scotch Pint.

GILLAROO, Trout. See Trout.

GilleM's Bay, in Geography, a bay on the S. coast of the island of St. Christopher; two miles W. of Basil-terre.

Gille-le-Vicomte, St., a town of France, in the department of the North Coast; six miles N.N.E. of Gungamp.

Gilles-les-Boucheries, St., a town of France, in the department of the Gard, and chief place of a canton, in the district of Nîmes; 10 miles S.S.E. of Nîmes. The place contains 5574, and the canton 6557 inhabitants, on a territory of 180 kilometres, in 2 communes.

Gilles-Sur-Vic, St., a town of France, in the department of the Vendée, and chief place of a canton, in the district of Les Sables-d'Olonne; 13 miles N.N.W. of this latter town. The place contains 759, and the canton 12535 inhabitants, on a territory of 4321 kilometres, in 17 communes.

Gilles, Peter, in Biography, was born at Abbe in 1492, and became distinguished as a scholar and traveller. Having acquired an extensive knowledge of the learned languages,
gases and the philosophy of the times, he set out on his travels with a view of making observations in natural history and antiquities. On his return he was introduced to the notice of George de' Amargana, bishop of Rhodes, who engaged him to compose his book "De Vrct Natura Anim.

This work, which consisted of extracts from Allian and others, with observations of his own, he dedicated to Francis I., who sent him to travel in the Levant, but without furnishing him with proper supplies, so that he was reduced to great difficulties, and was obliged to enlist in the troops of the sultan Soliman II. for subsistence. He left Constantinople in 1550 and went to Rome, where he died 1555. He was the author of two geographical works, "De Bosphoro Thracic," and "De Topographia Constantinopolae," which are esteemed for their learning; and also of some translations from the Greek. 

GILLESAY, or GILLISAY, in Geography, one of the smaller Hebrides, between Lewis and North Uill. N. lat. 57° 45'. W. long. 6° 59'.

GILLESAY Point, a cape on the S.W. coast of the island of Cebeles. S. lat. 5° 15'. E. long. 119° 48'.

GILLESKAIL, a town of Norway, in the diocese of Drotnenheim; 240 miles N. of Drotnenheim.

GILLETTE, a town of France, in the department of the Maritime Alps, and chief place of a canton, in the district of Puget-Théniers. The place contains 456, and the canton 1712 inhabitants, on a territory of 105 kilometres, in four communes.

GILLIAN, GUILSAIN, or Ghillieain, St., a town of France, in the department of Jemmappe, situated on the river Hainne and surrounded by marshes, and deriving its name from a celebrated abbey founded in the year 651 by Gillian, the friend of St. Amand. Having been successively in the possession of the Dutch, the French, and the Spaniards, and of the allies, it was taken by the French in 1792. St. Gillian was called the key of Mois, and is distant three miles W. of it.

GILLIFREE. See JILLIFREE.

GILLINGHAM, a parish in the hundred of Chatham and Gillingham, Kent, England; is seated on the river Medway, at the distance of two miles from the town of Chatham, and 32 from London. It contains 715 houses and 4133 inhabitants, the greater part of whom are immediately or indirectly employed in the business connected with the neighbouring dock-yards. This village, though now deprived of its consequence by the increase of Chatham, was formerly of much note. In the time of queen Elizabeth here were four quays, and twenty-seven ships and boats; the largest of these, however, was only twenty tons. The archbishops of Canterbury formerly had a palace here; one of whom, John Stradford, in the tenth year of Edward III.'s reign, obtained a charter for a weekly market, and an annual fair to continue eight days; but these have been long discontinued. William of Gillingham was a native of this place. He was a monk of Canterbury, in the time of King Richard II., and wrote a history of Britain; also one of his own monastery. Hallel's History of Kent, vol. iv. p. 80.

GILLI, an island on the coast of West Florida, divided from Dauphin island by a very narrow channel, through which a boat cannot pass without some difficulty; and between Gilli and the main land, on the west side of Mobile bay, there is a chain of small islands and oyster shells, through which is a passage of four feet, called "Passe au Heron."

GILLS, BRANCHLE, in Ichthyology. See Fish, Organ of Respiration.

GILLS, Leaf of the. See Folium branchiastum.

GILLYFLOWER, in Gardening, the common name of a fine fragrant flowery plant, common in gardens, &c. See DIANTHUS.

GILLYFLOWER, Queen's. See Hesperis.

GILLYFLOWER, Stalk. See CHIRANTHUS.

GILLY-LAVAS, in Geography, a lake of Ireland, in the county of Sligo; and on the river by which its waters are discharged into the sea stands the town of Sligo. This lake exhibits that variety of charming prospects which belong hills, wooded lawns, and large islands clothed with verdure and crowned with trees, united with a great extent of water, cannot fail to produce. Beaumar.

GILMANTOWN, a post-town of America, in Strafford county, New Hampshire, S.W. of lake Winnipesaukee, and 52 miles N.W. of Portsmouth; incorporated in 1727, and containing 3752 inhabitants.

GILMARGUEY, a town of Hindoojan, in Downetabaud; 13 miles N.E. of Nander.

GILIOH, or GELO, in Scripture Geography, a town of Palestine, situated in the mountains of the tribe of Judah. Josh. xv. 41.

GILIOLO, in Geography, one of the Molucca islands, in the East Indian ocean, of considerable extent, and in its irregular form resembling Cebeles, which see. Its length is about 230 British miles, and the breadth of each limb fathom above 40. The shores are low; but the interior rises to high peaks, perhaps of granite. This island is said to have been once governed by one sovereign, a chief from Meeja; but the sultans of Ternate and Tidore now seem to share it between them, the former polishing the northern part with Mortay, Bakian, Motir, and some Celebesian islands, and part of Papua; while the sultan of Tidore holds the southern part with Myofel, and some other isles. One of the chief towns is Tatany, situated on a point or promontory of the eastern limb, faced with precipices, so as to be accessible only by ladders. Gilolo abounds with oxen, buffaloes, goats, deer, and wild hogs; but the sheep are few. The bread-fruit and fago-tree are common; and, in spite of the Dutch extermination, there are probably clowns and nutmegs. The natives are industrious, particularly in weaving; but their exertions are suppressed by Batavian jealousy. The equinoctial runs through the southern part of the island. E. long. 128°.

GILP LOCH, in Argyleshire, Scotland, is a kind of gulf branching from Loch Fine on its W. side, which is navigable for vessels to the entrance of the Crinan channel, through which they pass to Loch Crinan, and the Irish sea. See CANAL.

GILPIN, BERNARD, in Biography, was born at Kentmore, in Wellmoreland, in the year 1517. He was defined by his parents for the church, and educated with that view. At fifteen years of age he was entered at Queen's college, Oxford, where he became distinguished for the diligence with which he applied to his academical studies. He was led to think for himself, and freely, by the writings of Erasmus; and so determined to apply himself to the study of theology, he set about acquiring a thorough knowledge of the Greek and Hebrew languages, in order that he might investigate the Scriptures in their original tongues. In 1539 he took his degree of B.A., and in 1541 that of M.A., and about the same time he was elected fellow of his college, and admitted into holy orders. Shortly after he was invited to become a member of cardinal Woffley's new foundation at Christ-church, which he accepted. Here he continued his former studies, but it does not appear that his course of reading had produced any doubts in his mind respecting the
the popular religion, for he even entered into a vindication of the Catholic doctrines in a dispute with Hooper, afterwards bishop of Winchester. The discussion was however favourable to his improvement and candour, as it afforded him the opportunity of discovering that his own opinions were not so well supported by scripture as he imagined. Upon the accession of Edward VI., Peter Martyr was sent, under the patronage of that prince, to Oxford to read divinity lectures, a duty which he performed in a strain to which that university had been but little accustomed. He attacked many established doctrines, which had been long regarded as the truth, and the only truth. Gilpin was looked up to, as capable of defending the established doctrines in opposition to modern innovations, but his faith was shaken, and he chose to remain an unprejudiced spectator, ready to embrace whatever should appear the truth, after deliberately weighing the arguments which the discussion might provoke. At length, however, he consented to enter the lists with Peter, and the dispute ended in the conviction of Gilpin that there were great corruptions in popery, and that there was need of a total reformation. He continued at Oxford till he was thirty-five, and took his bachelor's degree in divinity. In 1552 he was prented with a living in Durham, but before he went to reside there, he was appointed to preach before his majesty at Greenwich. The king was not pleased, but Gilpin's discourse was a serious and very bolting reproof on the prevailing avarice and corruption of the age; he spared neither the court, clergy, magnates, nor gentry. The freedom which he made use of at this time recommended him to the notice of many persons of the first rank, particularly of Sir William Cecil, afterwards lord Burleigh, who obtained for him a general licence for preaching. While Mr. Gilpin was in London, he frequently visited his uncle Townfall, bishop of Durham, at that time a prisoner in the Tower, under a sentence of mifprision of treason. When Mr. Gilpin was settled in the country, he felt many doubts how to proceed in the instruction of his people; he had not made up his own mind on many important doctrines, and therefore felt but ill qualified to teach others, or indeed to guard them from the prevailing errors. He accordingly resigned his living, and determined, at the advice of Townfall, to spend some time abroad. He had now an opportunity of re-examining all his opinions; he began to have just notions of the doctrines of the reformed; saw things in a clearer light, and felt a satisfaction in the change that he had made, to which he had hitherto been a stranger. On the death of king Edward, Townfall was released and reinstated in his bishopric; he immediately offered his nephew a good living, which was respectfully refused on conscientious principles. He returned from the continent in the year 1556, and immediately visited bishop Townfall, who received him with great friendship, and presented him with the archdeaconry of Durham, to which he annexed the living of Infington. He now repaired to his parish, determined to do what good he was able in reprobating vice, and encouraging virtue. His zeal and fidelity in the good work of reformation made him many enemies, and the cry of heresy was continually founded against him, but by the skilful management of his uncle, the charge, though formally and publicly brought, was diffimmed. After this, he resigned his preferment in the church, and became domestic chaplain to the bishop. Mr. Gilpin did not remain long without a benefice, but was inducted to the living of Houghton-le-Spring, and upon his arrival at the place, people crowded to him from all quarters, perceiving that he was a teacher very different from those to whom they had been accustomed, and by his truly affectionate treatment of them, he quickly gained their confidence, respect, and attachment. The bishop was still anxious for the advancement of his nephew, and prefented to him a vacant prebend in the cathedral of Durham, which Mr. Gilpin modestly, but firmly declined, and told the prelate, "that by his bounty he had already more wealth than, he was afraid, he could give a good account of; and he hoped his lordship would rather believe this preference on one by whom it was more wanted." A fresh set of articles of impeachment were drawn up and presented against him, and he was again protected by his uncle, but from this period the bishop's favour to him manifeftly declined, and he struck him out of his will. He was exceedingly concerned to have in any way offended so good a benefactor, but he could not compromise the matter; he was bound to satisfy his conscience, and Townfall was vexed that he should carry his piety and zeal to what he thought an excess. The malice of Mr. Gilpin's enemies was not satisfied with the loss which he had experienced in his uncle's esteem; they accused him before the savage Bonner, who, in the moment of his frantic zeal, declared that he would bring him to the stake in a fortnight. Gilpin refused to listen to the entreaties and intercessions of his friends by leaving the country, but was prepared to suffer for the truth, as he had been zealous in propagating it. He accordingly waited with great composure for the arrival of the bishop's messenger. He was apprehended, but fortunately, before he could reach London, an account of the Queen's death met them on the road, an event not more favourable to our worthy pastor, than important for the country at large. The mericles favage might now gnash his teeth, but he could no longer inflict the venom of his malignity upon the unoffending reformers. Gilpin, thus almost miraculously delivered, returned to Houghton through crowds of people, who regarded him as a father, and who expressed their utmost joy, and offered up their thanks to Almighty God for his deliverance. Mr. Gilpin was soon nominated to the bishopric of Carlisle, which he declined, giving as a reason, that in this diocese he had many friends and acquaintance, of whom he did not think very highly, and that he must converse at many irregularities, or draw upon himself so much hatred as to prevent his usefulness. In 1561 he was offered the provostship of Queen's college, Oxford, which he likewise declined, contenting himself with the living of Houghton, the duties of which he performed in the most exemplary manner. He employed much of his time in endeavouring to improve the minds of the younger part of his parish, suffering none to grow up in an ignorance of their duty, but urging all to intermix religion with labour, and amidst the cares of this life to have a constant regard to the next. He was always in preventing lawsuits among his parishioners, and his hall was frequently thronged with people of his own or neighbouring parishes, who came to settle their differences. He had a tender concern for all under affliction, and was a much readier visitor at the houses of mourning than at the house of feasting. To strangers and travellers there was always a generous welcome at the house of Mr. Gilpin, and he could not himself to perfections of all ranks in life. Once he received an unexpected visit from lord Burleigh, and the reception of the noble stranger was so liberal, that his lordship was accustomed to say, that he could not have expected more at Lambeth. When the great statesman left his hof, and had travelled about a mile from his residence, he turned his horse to take one more view of the place in which he had experienced so much content, and having kept his eye fixed some time, he exclaimed, "There is the enjoyment of life, indeed! Who can blame that man for not accepting a bishopric? What does he want, or what can he possess to make him greater or
or happier, or more useful to mankind." Mr. Gilpin's labours extended beyond his own parish; he every year visited divers neglected parishes in Northumberland, Yorkshire, Cheshire, Wiltshire, and Cumberland; and that his own flock might not suffer, he was at the expense of a constant attendant. In all his journals he did not fail to visit the great and small places of entertainment; and by his labours and affable manner of behaviour, he is said to have re-formed many abandoned persons in those abodes of human misery. He had set places and times for preaching in the different parts of the country, which were as regularly attended as the affix towns of a circuit. If he came to a place in which there was a church, he made use of it; if not, of barns, or any other large building, where great crowds of persons were sure to attend him, some for his instructions, more, perhaps, to partake of his bounty; but in his discoursing he had a sort of enthralling warmth, which roused many to a sense of religion who had never thought of anything serious before. "The dangers and fatigues attending this employment were, in his estimation, abundantly compensated by the advantages which he hoped would accrue from them to his un instructed fellow-creature. He did not spare the rich; and in a discourse before the bishop of Durham, who had already conceived a prejudice against him, he spoke with so much freedom, that his best friends dreaded the result; they rebuked him for giving the prelate a handle against him, to which he replied, "If the discourse should do the good he intended by it, he was regarded of the consequences to himself." He then waited on the prelate, who said, "Sir, I propose to wait upon you your self." When they arrived at the rectory, and entered the house, the bishop turned suddenly round, and grasped him eagerly by the hand, saying, "Father Gilpin, I know you are fitter to be bishop of Durham, than I am to be parson of this church of yours. I ask forgiveness for palf injuries. Forgive me, father, I know you have enemies, but while I live bishop of Durham, none of them shall cause you any further trouble." Upon queen Elizabeth's recommending the establishment of free schools, Mr. Gilpin undertook to build and endow one, a design which he immediately put in execution. This school was no sooner opened than it began to flourish; and there was so great a retort of young people to it, that in a little time the town was fearfully afraid to accommodate them. He procured able masters from Oxford, and took every method to encourage those of his pupils who were most diligent in their studies. In the latter part of his life Mr. Gilpin went through his various duties with much difficulty: his health was impaired, and his constitution broken down by the great fatigues which he had undergone for many years. In addition to his infirmities, he met with an accident which had nearly proved fatal to him, and from the effects of which he never perfectly recovered. As he was crossing the market-place at Durham, he was thrown down, and almost trampled to death by an ox. After a long and tedious confinement, he was able to get out, but continued lame as long as he lived. He died in 1583, in the 66th year of his age. Such were the life and labours of Bernard Gilpin, who, for his exemplary piety, laborious virtue, and unbounded benevolence, deserve to have his name transmitted to posterity with respect and reverence, and who obtained, and most deservedly among his contemporaries, the title of the Northern Apostle. By his unwearied application he had amassed a great flock of knowledge, and was indeed ignorant of no part of learning that at that time was in fashion. He had given more than common attention to the study of the dead languages, to history and divinity; he is said to have excelled in poetry, but he expended little time in the pursuit of any thing that was foreign to his profession. His temper was naturally warm, but, by degrees, he succeeded in obtaining an entire command of himself. His disposition was serious, yet, among his particular friends, he was cheerful and even facetious. His severity had no other object but himself; to others he was mild, candid, and indulgent. *Biot, Brit.*

**GIMESCH** in *Geography*, a town of Würtemberg, 25 miles E. of Tubingen.

**GIMMER** in *Agriculture*, a small boring tool, which enters the wood with a screw; the part above is cylindrical, both inside and out: its use is to make a way for nails, in order to drive more easily, or to prevent the wood from splitting.

**GIMMERLING**, in *Sea Language*, is applied to the anchor, to denote the action of turning it round by the block, so that the motion of the block appears similar to that of the handle of a gimlet, when it is employed to turn the wire.

**GIMBOLS**, denote the braies-rings by which the seacompas is suspened in its box that usually stands in the balanc.
GIN

GINZO, in Scripture Geography, a city of Judah, which the Philistines took from Ahaz. 2 Chron. xxviii. 18.

GIN, in Geography, a town of China, of the third rank, in Pe-cheli; 10 miles S.E. of Chunch-te.

GIN, formed probably by corruption from engine, in Artillery and Mechanics, is a machine for raising great weights, composed of three long legs, two of which are kept at a proper distance by means of two iron or wooden bars fixed to one of the legs by means of a bolt at one end, and by the other end to the other leg with a bolt and key, so that it may be put on or off at pleasure. At three feet from the bottom is a roller moving in cheeks, that are fastened to these poles by two iron bands and two iron bolts. The three legs of this machine are joined together with an iron bolt, about which they move; to this bolt is fixed an iron half ring to hook on the windlass, containing two brafs pulleys. When the gin stands upright, and its legs are at a proper distance, one end of the cable is fixed to the dolphins of a gun or mortar with another windlass, containing likewise two brafs pulleys, and the other pulleys through the pullies and round the roller, which is turned round by means of handspikes passing through the holes in the ends of the roller; while a man holds the cable tight, the gin is raised to such a height as to admit a carriage being put under it.

The gin is used in loading a timber-carriage with timber; it consists of an acute triangular frame, in the lower part of which is a roll or windlass; at the apex is a fet of pullies, and a hole to receive the top of a strong pole, which is set up opposite the triangular frame, which by this means forms a sort of tripod (or triangle, as it is commonly called among workmen) hanging across a tree to be raised and loaded: the gin-rope is then reeled through a moveable block of pullies, fastened by a chain to the tree, through that in the top of the gin and round the roll; and then, by means of handspikes or levers used to the roll, the tree is drawn up to a sufficient height for the timber-carriage to be passed under it. Long trees are raised at one end first, and two of the wheels of the timber-carriage are passed under them; when the other ends are raised in like manner, and the other two wheels (which are made to separate for this purpose) are passed under them, and then are joined to the other wheels by the long adjustable pole with which the carriage is furnished. See Timber-Carriage.

An erect axis or drum, turned by the force of horses walking in a circle, and used for raising coals and other weights, is also called a gin; the buckets being attached to the opposite ends of a rope, which passes round the drum, and which is drawn by means of its adhesion to the drum. One of the buckets defends empty, while the other is drawn up full; and when the motions of the buckets are to be changed, the horses are turned, or the wheels are made to impel the axis in a contrary direction, when any other moving power is employed.

For hollow mines or shafts, these are worked by horses, and are called horse-gins; and in deep mines thus worked, it is usual to have two levers projecting from the shaft, so as to employ two horses, and even four in some caves, with a box to each pair, or single horse, to stop and turn them, so as to draw from the other side of the lever, as often as a corve or bucket arrives at the top of the shaft. See the article Coal.

The increasing depth of the pits, and demand for coals at Newcastle, occasioned Mr. Smeaton, the engineer, to be applied to in the year 1777, by the proprietors of Long Benton colliery, to contrive them a mode of drawing more expeditiously, and larger baskets of coals than the horse-gins then in use, and he accordingly erected for them a water-gin, the supply for which was raised by the steam-engines employed at the pits. Since the above period, small steam-engines, called winneys in many places, have been applied to the winding of coals, and other minerals, and have already superseded all other modes of drawing at the large collieries; these several modes of drawing or winding we shall describe particularly in the article Winding-Engine.

GIN, in Mining, horse-gin, or coal-gin, is a machine used for drawing buckets or corves of earth or minerals up a mine-shaft or tunnel-pipe of a canal: it consists of a large vertical drum or barrel, on which a rope winds, which is conducted to pullies over the shaft; and usually as one bucket or corve descends another ascends. See the preceding article and Mine Winding Engine.

GIN-driver, is the man or boy who attends the gin-horse and turns him, when a full bucket or corve has arrived at the top of the mine-shaft.

GINATIRI, in Geography, a town of Africa, in Kumbo.

GINANNIA, in Biaury, so called by Scopoli and Schreber in memory of Count Joseph Giannini, a native of Ravenna, whose palpitumus works in Italian, composing two folio volumes, with above 60 plates, were published at Venice in 1755. They chiefly relate to the marine productions of the Adriatic, as corals, sea, a few shells, &c. but are perhaps not too feverly characterized by Linnaeus, in a letter to Gerard, as of no manner of uie. The author was recommended to the study of natural history by his friend Valfiner, as a cure for hypochondriacal disorders, but this is hardly a sufficient reason for the publication of his book. Haller appears to have seen the first volume only. Schreb. 271. Mart. Mill. Dict. v. 2. (Paloue; Aubl. Guian. 365. t. 141. Polave; Juff. 351. Brownca paciforum; Wild. Sp. Pl. v. 3. 716.) See Brownsea, to which genus we are parasized this plant is really referred by Willdenow at the suggestion of Sreber, Addend, 829. The stem is thrubly, 15 feet high, branched, the branches alternate, straight or declining. Leaves simple, alternate, nearly felse, ovate, entire, pointed, smooth and shining. Stipulae minute, acute. Flowers terminal, few, red, large, and handformc, their short flanks enveloped in large concave imbricated bracteas. Leaves reddish, linear, compressed, three inches long, somewhat like that of Ceris filifera. Native of the forests of Guiana, flowering in February, and bearing fruit in May.

GINASSERVIS, in Geography, a town of France, in the department of the Var, and chief place of a canton, in the district of Brignoles, nine miles N.W. of Barjols. The place contains 752, and the canton 8oo inhabitants, on a territory of 5214 kilometres, in 44 communes.

GINIKUS, in Ancient Geography, a town of Asia, in Syria, situated on a mountain, E. of the gulf of Hucus.

GINDELH, in Geography, a town of Candahar, on the Behut; 48 miles E.S.E. of Cabul.

GINERE, a town of Ceylon; five miles N of Point de Galle.

GINERCA, a town of the island of Corica, situated in a small bay to which it gives name; 13 miles S of Calvi.

GINESTAS, a town of France, in the department of the Aude, and chief place of a canton, in the district of Narbonne: seven miles N.W. of Narbonne. The place contains 551, and the canton 6753 inhabitants, on a territory of 1674 kilometres, in 15 communes.

GINETO, a town of Naples, in Calabria Citta; 16 miles N.W. of Rigiana.

GINETTA, GENETTA, OF GENET, in Zoology, the Viverra genetta of Linnaeus, which see.
GINGEE, in Geography, a town and fortress of Hindoostan, in the Carnatic, once the capital of a kingdom of the same name, situated on a mountain and defended by three castles; 33 geographical miles from Pondicherry and 23 from Trincomalee. N. lat. 12° 16'. E. long. 79° 36'.

GINGER, in Botany. See Amomum.

GINGER, Zingiber, in the Materia Medica, &c. Ginger is either black or white. In Jamaica this plant attains its full height and flowers about August or September, and fades about the close of the year. When the stalks are entirely withered, the roots are in a proper state for digging, which is generally performed in the months of January and February. After being dug, they are picked, cleaned, and gradually feethed, or scalded in boiling water; they are then spread out, and exposed every day to the sun till sufficiently dried; and after being divided into parcels of about 10 lbs. weight each, they are packed in bags for the market; this is called the "black ginger." "White ginger" is the root of the same plant, but instead of scalding the roots, by which they acquire the dark appearance of the former, each root is picked, crushed, separately washed, and afterwards dried with great care; by this operation more than double expence is incurred, and the market price is proportionally greater. Black ginger is paid by Jacobin to lose part of its essential oil by being thus immersed in boiling water; and on this account it is less useful for medical and other purposes than the white, which is always good when perfectly found and free from worm-holes; but that imported from the East Indies is stronger than any we have from Jamaica. This warm aromatic root appears, says Lewis, to be much less liable to lose the conititution than might be expected from the penetrating heat and pungency of its tafle, and the fixedness of its active principles. But Dr. Cullen is of opinion, that there is no real foundation for this remark. It gives part of its virtue to water, and the whole to rectified spirit, tinged the latter of a deep, and the former of a pale yellow colour. This latter property it possesses in so considerable a degree, that if a watery infusion of this root be boiled down to a thick confection, dissolved elsewhere in a large quantity of water, and strongly boiled down again, the heat and pungency of the root remain, but with little or nothing of its smell. It is used medi cally as an antispasmodic and carminative. The cases in which it is more immediately serviceable are flatulent colics, debility and laxity of the stomatch and intestines, and in torpid and phlegmatic constitutions to excite bitter vascutar action. It is seldom given but in combination with other ingredients. In the Pharmacopoeia it is directed to be administered under the form of a syrup and tincture; it is also prescribed as a condiment, and as a subsidiary ingredient in many compositions. The syrup of ginger is prepared by macerating two ounces of the ginger root in a pint of boiling water for twenty-four hours, and then straining, and adding two pounds of refined sugar, as in other syrups. The tincture of ginger is formed by macerating two ounces of ginger root in two pints of proof spirit for 14 days, and then straining the liquor. The dietetic qualities and ufe of ginger are well known; and it is employed under various forms. It is not uncommon to candy the root, when green, with sugar and honey; having first steeped it some time in water, to take away part of its acrimony, and to disfop it to let go the outer skin. This candied ginger, brought from abroad, is moderately aromatic. They also make a marmalade of it, and dry cakes.

The northern people make great ufe of this confection, as holding it sovereign against the scurvy. The Indians eat the root, when green, by way of salad, first chopping it small, mixing it with other herbs, and seafoning it with oil and vinegar.

Ginger may be preferred by washing it, and laying it to steep for ten or twelve days in white wine and water, straining them every day; then boil a pound of roots with two quarts of white wine, and about a pint of lemon juice, for a quarter of an hour; then add two pounds and a half of fine sugar, and boil it to a syrup, cuminning it as it rises; let it by till the next day in a glazed pan; then boil it for half an hour, and repeat this boiling at the fame interval till the ginger is cleare. Put it into glaffes, and cover them with paper, and it will affure a fine sweetmeat for the winter. A wine is made of ginger, which is a pleasant and fabulous beverage.

GINGER, in Geography, one of the smaller Virgin isles in the West Indies; 10 miles S. W. of Virgin Gorda. N. lat. 18° 21'. W. long. 62° 53'.—Alto, a town of Egypt, on the E. branch of the Nile, opposite to Naufiah.

GINGEBREAD, a richer kind of bread; the flavour and tafle of which are heightened and improved with spices, and particularly ginger; whence the name.

There are various forms and preparations of gingerbread; we shall contain ourselves with the following receipt, which is well recommended.

Into a pound of almonds, blanched and pounded, grate a penny white loaf; sift and beat them together; to the mixture add an ounce of ginger, scraped fine; and liquorice, and anniseed in powder, of each a quarter of an ounce; pour in two or three spoonfuls of rum-water, and make the whole into a paste, with half a pound of sugar: mould and roll it, print it, and dry it in a flaye. Others make it of treacle, citron, lemon, and orange-peel, with candied ginger, coriander, and caraway-seeds, mixed up with as much flour as will make it into a paste.

GINGERO, or LENDEREO, in Geography, a kingdom of Africa, situated on the S.W. of Abyssinia. N. lat. 6°. E. long. 35°.

GINGHAM, a town on the north coast of Sumatra. N. lat. 5° 10'. E. long. 96° 10'.

GINGIDIUM, in Botany, a name adopted by Forster, Nov. Gen. t. 21, for an unbelliferous plant, found on the hills of New Zealand, which he himself suspected to be a Lignium, and which has been so confirmed by following botanists. It is Lignium Gintidiun of Willd. Sp. Fil. t. 1. 1428. See LIGNICUM.

The 515560 a of Dioecorides appears to be likewise of this natural order, but the species can scarcely be determined with certainty. Dr. Sibthorp supposed it might be Daucus Gintidiun of Linney, merely from the coincidence of the name, for it agrees better with D. Vifhago, Annu Vifhago, Prod. Fl. Græc. n. 650; not that any thing can be gathered, from the description of Dioecorides, to quote him, in such a case, with any propriety. He says it is " by some called Lepidium, and grows very abundantly in Cilicia (now Carna-ma) and Syria. It is a little herb, like wild carrot, but more tender and more bitter, with a whitish and bitterish root." This will be found to accord equally well with many plants of those countries. Matthiolius, milled, as it seems, either by a Latin version, or by the opinion of those who take the cæcum of Dioecorides for the Podinae, or Partlip, whereas it is evidently by the description a Daucus, or Carrot, took for the 515560 a Syrian plant, first decribed by himself, and which indeed is smaller and tenderer than the Partlip, though larger and broader than the Carrot. Hence he conjectures those who have taken the Cervil, Scandius Coriandrum, for the herb in question, though they really appear to be more in the right than himself. However this may be, the plant of Matthiolius is the Daucus Gintidiun of Linney, as well as his D. icaria.

GIN-PALIAGARUM, a town of Hindoosan; 25 miles E. of Calcut.

GINKO, in Botany, Linn. Mant. 313. Komp. Ameon. 814. t. 813.—The Japanese name of a tree, as large as a Walnut-tree, with leaves resembling an Aclanum. The male flowers are in catkins, the female solitary, on flanks, producing a drupa, whose nut resembles that of a Pigeon, with a white, somewhat allistening, kernel, which is eaten in Japan, being supposed to afford digestion. This tree is hardy in our gardens, sometimes bearing catkins, but no fruit. The late Mr. Gordon sent a living plant to Linneus, who mentions it in an appendix by the above appellation, not being able either to define the genus, or to name it properly, till he knew the fructification. Mr. Salisbury having with great affility determined its essential characters, it was dedicated to him, by Dr. Smith in the Trans. of the Linn. Soc. v. 3. 359, and his botanical merits will ever justify the approbation. See SALISBURY.

GINLIA, a town of Naples, in Abruzzo Ultra; 12 miles N. E. of Teramo.

GINNANI, Francis, in Biography, was born at Ravenna in 1716. He was educated in his father's house, and at the age of fourteen was placed at Parma, as page to the duke of Antony Farneze. The duties of this situation did not prevent him from pursuing his studies, and he was particularly attentive to natural history, under the direction of his uncle Joseph Ginnani, who was well known for his researches into marine productions. He devoted himself to a retired and studious life, and was the inventor of divers agricultural instruments and other machines, useful as well as curious. His writings, which relate to almost all the departments of natural history, obtained for him an admission into the learned societies of London, Paris, Bern, and Pavia, and he held a literary correspondence with many of the most eminent natural philosophers of the age. In private life he was courteous, modest, and benevolent, and he was particularly obsequious to the duties of religion. He died at the age of forty. His principal work was a treatise on the diamonds of corn, with observations on the culms and seeds. He published an account of the natural productions in the museum of Ravenna, and he greatly interested himself in the instruction of the society of that town. He left behind him some manuscripts, among which was a "Natural and Civil History of the Fine Forests of Ravenna." Gin. Bibl.

"Gin-Pin," in Geography, a town of China, of the third rank, in Chau-tung; 17 miles N. E. of Tong-chang.

"Gin-Seng," or Nin-seng, in Botany. See Pinax. "Gin-Seng," in the Materia Medica, is one of the principal medicines of the Chinese and Tartars; and their most eminent physicians have written many volumes concerning its virtues.

It is known among them by divers other names, expressing only spirit, or the pure spirit of the earth; the plant that gives immortality, &c. It makes, in effect, the whole materia medica for the people of condition, but is too precious for the popular use.

All the writers of the Chinese affairs make mention of the gin-feng: as Martinus, in his Atlas; F. Kircher in his China Illustrata; F. Tachard, in his Voyages; and F. Le Comte, in his Memoirs.

And yet we knew but very little of this plant before F. Jartoux, a Jesuit, and missionary in China; who, being employed, by order of the emperor, in making a map of Tartary, in the year 1769, had an opportunity of seeing it growing in a village about four leagues from the kingdom of Corea, inhabited by Tartars, called Caliu-Tatze.

That father took this opportunity to make a draught of the plant, and give an accurate description of it, with its virtues and manner of preparing it. The gin-feng, according to his description and drawing, has a white root, somewhat knotty; about twice the thickness of the item, and which grows tapering to the end; at a few inches from the head it frequently parts into two branches, which gives it some resemblance of a man, whose thighs the branches represent; and it is hence it takes the denomination gin-feng, which signifies a figure of a man.

It is hard to say, why the Chinese should call it gin-feng, a word which signifies figure or representation of a man; neither that father, nor any he enquired of, could ever find, that at more resemblance to the figure of a man than is ordi-
This army of herbalists observed the following order: after they had divided a certain tract of land among their several companies, each company, to the number of a hundred perons, spread itself out in a right line, to a certain fixed place, every ten of them keeping at a distance from the rest.

Then they searched carefully for the plant, going on leisurely in the same order; and in this manner, in a certain number of days, they ran over the whole face of ground appointed them.

When the time was expired, the mandarins, who were encamped in their tents in such places as were proper for the subsistence of their horses, sent to view each troop, to give them fresh orders, and to inform themselves if their number was complete.

If any one of them was wanting, as it often happened, either by wandering out of the way, or being attacked by wild beasts, they always looked for him a day or two, and then returned again to their labour as before.

Gin-feng was formerly supposed to grow only in Chinese Tartary, affecting mountainous situations, shaded by close woods, but it has now been long known that this plant is also a native of North America, whence M. Saratian transmitted specimens of it to Paris in the year 1704; and the gin-feng since discovered in Canada, Pennsylvania, and Virginia, by La Fonte, Kalm, Bartram, and others, has been found to correspond exactly with the Tartar species, and its roots are now regularly purchased by the Chinese, who consider them to be the same with those of eastern growth, which are known to undergo a certain preparation above-mentioned, by which they assume a somewhat different appearance. This plant was first introduced into England in 1740 by that industrious naturalist, Peter Collinson. The dried root of gin-feng, as it is imported here, is scarcely as thick as the little finger, about three or four inches long, frequently forked, transversely wrinkled, of a horny texture, and both internally and externally of a yellowish white colour. To the taste, says Lewis (Med. Bot.), it discovers a mucilaginous sweetness, approaching to that of liquorice, accompanied with some degree of bitterness, and a slight aromatic warmth, with little or no smell. It is far sweeter, and of a more grateful smell, than the roots of fenugreek, to which it has by some been supposed similar; and differs likewise remarkably from those roots, in the nature and pharmacetical properties of its active principles: the sweet matter of the gin-feng being procured entire in the waterys as well as the spirosus extract, whereas that of fenugreek is destroyed or dissipated in the infusion of the watery tincture. The flight aromatic impregnation of the gin-feng is likewise in good measure retained in the watery extract, and perfectly in the spirosus.

The gin-feng, we have observed, is an ingredient in most of the medicines which the Chinese physicians prescribe to the better fort of patients; they affirm, that it is a sovereign remedy for all weaknesses occasioned by excessive fatigues, either of body or mind; that it attenuates and carries off pitious humours; cures weaknesses of the lungs and the pleurisy; stops vomitings; strengthens the stomach, and helps the appetite; diffuses fumes or vapours; fortifies the breath; is a remedy for short and weak breathing; strengthens the vital spirits, and is good against dizziness of the head and dizziness of the head and dizziness; and that it prolongs life to extreme old age. Nobody can imagine, that the Chinese and Tartars would set so high a value upon this root, if it did not con-stantly produce a good effect; those that are in health often make use of it to render themselves more vigo-rous and strong. And I am persuaded, adds Father Jartoux above-mentioned, it would prove an excellent medicine in the hands of any European who understands pharmacy, if he had but a sufficient quantity of it to make such trials as are necessary to examine the nature of it chemically, and to apply it in a proper quantiy, according to the nature of the disease for which it may be beneficial.

It is certain, that it sublimes, increases the motion of, and warms the blood, that it helps digestion, and invigorate in a very sensible manner.

After I had designed the root, he goes on, I observed the state of my pulse, and then took half of a root, raw as it was, and unprepared; in an hour after I found my pulse much fuller and quicker: I had an appetite, and perceived myself much more vigorous, and could bear labour better and easier than before. Four days after, finding myself so languid and weak, that I could scarcely sit on horseback, a mandarin, who was in company with us, perceiving it, gave me one of these roots; I took half of it immediately, and an hour after I was not in the least fatigued of any weariness. I have often made use of it since, and always with the fame success. I have observed also, that the green leaves, and especially the fibrous part of them, chewed, would produce nearly the same effect. The Tartars often bring people the leaves of gin-feng instead of tea; and I always find myself as well afterwards, that I should readily prefer them before the best tea; their decoction is of a grateful colour, and, when one has taken it twice or thrice, its taste and smell become very agreeable.

As for the root, it is necessary to boil it a little more than tea, to allow time for extracting its virtue, as is practiced by the Chinese, when they give it to sick persons; on which occasion they seldom use more than the fifth part of an ounce of the dried root.

To prepare the root for exhibition, they cut it into thin slices, and put it into an earthen pot well glued, with about half a pint of water; the pot is to be well covered, and set to boil over a gentle fire; and, when the water is consumed to the quantity of a cupful, a little sugar is to be mixed with it, and to be drank; immediately after this, as much more water is to be put to the remainder, and to be boiled as before, to extract all the juice, and what remains of the spirits part of the root.

These two doses are to be taken, the one in the morning, and the other in the evening. Phil. Trans. N 337, or Alberici, vol. iv. part ii. p. 412, &c.

Gin-feng has been considered by the Chinese as a powerful aphrodisiac; but a fact to the contrary is alleged by Dr. Cullen in his Med. Bot. v. ii. p. 261. Highly as the virtues of this root have been extolled by the Chinese, and by others, upon their authority, we know of no proofs, says Dr. Wodville (Med. Bot.), of its efficacy in Europe, and from its sensible qualities, we judge it to supply very little power as a medicine. It is recommended in debility, vae, a drachm of the root to be long boiled in a sufficient quantity of water for one dose; but it has been omitted in the last edition of the London Pharmacopoeia.

GIOCONDO, FRAN. GIOVANNI, in Biography, who flourished in the sixteenth century, was a native of Verona, where he taught the learned languages for a subsistence. Among his pupils was the celebrated Julius Caesar Scaliger. He afterwards became a monk, and was chosen as a brother both by the Dominicans and Franciscans. He was extremely learned in mathematics, and contributed much to the revival of classical learning, by the collection of ancient monuments and manuscripts. He presented to Lorenzo de Medici a collection of ancient inscriptions which he had compiled in Rome. Giocondo was sometime at the court of the emperor Maximilian. He visited France, and was employed to build two bridges over the Seine. After this he obtained the title of Architect-royal in France. The time of his death has not been ascertained; it is supposed he did not survive, very long, the year 1521, as he calls himself an old man, eight years before this, in the dedication of a work to Juliano de Medici. He materially served the cause of literature by several works, which did him much credit as a writer, as they likewise extended his fame as an artist. He published an edition of Pliny's epistles, and gave a correct edition of Vitruvius, illustrated with figures, which he dedicated to pope Julius II. He took a part in editing many other works of the ancients, and was the first person who gave a definition of Caesar's bridge over the Rhine. In 1526 he wrote four dissertations, addressed to the magistracy of Venice, concerning the waters of that city. He was employed with Raphael and San Gallo in superintending the erection of St. Peter's. His last work was, probably, the rebuilding of the Rome bridge of Verona. Gen. Biog.

GIOFAR, AL, in Geography, a town of Arabia; 8 miles S. S. E. of Rabigh.

GIOGL, a town of Transylvania, situated near the Maros; 14 miles S. W. of Millenbach.

GIOJA, or GIOVA, FLAVIO, in Biography, was born at Pastrano, near Amalfi, in the kingdom of Naples, about the year 1300. Little is known of the history of his life, except that he is thought to have been the discoverer of the directive power of the magnet, by which it diposes its poles along the meridian of every place, or nearly so, and to have applied this important fact to the purposes of navigation, under the form of a compass. As a proof that this instrument was the invention of a subject of the king of Naples, who was a junior branch of the royal family of France, it is said he marked the north point with a fleur-de-lis, by which it is distinguished by the people of every country. As a memorial of this discovery, the territory of Principato, in which Gioja was born, bears, for its arms, a compass. It must not, however, be concealed, that the French and the English have claimed for themselves the honour: and many authors of reputation have given it to the Chinese, who are reported to have known its use long before their intercourse with Europeans, and that the secret was brought to Italy by Marco Polo. Morei. See the article Compass.

GIOBRASH, a town of Arabia, in Yemen; 60 miles N.W. of Sado.

GIORDANI, VITAL, in Biography, was born at Bitonto, a town belonging to the kingdom of Naples, in 1633. He was intended for the church, but deserted the studies necessary for that profession, and married when he had no means of providing for the support of a family. After this he led an idle life, quarreled with his relations, murdered his brother, and sought for safety by leaving his country. He entered as a common soldier on board the jolly, with which pope Innocent X. went against the Turks in the Levant. He was present in several actions, and gave abundant proofs of his courage and heroism. His talents led him to promotion and he was made purveyor, a situation which obliged him to improve himself in arithmetic, of which he scarcely knew the elements. What his duty required him to learn, his inclination led him to pursue with pleasure and delight; he became an able mathematician, and was at length chosen professor of mathematics to Christina, queen of Sweden. Lewis XIV. appointed him professor of the same branch of science in the Academy of Sculpture and Painting. This was in 1666, and in 1672 pope Clement X. made him his engineer, and professor at the College of Wisdom. By his great prudence, regularity, and temperance, he redeemed his character, and died in his 78th year. His principal works are "Euclide Refituto," 1666, folio. "Fundamentum Doctrinarum Gravium," and "Ad Hymnorum Christianorum Epistoliarum." Morei.

GIORDANO, Luca, an historical painter, born at Naples in 1629. His father was an artist of no great repute, who, fancying his son, Luca had an inclination to painting, employed him very early in the practice of the art; by which means he acquired an uncommon facility of handling the pencil, and succeeded in imitating the works of great masters. By this, when very young, he gained for his parents considerable wealth; and so eager was his father to make advantage of his ingenuity, that he scarcely allowed the youth time to eat his meals, but was continually urging him to pursue his labours by repeating to incessantly Luca in præfio, (Luca make chief,) that in præfio became his nick-name among his companions.

His first matter of any note was Joseph de Ribera, called Spignolette; to whose style he, for a time, so much adhered, as to puzzle the most discerning critics. From Naples he removed to Rome, where he indifferently finished the noble remains of antiquity, and the works of eminent masters in the art. He fixed himself unhappily with Pietro Cortona, by which it is probable his brilliant imagination was taught to expand itself in a more imperfect and trifling manner than it was originally capable of entertaining. His ready hand, and the freedom, boldness, and precision of his touch, was exactly what Cortona required, and with him he brought on many noble works in fresco; and was so incredibly expedient in that art, that he could dispatch as much as twenty paintings in a day, as any other painter could in a week.

His imagination was exceedingly fertile; and this, with the readiness of his hand, and the consequent abundance of his
his productions, soon spread his fame over Europe. The king of Spain (Charles II.) desiring to see him paint, and to have the Escorial adorned by his hand, invited him there, ordering him to be paid 1500 ducats de Plata for the voyage, and allowing him to freight the ship that brought him over duty free. He also made him groom of the bed-chamber, honouring him with a golden key, but denying with his attendance, that he might be more his own master.

Velazquez says, "that it is impossible to express the number and beauty of his compositions in Madrid, Toledo, and at the Escorial; and that he employed only two years to paint ten arched cedings of the church and shrine of that palace. He was exceedingly industrious, generally painting six or seven hours every day, and being highly favoured by the King, became exceedingly rich. It was in 1692 he first arrived at Madrid, and did not return to Italy till 1702, when he accompanied Philip V. to Naples, and in 1704 died there.

Previously to his going into Spain he had executed numerous works in Rome, Genoa, Milan, and other places; and had produced a vast number of pictures in imitation of Titian, Tintoret, Giorgione, &c. &c. which are extremely correct, and exhibit the amazing power of his memory, and the facility of his genius. The extraordinary facility of painting which he possessed, enabled him to work with great success in sfresco, as well as in oil. This very facility is, however, the cause that Giordano's works will never be regarded as standards in the art of painting. Too great a degree of freedom is an enemy to grandeur of style, and the person who possesses it is apt to be too easily satisfied with his productions; and indulging himself in the pleasure afforded by the freshness and cleanliness of colour and effect produced by it, is unwilling to disturb it in order to render the parts more positively correct; and thus, though ever agreeable, yet works wrought in this manner are too often finny and weak in their effect on the mind. This is the character of Luca Giordano, who, though a great master in the art, ranks only in a second or third rate. One of his most considerable productions is the altar-piece of the church of the Ascension at Naples, representing the fall of Lucifer. And in the Durazzo Palace at Genoa, is a fine picture of Seneca dying in the Bath; of which, also, there is a duplicate in the gallery at Dresden.

GIOGIEV, in Geography, a town of Walachia, on the N. side of the Danube; 40 miles S.W. of Bucharest. In June 1771, the Russians defeated the Turks near this town, killing 5000 of them, and taking 180 pieces of cannon, with artillery and baggage, for 50,000 men. N. lat. 43° 38'. E. long. 25° 18'.

GIOGIO ANTONIOTTO, in Biography, an Italian writer on music, who, having been a considerable time in England, had a work entitled "L'Arte Armonica," translated into English, which he published in two vols. folio, by subcription, under the title of "A Treatise on the Composition of Music," in three books, with an Introduction on the History and Progress of Music from its beginning to this time, written in Italian by Giorgio Antonio, and translated into English, 1760, printed by Johndon, Cheapside.

We had at this time no well digested, clear, and ample treatise of composition in our language. Morley's treatise became scarce, obsolesce, and totally defective in every thing that concerns modern music. We had indeed Malcolm's treatise published in 1721, and that of Dr. Pepusch in 1731. The first is dark and awkwardly written; the second, though excellent as far as it goes, has some prejudices of the old school, which were totally abandoned in 1760, and it is too concise in many particulars to enlighten or satisfy the doubts of young students in many essential points, which were now necessary to be explained, and which in the year 1751 had no existence. Ceminini's "Guida Armonica," to long expected, and published about the year 1746, puzzled the cause, and disappointed every reader. Much therefore was expected, even by professors, from a work in two vols. folio, written by a learned Italian, and nearly half the list of subscribers consisted of the names of the principal composers and organists of the time.

We had a miserable translation of Rameau's treatise, written originally in a musical technica, totally different from that to which we were accustomed, which, with the ungrammatical and bad English into which the rest was translated, threw every one who attempted to read it into despair.

The sonatas and concertos of Corelli, published in score by Dr. Pepusch, and the works of Handel and Ceminini, for those who took the trouble to score them, were excellent lessons of counterpoint, if they had been properly studied. But it is astonishing how long even great performers upon instruments remain in utter ignorance of composition. Jack James, Magnus, and Kilway, though admirable organists, never attempted composition, and if they had, after a certain time, they would never have been sure of their ground, but even in making a bafe to a minuet or country dance would have discovered to real judges, that they were not regular bred contrapuntists.

Signor Antoniotto, we believe, was a perfect judge of the mechanical rules of harmony; but his method is not clear and intelligible to a student out of the reach of a master. His introduction, and historical account of the progress of music from the yew of the Greeks to the present time, will amuse, though not accurately instruct, curious readers.

He enquires to Guido the invention of harmony, and to John de Muris the invention of musical characters, as had been long done by others who, confusing with tradition, had never seen the Micrologus of Guido, nor the Compendium of John de Muris, by which it has been lately proved, that the laws of harmony were unknown to Guido, and that de Muris himself affirms the invention of musical characters to Magnifery Franco, who flourished 1547, near 300 years before John de Muris was born. (See Franco and De Muris.) So much for fig. Antoniotto's historical part.

When he comes to practical music, his definition are so far from clear to readers in the first stages of counterpoint, that they multiply the student's doubts. "His plates have prima facie no scientific an appearance as to frighten a principiante as much as teaching geometry or algebra would do. His examples of notation are methodically stated; but the joining the old and modern characters in the same table will confound the student's ideas. He begins with three characters no longer in use, and the semibreve, now the first and longest note, ranks only as the fourth."

His general scale and fylom of intervals will terrify a young student by the manner in which it is represented; its fylom of harmonic combinations the same. Plastos 14 and 15 of transposed scales are clear and useful, as are the fylom in the feveral keys.

The rôge de foncave seems unknown to the author, and his plain counterpoint is written entirely on a series of sevenths to bases rising or falling by fourths and fifths totally without modulation. No instructions are given for the use of discord, but in examples du duo di lui gives discords indiscriminately to every note, without informing the student when and where to use them, or speaking of accented or unaccented parts of a bar.
GI O

At plates 48 and 49 the answers to short examples of figure and imitation are clear and ingenious; but no instructions are given for melody throughout the work. An musical composition consisting of the union of melody and harmony, it seems, at least, to have merited a definition. He might have told the student that it consists of a pleasing series of figure notes of various lengths, arranged with grace, divided into equal measures by bars, phrased and governed by rhythm.

At p. 49, ex. vii. there are observations in abundance between the second and third lines, unnoticed by the author.

Page 169, vol. i., the author very judiciously confines vocal fugues and canons, in which the several voices are singing different words and syllables at the same time; but Rouland had done this before, in his "Lettre sur la Musique Française," 1751. His examples of fugue and canon, which he allows to have an admirable effect in instrumental music, are few and artless. No other examples are given of melody than chords broken into very common pallsages as variations. Nor of harmony or melody do we find more than two or three examples in triple time, and those of a very common and unmeaning fort.

We remember that the public was much disappointed by this work, which was silently put on the shelf, and has scarcely ever been mentioned since its publication.

GIORGIO GANDINI, a painter, famneed del Grasso.

He was of Parma, and, as we believe Orlandi, not merely one of Correggio's school, but a pupil, whose works the master himself retouched. The principal picture in St. Michael, erroneously ascribed to Leoli Orlo, is claimed for him by P.-Zapata; a performance, though in parts capriciously conceived, of an impasto, a relief, a sweetness of colour and pencil, to confer honour on the bell of that school. The effect in which he was held by his fellow-citizens may be conceived, from the commendation which they unanimously conferred on him after the decease of Correggio; viz. to paint the Tribune of the Duomo. Death prevented him from the execution of it, and the commision fell to a third to Girolamo Mazzutti, though not yet ripe for an enterprise of such magnitude. Fuseli's Pillington.

GIORIO, St. in Geography, a town of Naples, in Calabria Ultra; 17 miles S.E. of Nicotera.—Alfo, a town of the island of Liparia; 44 miles E. of Liparia.—Alfo, a town of France, in the department of the Po; 31 miles N.W. of Chivasso.—Alfo, a town of Naples, in the province of Otranto; 4 miles E. of Taranto.—Alfo, a town of Naples, in the same province; three miles N.N.W. of Nardo.—Alfo, a town of Naples, in the province of Prin- ciupato Ultra; three miles S.E. of Benevento.—Alfo, a town of Italy; 10 miles N.W. of Verona.—Alfo, a town of Italy, in the department of the Reno; 11 miles N. of Bol- logna.

GIORGIO, a town of Africa, in the country of Mogambique, at the bottom of a bay not far from Sofala.

GIOTTO, in Biography, a painter, conspicuous among those who revived the knowledge of the art in the 14th century. His father was a labourer, who lived at Vespignano, near Florence, and whose name was Bondoni; but he gave the name of Giotto to his son, who was born in 1266, and whom, at an early age, he placed with some shepherds to affix in tending their flocks. Whilst engaged in this employment, he was found by Cimabue drawing a sheep in the field with so much ingenuity, that that painter was induced to adopt him of his father, that he might teach him the art of painting. In a short time he not only learned to imitate his master, but also paint from nature; and, throwing off the dry Gothic manner, which reigned till then, endeavoured to give the actual imitation of nature. He soon became far superior to
his mother, and arrived at a degree of art which, in grace at least, was not excelled before Maffiaccio. M. Fufi, in his last edition of Pilkington's Dictionary, observs, that "it is not easy to account for the rapidity of his progrs, unless we ascribe it to the study of the antique, with which he might have become acquainted at Florence, and afterwards at Rome; and as we know that he was likewise a sculptor, and that models of his existed at the time of Lorenzo Ghir- 
berti; this conjecture becomes highly probable, when we consider the character of his heads, the irregularity of his forms, the broad and majestic folds of his draperies, with the grave and decorous attitudes of his figures." Being contemporary with Dante, it is to him we owe the portrait of that illustrious poet, and also those of many other personages of that period famed for their birth and talents. The great work now remaining, though in a ruined state, which tellifies most fully the full ground on which he earned the fame he receives, is at Altilh, in the church of St. Franc-
cisco, where, in 32 pictures, he has represented the various actions of that faint in the course of his life. These, together with many others, have remained in the same place, are in fresco, and have ever been esteemed of suprme excellence for expression and beauty of composition, and for the grace and truth of actions, and proportions of the figures. His fame reached the ears of pope Benedict IX. who sent for him to Rome, and employed him in the Vatican, and in St. Peter's. Clement V. took him to Aigignon, where, and in other places in France, he painted many pictures in fresco, and thence drew great riches; returning to Florence in 1316. He afterwards painted in most of the principal cities of Italy, but more particularly at Florence, where his works were studied by succeeding artists, and highly ap-
plauded even by Michael Angelo Buonarroti. He died in 1336, aged 60, having enjoyed a life of fame and esteem; and honoured by admittance to the citizenship of Florence, as a reward for the honour his great talents conferred upon his country.

GIOVANII, in Geography, a town of Peria, in the pro-
vince of Kerman; 57 miles E. of Sirjan.—Alfo, a town of Peria, in the province of Farilfan; 10 miles N. of Schiras.—Alfo, a town of Peria, in the province of Segelitan; 55 miles W.N.W. of Zaren. GIOVANA, a town of the republic of Lucca; seven miles N. of Lucca. N. lat. 44° E. long. 10° 40'.

GIOVANNI ASSASSI, in Biography, a celebrated Ita-
lian opera singer, with a tenor voice. His first appearance on the stage was at the Theatre Royal at Copenhagen, where he remained three years. In 1772, we say, he heard him at Hamburgh, and in 1773 he went to Amster-
dam, where, as well as at Hamburgh, he only sung at concerts, there being no opera established in those cities at that time. In 1775 and 1776, he sung at Turin with the Agajari. In 1777 at Naples with Rubiniel. In 1779 he arrived in England, where he found Roncaglia, whose bounded abilities excited an ambition in the tenor singer to take the pas of the soprano. Anfani had one of the best tenor voices we had ever heard on our opera stage. It was sweet, powerful, even, and of great compass and volubility. Nor could any defect be justly ascribed to it, except perhaps a little want of variety, spirit, and anima-

GIOVANNI, St. in Geography, a town of Naples, in the cap-
itanata; six miles N. E. of Accli.—Alfo, a town of the duchy of Carinola; two miles N. W. of Duino.—Alfo, a town of Italy; 19 miles N. of Bergamo.—Alfo, a town of Filria; nine miles N. E. of Pula.—Alfo, a town of Naples, in Abruzzo Utra; 13 miles S. of Celano.—Alfo, a town of Naples, in Ballisicata; 17 miles S. W. of Materia.—Alfo, a town of Italy, in the ducry of Piacenza; six miles W. of Piacenza.—Alfo, a town of Etruria; 18 miles S. E. of Florence.

GIOVANNI, St. or St. John, an island in the Mediterra-
near. N. lat. 36° 27'. E. long. 26° 24'.

GIOVANNI Katanla, St. a town of Naples, in Capitanata; 10 miles N. W. of Manfredonia.

GIOVAR, a town of Peria, in the province of Farilfan; 55 miles S.S.W. of Schiras.

GIOVELLINO, a town of Cortica; 25 miles E. of Corte.

GIOVENAZZO, a town of Naples, in the province of Barl, situated near the sea, the fee of a bishop; con-
taining four churches, four convents, and defended by a castle; eight miles W. of Barl. N. lat. 41° 17'. E. long. 16° 42'.

GIOVI, a town of Etruria, on the Chieno; five miles N. of Arezzo.

GIPPINI, a river of England, in Suffolk, which joins the Orwell, and falls with it into the Stour.

GIPSIES. See EGYPTIANS; under which article the reader will find an account of their supposed origin, migra-

Schedini, with whom Anfani contrived to quarrel, took

attacks, and from the tenor singer's pride, impatience, and irreconcilable dis-

putions, he was in a perpetual warfare during the two

years he remained in this country.

His figure and countenance on the stage were good; he

was tall, thin, and had the look of a person of high rank.

He told us, we believe with great truth, that he was

famous in Greece, always in vogue. He was husband to the

Machecchi, who came hither as first woman of the famous

opera, without a voice. If ever she had a voice, he had

lost it before her arrival in this country. We never could

receive any pleasure from her performance; every note,

feebly as it was, was the squeezed out with such difficulty, and

with a look so croft and miserable, that after her first ex-

hibition we never wished more either to hear or see the

Signora Machecchi, who was so proper a match for her

husband in sweetness of disposition, that in Italy, when

employed in the fame theatre, if one happened to be ap-

plauded more than the other, they have been known mutu-

ally to employ pertons to lift the失败ed rival. The

Machecchi is laid to have been once a very agreeable singer,

and a considerable favourite on the continent during her

bloom; but soon after her first appearance she ran away

with an English nobleman, from the theatre in Florence, in

her stage drees during the middle of the performance.

GIOVANII DA SAN GIOVANNI, a painter whose real

name was Gio. Manuzzo. He was one of the best Italian

artists in fresco. Poffessing a vivid imagination and a ready

hand, his works are numerous, and adorn many of the

churches and palaces of Rome and Florence. He did not

begin to paint till he was 18 years old, his success is there-

fore the more extraordinary. The genius he was endowed

with being of an irregular nature, he frequently took great

liberties in his designs; but his fresco-paintings at Florence

shewed how well, when he pleased, he could restrain the

improper exuberancies of his imagination. He died in 1656,

aged 46.
tions, and character, and of the treatment they have undergone in several countries in which they have appeared. We shall here add, that Muratori, in his "Antichita Italiane," fuggites, that it was not before the year 1430 that this singular race of people, like from the king's bounty, pretended that Egypt was their native country, and that they were deprived of their settlements by a king of Hungary. Nothwithstanding the geographical absurdity of this alteration, it was readily credited by the ignorant vulgar. It appears probable, according to this writer, that they drew their origin from Wallachia, or the neighbouring countries, as they are still found in great numbers in Hungary, Servia, Bulgaria, and Macedonia. Whether they were expelled from their native dens, or left them spontaneously, and we may add, whatever was the country from which they migrated, it is certain that about this period they began to appear in the western provinces, and by their fraudulent arts were able to gain a footing there, though by nature ever addicted to a vagabond life. They were neither cultivators of the soil, nor artisans, but found an inexhaustible supply of their necessities in theft, rapine, and deceit. Although their mode of life was not unknown to the Italians, their infamous practices were tolerated, because they made the simple people believe, that a penance was imposed upon them of wandering about for seven years; and still more, because they pretended to the gift of divination and foretelling future events. An opinion long prevailed, that they were forbidden to remain longer than three days in one place, and that they had a privilege from the pope of providing themselves with necessary food wherever they should be. The time in which the "Zingari," or "Zingari," as they were called, first made their appearance in Italy, may be collected from the "Mecella Bolognese," published in the 18th volume of the "Recueil Italienarum." Hence we learn, "that on July the 18th, 1432, there came to Bologna a duke of Egypt, named duke Andrew, together with men, women, and children of his country, in number about 100. They had a decree from the king of Hungary, who was emperor, authorizing them to rob wherever they should go for the space of seven years, without being amenable to justice. When they arrived at Bologna, they lodged within and without the Porta di Galliera, and kept under porticoes, except the duke, who was lodged at the king's hotel. They were in Bologna 25 days. During that time many persons visited them, on account of the duke's wife, who understood divination, and could tell what was to be a person's fortune, what was his present condition, how many children he was to have, if a woman was good or bad, and the like. In many things they spoke the truth; and when people went to have their fortunes told, few escaped without having their pockets picked, or, if women, their clothes stripped of their ornaments. Their women went, by six or eight together, through the city, entering the houses of the citizens and praying with them, at the same time telling what they could lay their hands on. They also went into the shops, pretending to buy something, whilst some of the party were employed in pilfering." Italy did not suffice for this crew, which was gradually augmented by accessions from the men and women of the countries through which they passed. Krantz, in his history of Saxony, writes, that they began to be seen in that country in the year 1417, and he gives a lively description of their customs and cheats, under the name of "Zigeni," or "Zigeuni." Aventine also mentions their arrival in Bavaria, and their mal-practices in 1411. They spread in like manner through Flanders and France, in which country they were called "Egyptians" and "Bohemians," and in Spain they were named "Cattanesi." They are also found in the Turkish dominions. Although they have been frequently banished from various districts, and severe edicts have been issued against them, they still continue to keep up the race, and carry on their trade of petty pillage and deception.

GIR, or Ginn, in Geography, a river of Africa, which Ptolemy delineates as equal in length to the Nigir, the course of each being probably about 1000 British miles; but running from east to west, till it be lost in the same lake, marly, or desert, as the Nigir, which see. The Arabian geographer Edrisi seems to indicate the Gir, when he speaks of the Nile of the Negroes, as running to the west, and lost in an inland sea, in which was the island Ull. Some have supposed the Gir of Ptolemy to be the river of Arnon, or Uper-al-Gazel, which joining another considerable river, flowing from Kuku, discharges itself into the Nubia Palus, or Kranga, and it is so delineated in Renault's map; but others apprehend, somewhat better reason, that the Gir of Ptolemy is the Behr Kulla of Browne, in his history of Africa. This river, the Niles Nigurum, as well as the Nile of Egypt, have their source in the mountains of Kemri, which Browne lays down in the 8. S.E., as to correspond with the Beir Kolla, though he be a stranger to its remote source. This river represents the Nile as receiving two tributary streams from two lakes; and among other cities on its bank is a metropolis called Gira. The termination of the Gir is not a little obscure, but it seems to be delineated, as falling under a chain of hills, on the N. of the Lybia Palus, on central lake of Africa, and afterwards joining the Niger in its course to the west. The Pamiers of Ptolemy, between the Gir and the Nigir, may be the Wangara of the Arabs, and his Lybia Palus, which forms the termination of the Nigir, as Rennell observes, either for the largest of the lakes, or for the lakes of the country (of which there are several) collectively. From an accurate examination of Edrisi, who wrote in Sicily in the 12th century, and who, from his minute attention to central Africa, has been called the Nilotic geographer, it will appear, that while the Nile of the Negroes, which he says runs to the west, has been mistaken for the Nigir, he really knew nothing of that river; and his Nile of the Negroes is the Gir of Ptolemy, terminating in an island lake, in which was the island of Ull, one day's sail from the mouth of the river; and in which island another Arabian geographer places the capital city of all Sudan. Beyond this lake and island, Edrisi appears to have had no knowledge of central Africa; all the regions and towns he mentions forming part to the Gir, his Nile of the Negroes, running to the N.W.; and from his account it would appear that Wangara is the Delan of the Gir.

Gir, in Botany, a species of grass growing plentifully near Rais el Fedd, on the borders of Algyeria. It is said, says Mr. Bruce, to flourish in the end of April, and specially advanced to its full height of about three feet four inches. It is ripe in the beginning of May, and stays green for some afterwards. This species of grass was one of the acquisitions of our author's travels. It was not before known in Europe, nor when he published his work had the feed of it...
GIR

produced a plant any where but in the garden of the late French king.

GIRA, in Geography, a town of Peria, in the province of Mazanderan; 18 miles S. of Sari.

GIRA, in Antiqu Geography, a metropolis of Libya interior, seated on the river G. Ptol. See GIR.

GIRAFFE, in Zoology. See Camelopardalis.

GIRAGLIA, in Geography, a small island near the N. coast of Corsica; 23 miles N. of Baffia. N. lat. 43° 1'. E long. 9° 35'.

GIRALDI, GIOVANNI GREGORIO, in Biography, one of the most learned men of his time, was born at Ferrara in the year 1493. He pursued his studies at his native place, and having attained considerable eminence in the languages, he was chosen by the countess Rangone as preceptor to her son Herder, afterwards a cardinal. He accompanied the court to Rome during the pontificate of Leo X., and had apartments assigned him at the Vatican. He appears to have been employed in the instruction of other young persons in polite literature, and continued at Rome during the next two pontificates. He enjoyed but a slender portion of health, and at the age of Rome he lost all his property, and even his books. This was in the year 1527, when, having left his friend and patron the cardinal Rangone, he was obliged to leave the capital. In his distress, which was very great, he went to Bologna, and thence to Mirandola, where he met with a very kind friend in Gian-francesco Pico. This patron was murdered in 1533, and Giraldi with great difficulty escaped to Ferrara with his life. His poverty was now extreme, but he was not without friends, by whose liberality, especially that of the duchess Renata, he was enabled to lay up a store for the future. He died, after a life of much torture, in the year 1532. So varied was his life, and severe his afflictions, that towards the close of life he complained that he had always to combat against three enemies, Nature, Fortune, and Injustice. His great work was entitled "Syntagma de Dis Gentium." This is the first treatise in which mythology is discussed in a truly learned manner, and it is a treatise which exhibits the vast extent of the author's reading, and for which the learned world is under very great obligations. He was author of several other treatises, "On theMuses;'' "The life of Hercules;'' "Explanations of the Pythorical Symbols;'' and other ancient enigmas; "A Treatise of Years and Months, with Greek and Latin Calendars, and thirty Dialogues on subjects of Eрудition." He gave "A History of the Greek and Latin Poets, and of the Poets of his own Time." He was a considerate Latin poet, and it is thought a feeble of his own misfortunes induced him to write two small pieces against ingratitude, entitled "Prognosticata adversus litteras et litteratos." Morevi.

GIRALDUS, SILVESTER, CAMBRENSIS, one of the most learned and eloquent divines of his time, was born near Pembroke, in South Wales, 1145. Among his numerous works that have been preferred, printed and manuscript, we shall here only advert to an extraordinary paflage relative to music, in his "Cambrice Descriptio, cap. XIII." which has been lately quoted by musical writers, and on which great stress has been laid by Eximeno (Dobbio sopra il faggio fond. prat. di contrap. di P. Martini) and by Mr. Ed. Jones, Mus. Relics of the Welsh Bards.

After all the enquiries that we have made concerning the origin and antiquity of counterpart, or music in parts, the passage to which we allude surprised us extremely. Many ecclesiastical historians tell us that the organ was first admitted into the church at Rome by pope Vitalian, 666,
the same pontiff who two years after sent fingers into Kent, to finish the work which Aulin, the first Roman millinary, had begun. In 682, according to Bede, John, the precentor of St. Peter's in Rome, was sent over by pope Aga tho to instruct the monks of Weremouth in the manner of performing the ritual, who opened schools there and in other places of the kingdom of Northumberland for teaching music.

This may, perhaps, reconcile to probability some part of the following account, which Giraldus Cambrensis gives of the peculiar manner of finging that was practised by the Welsh, and the inhabitants of the north of England, about the end of the twelfth century.

"The Britons," says he, "do not finge in uniform, like the inhabitants of other countries; but in many different parts. So that when a company of fingers among the common people meets to finge, it is usual in this country, as many different parts are heard as there are performers, who all at length unite in consonance, with sweet finges. In the northern parts of Great Britain, beyond the Humber, on the borders of Yorkshire, the inhabitants use the same kind of symphonious harmony; except that they only finge in two parts, the one murmuring in the base, and the other warbling in the acute or treble. Nor do these two nations practise this kind of finge so much by art as hobby, which has rendered it so natural to them, that neither in Wales, where they finge in many parts, nor in the north of England, where they finge in two parts, is a simple melody ever finge. And, what is still more wonderful, their children, as soon as they attempt using their voices, finge in the same manner. But as not all the English finge in this manner, but those only of the north, I believe they had this art at first, like their language, from the Danes and Norwegians, who used frequently to invade and to occupy, for a long time together, those parts of the island.

This extraordinary passage requires a comment. And first, it may be necessary, before we reason upon the circumstances it contains, to be certain of their authenticity. Giraldus Cambrensis is indeed an author who has been often supposed inaccurate and fabulous; and the glaring improbabilities in the above account, with the manifest ignorance of the subject in question, by no means contribute to augment his credibility. For whoever is acquainted with the laws of counterpoint, or with the first difficulties attending the practice of finging in parts, can have no exalted idea of the harmony of an untutored crowd, turba canentium, or suppose it to be much better than the deficient parts of a good-humoured mob; in which the parts would be as various as the pitch of voices of which their chorus was composed. But have all these united at last in the consonance of organic melody, and the soft sweet fings of B mollis, will long remain an impenetrable secret:

"As true to no meaning puzzles more than wit."

With respect to what he affers of the people in Northumberland finging in two parts, it is more reconcilable to probability, from the circumstances just mentioned, of the cultivation of music in that part of the world under Roman maiters, who may probably have first brought over the art of finge, or double finge, which the newly invented organ had suggested, by the facility it afforded of sounding two or more notes at a time; which art, when practised by voices, was thence called organum, organae. But as to what Giraldus fays of children naturally finging in this manner as soon as they were out of the cradle, the reader will afford it what degree of weight he pleases; but for
our own part, we must own that it is not yet admitted into our musical creed.

GIRAN, in Geography, a town of Algiers, anciently called Arissa; 45 miles S.E. of Oran.

GIRANA, a town of Abyssinia; 60 miles N.W. of Gondar. N. lat. 13°. E. long. 36° 37'.

GIRANDOLE, a large kind of branched candlestick. See Branch and J E N E.

GIRAPATRA, in Geography, a town of the island of Ceylon; 16 miles S.W. of Settin.

GIRAR, a fortress of Hindooftan, in Malwa; 40 miles S.W. of Chandercer. N. lat. 24°. E. long. 79° 18'.

GIRARD, Gabriel, in Biographia, a distinguished member of the French academy, known as the author of a work entitled "Synonymes Françoisi," the object of which is to prove that the French words, usually accounted synonymous, have, almost all, certain shades of difference, which, in correct speech, should prevent them from being used indifferently. No grammatical work was ever better received by the public, and it was the opinion of Voltaire that it will subist as long as the language. This work has been imitated in English, in one entitled "The difference between words efeemned synonymous in the English language, and the proper choice of them determined," in two vols. 12mo. 1766. The abbé Girard also wrote a French grammar, entitled "Principes de la Langue Françoife," which has much merit in its plan and theory, but is thought very defective in point of style.

GIRARDO, Francis, an eminent sculptor, intended by his father, who was a founder, for the profecution of the law. His inclination for the fine arts could not be controlled, and he was educated as an artist. He was brought up at Troyes, but having acquired much reputation and practice there, he went to Paris to improve his taste and judgment under the sculptor Anguier. His performances obtained for him a high degree of reputation; he was noticed by the king, and by him lent with a liberal pension to Rome. In 1657 he was admitted into the academy, and patronized by Le Brun. Girardon is reckoned to have had more correctness than invention; and he is said to have modelled with more facility than he worked in marble. His principal works are, four figures composing the group of the baths of Apollo, and the rape of Proserpine in the gardens of Verailles; the equestrian statue of Louis XIV, and the mausoleum of cardinal Richelieu, in the church of the Sorbonne. He cultivated the friendship of the fine writers of the age, several of whom have done honour to his merits and memory. He was nominated to the chancellorship of the academy in 1695. After having adorned the capital and many other parts of the kingdom with a number of works, and risen to the very head of his profession, he died in 1715 at the age of eighty-five. Moreau.

GIBE', in Geography, a town of Egypt, on the right bank of the Nile; 26 miles N. of Syene.

GIBEH, a river of Switzerland, which runs into the Aar, two miles S. of Berne.

GIRCH, a river of North Wales, which runs into the sea near Pullhely, Caernarvonshire.

GIRCHSBECK, a town of the duky of Hohlenstein, six miles W.S.W. of Oldenfohe.

GIRCZENI, a town of Moldavia; 30 miles N.E. of Galatz.

GIRDERS, or GIRDING beams, in Carpentry, are those large beams thrown across a room, in order to threnit the bearing of the joists.

When the bearing is not very great, the girder confids of a single beam; when it is more than common, the baulk, or piece of wood out of which the girder is made, is fawn down the middle, and the two pieces are reversed and bolted. In great bearings the girder is framed like the principals of a roof, for the construction of which we refer the reader to the article Carpenter, and Naked Flooring.

No girder ought to be less than ten inches in the wall, nor ought they, or any principal beam, to be placed over an aperture. They ought to be of the same heart of wood, and as free of knots as possible, for knots destroy the continuity of the fibres, and consequently impair the strength.

GIRDING-GIRT, in Sea Language. The freeman say a ship is girt, or hath a girding-girt, when her cable is so tight or strained, that upon the running of the tide she cannot go over it with her stern part, but will lie across the tides.

GIRDLE, CINQUELS, or ZUZ, a belt or band of leather, or other matter tied about the loins, to keep the part more firm and tight.

It was anciently the custom for bankrupts, and other insolvent debtors, to put off and surrender their girdle in open court. The reason was, that our ancestors used to carry all the necessary utensils, as purse, keys, &c. tied to the girdle; whence the girdle became a symbol of the estate. History relates, that the widow of Philip I. duke of Burgundy, renounced her right of succession by putting off her girdle upon the Duke's tomb. Accordingly the girdle among the ancients was used for a purse. Our Saviour forbids his apostles to carry money in their girdles, Matt. x. 9. Haggai, i. 6. Horace says, that he who has lost his girdle (his money) is ready for any thing. "Itb e quod vis, qui zonam perdidit." Hor. Ep. I. n. c. 1. The Romans always wore a girdle to tuck up the tunics, when they had occasion to do any thing; this custom was so general, that such as went without girdles, and let their gowns hang loose, were reputed idle, dissolute persons.

GIRDLE, Maidens' or Virgins'. It was the custom among the Greeks and Romans for the husband to entie his wife's girdle. Homer, lib. x. of his Odyssey, calls the girdle της φίλου ζώνη, maid's girdle. Felix Fabius, that it was made of sheep's wool, and that the husband untied it in bed; he adds, that it was tied in the Herculanean knot; and that the husband untied it, as a happy preface of his having as many children as Hercules, who, at his death, left seventy behind him.

The poets attribute to Venus a particular kind of girdle, called πλατύ, to which they annexed a faculty of inspiring the passion of love.

GIRDLE, Quicksilver, in Medicine, is a sort of girdle smeared over with mercury, or having mercury inclosed within it.

It is made of leather, linen, cloth, cotton, stuff, or the like; and the mercury is prepared or killed various ways; as with falling spittle, fat, or the like.

It is applied as a topical medicine about the waist, sometimes with good effect; but frequently it proves dangerous, principally in weak constitutions, and these subject to convulsions. Its intention is, the cure of the itch, driving away vermin, killing lice, &c.

GIRDLE, Queen's, is an ancient duty or tax, raised at Paris every three years, at the rate of three deniers upon each muid of wine, and fixed for each queue; it was intended for the maintenance of the queen's household; afterwards they augmented and extended it to other commodities, as coals, &c.

Vignere supposes it to have been originally thus called, because the girdle anciently served for a purse; but he adds, that a like tax had been raised in Persia, and under the same name, above two thousand years ago; as appears from Plato, in his Alcibiades, Cicero, Athen. &c.

GIRDLE,
GIRDLENESS, in Geography, a cape on the E. coast of Scotland. N. lat. 57° 4'; W. long. 2° 2'.

GIRELLI, Agnese, in Biographia; a female opera singer, who arrived here the same season as Miller, in 1772. Her style of singing was good, but her voice was in decay, and her intonation frequently failed; when she arrived here; however, it was easy to imagine from what remained, that she had been better. She remained here only one season, and was succeeded by Mrs Cecilia Davies.

GIREST, in Geography, a town of Perseia, in Kerman; 100 miles E. N. E. of Gonron.

GIRET, a town of Persia, in Mazanderan; 30 miles S. of Febrashab.

GIRGASHITES, in Scripture Geography. See CALSHITES.

GIRGE, the capital of Upper Egypt, and the residence of the Bey, situated about 400 yards from the left bank of the Nile. This town is about a league in circumference, and has several mosques, bazaars, and public squares; but it has no remarkable buildings nor ancient edifices, whence some have inferred that it is a modern building, more especially as Abufida does not mention it. The Bey lives in great state, and continues in office three or four years, according to the pleasure of the divan at Cairo. His soldiers commit innumerable outrages. The Copts are not allowed to have churches in that town; and therefore when they would join in divine service, they are obliged to go to a convent situated on the other side of the Nile. The Franciscans, who have a convent here, pass for physicians, but they are frequently exposed to danger from the influence of the Janizaries, the most refractory of whom are bent hither from Cairo; 160 miles N. of Syene. N. lat. 26° 30'; E. long. 31° 32'.

GIRGENTI, or Agrigenti, a town of Sicily, near the S. coast of the valley of Mazara, erected near the ruins of the ancient Agrigentum (which see); and occupying the ground on which the ruins of the ancient city stood; the site of a bishopric, situated on the river St. Blaise, about three miles from the sea; 47 miles S. of Palermo. N. lat. 37° 22'; E. long. 13° 33'. Its situation on a mountain renders almost all the streets impassable, not only for carriages but even for men. The population of Girgenti falls short of that of the ancient Agrigentum, which Empedocles reckons at 820,000; whereas at present, reckoning the city, properly so called, which was the ancient city, the suburb of Camiico, and that built by Henry and Constance in the 12th century, it is reduced to 15,000 persons, generally poor and of a melancholy appearance. The nobility here are poor, and live in great privacy; the merchants, wholly taken up with their own affairs, live nobody but at the exchange; without society and without amusements, every body is, or appears to be, gloomy and devout. The port of Girgenti, very different from the mole of the ancient Agrigentum, which was at the mouth of the Aragona, and of which not a space is left, is subject to the same inconvenience with that of the harbours of Apulia and Calabria, which is that of being liable to be filled up equally by two opposite winds, viz. the south-easterly and north-westerly. The two piers erected to remedy this inconvenience having been found insufficient, the government has been obliged, as at Cortona, to employ galley-slaves for emptying and cleaning the entrance of this port; nor can their laborious work be abandoned on account of the importance of this harbour in the exportation of commodities from all the southern part of Sicily; and the shelter it affords to the Neapolitan vessels in the seas most exposed to the Bar- bary corsairs, being almost within sight of Africa. Near the mole are the admirable magazines of the Caritatoria,' the richest in Sicily, confiding of caverns or cellars cut out of the rock, in which the corn is preferred without the least injury. These magazines belong to the kings, and secure the sufficiency of the island. Foreign merchants resort hither to purchase the surplus, after referring enough for the home consumption. The king is accountable for the corn lodged there, and the proprietors have only a small sum to pay for flore-house rent.

GIRGITES, a name used by some chemical writers for a sort of white fluxes found in rivers, of which they make a peculiarly strong line. The fluxes are of the parry kind, wrought into round balls by the motion of the water; and they have their name girgites, from the word gir, used by the chemists for lime.

GIRGITZA, in Geography, a town of Walachia; 40 miles N. N. E. of Bucharest. N. lat. 43° 17'; E. long. 26° 19'.

GIRIA, a town of the island of Cephalonia; 16 miles W. of Cephalonia.

GIRKIN, among Gardeners. See GUERRIN.

GIRLE, or Gyrles, among Sportsmen, denotes the roebuck in its second year.

GIRMANO,
GIRMANO, in Geography, a town of Prussia, in Samland; 25 miles N.W. of Königsberg.

GIROMAGNY, a town of France, in the department of the Upper Rhine, and chief place of a canton, in the district of Beynost. The place contains 1700, and the canton 9572 inhabitants, on a territory of 150 kilometres, in 19 communes.

GIRON DE LOYARA, GARCAS, in Biography, a learned Spanish prelate, who flourished towards the close of the 16th century, was born at Talavera. In the course of his studies he had paid a marked attention to philosophy and theology; to history and the councils, with which he became intimately conversant. He lived in a retired way as a canon, till his uncle refused to him the archdeaconry of Guadahorn, which is one of the dignitaries belonging to the church of that city. In 1585, Philip II., king of Spain, sent for him to court, made him master of the royal chapel and almoner; and likewise entrusted to his care the education of his son Philip, infant of Spain. In 1596, Cardinal Albert assumed the government of the Low Countries, and appointed Giron his vicar-general over the archbishopric of Toledo; to which valuable see he was himself afterwards preferred. He died in 1599, and his death has been imputed to the chagrin which he felt for the neglect shown him by his pupils, who had lately succeeded to the throne. He was author of a valuable collection of Spanish councils, under the title of "Collectio Conciliorum Hispaniae, cum Notis et Emendationibus." Moret.

GIRON, in Geography, town of Africa, on the Ivory coast.—Also, a town of S. America, in the province of Quito; 25 miles S. of Quito.

GIRON, or Girvan, in Heraldry, denotes a triangular figure having a long sharp point, not unlike a wedge, terminating in the centre of the escutcheon.

The word is French, and literally signifies the germination or lap; because, in cutting, the keys being suppurated somewhat afunder, the two thilids, together with a line imagined to pass from one knee to the other, form a figure somewhat similar to this.

When a coat has six, eight, or ten of these girons, meeting or centering in the middle of the coat, it is said to be gironne or gironnay.

GIRODNE, in Geography, a river of France, formed by the union of the Garonne and Dordogne; 12 miles N. of Bordeaux, which runs into the Atlantic, after a course of about 27 miles N.N.W.

GIROINV, one of the nine departments of the south-west, or Garonne region of France, deriving its name from the river Gironda. It is a maritime department, composed of a portion of Guienne, in N. lat. 44° 40', and bounded on the N. E. by the department of the Lower Charente, on the E. by the departments of the Dordogne and Lot and Garonne, on the S. by the department of the Landes, and on the W. by the sea. Its capital is Bordeaux. This department contains 11,727 kilometres, or about 547 square leagues, and 519,685 inhabitants, and is divided into six districts; viz. Blaye, comprising 4 cantons, 61 communes, and 52,026 inhabitants; Libournne, including 59 cantons, 143 communes, and 108,576 inhabitants; La Reole, comprising 6 cantons, 118 communes, and 357,705 inhabitants; Bazas, containing 7 cantons, 68 communes, and 475,449 inhabitants; Bordeaux, comprising 18 cantons, 193 communes, and 333,621 inhabitants; and Libourne, containing 4 cantons, 57 communes, and 30,808 inhabitants. Its contributions amount to 5,853,653 francs, and the expenses for administration, justice, and public instruction to 533,643 francs. The soil of this department is various; the cast and north-east districts are the most fertile. In the valley between Agen and Bordeaux, the soil, though light, is of an excellent quality. The west and south-west tracts are sandy, marshy, and barren, or indifferently fruitful. The products of the soil are grain, hemp, tobacco, wine and fruits, pastures, considerable forests of pines, stone quarries, mineral springs, &c.

GIRONELLA, a town of Spain, in Catalonia; 7 miles E. N.E. of Sollomana.

GIROVNE. See Giron.

GIROVS, St. a town of France, and principal place of a district, in the department of the Arrons; 21 miles W. of Tarascon. N. lat. 42° 59'; E. long. 1° 13'. The place contains 5854, and the canton 14,953 inhabitants, on a territory of 287¼ kilometres, in 16 communes.

GIROST, a town of Peria, in the province of Kerman; 125 miles S. of Shirjan.

GIROCK, in Ichthyology, the common English name of the fish called the Lucius, a large species of garfish, caught in the Mediterranean and English seas.

GIRONNAY, Girone, in Heraldry, is when a shield or coat is divided into several girons, which are alternately colour and metal.

When there are eight pieces, or girons, it is absolutely said to be gironne; when there are more, or fewer, the number is to be expressed: gironne de four, of fourteen, &c.

Some, instead of gironne, say, pair, couple, tuncle, and taille, because the girons are formed by such divisions of the field. Four girons form a tunic, and eight a croix.

GIRT, in measuring timber, is used for the circumference of a tree. See Goggsfield's Sliding rule and Dendrometer.

Some call the fourth part of the circumference the girt, and fuppose the square of this equal to the area of the section of the tree.

GIRT, in Architecture, the same with fillet. See Fillet.

GIRT, gilt, in Sea Language. See Girdling-girt.

Girt-line is a rope passing through a single block, on the head of the lower masts, to hold up the rigging thereof; this is the first rope employed to rig a ship, and by means of this all the rest are drawn up and fixed; after which it is removed till the ship is to be unrigged.

Girths, of a Saddle, the long straps, made of a canvas stuff called girth-web, which being buckled under the horse's belly, serve to fix the saddle.

GIRTIN, Thomas, in Biography, a draftsman of uncommon capacity, who lately adorned our days, and if he had not been cut off by an early death, would probably have exhibited unrivalled talents in the peculiar branch of the art he adopted. He was born in 1775, and was one of those who have contributed to raise almost a new species of art by the use of water-colours in landscape painting. He drew with a ready hand, in a little entirely his own, and with great taste and effect; though not always with a strict adherence to truth. He died of consumption, brought on by irregularity, at the early age of 27.

GIROVE, in Geography, a town of Peria, in the province of Musanderan; 5 miles E of Pehrubad.

GIRVAN, a sea-port of Scotland, in the county of Ayr, situated at the mouth of the river Girvan, which rises in the N. E. part of the county, and runs into the sea a little below the town. It has a commodious harbour, capable of great improvement. The chief employment of this town, which is a burgh of barony, governed by bailies and councillors, annually elected, is weaving of cotton and woollen cloths. In 1801 the number of inhabitants was 1629, of whom 1360 were employed in trade and manufactures. The neigh-
neighbourhood abounds with limestone and coal; 21 miles
S S W of Avr. N lat 55 18'. W long. 4 44'.

GISARMS, or GUSARMS, in our Old Writers, an hab-
bert or handek; it comes from the Latin bis arm., because
it wounds on both sides. Shen. "El armorum genus
largo manambio et porenta cupide." It is mentioned in
the statute 13 Edw. I. cap. 6.

GISBOROUGH, in Geography, a market town and
parish in the North Riding of the county of York, is feated
near the mouth of the river Tees, 8 miles from Stockley,
and 248 from London. By the population returns, printed
by order of parliament in 1801, this parish contained 538
houses and 1719 inhabitants. In the time of King James I,
some stone mines were discovered here, and were worked
for several years with great success. The bay at the mouth
of the Tees forms a commodious harbour. In this town
was formerly a spacious monastery, of which some consider-
able ruins remain. Here are a weekly market on Friday,
and five annual fairs.

GISCALA, in Scripure Geography, a town of the tribe
of Abieth, in Lower Galilee; S E of Jotapata.

GISMA, in Botany, named by Linnaeus in honour of
his pupil Dr. Paul Dietrich Gilke, professor of Natural
History at Hamburg, and editor of the "Predictriones in Ordines
Naturales Plantarum," compiled from his own notes and that
of Fabrius, taken from the mouth of Linnaeus, and pub-
Goota. v. 3. 67. t. 2. f. 1.)—Cliffs and order, Pentadactyla

Gen. Ch. Cal. Perianth of five ovate, concave, obu-
te, permanent leaves, with membranous edges. Cor. none. Stam.
filaments five, short, awl-shaped, ovate at the base; authors
roundish. Pif. German superior, roundish, retuse, deeply
five-lobed; styles five, short, recurved; stigma obtuse.
Peric. Capsules five, roundish, slightly compressed, rough,
often, clothe together, each of one cell. Seeds solitary, ovate,
smooth.

five, approximated, roundish, sgle-feafed.

Earl-Indies. A smooth annual herb, with the aspect of an
Illecebrum or Pharmacum. The flower are prostrate, a foot
or two in length, furrowed along their upper side, alternately
branched. Leaves opposite,环节ed, ovate, entire, light
green, rather flabby. Flowers small, green, in little axillary
umbels Fruit blackish. On the short axillary branches, the
leaves, as Juciféru well observe, are oppoite. No other
species has been discovered.

GISIO, in Geography, an island on the E. side of the
gulf of Bothnia. N lat 61 42'. E. long. 21 22'.

GISGI, a town of Transylvania, near the Maros; 14
miles S W of Milkenbach.

GISH, a town of Georgia, in the province of Kaka;
115 miles S E of Tiflis.

GISUBEL, a town of Bohemia, in the circle of Ko-
ingenugratz; 22 miles E N E of Konieugratz.

GISING, a town and castle of Hungary; 14 miles
S W of Steinam-Auger.

GISIO, a town of Sweden, in Angermannland, on the
Gides; 16 miles W of Nordmalling.

GISLAVY, a town of Sweden, in the province of Sma-
land; 40 miles S W of Jonkoping.

GISON, or GISIO, in the Jewish Antiquities, a little
wall about breaf high, made round the temple properly fo
called, and the altar of burnt sacrifices, to keep the people
at a distance. Josephus, in his Book of Antiquities, makes
it to be three cubits high; and but one, in his History of the

GISORS, in Geography, a town of France, in the depart-
ment of the Eure, and chief place of a canton, in the dis-
trict of Les Andelys; 27 miles N E of Evreux. The
place contains 3500, and the canton 9496 inhabitants, on a
territory of 1451 kilometres, in 23 communes. N. lat.
49 17'. E. long. 17 50'.

GISINGHEIM, a town of Germany, in the county of
Wertheim; 15 miles S of Wertheim.

GISTAIN, a town of Spain, in Aragon, situated on a
brook in the Pyrenees, on the confines of France, having
in its vicinity mines of coal; 15 miles N of Afnla.

GISTO, a small island in the Adriatic. N. lat 44 36'.
E. long. 14 51'.

GISUND, a town of Norway, in the diocese of Dro-
them; 44 miles N W of Drontheim.

GITHAGO, in Botany, a name used by some authors,
particularly by Pliny, for the lobulum or dama gracilis.
GIT, in Geography, a town of Thibet; 234 miles N E
of Delhi. N lat 32 10'. E. long. 79 56'.

GITPOUR, a town of Mocammpour; 47 miles W S
of Mocammpour.

GITSCHIN, a town of Bohemia, in the circle of Ko-
ingenugratz; 22 miles N W of Konieugratz. N lat 50 23'.
E. long. 15 20'.

GITTITH. This word occurs frequenfly in the Pfalms,
and is generally translated wise-loquent. The conjectures
of interpreters are various concerning this word gittith. Some
think it signifies a fort of musical instrument; others, that
the Pfalms, with this title, were sung after the vintage;
lastly, others, that the hymns of this kind were invented
in the city of Gath. Calmet is rather of opinion, that it was
given to the clafs of young women, or songresses of Gath,
to be sung by them. (Pl. viii. 1. xxxi. 1. xxxiv. 1.) Dr.
Hammond thinks that the Pfalms, with this title, were all
set to the fame tune, and made on Goliah the Gittite.

GIVA, in Geography, a town of Attic Turkey, in Na-
tolus; 32 miles S E of Miletus.

GIVANROTOMO, a town of Naples, in Capitanata;
9 miles W of Monte St. Angelo.

GIUDEL, a small island, near the south coast of Sar-
dinia. N. lat. 39 1'. E. long. 9 3'.

GIUDUCCA, L. A. or LIEUCCA, one of the islands ad-
joining to the city of Venice, which is said to owe its name
to the Jews, who formerly refided there. It contains 10
churches, 4 monasteries, and as many nunneries.

GIVEN, DATUM, a term very frequently used in Ma-
thematics, signifying a thing which is supposed to be known.
Thus, if a magnitude be known, or we can find another
equal to it, we say, it is a given magnitude, or that such a
thing is given in magnitude.

If the position of any thing be supposed as known, we
call it given in position.

Thus, if a circle be actually decribed on a plane, its cen-
tre is given in position, its circumference given in magnitude,
and the circle is given both in position and magnitude.

A circle may be given in magnitude only, as when only
its diameter is given, and the circle not actually decribed.

If the kind or species of any figure be given, they say,
given in specie. If a ratio between any two quantities is
known, they are said to be given in proportion. See Data.

GIVET, in Geography, a town of France, in the depart-
ment of the Ardenes, and chief place of a canton, in the
district of Rocroy; 15 miles N E of Rocroy. N lat 50 7'.
E. long.
GIU

E. long. 4° 51'. The place contains 3533, and the canton 8445 inhabitants, on a territory of 150 kilometres, in 29 communes.

GIUF, Lj, a district of Arabia, in the province of Nedjed; E. of mount Ramleh.

GIULA, a town of Hungary, situated on the river Keres; 52 miles N. N. W. of Temeswar. N. lat. 40° 35'. E. long. 20° 55'.

GIULAB, a town of Abashe Turkey, in the government of Diarbekir; 18 miles N. E. of Ourfa.

GIULEN', a small island in the Caspian sea; 130 miles S. of Afrachan. N. lat. 44° 15'. E. long. 47° 49'.

GIULIA Neoven, a town of Naples, in Abruzzo Ultra, on the coast of the Adriatic; 12 miles E. N. E. of Teramo.

GIULLA, St. a town of France, in the department of the Sura; 12 miles S.G.W. of Acquit.

GIULIANO, Sr. a mountain of Etruria, near Pisa, at the foot of which are warm baths, known in the time of Pliny.—Albo, a town of Naples, in Capitanata; 9 miles W.S.W. of Dragonera.—Allo, a town of Naples, in the county of Molife; 13 miles S.E. of Molife.—Albo, a town of Naples, in the province of Ortona; 17 miles S.S.W. of Brindisi.—Albo, a town of Italy, in the department of the Omon; 7 miles S.E. of Milan.

GIVORS, a town of France, in the department of the Rhone, and chief place of a canton, in the district of Lyons; 12 miles S. of Lyon. The place contains 5265, and the canton 19,590 inhabitants, on a territory of 97 kilometres, in 13 communes.

GIVRY, a town of France, in the department of the Saone and Loire, and chief place of a canton, in the district of Chalon-sur-Saone; 4 miles W. of it. N. lat. 48° 47'. E. long. 4° 50'. The place contains 2582, and the canton 11,405 inhabitants, on a territory of 132 3/4 kilometres, in 19 communes.

GIUSEPE April. See TENDUCCI.

GIUSEPE ARENA, in Biography, an able composer of Naples, whose style had much of the brilliancy of that school. In 1741 he set the serious drama of Tigrane, written by Goldoni, to music, for the great theatre of St. John Chry- fitosom, at Venice, which established his character.

GIUSMARK, in Geography, a town of Curtidjan; 80 miles S.S.E. of Batlis.

GIUSTENDIL, a town of European Turkey, in Bulgaria; 24 miles S. of Sophia.

GIUSTINELLI, in Biography, a second-rate Italian singer in soprano, arrived here, in 1762, with De Amicis and her family, as first serious man in the burletta operas. He had a good voice, and sufficient merit to supply the place of second man on our stage, in the serious operas, for several years after.

GIUSTINIANI, AUGUSTIN, was born at Genoa in 1470, was educated for the church, and in 1514 was made bishop of Nebbio in Corsica. He published, in 1516, a Pflater in four languages, viz. the Hebrew, Greek, Arabic, and Chaldean, with interpretations: this was the first of the Polyglott editions of the books of scripture. After this, he was invited by Francis I. to Paris, and appointed to the professorship of the Oriental languages in that university, an office which he held about five years. During this period he received a pension from the crown, and was enabled to collect a very choice library, which he afterwards presented to the republic of Genoa. In the year 1536, in passing by sea to his bishopric, he was lost with his ship. This prelate revised and edited the treatise written by Porcheti, entitled "Victoria adversus impios Judaeos." Some time after his death, were published his "Annals of the Republic of Ge- noa," from the foundation of the city, to the year 1528: this work is highly esteemed for its information, and for the veracity of the facts. Moreri.

GIUSTINIANI, BERNARDI, a Venetian nobleman, born in 1408, was educated under the most learned persons of his time, and obtained a high celebrity for his own knowledge and eloquence. He was employed on several honourable occa- sions by the republic. In 1451 he was appointed to receive the emperor Frederic III when he passed through the Venetian territories. He was afterwards elected as a fit person to be sent on embassies to Ferdinand, king of Naples, to several of the popes, and to Lewis XI, king of France, who honoured him with knighthood. In 1467 he was made captain-general of Padua, and admitted to almost all the honours of the state, and finally procurator of St. Mark. He died in 1480. He was author of many works: as public orations: the life of his uncle "The blessed Lorenzo Giustinianii"; three pieces on the life, the translation, and the appearance of St. Mark: a version of the book of Socrates to Niccolis; some Latin letters of his father Leonor; and the ancient history of Venice, written in Latin. This last was translated into Italian by Lodov. Domenichi. It was the work of his old age, and is highly esteemed, because the authorities are drawn from the best sources, and the author rejects the fables handed down by some other writers. Moreri.

GIZE', GIZAI, or Jiza, in Geography, a considerable town of Egypt, extending along the west bank of the Nile, on the other side of the island of Kouda, or Raonda, with respect to Cairo; 3 miles S. W. of Cairo. This town was fortified by Imam Bey, who also built a palace there, completed and finished by Murad Bey, who has established a cannon foundry. Here is also a manufacture of sal ammoniac. The walls of Giz are of great extent, and have only one gate to the country; they are ten feet high, three feet thick, and have six half-moons; but are only fit to repel cavalry, the original intention in building them. Murad Bey has suffered the iron-work about the loop-holes to be plundered or ruined. The palace is in the southern quarter of the city, close to the water; it has numerous apartments for the Mamluks, and every convenience for cafe or luxury. Murad Bey has, of late years, thought it necessary to substitute a marine, having purchased some vessels of the Europeans, and built three or four others. The largest of these vessels carries 24 guns; those that are occasionally moored before Giz cannot be navigated hence, except during the time of the Nile's increase. The mariners are chiefly Greeks of the Archipelago. Not far south of Giz is "Geziret-el-dahah," a small island, which Diodorus Siculus denominated "Venus Auroa." N. E. of the city are gardens, and some spacious houses, occupied by the affluent and great, who occasionally leave the city to amuse themselves in this retreat; and they have there an open space where the Mamluks perform their military evolutions, and exercise their horses. The ground under the mountains to the east is filled with tombs. The mountain is of white sand and calcareous stone, and delittu of verdure. The numerous date-trees by which Giz is surrounded, interpenetrated with the lofty turrets of the mosques, and the river, whose waves wash the very foundation of the houses, give it, at a distance, a very pleasing aspect. Dr. Shaw is of opinion, that the ancient Memphis stood on the site of Giz; but this is disputed by Savary and others. (See MEMPHIS.) This is the nearest spot, says Sennini, to the most valuable monuments which ancient Egypt has left behind of her glory and her power. The nearest pyramids are at the distance of three leagues, and they are indiscrimi-
nately called the "Pillars of Memphis," or the "Pillars of Giz". This town was taken from the French by the Brit- 
his June, 1801. Browne's Travels in Africa; Savary's Letters on Egypt, vol. i. Sommii's Travels in Upper and 
Low Egypt.

GIZIGNSKAIA, a gulf at the N. W. extremity of 
the Psenndoi sea, extending about 50 miles in length, and 16 
breadth. M. lat. 67 to 68. E. long. 160 14'.

GIZZARO of Birds. See Anatomy of Birds.

GIZZIELLO, Gioachino, Conti, in Biography, one of 
the greatest Italian singers of the last century, arrived in 
England in 1756, as Handel's first singer, at the time that he 
had quitted the Royal Academy in the Haymarket, upon a 
quarrel with Samphire, and set up for himself at the new the- 
atre in Covent Garden. The nobility and gentry who seem 
-to have abetted Samphire, engaged for the Handel 
Haymarket Porpora as a composer, and Farinelli, Cazzoni, and 
complete company of vocal and instrumental performers to 
oppo he. Handel, May 5th, opened his summer cam- 
paign with the revival of "Ariodante," an opera of the pre- 
ceding year.

The next day the following eulogium on his new finger 
was inserted in the Daily Poet: "last night Signor Gio- 
chino Conti Gizzuelo, who made his first appearance in 
the opera of "Ariodante," met with an uncommon reception; 
and in justice both to his voice and judgment, he may be truly 
commended one of the best performers in this kingdom. Ne- 
ather his friends nor the friends of Handel could ventute to 
fare more, while Farinelli was in the kingdom. Conti was 
at this time a young singer, more of promising, than mature 
abilities; and to modell and difficult, that when he first heard 
Farinelli, at a private rehearsal, his heart burst it tears, and 
fainted away with despondency. He had been confraternized 
Gizzuelo from his master, Gius, once an eminent flage 
singer, who, in his old age, became an excellent master.

The next opera in which Conti appeared, was "Ata- 
lanta," composed as an epithalamium on the marriage of his 
royal highness Frederic prince of Wales, with his serene 
ligeous the princes of Saxo-Gotha. The casts in "Atalanta," which Handel composed expre- 
ply for his new finger, Conti, feem, upon examination, 
to have been written in his new, graceful, and pathetic stye 
of singing. The hals and accompaniments, too, are of 
a modern cast, and, except the closes and two or three of the 
divisions, the whole feems of the present age.

Handel, till now ill, had a first man to write for which 
so high a soprano voice. Nicollini, Samphire, and Carefelli, 
were all contraltos. There was often dignity and spirit in 
their style; but Conti had delicacy and tenderness, with the 
accumulated refinements of near thirty years, from the time 
of Handel's first tour to Italy. We think it is not difficult to 
discover, particularly in the first act, that in composing 
Conti's part in this opera, he modelled his melody to the school 
of his new finger. Indeed, Handel was always remark- 
ably judicious in writing to the tale and talents of his 
performers in displaying excellence, and covering imperfec-
tions.

While Conti was his first male singer, and the Strada his 
first woman, he revived his opera of "Alceina and Farandoni," 
and composed his part in the opera of "Arminio," expressly 
to display his peculiar talents; in the airs of which it feems 
as if Handel had more busses and accompaniments in iterated 
notes, than in any preceding work.

He was advancing rapidly in the modern style of opera 
songs when he quitted the stage, and retreated back to a 
more elegant and ballad style for the church.

GLA

It is chiefly in writing for Conti and Anibali, that the con- 
formity to a different style from his own appears.

DOMENICO ANIBALI, who should have had an article in 
the letter A, had he been remembered, shall be characterized 
here, in apology for the omission. His first air in the opera 
of "Arminio," in which he performed with Conti and the 
Strada, discovers his voice to have been a contralto, which 
Handel gave him an opportunity to display by a farewell, ad 
bidding, at the beginning; but no peculiar taste, expression, 
or powers of execution, appear in his part; his bravura air 
in the second act, St. cedus, contains only common and easy 
passages. His abilities during his stay in England seem to 
have made no deep impression, as we never remember him to 
have been mentioned by those who constantly attended the 
operas of those times, and were rapturized in speaking of the 
pleasure which they had received from fingers of the first clafs.
But to return to Conti, who, after he quitted England, stud- 
ed with such diligence, that being engaged at Madrid to 
sing in the opera under the direction of Farinelli, he turned 
the tables on that wonderful finger, in whom it has been 
said, that he excited envy by his new and refined taste and 
patios.

He was one of the constellation of great fingers which the 
king of Portugal had assembled together in 1755.

There were, according to Pacchi rotto's account, Elfi, 
Manzelli, Cialarelli, Gizzuello, Veroli, Batti, Luciani, Raef, 
Raina, and Guadagni. No females were then allowed to 
appear on the opera stage in Portugal. Gizzuello, narrowly 
escaping with his life during the dreadful earthquake which 
happened at Lisbon that year, was impressed with such a 
religious turn by that tremendous calamity, that he retreated 
in a monastery, where he ended his days. It was soon after 
this event, that Guadagni find himself up in the fame con- 
vent not so much for spiritual consolation as for musical 
counsel; which he so effectually obtained from the friendship of 
Gizzuello, that from a young and will finger of the second 
and third clafs, he became, in many respects, the first finger 
of his time.

GLABALK, in Geography, a town of France, in the 
department of the Dyle, and chief place of a canton, in the 
district of Louvain. The place contains 230, and the 
canton 67,71 inhabitants, on a territory of 120,000 ofare, in 
19 communes.

GLABELLA, in Anatomy, from glaber, smooth; the 
space between the two eye-brows, which is ordinarily not 
covered with hairs.

GLABER, in Biography, a Benedictine monk, who 
founded in the 11th century, and who has rendered his name 
memorable by a "Chronicle or History of France," 
written in the Latin language. It consists of five books, of 
which the first relates to the events of the monarchy pre- 
vioius to Hugh Capet, and the four subsequeute to 
three following it, as far down as the year 1046. 
This work is defective as a composition, and, at the same time, 
full of fabulous stories, yet it contains much valuable information 
relative to those remote ages. He was author of a life of William, abbot of St. Benignus at Dijon. 
Moreni.

GLABRARIA, in Botany, so denominated by Lin- 
neus, on account of the smooth, shining, silky appearance of

half as long as the corolla, cut half way down into five equal 
webu
GLACIALIS. Ice, or glaciers, is, something relating to ice; and particularly a place that abounds in ice.

We thus lay, the Marc Glacier, or Congladium, that is, the ice or frozen sea; called also the Chthonian or Sarumian sea.

GLACIERS, a denomination applied to large sheets or fields of ice among the Alps, and which are numerous in Switzerland and Savoy. Of these there are five, that stretch towards the plain of Geneva, and unite at the foot of Mont Blanc; they are called Tacona, Boloni, Montanvert, Argenburi, and Tour. The origin of these glaciers, extending into fields of corn and pasture, and lying, without being melted, in a situation where the heat of the sun is powerful enough to bring vegetation to maturity, is a very curious subject of investigation. Mr. Coxe has given us an abstract of the theory of Gruner, with regard to their formation, and other particulars respecting them, confirmed and amended by that able naturalist Saussure; which appears, upon the whole, to be the most simple and natural. If a person, says this interesting traveller, could be conveyed to such an elevation as to embrace, at one view, the Alps of Switzerland, Savoy, and Dauphiné, he would behold a vast chain of mountains, intersected by numerous valleys, and composed of many parallel chains, the highest occupying the centre, and the others gradually diminishing in proportion to their distance. The most elevated, or central chain, would appear bristled with pointed rocks, and covered, even in summer, with ice and snow, in all parts that are not perpendicular. On each side of this chain lie would discover deep valleys clothed with verdure, peopled with innumerable villages, and watered by many rivers. In considering these objects with greater attention, he would remark, that the central chain is composed of elevated peaks and diverging ridges, whose summits are overspread with snow; that the declivities of the peaks and ridges, excepting those parts that are extremely steep, are covered with snow and ice, and that the intermediate depths and spaces between are filled with immense fields of ice, terminating in those cultivated valleys which border the great chain. In pursuing this general survey, and moreover observing that the branches most contiguous to the central chain would present the same phenomena, only in a lesser degree; the glaciers would be obviously divided into two sorts; the first occupying the deep valleys situated in the bottom of the Alps, and termed by the natives "Valées de Glace," distinguished by Mr. Coxe by the name of "Lower Glaciers." These lower glaciers do not communicate with one another, and few of them are parallel to the central chain. They mostly stretch in a transverse direction, being bordered at the higher extremity by inaccessible rocks, and on the other extending into the cultivated valleys. Saussure found the general depth of the ice in the glacier des Bois from 82 to 100 feet; but there is reason to believe that its thickenings in some places exceed even 625 feet. These immense fields of ice usually rest on an inclined plane; being pushed forwards by the pressure of their own weight, and weakly supported by the rugged rocks beneath, they are intersected by large transverse chains, and present the appearance of walls, pyramids, and other fantastic shapes, observed at all heights and in all situations, wherever the declivity exceeds 33 or 40 degrees. But in those parts, where the plane on which they rest is nearly horizontal, or gently inclined, the surface of the ice is nearly uniform; the chains are few and narrow, and they are crooked without much difficulty. The surface of the ice is less slippery than that of ponds or rivers; it is rough and granulated, and only dangerous to those who pass it in deep defiles. It is not transparent, is very porous, and full of small bubbles, and is of course less compact than common ice. Its perfect resemblance to the congladion of snow impregnated with water, in opacity, roughness, and the number as well as fluidness of the air-bubbles, led Saussure to conceive the following simple and natural theory concerning the formation of the glaciers. An immense quantity of snow continually accumulates in the elevated valleys enclosed within the Alps, as well from that which falls from the clouds during nine months in the year, as from the mists incessantly rolling from the steep sides of the circumjacent mountains. Part of this snow, not dissolved during summer, impregnated with rain and snow-water, is frozen during winter, and forms that opaque and porous ice of which the "Lower Glaciers" are composed. The "Upper Glaciers" may be subdivided into those which cover the summits, and those which extend along the sides of the Alps. The former owe their origin to the snow that falls at all seasons of the year, and which remains nearly in its primitive state, being congealed into a hard substance, and not converted into ice. The substance which clothes the sides of the Alps is neither pure snow, like that of the summits, nor snow which forms the Lower Glaciers, but an assemblage of both. It contains less snow than the summits; because the summer heat has.
has more power to dissolve it, and because the liquefied snow descending from above, the mass absorbs a larger quantity of water. It contains more snow than the Lower Glaciers, because the dissolution of the snow is comparatively late. Hence the ice is even more porous, opaque, less compact than that of the Lower Glaciers, and of so doubtful a texture, as renders it, in many parts, difficult to decide, whether it may be called ice or frozen snow. In a word, there is a regular gradation from the snow on the summits to the ice of the Lower Glaciers, formed by the intermediate mixture, which becomes more compact and less porous in proportion as it approaches the Lower Glaciers, until it unites and assimilates with them. And it is evident, that the greater or lesser degree of density is derived from the greater or lesser quantity of water, with which the mass is impregnated.

It has been a contested point among naturalists, whether the glaciers are in a state of increase or diminution. The following observations may be alleged in proof of the latter alternative. In 1785, the inferior glacier of Grindelwald was diminishing at least 400 yards since the year 1776; in the valley of Chamouny, the glaciers called "les marmailles de glace," from their resemblance to walls, and which rise in very thick, solid, parallel ranges to a height of 150, or, as some say, 400 feet above their real base, and forming the border of the glacier of Boffon, no longer existed, and young trees had shot up in the parts which were then covered by the glaciers of Montanvert. The advocates for the increase of the glaciers, notwithstanding these facts, applicable, as they say, to the lower regions, assert, both from theory and observation, that more snow falls, and more ice is annually formed in the Alps than can be annually dissolved. From theory they argue, that the cold occasioned by the mass of ice already formed ought to augment it still further; and from experience they deduce, that within the remembrance of the present generation, many mountains have been covered, many pastures and habitats invaded, and many passages irrecoverably obstructed by the ice. In reply to the argument from theory it is maintained, that the causses which lead to the diminution of the ice are not less powerful than the augmentation of the cold, which is supposed to occasion its indefinite increase. These causses are principally rain and snow in the lofty elevated regions, evaporation, defeat of the snow and ice, both precipitous and gradual, heat of the atmosphere, and mean temperature of the earth, which is always above the freezing point, as is evident from the heat of the springs which issue from the bowels of the earth. With regard to the argument derived from experience, it is thought sufficient to observe, that while the facts that prove the progress of the ice are admitted, it by no means seems to follow, that its mass is perpetually increasing. For the advocates of this opinion, while they scrupulously enumerate the places which have been invaded by the ice, do not take notice of these facts, no less numerous, from which the ice has receded. Upon the whole we have reason to conclude, that if the collection of ice and snow gains in some places, it is diminished in others, and that, upon an average, the aggregate quantity is nearly the same. Coxe's Travels in Switzerland, vol. ii. GLACIES MARLE. See Specularis Lapis.

GLACIS, in Building, an easy inflexible slope or declivity. The descent or inclination of the glacis is less steep than that of the talus. In gardening a descent sometimes begins in talus, and ends in glacis.

The glacis of the corniche is an easy imperceptible slope in the cymatium of the corniche, to promote the descent and draining off of the rain-water.

GLACIS, in Fortification, is particularly used for that of the counterescarp, being a sloping bank, which reaches from the parapet of the counterescarp, or covert-way, to the level side of the field, at the distance of about twenty fathoms.

The construction of the covert-way and glacis is more distinctly illustrated in Plate V., Fortification, fig. 6. When the body of the place, and all the necessary out-works are constructed, lines are drawn parallel to the outermost counterescarp of the ditches, at six toises distant from it; and the space \( \times \times \times \), included between that line and the counterescarp, will be the covert-way required. If lines are drawn parallel to the lines which terminate the covert-way, and the places of arms \( \times \times \), at twenty toises distant from them, the space \( \times \times \times \), between these lines will be the glacis. As in this figure, represents the arrow; \( \times \), the detached redoubt; \( \times \times \), the traverses; \( \times \times \times \), the full-ports. When the ground is low, and water to be found, there is often a ditch of about ten or twelve toises made round the glacis; beyond which there is a second covert-way of four toises, with traverses and places of arms, and a second glacis from fifteen to eighteen toises broad. Muller's Fort. p. 42.

See Military Construction.

GLADBACK, or GLADBACH, in Geography, a town of Germany, in the circle of Weilphalia, and duchy of Juliers; 16 miles N. of Juliers. N. lat. 51° 14'. E. long. 6° 15'.

GLADDON, or GLADWIN, the name of a plant, otherwise called pursue-wort.

GLADE, in Agriculture, Gardening, &c. a vilia, or open and light passage made through a thick wood, grove, or the like, by lopping off the branches of trees along the way.

GLADE, in Zoology. See GLAD.

GLADENBACH, in Geography, a town of Germany, in the principality of Upper Hesse; 12 miles N. of Gießen.

GLADIATORS, in Antiquity, persons who were retained to fight ordinarily in the arena, for the entertainment of the people.

The gladiators were usually slaves. and condemned criminals, who fought from necessity; though, sometimes, free men made profession of this practice, like our prize-fighters, for a livelihood. After a slave had served on the arena three years, he was dismissed.

The Romans borrowed this cruel diversion from the Aetaciscs: some suppose that there was policy in this practice, the frequent combats of gladiators tending to accustom the people to despise danger and death.

The origin of such combats seems to be as follows: From the earliest times with which we have any acquaintance with profane history, it had been the custom to sacrifice captives, or prisoners of war, to the names of the great men who had died in the engagement; thus Achilles, in the Iliad, lib. xxiii. sacrifices twelve young Trojans to the names of Parados; and in Virgil, lib. xi. ver. 81. Augustus sends captives to Evander, to be sacrificed at the funeral of his son Pallas.

In course of time they came also to sacrifice slaves at the funerals of all persons of condition; this was even esteemed a necessary part of the ceremony; but, as it would have appeared barbarous to have sacrificed them like beasts, they were appointed to fight with each other, and encourage to save their own lives by killing their adversaries. This seemed somewhat less inhuman, because there was a possibility of avoiding death by an exertion of skill and courage.

This
This occasioned the profession of gladiator to become an art; hence profane masters of arms, and men learned to fight and exercise this art.

These matters, whom the Latins called lanificii, bought slaves to be trained up to this rude trade, whom they afterwards sold to such as had occasion to prevent the people with so horrible a show.

They were at first performed near the sepulchre of the deceased, or about the funeral pile, but were afterwards removed to the circus and amphitheatres, and became ordinary amusements. See BUSTUARI.

The first show of gladiators, called munus gladiatorum, was exhibited at Rome, according to Valerius Maximus, by M. and D. Brutus, upon the death of their father, in the year of the city 488; though Livy (ix. 40) speaks of it in the 444th year of Rome, as practiced among the Campanians. On the exhibition by M. and D. Brutus, there were probably only three pairs of gladiators: in the year of Rome 537, the four sons of M. Emilius Lepidus the augur, who had been three times consul, entertained the people with the cruel pleasure of seeing twenty-two gladiators fight in the forum; and the show continued three days. In the year of Rome 547, the first Africanus diverted his army at New Carthage with a show of gladiators, which he exhibited in honour of his father and uncle, who had begun the reduction of Spain. In the 552d year the sons of M. Valerius Lavinus exhibited 25 pairs of gladiators; and in 569, 73, and 578, 74 fought on the like occasion. In precedes of time, the Romans became to fond of these bloody entertainments, that not only the heir of any great and rich citizen lately deceased, but all the principal magistrates, prevailed the people with shows of this nature, to procure their affection.

The audles, pretors, consuls, and, above all, the candidates for offices, made their court to the people, by entertaining them frequently with these fights: and the priests were sometimes the exhibitors of the barbarous shows; for we meet with the ludi pontificales in Suetonius, August. cap. 44, and with the ludi sacerdotales, in Pliny, Epil. ii. 77. As for the emperors, it was so much their interest to ingratiate themselves with the populace, that they obliged them with combats of gladiators almost upon all occasions, and as these increased, the number of combatants increased likewise. Accordingly, Julius Caesar, in his adileship, diverted the people with three hundred and twenty couple. Gordian, before he was emperor, gave these shows twelve times in a year. In some of these there were 500 pairs of gladiators, and never less than 50.

Germanicus and Claudius, both sons of Drusus, gave combats of gladiators in honour of their father. Nero's and Domitius's combats of gladiators are noticed in the last of this article. Otho employed 2000 gladiators in the war against Vitellius (A.D. 69), and Vitellius hired gladiators to fight in all the streets of Rome for the amusement of the people. The inhuman sights of gladiators, though long authorized by custom, afforded no pleasure to Vespasian. Titus, however, exhibited a show of gladiators, wild beasts, and representations of sea-fights, which lasted a hundred days; and Trajan continued a solemnity of this nature for a hundred and twenty-three days, during which time he brought out ten thousand gladiators. And Adrian, on his first visit to Rome, after his promotion to the empire, gave combats of gladiators for forty days the following winter. Before this time, under the republic, the number of gladiators was very great; that when the conspiracy of Catiline broke out, the Senate ordered them to be dispersed into the garrison and secured, lest they should have joined the disaffected party. See GLADIATORS' WAR.

These sports were become so common, and their consequences, in a variety of respects, so dangerous, that Cicero preferred a law, that no person should exhibit a show of gladiators within two years before he appeared candidate for any office. Julius Caesar ordered, that only a certain number of men of this profession should be in Rome at a time. Augustus decreed, that only two shows of gladiators should be presented in a year, and never above fifty couples of combattants in a show. And Tiberius provided by an order of Senate that no person should have the privilege of gratifying the people with such a solemnity, unless he was worth four hundred thousand sesterces. They were also considerably regulated by Novus.

The emperor Claudius restrained them to certain occasions; but he soon afterwards annulled what he decreed, and private persons began to exhibit them at pleasure, as usual; and some carried the brutal satisfaction too far, as to have them at their ordinary feasts.

And not slaves only, but other persons, would hire themselves to this infamous office.

The matter of the gladiators made them all first swear, that they would fight to death; and if they failed, they were put to death, either by fire, or swords, clubs, whips, or the like.

It was a crime for the wretches to complain when they were wounded, or ask for death, or seek to avoid it, when overcome; but it was usual for the emperor, or the people, to grant them life, when they gave no signs of fear, but waited the fatal stroke with courage and intrepidity: Augustus even decreed, that it should always be granted them. But fear and want of spirit were very rare on occasions of this kind; infamously, that Cicero more than once proposes the principle of honour which actuated the gladiators as an admirable model of courage and constancy; by which he intended to animate himself and others, to suffer every thing for the preservation of liberty and the defence of the commonwealth. (Tufc. ii. 1.)

From slaves and freedmen, the inhuman sport at length spread to people of rank and condition; so that Augustus was obliged to issue a public edict, that none of the senatorial order should become gladiators; and soon after he laid the same restraint on the knights; nevertheless, Nero is related to have brought upwards of four hundred senators, and six hundred Roman knights upon the arena; though Lippius takes both those numbers to be falsified, and, not without reason, reduces them to forty senators, and sixty knights. Not only senators, but even women of quality, fought in public in some of Nero's combats of gladiators. On occasion of the triumph of Probus, A.D. 281, about fourteen thousand gladiators, together with near 600 others, exhibited the most desperate courage, for the inhuman sports of the amphitheatre. Dismaying to flay their blood for the amusement of the populace, they killed their keepers, broke from the place of their confinement, and killed the streets of Rome with blood and confusion. After an obstinate resistance, they were overpowered and cut in pieces by the regular forces; but they obtained at least an honourable death, and the satisfaction of a just revenge (Zosimus, B. i. p. 65.); yet Domitian, that other monster of cruelty, relented upon Nero, exhibiting combats of women in the night-time.

Before Rome was become the capital of the known world, Antiochus Epiphanes, king of Syria, in imitation of the Romans, had introduced the combats of gladiators in his dominions. It is remarkable, however, that the Athenians, who were naturally beneficent and humane,
never admitted bloody shows into their city; and when it was proposed to establish combats of gladiators there, in order not to give place in that respect to the Corinthians, "First throw down," exclaimed an Athenian in the midst of the assembly, whose name was Demosthenes, a famous phi-
losopher, who flourished in the reign of Marcus Aurelius, "the altar which our forefathers above a thousand years ago erected to Mercy."

Some Persian emperors, lamenting the sad effects of this savage custom, endeavoured, as we have already seen, to moderate it. With this view Marcus Aurelius restrained the enormous expenses employed in these combats, and would not suffer the gladiators to fight with each other, except with very blunt swords, like foils; so that they might shew their address, without any danger of being killed. But the honour of suppressing these combats was reserved for Christi-
nanity; and it cost many efforts and much time to effect this purpose; so rooted was the evil, and so much had it established itself by the long preoccupation of many ages, and the opinion of the world, that these combats were accept-
able to the gods, to whom, for that reason, they offered the blood of gladiators lately shed, by way of sacrifice, as several of the Christian fathers observe.

Constantine the Great is said to have first prohibited the combats of gladiators in the East; at least, he forbade those who were condemned to death for their crimes to be em-
ployed; there being an order still extant to the prefectus praetorii, rather to fend them to work in the mines in lieu thereof; it is dated at Berytus, in Phoenicia, the 18th of October, 325.

But, notwithstanding this edict, which condemned the art and amusement of shedding human blood, the benevolent law exaimed the wishes of the prince, without reforming an inveterate abuse, which degraded a civilized nation below the condition of savage cannibals. Several hundred, perhaps several thousand, victims were annually slaughtered in the great cities of the empire; and the month of December, more peculiarly devoted to the combats of gladiators, still exhibited to the eyes of the human people a grateful spectacle of blood and cruelty. Amidst the general joy of the victory at Pollentia, gained by the emperor Honorius, Prudentius, a Christian poet, exhorted the emperor to extir-
pate, by his authority, the horrid custom which had so long reftilled the voice of humanity and religion. The pathetic repre-
sentations of Prudentius were not effectual than the generous 
holdness of Telemachus, an Asiatic monk, whose death was 
more useful to mankind than his life. The Romans were 
provoked by the interruption of their pleasures; and the rath 
munk, who had defended into the arena, to separate the 
gladiators, was overwhelmed under a flower of flowers. But 
the madness of the people soon fubducted; they respeeted the 
memory of Telemachus, who had deferved the honours of 
martyrdom; and they submitted, without a murmur, to the laws of Honorius, which abolished for ever the inhuman 
facrices of the amphitheatre. The citizens, who adhered 
to the manners of their ancestors, might perhaps inominate, 
that the last remains of a martial spirit were prefered in 
this school of fortitude, which encouraged the Romans to 
the fight of blood, and to the contempt of death—a vain 
and cruel prejudice, to beoly confuted by the value of an-
cient Greece, and of modern Europe.

It must be observed, however, that the practice was not 
totally abolished in the West before Theodoric, king of the 
Ostrogoths. Honorius, on the occasion first mentioned, had 
prohibited them; but the prohibition does not seem to have 
been executed. Theodoric, in the year 520, abolished them 
finally.

Some time before the day of battle, the person who pre-
fented the people with the shows gave them notice thereof, by programmata, or bills, containing the names of the 
gladiators, and the marks whereby they were to be dif-
tinguished; for each had his peculiar badge, which was, most 
commonly, a peacock's feather, as appears, from the Schol-
sia of Juvenal, on the 158th verse of the third Satire, and 
Tunuebus Adverf. lib. ii. cap. 8.

They also gave notice what time the shows would last, and how many couples of gladiators there were; and it even appears, from the 52d verse of the seventh Satire of the second book of Horace, that they sometimes made 
representations of these things in painting, as is prac-
ticed among us by those who have any thing to show at 
airs.

The day being come, they began the entertainments by bringing two kinds of weapons; the first were swords, or wooden files, called rudes; and the second were effective 
weapons, as swords, poniards, &c.

The first were called arma inuerio, or exercitio; the se-
cond decuritaria, as being given by decree or sentence of the 
prætor, or of him at whose expense the spectacle was exhibited. They began to fence or skirmish with the first, which was to be the prelude to the battle; and from 
these, when well warmed, they advanced to the second, 
at the sound of the trumpets, with which they fought naked.

Then they were laid versus armis; the terms of striking 
were potece et repetere; of avoiding a blow, evite; and 
when one of the combatants received a remarkable wound, 
his adversary or the people cried out, habes, or hoc habes.

The first part of the engagement was called annalizes, 
praetorii; and the second, decuritaria ad certum, or victis 
armis injure; and some authors think, with much proba-

dility, that it is to these two kinds of combat that St. Paul 
alludes, in the passage 1 Cor. ix. 26, 27. "I fought, not as 
one that beateth the air; but I keep my body, and bring it 
to subjection."

If the vanquished surrendered his arms, it was not in 
the victor's power to grant him life; it was the people during 
the time of the republic, and the prince or people during the 
time of the empire, that were alone empowered to grant the 
boon.

The reward of the conqueror was a branch of palm-tree, 
and a sum of money, probably collected among the spectacles; 
sometimes they gave him his congé, or dímmíssus; by 
putting one of the wooden foils or rudis in his hand; and 
sometimes they even gave him his freedom, putting the 
pikeus on his head.

The fign or indication whereby the spectatots shewed 
that they granted the favour, was premere pollieem, which 
M. Dacier takes to be a clenching of the fingers of both 
hands between one another, and holding the two thumbs 
upright, close together; and, when they would have the 
combat finished, and the vanquished slain, they vestivertis 
pollieem, bent back the thumb; which we learn from Juve-
nal, Sat. ii. ver. 36.

"Munera nunc edam, et verbo pollicie vulgi 
Quemlibet occidere populariter."

The gladiators challenged or defied each other, by shewing 
the little figner; and, by extending this, or some other, 
during the combat, they owned themselves vanquished, and 
begged mercy from the people; "Violi offendam digitii ve-
nianis a populo pollubant," says the old Scholastic on Per-
Politian.
GLA

There were divers kinds of gladiators, distinguished by their weapons, manner, and time of fighting, &c. as, the andabates, of whom we have already given an account under ANDABAT.

The caturarai, who always fought in troops or companies, number against number; or according to others, who fought promiscuously, without any certain order. Lipp. lib. ii. cap. 16.

The confonmati, whom authors mention as a species of gladiators, the fame with the radiarii and veterani; founding the opinion on a passage in Pliny, lib. viii. cap. 7. But Lippus thinks that the have mistaken Pliny. Saturn. lib. ii. cap. 16, and Turneb. Adverf. lib. xxx. cap. 35.

The cubicularia, which are a little precurious, being chiefly founded on a passage in Lampridius, in the life of the emperor Commodus: "Inter hire, habitu victoriiarn, victimas immolavit, in arena radibus, inter cubicularia; gladiatores paginant lucentibus aliquando mucronibus."

Turnebus reads radiarius instead of cubicularia: and understands it of those who had been disfigured, and could no longer be obliged to fight, except with foils.

Salmasius reads gladiator; and refers it to the emperor, who fought not only on the arena, and with foils, but also with blunted instruments, but at home, with his servants and valets de chambre, and with thumps.

Lippus will have nothing altered in the text: the gladium, or armis cubiculairis, he observes, were those who fought at private houses, during feasts, &c. Accordingly, Dion says expressly, that Commodus sometimes fought at home, and even killed some persons in such revellings; but that, in public, he only fought with blunted weapons.

The dunaga, who fought armed with two poniards, or swords; or with sword and dagger. Lipp. Saturn. lib. ii. cap. 13.

The affedarii, who fought in cars; called also, in an inscription lately discovered at Lyons, affedaria. Saturn. lib. ii. cap. 13.

The sículo, or Cafariosi, who belonged to the emperor's company; and who, being more robust and dexterous than the rest, were frequently called for, and therefore named allo postulatini. Lipp. lib. ii. cap. 16.

The other kinds were, the lophmaci, meridiani, myrmilloi, ordinarii, pinicarii, procuciones, retiarii, radarii, Samiti, scutarii, scipiatarii, and Thraci; which see described under NERIDIANI, RITARI, SECUTARI, &c.

Some authors, and particularly Vigenere on Livy, rank the obsoleti, or obsolete, as mentioned by Spartan, in his life of Marcus Aurelius, among the number of gladiators; Lippus ridicules him, Saturn. lib. ii. cap. 13, and with some reason: the obsolete properly were the troops which that emperor raised among the gladiators; or whom of gladiators he made soldiers.

GLADIATORS' war, bellum Gladiatorum, or Spartaeanum, called also the servile war, was a war which the Romans fulfilled about the year of their city 680. Spartaeanus, Cris. Oenomus, having escaped, with other gladiators, to the number of seventy-four, out of the place where they had been kept at Capua, gathered together a body of slaves, put themselves at their head, rendered themselves masters of all Campania, and gained several victories over the Roman pretors. At length they were defeated, in the year 682, at the extremity of Italy; having, in vain, attempted to pass over into Sicily.

This war proved very formidable to the Romans. Cassius was not able to finish it: the great Pompey was forced to be sent as general.

GLADIATORS, dying, is a most valuable monument of ancient sculpture, which is now preferred in the palace of Chigi. This man, when he had received the mortal stroke, is particularly careful, ut proculabat biceps, that he might fall gracefully; he is seated in a reclining posture on the ground, and has just strength sufficient to support himself on his right arm; and in his expiring moments, it is plainly seen that he does not abandon himself to grief and dejection, but is solicitous to maintain that firmness of aspect, which the gladiators valued themselves on preferring in this season of distress, and that attitude which they had learnt of the masters of defence. He fears not death, nor seems to betray any token of fear by his countenance, nor to shed a tear: quis medius erat gladiator ingemitus, quis vultum mutavit unquam, quis non modo felix, verum etiam decubuit turpiter?" says Cicero, in that part of his Tusculanum, where he is describing the astonishing manner of these persons. We fee, in this instance, not with standing his remaining strength, that he has but a moment to live, and we view him with attention, that we may see him expire and fall: thus the ancients knew how to animate marble, and to give it almost every expression of life.

GLADIOLUS, in Nosey. See DUTUMUS and LONELA.

Gen. Ch. Cal. Spatha inferior, shorter than the corolla, of two oblong permanent valves; the outermost larger, enfolding the inner one. Cor. of one petal, superior: tube cymose, swelling upwards, curved; limb somewhat bell-shaped, irregular, in six deep, oblong, slightly spreading, unequal segments, the upper and lowermost either without or within the lateral ones. Stam. Filaments three, inserted into the mouth of the tube, thread-shaped, ascending, shorter than the corolla; anthers ovate, incumbent. Petal. Germ. inferior, triangular; style thread-shaped; stigmas three, spreading, folded, recurved, obtuse, downy. Peric. Capsule ovate, triangular, obtuse, thin, of three cells and three valves. Seed numerous, smooth, surrounded with a membranous wing.

Twenty-four species of this genus are defined in the 14th edition of Linnæus's Systema Vegetabilum, of which the ramosus, Sp. Pl. 53, belongs, we believe, to Iris, or some of its near allies. Wildenow makes 50 species, but Mr. Ker (late Gawler) has, I think, with great propriety, established the old genus Waterania, to which some of them are removed, while others go to his Tritonit or elsewhere, so that he names but 28 species in Sims and Konig's Annals above quoted. He is followed by Mr. Dryander in the new edition of the Hortus Kewensis, except with regard to his bifolius, there called brevifolius, after Wildenow and Quinquin; while a more distinct species is figured in Curt. Mag. t. 574, by Mr. Ker as a variety of bifolius, is properly retained as being the true bifolius itself. Five of Mr. Ker's species are not found in Hort. Kew.

We judge it necessary to give a view of the whole genus in
its reformed state, adding the Linncean G. imbricatus to what the above-mentioned writers have defined.

1. G. Clusiana. Curt. t. 1. 31. (Antholiza Cumonza; Linn. Sp. Pl. 54. Willd. Fl. Pomm. t. 121. Curt. Mag. t. 34.) Redout. Lill. t. 12.—Leaves linear-forked. Upper segment of the corolla very long; lower very small. —Native of the Cape of Good Hope, nor does it appear to grow, as Linnceus affirms, in Peru. Remarkable: for the vivid scarlet of its fragrant and beautiful flowers, the three upper segments of whose corolla are broadly elliptical and violet, the middle projecting far beyond the other two; while the three lower are very small, and greenish. This is a hardy green-house plant. See Antholiza, n. 3.

3. G. quadrangularis. Ker. In Curt. Mag. t. 567. (G. abbreviatus; Andl. Rar. t. 166. Antholiza quadrangularis; Burm. Fl. Cap. according to Mr. Ker.)—Leaves with four angles and four furrows. Upper segment of the corolla very long; lower very small and sharp. —Imported from the Cape of Good Hope, by those excellent cultivators Meffrs. Lee and Kennedy in 1799. It first flowered with them in March 1801. The quadrangular leaves distinguish this from most others, except the triflta, n. 10, and permundtis, n. 7; the flowers more agree with G. Cuninna, at least in their large vaulted upper segment, but all the lateral segments are extremely short, ovate and acute, the lowermost being the least of all. The tube is yellow flecked with orange; large segment of the limb purplish; all the red variegated with dull green and brown. According to the Linncean idea of hybrid species, this might be guessed to have originated from G. Cunimna impregnated by G. triflta.

4. G. galatia. Andl. Rar. t. 122. (G. nanaquenfis; Ker in Curt. Mag. t. 592)—Upper segment of the corolla vaulted; two lateral rhomboid; three lower pendulous, spatulate, blunt with a little point. Leaves conicous, ovate. —Native of the Namaqua country, a considerable distance from the Cape of Good Hope; early propagated by seeds or offsets, and blooming freely. The leaves are very thick, many-ribbed, ovate, obtuse, curved or oblique. Stem low, bent or zig-zag, covered with bracteas and flowers. The latter are large and showy, their three narrow drooping lower segments, each half green half scarlet, strikingly contrasted with the large broad upper ones, which are of a rich scarlet, green white and purple at the base. No authority can induce us to prefer such a specific name as nanaquenfis, it being contrary to rule to give the name of a country, and so peculiarly barbarous in itself. The G. galatia of Jacquin is Speratis galatia of Ker.

5. G. alata. Linn. Sp. Pl. 53. Herb. Linn. Andl. Rar. t. 8. Ker in Curt. Mag. t. 586.—Upper segment of the corolla ovate, recurved; two lateral rhomboid; three lower pendulous, spatulate, pointed. Leaves rigid, lanceolate. —Common about the Cape of Good Hope; easily increased by seeds or bulbs, but rarely flowering with us. Bears a considerable resemblance to the lath in form and colours, but the lath are narrower and very differently shaped, the lower segments of the corolla more lanceolate, the upper one reflexed. Linnceus once called this species Lathitis, but his son changed it to alatus, in allusion to the wing-like lateral segments.

6. G. viridis. Ker in Curt. Mag. t. 699. (G. alta—Jacq. Lc. Rar. t. 239. G. orchisflorous; Andl. Rar. t. 241.)—Upper segment of the corolla spathulate, archd, curved; two lateral rhomboid; three lower spathulate, pendulous, acute. Leaves straight, linear-forked. —Native of the Cape; rare in our collections. Plukcnets rude figure, t. 223. f. 8, is supposed to belong to this species rather than to the lath, for which it is quoted by Linnceus. This differs from the two preceding in having long erect narrow leaves and flowers variegated with dull green and purple, which are insufficiently fragrant. The stem is tall, and sometimes branched.

7. G. permundtis. De la Roche Diff. t. 27. t. 2 Ker in Ann. of Bot. v. 1. 323.—Leaves awl-shaped, quadrangular, erect. Upper segment of the corolla broadest, vaulted, undulated; two lateral narrow-rhomboid; three lower spathulate, acute, recurved at the points. —Native of the Cape of Good Hope. We know it only by De la Roche’s figure and description. He says the flowers are of a very pale violet, diluted with purple and yellow. The name alludes to their being perversus between the segments, but this is not peculiar. That supprised variety of triflta, figured by Jacquin, Lc. Rar. t. 244, seems to be very near the present species.

8. G. verisylbora. Ker in Curt. Mag. t. 1042 and 556. Andl. Rar. t. 19.—Leaves linear-forked, with three ribs on each side. Segments of the corolla longer than the tube, pointed, recurved. —Native of the Cape, from whence it was received by Meffrs. Lee and Kennedy in 1794. Its flowers are among the largest of its genus, with peculiarly long undulated recurved segments, and are remarkable for changing colour several days successively. In the morning it is of a purplish brown, but becomes grey in the course of the day, and finally of a light blue in the evening. The most wonderful, and, as far as we know, unique circumstance, is, that the original brown hue returns in the course of the night, and this happens for nine or ten following days. There are moreover some varieties of colour observable in different plants, some attaining more of a yellow hue. It differs essentially from the following in having a sword-shaped, not a quadrangular, leaf.

9. G. triflta. Linn. Sp. Pl. 53. Ker in Curt. Mag. t. 272 and 1098. Jacq. Lc. Rar. t. 245 and 243. (Lilio-gradusdiulbus et biflorus, foliis quadrangulis; Trew. Ehrn. t. 39.)—Leaves with four angles and four furrows. Segments of the corolla nearly equal, pointed. —Frequent at the Cape, and not uncommon in our green-houses, where it is justly admired for its rich evening eence, like a pink, or a bergamot pear, especially in the most common or particular coloured variety, to which the first-quoted figure of Curtis and Jacquin refer. The deeply furrowed quadrangular corolla, like those of the Snake’s-head Iris, tub. roth, distinguish it clearly from the lath, for which Mr. Ker, we presume by mistake, quotes Jacquin’s t. 245. He likewise cites and Trew’s Ehrn is the yellowish variety, which is in a fine plate, though rather too pink, of the particular one.

Canta
GLADIOLUS.

Cant. belgicantis, nor have we seen any specimen. The short, upright, straight leaves are remarkable. The flowers are smaller than in the two last, slender; the base of their segments semi-transparent, the extremities yellowish, striped and dotted with purple. The upper segment is by far the largest; the others gradually smaller, to the lower one, which is leaf of all. Tube funnel-shaped, semi-pellucid, very pale purple, as long as the largest segment. —Jacquin first called this species fritatus; see Collect, v. 4, 170.

11. G. pendula. Jacq. Ic. Rar. t. 248 Coll. v. 3, 255; and v. 4, 256 t. 3, f. 1. Ker in Ann. of Bot. v. 1, 231—Leaves linear, convoluted, smooth. Stem zig-zag. Segments of the corolla elliptical, bluish, nearly equal, shorter than the tube. —Native of the Cape. Jacquin, from whose figures alone we are acquainted with this plant, says it blooms with him in November. The stem is a spn high, curved and zig-zag. Flowers one or two, yellowish, more or less variegated with pale purple, smooth, about an inch and half long.

12. G. sericeus. Thumb. Diff. 18. Linnae. Suppl. 96. Ker in Ann. of Bot. v. 1, 231—Leaves linear, convoluted, smooth. Stem zig-zag. Segments of the corolla elliptical, bluish, nearly equal, shorter than the tube. —Native of the Cape. Jacquin, from whose figures alone we are acquainted with this plant, says it blooms with him in November. The stem is a spn high, curved and zig-zag. Flowers one or two, yellowish, more or less variegated with pale purple, smooth, about an inch and half long.

13. G. praecox. Jacq. Ic. Rar. t. 246. Ker in Curt. Mag. t. 562. —Leaves linear, ribbed, deeply furrowed on each side, with a very thin midrib. Corolla somewhat bell-shaped; segments ovate, nearly equal. Native of the Cape, easily cultivated with us, blooming in March or April. Flowers wavy, pale blue, more or less speckled with black and white on the two lower lateral segments, without scent. Bulb very small. Stem variously bent, slender, two or three feet high.

14. G. recurvus. Linn. Mant. 28. Ker in Curt. Mag. t. 573. (G. carinatus; Wild Sp Pl. v. 1, 211. Ker in Ann. of Bot. v. 1, 231. G. punctatus; Jacq. Ic. Rar. t. 247. G. ringens; Andr. Repol t. 27 and 227. Redout. Liliac. t. 123; G. alatus; Schnee Ic. t. 12.) Leaves linear, flat; rib prominent on each side. Radical sheath speckled. Segments of the corolla nearly equal, ovate, recurved. Native of the Cape, cultivated and badly figured by Miller, and now frequent in gardens, where it is valued for the fine violet fragrance of its blue and yellow blossoms, more than even for its beauty or size, which equals that of most species. The leaves have a strong rib, prominent on each side, and the first sheath from the root is curiously speckled with brown, like the flanks of Arum Dracunculus. Thunberg confounded this and gracilis with r好消息.

15. G. breviflorus. Jacq. Ic. Rar. t. 249. Dryand in Att. Hort. Kew. ed. 2 v. 1, 98. (G. breviflorus; Ker in Curt. Mag. t. 592; and Suppl. t. 727. G. carinatus; Andr. Repol. t. 240)—Leaf of the barren bulb solitary, linear, slightly downy; of the flowering one scarcely any. Corolla somewhat ringed. —Native of the Cape, readily cultivated and propagated with us. The flowers are among the smaller sized, all bearing one way, variously tinged with pale purple or rose-colour, with some yellow; their three lower segments most speckled, and nearly of equal size, the uppermost one rather larger, vaulted, recurved at the summit. The leaves are minutely downy, upright, linear or slightly lanceolate; very short, or rather mere lances, on the

flowering stem; solitary and larger on the bulb, which produces no flowers.

16. G. biflorus. Jacq. Ic. Rar. t. 250. Dryand in Att. Hort. Kew. ed. 2 v. 1, 98. Ker in Curt. Mag. t. 574. (G. biflorus; Andr. Repol t. 111)—Leaves linear, two, deeply downy. Corolla nearly regular. —Native of the Cape; introduced into our green-houses in 1755, when it first flowered in the collection of Mr. Orde at Fulham. The broadish, downy, red-edged leaves are remarkable. The flowers are large and fragrant, rose-coloured; their segments elliptical, pointed, nearly equal. Jacquin's figure is indeed a poor one, but we can scarcely suppose, with Mr. Andrews, that it is drawn from a dried specimen, as the author says it flowered in his green-house, nor does he, like Pallas, often practice this without acknowledgment.

17. G. neglectus. Thumb. Diff. 9 t. f. 1. Linnae. Suppl. 96. —Leaves linear, involute. Corolla ringed; segments elliptical-lanceolate, nearly equal, shorter than the tube. Stem zig-zag. —Gathered at the Cape by Thunberg, from whom we have a wild specimen. The stem is a spn high, irregularly curved, and zig-zag. Leaves lanceolate, blue, linear, acute, smooth, involute. Flowers large, swelling, sharply pointed. Flowers very pale flesh-coloured, with red ribs; tube capillary, an inch and half long; segments of the limb narrow, nearly equal in size, but ringed.

18. G. carneus. Jacq. Ic. Rar. t. 255. Ker in Curt. Mag. t. 591. (G. ccephalophus; Andr. Repol. t. 147. Redout. Liliac. t. 356.) —Leaves sword-shaped, many-ribbed. Segments of the corolla shorter than the tube; the uppermost broader, with an involute recurved point; the three lower narrowest, dependent. —Native of the Cape. A tall and handsome plant, with several many-ribbed leaves. Flowers inodorous, two-ranked, large, flesh-coloured with a rosy hue; their three lower segments oblong, bluish, each marked with a red rhomboidal central spot; the three upper broader, especially the top one, with long recurved points, whole edges are involute. The tube is flatter, longer than the limb, twice as long as the spathe. This freely blowing species is a desirable ornament for the green-house in the spring.

19. G. cephalephus. Jacq. Ic. Rar. t. 257. Ker in Curt. Mag. t. 582. Redout. Liliac. t. 136. Andr. Repol. t. 219. (G. undulatus; Linn. Mant. 27.) —Leaves sword-shaped, many-ribbed. Segments of the corolla half the length of the tube, nearly equal, pointed, undulated, reflexed. —Native of the Cape; now become pretty frequent in gardens, for the sake of its elegance of form and colour, and its fragrance in the evening. The very long narrow segments of the corolla, each of which has a recurved, channelled, undulated point, and the much greater length of the tube, are striking characters. The colour is pale greenish yellow, or buff, with a remarkable lanceolate spot, flamed with purple and red, on each of the three lower segments. Anthers deep blue. The Linnaean name ought to have been retained for this species, but to change the present appellation would now cause mere trouble than advantage.

20. G. blainius. Att. Hort. Kew. ed. 2 v. 1, 63. Ker in Curt. Mag. t. 625. 645. 648. Andr. Repol t. 99. (G. carinatus; De la Roche Dill. 30 t. 4. Redout. Liliac. t. 65. G. albus; Jacq. Ic. Rar. t. 256. G. campanulatis; Andr. Repol. t. 185.) —Leaves many-ribbed. Tube of the corolla shorter than the spathe, equal to the limb, which is ringed, bell-shaped, its upper segment convache; three lower narrowest, downy. —Native of the Cape. Succeeds well with us in the open ground, but the bulbs must be taken up every year. —This is an elegant species, with
lower of the sword-shaped many-ribbed kind like the two half. The flowers vary in colour, from white to a pale pink, their three lower segments bearing each generally a pair of crimson spots. They vary a little in size, sometimes varying in this respect with the larger. They have no scent.

We cannot but complain of those authors who burthen the plate with figures of trailing varieties of this and other plants, for which a single plate ought to have been sufficient; nor does the contrivance of a new name, though it may conceal the imposition, by any means stone for it.

21. G. amygdalus. Lam. Sp. Pl. 52. Hort. Cliff. t. 6. Jacq. Ic. Rat. t. 252. Ker in Curt. Mag. t. 622. Andr. Repof. t. 589. Mill. Ic. t. 142. f. 2 —Leaves linear; mid-rib prominent on each side. Tube of the corolla longer than either spathe or limb; three upper segments ovate; three lower each marked with a triangular flaked spot.—Native of the Cape, from whence it was brought to Holland, and from the latter country to England by Mr. Graffier; before 1789, unless we are greatly mistaken. It will bear an open border in a warm situation, but the bulbs must be taken up yearly to make it flower in its natural magnificence. The rich scarlet of its 

25. G. cardinalis. Curt. Mag. t. 135. Schulze. Ic. t. 27. Redout. Lilac. t. 112. —Leaves many-ribbed, Spoon branched. Flowers erect, in one row, funnel-shaped; segments elliptical; three lowermost smallest, each with a lanceolate white spot.—Native of the Cape, from whence it was brought to Holland, and from the latter country to England by Mr. Graffier; before 1789, unless we are greatly mistaken. It will bear an open border in a warm situation, but the bulbs must be taken up yearly to make it flower in its natural magnificence. The rich scarlet of its 

2. The same alludes to the scarlet colour, like that worn by the cardinals at Rome, as used by Linnaeus in Lob hie and Lob. The piaze Scopoli thought the application profane, and changed it in the latter instance to ribara. See his Annales, 1792.
G L A

specimens. We have this species from M. Favrod’s herbarium, gathered wild in Switzerland, so that it appears to be Haller’s n. 1261, the smaller variety; his larger being probably the following species. There is much difficulty in determining the synonyms of old authors, their cuts not being correct in those parts on which our characters are founded; Parkinson’s G. italicus, for instance, Parad. 191. f. 2, has precisely the lower lip of this present species, but not the inflorescence, whilst his f. 1. does not shew the lip so well as the position of the flowers. As however he mentions but two white stripes in his description, so many only being visible, as the segments naturally stand in our communis, we have little doubt of his synonym. The communis of the Linnaean herbarium is our’s, and has winged seeds, so that we trust this name will remain fixed, as belonging to the most common and general species, whatever Linneus might comprehend under it as varieties.

28. G. foetidum. Ker in Curt. Mag. t. 719. Dryandri, in Ait. Hort. Kew. ed. 2. v. 1. 102. (G. communis; Bulliard. Herb. de la France, t. 8. Sm. Pl. Grec. Sibth. v. 1. 27. t. 37. 38. Lamarck Ill. 32. Tourn. t. 190. G. italicus; Ger. ed. 104.)—Leaves many-ribbed. Spike one-ranked. Flowers horizontal; upper segment dilated; three lowermost equal, each with a linear-lanceolate bordered stripe.—Native of corn-fields in the south of Europe, common in Italy, Greece, and the neighbouring countries, flowering in the spring; hardy, but not frequent in gardens. It is distinctly represented in the Hortus Elytensis, by the name of Victoriae rotunda; Ord. Ed. 4. t. 10. f. 2, though the other Gladiosi of that huge book are less precise. This is distinguishable from the two last by the distance between the uppermost lobe of its blossoms and the two next, which are peculiarly narrow; while the seeds, according to Mr. Ker, are round, with a somewhat pulpy coat, not flattened and winged as in the whole of the genus besides, which is a soft material specific distinction, and even forms an exception to one of the general characters. Mr. Kersuspects the existence of other European species, still confounded as varieties of thefe, and which may perhaps account for anomalies and incongruities in the figures of authors. Whether t. 38. of Flora Graece may be one of these, we must submit to future enquiry. Though small, it is said to be a native of fertile ground; the three upper segments seem more approximated, and the three lower ones united by a longer base, than in G. foetidum; but this we learn merely from the figure, nor was the artist acquainted with the characters subsequently found out in this tribe, so as to give peculiar authority to what he has expressed in his drawing. The acquisition of living specimens at some future time can alone settle the question.—It is proper to mention that G. speciosus of the Linnaean herbarium, alluded to by Mr. Ker, is a Siberian specimen, with very broad lateral segments to the corolla, and as far as we can judge seems rather to be communis, if not, as is possible, a species hitherto undefined. It is probably different from the African plant of Van Royen, intended in Sp. Pl. ed. 1. nor has it the authentic marks of originality. What might chance to be compared with it in the Bankian herbarium, when none of the parties present had any precise ideas about these plants, we cannot answer for, but our specimens was then voted to be communis.

29. G. imbricatus. Linn. Sp. Pl. 52. Lamarck. Dict. v. 2. 723.—Leaves many-ribbed, spike of numerous, crowded, upright flowers; upper segment rather dilated; three lowermost nearly equal.—Gathered by Gerber near Luban in Livonia. His own specimen in the Linnaean herbarium is the only one we have seen, nor do recent writers appear to know any thing of this species, which appears to us very distinct, skin the three leaf in leaves and habit; but differing widely in its curved ascending spike, and crowded erect flowers, which are smaller than those of G. communis, of a purple or crimson colour, pervious at the base, in consequence of a considerable distance between the claws of the upper and lateral segments, while their upper parts seem to fold over each other; but of these characters we cannot, of course, speak absolutely, from the dried flowers; the three lowermost segments seem equal and rather narrow. No white stripe is discernible in their present condition. The leaves arise above the spike of flowers, and have each an oblique point, but this may not be constant.

Whatever species of Gladiosi (exclusive of such as are now referable to the genera Sparaxis, Aphanthoeca, Tritonia, Waslonia, Melapharadu or Baliana of Mr. Ker), may be found here and there in authors, we decline describing without seeing living specimens. The discordance between several of the figures, above quoted for the same species, proves how variable many of them are, especially from accidental circumstances in cultivation. The Botanical Magazine is now become a faithful and valuable repository of this family, so that however botanists may differ about definitions, the memory of the plants can never be entirely lost.

GLADIUS, in Gardening, comprise plants of the tuberosous-root, flowery, perennial kind; of which the species mostly cultivated are the common sword-lily, or corn-flag (G. communis); the imbricated flowered gladiole (G. imbricatus); the square-talked gladiole (G. trilis); the narrow leaved gladiole (G. angustus); and the superb scarlet gladiole (G. cardinæ). There are several varieties of the fift species, as the Italian and French corn flags, with the bluish, the white, and the small purple coloured.

Method of Culture.—In the first fort and varieties the culture may be readily effected by planting the off-sets from the old roots in the beginning of the autumn in the places where they are to grow. And the other sorts may be raised in the same way as well by seeds. These should be planted in a warm border, and be protected in the winter by glafs or some other means, when there is a necessity for it, as during very severe weather, &c.

When increased by seed it should be sown towards the end of August, in pots filled with light earth, placing them in a shady situation at first, but afterwards where they may be exposed to the sun, being protected during the winter in a hot-bed frame, free air being admitted when the weather is mild. In the spring the pots should be removed to a shady situation, with only the morning sun. When the fows decay, the roots should be taken up and kept in sand in a dry place till the time of planting. In the second year’s planting they should be put in separate small pots, filled with mould formed from the turf or earth.

With respect to the old roots they may be taken up every two or three years, to have the off-sets taken off from them, in order to their future increase.

All the sorts afford a fine effect and variety in the flower borders and other parts among other plants of the flowery kinds, being properly arranged in mixture with them.

GLADIUS, Sw.nd. Jus Gladii, or right of the sword, is used, in our ancient Latin authors, and in the Norman laws, for suprême jurisdiction.

Camden, in Britannia, writes “Comitatus Fliet pertinet ad gladium Celtribri:” and Selden, Tit. of Honour, p. 549, “Curiam fuan liberam de omnibus placitis, &c. exceptis ad gladium ejus pertinentibus.”

And it is probably from hence, that at the creation of an
GLA

earl, he is gladio fascinatus; to signify, that he had a jurif-
diction over the county.

GLADIUS, in Ichthyology, a name used by many for the
sword-fish, called also the alphon, which see.

GLADKA, in Geography, a fort of Russia, in the go-

government of Caucasus, on the Malva; 36 miles W. of

Kiliar.

GLADWIN. See Iris.

GLADWIN, John, in Biography, the late organist of South
Audley chapel, was the first performer on the organ at
Vauxhall, after the building of the orchestra in the middle
of the gardens, and the establishment of a regular band. He
was a pleasing player in his day, and a worthy man, who
lived to a great age, and died in 1799.

GLAIR of Eggs, is the same as the white of eggs, and is
used as a varnish for preserving paintings. For this
purpose it is heat to an unequable consistence, and commonly mixed
with a little brandy or spirit of wine, to make it work more
freely, and with a lump of sugar to give it body and prevent
its cracking; and then spread over the picture or painting
with a brush.

GLAIZE, Au, in Geography, a S.S.W. branch of the
Miimi of the lake in America, which interlocks with St.
Mary’s river. By the treaty of Greenville, the Indians
have ceded to the United States a tract of land, six miles
future, at the head of its navigable waters, and six miles
square at its confluence with the Miami, where port Defiance
now stands.

GLAMA, in Zoology. See Camelus.

GLAMMISS, in Geography, a small town in the county
of Forfar, Scotland, contains 383 houses, and 1931 inhabit-
ants. Here are two small manufactories of yarn, and coarse
linen cloth. The ears of Strathmore formerly possessed, and
occupied a noble castle in this parish. The remains of this
baronial fortress are still very considerable, and occupy a
commanding feite on the banks of the river Dean. In this
parish are several ancient obelisks, or stone crosses; also many
cairns. These are traditionally said to commemorate the
murdered King Malcolm II. Glammiss is divided into two
parts respectively, called the New, and the Old Town.

GLAMORGANSHIRE, the south maritime county of
South Wales, is suppos’d to have derived its name from
having afforded a temporary, though insecure, retreat to an
ancient prince, at a very early period of British history.
The story is briefly recapitulated by Spencer, in his Chroni-
cle of British kings (Fairy Queen, b. ii. c. 10.) Glamor-
gan was in succeeding ages an independent soveign prin-
cipality, disdint, as those who profess to be acquainted with
the ancient history of Wales aver, from the rule and go-
government of South Wales. The principality, or soveign
lordship of Glamorgan, as these persons say, contained the
present counties of Glamorgan and Monmouth, the southern
and eastern parts of Brecknockshire, and that part of Here-
fordshire lying to the west of the river Wye.

The lordship of Glamorgan was subdivided, at an early
period, into a great many petty lordships, in every one of
which their lords exercised “jura regalia,” referring, how-
ever, to the subject a right of appeal to the court of the
chief lord, or, as he was term’d, the lord paramount.
There are at least 50 ancient buildings still remaining in the
district, universally understood to be the halls in which the
courts of legislation and of justice were held for the respec-
tive petty lordships. They are now commonly called
“Church-houses,” and belong to the parishes in which they
stand. They are at present used as school-rooms, and occasi-
onally for dancing; an amusement still common in Glamor-
ganshire, though now beginning to decline. The ground-

floor apartments under these halls are used as almshouses for
the poor of the parish. From ancient surveys and other ac-
counts of the lordships it appears that before the reformation
a market was held in each of these halls every Sunday morn-
ing, till the tolling of the first bell, which is said to have
been intended as a notice for the hushefs of the market to
cease. The second bell was a signal of preparation for
church, and the third for the commencement of divine ser-
vice, during which no door, but the church door, was allow-
ed to be open seen.

This county, extending about forty-eight miles from east
to west, and 27 from north to south, is bounded on the N.
by Brecknockshire, on the E. by Monmouthshire, from
which it is separated by the river Remany, on the S. by the
Britol channel, and on the W. by Caermarthenshire.

The greatest part of the sea-coast forms a semi-circular curve;
the western extremity being formed into a narrow break be-
tween the open channel on the one hand, and an arm running
round to the Caermarthenshire coast on the other. (See
Gower.) An ample account of the manner in which the
lordship of Glamorgan was obtained by its conquerors, is to
be found in Trevor’s History of Wales, written in the time
of Elizabeth, or in Evans’s edition of Wynne’s History of
Wales. The following abstract is taken from Malkin’s
work. Jeflin ap Gurgant, a petty prince of odious charac-
ter, waged war, in the year 1688, against Rees ap Tudor, and
was affilited by Encon ap Collwyn. Unable to make any
impression on his enemy’s dominions, Jeflin commissioned
Encon to go to England, and to procure some more pow-
ful ally. His propositions were eagerly received by Robert
Fitziawan, and twelve other Norman adventurers, who came
to Glamorgan on an expedition, professedly for the purpose
of retrieving the affairs of Jeflin. The allies, marching against
Rees ap Tudor, came up with his forces on the borders of
Brecknockshire. In a battle which ensued at a place called
Hirwin, Rees was entirely defeated: and in his flight was
taken prisoner, and put to death. On this occasion, Jeflin
betrayed his character of treachery, by violating his agree-
ment with Encon, to whom he had promised his daughter in
marriage, as a recompense for his services. Encon, justly off-
censed, was determined on revenge; and therefore, when the
Normans, after having fulfilled their engagements, and hav-
ing obtained satisfaction for their services, quietly returned
home, Encon represented the injuries he had sustained by the
treachery of Jeflin, and all the hatred of the country to its
tyrant. He also stated how easy it was to obtain po-
fession of this fertile country, with the aid of the differ-
ent princes at variance with Jeflin. R. Fitziawan, and his fol-
diers of fortune, availing themselves of the favourable mo-
turned their arms against their employer, who was
unprepared for so formidable a reverse, and overran the coun-
try; whilst Jeflin fared himself by flight, and died soon after
which were untreated and unavenged. Fitziawan, upon a division of
the conquered territory, took for his own share the castles of
Cardiff and Keuffig, with the market town of Cowbridge,
and the demeine of Llantwit; appropriating to himself the
lands belonging to them, together with the sovereignty of
the whole country. The other parts were distributed in va-
cious proportions among his followers. Encon ap Collwyn,
in particular, possess’d Caerphilly, with Jeflin’s daughter in
marriage, the prize which occasioned the contest. (See
WALES.) With respect to the picturesque character of this
county, it is distinguished by unbounded variety. It has
sea, mountains, valleys and rivers; and it is said to resemble
North Wales in general aspect more than any of the fix coun-
ties. Its mountains are not so high as those of Breck-
nockshire, but they present, in a considerable degree, the
appearance

GLA
The antiquity of the cottages is a strongly marked feature in the appearance of this county. Many of them are probably as ancient as the castles, to which they were attached. Their architecture is particularly deserving of notice. The pointed door-ways, and pointed windows, sufficiently evince their date; and though Welsh towns are universally censured by strangers, for the negligence in the maintenance of their houses, the direct reverse is the fact with respect to the habitations of the peasantry. There is one circumstance, besides their general structure, that of many of which is the ancient Gothic, which adds to the respectable appearance of the cottages, and that is, the universal practice of lime-whitening them. This has been the custom of the county from very remote ages, and is extended even to the barns and stables, to the walls of yards and gardens. It is noticed and praised in the most ancient Welsh poems, and certainly evinces a very early sentiency to the arts and decencies of life. The price of provisions in this county has of late very much increased, and is comparatively very high, on account of the increased demands of the manufacturing districts, which are numerous. The price of labour is equally enhanced from the same cause. The increase of population, owing to the influx of commerce, and the magnitude of its establishments at Swansea, Merthyr-Tydvil, Neath, Aberavon, Melin Gruydd, near Cardiff, where are the largest tin works in the kingdom, &c. afford another reason why the cheap comfort and elegancies of life are no longer to be sought for here.

The drefis in Glamorganshire is not so strongly marked as in some other counties, except that the women universally adopt the mantle; but they wear it with a very good grace, and are remarkably neat in their attire, as well as in their persons, and graceful in their carriage, which may probably be attributed to the habit of dancing, which is their favourite amusement. Their modes of greeting are uniformly affable, sometimes bordering on the ludicrous, particularly among the women, who are constantly seen saluting each other at market, and on the most ordinary occasions of business, as well as on occasions of diffire. At a wedding it is the custom of all who are invited, both men and women, to ride full speed to the church porch, and the person who arrives there first has some privilege or distinction at the marriage feast. In case of death, the bed on which the corpse lies is always adorned with flowers, and the same custom is observed after it is laid in the coffin. It is an invariable practice, both by day and night, to watch the corpse; and the hospitality of the country is no less remarkable on melancholy than on joyful occasions; for the invitations to a funeral are very general and extensive; and the refreshments are not light, and taken standing, but substantial and prolonged. The grave of the deceased is constantly overpoured with plucked flowers for a week or two after the funeral: the planting of graves with flowers is confined to the villages, and the poorer people. It is very common to dote the graves on Whit-Sunday, and other festivals, when flowers can be procured.

The Roman stations, forts, and camps, in this county, are generally understood to be at Cardiff, Cefnphilly, and Caer, which lies between Neath and Aberavon, a large balsam tree being built in the castle called Merthyr. The Colliery road was over Newton Down, leaving the present road on the right, and passes through Kenfig to Margam, and as straight as the nature of the country will admit, through Aberavon parish to Neath. Glamorganshire contains one episcopal town, viz. Llandaff, and several others, as Cardiff, the capital of the county, Cefnphilly, Llantrisant, Cowbridge, Bridgend, Neath, Merthyr-Tydvil, etc.
G L A

and Swansea; which see respectively. The principal rivers are the Remney, the Taif, the Elwy, the Rhonhas, great and small, the Ogmore, the Cunno, the Nedd or Neath, the Tawe or Tave, and the Loughor. In this county are several rail-ways and canals. (See Canal.) The canal from Merthyr-Tyst to Cardiff was completed in 1798. From the tide-lock, where it enters Penarth harbour, up to the town of Cardiff, it is navigable for ships of 400 tons; but from Cardiff to Merthyr-Tyst, it is navigable for barges of 150 tons. The head of this canal at Merthyr-Tyst is 568 feet five inches higher than the tide-lock two miles below Cardiff, where it falls into Penarth harbour. This canal has upwards of 40 locks upon it in the space of 26 miles, which is its whole length; and it is crossed by more than 40 bridges. For an account of the bridge with one arch upon Taff; see Bridge. In a vale S. W. of Cardiff, near Duffrin house, and not far from the village of St. Nicholas, are some ancient monuments, supposed to be Druidical. The most remarkable of these monuments is a grey stone, which affames among those pieces of antiquity called Cromlechau. (See Cromlech.) This monument is supported by five large stones, enclosed entirely on the east, west, and north sides, and open to the south, forming a considerably large, though low room, 16 feet in length, 15 wide, and, at the east end, fix feet high, but only 44 at the west end. The rubblish about it prevents the investigation of its original height. The supporting stone to the north is 16 feet long; that on the west end about nine feet in length. At the eastern extremity three stones are let closely together; the middle stone is 44 feet wide, the northern stone of these three about three feet, and the southern nearly two feet in width. These stones, standing upright, support a large stone on the top, which forms the roof of this rude apartment. The length of this horizontal stone is 24 feet; it is 17 feet in its widest part, and of different breadths at other places; it is 10 feet at one extremity, and 12 about the middle; and from two feet to two and a half thick. The area of the top-stone, therefore, having for its mean breadth 13 1/2 feet, and 24 feet for its length, will contain 324 square feet; whereas it appears that it is nearly twice as large as that of the famous Cromlech near Newport in Pembrokehire. Near this cromlech are other heaps of stones called Carnco or Cairn. Of these cromleches different opinions have been entertained. Some have supposed them to be places of shelter for the Druids, who always worshipped in the open air, and after them, for the first Christian priests, in rain and other inclemencies of the weather; others have supposed them to be oratories, from the tops of which they delivered their discourses; and others again, that they were altars on which victims were offered in the times of Druidism.

Glamorganshire is divided into ten hundreds, and 118 parishes, which, in 1801, contained 71,525 inhabitants, of whom 6903 were employed in trade and manufacture, and 10,515 in agriculture. Two members are returned for Glamorganshire to the British parliament, viz. one for the county, and one for the boroughs, Cardiff, &c. Malkin's South Wales.

GLAMOUR, or GLAMER, an old term of popular superstitition in Scotland, denoting a kind of magical mist believed to be raised by forcerers, and which debaid their spectators with visions of things that had no existence, altered the appearance of things really existing, &c.

GLAN, a river of France, which runs into the Nahe, three miles E. of Sobernheim—A1lo, a river of Carinthia, which rises near Kofiber, and joins the Gurz, four miles E. of Clagenfurt.

G L A

GLAND, in Anatomy, is a name applied to those organs of the body, which separate from the blood conveyed to them by their blood-vessels various substances, generally of a fluid nature, and discharge them through one or more tubes, called excretory ducts. The term has been, and is employed more extensively, having been applied to various organs, which, although analogous in their structure, on superficial observation, to those already designated, do not resemble them at all in their functions. Thus, the small bodies belonging to the lymphatic system have been called lymphatic or clogged glands; although the knowledge hitherto acquired by physiologists concerning the action of these bodies, and their anatomical relations and connections do not warrant us in ascribing to them any function similar to those exercised by the glands properly so called: the account of these will be found under the articles Absorbrnts and Absorption. The pincel, thyroid, and thymus glands, the renal capsules and the thymus, have all been included in the glandular system of the body, but will not be considered in this article, as we know nothing at all of their offices, and have no reason to suppose that they secrete any fluid. Our definition will include the salivary, lacrimal, and Meibomian glands, the tonsils, the seminiferous glands of the ear, and the febaceous glands of the face, in the head; the mammary glands in the chest; the liver, pancreas, and kidneys in the abdomen: the prostate, uterine, Cowper's glands, and glandula odonfera about the penis; and the extensive sytem of mucous glands about the head and trunk. These parts, although differing widely from each other in many respects, agree in a sufficient number of points to allow of their being arranged in one organic system, which has been named the glandular: the other organs just enumerated, belonging to this only in name, are excluded from the arrangement by their texture and properties, their mode of vitality and functions. The extremities contain no parts belonging to the glandular system; the fluids formed in the different organs of this apparatus belong almost entirely to the organic functions, while the limbs are particularly designed to execute the offices of the animal life.

As the physiology of these organs cannot be conveniently separated from the history of their structure, we shall consider the vital properties as well as the organization of the glandular system; and we should make a very unnatural and arbitrary division of the matter, if we did not give at the same time a view of secretion in general. We shall present the reader, in the first place, with an enumeration and arrangement of the secreted matters; we shall proceed, secondly, to give a general view of the organization of the glandular system; and shall exhibit, in the third and last place, the opinions of physiologists concerning the mode of action of the glands and the subject of secretion in general. The reader will observe that the present article is of a general nature; the structure of the particular organs will be described on other occasions, and detailed accounts of the nature and properties of the various fluids will be found under their respective titles, or in other articles of the work.

The blood, apparently an homogeneous fluid, is composed of various matters, which chemical examination can detect and separate. It contains gelatine, albumen, fibrine, acids, alkalis, earths, saline and colouring matters, which are employed for the renovation of the solids and fluids of the body. It prehents thee to the various organs, which, by converting them into their own substance, derive the means of supplying the waste occasioned by the natural actions of the parts, or form out of them various products, distinguished by new characters, and extraneous to their own composition.
G L A N D.

The former of these proceffes is nutrition or aflimilation; the latter secretion: they resemble each other in their commencement, in which the organ, by some powers of a nature entirely unknown to us, but peculiar to living bodies, and forming part of that complicated notion, which we express by the term vitality, feeks from the blood such principles as suit its nature or functions; but they differ in the employment of what is thus selected, which is retained in the body, and aflimilated to the already existing organization in the former cafe, and applied to some other purpofe in the latter. The fubject of nutrition does not come under our notice at prefent.

The products of secretion refult from an effential change in the compound conveyed to the organ, from a new combination of the principles contained in the blood, which is transformed by the specific action of the various organs into different fluids, retained in or expelled from the body, according to the qualities of each. Hence, there are organs which, after forming certain fluids, collect and retain them; while others separate and expel their secretions from the body. The object of the secretions is, to collect those which are defigned to fulfil important ufe in the body; while that of the excretions is, on the contrary, to expel matters which would be injurious to the frame. The two functions then of secretion and excretion resemble each other in many respects: there is in both a separation and collection of fluids. The difference consists in this, that in the former cafe the separated fluid remains in the body, while it is soon expelled in the second. Thus secretion always precedes excretion; and, in order to understand the latter, it is neceffary to know how the former takes place.

The word secretion, derived from fecernu, I separate, signifies fairly the act of separating; and its physiological import is conveyed in that notion. It denotes, in phyfiology, that function of a living body, in which various fluids, diftinguishing from the blood and from each other, are prepared from the common mafs of the blood, the fame fluid being constantly formed in the fame organ. No part of phyfiology is more obscure, and more difficult in its investigation, than this very function. Malpighi, who had bellowed great labour on the structure of the glands, and was confidered to have unveiled, in a great meafure, the mysteries of their organization, confessed his ignorance on this subject; and, as the avowal, from fuch a quarter, is interesting, we fubjoin the passages, of which the remarks here made, confemning the kidneys, apply equally to all other secretions. He fays of the urinary secretion, "quanum arte id contingat obfcurifimus: licet enim glandularem minifinum totum hos subfeqvi rationi fit confonum, quoniam tamen minima illa, simplicexque metatum in glandulis structura nos latet, ideo quaedam tantum meditari potuit, ut huic quaefe probabiliter fatisfaciamus. Necelle eft hanc machinam interna configuratione feparationis opus peragere: an vero his, quae ad humanos usus paflim uturpares, quibus fere conftitutus effigimus, confection, dubium; licet enim occurrent analoge fpongiae, incerrifici, fublimis crirbrorumque structura, cui tam in his conftitutus undequeque fit renum fabrica, difficultium eft affignare, et cum natura operando in一刀ia fecundarea fit, ejufdem ignoto nobis reperientur machina, et quas nec mente quidem assequi licet. Illud mirar tam copiosa, diversa corpora separari per has glandulas in natura fit, etiam minima aqua cum faldinis, faphture et conftitutus particulis, et ex morbo etiam afceffuum religie, et totius quandoque corporis inquinamenta separantur de tentis fanguineis particulis," &c. De Vifcerum Structura; De Resinibus, cap. 6. The whole business is carried on in the

minute, and, as we may call them, elementary parts of the viscera and glands, the structure of which eludes the research of our fenses, and can still less be developed by reaoning or reflection. Observation cannot follow the work throughout; nor does it admit of elucidation by experiment, like some other fubjeets which have been explained by artificial imitation of the proceedings of nature.

Unwilling to confefs their ignorance and leave their systems imperfect, phyfologists have attempted to raise, on hypotehesis, that structure, for which anatomy afforded no foundation. Their notions, refting merely on probabilities and loose analogies, have flourifhed and fallen in succession; and we fhall find that the lift of truths and ascertained facts is much shorter than that of opinions and errors.

The composition of the secreted fluids presents various differences in the nature and proportions of their conflituent parts. They poifeft, in common, all the general characters which belong to animal subftances: but each has certain particular distinctive qualities, depending on the various simple or compound principles, the union of which determines its specific nature. Thus, setting aside the resemblance of all our fluids, considered as animal productions, fat does not resemble bile; the latter is very different from milk; which, again, has no resemblance to the saliva, galzrie, pancreatic, feminal fluids, &c. which must be referred to so many different classes.

The arrangement of the animal fluids is more difficult than we should have expected at first flight. The false and imperfect notions, which were long entertained of their chemical composition, lead to classifications founded on the ufe to which they seemed to be defigned. Those employed in the nourifhment and growth of the body were called recreementitious, fuch as chyle, blood, ferum, lymph, &c. The excrementitious included those which are expelled from the body; as the urine, perfpiration, &c. A third clafs was made up of fuch as partake of the characters of both thefe; of which a part is rejected as noxious, while the reft is retained, in order to answer some particular purpofe.

Under the head of excremento-recreementitious humour, were arranged the saliva, bile, pancreatic juice, mucus of the intestines, &c. The objections to fuch an arrangement are too obvious to need enumeration. This division, as well as that before alluded to, of excretions and secretions, cannot be adopted with any benefit, while the nature and objects of many secretions are fo little understood, that we cannot determine whether they are expelled as noxious, or serve very useful purpofes in the economy. The bile, for example, has been very commonly deemed an excrementitious fluid, but by a completely arbitrary assumption: what proof have we that perspiration separates any thing noxious from the blood? For what reafon is the secretion of the pancreas placed in one rather than in the other of these divisions?

Pitcairne, who was followed by Micheleotti, divided the animal secretions in which has, at leaft, the merit of simplicity, and leads to no false notions concerning their ufe; he diftinguished them merely as being thick or thin.

Haller distributed the fluids into four classes, according to the chemical notions of his time, and to the degree of complication in their elements. 1. The aqueous fluids. These have a very large proportion of water in their composition; hence they are distinguished by their fluidity, and have no ripoints. Fire dissipates them almost entirely, excepting a very small proportion of earthy radicals; neither alcohol nor acids coagulate them. Besides a little earth, they
they contain some fatty and oily matters. Many of our fluids belong to this division. Some are expelled from the body, and are ordinarily deemed excrementitious; such are the urine, which is not coagulable in the natural state; the inoffensive Sanctorian perspiration, and the pulmonary exhalation. Sweat is a mixed fluid, containing oily or febaceous matter, together with water. Several of the fluids, which are defined to serve particular purposes in the animal economy, contain very little except water. This is the case with the secretion of the proper salivary glands, with that of the pancreas and lacrymal gland; with the perfectly pure and transparent aqueous humour of the eye, and other watery fluids in the same organ.

2. Mucous fluids. These differ from water in being less fluid; they are tenacious, so as to adhere to solid bodies, and dry with. They mix with water, are impud and odorous, and nearly colourless. The evaporation of their aqueous parts reduces them into hard and dry cucts. Acids do not coagulate them; but alcohol has a flight effect. They yield, on distillation, a large quantity of water, volatile oil, and a carbonaceous residue. To this division belong the lubricating fluids, which are poured out over the extensive surfaces of the respiratory, digestive, urinary, and genital organs, and all the parts connected with them.

3. Gelatinous fluids, which are coagulable by heat, warm water, alcohol and acids, remain fluid below 143° Fahrenheit; and have a mild or slightly fatty taste. Haller places in this order the serum of the blood, the lymph conveyed by the arteries, the water of the amniotic, the serous exhalations of the circumscribed cavities, the lymph of the cellular substance, and the fluid of the Graafian ovula. He also places in this division the synovia of the joints, and the fluid of the tendinous sheaths, observing, at the same time, that these are partly composed of oily matters.

4. Oily fluids. These are represented by Haller as more perfectly animalized productions; they are freed from the superfluous quantity of water, and are inflammable; or at least contain much of that matter which takes fire and degrades. At their first production they contain much water, so as not to be capable of inflammation, nor to possess their peculiar character, but rather to resemble mucus or gelatine; they undergo changes afterwards, which deprive them of their aqueous parts, and render them more viscous and oily. The fat and the medullary substance of the bones, are the most extensive specimens of this order; it contains also febaceous matters of various kinds, as the greatly cutaneous matter, the Meibomian secretion of the eye-lids, that of the glass penis, and of the external organs in the female. The bile, eruct of the blood, milk, and prostatic fluid, belong to the same class.

Such are the four divisions, in which Haller has arranged the animal fluids; he observes that several, being of a mixed nature, do not belong exclusively to either class, but ought, from the diversity of their principles, to be referred to more than one; indeed there is hardly any, which can be rigorously said to consist of a single element. Then, again, many evidently contain more fluids than one, formed separately in the first instance, each in its appropriate organ, and afterwards mixed together. Thus the semen contains the secretions of the testis, prostrate, and vesicula; the sweat is made up of the water of perspiration with the cutaneous oil; the tears are a mixture of water, mucus, and febaceous matter; spittle contains water and mucus, &c.

The vast improvements in the science of chemistry since the time of Haller must necessarily have subverted the basis of the arrangement just described; which, when considered by a chemist of the present day, would be found open to objection at all points. The deficiencies of the classification are too obvious to render it necessary that we should particularize them.

Blumenbach has classed the products of secretion on a somewhat different principle. "The secreted fluids," says he, "display on one hand so much variety, while on the other they seem to be joined by so many points of affinity, that their arrangement in classes must be in great measure arbitrary. They may, however, be disposed in the following order, according to the lighter or more essential changes and modifications which their elements, contained in the media of the blood, undergo in the secretory organs. Milk may be placed in the first rank, as confuting apparently of a very simple modification of chyle, and formed from the blood by a very slow process after the influx of the chyle. The watery secretions come next, so called from their fluidity and transparency, although they differ materially from water in the nature of their constituent elements, particularly in containing a portion of albuminous compound matter—including the fluids of the eye; the tears, the matter of perspiration, the exhalations in the cellular substance, and in the thoracic and abdominal cavities, to which the liquor pericardii and the fluid of the ventricles seem to be analogous. The urine, ordinarily referred to the aqueous fluids, is distinguished by very remarkable peculiarities. The salivary fluids, concerned in the functions of mastication, digestion, and phlegmification, seem to be rather more altered. They then follow the mucous secretions, spread over the surfaces of most of the visera belonging to the nature of the generative organs, as well as the cavities of the nose, larynx, and respiratory organs. The mucus in the interior of the eye, as well as that under the epidermis, do not appear to differ essentially from the preceding. Under the title of adipous fluids may be classed, besides the common fat, the medulla of the bones, and the febaceous matter of the skin (including also the cerumen of the ears). The grasy matter formed under the prepuce about the corona glandis of the male, and the similar production in the female pudenda, may be referred to the same class; as well as the secretion of the Meibomian palpebral glands. The liquor of the amnios, and the synovial fluids, are commonly deemed gelatinous; but their real nature is not yet understood, neither is that of the fluid, hitherto unnamed, thrown out in the uterus under the venereal stimulus, known. The fluid contained in the early months of conception between the chorion and amnios, that of the velica umbilicalis, and that which surrounds the veins of the umbilical chord, is as yet little understood. The contents of the Graafian vesicles, and the prostatic fluid, seem to be truly serous or albuminous. The male semen is quite a peculiar product, not to be compared to, or classed with, any other; and the same remark will hold good also of the bile." Inflit. Physiol. sect. 32.

The division of this able physiologyst would be natural and instructive, if the animal fluids deviated from the nature of chyle by gradations which could be easily perceived and marked. But we really cannot establish among them any order corresponding to their natural composition; and the differences observable between chyle and fat, between the aqueous fluids and bile, constitute intervals, which we cannot appreciate or measure. Indeed there are often so many differences and so few relations between one fluid and another, that we can fearlessly compare them at all.

The vast improvements which chemistry has made of late years, and the valuable discoveries with which the analysis of
Of animal substances, as well as other parts of the science, has been enriched; might have led us to expect that the classification of the fluids would have been reformed according to their constituent principles, and brought into a condition corresponding to the rest of the science. Fourcray has indeed given such a distribution of the subject in his Elements of Chemistry; but he does not seem to value the arrangement very highly, as he has not continued it in his last great work, the "Système des Connoissances Chimiques." In proportion as the various animal products are analysed with more accuracy, they are found to possess specific characters which distinguish them from each other; and therefore render it impossible to refer them without impropriety to any general heads: accordingly in the most recent and able chemical works, they are enumerated and considered separately. In this point of view, therefore, the exactness and perfection of modern analysis renders our attempts at a general arrangement of the animal fluids unnerving; and it has only served hitherto to shew the defects of such methods.

Dumas, in his "Principes de Physiologie," adopts a different plan, which he calls a natural physiological one, and to which he ascribes the advantage of connecting closely the knowledge of the fluids with that of their uses. "This method," he observes, "is the most natural and useful of all, to refer the fluids to the various organic systems in which their secretions take place, to make a class of humours for each system, to consider each of them as inseparable from the system to which it belongs, and to conduct the study of both together. We shall therefore have as many different classes or species of fluids as there are organic systems in the body. This simple and natural method of considering the subject appears to me to be preferable to the more laboured arrangements founded on the essential nature and chemical composition of the fluids, because it is not exposed to that uncertainty, which the imperfection, the variations, and even the progress of our knowledge concerning the nature and properties of animal matters, must unavoidably occasion. It is, moreover, the most easy and instructive way to consider the secreted fluids in their relations to the solid organs, with whose functions they are concerned. The distribution of the animal fluids with regard to the seven organic systems of which the human body is composed, will be better understood by presenting it in a tabular view, where their relations, influences, and uses, will be immediately perceptible.

Fluids of the nervous or sensitive system.

Fluid of the ventricles of the brain, Aqueous, vitreous, and crystalline humours of the eye, Tears, Meibomian secretion, Mucus of the nose, Cerumen, Fluid of the labyrinth of the ear, Saliva.

Of the muscular or moving system.

Fibrine, Serosity, Fat, Mucus of the trachea and air-veins, Fluid of the pericardium, Pleura, Pulmonary exhalation, Blood.

Of the visceral or organ of supply.

Mucous of the mouth, pharynx, and oesophagus, Stomach, Intestines, Kidney and bladder.

Gastral fluid, Pancreatic fluid, Intestinal fluid, Exhalation of the abdominal cavity, Bile, Liquor of the renal capsules, Urine.

Residue of all the fluids, and of nutrition, Lymph, Fat of the cellular tissue, Mucous fluid, Prostatic liquor, Mucus of the urethra, Vagina.

Of the lymphatic or collecting system.

Semen fluid, Exhalation of the tunica vaginalis, Contents of the ovarian vesicles, Liquor amnii, Meconium.

Of the bony or supporting system.

Gelatine, Medulla, Synovia.

Of the fluids just mentioned, some are secreted in certain organs belonging to their respective systems; e. g. those of the conglomorate glands, of the glandular viscera, &c.; others are formed over whole organic systems, without any particular apparatus, as the exhalation in the cellular membane, that of the circumscibed cavities, &c.; while others are not the produce of secretion, but more freely through all parts of the system in which they are concerned, as the blood and contents of the absorbing system. With the latter we have nothing to do at present; neither does the organization, from which the fluids of the middle classes are produced, come under our consideration in this article, but it will be described in INTEGUMENTS, MEMBRANE, and CELLULAR SUBSTANCE.

The physiological theory of the secretions must be founded on a perfect knowledge of the nature of the animal fluids, and of the structure of the secretory organs. The solution of the interesting problems arising out of this subject, can be expected only from the union of anatomy, enlightened by just views of physical science, with chemistry, supported and directed by physiological observation. The secretory organs are of various kinds, and preserve a constant relation to the kind of secretion, and the manner in which it is effected. Those fluids, which seem to be derived from the blood, with the least change, are not produced by a complicated organic apparatus. The exhalation, which moistens the surfaces of the circumscibed cavities, the aqueous vapour of the lungs, and the cutaneous perspiration are formed by organic systems, composed chiefly of vascular ramifications, without possesting anything that is at all analogous to glandular structure. The arrangement of the fibrous tissue of muscles, and of the bony fabric, admit of the same remark; if we suppose that these organs habitually secrete fibrine or bony matter. But these are cases, which come under the description of nutrition, and in this sense all parts of the body may be called secretory or-
gans. The mucous fluids, which appear to differ more considerably from the materials in the blood, are generally separated by particular glands, which are called crypts or follicles, contained in the substance of the membranes or vilceae. But it seems probable, that these also may be separated from the vascular ramifications of a simple membranous tissu without any express glandular structure, as in the case of several mucous membranes. It remains therefore for us at present to explain, in a general way, the anatomical structure of the various glands, by which the other animal fluids are secreted.

The glandular differs from most other systems, in the animal economy, in this circumstance, that its peculiar tissu is not exactly identical in all the organs belonging to it. The fibres of any voluntary muscle would serve equally well to compose any other of the same kind. Tendinous fibres, cartilaginous and bony structures, are the same everywhere. The substance of the liver, on the contrary, is widely different from that of the kidney; which again is very different in its character from that of the salivary glands. The glandular systen, therefore, is marked in its various parts with very few general attributes, which also fuller many exceptions.

Situation, forms, division, &c. of the glandular system.—Glands have two different situations in the body. Some are superficial, as the breasts and salivary glands; others deeply seated, as the liver, kidneys, pancreas, and most of the mucous glands, and consequently, not exposed to the action of the external bodies. Many of them occupy situations where there is much motion, as the salivary glands near the jaw, the mucous in close contact with a plane of mucous fibres, the liver in the vicinity of the diaphragm, &c. These facts have led to the supposition that the neighbouring motion, extraneous to their functions, determined the excretion of the secreted fluids. But, in the first place, the palatine glands, the pancreas, the tefficles, and even the kidneys, are so situated, as to be out of the way of such external affilience. And we observe, further, that mucus is secrated as abundantly by the pituitary membrane, as in any other part, although there is no mucous plane here; that the lining of the bladder produces an equally copious supply, when the vicus is paralytic; and that various causes augment the secretions, without any connection with the circulation first alluded to, as analagous medicines, or the fight of food in the case of salivary glands. We cannot doubt, therefore, as Bordet has observed, that this mechanical cause has nothing to do with the matter, and that the essential cause of all excretion confisits in a peculiar vital action.

Some glands are single, as the liver and pancreas; others are arranged in pairs, as the kidneys, salivary, and lacrymal glands. The latter are similar on both sides of the body; but the resemblane cannot be compared, in respect to its exactness, to that of the double organs in the animal life. One kidney is lower than the other; their arteries, veins, and nerves, are not analogous in length or size; often various notches exit in one, and not in the other: the same observations will apply to the salivary glands.

Generally the forms are not determined in a very certain manner in this system: they are subject to innumerable modifications in volume, direction, and the different proportions; and differ remarkably, in these respects, from the precise and rigorous laws which govern the conformation of the organs of animal life. Take some one organ, by way of example, from both lives. A small brain will be found to possess a corpus callosum, thalamo optic, and corpora striata of corresponding size; while, on the contrary, a large liver often has a small lobulus Spigelii, and vice versâ.

A kidney will often be larger in its upper portion only, or in the lower. These variations in the animal life affect the whole organ; while they frequently are observed in some part only in the organic. Bichat, who makes this remark, endeavours to explain the fact, by his opinion concerning the necessity of a harmony of action in the animal life. If one side of the brain were developed more than the other; if one eye, one ear, or one side of the nose exceeded the corresponding organs, the operations of the mind, the sense of sight, hearing or smelling, would be inevitably disturbed; while the secretion of bile or urine would go on equally well, although some particular part of the secreting organs were proportionally larger or smaller than the others. The glands, which are surrounded by membranes, as the liver, kidneys, and even the pancreas, are less subject to these variations of figure, than those which are contained in the cellular substance, without any membraneous covering, as the salivary, lacrymal, mucous glands, &c. Those of the latter description in the mouth, and along the trachea, are never alike in two subjets. The parotid sometimes is prolonged over the maffeter, and at others leaves that mufcle uncovered; varies in its breadth, &c. When either of a pair of glands is fometimes enlarged, as to be incapable of continuing its function, that on the opposite side of the body either increases in bulk, or we may sometimes observe in the kidneys; or its secretion is augmented.

The surface of such glands as are not covered by membranes is uneven and tuberculatated; it may be in contact with muscles, veflels, nerves, &c. even with bones, as in the salivary and lacrymal glands. In general, they are surrounded by less cellular tissu, than organs which have considerable motion. That which is in immediate contact with them is dense, like the exterior covering of arteries and veins, but it is not firm. It does not usually contain fat; and by isolating the gland to a certain degree, it is analogous to the peritoneal covering of the liver, or to the proper membrane of the kidney or spleen. Anatomists have very commonly divided the glandular systen into the convolute and conglomerate glands. The former name denotes the gland-like bodies belonging to the lymphatic systen, and was designed to shew that each formed only one mass. The latter term is most properly applied to the salivary and lacrymal glands and pancreas, which are made up of numerous smaller particles united together. It cannot well be given to the liver and kidneys, which poiffe nothing of a conglomerate structure; and these, accordingly, have been generally called glandular vilceae.

Organization of the Glandular System.

1. Peculiar tissu of this system.—The glandular tissu differs from most others, in poiffeing no marks whatever of a fibrous dispostion. Its component elements are not placed by the side of each other, according to longitudinal or oblique lines, as in the muscles, the fibrous systen, the bones, nerves, &c.; but they are heaped together, by a kind of confused, and, as it were, casual approximation, and adhere together but weakly. Thus, while organs, which poiffe distinct tissu, have considerable powers of reflation, particularly in the direction of their fibres, glands are torn easily by slight degrees of violence. The broken surface is uneven, full of projections and deprivations, which distinguishes these organs from cartilage; the rupture of which is generally smooth. The prolife, tonsils, and mucous glands relit much more powerfully than the liver and kidneys, in which the phenomenon just mentioned is the most easily observable. The pancreas and salivary glands are elongated by any diluting force, without tearing; but this circum-

stance
face arise from the abundant cellular tissue distributed throughout their substance, and not from any peculiar property of their glandular tissue. Their lobes are separated in proportion as the intermediate cellular filaments are elongated.

The glandular tissue, which anatomists have generally called parenchyma, is disposed in three different ways. 1. In the salivary, lacrymal, and pancreatic glands, which are properly called conglomerates, the organ is made of distinct portions, connected together by a loose and copious cellular texture, the intervals of which transfix vesicles and nerves. There are again made up of smaller lobes united in the same way; and the divisions are more easily pursued when water has penetrated into the composing substance. Repeated divisions flew us smaller and smaller component portions, till we come at last to very small bodies, all conspicuous to the naked eye, and called glandular acini (grains glandulares, &c.). These component parts are flimmer in proportion to their smallness, as they are surrounded and connected to the adjoining portions by shorter and firmer cellular substance. We can easily follow the 2d, 3d, and even the 4th division of these lobes with the sepal.

The acini are of a roundish figure and pale colour, and distinguishable from anything else of a mucular nature by the absence of fibres. When examined with magnifying glasses, they are seen divided into smaller portions by cellular interlaces, and we can hardly come to an end of these divisions, if we employ successively greater magnifying powers. 2. There are no traces of the primary divisions just described, into the larger and succeeding lobes, in the liver and kidneis. They consist of an uniform and even tissue made up of glandular acini, closely united together into one substance. The connecting cellular structure of these particles, if there be any, is very small in quantity and short; hence the facility with which these bodies may be torn, and the kind of granulations which their rupture presents. 3. The profile, tonisls, and all the mucous glands, have no appearance either of primary or secondary lobes, or acini. The first of these consists of a dense parenchyma: the latter of a soft and almost pulpy substance. They cannot be torn, like the liver and kidneis.

Controversy concerning the structure of the glandular acini.—It is easy to proceed far in analysing the composition of the glands; but these researches do not at all contribute to explain the mechanism of secretion. In the hope of accomplishing that object, anatomists began, as soon as the improved condition of the science furnished the means of professioning such investigations, to subject the various secretory organs to a very attentive and close examination, and endeavoured to shew the nature of the acini, into which most of the glands were ultimately resolvable. The aid of magnifying glasses, and of anatomical injections, was referred to on this occasion; but the opinions of two individuals, who had devoted much time to the subject, were completely at variance, and gave rise to a controversy, which had at least this good effect, that it occasioned a very thorough examination of the subject.

Malpighi taught that the acini are hollow; that the arteries distributed on their surface deposit the secreted fluid in their cavities, and that it is conveyed thence by an excretory duct; that the union of these tubes forms larger excretory canals, &c. He deemed the mucous glands of the alimentary canal, mouth, &c. to be the most simple forms of glandular structure, and considers that the larger glands differ only in confiding of an aggregation of such simple ones. « Glandula, qua palatino, gsthpa, intellis, et contimilas partes copiosa distantur, et omium simplicissima, et idea reliquarum glandulorum.» Hist. Vol. XVI.
blood-vessels into the excretory ducts; e. g., in the kidney and liver. As Ruyfch continued his investigations, he found that the bodies considered as glandular and hollow acini by Malpighi, are mere blood-vessels. After accurately injecting the liver and kidney, and macerating them in water, he found them resolved into small clusters of blood-vessels, and proved this so clearly by his preparations, that Boerhaave, who had been a warm defender of Malpighi's doctrine, in defence of which he wrote the Epitola de Fabrica Glandularum, ad F. Ruyfch, was induced to renounce his opinion. The elegant preparations of Ruyfch, and his appeal to the evidence of dissection, and other anatomical investigations, brought most anatomists over to his opinions, which, indeed, are generally received in the present day. Haller gives the following summary of his opinions on this subject. "Viserca nonpex secretohunc definita, corumqueimprimis acini, glandulare et conglomeratam, meris cum domesticis, cellulisque ope conjunctis, eo cum vinculi rebure ut convixit acini, aque ficti sociis, Laxiborium fidi fidi annexis, totus et integer deduci potest. In quolibet praecito acini, valorumquae glomeris, ex cadem fonte, ductus excretorius eff, phaseone ductuli, qui de arteriola minima, tanquam ramulis minor et fanguini imperi, decessit videre, quia in fabrica in raro continebantur, in alius quidem colis magna cum veri specie ex concealta admissit. Secretum adeo a vulgari fanguinis circuito battebus differt, quod in aliqua quidem arteriola minima cylindracea, in venas fidi aequales, aut ampliorum continetur, quae fanguinem reperire apta est, in humorum vero separatione ductus excretorius, rubro vaso arterioso minor, tanquam ramus exer vaso prodibat." Element. Physiolog. lib. 7, sect. 2. § 14.

The opinions and arguments of Ruyfch may be collected in his answer to the letter of Boerhaave mentioned above, in some of his other epistles, and in various of his Thesauri. He has given several figures representing the distribution of the minute vessels in various organs, and proves satisfactorily that the bodies called acini by Malpighi are merely minute vessels; he shews this concerning the spine and brain, as well as in the glandular viscera. On the subject of this controversy, we may observe, that its importance does by no means warrant the pains bestowed on it, and the noise made by the combatants in conducting it. The nature of the investigation, which is carried on entirely in the minute elements of the body, and prosecuted by means of magnifying glasses, injection, maceration, and corrosion, renders the conclusions, which we arrive at, in great measure, uncertain; and the parts, of which the structure is sought, are so exceedingly small, that neither opinions can be considered as clearly demonstrated, or satisfactorily refuted. The mode, in which secretion is effected, is equally obscure, whichever of the two suppositions we may adopt: neither of them solves the mystery. Let us admit with Ruyfch that the excretory tube is continuous with the secreting artery; shall we then understand how such infinitely diversified products, all differing from each other, and from the blood, are formed from the common mass of that fluid? Shall we be able to point out the precise spot in the continuous canal where the blood ends, and the bile, urine, or milk begins? and to explain how the change is effected? If, on the contrary, we suppose, with Malpighi, that arteries, ramifying on small membranous cavities, deposit the new products in these receptacles, our ignorance of the points in question is neither more nor less complete than in the other case. Too much labour has been already spent on these idle disquisitions; modern anatomists have judged wisely in abandoning them, and in preferring the talk of collecting facts concerning the natural and dissected structure and functions of our frame.

With such impediments, concerning the value of these pur-

fuits, we were much diverted, at observing the complacency with which Ruyfch, the great authority of the two last centuries on the structure of glands, comprehends his own doctrine, and the fancied victories with which he represents his own discoveries, as the immediate produce of a direct divine revelation. "Placuit bonitati divinae lux revelare orbis luminibus jam sensilibus. Invidi, et inimici mei lucis ridicitarum, in initio, fed Deus cui foli ornis gloria et honor, habeat benedictum potest, &c. Epitola Anat. ad v. c. H. Boer-
haave.

The organization of all the glands is by no means so uniform as to admit of our referring the mode of glandular secre-

tion to any one mechanism. The mammary gland and teflis do not resemble the texture of the organs already de-
scribed. In both of these, which again are widely different in all their feasible properties from each other, there is a vast congeries of secretory tubes, infinitely convoluted, with vascular ramifications copiously distributed among them. In the ultimate elementary parts of these glands, as far as our senses can pursue them, we discover nothing but minute, serpentine, and very slender tubes; which are particularly obvi-
ous in the teflis, without any trace of Malpighian or Ruyfch-
ian acini. In the breast, indeed, the existence of these bod-
ies has been a matter of dispute, and arguments, not de-
cient in plausibility, have been adduced on both sides of this important question, which, like many religious myster-
iess, is involved in just so much obscurity, as to make it a very suitable subject for polemical exercise.

The organs of the mucous secretion, in general, do not fall within the description already given of the glandular structure. These seem to exhibit, in many instances, a very simple form of gland, of which, however, the action is no more understood, than that of the more complicated kinds. They consist of small receptacles, lined by the membrane covering the part, receiving the secretion, and pouring it out by a single orifice in the centre. Very simple glands of this kind are seen in the root of the tongue; their figure is circular or elliptical; the cavity is lined by a thin membrane, sur-
rounded by a pulpy vascular substance, which causes a super-
ficial prominence, in the centre of which is a simple aperture, affording mucous on pressure after death.

In other instances, the membranous part is more con-
picuous, and the glandular substance less considerable, or in-
deed hardly perceptible, so that the whole seems to be form-
ed merely of membrane. These have been called crypts, folliculi, &c. Their figure is generally circular or oval, and they are lined by continuations of the membrane, to which they belong. They are placed in the cellular fibres, and may possess more or less of the pulpy vascular matter. They have simple excretory tubes, commencing from the hollow of the membranous cavity, and terminating by open orifices in the surface of the part to which they belong, as the mouth, fauces, trachea, or intestines. Pressure forces the secreted mucous from the open orifice. To these clafs may be referred the glands of the lips, cheeks, epiglottis, pharynx, and eulo-
phages, thefe of the soft palate, trachea, larynx, and intest-

ines.

These more simple kinds of crypts or follicles are united in different instances, so as to compose larger masses. Sometimes they are simply contiguous, connected by loose cellular sub-
stance, and possess each its proper duct; e. g., at the back of the tongue, and about the artenoid cartilages. Such have been called glandulae congregate. In other instances, nu-
merous follicles, included in a common covering, deposit their mucous in one or more large cavities, into which several follicles open. The tomils afford an example, as have been called glandulae congregate.
The secretion of mucus is often performed in a species of structure, which does not seem to possess any thing of a glandular nature: in small membranous canals, which will admit bristles for about half an inch in length, ending by blind extremities in the cellular substance, and terminating by oblique apertures on the surfaces of the mucous membranes to which they belong. Neither acini nor round follicles can be discovered opening into such canals, which are technically named finulae or lacunae, and which, in the urethra, have a perfectly smooth surface. Some of these are simple, as in the septum narium, the urethra of both sexes, the entrance of the vagina, &c.; others are ramified, as in some instances in the male urethra; in the neck of the uterus, &c.

The glands, which produce various matters of an unctuous description, appear to be very simple in their structure, but they are mostly insufficient to prevent us from entering into much detail concerning their organisation. The cavernous glands of the ear are small round bodies, differing in the surfaces of the cellular substance, and each of which secretes a duct, penetrating the integuments of the meatus auditorius, and ending on its surface by an open mouth. They seem to consist of simple membranous cavities. The organs, which secrete sebaceous matter, in various parts of the integument, do not seem to differ essentially from these. They are round membranous cavities, with their sides covered by numerous vascular ramifications, opening on the surface of the part to which they belong, with or without the intervention of a simple duct. Where they produce a fluid which concretes, it may be expressed from them in the form of a flaky white thread. The areola of the nipple, the nymphse, and the other external female organs, the corona glands of the male, the nose, and particularly the cavity between its ala and the cheek, the upper lip, and the hollows of the external ear, possess numerous glands of this description. The Meibomian apparatus of the eye-lids is only a rather complicated specimen of the same structure; several simple glands open into a common duct.

The prostate possesses a peculiar structure, which can hardly be referred with propriety to any of the species first enumerated.

The glandular tissue, cut in slices and dried in the air, loses its original colour, acquires a dark hue, and even a blackish tint in the liver and kidney, on account of the large quantity of blood which they contain: if the latter vessels are repeatedly washed, before they are dried, they continue to appear greysih. The glandular tissue, in its dried state, is remarkably hard and brittle. If kept moist and exposed to the air, it becomes putrid very rapidly, and exudes in that state a highly disagreeable odour. A greater quantity of ammoniaceal matter is formed. The liver is particularly distinguished for the insipitable stench caused by its putrefaction. The kidney goes lefs rapidly into that state.

When boiled, the glandular substance produces at first a greyish substance, which troubles the water uniformly at first, and is then collected in an abundant froth at the top. This product is most abundant in the prefont, the muscular, mucous, and cellular tissues; and lefs in the cartilaginous, tendinous, fibrous, &c. The froth produced by its boiling is of a deeper colour, and seems to contain more numerous pricks, than that derived from the white organs.

Like all other tissues, the glands grow hard at the first periods of ebullition, but instead of becoming softer afterwards, as the others do, the continued boiling makes them more and more hard; so that after five or six hours of ebullition, their firmness is triple or quadruple that which belongs to them naturally. This phenomenon is most remarkable in the liver. When removed immediately after the first corregating effects of the hot water, they do not display the elasticity which the other tissues possess at this time. A tendon or muscle in such a state, if drawn, restores itself immediately, while a slice of liver breaks. The absence of fibrous matter perhaps is the real cause of this difference. The sudden action of naked fire crisp, and corrupts the surface, as in all the other solids, and produces a hard exterior crust.

Maceration in water produces different effects on the different glands. The liver yields longer than the kidney, which, after two months, is reduced to a reddish pulp沉重meric in the water, while the former still preserved its form and density, and had undergone no other change than from a red to a bluish brown colour. The salivary glands exhibit much of the whitish, unctuous and firm matter, which is seen in all cellular organs after long maceration. This does not arise from an alteration of the glandular tissue, but from the fat contained in the abundant cellular texture of these parts.

Acids act on the glandular tissue nearly as upon the others. They reduce it into a pulp, varying in its colour, and in the promptitude of its formation according to the nature of the acid employed. The sulphuric acts most quickly, and gives a black pulp, while the nitric renders it yellow. They act much more slowly on the glands after boiling than before.

Generally speaking, the glands are much less digestible than most other animal substances; particularly in their boiled state: for coction produces in them quite opposite effects to those which it exerts on the cartilages, tendons, and all the fibrous organs, which are rendered less dense, more gelatinous and viscid, and more speedily digestible by the gastric juice. The glands would probably be digested more easily, if eaten raw. Liver is less digestible in proportion as it is longer boiled. Bichat made a comparative trial of it in a raw and dressed state: the former was reduced into a pulp in the stomach of a dog, when the latter had undergone a very slight alteration.

Excretory tubes.—All glands have tubes for the purpose of conveying away the fluids, which they separate from the blood; and as these canals are only found in glands, their consideration belongs to that of the peculiar tissue of the gland. The excretory ducts have an uniform origin in all glands. They arise like veins, by an infinite number of capillary tubes, which appear to begin at the acini, where they exit. Each acinus is said to have an arterial and venous, as well as an excretory tube. Arising in this way from all the interior of the gland, they soon unite together, into more considerable tubes, which generally run in straight lines through the glandular tissue, unite to each other, and form at last one or more large tubes.

Glands are to be distinguished into three kinds, with respect to their excretory tubes. 1. Some transmit their secretion through several ducts, each formed by smaller ones, and opening near together, but distinctly, and with perfect separation. In some cases these separate apertures are found on a more or less distinct prominence, as in the breast, prostate, and sublingual glands. Sometimes the orifices are found in a depression, in a kind of cul-de-sac, as in the tonsils, the foramen caecum of the tongue, &c. 2. Other and more numerous glands pour out their fluids by a single tube, and there is nothing remarkable in general in the orifice. 3. Some glands deposit the produce of their secretion in a reser voir, where it is retained, in order to be expelled at particular times. Such are the kidneis, liver, and testicles. In this case there must be two excretory tubes; one to convey the secretion from the gland to the reser voir, and the other to transmit it to its final destination. These reser voirs are therefore evidently connected with the excretory tubes.
G L A N D.

Although the two first classes of glands have no reservoirs, we may, in some degree, regard the different ramifications of their excretory tubes as supplying their place. These, indeed, as well as in the glands, which have reservoirs, are habitually full of the secreted fluid. Under whatever circumstances the individual may have died, we may always produce a considerable fluid by mere pressure on the gland. The papilla of the kidney affords urine on the pressure, sections of the liver show bile in the hepatic ducts, and the testicular vesicles are full of milk, for which there is no other reservoir. From variations in the quantity of fluid, in the latter instance, the greater or less size of the breast, during suckling, entirely depends.

It appears in general that the passage of the secreted fluids in the excretory ducts is much slower than that of blood in the veins, or of lymph in the absorbing vesicles. Urine is constantly flowing through the ureters; but a much greater proportion of blood would pass through a vein of equal diameter, while the bladder was filling. The rate of motion however varies under different circumstances, the fauna is secreted much more quickly during a meal, and urine passes off much faster after watery drinks.

The size of the excretory tubes varies very considerably:

1. Where several are produced from one gland, they are very small, and sometimes scarcely perceptible. They run in a straight line, have no communications, and open immediately on quiting the gland.

2. Those which are single are larger; bearing a proportion however to the size of the gland, excepting the hepatic duct, which is manifestly very small in comparison to the bulk of the liver. They pass for some distance after quiting the gland, and are produced by the union of such tubes as belong to the last mentioned class; so that if their isolated excretory tubes were to be united together, a common single duct would be formed resembling those of this second kind. The pancreas is the only instance in which the common duct is encased in the substance of the gland; and there is no other instance, but the teeth, where it forms convolutions, so as to be much longer than the course through which it passes.

Whatever the arrangement of the excretory tubes may be, they all pour their fluids either on the surface of the body, as in the ceruminous and sebaceous glands, a'd the breast; or on the surface of mucous membranes, as the mucous, salivary, pancreatic and hepatic excretories. The skin and mucous membranes, therefore, are the only parts moistened by glandular fluids: no ducts terminate on serous or synovial surfaces. The excretories of the pretended articular glands would form an exception to this observation, if the glands existed. They never terminate in the cellular membrane; and if a communication should take place, by accident, abscesses are formed by the suppurative iritation, as in urinary fistula; or inflammation occurs in the track of the extravasated fluid, producing adhesions, which procure the cellular system from more extensive infiltration. Thus the alimentary canal may be regarded as a kind of general excretory, super-added to those of the liver and pancreas, &c., and expelling in one mass all the fluids separately poured through their respective ducts into its cavity. Indeed, all secreted fluids seem designed to be thrown out of the body. Separated from the mass of blood, they are heterogeneous to it, and do not enter the general circulation again in a state of health.

All the excretory ducts have an internal mucous membrane, which is a continuation of the cutaneous or mucous surface, on which they terminate. In addition to this they all possess an exterior substance, including the mucous canal, and differing considerably in the particular gland. It is a very thick and peculiar substance in the vas deferens: an extremely dense and close texture, resembling that of the arteries and veins in the hepatic and salivary tubes, &c. The latter is very different from ordinary cellular substance.

It does not appear that these tubes possess any membrane besides the tiliol, i.e. described, and the mucous lining. Every excretory tube possesses its blood-veils. They receive very manifest arterial branches from the renal and pancreatic arteries: the hepatic artery supplies the biliary tubes, and the Stenonian duct has its branches from the transversalis fascia. Various nerves from the ganglia accompany the blood-veils; but they never form such intricate plexuses as round the arteries.

The excretory ducts possess chiefly the vital properties of the mucous system, which has the greatest share in their formation. Their sympathies are, therefore, nearly of the same kind.

2. Of the other Systems belonging to the formation of the Glands.

Cellular substance.—Glands differ much in the proportion of this tissue, which they contain, and may be divided according into two classes. It is very abundant in the salivary organs, in the pancreas, and hepatic gland, and in all such as have a conglomerate or granulated structure and white appearance. Every gland of this class is divided into lobes very distinctly isolated by grooves filled with this texture, and determining the tuberculated surface which characterizes the exterior of the organ. Each lobule, and every glandular acinus, down to the smallest division, is covered by cellular substance: hence the whole consists of an assemblage of small distinct bodies, connected together only by the circumstance of their excretory tubes being united to form a common duct, and which we could conceive to be perfectly capable of exercising their functions if actually separate. We see this in the parotid; where small accessory portions are often seen in the course of the duct, completely unconnected with the principal gland. The submaxillary and sublingual are sometimes continuous, sometimes isolated. The cellular tissue in these glands often contains an abundance of fat. This is particularly observable in the breast, the volume of which sometimes depends on the size of the gland, sometimes on an accumulation of the adipose substance; a difference, which is very easily recognized by the touch. Hence the quantity of milk is not always in proportion to the apparent size of the mammae. In the proper conglomerate glands, however, the adipose substance seldom amounts to a very considerable quantity. The connecting threads are very short and slender in the teats. In those glands, which have a dense parenchyma, as the liver, kidney, prostate, and mucous organs, there is very little cellular tissue, and hence the facility with which some of them may be torn. Their substance never contains fat. The mucous coat of the liver in various diseases does not invalidate this observation: for the fat then enters into its composition as an essential element of the organ, and is substituted in place of the colouring matter, which disappcears; it is not contained in cells. Fat may be seen also in the interior of the kidney, but it is round the pelvis, and not in the proper parenchyma of the gland. The tonsils, prostate, and mucous glands never contain any. Serious fluids are never thrown out in the substance of glands, which have a close parenchyma; they are not affected in cases of the most general and extensive anaemia. We cannot, however, doubt the existence of cellular tissue in such glands: necrosis demonstrates it. The fungous tumours, growing from these organs, contain much of it; and it is principally seen round the vessels, as in the capsule Chiffon. This texture, indeed, is often diffused, while the proper substance of the gland remains.

Found.
found: hence the development of inflammatory tumours in the liver, of serous cysts in the kidneys, and of hydatids in both, without the secretion being at all disturbed. The liver is sometimes surrounded by three or four fold by internal tumours, without its proper tissue being augmented: the latter forms a kind of capa between the swellings in which the biliary secretion goes on.

Blood-vessels.—Glands, which are not surrounded by a membrane, receive their arteries from all quarters. An abundance of small branches from the neighbouring trunks penetrates the surface of the salivary and lacrimal glands, the pancreas, &c. They first run between the lobes, penetrate into the smaller divisions, and are finally dispersed on the acini. The branches coming from different quarters anastomose freely in the gland.

Where the organ is surrounded by a membrane, as in the liver, kidney, salivary, &c., the arteries penetrate on one side only, generally at a more or less deep notch, and in a single considerable trunk, which, however, is sometimes previously divided into a few smaller branches. The part, at which the artery enters, is always the farthest removed from the action of external bodies; a remark, which is common to all important organs, as the lungs, intestines, spleen, &c. The convex surface of the liver, where the vessels are the smallest, and where hemorrhage would consequently be attended with the least danger, is always turned upwards. When it has entered the gland, the main artery quickly divides into various branches, which diverge and are subdivided as they approach the convexity. They have various branches in the body of the organ, as they proceed, and end by producing a large number of capillaries, covering the surface of the organ. Sometimes they come through, are visible on the surface, and ramify between it and the investing membrane. The most favourable method of observing the distribution of the arterial system in these organs is to inject them with hard injection, and to destroy the animal substance by means of immersion in muriatic or nitric acids: a part of the vascular system, even to its very minute divisions, may be obtained in this way, and such preparations, on account of their elegance, are contained in all cabinets.

Rufch, who was remarkable for his dexterity in these processes, found that the small arteries were differently arranged in the different organs. In the kidney they are convoluted, so as to form, through the whole substance of the organ, small granular bodies less than a pin's head, which are the anastomosis already alluded to. The surface of the liver is covered, after a successful injection, with innumerable capillaries arranged in a fluted form, and giving the appearance of little tufts of minute arteries, when the part is corroded, which have been compared to camel's hair pencils; and this arrangement has been termed the penicillus. A similar disposition is observable in the spleen.

Some have conceived that the large arterial trunks of glands comunicate to the organs an interior motion very favourable to the execution of their functions. These bodies are placed, for the most part, in the trunk, and therefore near to the heart; and their vessels generally enter after a short course, so that the impulse has been considered, from this cause, to be more powerful. The spermatic artery is a remarkable exception to this observation, and the flow of the seminal secretion has been explained from this cause. We own that we cannot discover any very convincing arguments in proof of these opinions.

The veins accompany the arteries throughout, in their distribution to the glands; we have no distinction here of a superficial and deep seated set. The liver is the only exam.

ple in which red blood enters on one side, and black goes out in the opposite direction.

Blood of the glands.—The quantity of blood contained habitually in these organs differs remarkably in the different parts of the system. The conglomeration glands contain very little. It imports no small to these organs, which are whith in their appearance, and only require the water to be changed two or three times in one hour. 2. The mucous glands, profuse, and teedle contain a large quantity. 3. The liver and kidney have such a considerable portion, that they differ widely in this respect from the rest of the glandular system. They contain a large quantity even after death from hemorrhage, or when the glands are suddenly removed from a living animal. Hence, when we consider these organs, it is necessary to renew the water at least twelve times before it ceases to be bloody; when we prefer them in alcohol, previous maceration is necessary, to prevent the spirit from becoming turbid by the blood. This large quantity of blood occasions the glands now under consideration to be heavier than the other parts of the sympathetum; hence, too, erites their distinguishing red color, which is not more essentially inherent in their tissue, than in mucous surfaces or mucus: in fact repeated washings will discharge it as effectually. The liver then exhibits a greyish appearance, which appears to be the proper colour of its tissue, as white is that of the muscular tissue. The appearance of the kidney seems to be less immediately influenced by the blood. It retains a degree of redness after frequent renewals of the macerating water; and the pulp produced by leaving it in water for some months, with frequent changes, still has a red tint, although less deep than in the recent state. Does the state of the secretion influence the quantity of blood contained in glandular organs? Is there more blood sent to the kidney, when the urinary fluid is separated abundantly, than when it passes off slowly? or is there less returned by the veins in the former case?

Nerves.—Glands receive two kinds of nerves. 1. The lacrimal and salivary glands, the tonsils, &c. are supplied almost exclusively from the cerebral nerves. 2. The salivary, profuse, and liver, derive nearly an equal portion from the brain and the ganglia. 3. The kidney and most of the mucous glands, &c. are almost entirely supplied from the ganglia. These remarks apply to those nerves only, which are unconnected with the arteries; for each arterial trunk penetrating a gland, is surrounded by a nervous network belonging to the system of the ganglion, and very manifest in the larger organs, as the liver and kidney, where the plexuses come from the semilunar ganglion, in the salivary glands, where it is derived from the superior cervical, in the testis from the lumbar, &c.

The nerves are small compared to the size of the glands. We must not decide on this subject from those which enter the parotid and submaxillary; for the nerves merely traverse these organs, leaving a few branches behind them. But the liver obviously poleusses as small a supply as any organ in the economy, which receives nerves at all. Nerves enter the glands, like the vessels; that is, they come in on all sides where there is no surrounding membrane; and enter at the notch in odd cases. They divide and subdivide, as soon as they reach the gland, and are quickly lost. There are never any ganglia in the interior of these organs.

We know but little of the exhaline and absorbing vessels in the substance of glands, where they are merely subervient to the purposes of nutrition.

1. Properties derived from their Organization.—These are
very slightly marked in this system, probably from its texture not partaking at all of the fibrous nature. In order that an organ should be susceptible of elongation and subsequent contraction, without injury, its component parts must possess a certain degree of cohesion; and this attribute particularly belongs to fibre. The glandular system, too, is subject much less frequently to causes of diffusion and contraction, than those which are made up of fibres. Where the liver contains a large quantity of blood after death, in consequence of the venous system being overloaded, its bulk remains the same; its fibres are compressed by the weight. The enlargement of the vesicle in gonorhea, and of the parotid glands under certain circumstances, and their speedy subsequent reduction, prove that these organs possess a certain degree of extensibility and contractility.

Are the liver, kidney, and other internal glands subject to similar acute enlargements? The phenomena now cited may take place in the cellular tissue of the glands, and therefore suppose a less degree of extensibility in the proper substance of the gland than might at first have been supposed.

2. Vital properties of the glands, and physiology of secretion.—The remainder of the investigation is much more difficult than what we have already gone through. The nature and properties of the fluids, and the structure of the secreting organs, may be determined in a great measure by the evidence of our senses; but when we endeavour to explain why each particular fluid is separated by its respective organ, the determination of the question implies a knowledge of the hidden structure of the minute elements of our body, about which we must either be silent, or attempt conjectural explanation, at some risk of exposing ourselves. The object then is, to show, why, in the healthy state of the body, salivary, and no other fluid, is constantly separated from the blood in the parotid gland, bile in the liver, and urine in the kidney; and how it happens that the nature of the secretion never changes, so that urine should be formed in a salivary gland, salivary in the kidney, bile in the mammary glands, &c. The difficulty of the undertaking is increased, and the prospect of arriving at a satisfactory conclusion diminished, by this circumstance; that in the different classes of fluids, each is not constantly separated in an organ of a particular structure. If that were the case, it would only be necessary to determine the relation which the structure of the gland bears to the nature of the secreted fluid; but the very contrary is the case. Fluids of each kind are produced by every variety of glandular apparatus; thus water is formed by the arteries of the skin, without any glandular arrangement, by conglomeration glands, in the inanimate of the cutaneous apparatus, and by a glandular vein in the caudal of the kidney: mucous is secreted by mucous membranes, and by different kinds of glands; and lastly, oily matter is poured from the arteries of the cellular membrane, from various subcutaneous glands, from the vessels of the skin, from the liver, &c. Again, there are instances in the body, of organs, which we should, a priori, have pronounced, without hesitation, to be glandular, and which yet perform no secretion. Such are the spleen and thyroid gland, to which we may perhaps add the thymus and renal capsule. The spleen is a remarkable instance of the arrangement of the minute arteries, called the pedicillaries, which is seen also in the liver, and considered to have much connection with the peculiar functions of the secretory organs. In this place, too, we should mention the curious facts, concerning the formation of certain fluids, under particular circumstances, by other glands than those which ordinarily produce them. Haller has collected, in his great work, a vast number of facts of this description; of which, if we should reject all that may seem insufficiently authenticated, there will remain quite enough to prove the points decisively. To the chapter in which these details are contained, he prefixes this sentence: "Suce quidem humor per quodunque columna separat, et the cases which he cites, fully justify his concluding paragraph: "Quando hac exempla repetemus, constabat, non ejusdem unice chartis diversos hodie, tabulae colli communia, sed utam per muci organi aequum, per mucis squamosula, et adipsa colli lymphem et tiglonem, per aqua, mucis et lymphem suis adips, bene lugubrum, fecundum atque adaequandum, nullum in animato corpore separato organis efferre, quod non omnium chilidum hominum suis cum dotibus fecercere quidem." Element. Physiolog. lib. iv. cap. 1, sect. 9. When these circumstances are considered, it will very probably be suspected that the causes of the differences in the secreted fluids cannot be traced in the obvious structure of the glands; but that the reason why a peculiar fluid and no other is separated from each gland, in the healthy state of the body, lies much deeper, and flows from some conditions of the organs, which are inaccessible to our senses. We shall endeavour to illustrate the subject as far as well authenticated facts will afford us, and shall mention the opinions which have been most prevalent on the subject. It will be an easier task to shew how unsatisfactory most of these are, than to substitute any thing more rational in their place. We proceed to point out the vital properties of the glands.

No part of the system possesses animal contractility, or the power of voluntary motion. Different glands seem to be differently circumstanced with respect to the corresponding species of sensibility. The peculiar and oppressive sensation occasioned by compression of the vesicle, is well known. Considerable and continued pressure on the parotid gland has produced great suffering; but large nerves pass through this organ. The liver may be injured in a living animal, without causing any of the usual signs of pain; and Haller makes the same observation concerning the glandular system in general, but his statement is not perfectly explicit: "Universe glandulae experiemini minime irritabilis videntur, neque vehementer aut morbosos fictuant, aut illata professores injurias." Elem. Physiol. t. 2, p. 377. Stones in the kidneys often cause very severe pain. From these apparently contradictory circumstances, we can only conclude that animal sensibility, which is variously modified, may exist in organs, where certain agents do not excite it at all, while others develop it very readily. In fact, various morbid alterations render this property very manifest in the glands. The pain of inflammation bears, indeed, a peculiar character in the glandular system; it is generally acute and heavy.

Properties of the organic life.—Sensible organic contractility does not exist in the glandular system; but the two other organic powers are exhibited in their highest state of development, and are almost constantly in operation, being concerned in secretion, excretion, and nutrition. Organic sensibility enables the gland to distinguish in the veins of blood those materials which are fitted to its secretion; and by its insensible contractility, it has the power of rejecting whatever is heterogeneous. The blood contains the materials of all the secretions, of the nutrition of all organs, and of all the excretions. From this common reservoir each gland draws what is requisite for its secretion, each organ for its nutrition, and every fleshy surface for its excretion. The peculiar mode of organic sensibility enables each living part to distinguish what its functions require. The whole business of glandular action rests on the two powers just mentioned;
mentioned; and as this action is nearly constant, they are almost incessantly exerted.

It is evident that all glandular affections must imply a disorder in the powers above-mentioned; since diseases of an organ are particularly determined by alterations of the feeding properties; of those which constitute the peculiar life of the part. Observation proves this; we see these properties, when augmented or diminished, producing on one side increased secretion, as in diabetes, mercurial salivation, cholera morbus, &c.; on the other, a decrease or even suspension of the function, as in acute diseases, where all the secretory tubes seem, as it were, closed for a time; for instance, in suppression of urine, dry state of the mouth, &c. On other occasions the nature of the glandular sensibility is changed, and it harmonizes with substances which are not admitted in the healthy state; hence the innumerable varieties of the secreted fluids under circumstances of disease. The cystic bile in the dead body presents numerous varieties of taste, smell, colour, and consistence. The numerous alterations of the urine are well known. The saliva is less liable to change; but how different is it in many diseases from its ordinary condition. Nothing can less resemble urine or bile than the fluids often discharged from the bladder and liver; whence these differences? From the variations in the organic sensibility bringing the part into a relation with these substances, which were foreign to it in the natural state. Thus the same gland, without any change in its structure, but merely by altered modifications of its vital powers, may be the source of infinitely varying fluids. Might not this be carried so far as to allow that the kidney, by assuming a sensibility analogous to that of the liver, may actually form bile? why should it not secrete bile, if it does secrete other fluids so widely different from the urine?

In the healthy state, the mode of sensibility in each gland is nearly uniform; and the secreted fluid is consequently nearly the same in its composition and properties. But the mode is changed by numerous causes in disease. An hysterical attack comes on; suddenly the kidney refuses to transform the principles which colour the urine, and that fluid is consequently discharges limpid; as the paroxysm subsides, the natural type of the sensibility is restored, and the urine has its accustomed characters. In an epileptic fit, a thick frothy saliva is discharged from the mouth in abundance; as the attack goes off, the salivary secretion returns to its natural state.

The various changes in the organic sensibility, and the sensible contractility of the glands, do not affect the function of secretion only; but when they last for some time, they influence nutrition also. From the disturbances of this process arise those various organic affections, of which the glandular system offers the most abundant harvest to the pathological anatomist. We cannot avoid noticing, in dissecting rooms, the numerous diseases observed in this part of the body compared to others. The glands, the skin, the mucous, venous, and cellular system, hold the first rank in this respect; and in all these the two properties above-mentioned exist in the highest degree, and are called into action, not merely by nutrition, but also by various other functions, which reiterate in the capillary system, as exhalation, abstraction, and secretion.

The preceding account of the physiology of secretion, chiefly derived from the "Anatomie Generale" of Bichat, seems to amount to little more than this, that each secretory organ produces its peculiar product, in consequence of its possesting peculiar vital properties, which, when variously modified under particular circumstances, enable the organ to separate very different fluids from the blood. And this we believe to be a pretty correct statement of the extent of our knowledge of this subject. But anatomists and physiologists, not satisfied with this simple fact, have endeavoured to develop the exact mechanism of the process, and it will be necessary for us to recount some of their opinions. In all observations on this subject, it will be well for us to remember that secretion is not confined to the animal kingdom, but prevails also in the vegetable world. We frequently observe the sap giving origin to peculiar and different juices in the various parts of the same plant, and reasoners from analogy have gone so far as to admit the existence of a glandular system in vegetables. We shall be induced, by this circumstance, not to lay too much stress on the peculiar structure of the secretory organs in the more complicated animals, as essential to the business of secretion. Many of the facts already noticed, concerning the separation of perfectly similar, or at least very closely resembling fluids, by means of totally dissimilar organs, will tend to the same deduction. And this mode of argument may be still further supported by various examples in comparative anatomy: where we find fluids of the same class secreted in animals of different orders, in organs of very different external appearance. The kidneys of birds are really conglomerate in their structure; and a fluid, exactly resembling the pancreatic of warm-blooded animals is formed by the tubular pyloric appendages, variously constituted in different genera of fishes.

Of the different explanations, by which physiologists have successively attempted to elucidate the function of secretion, most are completely hypothetical and improbable. In most instances it has been affirmed that the various animal fluids are all contained in the blood; and secretion, according to this opinion, consists simply in their separation by means of the glands. Differences in the diameter, length, and folds of the vessels, and stratified varieties in the walls with which the glandular system is supposed to be perforated, have been employed as the means of rendering the mechanism of secretion intelligible; hence the expressions of filters, filters, and strainers, so frequently employed in physiology. We are dispelled from the necessity of commenting on the glaring absurdity of comparing a gland to a sieve or filter, and of deciding which of these mechanical explanations is the most exquisitely foolish, by the completely gratuitous nature of the fundamental proposition. The modern analyses of the blood have no longer even the shadow of an excuse for regarding this fluid as a mixture of all the animal liquids, and for supposing that it is formed of saliva, bile, gastric juice, urine, &c. since we can discover no trace of such fluids in it. Although all the elements necessary to form these products, as well indeed as those of the solids, are in fact found in the blood, they exist in it in a different state of combination. The blood is manifestly an homogeneous liquor, capable of forming all animal matters from the most transparent and pure water, as the cutaneous exhalation, to the firm fabric of the bony system; from it are formed saliva, bile, and urine; and it serves also for the nutrition of muscular, membrane, and nervous; but none of these modifications of animal substance are contained in it perfectly formed.
