It has been observed in the fifth volume of the Annals of Agriculture, that "larch wood is polished of to many valuable qualities, that to enumerate the whole would appear an extravagant hyperbole. It is known to refit water, without rotting, almoi for ever. The piles of larch timber on which the houses of Venice were built many hundred years ago, when examined, are still found as fresh as when first put in. And it has been told, flakes of it have been tried in the decays of Lincolnhire, which, between wind and water, have already out-worn two or three sets of oak flakes, and do not yet discover any symptoms of decay. It is a fo known to polish the valuable quality of neither shrinking nor warping, when put into work; nor is it liable to be pierced by worms in our climate, as many of the paintings of Raphael Urban, which are done on this wood, and are still perfectly entire, sufficiently prove. Experiments have not yet ascertained whether it will refit the tea-worm in tropical climates, like the Bermuda cedar; but there is reason to think it would, as, in many of its other properties, it resembles that wood very much. Along with these valuable properties, it is known to be one of the quickest growing trees in this climate, remarkably hardy, and extremely beautiful when growing. It is, besides, much more easily reared than the oak, and could be spread over a great extent of mountains, if sufficiently bare of herbage, at next to no expense, by the natural shedding of its seeds, like birch or fir in fields that favour them, merely by keeping out cattle from those fields in which small clumps of this kind of wood had been planted some years before. In this way very extensive tracts in the condition just described might be entirely filled with this valuable timber. The uses to which it might be applied are innumerable. It would be valuable not only for ship-planks, but even crooked timbers might be obtained by using a little art, when young, to bend it, as the Bermudians do their cedar; for flood-gates in navigable channels and wet-docks it would exceed every thing that can be obtained in this climate. For barrel-flaves it would be inimitable, and would enable us to furnish that article as cheap as any other nation whatever; and in building it would answer all the purposes to which fir is now applied, being much stronger and more durable than that wood. And when it is also adverted to, that it is next to incombustible, the reader will not think it strange that he in this manner so strongly recommends it to the attention of his countrymen, particularly those in the most rugged and barren districts; for, in such situations, it would be easy to shew, that, at a very trifling charge, they might, in a short period of years, bring their estates to a hundred times the value they bear at present, or even be made to bear by any other kind of improvement. This would be a much more eligible plan of bettering their fortunes than that of trying to squeeze, with difficulty, from a poor people, a raised rent, for a subject that does not admit of proportionable improvement. See PLANTING. The common cone-bearing larch-tree grows naturally upon the Alps and Apennines, and has been lately much propagated in England. Tho' trees raised from seeds thrive beli in the word soil and situation. There are two varieties of this tree, one of which is a native of America,
and the other of Siberia; neither of which thrive well in this climate. In Switzerland the wood of the common larch-tree is used for building and covering the houses; and in other countries, where it abounds, it is preferred for every purpose to all the kinds of fir. In many places there are ships built of this wood, which are said to be durable; and, therefore, this may be a very proper tree for planting upon some of the cold barren hills in many parts of England, which, besides the profit they would yield to their proprietors, would also conducive to national benefit. The Venice turpentine is extracted from the larch-tree. See Turpent.

LARCHIE, in Geography, a town of France, in the department of Corrèze, and chief place of a canton, in the district of Brives. The place contains 569, and the canton 6679 inhabitants, on a territory of 135 kilometres, in nine communes.

LARCIONO, a town of Etruria; five miles S. of Pifola.

LARDNER, Nathaniel, in Biography, was born at Hawkerell, in the county of Kent, on the 6th of June, 1684. He probably received his grammatical learning at Deal, which was his father's residence, and where he was pastor of a congregation of Protestant Dissenters; and from school he was removed to a dissenting academy in London, under the care of the Rev. Dr. Joshua Oldfield; but after staying here a short time, he was sent, in the year 1699, and was only in his sixteenth year, to prosecute his studies at Utrecht, under professors D'Urrias, Gravius, and Burnman. In his journey he was accompanied by Mr. Martin Tomkins, and on their arrival they found there Mr. Daniel Neal. After spending somewhat more than three years at Utrecht, Mr. Lardner removed to Leyden, where he studied about six months. In 1703, he returned to England, and from this time to 1709, we have no memorials concerning him. In the last mentioned year he preached, for the first time, at Stoke Newington, from the words of the Apostle Paul, "For I am not ashamed of the gospel of Christ," &c. "There could not," says his biographer, the excellent Dr. Kippis, "have been a more proper text, for a man who was delineated, in the order of divine providence, to be one of the ablest advocates for the authenticity and truth of the Christian revelation that ever exilid." In 1715, Mr. Lardner undertook the tuition of Mr. Brindley Treby, son of Sir George Treby, Knt., late lord chief justice of the common-pleas. Having conducted the studies of the young man, about three years, in lady Treby's house, where he was domestic chaplain, he accompanied him in an excursion into France, the Austrian Netherlands, and the United Provinces, which employed them about four months. It does not appear how long his connection, in lady Treby's family, as tutor, lasted, but he continued to reside in the house till she died, in 1721. In 1723, Mr. Lardner was engaged with a number of ministers, in carrying on a course of lectures, on a Tuesday evening, at the Old Jewry. The gentlemen who conducted these lectures preached a course of sermons on the evidences of natural and revealed religion. The proof of the credibility of the gospel history was assigned to Mr. Lardner, and he delivered three sermons on this subject, which probably laid the foundation of his great work, as from this period he was diligently engaged in writing the first part of the Credibility. In 1727, he published, in two volumes octavo, the first part of "The Credibility of the Gospel History; or the facts occasionally mentioned in the New Testament, confirmed by passages of ancient authors who were contemporaneous with our Saviour, or his Apostles, or lived near their time." This has been esteemed by persons of all parties an invaluable performance, that has rendered the most essential service to the cause of Christianity. It has passed through several editions. In the year 1728, Mr. Lardner's life was long despaired of, by the attack of a violent fever, from the effects of which he slowly recovered. With all his great merit, Mr. Lardner, dejected of a settlement as a dissenting minister, did not receive an invitation for this purpose till he was 45 years of age. It was in 1759 he became assistant to Dr. Harris, minister at Crotcheds Crotchesh Friars. About this period he published "A Vindication of three of our blessed Saviour's Miracles; viz. The Raising of Jairus's Daughter, The Widow of Naim's Son, and Lazarus," in answer to Mr. Woolton's attack on the scripture account of Christ's miracles. In 1733, appeared the first volume of the second part of "The Credibility of the Gospel History;" this volume comes down to the year 1758, and is prefaced by an introduction, giving a clear and very luminous history of the New Testament. It was immediately translated into the Low Dutch and Latin languages. The second volume was published in 1755, and concludes the author's remarks out of Christian writers of the second century. In 1736, he was attacked with another dangerous fever, the effects of which prevented him from preaching for several months. In 1738, Mr. Lardner published the third volume of the second part of "The Credibility," ending with the year 1739, in 1740, the fourth volume, which comes down to the year 1748; and, in 1743, he published the fifth volume, which concludes with the year 1766. About the same period he sent into the world another performance, entitled "The Circumstances of the Jewish People, an Argument for the Truth of the Christian Religion, in three Discourses." He brought out the remaining volumes of "The Credibility," at intervals between this period and the year 1755, and in the next two years he added to this great and valuable work a supplement, in three volumes, comprising a history of the apostles and evangelists, with remarks and observations upon every book of the New Testament. Our author, on account of his very high merit as a writer, had, in 1745, received a diploma, conferring upon him the degree of doctor of divinity. In the year 1751, he resigned the office of preacher at Crotcheds Friars, having, during the preceding year, published a volume of Sermons, the subjects of which are entirely of a practical nature; and, in 1760, he gave the world a second volume of these sermons. He had also published many other smaller pieces which were well received by the public; such as a sermon entitled "The Counsel of Prudence, for the Use of Young People," for which he was thanked by Dr. Secker, at that time bishop of Oxford. The discourse has been very frequently printed, and has at the present moment a large sale. Lardner had also published "A Discourse upon the two Epistles addressed to Clement of Rome, &c.;" "An Essay on the Mosaic Account of the Creation and Fall of Man;" "The Case of the Demons, mentioned in the New Testament;" "A Letter to Jonas Hanway, Esq." to shew that Mary Magdalen was not the inner mentioned in the seventh chapter of St. Luke's gospel, but a woman of distinction and excellent character, who for a while laboured under bodily indisposition, which our Lord miraculously healed; and that, therefore, houses intended for the reception of penitent prostitutes, ought not to be denominated Magdalen houses. In 1762, he published "Remarks on the late Dr. Ward's Dissertations on several Passages of the sacred Scriptures;" to which succeeded, in 1764, "Observations upon Dr. Macknight's Harmony, so far as related to our Saviour's Resurrection." Amidst these various productions of a smaller nature, Dr. Lardner continued the prosecution of his grand object, and in the last mentioned year he gave the world the first volume of "A Large Collection of ancient Jewish and Heathen Testimonies.
Testimonies to the Truth of the Christian Religion," comprising the Jewish and Heathen authors of the first century. The remaining three volumes were published in intervals between this and the close of the year 1767, and in them the biblical student is presented with a noble treasure of curious and valuable information, and of able and judicious criticism, for which the Christian world is deeply indebted to the author. They compose the grand design which had occupied a large portion of forty-three years of Dr. Lardner's valuable life; and by them, though far from profitable, he has raised a monument to his fame, which can never perish. Dr. Lardner lived to a very advanced age, and, with the exception of his hearing, retained the use of his faculties to the last, in a remarkably perfect degree. In the year 1768, he fell into a gradual decline, which carried him off in a few weeks, at Hawkhead, his native place, at the age of eighty-five. He had, previously to his last illness, parted with the copy-right of his great work for the miserable sum of 150l., but he hoped, if the book-sellers had the whole interest of his labours, they would then do their utmost to promote the sale of a work that could not fail to be useful in promoting the interests of his fellow creatures, by propounding the great truths of Christianity on a rational foundation. After the death of Dr. Lardner, some of his posthumous pieces made their appearance; of these the first consisted of eight sermons, and brief memoirs of the author. In 1776, was published a short letter, which the doctor had written in 1753, "Upon the Personality of the Spirit." It was part of his design, with regard to "The Credibility of the Gospel History," to give an account of the heretics of the first two centuries. In 1780, Mr. Hogg of Exeter published another of Dr. Lardner's pieces, upon which he had bestowed much labour, though it was not left in a perfect state; this was "The History of the Heretics of the first two Centuries after Christ, containing an Account of their Time, Opinions, and Testimonies to the Books of the New Testament; to which are prefixed General Observations concerning Heretics." The last of Dr. Lardner's pieces was given to the world by the late Rev. Mr. Wiche, then of Maidstone in Kent, and is entitled "Two Schemes of a Trinity considered, and the Divine Unity affected;" it consists of four discourses; the first represents the commonly received opinion of the Trinity; the second describes the Arian scheme; the third treats of the Nazarene doctrine; and the fourth explains the text according to that doctrine. This work may perhaps be regarded as supplementary to a piece which he wrote in early life, and which he published in the year 1759, without his name, entitled "A Letter written in the Year 1730, concerning the Quelion. Whether the Logos supplied the Place of the Human Soul in the Person of Jesus Christ?" in this piece his aim was to prove that Jesus Christ was, in the proper and natural meaning of the word, a man, appointed, anointed, beloved, honoured, and exalted by God, above all other beings.

For the many testimonies given of Dr. Lardner's character, the reader must be referred to Kippis's life, prefixed to a complete edition of his works, published in 1788, in eleven very large volumes, by the late J. Johnson. One or two only shall be quoted in this place. "The name of Lardner is well known in the literary world. No writer, from the very excellence of Christianity, ever conferred so essential service upon true religion, or contributed more to clear up its evidence and elucidate its antiquities. Accordingly, there is no country, where the Christian religion is professed, in which his name is not held in the greatest esteem. Every church would have been proud to boast of him as their member, and his voluminous productions have been translated into almost all the languages of Europe."

"Dr. Lardner," says his most excellent biographer, "may be held out, in particular, as a fine example to those of his own profession. As the Dissenters had the honour of producing Dr. Lardner, he will naturally be the object of emulation to the dissenting clergy. They will so far look up to him as their pattern, as to endeavour to qualify themselves for appearing, when occasions call for it, in the great departments of literature, and especially in the cause of religious truth and liberty, and in defence of the sacred writings."

The piety of Dr. Lardner was sincere and ardent; it was the governing principle of all his actions, and founded on just and enlarged views concerning the nature of religion. The love of truth appears manifestly in all his works; and no one ever seems to have preferred a greater impartiality in his enquiries, or to have been more free from any undue bias. He followed truth wherever it led him; and for the attainment of it he was admirably qualified, both by the turn of his disposition and his understanding. The candour and moderation with which he maintained his own sentiments, constituted a prominent feature of his character. Benevolence, as well as piety, entered deeply into Dr. Lardner's character: he was ready to promote every good work; and to persons in distress he was ever willing to contribute, to the highest degree which his fortune would admit. His manners were polite, gentle, and obliging; and he was attentive in every respect to the laws of decorum.

We may observe, that to Dr. Lardner's great works we are unquestionably indebted for Dr. Paley's "View of the Evidences of Christianity," &c.; nor is it too much to say that if the former had not been published, the latter, probably, would never have appeared; and justice requires us to add, that sufficient acknowledgments were not made for the assistance which was derived from the labours of the excellent Lardner. It must, however, be admitted, that the deficiencies of the amiable Paley have been supplied by his biographer Mr. Meadley; who, in speaking of his "View of the Evidences of Christianity," which appeared in 1794, in three volumes, 12mo. but which have in all subsequent editions been printed in two volumes, 8vo. Mr. Meadley says, "the direct historical testimony for the authenticity of the Christian revelation, already adduced by the indefatigable Lardner, is admirably selected and arranged in this important work; and the general argument drawn up with great clearness and felicity. The most striking of those collateral proofs of the credibility of the gospel history, produced by the same writer, are also here again prefented, in a novel and improved manner, and established by auxiliaries of a different kind." Of Dr. Paley's works, and of his motives in the publication, too high encomiums cannot be paid, and it is to be regretted that in his preface he had not acknowledged his obligations to our author. Paley's View is capital as an abridgment of Lardner, Douglas, &c. and his work has been twice, at least, abridged or analysed; one of these abridgments was published at Cambridge in 1795, and another in London in 1810. Lardner's Works, and Life by Kippis; Meadley's Life of Dr. Paley; and private information. LARE, in Geography, a town of the principality of Georgia, in the province of Carduel; 80 miles S. of Tbilis. LARE Point, a cape on the E. coast of Madagascar. S. lat. 16° 40'. LAREDO, a sea-port town of Spain, in the province of Biscay, with a good harbour, in a gulf of the same name; 20 miles E. of Santander. N. lat. 43° 25'. W. long. 3° 21'.
LAREK, or LAREDI, a small island in the Persian gulf; the soil of which is bad and the water brackish. The Persians have prevented the attempts of the Dutch for settling a factory in this island; 12 miles S.S.E. of Cambon. N. lat. 26° 50'. E. long. 56° 38'.

LARENDEBA, a town of Asiatic Turkey, in Carmania; 40 miles S.S.E. of Cogni.

LARENTIS, in Ancient Geography, an episcopal see of Africa, in the Proconsular province.

LARENTINELIA, in Antiquity, a feast held among the Romans on the 23rd day of December, but ordered to be observed twice a year by Augustus; by some supposed to have been in honour of the Lares, but by others, with more probability, in honour of Acca Laurentia; and to have been the same with Laurentia.

LA REOLA, in Geography. See La Reola.

LARES, among the Ancients, derived by Apuleius, De Deo Socratis, p. 689, from lar, familiaris; a kind of domestic genius, or divinities, worshipped in houses, and esteemed the guardians and protectors of families; supposed to reside more immediately in the chimney corner.

The Lares were distinguished from the Penates, as the former were supposed to preside over house-keeping, the servants in families, and domestic affairs; and the latter were the protectors of the masters of families, their wives and children: accordingly, the Lares were dressed in short succinct habits, to shew their readiness to serve, and they held a fort of cornucopia in their hands, as a signal of hospitality and good house-keeping. According to Ovid there were generally two of them, who were sometimes represented with a dog at their feet. Fast. 5. v. 146.

Plutarch distinguishes good and evil Lares, as he had before done good and evil Genii.

There were also some public, others private Lares.

Apuleius tells us the domestic Lares were no more than the souls of departed persons, who had lived well, and discharged the duties of their station; whereas, those who had done otherwise, were vagabonds, wandering about, and frightening people, called Larus and Laremis, which see.

The Lares were also called Penates, and were worshipped under the figures of little marmousets, or images of wax, silver, or earthenware.

The public Lares were also called Comitales, from com- pium, a crowd-way; and Viales, from via, a way, or public road; as being placed at the meetings of roads, and in the highways, and esteemed the patrons and protectors of travellers.

Their private Lares took care of particular houses and families; these they also called Prefilites, from prefio? or "Quod praefrent oculis omnia tuta fuis." Ovid. Faust.

They gave the name Urbani, i.e. Lares of cities, to those who had cities under their care; and Hostilibi, to those who were to keep their enemies off. There were also Lares of the country, called Rurales, as appears by several antique inscriptions.

The Lares were also genial gods, and were supposed to take care of children from their birth. It was for this reason that when Macrobeus tells us the Egyptians had four gods who presided over the birth of children, viz. the Genius, Fortuna, Love, and Neceslity, called Prefilites, some interpret him as if he had said, the Egyptians had Lares; but they have mentioned that there was a great difference between the Lares of the Romans, and the Prefilites of the Egyptians. However, the learned Mr. Bryant affirms that they were the same.

The ancients differ extremely about the origin of the Lares. Varro and Macrobeus say, that they were the children of Mania; Ovid makes them the issue of Mercury, and the naiad Lara, whom Laetantius and Aufonius call larunda; Apuleius affirms us they were the protectors of the Lemures; Nigidius, according to Arnobius, made them sometimes the guardians and protectors of houses, and sometimes the same with the Curetes of Samothrace, which the Greeks call Islai daili. Nor was Varro more confident in his opinion of these gods; nor did Arnobius make them the names of heroes, and sometimes gods of the air.

T. Tatius, king of the Sabines, was the first who built a temple to the Lares. The chimney and fire-place in the house were particularly consecrated to them.

Tertullian tells us the custom of worshipping the Lares arose from this, that they anciently interred their dead in their houses; whence the credulous people took occasion to imagine their souls continued there also, and proceeded to pay them divine honours. To this it may be added, that the custom being afterwards introduced of burying in the highways, they might hence take occasion to regard them as gods of the highways.

The victim offered to the Lares, in the public sacrifices, was a hog: in private, they offered them wax, incense, a crown of wool, and a little of what was left at the tab. They also crowned them with flowers, particularly the violet, myrtle, and rosemerry. Their symbol was a dog, which was usually represented by their side, on account of its fidelity, and the service it does to man, in watching his house. They were sometimes also represented as clothed in a dog's skin.

The term Lareus, according to Mr. Bryant, was formed from laren, an ancient word by which the ark was represented; and he supposes that the Lares and Manes were the fame domestic deities under different names; and that by these terms the Etrurians and Latins denoted the dix arkus, who were no other than the arkite ancestors, or the perfons preferred in the laren or ark; the genius of which was Isis, the reputed parent of the world. He observes farther, that they are described as demons and genii, who once lived on earth, and were gifted with immortality. Arnobius, lib. iii. p. 124, lilies them laren augustum genus & funtum anus; and he says, that according to Varro de Ling. Latin, lib. viii. p. 113, they were the children of Mania. Huetius De- monst. Prop. 4. p. 119, adds, that Mania had also the name of Larunda; and she is stylized the mother of the demons. By some she is called Lara, and was supposed to preside over families; and children were offered at her altar in order to procure her favour. Macrobi. Sat. lib. i. c. 7. p. 154. In lieu of these they in aftertimes offered the heads of poppies, and pods of garlick. Anal. of Ancient Mythol. vol. ii. P. 449. &c.

The pantheons, or images representing several gods at once, were also called Lares. Harpocrates was one of these.

LARES, or Laris, in Ancient Geography, a town of Africa Propria, according to Ptolemy, who places it in the territory of Cithara.

LARG, in Geography, a small island near the W. coast of Sumatra. S. lat. 3° 30'; E. long. 100° 3'.
LAR

LAR, in Geography, a town of Arctic Turkey, in the government of Sivas; eight miles N.N.E. of Amashil.

LARINO, a town of Naples, in the Molise; the see of a bishop, suffragan of Benevento; 25 miles N.E. of Molise.

LARINUM, in Ancient Geography, Larino, a town of Italy, in Samnium, towards the south; it had the title of municipal.

LARIO, in Geography, a department of Italy, occupying the whole of the W. coast of the lake of Como, anciently "Larius lacus." Its population amounts to 137,264, perfous, who elect 12 deputies. The capital is Como.

LARIOZO, a town of the island of Cuba; 48 miles E. of Spirit Santo.

LARissa, in Ancient Geography, a town of Thessaly, upon the right bank of the Peneus; 10 miles above Atrax, E. of the mouth of the Apidanes or the Peneus, 44 miles from Demetrias, and 24 from Dian. Acrisius, king of Argos, retired to this town, in order to avoid the death which the oracle had menaced; but taking a part in the games which were celebrated in this place, he was killed by a stroke of the darts of Perseus. Larissa always maintained a distinguished rank among the towns of Thessaly; but it declined from the time of Lucan. However, it still enjoys under the same name in European Turkey, near the celebrated mount Olympus, and is inhabited by Christians, Turks, and Jews; the former having an archbishop and several churches; and the Turks having several mosques. The number of inhabitants is estimated at about 25,000. Its situation, on an eminence, is pleasant. By the Turks it is called Georaphy, or Georgiaphi. N. lat. 39° 45'; E. long. 21° 29'.—Alle, a town of Aetolia, in Aetia Minor, situated E. of Phocaea and S.E. of Cyre, forming with these two towns the vertex of a triangle. Xenophon calls it the Egyptian Larissa, because it was one of the towns which Cyrus, the first king of Persia, gave to the Egyptians.—Alle, a town of Aetia, on the banks of the Tigris. Xenophon says, that it had been large, but deflected, and that it had been deflected by the military force of the Medes. —Alle, a town of Triphylia, in the northern part of the province of the Larithus, near the frontiers of Arcadia.—Alle, a town of Crete, according to Strabo.—Alle, a town named Georaphy, according to Strabo; who says, that it was called Pelagia, though situated out of the Pelasgian territory. Livy places it on the sea-coast, between Lebannus and Anthrasy. Eutalithius and Porphyrogenus say, that it had been formerly named Argos.—Alle, a town of Italy, in Campania; said to be built by the Pelasgians, but deflected and ruined in the time of Dionysius Halicarnassius.

LARISTAN, a small province of Persia, formerly a kingdom conquered by Abbas the Great, in 1618; bounded on the N. and E. by Kerman, on the S. by the Persian gulf, and on the W. by Farfadil or Fars, of which some have regarded it as a part. The subdivision seems not to have been known in ancient times, though the long ridge of mountains on the S. of Fars, and generally about 60 British miles from the Persian gulf, naturally indicates a maritime province; which, if the ancient Persians had been addicted to commerce, would have been the seat of great wealth by intercourse with Arabia, Africa, and India. But the Persians were high-spirited horsemen and warriors, totally averse from maritime enterprise, either of war or trade, from a contempt of the Arabian fish-eaters on their coast, or more probably, from particular precepts of Zoroaster, the founder of their faith, which rendered a maritime life incompatible with the practice of their religion. The air of this province

LARGA, a small island in the Spanish Main, near the coast of South America. N. lat. 10° 11'; W. long. 76° 6'.

LARGE, a Sea Term, applied to the wind, when it crosses the line of a ship's course in a favourable direction, particularly on the b-um or quarter. Thus, if a ship fler well, then the wind in any point of the compass to the northward of the south or north, may be called large, unless when it is directly east, and then it is said to be right aft. Large large, is, therefore, advancing with a large wind, so as that the winds are slackened and flowing, and the bowlines entirely difused. This phrase is generally opposed to taking close-hauled.

LARG, in the Monera. A horse is said to go large, or wide, when he gains or takes in more ground in going wider from the centre of the volt, and describing a greater circumference. To make a horse go large, you must give him the aid of your inner heel. See ENLARGE.

LARGE, synonymous with maxima, the longest note in the first time table, equal to two large, four breves, and eight minims. Its form is an oblong square, with a tail on the right side, thus | [See Character.]

LARGE RIVER, in Geography, a river of Louisiana, which runs into the Mississippi. N. lat. 38° 25'; W. long. 95° 7'.

LARGENTIÈRE, a town of France, in the department of the Higher Alps, and chief place of a canton, in the district of Briançon. The place contains 978, and the canton 5771 inmates, on a territory of 484 kilometres, in 7 communes.

LARGENTIÈRE, a town of France, and chief place of a district, and seat of a tribunal, in the department of the Ardèche; 18 miles W. of Privas. The place contains 1995, and the canton 9945 inhabitants, on a territory of 1775 kilometres, in 11 communes. N. lat. 44° 32'; E. long. 4° 42'.

LARCHETTO, latis the diminutive of large.

LARGO, in the Italian Music, slow movement, one degree quicker than adagio, and two steps than grave. See Time.

LARZO Golf, in Geography, a bay on the coast of Aria, near Prains.

LARI, a town of Etruria; 10 miles E. of Leghorn.

LARIUS COLONIA, in Ancient Geography, Laribus, a Roman colony in Africa, situated on an eminence, five leagues N.E. from Sicca.

LARICAX, a province of South America, in the government of Buenos Ayres, about 250 m. W. of the S. of Fars, and 25 from N. to S. Its climate varies in different parts, and its products are the same with those of Carabaya, which terminates it northward. It abounds in gold mines, the metal being 35 cents and 3 grains fine. The celebrated mountain of &n bull in this province, about half a century ago, yielded gold in great quantity of this standard, but its mine was overworked, and no labour could recover it.

LARICE, in Ancient Geography, the name given by the Romans to the province of India, now called Gujerat.

LARICOF, Fr. an acute stop in the organs of France, a 3d above the major 7th, and an octave above the 12th in our organs, which would be a 19th above the daspafon.
LAR

is infallible, and varies frequently from extreme heat to extreme cold: water fit for use is scarce: that which is
clank being found, as it is said, to breed worms in the legs
and thighs of those who use it. Camels are the principal
articles of trade. The capital is Lash, which fee.

LARIX, in Botany, an ancient Latin name, the Larix.
See Pinus. The older botanists distinguished Larix as
a genus by its furcated leaves, but no difference is discover-
able in the fructification, at least between it and Abies,
which all Linnaean botanists refer to Pinus. Jullien keeps
the two latter distinct, and hints at separating Larix.

LARK, in Ornithology. See Alauda.

LARKSPUR, See Delphinium.

LARKNER, Fr. in Architecture, the same as Carina; which
see.

LARNE, in Geography, a sea-port and post-town of
Ireland, in the county of Antrim. It is situated on
the north-western extremity of Larne Lough, and has a
good yarn market once a month. There are great salt-works
here, and its exports confit of salt, lime, limetones, and some
provisions. It is 97 miles N. by E. from Dublin. N. lat.
54° 15'. W. long. 5° 44'.

Larne Lough, a bar on the east coast of the county of
Antrim, Ireland, called Oldfleet haven by Booth, and Wol-
derftfrth in the enumeration of the havens by Staniforth.
It is formed by the peninsulas called Island Magee, and is said
by M'Kenzie to be a small but safe harbour, where vessels
that draw not above ten feet water may ride on clean good-
holding ground. It is about six miles long and one wide.

LARNIC, or LARNSA, a sea-port town on the coast
of the island of Cyprus, the see of a Greek bishop, and the
residence of several European consuls. The Turks have a
mosque, and the Greeks have three churches. It is now a
poor place, though the road-lead is good; 30 miles S.W.
of Famagusta.

LARNUTKA, or LARNUTKA, a sea-port town on the
S. end of Eubea, one of the Molucca islands, with a good
harbour. S. lat. 35° 15'. E. long. 123° 57'.

LAROA, a town of Hindoostan, in Guzarat; 10
miles E. of Barooch.

LAROCHE, a town of France, in the department of
the Sambre and Meuse, and chief place of a canton, in the
district of Marche. The place contains 1006, and the can-
ton 6167 inhabitants, on a territory of 250 kilometres, in
20 communes.

LAROS, a town of Turkish Armenia, on the coast of
the Black sea; 18 miles S.W. of Gomieh.

LAROTA, a town of the island of Tenerife.

LAROW, a town of Hindoostan, in Bahar; 10 miles
S. of Gayah.

LARKAYA, a town of Spain, in Navarre; 11 miles E.
of Estella.

LARRASOAANO, a town of Spain, in Navarre;
12 miles N.E. of Pamplona.

LARREA, in Botany, named by Cavanilles, in honour
of Don John Anthony Hernandez de Larrea, dean of Sa-
ragossa, a liberal encourager of chemistry, botany, and agri-
culture. The author laid, in his fourth volume of Icones,
p. 65, suppressed this name, given by his countryman Ge-
tega to another genus, and had changed it to Hymenogidis,

being then, as it seems, not so favourable of the dein of Sar-
ragossa's botanical merits as he afterwards became.—Cavan. l. c.

Gen. Ch. Col. Perianth inferior, of five ovate, concave,
rather unequal, deciduous leaves. Cor. Petals five, equal,
over, with claws. Stam. Filaments ten, rather shorter
than the corolla, awl-shaped, equal, each furnished at its base,
or rather, with a cloven scale, applied close to the garden;
ners hearts-shaped, erect, simple. P. St. Germen superior,
globose, with five deep furrows; style awl-shaped, with
five angles, nearly equal to the stamens; stigma simple.
Peric. Drupas five, dry, cohering by their acute margin,
externally convex, of one cell. Nuts solitary, ovate-
olong.

Ofi. There are the rudiments of several feeds in the young
fruit, though only one of them comes to perfection in each
nut. The genus comes near Zygophyllum and Eupogon.

Eff. Ch. Calyx of five leaves. Petals five. Nectary
of five cloven leaves, covering the garden. Drupas five, fingle-
folded.

Leaves pinnaate. Fruit smooth.—Gathered at Buenos
Ayres by Louis Nee, flowering in April. It has been
raised with good success in the garden of Madrid, and we
have specimens from Cavanilles himself. The stem is shrubby,
nine feet high in its native country, hard, knotty, very,
much branched, the branches round, rather zig-zag, repeat-
edly subdivided, spreading, two-ranked, leafy, rough,
viscid. Leaves opposite, fleshy, twice as long as broad,
about half an inch in length, thinning, glutinous, smooth,
mattedly dotted, each composed of about seven or eight
pair of crowded, two-ranked, oblique, fleshy, oblong,
obtuse, entire leaves, of which the two uppermost are unequal
and very small, looking as if there were an odd one at the
end. Stipulas opposite, triangular, acute, red circus.
Flowers axillary, solitary, alternate, deep yellow, on roughish flails,
shorter than the leaves. The sereens is hairy, though the
fruit is naked, or only clothed with fine short down. Its
outer coat is coriaceous and rugged. Nuts without valves
or futures.—The whole plant exudes a copious glutinous
resin, of a strong scent, full very powerful in the dried speci-
mens, and intolerably so on their being moistened with proof
spirit, which extracts from them abundance of a yellow fetid
solution.

2. L. d'varicata. Spreading-leaved Larrea.—Cavan. ic.
t. 562. f. 1. — Leaves simple, with two deep spreading lobes.
Fruit hairy. Found with the former, flowering at the same
season. The stem is shrubby, six feet high, with much of the
habit of the foregoing; but the leaves are simple, very
densely cloven into two spreading acute lobes. The flowers
are yellow, larger than those of L. nitida, with obtuse
petals; and the fruit is beft externally with long prominent
hairs.

t. 562. f. 2. — Leaves wedge-shaped, cloven at the end, with
an intermediate bristle. This appears to differ in folioage only
from the last, along with which it was found.

These plants promise to be not unworthy of attention for
their dyeing qualities. Cavanilles says, ten leaves of the L.
d'varicata, boiled in a quart of water, with the little branch
on which they grew, tinged the whole liquid of a deep
faffon colour.

LARREY, Isaac de, in Biograpby, born of a noble
French family in 1648, was brought up to the profefion
of the law. He acted some time as an advocate in his na-

L R
tive province, but having been educated in the reformed religion, he was obliged to quit his country at the appeal of the edict of Nantes. He went from France to Holland, and obtained the office of historiographer to the States-General. An invitation from the elector of Brandenburg induced him to remove to Berlin, where he died, in 1719, at the age of eighty-one. His principal works are "Histoire d’Angleterre," 4 vols.; "Histoire de Louis XIV." 3 vols. quarto; "Histoire d’Angleterre;" "Histoire des Sept Sages," 2 vols. 1713. Of these his History of England is most esteemed, and was in high reputation on the continent till that of Rapin was published. Larrey was a man of great integrity, zealous for his religion, and warm both in praise and cenature. Moreri.

LARISOUN, in Geography, a town of Peria, in the province of Mazanderan; 65 miles S.W. of Tehran.

LARROQUE, MATTHEW DE, in Biography, an eminent French Protestant divine in the 17th century, was born at Leirac, a small city of Guienne, near Agen, in the year 1619. He was educated with a view to the church, and applied himself, in early life, with great diligence to the study of the belles-lettres, philosophy, and theology. Having made great progress in all the various branches of useful knowledge, he was admitted a minister with great applause in the province of Guienne. He was afterwards appointed, by the ducchef de la Tremouille, minister of the church of Vitré, in Brittany. Here he officiated nearly thirty years, during which time he applied himself most earnestly to the study of the fathers, and Christianity. He was next invited to become both minister and professor of divinity at Saumur: he readily accepted the former office, but declined the latter, not thinking it to be consistent with the course of study in church-history, to which he had a prevalent inclination. Before he could take possession of his office, he received a prohibition from the intendant of the province, forbidding him to enter upon its duties. He therefore continued at Vitré, and employed his time very usefully in composing works of merit. In a short time he received three invitations at once, from three of the most considerable churches in the kingdom, viz. those of Montauban, Bourdeaux, and Rouen. He made choice of the latter, at which place he died in 1684, at the age of sixty-five. His works are numerous, and they acquired for the author a high reputation for real learning, as a theologian. He was a pious and faithful pastor in the church; and in the world an honest man. Moreri.

LARRY-BUNDE, in Geography, a sea-port of Hindostan, in the province of Sind, on a branch of the Indus, called the Pitti, about 20 miles from the sea. It has a good road for shipping, and the river is navigable for small vessels. The town contains about 100 houses, and is defended by a fort; 48 miles W.S.W. of Tatta. N. lat. 24° 45'. E. long. 66° 43'.

LARRY-BUNDER is also the name of a branch of the Indus; which see.

LARK, a town of Russia, in the government of Caucasus; 56 miles S.E. of Ekaterinograd.

LARSMO, a small island on the E. side of the gulf of Bothnia. N. lat. 63° 46'. E. long. 22° 39'.

LARVA, in Natural History, a name given by Linnaeus to insects in that state, called by other writers eruc or caterpillar. See Entomology and Insects.

LARVE, in Antiquity, derived from the Etruscan word lar or laris, signifying prince or lord, denoted the ghosts of the deceased, considered as wicked and mischievous. Hence it formed the term larvatus; i.e. larva indita, or demoniac.

The ingenious Mr. Farmer urges the etymology and use of this term to prove, that the heathen demons were defied human ghosts. The term lar was applied not only to their domestics, but also to their celestial gods, the dī majorum gentium, who were all natives of this lower world; and answers to the word ἄγαλμα. Quos Græci ἄγαλμα, nolri, opinor, lare. Cicer. in Tim. v. 3. (See Larves.) The larvae were considered as mischievous spirits: and this author says, that the larvati were demons; but the larvae, with which they were posseied, were human ghosts; such also as demons were. Eff. on the Demoniacs, p. 27, &c.

The larvae were also called lemures.

LARUCACHI, in Geography, a town of Peru, in the diocese of La Paz; 110 miles N. of Chucuito.

LARVIGEN, or LAURWIG, a sea-port town of Norway, in the diocese of Christiander, and capital of a county, deriving from it its name, situated at the conflux of two rivers near the sea. Its trade is considerable, and its iron-works are the most valuable in Norway; 56 miles S.S.W. of Christiander. N. lat. 59° 3'. E. long. 10° 15'.

LARUNS, a town of France, in the department of the Lower Pyrenees, and chief place of a canton, in the district of Oron; 18 miles S. of Pau. The place contains 1607, and the canton 3655 inhabitants, on a territory of 445 square miles, in 8 communes.

LARUS, in Ornithology, a genus of the order Anseres. In this tribe the bill is straight, acute at the edges, hooked at the tip, and denticulate on the teeth; the lower mandible gibbous below the point; nostrils linear, broader on the fore part, and placed in the middle of the bill. There are the gulls of English writers, a race of birds very widely diffused throughout the globe, some of the species inhabiting Asia, Africa, and Europe, others Europe, Asia, and Americas, but the far greater number of species are natives only of the northern regions of America and Europe, as Hudson's Bay, Iceland, Greenland, and the north of the European continent, beyond which, towards the southward, their number materially diminishes. Many of the species found in northern latitudes inhabit the British isles, reposing on our shores the whole year; others are extremely rare with us, or at least can be considered only as accidental visitors driven from more northern countries in severe winters. The haunts of the gull tribe are the borders of the sea, and marths immediately in its vicinity, or in the depth of winter they sometimes retire inland, but only into such parts as are abundantly supplied with water, their food consisting principally of fish and worms. The gulls have a light body, the wings long; tongue rather cloven; legs short, naked above the knee, and the foot toe very small. They are very voracious, and when terrified are said to cast up the indisgested food they have lately swallowed. The species of this genus are not very clearly discriminated, owing to the variations that prevail in the colours of the plumage in different states of growth, till the birds have attained their third year. This genus is divided into two sections, in the first of which the nostrils are without a cere, and in the other are covered by one.

Species.

* Nostrils without a Cere.

A native of the borders of the Caspian sea. The size that
of the bernacle goose, or larger. The bill is scarlet, with yellow base, the tip yellow with a brown spot; the inside of the mouth red; tail white, even at the end, and reddish brown. This species lays its eggs on the bare sands; the eggs are of an elongated oval form, marked with brown spots intermingled with others paler. When in flight it utters a hoarse cry like that of a raven.

Length fourteen inches; the bill yellowish; mouth fawnish within; head, neck, belly, and tail snowly; wings hoary, the outer edge of the first and tips of the four or five feathers next succeeding white; legs dull; posterior toe resembling a wart. It varies in sometimes having behind the ear a dully spot.

This kind of gull inhabits the cliffs on the north coasts of Wales and Scotland, from whence it extends as far as Greenland, Spitzbergen, and Iceland, the arctic coast of Asia, and Kamtchatka. The Icelanders call it Rista. Fabricius, in his Fau. Gmeln, describes this as the adult state of the Tarrock, an affrontation contradicted by some authors and admitted by others, while again some few are of opinion they may be the two sexes of the same species.

**Tridactylus.** Whitth, back hoary; tips of the tail feathers, except the outer one, black; feet three-toed. Linn.

Frequents the same rocky coasts of the sea as the former. The eggs, two in number, are greenish-brown, spotted with brown; they are noisy, swim well, and remain on the wing for a considerable time. The flesh and eggs are esteemed by the natives of Greenland, and their skins used as garments. Length fourteen inches; bill and legs dull; head, neck, and body beneath white; wings variegated black and white; tail black at the tip.

In the Bankin collection is a supposed variety of this species exceeding the common tarrock in size, being five inches longer; in this the wings are marked by an oblique black band, and the chin white; the outer tail-feathers entirely white. This inhabits Kamtchatka.

**Minutus.** Snowy; head, and beginning of the neck black; back and wings suffused; bill brown-red; legs scarlet. Pallis. Gmel. *La plus petite des mouettes, Vieill. Little gull*, Linn.

Size of a thrush; irides blueish; tail equal and white; inhabits near rivers in Siberia and Russia.

The length of the species is fifteen inches, the breadth thirty-four; the bill paler at the tip; wings much longer than the tail; legs lead colour, the claws black. This bird inhabits the frozen seas between Asia and America. From its flatly gait when walking on the ice, and the slenderness of its voice, it is said to have obtained the name of Ratcher, or Senator. The flesh of the morse constitutes its favourite food; besides which it subsists on worms and fishes. During the summer, it visits the little lakes and lakes in the interior, where it forms a nest composed of dried herbage, and lays four eggs of a white colour. The young are spotted with black principally on the back and wings, and the beak is of the same colour.

Common on the coast of Britain, and in various parts of Europe and America. The length seventeen inches; bill yellow; legs greenish-white, or sometimes reddish. It forms a nest chiefly of sea-weeds; the eggs are large, deep olive, and marked with dark irregular blotches. (Vide Brit. Birds.) This kind of gull extends as far north as Iceland and the Russian lakes, and occurs also on the borders of the Caspian sea, the various shores of the Mediterranean, and those of Greece. Its breeding places are the hollows in rocks and cliffs near the sea.

Feeds on reptiles and small fishes. This kind is very common in England, and is observed to inhabit further inland than any other of the gull tribe. In Ind. Orn. of Latham it is described as the young of the foregoing species. Length seventeen inches.

Length fourteen to fifteen inches; the eye-lids the same colour as the bill and legs; first ten quill-feathers white, with the edge and tip black. Inhabits Europe and America, and makes a laughing kind of noise. The eggs, three in number, are greenish-brown, spotted with tawny. Gmelin admits two varieties of this species; one of a white colour, with hoary back, and the head and bill blackish, as described by Nozzen; the other is white, with blue legs, the bill at the base blue, at the tip yellow. Latham in Ind. Orn. considers as varieties of rubinus the Linnæus carinatus, and also larus erythropyus of Gmelin, both which are placed as distinct species in the preceding publication. Gen. Syn.

Native of the maritime parts of Europe and America, the Cape of Good Hope, New Holland, &c. The length twenty-nine inches; the bill yellow, with a red spot near the tip, and in the middle black; quill-feathers black, with the tips white, and the legs flesh-colour. Feeds on fish and young birds.

This species inhabits the shores of European seas. Its length is about two feet; the bill black; legs dirty flesh-colour. This is by some esteemed the female of the foregoing (marinus), and by others as either a variety rather than a distinct bird, or as the younger bird. The bird described by Brunich under the name of larus argentatus, the sylvia gull of Latham, is likewise considered as a variety of L. marinus.

**Fuscus.** White; back brown. Linn. Fn. Suec. *Lar-
**Lar**

Inhabits Europe, America, and Asia. The length twenty-three inches; bill and legs in the adult bird yellow; eyes straw colour. The birds feed on the herring, the flacks of which it pursues, and thus directs the fisherman to the capture of that fish. The eggs, three in number, are whitish, spotted with black.

Inhabits Sweden; is larger than the herring gull, very voracious, and feeds on smaller birds, fish, and carrion.

Length eighteen inches. Flies in flocks, with a continual clamour; builds in pine trees, and inhabits America and Europe.

Smaller than the former. This inhabits the salt marshes of Siberia.

**Nostrils covered with a Cere.**

Length twenty-one inches; the bill and legs dusky; body above dusky, beneath, with the temples, and front white; breast with a dusky band; female brown beneath. Very rare in Britain. The species is found in the north of Europe, and also in Asia and America. It is of a rapiocious disposition, and will pursue the lesser gulls in the air till they mort, when, instantaneously darting down, it dexterously catches the excrement before it reaches the water, and devours it. The eggs are cinnereous, spotted with black.

This, like the former, is very scarce in Britain; its length is sixteen inches; the bill black, with the tip orange; breast and belly white, with numerous darkish lines. The two middle tail-feathers longer than the red; and the anterior half of the feet black; the posterior, with the legs, pales and yellowish, or, as it sometimes appears, blueish.

The description of the black-toed gull in Dr. Latham’s Synopsis, is an extract from Pennant’s British Zoology, besides which Dr. Latham mentions another bird of the same kind in the late Leverian museum, which had the lighter half of the feet, with the legs, yellow instead of blue. In the description of this latter bird Dr. Latham observes, however, that “the two middle tail-feathers are not particularly longer than the others;” and again in Ind. Orn., this author hesitates apparently from this circumstance, in addition to the yellow colour of the legs, whether it should be admitted as a variety of Larus crepitatus, or be esteemed a distinct species. It becomes therefore desirable to add that the description afforded us by Dr. Latham is not, in this respect, entirely free from error; that able ornithologist was, in some manner, deceived, perhaps from the situation of the bird itself, which might preclude the possibility of an attentive inspection. De as this it may, the Leverian specimen recorded by Dr. Latham, and also another from the same collection, are both in the museum of the writer of this article; in one of these (which we conceive to be the male) the two middle tail feathers are nearly as conspicuously longer than the rest, as in the Arctic gull projecting beyond them fearlessly less two inches; and in the other, which we apprehend must be the female, they are advanced above an inch beyond the rest; in other particulars they accord pretty generally with Dr. Latham’s description, and, as that writer observes, the lighter parts of the feet, with the legs, are yellow. We have besides this another example of this bird, a specimen recorded as being near Oxford, in which the legs are black and yellow, as in the former, from whence we may conclude those to be the true colours, except perhaps in certain varieties.

Length two feet; the bill dusky, and much hooked; upper mandible covered half way down with a black cere; body brown; beneath rufy-cinnereous; legs blackish, rough, and warty; claws hooked and black; posterior toe short, and armed with a sharp hooked claw. This voracious bird inhabits Europe, Asia, and America, and is remarkable for its voracity and ferocious disposition, especially in the breeding season. It feeds on fish, and all the smaller kinds of water-birds, and is the terror of the lesser birds of its own tribe, which it haunts on the wing, till they mutter or vomit up what they have eaten, and then devours it.

Inhabits America, as far as Hudson’s bay; the length is twenty-two inches; the bill and legs black; toes and tement half black, half white. It arrives at America in April, constructs a slight nest of grass, and lays two pale furrowous eggs spotted with black.

*Laryngeal in Anatomy, an epithet applied to parts belonging to the larynx. The laryngeal arteries are the veins more commonly decribéd under the name of thyroid arteries. The laryngeal nerves, superior and inferior, are branches of the par vagum. See Nerve.

*Laryngotome*, (from λαρυγξ, the upper part of the windpipe, and τόμος, to cut,) an operation in Surgery, which consists in making an artificial opening into the larynx with a knife, a measure sometimes necessary in certain cases of disease to prevent suffocation, as well as to enable the practitioner to inflate the lungs in instances of suspended animation. The incision is now generally made in the windpipe itself, and the operation called tracheotomy. See Tracheotomy.

*Larynx*, in Anatomy, a hollow organ, placed between the root of the tongue and the trachea, giving passage to the air into and out of the lungs in respiration, and producing the voice.

The organs of locomotion, whether those of the limbs or of the trunk, are the principal means by which man re-acts on those external objects which have acted on him through the medium of the senses. They are particularly defined in the natural state, to provide for the wants of digestion, of which they collect the materials. They also furnish the animal with
L A R Y N X.

the means of offence and defence, of which digestion is in general the immediate object. But focal man has vastly extended the domain of this function. Submitted, through the cerebral nerves, to the direction of intellect, it is the instrument by which most of the conceptions of the latter are executed: and if the vital field of activity opened to our view in the arts the extensive agency of this power, it proves no less clearly how greatly the sphere of action of the locomotive organs has been increased. Man in society not only derives from his voluntary muscles, by acquiring extreme precision in their motions, much greater advantages than those to which the limited operation of instinct confines animals, but he has also given to them another direction—they serve him as a silent language, and a mode of intellectual communication. The head, the arms, the eyes indicate to us what the voice does not disclose; but gestures are in general only supplementary to the latter function.

Speech is the chief means of our intellectual communications: and here we have occasion to observe how vastly the functions of the larynx are extended by man in society. This extension is still greater than that which the locomotive agents offer to our view in the arts where industry has been pulsed the farthest. Originally nature bestowed on man merely a voice, the chief object of which was to establish those relations which bring together the sexes. Hence the close connection between the voice and the generative organs: it has, like them, a true period of puberty, whether in animals in whom it does not exilt at all until that epoch, or in those, where, existing antecedently, it undergoes at this time a remarkable change. Remove those organs, and a new and peculiar modification of the voice soon follows itself. Each sex has a voice distinguished by particular characters; energy and force belong to that of the male, flexibility to that of the female. Most animals employ their voice chiefly at the rutting season; many are dumb at all other times. We cannot therefore avoid the conclusion, that, in the natural state, the communications of the two sexes relating to generation are the particular object of the production of sound. Man in society has destroyed this original definition, and at the same time created another, of which the extent is bounded only by the limits of his intelligence. The more voice, which sufficiently enables the individuals of both sexes to express the mutual wants connected with the generative functions, is inadequate to the conveyance of those which have arisen out of the state of society. It has therefore been modified; speech is the result of that modification; and thenceforth the larynx has performed a part in society not less important than that of the locomotive organs. These two modes of communication, which man enjoys, are almost equally employed, and produce, each in its way, nearly equal effects. If one be the organic instrument of all the arts, and of all the affections which the mind experiences in any instance through the eyes, the other is the agent of all that belongs to the domain of intelligence, of all that the mind perceives through the ears. Compare the vast stock of ideas, which are transmitted from man to man, with the material objects employed in their reciprocal commerce, and you will find the amount of each nearly the same. Yet, although the sum of the locomotive agents forms more than half of the entire volume of the body, the vocal instrument takes up a little room in a small part of the same body. The great disproportion between the organs of the voice and the important effects which they produce in society, is very striking.

The voice, from its declaration, would naturally fall under the immediate empire of the brain. Hence the structure of the larynx has much analogy to that of the locomotive apparatus. It is composed of cartilaginous pieces, moved in various directions by voluntary muscles, on the motions of which the habits of society have conferred a precision foreign to the natural state, as it has on those of the fingers in certain arts, and on those of the lower limbs in others. Thus the voice is to speech, in relation to the muscles of the larynx, what the rude movements of the fingers of the savage are to the precise and delicate motions of the man who has employed himself on a mechanical art; in relation to the muscles of the upper extremity. The principle is the same, the results only are different. It is a general law in the organs of voluntary motion, that they acquire perfection by exercise, that they are in short susceptible of education.

This dependence of the functions of the larynx on the brain is not only marked in the state of health, but also in diseases. Paralysis, convulsions, and spasms of the muscles of this cavity have the same characters as in the locomotive organs, and have no analogy to the affections of involuntary parts. Hence Bichat has followed the indications of nature, in separating the vocal organs from the lungs in his physiological and anatomical arrangement: their proximity has generally led to their being confounded together, in treatises of anatomy and physiology.

The following arrangement will be adopted, in considering the vocal organs: 1st, General considerations on the larynx; 2dly, Particular description of the component parts; 3dly, The affinage of those parts in the general conformation of the cavity; 4thly, Mechanism of the larynx; 5thly, Its development in various ages; 6thly, The organs of speech; 7thly, The physiology of the voice and speech.

General Considerations. - The larynx is a cavity composed of cartilaginous pieces, of a form not exactly defined, and occupying the anterior and superior region of the neck. It is situated on the median line, and consequently regular and symmetrical in its form, like all the organs of the animal life. It terminates the trachea above, and forms a striking contrast with the lower extremity of that organ, which, formed by the bronchi, and concerned merely with the functions of the organic life, is made up of two lateral portions not resembling each other. The lateral portions of the larynx are, on the contrary, exactly similar. This symmetry of the larynx is necessary to the harmony of its functions: a discordant voice would inevitably result from different organizations of the two sides, or from inequality in the powers of the muscles of the right and left sides. The organ is placed below the os hyoideum, to which it is fixed: it is superficial in front, and rests behind on the vertebral column, from which the pharynx alone separates it.

Derived, on the one hand, to allow a continual passage to the air in respiration, which is to a certain point involuntary; and concerned, on the other, in producing the voice entirely under the influence of the will, the larynx offers to our view a structure accommodated to these two very different phenomena. Several cartilages united together form its cavity, and their eladiacity prevents it from being ever closed: hence a free passage is secured for the air. To these movable cartilages are attached muscles, of which the voluntary contraction may increase or diminish the dimensions of the cavity; circumstances which are essential to the production of the voice. One of these cartilages, very different in its structure from the others, can close the cavity momentarily, by being depressed on its aperture. Lastly, a mucous membrane, continuous with that which lines the mouth, lines all these parts, and is prolonged into the lungs, following all the ramifications of the bronchi.
The size of the larynx does not follow the proportions of the general stature; it may be as large in a little person as in one of considerab]e height; and this corresponds to what we know of the voice, the force or weakness of which do not depend on the size of the individual. It would be an interesting research to compare the different kinds of voices, with the organization of the larynx. We cannot doubt that the tenor, counter-tenor, &c. are produced by some peculiarities in the laryngeal structure; but the impossibility of knowing, in the case of subjects employed for dissection, what kind of voice the individuals possessed, prevents us from ascertaining any thing concerning this point. The difference in the voices of man and woman cannot but have been always observed; and their larynxes exhibit, on a merely superficial inspection, a great disproportion in size. The organ is large and broad in man: it appears contracted in woman, so as to be about one-third less: often it is not more than half as large as that of the male. This does not depend on stature: a large woman and a short man have this distinguishing character, as well as two individuals of equal size, or as a tall man and short woman. The same circumstance runs through all parts of the larynx: it is observed also in the neighbouring organs, as the trachea, the os hyoides, and their dependencies: it takes place also constantly.

The general form of the organ is nearly the same, or at least the differences are much less remarkable than those which affect the size. However, the sexes are distinguished in several points. The two plates of the thyroid cartilage are much more oblique and proportionally less separated in man than in woman: hence they form in the former, where they are united in front, a much more considerable prominence under the integuments, and a much more acute angle. This projection is named pommum Adami: in women the angle is very obtuse. The excavation which terminates it above is superficial and rounded in the female; much deeper and terminated by an acute angle in the male. The cricoid cartilage shows no difference in the two sexes in front. The male and female larynxes are distinguished almost solely by their size behind; yet, as the two sides of the thyroid are more widely separated in women, there is in them a greater relative breadth in the triangular spaces which separate this cartilage from the proper cavity of the larynx. The organ is surmounted in man by a much broader and thicker os hyoideus than in woman. The epiglottis is also broader, more prominent above, and thicker: its general form is the same in both sexes. The glottis is also of the same form in both, and distinguished merely by its dimensions. As the arytenoid cartilages are longer, and consequently more elevated in man, the ventricles of the larynx are more deeply seated, and more distant from the external opening. The only difference observed below is the greater circumference of the cricoid in man. The trachea corresponds in size to the larynx, and is consequently smaller in women than in men. From the preceding observations it appears that the form of the larynx, although differing slightly in the two sexes, as well as the texture, which is the same in both, cannot be the essential cause of the differences in the key or pipe of the voice, which appear much rather to depend on the striking disproportion in size. It will be seen afterwards, that the particular character of the voice in the infant depends on the same cause.

Description of the Parts of the Larynx.—We may distinguish, in this organ, the cartilages which essentially compose its cavity, and give it solidity; 2. The ligaments which unite these together; 3. The muscles moving the cartilages, and thereby constituting the active instruments of the voice; 4. The glandular bodies situated in the neighbourhood of the cavity.

Cartilages of the Larynx.—These are five in number. The first, named the thyroid, is broad and tolerably thick; it covers the organ in front, but is no farther concerned in forming the cavity than by the attachment it affords to certain ligaments and muscles. The second or cricothyroid cartilage, which possesses, as its name implies, an annular figure, forms the solid part of the cavity. Two arytenoid cartilages, situated behind, and much smaller than the others, give to the glottis that mobility which makes it the seat of the voice. Lastly, the epiglottis, a true fibro-cartilage, has the office of closing the larynx occasionally.

The thyroid or scimitar cartilage occupies the front and lateral part of the larynx, measuring more from side to side than from above downwards, and being broader above than below. It consists of two lateral portions obliquely united in front, where they form a more or less prominent acute angle, corresponding to the median line, and producing a conspicuous prominence in the neck of the male, already mentioned by the name of pommum Adami. This angular prominence is bifurcated above, simple and rounded below. Each of the lateral divisions offers in front a nearly plane surface, slightly concave, covered principally by the thyro-hyoides muscle. An oblique line bounds this surface externally, and affords attachment to the thyro-arcoides, sterno-hyoides, and the inferior constrictor of the pharynx. Behind it is a small surface covered by the two latter muscles. This cartilage presents behind a concavity in the median line, corresponding to the front prominence: the ligaments of the glottis and the thyro-arytenoidei muscles are attached to this. Two plane surfaces, sloping backwards, correspond above to these muscles, from which a fatty cellular substance separates them, and below to the lateral crico-arytenoidei muscles, and to some fibres of the crico-thyroidei.

Four edges terminate the surfaces of the thyroid cartilage. The superior is the largest, affords attachment throughout to the thyro-hyoides membrane, has in its middle the notch surmounting the angle of union of the two pieces, then proceeds outwards on each side nearly horizontally, presenting a slight prominence corresponding to the external oblique line, and terminates beyond this by an appendix which will be mentioned. The inferior edge is shorter, concave in the middle, and has on the sides two convex prominences corresponding to the lower ends of the external oblique lines, and then two depressions. It affords attachment to the crico-thyroidei and to the crico-arytenoidei muscles. The posterior margins, two in number, are directed obliquely, and rest against the spine: rather concave above and convex below, they afford attachment to some fibres of the stylo- and palato-pharyngei. A rounded process, of different lengths in different subjects, directed obliquely backwards, surmounts each of these margins, and is connected by a ligament to the extremity of the os hyoideus: these are the superior cornua of the thyroid cartilage. A similar rounded process, shorter than the former, directed rather forwards, terminates each of the perpendicular margins below: these are the inferior cornua, and are articulated by their extremities to the sides of the cricoid cartilage.

A round opening is sometimes seen on each side of the cartilage, towards its upper part, transmitting an artery and nerve to the cavity of the larynx.

The cricoid or annular cartilage occupies the lower and back
back part of the larynx, of which it more particularly com-
poles the cavity by its ring-like figure. Its general figure
is completely circular. It is narrow in front, where it is
placed immediately under the lower margin of the thyr.
ion; grows broader at the sides, and swells behind into a con-
iderable size, where it lies into the middle of the interval
left between the two posterior borders of the thyroid.
The external surface must be every where convex, from the cir-
cular figure of the part: in its middle and front portion it
is covered only by the integuments; on the sides by the
crico-thyroidei muscles; and further back by the thyroid
cartilage, whose inferior cornua are articulated to two small
rounded surfaces. The broad posterior surface is nearly
quadridilateral, and presents, in the middle, a perpendicular
riling, covered merely by the membrane of the pharynx;
on the sides, two strongly marked depressions, in which the
posterior crico-arytenoidei muscles are placed. The internal
surface of the cartilage, every where concave, is lined by
the laryngeal membrane. The superior circumference pre-
ents in front a broad and superficial excavation, to which
the crico-thyroidal membrane is attached, and on the sides
of this the impression of the lateral crico-arytenoid muscles.
Behind, the edge of the cartilage riles considerably, and
presents two smooth surfaces for articulation with the ary-
tenoid cartilages: these two surfaces are oblique, narrow,
and convex; between them the arytenoid muscle is in
contact with the cricoid cartilage. The inferior circum-
ference is placed horizontally, and forms nearly a circular
outline; the margin is a little convex in front, then slightly
concave; rather convex again where the thyroid is arti-
culated to it, and slightly hollowed at the middle of the
posterior portion. It is joined to the first ring of the trachea
by a membrane similar to that which joins together the other
rings, and affords attachment behind to the posterior tracheal
membrane.
The arytenoid cartilages, two in number, a right and a
left, are much smaller than the preceding, placed at the
back of the larynx, on the upper edge of the broad pos-
terior portion of the cricoid. When viewed in the dead
subject, before the membranes and muscles have been re-
moved, they form a single prominence, concave above, so
as to reliefe slightly the mouth of an eaver, from which
their name is derived. They are movable articulated to the
cricoid cartilage, and caufe, by their motions, the enlarge-
ment or diminution of the glottis, by which the voice is pro-
duced. The form of the arytenoid cartilage is triangular
and pyramidal; but the apex is bent backwards, or towards
the pharynx. It polleys a posterior concave surface, filled
by the arytenoid muscle; an anterior convex one, with
excavations filled by the arytenoid gland; an internal flat
and perpendicular one, turned towards the opposite cartil-
ge, and covered by the membranous lining. These sur-
fakes are united by three angular edges; an internal, an ex-
ternal, and anterior: in the latter there are sometimes in-
equalities. The bafus offers behind a concave oval articular
surface, covered by a synovial membrane, directed down-
wards and outwards, and resting on the convexity of the
cricoid, to which it is articulated. In front of this there is
a considerable triangular elevation, forming the side of the
Glottis behind, sometimes confluting of a small distinct carti-
lage, and always affording attachment to the arytenothyroid
ligament. The apex, brought to a sharp point, is inclined
backwards and inwards. It is commonly hurnouned by a
small bit of cartilage, connected to it, involved in the mem-
brane, and turned towards the pharynx. Soennerring calls
these cornicula laryngis. Another small rounded portion is
seen on each side in the membrane, which passes from the
epiglottis to the arytenoid cartilage. The same author calls
these cartilages laryngis cuneiformes.
All these cartilages have a common structure. Their
dens and solid tiflie, and greyish colour, which is not
struck from like that of the articular cartilages, approximate
them to the bone system. In the progress of years, they
come still nearer to it: they are constantly found ossified
in old subjects, particularly the thyroid and cricoid. Even
before this time we very frequently find them reddish
points, the nuclei of an incipient and often extensive ossifica-
An areolar substance, analogous to the spongy tex-
ture of bones, forms at the same time, and contains a little
medullary texture, from which an oil may often be ex-
prefsed.

**Fibro-cartilage of the Epiglottis.**—This has not the same
uses as the parts just described. Situated at the upper part
of the larynx, between it and the root of the tongue, it
varies in its direction. It is perpendicular in the ordinary
state, so as to leave the glottis free for the purposes of re-
piration: it becomes nearly horizontal at the moment of
deglutition, so as to cover the glottis, and prevent the
entrance of the food into its cavity. (See Deglutition.) Its
form has been compared to that of a myrtle leaf; it is flat-
tened in its figure, and has its extremity slightly recurved.
We divide it into a lingual and a laryngeal surface, and a cir-
cumference. The lingual surface is concave from above
downswards, but convex transversely: it is directed anteriorly,
or towards the mouth, in the perpendicular position of the
organ; superiorly, or towards the pharynx, in the horizontal
state. It is covered by the mucous membrane of the
mouth, continued to it from the tongue, and forming three
folds between these two organs. The middle, which is the
most strongly marked, is prolonged on the lingual surface:
this is sometimes called framus epiglottis. The lateral du-
plicatures are looser and less conspicuous, and end on the
circumference of the epiglottis. The framus, being stretched
when the epiglottis is depressed, must assist a little in elevat-
ing it, when the tongue is carried forwards: but if we cut
the framus, the epiglottis still recovers its perpendicular
position, so that this fold can affect it but very slightly.
The two other duplicatures have no connection whatever
with the motions of the part. In the inferior part of its
anterior surface the epiglottis is separated from the thyro-
hyoideal membrane by the peculiar tiffue constituting the
epiglottic gland. The laryngeal surface is convex from
above downwards, and concave transversely: it is covered
by a continuation of the laryngeal membrane, and its as-
spects, in the different positions of the organ, may be un-
derstood, from what is said concerning that of the lingual
surface. The circumference of the epiglottis is free above,
and here the membranes covering its two surfaces are con-
tinuous. From each side a fold of the mucous membrane is
continued to the arytenoid cartilage. The lower part,
sometimes called the bafs of the epiglottis, where the two
fides are united into an acute angle, is connected to the
hollow surface of the thyroid.

The fibro-cartilage, composing the epiglottis, is thicker
below than above, on the median line than on the sides:
it belongs to the membranous fibro-cartilages. (See Fibro-
cartilage.) Its two surfaces, particularly the laryngeal,
present a great number of small holes, like the prickles
of a pin, lodging glandular bodies: these are closed by the
mucous membrane, and may be seen by removing that part.
Several of them communicate from one surface to the other.

**Articulations of the Larynx.**—Its cartilages are united to
each other, or to the surrounding parts, by fibrous and mem-
brane.
branous connections; we shall consider at present only those of the first kind, the others belong to the general description of the organ.

The thyroid is connected to the cricoid cartilage in front and on the sides. In the former situation, a membrane, called the crico-thyroid, proceeds from the upper edge of the cricoid cartilage, and is attached to the middle of the lower border of the thyroid; it is lost insensibly on each side on the mucous membrane of the larynx. It is deepest in front, and grows narrow and less distinct towards the sides; it has a fibrous appearance in the former, which it loses in the latter of these situations. Covered on the sides by the crico-arytenoid muscles, it is fibrous in front, and corresponds to the arytenoidal membrane behind. It allows a considerable motion between the two cartilages. On the sides there are two small articulations, formed between the inferior cornua of the thyroid, and the lateral articular faces of the cricoid: they are lined by loose synovial membranes, and lubricated by a tolerably copious synovial secretion. The surfaces, which admit readily of a gliding motion on each other, are held together by very distinct ligamentous fibres. An anterior fasciculus is continued obliquely downwards and forwards from the front of the thyroid cornua to the side of the cricoid cartilage. A posterior goes from the back of the same process, and ascends to be fixed to the back of the cricoid under the arytenoid cartilage. There are some irregular fasciculi, besides the two first described.

The opposed surfaces of the arytenoid and cricoid cartilages are covered by very loose synovial membranes, lubricated by a copious secretion, and strengthened by ligamentous fibres at some parts. The most remarkable of these fibres are on the infixed and back; externally they are little apparent, and seem only hardly to exist at all.

Each of the arytenoid cartilages is connected to the thyroid by a fibrous fasciculus, particularly important on account of its concern in the production of the voice. They are called the aryteno-thyroid ligaments, ligamenta glottidis, or chordae vocales. The ligament composed of parallel fibres, and about half an inch in length, arises from the anterior prominence of the base of the arytenoid cartilage, passes horizontally forwards and inwards, and is fixed to the concavity of the angle formed by the junction of the two sides of the thyroid, uniting at this point with that of the opposite side. It is covered externally by the thyro-arytenoid muscle, and corresponds everywhere else to the mucous membrane. The slit-like aperture left between the right and left ligaments is the glottis, or rima glottidis.

The two arytenoid cartilages are connected together merely by the membrane of the larynx, and by the arytenoid muscle. It is said that a transferiv fibrous fasciculus is sometimes placed in front of the latter, to prevent the two cartilages from being separated too widely.

The acute and elongated angle, which terminates the epiglottis below, gives origin to a narrow fibrous fasciculus, about half an inch in length, which is covered in front by the epiglottic gland, and is fixed to the angle of the thyroid, just above the attachment of the ligamenta-glottidis.

The arytenoid cartilages are not connected to the epiglottis by any fibrous union; two considerable membranous folds, forming the principal part of the upper aperture of the larynx, proceed from the former to the sides of the latter; they seem to be the ligaments thyroidea superioria of Soemmerring.

Muscles of the Larynx.—The organ is moved by two kinds of muscles, of which one is common to it with other parts, the other belongs particularly to it. The first are the muscles of the os hyoides, and move the whole organ together, these, as well as the os hyoides, are described in the article deglutition. The others are concerned in moving on each other the parts of the larynx.

The crico-thyroidus is a thin quadrilateral muscle, situated in front of the larynx, and often divided into two parts by a fatty line. It is attached to the front and sides of the cricoid, and proceeds upwards and outwards to the inferior edge of the thyroid, to which, as well as to a little of the posterior surface, the internal fibres are fixed. The external are long, and reach to the front of the inferior thyroid cornua. An internal appears between the right and left muscles, in which the crico-thyroid membrane is visible. It corresponds in front to the fibro thyroidus, and to the inferior constrictor of the pharynx; behind to the crico-thyroid membrane, and to the crico-arytenoideus lateralis.

The crico-arytenoideus posterior is a strong muscle, flattened on its surface, triangular, and placed at the back of the larynx. Its origin fills the lateral excavation of the posterior surface of the cricoid. The superior fibres are the shortest, and proceed nearly transversely; the following are longer, and gradually more and more oblique from below upwards and outwards; they are attached to the posterior and outer part of the bases of the arytenoids, between the insertions of the arytenoideus, and of the crico-arytenoideus lateralis. In front it corresponds to the cricoid cartilage, and belongs to the membrane of the pharynx.

The crico-arytenoideus lateralis is a thin and flattened muscle, rather elongated and quadrilateral, proceeding from the side of the cricoid to the side of the arytenoid cartilage. It arises from the superior margin of the former, passes obliquely backwards and upwards, and is fixed externally to the bases of the arytenoid. It is connected in front with the thyro-arytenoideus, separated on the outside from the thyroid cartilage by cellular substance, and lined on the inside by the laryngeal membrane.

The thyro-arytenoideus is a thin and flattened muscle, of irregular figure, situated within the concavity of the thyroid cartilage. It arises near the angle of that cartilage, from the lower part of its posterior surface, proceeds backwards and upwards, becoming rather narrower, and is inserted in the front of the arytenoid cartilage, below the preceding, to which it is closely connected. It corresponds externally to the thyroid cartilage, and internally to the laryngeal membrane.

The arytenoideus is the mass of muscular fibres filling the posterior concavities of the arytenoid cartilages, and occupying the interval between them. The fibres arise from the concave surface of one cartilage, go acrrois, and are inserted in the corresponding part of the opposite cartilage. They are partly oblique and partly transverse; the former consist of a few superficial fibres crossing respectively from the bases of one to the apex of the other cartilage, and consequently decussating like the two parts of the letter X. The great mass of the fibres has however a transverse direction. From the different courses of these two descriptions of fibres, two arytenoideus muscles have been distinguished; viz. an obliquus and a transversus. These fibres are placed between the membranes of the larynx and pharynx; in front they are also partly in contact with the arytenoid cartilages.

Under the names of thyro-epiglotticus, major and minor, some anatomists have described a few slender fibres proceeding from the posterior surface of the thyroid cartilage to the side of the epiglottis. Others do not admit the existence of these muscles, which are allowed by all not to be found generally. Haller regards these fibres, when they...
exist, as a part of the thyro-arytenoides. The motions of the epiglottis, in the human subject, are all entirely of a mechanical nature, and not performed by muscular action.

Glands of the Larynx.—There are three bodies of this description in the neighbourhood of the organ; viz., the epiglottic, the arytenoid, and the thyroid.

Glands of the Epiglottis.—In front of, and below the epiglottis, a triangular space is left, bounded behind by this cartilage, in front by the thyro-hyoid membrane, below by the thyro-epiglottic ligament, and on the sides by the lateral folds of mucous membrane which line the two spaces left between the sides of the thyroid and the cricoid cartilage. This space is filled by a body, manifestly cellular and adipous for the most part, but covering below small granular glands, sometimes united together, sometimes inflamed, and sending prolongations into the holes with which the epiglottis is pierced. The latter open on the laryngeal surface of the organ by very distinct apertures. The glandular bodies are sometimes so much covered and concealed by the surrounding fat, that they can hardly be distinguished. In all cases we may remove by dissection these bodies from the openings in the epiglottis, which then appear as empty spaces. We may distinguish as many as thirty of these. The superior excavations of the epiglottis contain small distinct grains: the epiglottic gland and its cellular tissue belong only to the inferior half of the organ. The openings in the epiglottis are of different sizes; they are very regularly formed, with rounded edges, and penetrate always straight through, never obliquely.

Arytenoid Glands.—In the fold of mucous membrane, proceeding on each side from the epiglottis to the arytenoid cartilage, a small body is found, evidently of a glandular nature, presenting small distinct grains, very analogous to those which compose the laryncal gland, and generally of a greyish hue. It may be compared in form to a carpenter's square. The perpendicular branch, which is rounded, and may be felt by the finger, when we seize the fold that contains it, lies against the front of the arytenoid cartilage, and is loose above. The horizontal branch runs along the superior fold of the ventricle of the larynx, and is less prominent than the other. The situation, at which the two branches form their angular union, is in front of the base of the arytenoid. The glandular grains of this small body, probably, have excretory ducts terminating on the edge of the superior aperture of the larynx; but these apertures are not visible like those of the ducts of the last-mentioned glands.

The epiglottic and arytenoid glands furnish a mucous secretion, and are of the same nature as the others which belong to the laryngeal membrane. The passage of the food in deglutition, and of the air in respiration, requires that these organs should be defended by a mucous fluid.

The thyroid gland is one of those organs, of which the use is entirely unknown to us, although its constant existence, through all periods of life, and the great number of vessels which it receives, do not allow us to doubt that it performs some important office. Its situation immediately below and in front of the larynx, leads us to connect its history with that of this cavity, although we are ignorant whether it has any concern in the same functions. This organ, as well as the spleen, capsule renalis, &c. suggests a very important reflection; viz., that our notions concerning the general relations of the functions of the animal economy must still be exceedingly imperfect, and that we should deceive ourselves if we suppose that we can embrace the plan of nature in one general view, and represent it accurately in our physiological classifications. Can we doubt that the unknown functions of these viscera are connected to the general plan, and make an essential part of it? How then can we be certain that a knowledge of them would not either partly overturn, or considerably modify our present notions on those subjects? Why is the theory of fixed existence still so obscure? Because the functions of several organs, at that time perfectly developed, and in a very active state, escape our observation, and we cannot arrive at general results when the particular facts are unknown.

The bulk of this gland, which is always very considerable, varies much in different individuals: perhaps no organ presents more striking variations. No particular condition of the body, no modification of any particular function, nor differences in the state of the larynx, trachea, lungs, &c. have been observed to account for these varieties. Its form is tolerably constant; but in this respect there are also varieties. It is composed of two distinct portions, nearly pyramidal in their figure, occupying the sides of the larynx, and of the upper extremity of the trachea, so that the base is placed downwards and forwards, and the apex stretches upwards and backwards. Variations are observed in the extent and direction of these two lateral portions. They are united in front by a small flattened transverse band, which may be large and thick, or small and narrow, or made up of distinct tubercles; indeed, we scarcely find it the same in two individuals successively. In a few instances this part does not exist, so that there are two distinct thyroid glands, one on each side. It does not extend above the trachea, so that the whole larynx is uncovered in front, nearly subcutaneous, and embraced by the curve formed by the two lateral portions of the gland united by the intermediate band.

In front the thyroid gland is covered by the sternothyroidei, sternohyoidi, omo-hyoidi, and latissimi colli. It reits behind and towards the outside on the vertebral column, to which a loose cellular substance connects it, and where, according to its bulk, it conceals or leaves exposed the nerves and blood-vessels of the neck. Internally, or towards the middle line, it covers the sides of the first rings of the trachea, part of the cricoid and thyroid cartilages, the crico-thyroidei, thyro-hyoidi, and inferior constrictor of the pharynx. Exactly in the middle and front it conceals the two first rings only of the trachea. A loose tisue separates it from all these parts.

It is surrounded by no membrane: the exterior cellular tisue is rather more dense and compact than the rest, as in the pancreas and salivary glands; but it forms no proper membrane. It never contains any fat.

With this external covering some muscular fibres are blended; not noticed by Albinus, nor by most other anatomists, but forming the levator gland. thy. of Hailer, the muculus gland. thy. of Soemmerring. It does not exist constantly; is generally a single muscle, situated in the middle of the larynx, sometimes is placed towards the right or left; and sometimes, but very rarely, is double. It arises by a narrow tendinous slip from the basis of the os hyoides; descends in a straight course, growing broader, and has its fibres expanded on the front of the gland, and blended with the covering of the organ. It must apparently have the effect of suspending and supporting the gland. Muscular fibres have sometimes been seen, extending over the surface of the gland from the crico-thyroideus. Besides the effects which these and the fibres just described may produce on the gland, it will be exposed to powerful compression against the larynx and trachea by the sternohyoidi and sternothyroidei, which embrace it very closely.

The proper tisue of the thyroid gland varies considerably.

S 1 2
in colour and density: it is often red, and even dull brown, like the spleen, sometimes yellowish or greyish. It may be flabby or compact; but its density varies less than its colour. The substance of the organ, like that of other glands, is disposed in distinct lobules, which are collected into more or less voluminous lobes. This conglomeration is never so perceptible as in the salivary glands, the pancreas, &c.; excepting, however, certain cases of increased volume without organic change, where the surface of the organ is tuberculated and irregular from the unequal prominence of the lobes. In the natural state of the part, we may distinguish the lobes by division, as the great vascular trunks run in their intervals; the latter, which are hardly perceptible at first view in consequence of the lobes being pressed against each other, become apparent by the use of the knife. A fine cellular tissue, never containing any fat, and small in quantity when compared to what is found between the lobes of other glands, is seen in these intervals.

The lobes of the thyroid gland are mixed in some subjects with rounded vessels, containing sometimes a yellowish, sometimes a transparent and colourless fluid. In most subjects these cysts do not exist, and in many we cannot observe the slightest traces of them. Yet slices of the gland recently cut give us a peculiar feeling of viscidity, not observed in other glandular bodies, and proceeding from the fluid just mentioned. If an acid be poured on the cut surface, a slight whitening is produced, as in most other organs.

Although provided with a great number of blood-vessels, the thyroid gland contains in its capillary system less blood than the liver, the kidney, &c. It only distils from the water of maceration once or twice, which arises evidently from the small number of its capillaries. It is not by the large vessels, in which the blood is influenced by the heart’s action, but by the capillaries, that we may judge of the quantity of blood habitually contained in an organ. As putrefaction generally proceeds more quickly, in proportion as the quantity of blood remaining in the organs after death is greater, the thyroid gland undergoes this change less readily than most others. Slices of it dried are greyish and friable. When boiled, they curl a little before evaporation, and then become considerably hard and corrugated as almost all the animal solids do. But, instead of growing soft again, like the muscles, tendons, &c. they are rendered still harder, like the glands, by a continuance of the boiling. Acids and alkalies have no peculiar operation on the tissue of the thyroid gland.

Nothing like an excretory duct has hitherto been discovered in this body; no communication has been pointed out between it and the trachea or larynx. The emphysema, of which it is sometimes the seat, proves nothing in this question; for the air is contained in the cellular tissue which unites the glandular lobes, and is introduced in consequence of its general diffusion in the cellular tissue of the neck. By infusing a blow-pipe into the substance of the organ, and inflating forcibly, it may generally be intimated so as to form an artificial emphysema. The air, in this case, is not contained in the vessels, but in the cellular interstices; it follows the course of the vascular trunks.

Some sexual differences may be noticed in the thyroid gland. It is generally larger in the female, and its lateral divisions are more prominent in front; which diminishes the apparent prominence of the thyroid cartilage. In man, on the contrary, the two lateral portions are thinner and proportionally flatter; and lie more close on the sides of the larynx, below the external oblique line of the thyroid cartilage. But there are so many varieties in other points, that this sexual difference is often little observable.

The differences from age are few. The gland is proportionally larger in the foetus and child than in the adult. Its front prominence is more striking at the first period: and its colour is deeper and brownish. Its proportional excess of volume cannot, however, be compared to that of the thymus, capsule renales, &c.: indeed, it is not sufficiently remarkable to authorize us in concluding that the use of the part is particularly relative to female existence, although several authors seem to have believed this.

The thyroid gland has four large arteries, two on each side, one of which is derived from the external carotid, the other from the subclavian trunk. No part in the body has so considerable an arterial supply as this organ; that of the brain is very much less in proportion. The inferior thyroid artery in the child is as large as the remaining trunk of the subclavian after its origin. These vessels are connected in the gland by large and numerous insinulations. The veins correspond in number and magnitude to the arteries, and terminate in the jugular and subclavians. The absorbing vessels are also considerable, and join the jugular glands. The thyroid arteries are accompanied by numerous filaments from the great sympathetic; but it cannot be easily decided whether the proper substance of the gland receives any nervous supply.

As we have stated already that the use of this organ is unknown, we shall not fatigue the reader with mentioning and refuting the aforesaid offices. Although they are very numerous, they are not grounded on any facts worthy of attention. Semmerring, in his 6th vol. De corporis humani fabrica, § 56, gives a long list of "opiniones de glandula thyroideae ultra" and there is a similar catalogue in Haller’s Elements, lib. ix. sect. 1. § 22

Of the Larynx in general.

General Conformation.—The larynx is a cartilaginous cavity moved by various muscles. It is broad above, narrower below, and poises an external figure, which does not correspond to that of the internal hollow. In fact, the latter, being essentially formed by the cricoid and arytenoid cartilages, and the membranous coverings belonging to them, poises nearly an uniform diameter throughout; and it is most contracted towards the upper part. This arises from what we have said of the thyroid cartilage, which rather protects than forms the larynx, although it is essential to its structure and action, from the attachment which it affords to muscles and ligaments. We may consider, in our view of this organ, the external and internal surfaces, the superior and inferior extremities.

The external surface, confided in front, presents, on the median line, the prominence formed by the union of the two portions of the thyroid, which exhibits, above, a considerable depression, particularly in man, then the membranous interval, which separates the two crico-thyroides, and below it the convexity of the cricoid: on the sides we see the two flat surfaces of the thyroid cartilage, covered by the hyo-thyroidei, the external oblique line, the triangular surface covered by the inferior constrictor, and terminated by the inferior cornu, lower down the crico-thyroideus, which, at this point, almost entirely covers the cricoid cartilage. Behind, the external surface of the larynx, more depressed in the middle than towards the sides, presents, on the median line, the middle prominence of the cricoid: on the sides, the hollows lodging the crico-arytenoidei pitiici, then a triangular space, broad above and narrow below, filled with a more or less adipous cellular substance; lastly, two rounded edges, bounding the spaces just mentioned, more prominent than any other parts in this aspect, and relying on the vertebral column, so as to allow a free motion.
to all the essential parts of the organ, particularly to the arytenoid cartilages.

The internal surface of the larynx, lined throughout by the mucous membrane, may be divided into two parts, one fold, the other moveable. The first is inferior, in point of situation, and formed entirely by the cricoid ring. The proportions of this part are constantly the same; and it contains nothing worthy of notice. The movable portion is above, formed behind by the arytenoid cartilages, in front by the thyroid and epiglottis, on the sides by the folds of the mucous membrane, continued between the epiglottis and the arytenoid cartilages. In the ordinary state this is triangular, broad in front, and narrow behind; but the motions of the epiglottis and arytenoid cartilages change its figure considerably. This part forms the opening by which the larynx communicates with the pharynx: the aperture is placed just behind and below the root of the tongue, and is often called the glottis, although it has no share in the formation of the voice. Of its relation to the pharynx, in respect to deglutition, see a further account in that article. The part, at which these two divisions of the larynx are united, is remarkable for the two membranous folds, called ligaments glottidis, or chordae vocales. These arise from the bases of the arytenoid cartilages, and pass obliquely, forwards and inwards, to meet together at the concavity of the thyroid, where they are fixed just under the epiglottis. They leave between them a triangular space, of which the bases is behind, and the apex forwards: this is the true glottis, and is placed about half or three quarters of an inch lower down than the opening described above: as the measurement of the opening from behind forwards considerably exceeds the transverse diameter, it has a flat-like appearance, from which the name of rima glottidis has been applied to it. The folds, which form the sides of the upper opening, differ essentially in their composition from those of the inferior aperture. The former are merely membranous: the latter contain the fibrous cartilages, described already under the name of the thyro-arytenoid ligaments. The interval left on each side between the superior and inferior folds constitutes the ventricles of the larynx, or sacculi laryngis. Their form must correspond to the direction of the folds, which have just been described; their depth is inconsiderable. Sometimes the mucous secretion of the internal lining accumulates here for a short time: sometimes foreign bodies become engaged in them, and produce suffocation by stopping the rima glottidis, or caufe great dilatations in such a state of lock. The ventricles, as well as the superior laryngeal folds, correspond on the outside to the thyro-arytenoidei muscles: the inferior folds separate these muscles from the crico-thyroid, one complete towards the outside of the space separating these folds from the circumference of the cricoid.

The inferior extremity of the larynx, formed by the inferior circumference of the crico-thyroid cartilage, is exactly circular. It is united to the frst ring of the trachea by a fibrous membrane, similar to those which unite to each other the remaining rings of this tube. Behind, the posterior tracheal membrane is attached to it.

The superior extremity, much larger than the inferior, is formed in front and at the sides by the upper edge of the thyroid cartilage. This edge is connected to the os hyoides, which is immediately above it, by the loose and soft thyro-hyoid cartilage: this is thicker in front than towards the sides, has very little fibrous appearance, but is more rather of a cellular nature. It is covered by the hyo-thyroid and larno-hyoidi; it corresponds behind to the epiglottis, from which the epiglottic gland separates it, and to the laryngeal membrane. It is shorter in the middle than at the sides; consequently the cornua of the os hyoideus can be elevated to a greater distance from the thyroid cartilage than the bases of the same bone, and the bases of the tongue, which is supported by the os hyoideus, can be drawn up higher at the sides than along the middle line; which disposition of parts is favourable to the formation of the channel, along which the food is conveyed towards the oesophagus. The two extremities of the os hyoideus are connected to the superior cornua of the thyroid cartilage by long, dense, and round ligaments, generally containing granular bodies of a cartilaginous or bony nature. These are named ligamenta hypo-thyroidea lateralis, to distinguish them from the former, which is called liga. hypo-thyroid, medium. The length of these lateral ligaments, in addition to that of the thyroid cornua, measures the distance between the os hyoideus and the thyroid cartilage behind, which is about double the front interval.

Behind the edge of the thyroid cartilage, and in front of the epiglottis, there is a triangular space filled by the epiglottic gland, and its adipous cellular substance. This space is bounded above by the fold of mucous membrane continued from the bases of the tongue to the epiglottis, and, moreover, by a kind of fibrous membrane, which lies immediately under the former, and over the gland. The membrane in question is stronger in the middle than at the sides: it arises from the concavity of the os hyoideus, and is attached to the middle of the epiglottis. Behind this space we see the epiglottis, and behind it the superior opening of the larynx, already mentioned. As the breadth of the epiglottis, which forms the front of this opening, is always the same, while the arytenoid cartilages, which compose the back part, admit of considerable motion, the figure of the aperture can undergo little change in front, while it may vary much more considerably behind. The position of the opening is rather oblique, from before backwards and downwards.

Membrane of the Larynx.—The interior of the cavity is lined by a mucous membrane, forming part of the general syflem common to the respiratory and digestive organs. It proceeds backwards from the bases of the tongue over the front of the epiglottis, forming, as it passes, the three folds already described: it is reflected over the loofe edge of this fibro-cartilage, covers its posterior surface, and then enters the larynx. On each side it is continued directly backwards to the arytenoid cartilages, being loose and unconnected at its edge, and corresponding only to the thyro-arytenoidei muscles. At the posterior edge of the opening of the larynx, it is continuous with the membrane of the pharynx. When it has arrived in the cavity of the larynx, and towards the bases of the arytenoid cartilage, it forms on each side a horizontal fold, directed obliquely forwards to the concavity of the thyroid, to which it is fixed, joining that of the opposite side. Below this point it lines the cavity of the ventricle, then forms another fold, which bounds this cavity below, and embraces the thyro-arytenoid ligament: it afterwards lines the lower portion of the larynx, and is continued into the trachea. In the whole of its extent the mucous membrane is of a pale rofe-colour, and distinguished by that character from the lining of the mouth, of which it is a prolongation, and which is much redder. Its density is considerable, particularly on the cartilages, where it is united with the perichondrium: in other parts it is more thin and loofe in its texture. On the laryngeal surface of the epiglottis, it is perforated by several holes, which are the terminations of excretory ducts. Mucous glands are apparent in several points of its surface. The capillary fytter of this membrane is not very considerable, and hence arises its paleness.
The larynx is moved in the same way, and by the same muscles, in the pronunciation of different sounds. When an acute sound is uttered, it ascends very sensibly; and this ascent, which is gradual, according to the tone, may be felt by placing the finger on the thyroid cartilage, while we go through the gamut. In the formation of grave sounds, there is, on the contrary, a very sensible depression. These motions can be very clearly seen in the throat of a finger: the rapid and considerable changes which take place in that mode of exerting the voice, render the motions very perceptible. The ascent of the larynx is necessarily accompanied by an elongation, and its descent by a shortening of the trachea; in the former case its diameter is diminished, and in the latter increased. Some have supposed that these changes in the trachea are concerned in producing the alterations of tone; but if they produce any effect on the sounds, it is very slight, and they seem rather to be merely consequent on the movements of the larynx.

What connection is there between the sounds uttered and the general motions of the larynx? We know very little on this subject. We may observe that they have no relation to the force or weakens of the sound; for as long as the voice remains at the same tone, the larynx does not move, however the sound may be changed in length or weakness.

The thyroid and criocoid cartilages admit of reciprocal motion; the former can be brought downwards and forwards upon the latter; in this case the chordæ vocales are relaxed. The crico-thyroidæus muscle has this effect.

But the motions of the arytenoid cartilages are the most important, on account of their connection with the chordæ vocales. They may be brought towards each other, until, indeed, they come into actual contact; this is attended with a proportionate approximation of the chordæ vocales. When the cartilages touch each other, the rima glottidis is completely closed; this is done by the arytenoid muscle. This flapping of the aperture is sometimes produced pathologically, as when the parts are irritated by acid vapours, or by foreign bodies coming into contact with them. Respiration may experience a temporary obstruction under such circumstances. When these cartilages are moved away from each other, the chordæ vocales are separated, and the rima glottidis proportionately enlarged; this is the action of the crico-arytenoideæus muscles.

The arytenoid cartilages admit also of being moved forwards and backwards; the chordæ vocales are rendered tense in the former state, and are relaxed in the latter. The thyro-arytenoideæ and crico-arytenoideæ laterales carry them forwards; and the crico-arytenoideæ pollici backwards.

**Development of the Larynx.**—The differences of this organ, according to the age of the individual, are not less conspicuous than the sexual distinctions in the adult. They refer to two principal periods; viz. the years which precede, and those which follow puberty; for the great changes in the structure of the larynx, which in this respect follows the development of the sexual organs, take place about this epoch. In the fetus and child there are no differences in the larynxes of the two sexes; until the period of puberty, the fame size, the same rounded form, and the same want of prominence are observed both in the male and female. At this time the organ is much smaller in proportion in both sexes, but more particularly in the male, than it will be in the adult. This will appear in a more striking point of view, if we compare the larynx to the os hyoideus, which furnishes it. That organ, already much advanced, in consequence of its connection with the tongue, which is developed early in life, projects before the larynx; while in the adult, and especially in the male subject, the larynx projects before it. The thyroid cartilage can hardly be said to have a prominent angle in the child. It is rounded at this part in either sex. Nothing particular is to be observed of the cricoid cartilage; and all the parts at the back of the larynx present the same dispositions as in the sequel, excepting the difference in size.

The nature of the voice is influenced by this diminutive size of the larynx, and by the sameness of its form in the two sexes. At this period of life we remark that its pipe or key is slender, and that its character is the same in both sexes. If there be any difference, it is not such as that which in the sequel distinguishes the voice of man from that of woman.

As the growth proceeds, the larynx approaches to the state in which we find it in the adult. Yet it does not follow the same course of development as most other organs. In children of six months it is often as large as in those of two years. Sometimes in a subject of three years it will be smaller than in one of a year, although the stature of the two may be suitable to their respective ages.

A change almost sudden, or at least much less gradual than any which had occurred before, in the functions of the larynx, is remarked at the epoch of puberty: this indicates an alteration in the organization of the cavity, and a more rapid development of its structure. The change is much more remarkable in man than in woman, because the larynx remains much smaller in the latter than in the former, even after puberty. At this time the larynx is enlarged in all its dimensions by a speedy growth analogous to what is observed in the generative organs. But while this change is going on, for several months, the voice has a peculiar pipe, which is neither that of infancy nor of adult age.

After puberty the larynx undergoes no well marked change: its form becomes more fixed, and the prominence of its thyroid cartilage more considerable in man.

In the old person, as the cartilages are confluently receiving fresh depositions of earthy matter, they at last nearly equal bone in hardness. This change affects the thyroid first; then the cricoid, and lastly the arytenoids. The epiglottis is barely ever affected, probably on account of its peculiar organization, which resembles that of the cartilages of the nose, ears, &c. This exception is very favourable to its functions, which require pliancy. The voice always becomes weak and broken in the aged: the weaknes of the muscles and the flatten of the joints accounts for this, as analogous changes explain similar phenomena in the organs of locomotion.

The remarkable change in the pipe of the voice produced by the removal of the telluric has been mentioned in the article Generation. It has not been ascertained whether there is any change in the organization of the larynx in these cases.

The parts hitherto described are the instruments by which the voice is produced; the action of other organs is required,
quired, in order to modify this, so as to form it into articulated sounds or speech. Of these the tongue and the hyoides are the most important; the latter bone is the basis of the tongue, the fixed point from which its muscles proceed, as also the point of attachment of the chief muscles of the larynx. The description of these organs, and of the mucular powers employed in moving them, will be found in the article De
dition. A knowledge of the parts about the throat, which anatomists generally term the fauces, is also essential in considering the subject of the voice. The larynx opens into a large membranous cavity, descending from the basis of the skull in front of the first upper cervical vertebra, and named the pharynx. A large opening in the front of this, and between the tongue and soft palate, leads into the mouth: this aperture may be either free or closed. Another passage goes above the palate into the nose; but this is not so changeable in its dimensions as the former. Thus the air, expelled from the larynx, must proceed either through the mouth or the nose, or both. The mouth is the large space bounded by the lips and cheeks, the tongue and palate. Into it the tongue projects below, with free power of motion in every direction, and in the ordinary state nearly fills the cavity. The two rows of teeth form a kind of division into an outer and an inner cavity. For the more particular description of all these parts, see De
dition.

It was formerly held that the palate and uvula had a considerable influence on the voice; but this seems doubtful. The softness of the part, which is drawn down against another soft part, the tongue, renders it unfit for producing any modification in the sound. Animals, for the most part, have no uvulas, and we know that the organ may be variously deformed without affecting the speech: "wherefore, says Haller, (Elem. Physiol. lib. ix. fec. 2. § 17.) if affections of the uvula have produced any considerable alterations in the voice, I should be rather inclined to ascribe them to some undue passage of the sound from the velum palatii being at the same time injured. Thus, when the nose is deformed, a peculiar modification of the voice takes place, not because the nostrils are moved in the vocal functions, but because they transmit or reflect the sonorous tremors of the air. Thus, too, when the voice is injured by destruction of the bony palate, an artificial plate, which restores the power of reflection, without adding any motion, remedies the deficiency. I have the fame opinion concerning speech. The guttural letters may be less perfectly formed, when the organs about the throat are deformed, because the allusions of parts cannot take place in the natural way: but the uvula is concerned in the pronunciation of no letter, and we might quote numerous authors who have seen it entirely cut out, or destroyed by disease, or originally deficient without the speech being impaired."

The passage from the pharynx, above the velum palatii, leads into a large and irregularly formed bony cavity, lined with a soft membrane, and increased by many excavations in the neighbouring bones. This is the cavity of the nose, divided by a nearly perpendicular partition into two halves, the right and left nostrils. This cavity is described under the articles Cranium and Nose. The air emitted from the larynx, rushes into these bony hollows, when they are not filled with mucus, strikes their sides, and throws the whole of the surfaces into vibrations, from which important modifications of the voice ensue.

Physiology of the Voice and Speech.—The voice, like all other founds, is a vibration communicated to the air; and it offers to our observation, like them, three distinct kinds of qualities, independent of each other. 1. The tone, or the various degrees of acuteness and graveness, which depend on the ve

locity of the vibrations. 2. The intensity, or the degrees of force, which depend on the extent of the vibrations. 3. The character or key, which arises from circumstances hitherto undetermined, and relating to the structure, the substance, or the figure of the sonorous body. The human voice is susceptible of a fourth order of modifications; viz. that which we represent by the letters of the alphabet, and which is itself divided into two other orders; the one relative to the principal founds, which we represent by the vowels; and the other to their articulations, which constitute the consonants. We do not exactly know what the two latter modifications depend on: and although we perceive to a certain point the circumstances under which they are executed, we are not yet able to imitate them by artificial instruments.

The found is produced by the passage of air through the rima glottidis, or the slit-like opening left between the two chordæ vocales. Almost invariably it is the passage of air from the lungs, in expiration, that produces the found: but there are some rare exceptions to this. In hiccough, and under some circumstances in coughing, found is produced during inspiration. Many conceive, moreover, that the phenomena of ventriloquism are to be explained by the exertion of the vocal organs, when air is admitted into the chest.

That the larynx is the primary organ, in which the original found is produced, is proved by the circumstance, that diseases and accidents affecting it destroy or modify the voice. If an opening be made in the trachea, below the larynx, so that no air shall pass through the latter, no voice is produced. When, on the contrary, an opening is made immediately above the glottis, the voice is not affected. Dichtar made an incision between the os hyoideae and the thyroid cartilage, and through the membrane, which connects the tongue to the epiglottis; through this tranverse opening he drew out the epiglottis with a hook, so that the found, instead of passing through the mouth and nose, came directly by the external wound. The voice was as strong as before, and very little changed in character. He drew the glottis between the sides of the wound, so that the found could not pass at all into the mouth and nose; the result was still the same. In these experiments the epiglottis may be completely confined, or even cut away, without affecting the phenomena, so that it can have no concern in the formation of the voice. When the arytenoid cartilages were cut through, or the thyroid divided longitudinally, as in the operation of bronchotomy, the voice was destroyed.

The two elastic ligamentary and membranous bodies, which form the chordæ vocales, are analogous, in the human instrument of the voice, to the various provisions for producing vibration in the different wind instruments. No found is produced by blowing into a tube through a simple opening; the only effect is a motion of the air, incapable of producing found, unless it meets with a body susceptible of being thrown into vibration. It is, moreover, ascertained that the sides of the instrument are not the vibrating parts; for the substance of which they are composed, or the manner in which they are held, produces no change in the tone or key. On examining the parts, to which the mouth is applied, in the various wind instruments, it appears, that vibrations are produced in the air contained in the tube, as they are in the external air; that is, the intervention of an elastic body is necessary, which the blowing of the player agitates, and the vibrations of which are communicated to the air in the tube; or at least some angular body, against which the air may break as it pales with violence, and thereby be thrown into vibration. In the flute with a mouth piece, in organ-pipes of various kinds, in the hautboy,
hautboy, balloon, &c. in trumpets, horns, &c. there are different provisions of this kind, to which the chordæ vocales are perfectly analogous. The tube then produces no sound itself, it only modifies, directs, or augments that which it produced at its embouchure by the sonorous body against which the air breaks. The trachea of an animal is a continuous tube without any contraction, or any piece susceptible of vibration, except at its upper extremity, or the glottis. As the sound is only formed at the end of the trachea, that tube cannot serve to modify it; it can only be compared to the pipe of the bellows of an organ, or to any canal which may convey air to the embouchure of the instrument; and the only part of the vocal organ in the mammals, which can be compared to the tube of one of our wind instruments, is that placed in front of the glottis, viz. the mouth and nasal cavity. If we consider, not only the want of resemblance between these two cavities and all the instruments which we are acquainted with, but also the almost infinite number of means by which we can change their length, diameter, figure, and vents,—means which it is almost impossible to determine with sufficient exactness to deduce from them physical consequences, we shall not be surprised at the difficulties which the theory of the human vocal organ presents.

But the mere passage of the air through the glottis is not sufficient for the purposes of this function. The voice connects us with the individuals of our own species, enables us to communicate our thoughts to them, and must, consequently, be under the regulation of the will. Hence it is produced by voluntary motion, and does not take place except under the influence of volition. We are constantly breathing during sleep, without the production of any sound: and we may expire, as strongly as we please, in the waking state without the voice being formed, until we exert a particular act of volition. Again, although the whole structure of the larynx is entire, the ligature or fixation of the recurrent nerves, or of the nerves of the eighth pair, destroys the voice. An injury of one nerve destroys half the vocal powers, but the voice is completely lost by operating on both. Galen performed this experiment repeatedly on pigs; Vefalius, and other more modern physiologists, have ascertained that the effects are correctly stated by Galen. In short, all the changes and conditions of the vocal organs, of whatever description, necessary to the production and modification of sound, are produced by the muscles of the part, under the influence of the will. The exact nature of the muscular motions, required for producing the voice, is not known. Bichat observed, in the experiments already alluded to, that the rima glottidis was contracted whenever a sound was uttered; and that this contraction was the more feasible, in proportion as the sound was stronger. He states that it never was dilated during the formation of sound. He observed, moreover, that inspiration and expiration were constantly attended respectively by dilatation and contraction of the glottis.

The air expelled from the lungs through the opening, prepared for its passage by the action of its proper muscles, throws the sides of this aperture, the chordæ vocales, into a state of vibration; the same effect is produced in the larynx, whose cartilaginous structure renders it particularly susceptible of such vibrations, and in all the surrounding organs. The sound produced by the tremulous motions of all these parts is the voice. Hence we understand why hoarseness and smallness of the voice accompany catarrhs, in which the unfeudal coverings of mucus render the parts less susceptible of vibration; why those animals which have the greatest quantity of cartilage and the least membrane in their vocal organs, have the strongest and most sonorous voices, and *vocifer*? We see also that all animals provided with a pulmonary organ will have a voice; since nothing more is required, for the production of this sound, than the accumulation of air in some receptacle, its expulsion in a mass, with a certain force, and its meeting on its passage with elastic and vibratory organs. Fishes, which have gills, and inféchts, in whom the distribution of air is by means of trachea, produce no sound. It seems impossible to explain how the passage of air through the human glottis should produce vocal sounds differing in man from all other animals, and how each animal should have his peculiar and characteristic voice, where the differences of structure, in a part of such simple formation, must be very slight. Yet it seems true that the glottis alone produces the specific character of the voice in each animal.

Numerous and respectable authors affirm, that the inflation of air through the glottis is sufficient, even in the dead animal, to produce its particular voice: this has been ascribed to the human subject, the cow, pig, cat, rabbit, hare, goose, and frog. It is directly adverse to what we have already stated concerning the necessity of some muscular action to the production of the voice, and is so contrary to those principles, by which these functions are subjected to the will, that we cannot help doubting the whole affection. After reciting what others have stated, Haller adds, "with me these experiments have not been so successful: I have sometimes obtained a found, that might be recognised as the voice of the animal, but could never imitate the character of the voice in the pig or dog, and much less in man." Elem. Physiol. lib. ix. fecl. 3. § 4.

As the sound, formed in the larynx, or the voice, proceeds through the mouth and the multiplied hollows of the nostrils, it undergoes various modifications, according to the nature of these parts, which produce in it changes affecting its key or pipe.

Ventriculoquium is, perhaps, one of the most singular phenomena connected with the vocal functions; and certainly one, of which the nature is very little understood. This name, as well as the Greek term of engafrith-muthinth, proceeds on the supposition that the sound comes from the abdomen: but we cannot doubt, in general, that the vocal organs alone are concerned, however unable we may be to explain the exact nature of the process. Ammann, the Swits, whole philosophical labours on the subject of language, and particularly in the instruction of the deaf and dumb, entitle him to much confidence, says, that he faw an old woman who could speak during inspiration, and others have explained ventriculoquium in the same way. We believe that the point has not been sufficiently ascertained by actual observation: and others, in their attempts at explanation, even suppose that it is produced, like ordinary speech, during expiration. Some conceive that the tongue is fixed, and that some motions of the pharynx and velum palati do the business. Richerand observed, that a man who could give a dialogue between two speakers, with different voices, as if placed at some distance from each other, did not inspire while he was doing this, but that he expelled air in much smaller quantity than usual. The same author observes, that a Mr. Fitz-James, who possesses the power of ventriculoquium in wonderful perfection, does it by means of an extremely gradual expiration, in which the air is brought out in a very slender stream. He precedes this by a very deep inspiration; hence a full state of the thorax renders the execution of his talent difficult, which all individuals, who have had the art in question, seem to experience. By accelerating or retarding the exit of this air, Mr. Fitz-James can
can imitate different voices, make his auditors believe that the interlocutors in a dialogue, which he carries on alone, are placed at different distances, and produce the most complete illusion on these points. See Richerand, Elements de Physiologie, § 2, p. 339.

In hawking the air is violently forced, by a kind of interrupted action, through the trachea, larynx, and faucets, so as to detach the secretions of the parts, or any thing else which lies on the surface. The peculiar noise is produced by the air thus violently dashed against the parts.

Snoring is produced by a kind of tremulous oscillation of the velum palati, generally in inspiration, but sometimes also in expiration. Wailing, or the plaintive sound produced in weeping, is the consequence of tremors of the soft palate, gradually diminished in force as the air is expired.

In humming the mouth is closed, and the expired air enters the nasal cavities with tremulous motions of the muscles of the faucets.

When the tongue is drawn upwards and pressed against the palate, and then suddenly depressed, so as to allow the air to pass quickly, the noise called chuckling takes place.

By drawing the lips between the teeth, and then quickly separating them, we can imitate the trill of the horse; and by exercise we can even produce a sound like the clapping of hands.

When we wish to ascertain the odorous properties of any body, we sniff at it; that is, the inspired and expired air is conveyed through the nose with a tremor of the alae nasi causing a particular noise.

Hissing is produced by expelling the air between the teeth, when brought close together.

In whistling, the tongue is rendered concave on its superior surface, and applied to the bony palate, and upper teeth, so as to have a passage for the air between it and those parts; the lips are at the same time contracted into a round aperture; and the point of the tongue is in contact with the front lower teeth. The vibrations of the parts through which the sound passes produce the peculiar effect, and the motions of the tongue and lips increase or diminish the dimensions of the openings through which it passes.

The production of a loud sound requires a large quantity of air, a strong and accelerated expiration, and a considerable tremor of the chordae vocales. The lungs must therefore be large and admit easily of dilatation; the trachea and larynx must also be ample, and the reflexion of the found in all the passages unimpeded. A dilated state of the stomach is unfavourable to the production of such sounds, as it impedes the descent of the diaphragm. The impervious state of the lungs in the confinement must be equally unfavourable; and we accordingly find that the voice becomes weaker, as the disease advances.

In forming high or acute sounds, a contracted state of the glottis, with tension of its ligaments, are required; the air passes rapidly through the narrow opening, and numerous oscillations of its sides are produced. The whole larynx is carried upwards and forwards; and, in uttering the most acute sounds, the head is thrown backwards, that the larynx may be elevated through a wider range. This elevation equals nearly half an inch for one octave. That the changes above-mentioned take place, is proved, by placing the finger on the larynx, which gives us immediate demonstration of its ascent, when we utter acute sounds; by the comparatively acute voice of children and women, in whom the larynx is small, and the glottis consequently narrow; by comparative anatomy, which shews us that the glottis is small and narrow in singing birds, large and relaxed in animals which utter deep sounds; by the blowing of wind instruments, in which the opening for the passage of the air is always contracted in order to produce the high notes; and also by this general fact, that the sounds are always more acute in proportion as these instruments are of smaller size.

If we talk too impetuously, the quick passage of the air throws the chordae vocales into too rapid oscillations, and the voice suddenly becomes exceedingly shrill. These changes have nothing to do with the loudness of the sound; a weak as well as a strong sound may be either acute or grave in its tone.

In the production of deep or grave tones, an opposite state of parts is required; the larynx is carried downwards, and the head itself brought towards the chest. This defect, like the ascet, is about half an inch for an octave. In the male sex, where the larynx is larger, and the glottis consequently more ample than in the female, the voice is habitually deeper toned. Eunuchs and women may be taught to sing sopranos, but not bas. When very low tones are formed, in which the chordae vocales are greatly relaxed, the production of found ceases altogether.

A human voice that has been much exercised, can pass through about two octaves and a half in either direction from the middle; consequently it has a range in the neck of nearly three inches.

The question has been much agitated among physiologists, whether the changes of tone in the voice depend on alterations in the diameter of the opening, or in the state of tension of the ligaments forming its sides. By the advocates of the former opinion, the organ of the human voice is compared to wind instruments, in which the enlargement of the aperture renders the found grave, and its diminution acute; and by some of the latter to stringed instruments. We admit, in the preceding account, the efficacy of both kinds of changes, but we consider the alterations in diameter as the most efficient. The change of the voice from acute to grave, at the time of puberty, when the larynx undergoes a remarkable development, as well as its acuteness in females, whose glottis is less by one-third than that of man, shews that the size of the aperture has a great influence. Observing, on the other hand, that the chordae vocales admit of considerable tension and relaxation, we must allow that these variations will render them susceptible of executing, in a given time, vibrations more or less extensive and rapid. And although they are neither dry, stretched, nor isolated, which are necessary conditions to the production of found in those stringed instruments to which the larynx has been compared, yet they are analogous to vibrating bodies placed at the top of wind instruments, as the reed in hautboys, the mouth piece in flutes, &c. and equally contribute to the formation and varied inflexion of vocal sounds. Haller, in his Elementa Physiologie, lib. ix., has given a long and very instructive account of the whole controversy. We shall be surprised at seeing how very small a change can alter the tone, when we reflect that the breadth of the rima glottidis does not exceed a line at its broadest part, and that there is an almost innumerable variety of tones distinctly perceptible.

Singing is the expression of love and joy, common to birds with the human subject. The pronunciation of words or letters is not essential to its nature. It includes the most varied variety of acute and grave sounds, and the most rapid transition from the one to the other. In general the tone of singing is more acute than that of talking. The great difference between these two modes of vocal exertion is in the transitions of singing; in order to execute these, the larynx, instead of resting, is sustained in a kind of equilibrium between the elevating and depressing powers. A person will soon perceive
towards this by placing his finger on the larynx while he sings, or by obstructing the throat of another. As singing requires the exertion of many muscles, it soon fatigues. It also exercises the muscles of respiration; as a large quantity of air is frequently required. The rapid passage of the air in singing dries the parts quickly.

Speech is the formation of the voice, produced, as we have already described, by means of the organs about the throat, nose, and mouth, into articulated sounds, by which men communicate their thoughts to each other. All animals have a voice, but man alone speaks in the sense now alluded to. Some, indeed, which have a broad tongue, have been taught to pronounce a few words; but they express no thoughts by these sounds. We believe that no sufficient reason can be drawn from organization, why man invariably should possess, and animals invariably want the power of speech.

The tones are not so quickly changed as in singing, consequently the larynx is much less moved. Recitative is a kind of mixture of singing and speaking, partaking equally of the characters of each.

If we consider a letter to be a sound, that cannot be resolved into more simple elements, speech is the formation of the voice into the sounds expressed by letters, and the composition of words from these.

Letters are divided into vowels and consonants. The former (vocales) are produced simply by the voice passing through the mouth opened to a greater or less degree, without the tongue being applied to the lips or to any other part. These sounds are produced in laughing, and something like them may be observed in the voices of animals.

In the formation of the vowels, the passage through the nose is closed; the voice proceeds straight through the tongue and lips, and the mouth is open. The larger the space left for the voice along the tongue and through the lips, or the lower the tongue is placed in the mouth, and the wider the lips are apart, the more deeply do the vowels sound. These sounds are the most clear and distinct, because the canal, through which they proceed, is free and unconfined in every direction.

The consonants are sounds pronounced with the vowels, and modifying or limiting them. They must therefore have vowels either before or after them. The sound of the vowel in these cases is altered by the tongue being applied to some part in the cavity of the mouth, striking against the teeth or lips, &c.

The consonants are distinguished into different classes according to different principles of arrangement. Soemmerring gives the four following classifications.

I. 1. Natales = m, n, ng. 2. Orales = l, r. 3. Sibilantes = s, s', s, s'. 4. Explovas = b, d, p, t, g, v. 5. Composite = x, z.

II. 1. Natales = m, n, ng. 2. Liquidae = l, r. 3. Mutae = b, d, f, v, z, c. 4. Explovas = b, p, d, t, k, g. 5. Vocalese = a, e, o, u, a.

III. 1. Mutae = b, d, f, v, z, c. 2. Explovas = b, p, d, t, k, g. 3. Vocalese = a, e, o, u, a.

IV. 1. Gutturales = g, c, b, th. 2. Palatines = d, h, n, r, f. 3. Labiales = b, f, m, p, v. De corp. hum. fabrica. t. 6. p. 110.

To point out the motions by which all these sounds are produced, would lead us into too wide a field. We refer the reader to the work of Soemmerring already quoted, and to Haller's Elements Physiologic, lib. ix.

The remarkable change which occurs in the voice, at the time of puberty, must be referred to the sudden development which the organ undergoes at that time, as we have already stated. The various affections of the mind are accompanied by the utterance of particular sounds; and this is strongly felt also in animals. In them, the wants connected with the generative functions, afford the most frequent cause for the exertion of the vocal organs. But we may observe farther, both in birds and quadrupeds that certain modifications of the voice express fear and anger, affection for the offspring, joy and pain, that other are used in calling the assembly together, and, in the case of quadruped animals, in imparting to each other something which we do not understand. Similar vocal expressions of what is passing internally are observed also in the dumb, who have not learned to speak; and even animals distinguing in man the sounds denoting anger, approbation, &c. In the sounds which we utter, on many of these occasions, in civilized society, there may be something arising from imitation or habit, or referrible in some way to a conventional origin; but much of it is so completely artificial, that we seem to obey merely a species of instinct, and to express the simple voice of nature. Various mal-formations and disfigurements of the organs concerned in speech impair or entirely destroy the power of pronunciation. From the importance thus attaching to the tongue has, in producing articulated sounds, we should expect that extensive injuries of it would be very injurious in this way. But experience shows us that it may be very extensively injured without greatly impairing the powers of speech. Indeed several letters may be pronounced without its aid. Mr. Louis has collected several cases in his "Memoire physiologique et pathologique, sur la Langue;" in proof of this point, he states, that after very serious injuries the power of speech was at first greatly impaired; but that it gradually returned. Memoires de l'Acad. de Chirurgie, t. v.

Stammering may be caused by too large and thick a tongue, by great length of the frenum; by any causes that impair the motions of this organ, whether they be referrible to organization, or to the state of the nervous system, as in drunkenness, apoplexy, &c.

Too great confinement of the organ, by its frenum, sometimes prevents children from learning to speak.

Want of the front teeth, as well as undue faze of the tongue, produces lip-slap.

The confinement of the tongue in the aged, consequent on the diminution of the cavity of the mouth from the loss of the teeth, very much impedes the powers of pronunciation.

When we allign certain organical defects, as the causes of defective pronunciation, we do not mean to assert that this is constantly true. A person who stammers, for example, will often be able to speak clearly, if he will speak slowly.

The obstruction of the passage of the sound through the nose, either by closing the front openings of the nostrils, or by the elevation of the palate, behind, produces a peculiar modification of the voice, which is strangely enough termed, in common language, speaking through the nose. Diseases of the palate, or its union, ulcerations, and preternatural openings in them, have also very considerable effect on the voice; the same may be observed of diseases affecting the bones of the nose.

Dumbfear may be accidental, or may subserve from birth. In the former case, it arises from organic injury, which either affects the mechanism of the parts, or which intercepts the communication between the vocal muscles and the brain. In dumbfear from birth, deafness seems to be always the cause; so that the absence of speech should here rather be called silence. This, at least, is constantly the case, according to the observation of Sicard on the numerous pupils committed to his care. Here there is an absolute ignorance of sounds, and of their representative value in letters of the alphabet. The vocal organs exhibit no marks of deficiency; they
they are fit, in short, to fulfil the uses for which nature has
defined them, but they remain in a state of inaction,
because the deaf infant is not conscious that he has the means of
communicating his thoughts. See the article Deumb-
ness.

Dichtat, Anatomic Decriptive, t. ii. Soemmerring, De
Corporis humani fabrica, t. vi. Haller, Elementa Physio-
logia, lib. ix.

LASAIA, in Geography, a town of Naples, in Principa-
tato Citra; 21 miles S.S.W. of Cangiano.

LASANOX, a word used by different authors in very dif-
ferent senses; one applying it to the things commonly used in
kitchens; others to a clove-wood; and others, among
whom are Hippocrates, and the ancient physicians, for
a sort of chair, contrived for a woman in labour to sit in,
as being so made, that the weight of the child, when born,
shall help to draw away the fecundines.

LASCARIS, Constantine, in Biography, a learned
descendant of the imperial family of that name, was born at
Constantinople. He quitted his native city when it was
taken by the Turks in 1454, and went to Italy, where he
was most amicably received by Duke Francis Sforza of
Milan, who placed his own daughter, a child of ten years
of age, under the care of Lascaris for instruction in the
Greek language. For her use he composed his Greek

grammars. From Milan he went to Rome, and from thence,
at the invitation of king Ferdinand, he repaired to Naples,
where he opened a public school for Greek and rhetoric.
Having spent some years in this employment, he was de-
fisious of repose, and embarked with the intention of settling
at a town of Greece; but having touched at Messina, he
was urged by such advantageous offers to make it his
residence, that he complied, and passed there the remainder
of his days. Here he received the honour of citizenship, which
he merited by his virtues as well as his learning, and by the
influence of scholars which his reputation drew thither, among
whom was the celebrated Bembo. He lived to a very
advanced age, but the time of his death has not been exactly
ascertained. He bequeathed his library to the city of
Messina. His Greek grammar was printed at Milan in
1476, and was the first book that issued from the Italian
press. A better edition of it was given in 1494, by Aldus
Manutius: Erasmus considered it as the best Greek gram-
mar then extant, excepting that of Theodore Gaza. Lascar-
is was a member of the courts of Sicilian and Calabrian
Greek writers.

LASCARIS, Joan Andrew, a learned Greek of the same
family with the preceding, came over to Italy, on the run
of his country. He studied at Padua, obtained a high reputa-
tion for his knowledge in the learned languages, and re-
ceived the patronage of Lorenzo de Medici, who sent him
to Greece with recommendatory letters to Sultan Bajazet,
in order to collect ancient manuscripts. After the expul-
sion of the Medici family from Florence, in 1494, he was
employed to France by Charles VIII., after which he was
patronized by Louis XII., who sent him, in 1503, as his
ambassador to Venice, in which office he remained till 1528.
He joined the pursuit of literature with his public employ-
ment, and held a correspondence with many learned men.
After the termination of his embassy, he remained some
years at Venice, as an instructor in the Greek language.
On the election of Pope Leo X. to the popedom in 1513,
he set out for Rome, being persuaded that, he should meet
with a favourable reception from that patron of learning.
At the instigation of Lascaris, Leo founded a college for
noble Grecian youths at Rome, at the head of which he
placed the author of the plan. In 1518, he quitted Rome
for France, whither he was invited by Francis I.; here he
was employed by the monarch in forming the royal library.
He was also sent as his ambassador to Venice, with a view
of procuring Greek youths for the purpose of founding a
college at Paris similar to that of Rome. After the accom-
plishment of other important missions, he died at Rome in
1553, at an advanced age. As an author he composed
epigrams in Greek and Latin; he translated into the Latin
language, a work extracted from Polybius, on the military
constitutions of the Romans; and he printed at Florence a
magnificent edition of the Greek Anthologia. By his con-
temporaries he was greatly praised, on account of the emi-
nent services which he performed for the extension of litera-
ture.

LASCHE, in Geography, a town of Bohemia, in the
circle of Crudum; eight miles E. of Chrudim.

LASCHI, in Biography, an admirable singer and actor
in the first burletta band of singers which arose in Eng-
l

land during the autumn of 1748, when serious operas were
discontinued by the abdication of Lord Middlesex, who was
as unsuccessful in his opera regency, as James II., in en-
devouring to establish the Roman Catholic religion in this
country.

The new troop consisted of Pertici, as buff caricats, La-
fchi, tenor, and Guadagni, counter tenor, (then very young),
as serious men. Trafis, and, afterwards, Mellini, for serious
women; and the comic female parts by the wives of Per-
tici and Laschi, the two best comic actors we ever saw on
any stage, formed a very good troop, and in the comic
operas of "La Comedia in Comedia," "Orazio," "Don Cola-
sciomi," "Gli tre Cicchibi Ridiculi," &c. composed by
Latilla, Mitata Refta, and Ciampi, who came over as maso-
fo to the company, pleased the public and filled the theatre
very successfully during the whole winter. Laschi was cer-
tainly the best first buffo, except Lovatini, that has ever
appeared on our stage: and the acting of him and Pertici
was undoubtedly the most amusing and ingenious that can
possibly be imagined.

LASCO, in Geography, a town of Naples, in Prin-
cipato Citra; 18 miles W. of Policiauro.

LASCO, John A., in Biography, a zealous promoter of
the Reformation, was born in Poland, of a noble family,
bout the close of the fourteenth century. He received the
early part of his education in his own country, and then
travelled into foreign parts for improvement. In Switze-

land he became acquainted with the celebrated Zwingle, by
whole influence he determined upon studying divinity, and
having by the example of his friend imbibed the spirit of
the reformation, he returned home with the design of propa-
gating the principles which he regarded as having their foun-
dation in important truth. At first he was promoted to a high
station in the Catholic church, and at length was nominated
bishop of Vepurn, in Hungary. His honours, probably,
did not fit easily upon him, and he determined to make an
open avowal of his sentiments; by this decided course he
drew upon himself the vengeance of the Catholic bishops,
who did not hesitate to pronounce him an heretic. He
appealed to the king, but the sovereign was either unable or
unwilling to extend the shield of his authority in protecting
his bishop, and he was obliged to quit Hungary in the year
1544. In 1542, he was chosen minister of a church at
Embden, and in the following year he went to Oldenburgh,
to establish the doctrines and discipline of the reformation in
that district. In 1544, he was invited into Prussia, by duke
Albert, for the same purpose, but as he was not altogether
Lutheran, he was obliged to relinquish this mission and
to return to Friesland. Here he resided about ten years,
when the publication of the Laterim by the emperor Charles V. compelled him to seek another asylum, which he found in England, on the invitation of Edward VI., which was conveyed to him by archbishop Cranmer. Here he became minister to a German Protestant church, which assembled for divine worship at Austin-Fryars. Of these Protestants, almost four hundred were admitted to the honour of citizenship; they were not tolerated, but guaranteed by royal patent, in the conientious discharge of their duties to God; while numbers of his majesty's natural born subjects were grievously perempted on account of their inability to join in all the ceremonies enjoined by the established religion. The preamble to the patent referred to, is a curious document confounding the times; it admits that the German church made profession of pure and uncorrupted religion, and was instructed in truly Christian and apophthegmatic opinions and rites, and it was permitted them to enjoy and exercise their own rites, ceremonies, and discipline, though they were different from those used in this kingdom. Lafo avowed the same opinions as those held by Hooper, Latimer, and other illustrious divines of that day; he was, however, permitted to live in peace during the reign of the youthful monarch; but upon the accession of the infamous Mary, he and his congregation were ordered to leave the kingdom. They embarked with their families and property, and at the commencement of a very severe winter arrived off the coast of Denmark, but were not permitted to land on account of their known tenets. For the same reason they were refused an asylum at Lubeck, Hamburg, and some of the cities of Saxony; at length, after they had been driven from place to place, they were hospitably received at Embden in March 1554. In the following year Lafo went to Frankfort upon the Main, and obtained leave from the Senate to build a church for foreign Protestants. In 1556, he wrote a letter to Sigismund, king of Poland, in vindication of himself and his doctrines, from certain misrepresentations which had been circulated by his enemies. In 1557, he published an apology for the church of the reformed Protestants at Frankfort, on the subject of the variation in their creed from that of the confession of Augsburg with respect to the Eucharist. He was answered by Weltphalus, who, feeling that he had the weakest side of the argument, exhorted the senate to interpose its power, and to withdraw its protection from the disciples of Zwingel, whom he denominated rank heretics, and the Devil's martyrs. Lafo, after a thousand vicissitudes, returned to his native country; but fearfully had he arrived, when the bipheros and other ecclesiastics set about every method to ruin him. A synod was convened to meet at Warsaw; the result of their deliberations was, that Lafo was a heretic; he was acquitted before the king, and a petition was drawn up praying that he might be banished. The sovereign nobly rejected their demand, and he was permitted to live free from persecution, though he was daily assailed by the black calumnies of his enemies. He died in 1560, leaving behind him many works which testify that he was a man of great talents and profound learning. He was the friend of Erasmus, who acknowledged the obligations he was under to him; and Peter Martyr calls him his most learned patron. He was highly esteemed, and frequently confuted by Sigismund, king of Poland; and he is commended by contemporary historians as a man possessing many virtues, and the most unaffected piety. Gen. Biog.

LASCORIA, in Ancient Geography, a town of Asia, in Galatia, belonging to the Trocmi. Ptol.ency.

LASDIPOL, in Geography, a town of Prussian Lithuania; nine miles N. of Pilskaden.

LASER WITIUM, in Botany, Lacerwort; an ancient name of uncertain derivation, synonymous with the species of the Greeks. Laser laceratum, alluding to its milky juice, or lasiptum, because that milky juice has a piorby smell, both fuggeled by etymologists, afford little satisfaction. The word is evidently compounded of Laser, the name of the gum which it produces, and from which Afa is by some thought to have been corrupted. Hence Afa-flaspira has supposed the true Lasier, or gum of the species, which is known to be of a fetid nature. Ambrofius affirms Lasier to be a corruption of Latiss, from las, milk. Whatever the species of the Greeks, or the Lasierium of the Latins may have been, the Silphium of modern botanists is a genus of the syngameous clas, and the Lasierium is one of the umbelliferous tribe, of which we are now to speak. It so far accords with the ancient plant, that several of its species discharge, when wounded, an acrid and strongly setentious gum.—Linn. Gen. 146 Schrdb. 186. Willd. Sp. Pl. v. 1. 1414. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. v. 2. v. 138. Sm. Proc. Fl. Grac. Sib. v. 1. 181. Juff. 222. Tourn. t. 172. Lamarck Illuttr. t. 199. Gært. t. 85. (Siler; Gært. t. 22.)—Classes and order, Pentandra Diggins. Nat. Ord. Umbellatae, Linn. Umbellifer. Julf.

Gen. Ch. General umbel very large, of from twenty to forty rays; partial of many rays, flat. General involucrum of many leaves, small; partial of many leaves, small. Perianth of five teeth, scarcely discernible. Cor. Universal uniform; all the flowers fertile; partial of five spreading, nearly equal, petals, their points bent in fo as to form the shape of a heart. Stm. Filaments five, bristle-shaped, the length of the corolla; anthems simple. Pfl. German inferior, roundish; styles two, rather thick, pointed, distant; stigmas obtuse, spreading. Peric. Fruit oblong, with eight longitudinal membranous angles, separable into two parts. Seeds two, very large, oblong, hemicylindrical, flat on the inner side, furnished each with four dorsal and marginal membranes on the other. Eff. Ch. Invilucrum both general and partial. Fruit oblong, with membranous angles. Petals uniform, inflated, embargate, spreading.

The species of Lasierium are in general of a larger proportion, with more ample foliage, than most other umbelliferous plants. To this nevertheless there are some exceptions.
tions, for we perceive a prodigious difference between the gigantic L. agastinum, Jacq. Autoit. t. 147, and the little L. juniper, Jacq. Misc. v. 2. t. 1. 2. The 4th edition of Syl. Veg. has fourteen species, comprehending Forster's genus Althypoha; Wildenow has twenty-three. In these forms, however, there are some ambiguous or doubtful plants, which, from variations incident to this tribe, relative to the occasional absence or presence of an involucre, are supposed to be described twice over in the Linnaean system. Such is the case with L. Chronium, supposed to be the same as Paffionna Opogona, we believe falsely. Wildenow doubts whether L. Archangelica of Jacquin, t. 2, is distinct from this plant of Linnaeus, but we are quite clear on this point, and are almost as perfectly satisfied that L. Chironium is Paffionna Opogona, which last name Linnaeus, in his note on the subject, has accidentally written Coiffa, apparently from having Baumi's synonym in his head; yet Reichard, Wildenow, and Laichardung copy him without reflection or remark.

Indubitable species of Laserpitium, which will serve to give a competent idea of the genus, are the following. None are natives of Britain.

L. latifolium. Broad-leaved Laferwort. Linn. Sp. Pl. 356. Jacq. Autrit. t. 146. (Libanotis Theophaniter major; Ger. em. 1010.)—Leaves obliquely heart-shaped, undivided, with sharp-pointed teeth.—Native of mountainous dry woods in various parts of Europe, flowering in July, ripening seed late in autumn. Jacquin observes that it varies greatly in size and roughness, being only a foot or two high on the Alps, while in less elevated situations it rises to four or five feet, with ample and handsome foliage. He allots also to wild plants of a very rough habit, on being brought into the garden, became smooth the next season. Hence he determines the L. aternum of Crantz, Diff. f. c. 50. t. 1. f. 2, and glabrum of the fame author, 54, to be one and the same species. This f. 2. of Crantz very correctly expresses a leaflet of our plant, such as is preferred in the Linnaean herbarium, and exhibited by Jacquin as above. The radical leaves are twice or thrice compound, with large, heart-shaped, stalked, undivided leaflets, unequal at the base, veiny, from one to two or three inches long; smooth and dark green above; paler, and more or less rough with rigid bristles, beneath; the margin beft with long broad sharp ferratures, the base entire. The stem is smooth and round, bearing a few smaller more entire leaves, whole common stalk is greatly dilated and inflated at the base. The umbels are broad. Flowers small, white. Wings of the seeds, according to Jacquin's plate, even, and scarcely at all undulated, rounded not angular at their summit, agreeing very well with the first figure of the seed annexed to Morison's Sect. 9. t. 19. f. 1, so that, if he be right, his whole fig. 1. must belong to our plant, though it is not a very good one. We cannot help thinking too that the Laserpitium of Rivinus, Pentap. t. 21, is the fame species. Professor Willdenow, however, seems to have been led by Crantz and Lamarck to ellabish another species, by the name of L. Liberatus, for which he quotes this plate of Rivinus, as well as another figure of Morison, Sect. 9. t. 19. f. 6. This he supposes to be the glabrum of Crantz, who cites as a certain though rude figure Libanotis alpina latifolia, feminis eris. Hoc. Mat. 24. t. 3. The plant of Boccone, according to all appearance, we have from Italy, and can aver its being totally different from L. latifolium and all the synonyms of Wildenow's L. Liberatus, being, as far as we can tell, not yet defined by any systematic author. The wings of its seeds, though called eris, are nearly even, and terminate in a lateral angle at the top, like Morison's t. 19. f. 6, which may possibly be a bad delineation of Boccone's plant. Wildenow does not mark his L. Libanotis as one that he had seen, and he might well be led into confusion by the writers on whom he has depended. Among these the most plausible is Crantz, who roundly affirms his aferum, (our latifolium,) to be L. Chironium of Linnaeus, which we can positively contradict, and which nobody but Lamarck has believed. The latter leaves with great firmness the opportunity of confounding Linnaeus on the subject of his synonymy, though in this instance unjustly, while he himself describes under the name of L. Liberatus, with extremely confused synonyms, what appears clearly by his account to be L. tribulum of Linnaeus, of which we shall now speak.

L. tribulum. Three-lobed Broad Laferwort. Linn. Sp. Pl. 357. (L. Libanotis; Lamarack Dict. v. 2. 423; by the very excellent description. Libanotus Ranwouli, foliis aquaticis; Bauh. Illust. v. 3. p. 2. 148. Pl. Phyt. t. 223. f. 7.) Siler folius aquilegii; Rivin. Pentap. Irr. t. 64.—Leaflets broad-obovate, three-lobed, cut and sharply serrated.—Native of Italy, and we believe also of Switzerland; though Professor Lachal, from whom we have a specimen of the true plant, afferts the n. 753. of Haller, taken for this, to be only a variety of latifolium, which according to him has occasionally two or three leaves in its lower leaflets. A Swiss specimen from Schleichcr seems to be the real tribulum, but it wants the lower leaves, and therefore cannot be absolutely determined. The leaflets of L. tribulum differ from the foregoing, in being by no means heart-shaped at the base, but either ovate or tapering, and more or less deeply three-lobed, sometimes to the very base as well as cut and sharply serrated. The umbel is very large and spreading, with long purple rays. Flowers small, white. Wings of the seeds even, and very narrow. Lachal sccns, when he wrote his remarks above alluded to, in Act. Helv. vet. v. 8. 145, not to have distinguifhed this from the following, though they are widely different.

L. aquilufoiium. Great Columbine-leaved Laferwort. Jacq. Autitr. v. 2.—Leaflets sessile, rounded, bluntly lobed and cut. Wings of the seed very narrow.—Native of Austria, Switzerland, and the Bithynian Olympus, first well determined by Jacquin. It is five or six feet high, with ample leaves, much resembling those of a Columbine in their rounded obtuse form and segments. The umbels are very large and spreading. Flowers white. Wings of the seed even, and very narrow. Crantz makes it a Siler, and infcribes under its synonyms which belong to the latt, and which he therefore justly favs „could never be guefed to belong to the present." Why then, as they certainly do not, are they quoted?

L. Siler, Mountain Entire Laferwort. Linn. Sp. Pl. 357. Jacq. Autit. v. 2. 27. t. 145. Sm. Prodr. F1. Græc. Sib. v. 1. 191. (Siler montanum officinarum; Ger. em. t. 48.)—Leaflets elliptic-lanceolate, entire, falked.—Found on the mountains of Austria, Switzerland, France, Greece, and other parts of the south of Europe. It is of more humble growth than any of the former, and distinguished by the form of its leaflets. The leaflets are shaped and winged much as in the dust. They are aromatic and very bitter. Haller complains of its being neglected as a medicinal plant, though strong in aromatic virtues.

Leaves light green, smooth, bipinnate; their leaflets pin-natifid, with elliptic-lanceolate, decurrent, pointed segments. Umbels rather large, white, with white-edged involucral leaves. Seeds small, their wings broad and wavy.

L. hierbatum. Hairy Fine-leaved Laserwort. Lamarck Dict. v. 3. 425, with a wrong reference to Linnaeus. (L. Halleri; Villar. Dauph. v. 2. 626. L. n. 795; Hall. Hist. v. 1. 551, t. 19.)—Leaves hairy, many times dec-omprised, with lanceolate decurrent segments, often three-leaved. Inflorescence with membranous edged spikes.—Native of the alpine parts of Switzerland, Savoy, and France. We gathered it on Mount Cenis, flowering in August. The broad, extremely compound, finely cut and hairy leaves, at once distinguish this species. The umbels are large, dense, and white. Wings of the seeds rather broad, pale, and slightly crisped.

Laserpitium, in Gardening &c. The plants of this genus grow naturally in the south of France, in Italy, and Germany, and are preferred in botanic gardens for the sake of variety; they have not great beauty. It has been generally supposed that the filipodium of the ancients was procured from one species of this genus, but from which of them (if any) we are at present ignorant. All the species, if wounded, drop a very acrid juice, which turns to a red or gummy substance, very acrimonious. This was externally applied by the ancients to take away black and blue spots that came by bruises and blows, as also to take away excrecences: it was also by some of the ancients prescribed in internal medicines, but others have cautioned people not to make use of it this way, from the effects which they mention to have been produced from the violence of its acrimony.

All these plants are extremely harsh, so will thrive in moss soils and situations. They are propagated by seeds, which, sown in autumn, will afford plants in the spring, that may be transplanted in the following autumn. Miller.

LASER, in Geography, a town of Corsica; 10 miles N.E. of Sarena.

Laserwort, in Botany, &c. See Laserpitium.

Laserguson, in Geography, a town of Sweden, in Halland; 56 miles E. of Hudvikswald.

Lash, or to lashe, is to make fast the booms, anchors, &c. by several turns of rope, to prevent their moving by the motion of the ship.

Lashing, which also denotes a piece of rope used to fasten or secure any moveable body in a ship, or about her masts, sails, and rigging, is chiefly used for binding up to the ship's side, masts, buoys, battens of water or beer, or pieces of timber to make spare top-masts.

Lashers are properly those ropes only which bind fast the tackles, and the breeches of the ordnance, when they are haled or made fast, within board.

Lashom Janas, in Geography, a town of Egypt, on the coast of the Mediterranean; 12 miles N.W. of Damietta.

Lasia, in Ancient Geography, an island situated on the coast of Lycia. Phly.—Allo, an island on the coast of the Peloponnesus, over against Troizen.—Allo, one of the names of the isle of Andros.

Lama, in Botany, from lama, hairy or bristly, because the plant is beset with numerous little bristles or prickles. Lourn. Cochin Ch. 81.—Claws and order, Tissandia Monogyna. Nat. Ord. Piperis, Linn. Avic. Jaff.

Gen. Ch. Cal. Spatha awl-shaped, twisted, coloured, very long. Spadix shorter than the spathes, entirely covered with florets. Car. Petals four, fleshy, obtuse, concave, clusely embracing the organs of impregnation. Stam. Fila-
ments four, short, flat, hidden by the petals; anthers two to each filament, rounded, concave, protruding beyond the corolla. Pfjfl. German superior, roundish; style none; stigma rather abrupt. Peric. Berry small, roundish, unequal. Seed solitary, roundish.

1. L. Alphata. Cu chahe gai, of the Cochlin-chines. Native of the moist plains of Cochinchina. A Remarkable plant, six feet high, with large, pinna-ted, leaves, on long, round, upright stalks. Flowers small, red, very simple, and naked, about as tall as the leaves. The leaves, and all the flowers are covered with numerous little short curved prickles. Loureiro justly indicates the affinity of this plant to Patlas, and no less justly prefers placing it in the fourth class, rather than in Gymandra. The prickly pubescence, if we may so term it, is very curious in this family. It is to be premised the anthers are each of one cell only, rather that each filament bears one anther, of two separated lobes and cells.

Lasio, in Ancient Geography, a town of the Peloponnesus, or Triphylia.—Allo, a mountain in the island of Crete, on which was the tomb of Jupiter.

Gen. Ch. Cal. Perianth inferior, of one leaf, wheel-shaped, hairy, in five deep, equal, ovate, folded, at length expanded segments, permanent, often coloured. Car. Petals five, minute, roundish, inserted into the base of the calyx between its segments. Stam. Filaments five, very short, opposite to the petals; anthers terminal, ovate, two lobed behind, opening by two pores at the top. Pfjfl. German superior, globose, with three furrows, very hairy; style short, straight, smooth; stigma simple, acute. Peric. Capsule involuted with the calyx, nearly globose, with three angles, downy, of three cells and three valves, partitions from the centre of each valve. Seeds few, roundish, inserted into the inner edge of the partitions.

Eff. Ch. Calyx wheel-shaped, in five deep folded segments. Petals five, minute, opposite to the filaments. Anthers opening by two terminal pores. Capsule superior, of three cells, and three valves, with the partitions from their centre.

Obf. The late excellent M. Ventenat, erroneously quoted as the author of this genus in the new edition of Hort. Kew. has justly corrected its original describer, who mistook for a corolla what is truly the calyx. This correction is the more important, as it leads to a knowledge of the true natural order to which the genus belongs, as given above. M. la Billardiere has observed a species with five intermediate abortive filaments, and no petals.

1. L. ferrugineum. Rilly—Woolly-bloom. Andr. Repof. t. 229. Venten. Malmaif. t. 59.—Leaves alternate, linear-oblong, dependent, Flowers racemose.—Native of marshes in New South Wales, from whence the seeds were received in 1791, by Meffia. Lee and Kennedy. It flowers during most part of the summer, being sheltered in winter in the green-house, and allowed but a small supply of moisture. Stem farinose, upright, slender, round, leafy, clothed with dense, ruly, flary pubescence, and, in its native situations, throwing out long, slender, extremely tough branches, to the extent, as it is reported, of many yards, amongst other shrubs.
shrubs. *Leaves* alternate, flaked, dependent, linear-oblong, blunfl, entire or slightly wavy, from two to four inches in length, and half an inch broad; heart-shaped, rather dilated, and often somewhat angular at the base; deep-green and smoothish above; white and downy, below a ruddy rib, beneath. *Flowers* in short, lateral, deflexed clusters, nearly opposite to the leaves, with three or more linear rufly bracteas close to each flower. *Calyx* half an inch broad, light green, belfinkled on both sides with dense, flary, rather rufly down. *Petals* and *anthers* brown. The whole shrub is more remarkable for finguarity than beauty. Sometimes, according to Ventenat, the flowers are four-cleft and tetradram only.

2. *L. fedifolium*. Rosemary-leaved Woolly-bloflom. Ven- ten. Malm. at p. 59—Leaves opposite, linear-lanceolate, spreading. Stalks single-flowered. Bracteas remote from the flower.—Seen by M. Ventenat in the herbarium of M. Thibaud, professor of botany at Strasbourg. We prefume it must be, like the former, and all the known species besides, a native of New Holland. It is defcribed as varying with broader and crowded, or narrower and more dilatant, leaves; and as being remarkable for the fignature of its bracteas, in the middle of the flower-flalk.

3. *L. purpureum*. Purple Woolly-bloflom. Ait. Hort. Kew. *n. 2.—Leaves oval, entire.—Found in New Holland by Mr. Brown. Sent to Kew in 1803 by Mr. Good. It is a green house shrub, flowering from April to July. Of this we have no further knowledge, not having seen any specimen.

4. *L. a torifens*. Nettle-tree-leaved Woolly-bloflom. Ait. Hort. Kew. *n. 3.—Leaves heart-shaped, deeply toothed. —Native of New South Wales, from whence it was fent by Mr. George Calcey in 1802, through Sir Joseph Banks, to Kew. It flowers from May to July, and is feltered in the green-houfe.

5. *L. triphyllum*. Three-leaved Woolly-bloflom. Billard. Nov. Holf. v. 1. 63. t. 88—Leaves three together; the middle one largest and lobed. Stamens ten, the intermediate ones abortive. Petals wanting.—Gathered by M. La Billardiere in Van Leewendal, and by Mr. Menzies at King George’s found, on the west coast of New Holland. We received a specimen in flower, by favour of Mr. Aiton, from Kew garden in May last. It is a *furfup*, kept, like others of its genus, in the green-house. The whole plant is clothed with rather soft flary pubifcence, like fome of the mallow tribe, which affurns a rufly hue on the flalks, and on the veins of the leaves. The foliage is remarkable. Three leaves grow on flalks from one spot, (at the fides of the branches,) of which the middlefott is much the largest, from one to two inches long and nearly as wide, heart-shaped at the base, more or less distinctiy five-angled, or five-lobed, and somewhat flattened, its footstalk nearly its own length; the fide ones are unequally heart-shaped and entire, on very fhort flalks, and refemble flipulas. Long fimple *cliflers*, of feveral *flowers*, grow folidary, opposite to the large leaves, between the small ones. The *calyx* is blufh-coloured, hairy, with pointed segments. *Anther* dark brown, with yellow tips; the barren ones smaller and paler.

6. *L. quadrifolium*. Oak-leaved Woolly-bloflom. Andr. Repof. t. 459. Ait. Hort. Kew. *n. 4.—Leaves three togethcr, all fiumated; the middle one largest and three-lobed, somewhat pinnatifid. Stamens five. Petals wanting.—Gathered by Mr. Menzies, at King George’s found, on the west coast of New Holland. Mr. Brown also observed it in that country. Seeds were fent to Kew, by Mr. Peter Good, in 1803. This is molt skim the last, but abundantly distinct. The leaves are smaller, somewhat glaucous, and much more harf, owing to the more rigid and prominent flary brifles on their upper surface; the three which grow together are more fimilar in fize and figure, being all fiumated, though the middle one is much the molt deeply lobed: the edges are flietly rovoluta. The flowers have their calyx of a deeper rose-colour, with fef of pointed segments. We perceive no barren flaments, nor any petals.

7. *L. corniculatum*. Horned Woolly-bloflom.—Leaves three together, cut and crenate; the lateral ones very small. Petals with linear points as long as the calyx.—Gathered by Mr. Menzies, at King George’s found. —The leaves are more densily and uniformiy hairy than in the last, as well as fopper to the touch. The flowers are racemofe, as in that, but much smaller, and are effentially diftinguifhed by the long prominent linear appendages, or horns, of their petals, which equal the calyx in length, and in its dry frieved flate extend much beyond it.

Several more species of this genus are in our posfession, but we forbear to attempt their defcription from imperfect dried fpecies, as they will doubtless be more correctly and amply illuftrated in the *Prodromus* of Mr. Brown, who has had the advantage of seeing them alive, and whole meritorious labours we never feel a defire to forefill.

Gen. Ch. Cal. Perianth inferior, of one leaf, very short, in five deep acute segments, with two small opposite fakes at its bafe. *Cor. of one petal, funnel-shaped, tube cylin- ericulal; limb in four acute equal fegments, villous on their upper fide. Stam. Filaments four, capillary, villous at their base, inferfed into the tube of the corolla; anthers oblong. *Pijl. Germen superior, ovate; fylle longer than the corolla; stigma obfure. Peric. Capfule orbicular, of one cell, with a brittle bark. *Seeds* two, hemifpherical.

Eif. Ch. Calyx five-cleft. Corolla funnel-shaped, hairy about the mouth. Capfule superior, brittle; of one cell, with two feds.

1. *L. cirrif. Willd. (Rouhamon guianenfis; Aubb. Guian. 93. t. 36. Lamarck. Illutr. 122.)—Gathered by Aublet on the banks of rivers in Guiana, bearing fruit as well as flowers in November. Rouhamon is the Cari- bean name. The woody trunk is seven or eight feet high, with many very long, knotty, opposite branches, climbing over the neighbouring trees, and clothed with reddifh down. *Leaves* oppofite, on short flalks, elliptical, pointed, entire, pale, smooth, three-ribbed. *Tendril* axillary, simple, rather longer than the leaves, recurved and thickened at the extremity, not always prefent. *Flowers* small, white, in axillary tufts. *Capfule* rather large in proportion, an inch in diameter, yellow.—Jussieu refers this plant to the genus *Strychnos*, apparently with great reason.

LASK, a term used by Farriars, for a loosening in horses, often fatal to them.

LASK, or *Lasks*, in Geography, a town of the duchy of Warfaw; 30 miles N.E. of Sidagia.

LASKETS, or *Latches*, in a Ship, are small lines, like loops, fafened by fewing into the bonnets and drablers, in order to lace the bonnets to the cuffses, or the drablers to the bonnets.

LASKING, a sea-term for going large, or veering.
LASNEBOURG, in Geography, a town of France, in the department of Mont Blanc, on the Arc, at the foot of mount Cenis, the pass of which is the principal support of the inhabitants. The fun is hidden from this town by the mountain during two months in the year; 20 miles N.N.W. of Sufa.

LASOY, a town of Thibet; 40 miles N.N.W. of Tacpoy.

LASSA, the capital of Thibet, is called by different names, which have occasioned no small degree of confusion. Its proper name, in the language of Thibet, is said to be Baronathala; but the Tartars call it Laffa or Labhafa. Others call it Tonker, and apply the names Laffa and Baro-nathala to the district which contains Laffa and Putala. Others again give the name of Putala, instead of Laffa, to the capital of Thibet. Rennell says that we ought to apply the name Laffa or Labhafa, to the capital, and to consider Putala as the castle and palace of the Lama, and his ordinary place of residence. Laffa, which is not considered as a large city, is situated on an extensive plain; the houses are of stone, and are spacious and lofty. The mountain of Putala (La Puta), the hill of Puta or Bodh, is signifying a hill in the native tongue, on the summit of which stands the palace of the grand lama, the high priest and sovereign of Thibet, (see Lama), is about seven miles E. of the city. On the north of Laffa stands another range of mountains, covered with snow, which are clearly seen from Kambala, a very high mountain on the N. of the lake of Palté. Laffa is in the province of Ou, and almost in the centre of Thibet. The river Sanpooa Burrampooter runs at the distance of 24 miles from the city. The royal palace at Laffa is called Laprang, where, among other ornaments, are maps of the various provinces, painted about 1665, by the orders of the king Tiffi, on 16 walls. Laprang is also one of the celebrated academies or schools of Thibet, which are frequented by the youth of many surrounding countries, as far as Cathgar, Yarkend, Camuli, Tourfan, and some from Kokonor, Amdoa, and China. The course of studies employs twelve years, occupied in logic, astronomy, philosophy, medicine, and, above all, the theology of Bond, or Xaca. In the city of Laffa are many foreign merchants, and the women have been recently employed by their conversation with the Chinefe. A beneficial traffic is carried on with Laffa, by exchanging gold dust for silver bullion. N. lat. 39° 30'. E. long. 91° 40'.

LASAN, or LESSA, a town of Anterior Pomerania, on a lake formed by the Peene; 38 miles S.E. of Stral-fund. N. lat. 53° 58'. E. long. 13° 52'.

LASAY, a town of France, in the department of Mayenne, and chief place of a canton, in the district of Mayenne; 9 miles N.E. of Mayenne. The place contains 2976, and the canton 14,428 inhabitants, on a territory of 132.4 kilometres, in 14 communes. N. lat. 48° 27'. W. long. o° 24'.

LASEUBE, a town of France, in the department of the Lower Pyrénées, and chief place of a canton, in the district of Oloron; 6 miles E. of Oloron. The place contains 2884, and the canton 4974 inhabitants, on a territory of 130 kilometres, in 5 communes.

LASY, a town of France, in the department of the Oise, and chief place of a canton, in the district of Compiègne; 6 miles W. of Noyon. The place contains 718, and the canton 10,575 inhabitants, on a territory of 135 kilometres, in 24 communes.

LASSIRA, in Ancient Geography, a town of Spain, in the Tarragonensis, in the interior of the country of the Edetani. Ptolemy.

LASSITI, in Geography, a town of the island of Candia; 22 miles S.E. of Candia.

LASSITUDE, in Medicine, a tenet of weariness and debility, independent of fatigue, by which a person is induced to seek for repose and quietness.

A latitude is felt in almost all febrile diseases; and in many chronic affections, in which the circulation is feeble and unequal, as in fcurvy, chlorosis, &c.; and in disorders of the bowels, liver, and alimentary canal. This feeling of weariness and indisposition to exertion, is indeed often the first and only perceptible symptom of approaching illness, as was remarked by Hippocrates: "Lattitudines (pointans morbus praemunratur)." (Aph. ii. 5.) It is a consequence also of most acute diseases, which leave the strength considerably impaired; and in this case it diminishes in proportion as the system regains its vigour in the progress of convalescence. As it is to be considered only as a symptom of various morbid states of the body, it requires no particular remedies to be specificaly adopted for its removal: the cure of it will be effected by remedying the particular morbid conditions with which it is connected.

LASSONE, Joseph Maria Francis de, in Biography, an eminent French physician, was born at Carpentras, on the 3d of July, 1712. His parents quitted their native province, to procure him the advantages of education afforded by the capital; and the ultimate success of the plan evinced their wisdom and prudence. In his early years, however, young Laffone was not remarkable for his perseverance in study: on the contrary, his family were frequently alarmed by the propensity which he exhibited for the gay pleasures of youth; but he as often raised their hopes by some ingenious performances, which merited academic honours, as well as the esteem of his preceptors. He wrote a comedy, which his parents intitled that he should suppress, and sacrifice the imprudent production: he submitted, and was never afterwards willing to declare the title of the piece, which had nevertheless been acted with much success, under a different name, and still remains on the theatre. This juvenile work, foreign as it was to his studies, gave an extraordinary proof of the facility and flexibility of his genius, which afterwards enabled him to acquire in the different sciences a just and elevated reputation. Determining upon a strict attention to study, he devoted himself wholly to the pursuits of anatomy, in which he made such rapid progress, that, at the age of twenty-five, he was received into the Academy of Sciences as associate-anatomist. He examined, with great care and perseverance, the structure of the bones, and of the arteries, and demonstrated the muscular coat of the latter. He also investigated the structure, and inquired into the economy and use of the spleen, attempting to reconcile the different accounts given of that viscus by Ruyfch and Malpighi. He had strong hopes of discovering the office of this viscus, when an extraordinary event put a period to his anatomical pursuits. In selecting among some dead bodies a proper subject for dissection, he fancied he perceived in one of them some very doubtful signs of death, and endeavoured to reanimate it: his efforts were for a long time vain; but his skill in perfusion induced him to persevere, and he ultimately succeeded in bringing his patient to life, who proved to be a poor peasant. This circumstance impressed to deep a sense of horror on the mind of the anatomist, reflecting on the consequences of his having selected this unhappy object for dissection, that he declined these pursuits in
in future. Natural history succeeded the study of anatomy, and mineralogy became a favourite object of his pursuit; he published his observations on the crystallized free-lobes of Fontainebleau. But chemistry, a science to which he was thus led, finally became the devoted occupation of M. de Laffone. His numerous memoirs, which were read before the Royal Academy of Sciences, presented a valuable train of new observations, useful both to the progress of that study, and to the art of compounding remedies; and in every part of these he evinced the faculty of an attentive observer, and of an ingenious experimentalist.

M. Laffone, although he had, by the number of his works, given every one reason to suppose that he had devoted himself exclusively to the sciences, had not neglected the practice of medicine. After having exercised it for a long time in the hospitals and cloisters, he was sent for to court; and he was the only example, except the celebrated Fernel, of one individual holding the office of first physician at Verfailles, successively to two queens, and afterwards to the king: the ministers and the courtiers had been all changed, but he preferred the friendship of his sovereigns. He lived in friendship with Pontencelle, Winlow, D'Alembert, Buffon, and other scientific characters; and the affability of his manners, and his ardent zeal for the advancement of knowledge, among the young scholars, whose industry he encouraged, and whose reputation was become one of his most satisfactory enjoyments, gained him general respect.

When from a natural delicacy of constitution, M. de Laffone began to experience the inconveniences of a premature old age, he became sorrowful and fond of solitude; yet reconciled to his situation, he calmly observed his death approaching, and expired on the 6th of December, 1758. Laffone, at the time of his death, held the appointment of first physician to Louis XVI. and his queen; he was confidant of state, doctor-regent of the faculty of medicine at Paris, and penfioner-veteran of the academy of sciences, member of the academy of medicine at Madrid, and honored associate of the college of medicine at Nancy. HutchinsoN, Biog. Med. Ely, Dict. Hist. Hist. de l'Acad. Roy, des Sciences, 1788.

LASOTH, in Geography, a town of Sileia, in the principality of Neisse; 10 miles N. of Neisse.

LASSOUR, a town of Hindostan, in the cirec of Aurungsabad; 32 miles N.W. of Aurungsabad.

LASSUS, ORLANDUS, or, as he is called by the Italians, Orlando di Laffone, was a native of Mons, in Hainault, born in 1520, and who not only spent many years of his life in Italy, but had his medical education there, having been carried thither surreptitiously, when a child, on account of his fine voice. The historian Thuanus, who has given Orlando a place among the illustrious men of his time, tells us that it was a common practice for young fingers to be forced away from their parents, and detained in the service of princes; and that Orlando was carried to Milan, Naples, and Sicily, by Ferdinand Gonzago. Afterwards, when he was grown up, and had probably lost his voice, he went to Rome, where he taught music during two years; at the expiration of which, he travelled through different parts of Italy and France with Julius Caesar Brancaninus, and at length, returning to Flanders, resided many years at Antwerp, till being invited, by the duke of Bavaria, to Munich, he settled at that court, and married. He had afterwards an invitation, accompanied with the promise of great emoluments, from Charles IX., king of France, to take upon him the office of master and director of his band; an honour which he accepted, but was fobbed on the road to Paris by the news of that monarch's death. After this event he returned to Munich, whither he was recalled by William, the son and successor of his patron Albert, to the same office which he had held under his father. Orlando continued at this court till his death, in the year 1588, at upwards of seventy years of age. His reputation was so great, that it was said of him: 'Hic ille Orlandus Laffus, qui recreat orbem.' As he lived to a considerate age, and never seems to have checked the fertility of his genius by indulgence, his compositions exceeded, in number, those of Palestrina. There is a complete catalogue of them in Dravinius, amounting to upwards of fifty different works, consisting of masses, magnificent psalms, motets, and plains: with Latin, Italian, German, and French songs, printed in Italy, Germany, France, and the Netherlands.

As Orlando di Laffone was the contemporary of Cypriano Rore, a composer of equal renown in the 16th century, and who so much remembled him in genius, abilities, and reputation, we shall here draw a parallel between them, as the two principal masters of Flemish and Netherlandish counterpoint. To form a comparative idea of the style of these two composers, with that of Palestrina, the specific difference seems to be this: that the two Netherlanders, by having spent the chief part of their time in the courts of princes, had acquired a lighter and more peculiar cast of melody than Palestrina, who, residing constantly at Rome, and writing chiefly for the church, had a natural and characteristic gravity in all his productions. Indeed, the compositions a capella of Cypriano Rore and Orlando Laffone are much inferior to those of Palestrina in this particular; for by striving to be grave and solemn, they only become heavy and dull; and what is unnoticed dignity in the Roman, is little better than the fruit of a dwarf upon flints in the Netherlanders. They were, however, great masters of harmony, and, out of the church, prepared the colours, and furnished the musician's pallet with many new tints of harmony and modulation, which were of great use to subsequent composers, particularly in dramatic painting.

In the same collection of songs, printed 1555, we have a Latin poem, set by Orlando di Laffone, in the manner of a madrigal, in which the modulation is curious; but though elaborate and recherché, it is pleasing, and has had many imitators.

Cyprian and Orlando were the first who hazarded what are now called chromatic passages. At the end of the fourteenth book of songs in four parts, printed at Antwerp by Tylman Sufata, there is an irregular Latin ode by Cyri- prian, set like wise in the madrigal style, in which not only an A 2, but an A 5, appear, for the first time, in the same movement, and almost every accident incident to modern music. Part of this curious composition is infected in Burney's General History of Music, vol. iii. as a specimen of the author's frequent attempts at new harmonies and modulation, which, as it is laid before the learned musical reader in score, it will afford him much better information concerning the real history and progress of the art of counterpoint at this time, than all the catalogues of books, and descriptions of their contents, which diligence and language could furnish. Many of the forced, crude, and unexpected modulations in the motet of Cypriano Rore, however they may have been admired for their boldness and novelty, were never adopted by subsequent composers. Beautiful, natural, and pleasing passages and effects are soon rendered common by plagiarism and imitation; whereas the unnatural and difficult are long left in the possession of the original proprietor. Perhaps in a series of years, some other composer, unable to follow by his inventions in a natural way, and determined...
to produce something that shall, at least, seem new, will pro-
voke them again to the public, who will again reject, and so.

But these musical hunters after novelty, without genius to find it, forget that such passages or mod-
dulations must have presented themselves to thousands in the course of their studies and ricercate, but that good taste and found judgment had rejected it. It is at all times easy to produce new arrangements and combinations of sounds, if nature, grace, and propriety be renounced; but at once to be new and natural, belongs only to genius of the first order.

The songs in the same collection by Orlando, are paid by the publisher to have been composed "à la nouvelle composi-
tion d'aucuns d'Italie." We find but little melody in any of them, though much modulation, different from the other Flemish masters of this period. There is another essential difference in the notation, as the diminutions into crotchets and quavers, particularly in the songs alla Napolitana, are more frequent than in any other compositions of the mid-
le of the 16th century. The chromatic accidental semitones are expressed by a sharp, and no longer left to the mercy and fagacity of the finger, as was before the contast custom. The occasional changes in the intervals, which are neces-
sary in counterpoint, though formed upon ecclesiastical melodies, were at first smuggled into harmony, perhaps by
fingers whose good ears suggested them, though the com-
poser had not dared to point them out, lest he should be ac-
cused of corrupting the modes. Orlando feems the first who,
in spite of ancient prejudice and pedantry, when he wished to alter a note, dared to express his intentions in writing.
In his more gay and comic style, however, the modulation is overcharged with wanton and unnecessary transitions from one key to another, without remaining long enough in any one to fix it in the hearer's attention.

Of the two compositions by Orlando di Lasso, and Cy-
prian di Rore, to Latin words, the first is in hexameter and pentameter, and the second an irregular ode, partly in the choral measures of the Greek tragedies. At this mark + in Orlando's compositions, the first A is occurs that we had ever seen used in counterpoint of equal antiquity; and this feems to have been suggested by the words novo in ungue melos. Which of these productions was first composed, we know not, as they were both published together at Antwerp, in 1555. The only copy of this work which we have ever seen, is preserved in the British Musewm. The madrigals are in general, of both Cyprian and Orlando, to Italian words, are excellent, in the style of the times. But as the fangularities in the two compositions before us seem innovations, and preparatory to that revolution in the art, which takes place soon after, they feemed proper subjects of diffusion; for the laboured and equivocal modulation, attempted by these composers, who, though often learned and ingenious, by abandoning the simplicity of their contemporaries, these productions border sometimes so much on caprice and af-
fection, as to fatigue the attention and offend the ear.

The pedantry of ende harmonies, and learned modulation, only suits depraved ears, that have grown callous to every thing that is easy and natural. The Italians, when they quitted madrigals, and no longer aspired at the applause of fastidious chamber-critics, whose approbation was bestowed on no compositions that did not smell of the lamp, simplified their secular music, and instead of puzzling and goading the hearer with complicated contrivances and extraneous modu-
lation, aimed at grace and facility in their melodies, which they clothed with such plain and tranquil harmony, as, in-
stead of disfigure and suffocation, added greatly to their ener-
gy and effet. Dramatic music was not yet even in idea, and
concerts, or other assemblages of gay and unlearned hearers,
seem now not to have existed; so that musical composers
could not be paid to write for the public, who will ever pre-
fer such pleasure and amusement as give them the leaft trou-
ble. Authors of all kinds, who seek for applause, conform
to the taste of their judges; and we find, in our own times,
that those musicians who are qualified by their genius and abilities, to direct and govern the public opinion, think it
necessary, however false and corrupt it may be, to humour
and flatter it, by all the concessions in their power. The art
never long remains stationary at any one point of cultivation;
and if perfection could be attained, its reign would inevita-
ably be short. In music, the learned are few and fiklen;
the ignorant numerous and noisy; in the chamber it was
right to please the former, and in the theatre, where

"—— the fair, the gay, the young

Governing the numbers of each song,"

there is no choice. A public and mixed audience is such a
many-headed monster, that all its ears cannot be pleased at
the same time; and whether the good or the bad predominate,
the greater number must be gratified at the expense of the
least.

Two of Orlando di Lasso's sons, Ferdinand and Rodolph,
were able musicians, and both in the service of Maximilin,
duke of Bavaria; the eldest as chapel-maister, and the other
as organist to that prince. These collected their father's
motets, as well those which had been published during his
life, as those which remained unpublished at his decease, and
printed them in a very splendid and sumptuous manner at Mu-
ic, in seven volumes, large folio, 1603, with a dedication
to their patron, the sovereign of Bavaria. The general re-
ception, however, of these compositions, seems not to have
equalled the expectations of the editors. Other produc-
tions had taken possession of the public ear and favour. It
is, we fear, in vain to hope for the revival of old music; too
many are interwoven in the successes of the new; and such are
the vicissitudes of what are called taste and expression in this
art, that if sufficient probity and zeal could be found in
fashionable performers to incline them to attempt doing
justice to the productions of former times, it is hardly possi-
bile for them to succeed; the accent, energy, and expression
are other lost in the execution, or unintelligible to the
hearers. There is, indeed, as little chance for a musician of
the present age to perform such productions in the manner
of the times in which they were composed, as to pronounce
a foreign language as well as his own; and if, against all
calculation, he should succeed, this music will still be an
unknown tongue to the public.

LAST, or LEST, in general, signifies the burden or load
of a ship.

LAST is also used for a certain weight and measure, which
is various in various countries; though, in the general, the
last is estimated at four thousand pounds weight. A lait
of cod-fish, white herrings, meal, and ashes for soap, is
twelve barrels; of corn, or rape-seed, ten quarters; of gun-
powder, twenty-four barrels, or two thousand four hundred
pounds weight; of red herrings, twenty cades; of hides,
twelve dozen; of leather, twelve dickers; of pitch, or tar,
twelve dozen; of wool, twelve facks; of hock-fish, a
thousand; of flax, or feathers, one thousand seven hundred
pounds weight.

LAST, in the marishes of Kent, a court held by the twenty-
four jurats, and summoned by the bailiffs; wherein orders
are
LAS

are made to lay and levy taxes, impose penalties, &c. for the preservation of the fad marines.

LAST Heir, is he to whom lands come by escheat, for want of lawful heirs; which, in many cases, is the lord of whom they are held: but in others the king.

LAST Will. See WILL.

LAST, Port. See PORT-LLAT.

LASTAGE, or LENTAGE, according to Raffal, is a duty exacted in some fairs and markets, for carrying things bought under one will.

LASTAGE, according to another author, is properly that custom which is paid for wares fold by the laf. In the law of Richard II. laffage is taken for the ballast, or for lading of a ship. See BALLAST.

LASTAGE is sometimes also used for garbage, rubifh, or fuch filth.

LASTEIN, in Geography, a town of Prufia, in the province of Samland; 15 miles S.E. of Ragnitz.

LASTISANA, a town of Italy, in Friuli; 7 miles E. of Concordia.

LASTRES, a sea-port town and cape of Spain, on the N.E. coaft of Africa; 30 miles N.E. of Oviedo. N. lat. 43° 33'; W. long. 5° 19'.

LASTRINGE, a town of Sweden, in Sudermanland; 12 miles N. of Nykoping.

LASULA, a small inland near the E. coaft of Lacon. N. lat. 43° 27'; E. long. 12° 57'.

LASUS, in Biography, was born at Hermione, a city of Achaia, in the time of Darius Hythapes, in the 58th Olympiad, 538 years B.C. Diogenes Laertius fays, that he delerves to be ranked among the seven fages. He was generally allowed to be the first among the Greeks who wrote about music, and was not only a theorifb and great practitioner, but a dilhymabic poet, perhaps the inventor of that kind of poetry in honour of Bacchus, which was fung in the Phrygian mode at the public games, and partook of all that fire and hiftary which the god to whom it was adreffed inspired.

Plutarch fays, that he introduced new rhythms in his poetry and dilhymabic music, and upon the lyre, imitated the compas and variety of the flute; for which he is mentioned, in the Dialogue on Muftic, as a great innovator. Among the corruptions complained of, in the new muftic, the frequent and licentious transitions from one mode and genus to another, was not the leaft. If the objeét for multiplying the ftrings of the lyre, and the holes in the flute, fo much complained of by the adherents to the old school, may be fuppofed to have occafioned the convenience by having an instrument nearly tuned for all the modes, like our hârphichords, it seems probable, that Lausus and other innovators might have been temperers, and have accommodated their doctrine to their practise.

Theon of Smyrna testifies that Latus, as well as the Pythagorean Hippafus of Metapontus, made use of two vales of the fame fize and tone, in order to calculate the exact ratio or proportion of concords. For by leaving one of the vales empty, and filling the other half full of water, they became octaves to each other: and filling one a fourth part full, and the other a third, the percuflion of the two vellfals produced the concords of 4th and 5th; from which proceed refulted the proportions of thefe three concords contained in the numbers 1, 2, 3, 4.

This affertion, which has been taken upon truft, like the anvil fatory of Pythagoras, is equally falfe: to tune glaffes by water has been lately practifed, and thought a new discovery; but that their tones are altered in the proportions given above, is by no means true. Most glaffes are lowered about a whole tone, by being half filled with water, and not more than a major 6th if quite filled.

LAT, in Anatomy. See LIGAMENTUM.

LATA, in Geography, a town of Africa, in the kingdom of Aquambo.

LATAC, or LADAK, a town and country of Thibet, forming a kind of detached sovereignty. The town is five miles N. of the river Luchu, which falls into the Ganges. N. lat. 30° 35'; E. long. 74° 34'.

LATACUNGA, a town of South America, and a jurifdiction in the audience of Quito. This jurifdiction is called Affiento Latacunga; affiento denoting a place lefs than a town, but larger than a village. This place is situated on a wide plain, having on the E. the eastern Cordillera of the Andes, from which projects a very high mountain, at a small distance from the foot of which is situated Latacunga, in S. lat. 55° 14'. W. long. 78° 16'; 50 miles S. of Quito. This affiento is large and regular; the streets broad and ftraight; the houses of stone, arched and well contrived; but on account of the dreadful earthquakes to which it is subject, conflating only of one fory; one of these happened in June, 1658, and its effect was fuch, that of 600 ftone houses, which the affiento then contained, only a part of one, and the church of the Jesuits, were ftanding in a damaged flate, and moft of the inhabitants were buried under their ruins. The ftone of which the houses and churches are constructed, is a kind of pumice, or fpongy ftone, ejected from volcanoes; inexhaftible quanities of it being found in the neighbourhood. This jurifdiction contains seventeen principal villages. The temperature of the air is cold; as this affiento is only six leagues diltan from the mountain of Cotopaxi, which, not being lefs in extent and height than those of Chimborazo and Cayamburo, is, like them, covered with ice and fnow; but the temperature is very different in the several villages of this jurifdiction, being hot in the valleys, temperate on the plains, and often exceflively cold in places bordering on the mountains. The villages are generally larger, and more populous, than thofe of the other jurifdictions in the fame province. Their inhabitants are Indians, Meflizos, and a few Spaniards. The affiento, besides a parish church, ferred by two priests, one for the Spaniards, and the other for the Indians, has convents of Francifcans, Augeftines, Dominicans, the Fathers of Mercy, and a college of Jesuits. The inhabitants amount to between ten and twelve thoufand, chiefly Spaniards and Meflizos. The Indians live in a feparate quarter, as they do at Quito. In this affiento all kinds of trades and mechanic arts are carried on; and, as in all the other parts of this jurifdiction, it has a coniderable number of manufactures of cloth, bays, and tucuyos. Great quan-"
containing twenty-five or thirty vessels, but the Turks haveheerd it to be blown up, so that it can scarcely admit four. Ships of above 400 tons cannot ride here; and hardly a year passes in which one is not stranded in the entrance. Nevertheless, Latakia carries on a very great commerce, partly of olives, but chiefly of tobacco, of which upwards of twenty cargoes are annually sent to Damietta; the returns from these are rice, which is bartered in Upper Syria for oils and cottons. In the time of Strabo, instead of tobacco, the exports consisted of its famous wines, the produce of the declivities of its hills. Even then, Egypt was the market by way of Alexandria. Neither Latakia nor Tripoli can be mentioned as places of strength; they have neither cannon nor soldiers; a single privateer would conquer them both. Each of them is supposed to contain from four to five thousand inhabitants; 50 miles S. of Antioch. N. lat. 35° 36'. E. long. 35° 50'. Veloux's Travels in Egypt, &c. vol. ii.

LATALATTA, one of the Molucca islands. S. lat. 0° 3'. E. long. 123° 5'.

LATANG, a town of Thibet; nine miles S. of Daprong.

LATANIA, in Botany, a name given by Comerfon to a kind of palm, found in the Isle de Bourbon, and which seems to be barbarously constructed of the French word late, a lath, this palm being called in that language latanier.

Eff. Ch. Male, Spatha of numerous imbricated leaves. Spadix brachied, its branches fingered at the top, catkin-like, somewhat cylindrical, of many imbricated single-flowered scales. Corolla in five deep segments; the three outer ones smaller. Stamens 15 or 16; anthers oblong, two-celled. Female unknown.

1. L. Borbonica. Lamarch.—Its trunk is straight, simple, cylindrical, leafy at the top. Leaves folded, fan-shaped, glaucous; their ribs cottony at the back. Footstalk without spines. Spatha at the base of the foliage. The flowers are yellow, imbedded in each scale of the catkin. Filaments united at their lower part into a thick column.

2. LATASI, in Geography, a mountain of Thibet. N. lat. 31° 35'. E. long. 77° 14'.

LATCHA, a lake of Russia, in the government of Olonetz, about 32 miles long and eight broad. N. lat. 61° to 61° 20'. E. long. 38° 30'.

LATCHETS. See LASETS.

LATCHET, or LACHT, in Geography, a river of Thibet, which runs into the Ganges, N. lat. 30° 50'. E. long. 77° 40'.

LATE, a town of Peru, in the jurisdiction of Lima.

LATEEN SAIL, in Sea Language, a long triangular sail extended by a lateen-yard, frequently used by xebecs, polacres, fetties, and other vessels navigated in the Mediterranean sea.

LATERAL. See COLLATERAL, MULTILATERAL, and QUADRILATERAL.

LATERAL Equation, in Algebra, denotes a simple equation; an equation whose root is of one dimension.

LATERAL Ligaments, in Anatomy, are those placed at the sides of the joints. See JONCT.

LATERAL Line. See LINE.

LATERAL Operation for the Stone. See LITHOTOMY.

LATERAL Polys, See PALSY.

LATERAL Sinuus, in Anatomy, the right and left; are the two branches into which the superior longitudinal sinus of the dura mater is divided at the internal transverse ridge of the occipital bone. See VEIN.

LATERALIS MORBUS, a name given by some writers to the pleurisy.

LATERALIS Naris Musculus, a name given by many authors to that muscle of the face which Albinus has called, from its office, the levator habitus superioris alaeque nae. It is also called the obliquus nai.

LATERALIS Recus Capitis. See Rectus.

LATERAN was originally the proper name of a man, whence it descended to an ancient palace in Rome, and to the buildings since erected in its place; particularly a church called St. John of Lateran; which is the principal see of the popes. The LATERAN Councils are those held in the basilica of the Lateran; of these there have been five, held in 1123, 1139, 1179, 1215, and 1513.

LATERAN, Canons general of the Congregation of the, is a congregation of regular canons, whereof that church is the principal place, or leat.

It is pretended there has been an uninterrupted succession of clerks, living in community from the time of the apostles; and that a number of these were established in the Lateran in the time of Conflantine. But the canons were not introduced till the time of Leo I. and thence held the church eight hundred years, till the reign of Boniface, who took it from them, and placed secular canons in their room: one hundred and fifty years after, the seculars were reinstated.

LATERCULUM, among the Romans, was used for a roll or list of all the magistrates and military officers under the Roman emperors, with an account of their respective offices and fees.

LATERE, a, a Latin term used to denote the qualification of cardinals, whom the pope sends as legates into foreign courts; who are called cardinals a latere, as being his holiness's counsellors in ordinary, and affiliates. See LEGATE.

The guards of princes were heretofore called laterones, because always attending at their sides, a latere.

Du Cange, in his Glossary, says there were anciently counts a latere, and monitors a latere.

LATESA, in Geography, a town of Naples, in Abruzzo Citra; 10 miles S. of Lanciano.

LATEWA, a town of Bengal; 45 miles N.W. of Ramsg.

LATENX, in Chemistry, a name by which Van Helmont has, in some of his writings, called the famous menilcum, which he boils Paracelsus and himself to have been poisoned of, and which he usually calls alkoeff.

LATH, in Building, slips of wood used in plastering, tiling, and slating. These are what Felius calls ambrices; or in other Latin writers they are denominated tempula; and by Gregory of Tours, ligature.

In plastering, the narrower the laths are the better; they are for the purposes, so as they are of sufficient breadth to hold the nails, as the number of interfaces is increased, the lime or sluff will hang more readily, and the thicker they are they will be the better adapted to resist violence; but then they would be much more expensive. The laths are generally made of fir, in three, four, and five feet lengths, but may be reduced to the standard of five feet. Laths are single or double; the latter are generally about three-eighths of an inch thick, and the former barely one quarter, and about an inch broad. Lath is sold in bundles; the three feet are eight score to the bundle, four feet, six score, and the five feet, five score. The lath for plain tiling is the same as that used in plastering. Laths are also distinguished into heart and flap-laths; the former should always be used in
in plain tiling, and the latter, of an inferior quality, is more frequently used by the plasterer. Heart-of-oak laths, by the flat-tate Edw. III., should be one inch in breadth, and half an inch in thickness; but now, though their breadth be an inch, their thickness is seldom more than one quarter of an inch; so that two laths, as they are now made, are but equal to one lath. According to the said flat-tate, pan-tile laths are nine or ten feet long, three-quarters of an inch thick, and one and a half inch broad, and should be made of the best yellow deal: the bundle consists of twelve such laths.

A square of plain tiling will require a bundle of laths, more or less, according to the pitch. The distance of laying laths, one from another is various, differing more in some places than in others; but three and a half, or four inches, are usual distances, with a counter-lath between rafter and rafter: but if the rafters stand at wide intervals, two counter-laths will be necessary. Laths are employed for various other purposes as well as plastering and tiling, as in filleting for fastening the ends of boards; in nailed flooring and roofing; for furring up the surfaces; and in every kind of small work, where the dimensions of the parts do not exceed the scantling of laths.

In making for plastering, it is too frequent a custom to lap the ends of the laths upon each other, where they terminate upon a quarter or batten, in order to prevent cutting them; but though this practice saves a row of nails, it leaves only a quarter of an inch for plaster, and if the laths are very crooked, as they frequently are, there will be no space whatever left to straighten the plaster: the lined surface must, therefore, be rounded, contrary to the intention and to the good effect of the work; but if the ends are to be lapped upon each other, they should be thinned at the lapping out to nothing at the extremity, or otherwise they should be cut to exact lengths.

Laths should be as evenly split as possible; those that are very crooked should not be used, or the crooked part should be cut out; and such as have a short concavity on the one side, and a convexity on the other, not very prominent, should be placed with the concave side outwards.

The following is the method of splitting laths: the lath-elevators having cut their timber into lengths, they cleave each piece with wedges into eight, twelve, or sixteen pieces, according to the scantling of the timber; the pieces thus cleaved are called bolts; then, in the direction of the fibré, with their draw-ax, into fissures for the breadth of the laths: this operation they call felting; and, lafly, with their chit they cleave them into thinckens by the quarter-grain.

Lath Bricks are bricks made much longer than the ordinary brick, and used instead of laths for drying malt upon; for which purpose they are extremely convenient, as not being liable to catch fire, and retaining the heat much longer than those made of wood, so that a very small fire is sufficient after they are once heated.

Latham, in Geography, is a township in the parish of Ormskirk, hundred of Welf Derby, Lancashire, England, situated 210 miles from London, and containing 343 houses, and 2719 inhabitants. In this township is Latham-houfe, the seat of Edward Wilbraham Bootle, esq. M. P. This place is noted in the Topographical Annals of Lancashire as the ancient seat of the Latham in the reign of Edward III., and afterwards of the Stanleys, and laflly, of the Bootles. In the civil wars of the 17th century, Latham-houfe was heroically and gallantly defended by Charlotte, countess of Derby, who was besieged here by colonels Egerton, Rigby, Ashton, and Holcroft, from the 28th of July, 1644, to the 27th of the following May. This is a memorable instance of feminine courage and fortitude: a similar example, however, was manifested in Blanche, lady Arundel, at Wardour-castle, in Wiltshire. A particular account of the former is recorded in the "History of the Houfe of Stanley," 8vo. 239; and of the latter in Britton's "Beauties of Wiltshire," 8vo. vol. i.

Latham Park is about five miles in circumference, and contains some fine forest scenery. Nearly in the centre is the house, built of stone, after a design of Leoni. In this township is also Croft-hall, once belonging to the earls of Derby, but is now the property of colonel Stanley, M. P. Near it is Blythe-hall, the seat of Thomas Langton, esq. Beauties of England, vol. ix.

LATHE, an engine of the most extended application in the mechanic arts, for forming wood or metal into any article of a circular figure. The mode of action in a lathe is essentially different from any other method of cutting, as the work is caused to revolve in a circle, while the tool is held upon a fixed support, and presented to it to cut away any parts projecting beyond the circle described by the motion of the work. To the mechanic the lathe is an invaluable machine, as a very great proportion of all the parts of machines is formed in it, and as it is the only method of working metal which may be considered as perfect. All things which can be turned are made in the lathe, both for accuracy and expedition. The common wooden lathe, in use among wood-turners for making articles of household furniture, is so generally understood, that it is needless to give a minute description of it; we have, therefore, given drawings in Plate (Lathe) of a metal lathe, the most perfect of its kind, proper for turning accurate and delicate works for mathematical instruments, or machinery: it was made by Mr. H. Maudelay, London, who has a great number of different sizes, but on a similar construction, in constant use, at his manufactory for stream-engines, and other machinery, in the Westminster-road. Figs. 1 and 2 of the plate are a front and end elevation of the whole lathe, where A A is a strong mahogany bench, supported on iron standards B B, which are drawn fully in fig. 2; beyond these are feet of drawers C C, to contain the tools, &c.; the standards D D carry the axis D of the great four-wheel E E, which gives motion to the work when it is turned by its crank D and treadle F, on which the workman presses his foot, at intervals, to turn the wheel round. The lathe itself, which is fixed upon the bench, consists of a triangular bar G G. See also fig. 3, which is an enlarged figure of it; it is supported on small standards a a, b b, c c, fixed to the bench A by screw-yielding through it: upon this bar the puppets H H, I I, and K K, are fitted with perfect accuracy, and H H, which is called the back puppet, can be fastened at any part of the bar by a screw beneath it; the other two puppets I I, K K, are screwed down upon the standards a a and b b, and are connected together by a piece of metal d d fitting upon the bar, and call in the same piece with them: these two puppets support the mandrel, or spindle L L, one having a screw with a conical head point to enter a hole in the end of the spindle, and the other having a hard steel collar to receive the neck of the spindle, which fits it with the most perfect accuracy, to turn round freely (by a band encompassing g its pulley M M), but without any shake in its collar; on the end of the spindle, beyond the collar, is a small screw to fix on the work to be turned. The back puppet H H has a hole through the top of it, exactly in a line with the spindle, and a conical point fitted into it to support the end of a long piece of work; the point is fitted by a screw g, in the top of the puppet, and has a screw f behind it to force it forwards: the bar G G, also, has the end, or support, for the tool fixed upon it, by a piece of metal g, (fig. 1.) fitted upon the
the bar; a slider is fitted upon this piece to slide in a direction perpendicular to the bar, and the same screw beneath fastens the roller upon the bar at any place, and the slider at any length across the bar. On this slider is a socket to receive a pin, on the top of which is a cross-piece, formed like a T, upon which the tool is laid; this T can be adjusted to the height of the work the tool is to be applied to, and can be fastened at any height by the screw in the side of the socket. The various kinds of work to be turned are fastened to the end of the spindle, so as to be turned round with it, by means of what are called chucks: these are pieces of wood, or metal, fitted to screw fast upon the end of the spindle, and a hollow, like a dish, being turned out in it; the piece of wood or metal to be turned is driven into this hollow, and thus held to be turned, by holding a tool over the T of the reft, which is previously fixed close to the work, and presenting the edge to the work as it revolves by the tredle F, turning the foot-wheel, &c.; this, by its hand turning the pulley M, and the work with an increased velocity. A chuck of this description is shown mounted in fig. 1, with what is supposed to be a plate of brasses, held in it to turn the flat face. Some chucks are flat, with holes through them, and the work is held by screws against it; others are provided with three jaws, like a vice, which can be altogether caufed to advance to or recede from, the centre, by turning a screw, so as to encompass a piece of work of any dimensions. This method of chucking is adopted to form all kinds of flat or hollow work, as cups, boxes, circular rings, or plates, wheels, &c. which are, therefore, termed chuck-work; but articles of considerable length are supported at both ends, which method is called turning between centres. In this method the puppet H is slid along the bar to the length of the work, and fixed there by its screw: the point e is now turned, to fasten the point e, upon which one end of the work revolves as a centre, the other end is received into a square hole in the end of a chuck screwed to the spindle. In other cases, the spindle has a chuck screwed to it, terminating in a conical point similar to that at e; this forms a support for the end, and an arm, projecting from the chuck, intercepts a pin or arm fixed to the work, and by this means it turns round with the spindle. This method of turning between centres is employed to turn spindles of wheels, bolts, ferews, rollers, the outsides of cylinders, or any other articles of greater length than their diameter. When a piece of work is to be turned, which is larger than the lathe will admit, the bar is to be drawn out, as in fig. 1, and supported by an additional standard g screwed to the bench. In the same flate it will admit longer work.

The particular manner of holding the tool to the work is not easy to define in words, but is soon acquired by practice. The tools for brasses are square or flat bars of steel, the ends of which are cut off obliquely, to form an edge like a chiftel, but with a very obtufe angle. It is held in such a position, that its upper flat surface points to the centre of the work to be turned: it is to be held down as firmly as possible to the reft, and advanced to the work at intervals, while the foot of it is cut, by having removed all the projections of the work without the circle it describes. For turning with extreme accuracy, the slide-reft is a very useful addition to the lathe. It is a reft with two sliders in different directions, to one of which the tool is fixed: by means of screws with handles, the sliders and the tool can be moved in either direction, to bring the tool to the work. Figs. 3, 4, and 5, explain the ingenious piece of mechanism. A NA

is a piece of metal, fitted to the bar of the lathe, and provided with a screw to fasten it at any place: upon the upper surface, which is flat, two pieces of brasses are screwed, to form a dove-tailed groove, in which a slider, b, is fitted, to move with freedom and precision; a screw, i, is mounted in the frame N, and is lapped into a piece projecting from the lower side of the slider, so that the screw, when turned round by a handle fitted on its square, advances or draws back the slider in its groove. Upon this slider, b, is a frame k, having at the top of it a slider l, provided with a screw m, as the former, to move it, and carrying a piece n, with square holes through it in two directions to receive the tool o, and a screw at top to fasten it in. The slide-reft being mounted, in the manner of fig. 3, upon the bar, the upper slider, b, is parallel with the spindle, and the lower one, b, perpendicular thereto. For turning flat work, the tool is put in as there shown: now by turning the screw, m, of the upper slider, the tool is advanced in contact with the work, which is mounted as in fig. 1; then by the other screw, i, it is drawn across the face of the work, turning it as it proceeds, to a perfectly flat surface. For turning a cylinder between centres, the tool, o, is put through its holder n, in a direction perpendicular to that shown in fig. 3; and then the lower slider, b, is moved to adjust the tool to the diameter of the intended work; and the upper slider is moved, to carry the tool along the length of the cylinder, and cut it as it goes. The slide-reft will also turn cones, by the following contrivance: the frame k, supporting the upper slider, is fitted to the lower slider by one pin, upon which the whole frame and upper slider may be turned round and fastened at any inclination, by two screws passing through circular grooves. By this means the upper slider is inclined in any angle to the spindle, to turn a cone either hollow or solid, as the tool is put into its holder in one or other direction.

The slide-reft can be made to cut screws by an ingenious application, which is explained in figs. 6 and 7. A short bar P, exactly of the fame dimensions as the large one, is fitted thereon, and faftened by its screw p. Upon this the slide-reft is placed: its sliders now fand in a direction perpendicular to what they did before, though on the fame level. The screw to be cut, repreftented by Q, fig. 6, is mounted between the centres, and turned to a true cylinder by a tool put in the holder n, and carried along parallel to the spindle, by turning the screw, i, of the lower slider: this being done, a cog-wheel, V, is fupported on the chuck, at the end of the spindle, and another, W, is attached to the end of the screw, i, of the lower slider, fo that it will be turned round at the fame time with the spindle. A tool, with a point of the proper form to cut the thread of the screw, is put in the holder n, and advanced by the screw, m, of the upper slider to touch the cylinder Q. The lathe being now put in motion, the tool is moved along by the screw of the lower slider, at the fame time the work revolves, and upon which it traces a spiral groove. When it arrives at the end of the screw, which it only reaches the firft time, the tool is drawn back clear of the work, and the lathe turned the contrary way, to return the tool to the place where it firft set out. The tool is then set by the screw m, to cut deeper than the firft time, and the screw is cut over again; this being repeated four or five times, the screw is completed. By this method a screw of any degree of fineness may be cut, by merely changing the proportion of the cog-wheels, V, W, which connect the fpinadle and the screw of the lower slider. It is plain, if thefe wheels are of equal size, a screw will be formed of the fame width of threads as the screw of the slide-reft at i; and if the wheel, W, on the screw, is the largest,
largest, the screw cut will be finer; if, on the other hand, the smallest wheel is fixed on the screw at W, it will cut a screw of a coarser thread than the screw i. The lathe is provided with wheels of all the different sizes, shewn by the dotted circles V, fig. 7, any of which may be fixed on at pleasure, either on the screw or the chuck. The screw cut in this manner will have its threads inclined in a contrary direction to the screw of the slide-reel; and if that is a left-handed screw, it will cut a right-handed screw, because the slider-screw revolves in an opposite direction to the spline. That the lathe may cut screws of either kind, an intermediate cog-wheel is introduced between the two, to cause them to turn the same way. This gives another advantage, viz. that any two wheels may be used together; the intermediate wheel communicating motion from one to the other, though they are considerably distant from touching each other. The application of the intermediate wheels is explained in figs. 8 and 9, where r is a projecting shelf from the standard a; upon this a piece of metal, s, is fastened by a screw, and a short hollow spline, v, is fitted into it, and fastened by proper screw-collars which allow its rotation; upon the end of the this the cog-wheel W, which turns the screw of the slide-reel, is fastened by a nut; an arm, w, is fitted on the short spline w, so as to have an angular motion round the centre; the arm has a groove in its length, in any part of which the centre pin of the intermediate wheel, x, can be fastened; and by these two motions this wheel may be fixed at any joint, so as to connect the wheels of any size. The hollow spline, v, is adapted to receive an arbor or axis y, which has a socket in the end adapted to the figure, upon the end of the slide-reel screw i; by this method the slide-reel may be set at any part of the lathe bar; when it is required to cut a screw at the end of a long bolt; the arbor y, forming the connection between the cog-wheel, W, and the screw, for which purpose it slides through the hollow spline v, but is caused to revolve with it, by a feather or fillet projecting from one side; the socket of the hollow spline may be fast and fastened at any required distance from the lathe bar, and fastened by its screw; the slide-reel being fast at a corresponding distance from the spindle of the lathe, by moving it upon the bar P, will admit a large piece of work, when a screw is required to be cut upon it. R, fig. 7, is an iron frame, fastened to the lower slider of the slide-reel, to support the screw from bending by the pressure of the tool, when it is long and slender. The frame is shewn in plan in fig. 10, where the holes are shewn for the two screws which hold down the frame upon the lower slider.

The methods of holding various pieces of work in the lathes to turn them are endless, and depending in a great measure upon the ingenuity of the workman to adapt them to the particular occasions he meets with. This subject, as well as the figure and manner of holding the tools, will be resumed under the article Turning; an art which, from the facility with which it produces so many beautiful forms, has become a fashionable amusement among gentlemen, who may require many practical instructions, which would be needless to the mechanic regularly educated in the workshop. We shall also describe the method of turning elliptic work, as well as circular.

**LATHE, in Law.** See LETHE and LATHEY.

**LATHE, in Rural Economy, a provincial term used in some counties to signify a barn.**

**Gen. Ch. Cal. Perianth inferior, of one leaf, bell-shaped, erect; its orifice deeply four-cleft. Cor. of one petal, ocellin; tube longer than the calyx; limb ocellin, swelling; its upper lip concave, helmet-like, broad, with a narrow hooked point; lower lip small, reflexed, obtuse, mostly three-cleft. Nectary a very short notched gland, depreased on both sides, inserted into the receptacle of the flower at one edge of the germen. Stem. Filaments four, awl-shaped, the length of the corolla, and concealed under its upper lip, two rather shorter than the rest; anthers oblong, two-lobed, barbed, flattened, colorin in pairs. Peri. Germin inferior, glabre, slightly compressed; style thread-shaped, of the length and situation of the flamburger; stigma tumid, abrupt, drooping. Peric. Capsule roundish, obtuse with a point, involuted with the enlarged spreading calyx, of one cell and two elastic valves, each bearing a central, longitudinal, fungous receptacle. Seeds few, nearly globular, inserted into the receptacles.

Ob. The neotiferous gland flows its very near affinity to Orabanche. Linn.

**Eff. Ch. Calyx four-cleft, inferior. A depressed gland at the base of the future of the germen. One capsule of one cell, with lateral fugous receptacex. Seeds glabre.**

1. **L. Clandisina. Subterraneous Toothwort. Linn. Sp. Pl. 843. Lamarck, fig. 1. (Clandissina flore subverso; Tourn. Initi. 652. t. 424. Orabanche, five Dentaria aphyllos purpures, cespile denso; Morif. Sect. 12. t. 16. f. 15.)—Stem branched, subterraneous. Flowers erect, solitary.—Native of shady woods in France, Italy, and the Pyrenees, growing parasitically on the roots of trees. The stem is subteranneous, at first short, and densely clothed with crowded, feilee, rounded, convex, very flexily, entire, whitish leaves. In this stage of the plant the flowers arise above the ground, and are at first nearly feilee, very large, the corolla being two inches long, of a blueish colour, sometimes white, and they grow in rather close tufts. Afterwards the stem is greatly elongated, the leaves become remote, and thrivelled, the corolla falls, and each calyx is elevated on its separate simple stalk above an inch long. This latter stage is represented in Rudbeck's Elys. p. 239. f. 2. As we find no correct account of the growth of this singular plant, the above may not be unacceptable. It seems to shew the herb, if not the root, to be but of annual duration. What have been called scales of the root in this genus, seem equivalent to leaves, and we have so denominated them above.

2. **L. Anblatum. Oriental Toothwort. Linn. Sp. Pl. 844. (Anblatum orientale, flore purpurascens; Tourn. Cor. 48. t. 481.)—Lips of the corolla undivided. Found by Tournefort in the Levant. Linnæus has taken up this species entirely from the plate and short definition of the great French botanist. It should appear to be most akin to the following, with which it constitutes Tournefort's genus of Anblatum, whose name is of German etymology, and adopted from Valerians Cordus.**

3. **L. Squamaria. Greater Toothwort. Linn. Sp. Pl. 844. Fl. Dan. t. 136. Engl. Bot. t. 50. (Squamaria; Rivin. Monop. Ir. t. 89. f. 2. Dentaria major Matthioli; Gem. em. 1583.)—Flowers racemose, pendulous. Lower lip three-cleft.—Native of shady woods throughout Europe, flowering in March or April, and growing parasitically on the roots of the haelf, for the most part. The subterraneous portion of the stem is branched, clothed with fleasty-white leaves, as in the first species; what rises above-ground is simple, purple, downy, racemose, bearing numerous drooping purple flowers, with a pale calyx, each partial donor...
flalk attended by a leaf like those that grow below the surface.

LATHREA Phyllea. See OROBANCHIE.

LATHREV, LEUGHREY, or TRIVNNGREY, was an officer under the Saxon government, who had authority over a third part of the county; and whose territory was therefore called triviny, otherwise a leid, leithin, or lathe, in which manner the county of Kent is still divided; and the rapes in Suffex seem to answer to the same. As to the jurisdiction of this officer, those matters that could not be determined in the hundred court, were thence brought to the triviny; where all the principal men of the three or more hundreds being assembled by the lathrevhe, or trivningre, did debate and decide it: or if they could not, then the lathrevhe sent it up to the county court, to be there finally determined.

LATIRUS, in Entomology. See SCARABEUS.

LATHYRIN, in Botany, a name given by many authors to a species of tithymalus, or spurge, commonly known by the name of tithymalus latifolius, the broad-leaved spurge, and called by some alio catespata.

Gen. Ch. Cal. Perianth inferior, of one leaf, bell-shaped; its segments lanceolate, acute; the two uppermost shortell, the lower one longest. Cor. papilionaceous. Standard very large, inerely heart-shaped, reflexed at the sides and fummit. Wings smaller, oblong, somewhat crescent-shaped, short and obtuse. Keel semicircular, the size of the wings but broader, separating about the middle inwards. Stam. Filaments in two sets, one simple the other in nine divisions, curved upwards; anthers roundish. Pilt. German compressed, oblong, linear; style in its upper part erect, flat, broader upwards, acute at the fummit; stigma on the upper or inflexed side of the style, extending from the middle to the top, hairy. Petio. Legumes very long, cylindrical or compressed, pointed, of two valves and one cell. Seeds several, either cylindrical, globose, or slightly angular.

Eff. Ch. Style flattened, downy above, broader upwards. Two upper segments of the calyx shortell.

Tournefort divides this genus into four by the foliage. His Lathyrus, t. 216, 217, has only a single pair of leaflets on each footstalk, the latter terminating in a compound tendril; his Glycineum, t. 218, has many leaflets to each flalk; his Njefeda, Init. 656, has simple leaves without any tendril; and his Aphaca, t. 223, bears flipulas without leaves, at least in the adult plant. These, however, are very jutly deemed by Linnaeus mere differences in habit, among the species of one great genus, which is on the whole sufficiently natural. His 14th edition of Syll. Veg. enumerates 21 species, Willdenow 36, in three sections. The first section, with single-flowered flalks, now and then varying to two flowers, embraces 13 species; the second, with two-flowered flalks, has 6; the third, with many flowers on each flalk, has 17. — Seven of the genus only are natives of Britain. The rest grow either in the warmer countries of Europe, or in the north of Africa, some in America, and one is said in Japan. They are stationed for the most part in cultivated fields, in meadows, or about hedges and thickets. Those referable to the first and second sections are, perhaps without exception, always annual plants, many of them capable of being used as pulse; those of the third are generally perennial, with very tenacious, deep or creeping roots, and more calculated for fodder. Examples are here subjoined.

* Stalks single-flowered.

L. Apacha. Linna. Sp. Pl. 1829. Curt. Lond. falc. 5. t. 51. Engl. Bot. t. 1167. (Apacha; Rail Syr. 325, Ger. em. 1550.) — Flowers solitary. Tendrils leafless. Flipulas between heart and arrow-shaped. Found in the borders of gravelly corn-fields, but rarely. The stem is weak, a foot or two high, supported by its numerous simple tendrils, each sprigging from between two large, angular, almost half-hearted flipulas, which give the plant a peculiar aspect. One or two of the very flat flipulas only are accompanied by a pair of small leaflets, with or without any elongated tendril. The flowers are small and yellow, very rarely two together on each flower-flalk.

— Native of Syria. A humble plant, remarkable for producing many of its pods, with perfect seeds, immediately from the root, or rather from the subterminal part of the stem; yet these are the offspring of perfect flowers, (at least as to flowers and pistil,) though born under ground; as we have verified by examining the plant in Kew garden 30 years ago. Whether the roots be annual or perennial, we are not certain, but this subterranean mode of fructifying is seen in two or three more species of Lathyrus or Field. Morrisian's figure exhibits the present plant very tolerably. What rife above ground bears linear-lanceolate rather glaucous leaflets, in pairs, with half arrow-shaped flipulas, and large solitary dull-purple flowers, which also produce seed.

L. articulatus. Linna. Sp. Pl. 1033. Curt. Mag. t. 253. — Stalks with one or two flowers. Tendrils accompanied by many alternate lanceolate leaflets, on a winged flalk. — Native of France and Italy. A common hardy annual in our gardens, to a place in which it is recommended by its elegance, though scentless flowers, whose crimson standard is prettily contrasted with their white wings.

* Stalks two-flowered.

— Native of Sicily, and some in Asia of Ceylon; but the latter may perhaps be doubted, the plant being in the English gardens so hardy an annual, as frequently to survive our winters, when it comes up in autumn. Its great beauty, delicious fragrance, and variety of colours, render it a general favourite. More than two flowers are frequent on each flalk, though the uppermost are commonly bighteed.

** Stalks many-flowered.

L. tuberosus. Linna. Sp. Pl. 1033. Curt. Mag. t. 311. — Stalks many-flowered. Leaflets oval, in pairs. Stem without wings. Roots tuberous. — A troublesome weed in some parts of Germany and Italy, spreading widely over all kinds of cultivated ground, by means of its tuberous fleshy perennial roots, hardly to be extirpated. In our gardens it is a beautiful hardy plant, confpicuous for the peculiarly delicate rose-colour of its blossoms, and we have never heard of its being troublesome in its increase. The field rarely
LATICLAVIUM, or LATU.S-CLAVUS, a garment which was a distinction and dignity among the Romans, contradistinguished from the angustilavium.

The latus-clavus was a kind of tunic or long coat, faced with one or two slips of purple, applied lengthwise to the two sides of the tunic.

- In the latus-clavus these slips were pretty broad, and in the angustus-clavus narrower; though there is nothing about which the learned differ more than the difference between those two habits.

There were buttons set on the latus-clavus, which appeared like the heads of large nails; whence some think it took its name.

The senators, pretors, and the chief magistrates of colonies and municipal cities, had a right to wear it. The robe called praetexta was worn over the latus-clavus. When the pretor pronounced sentence of death, he put off the praetexta; but retained the latus-clavus.

LATICZOW, in Geography, a town of Poland, in the palatinate of Bracław; 60 miles N.W. of Bracław.

LATILLA GAETANO, in Biography, an excellent Neapolitan composer, much esteemed by connoisseurs, in every species of vocal music. His comic operas, however, were the most ingenious and successful of all burletta compositions, till the Buona Figliuola of his nephew Piccini came out, which surpassed all preceding comic operas so much, that no other excited any curiosity in the public; till Pachiello's superior fertility was known and felt.

Latilla's comic operas, that were performed in London, from 1748 to 1753, when the Mingotti first arrived, were "La Comedia in Comedia," "Orazio," and "Don Calafecine," which were admirable. The melodies new, easy, and pleasing; humour without buffoonery; and the actors considered as well as the fingers, in allowing time for Pertici and Laschi, those nice observers of whatever was ridiculous in the voice, countenance, or gesture of man, to convey their observations to the spectators.

We met with poor Latilla 20 years afterwards at Venice, "fallen from his high estate," and shrunk into an humble deputy organist, at the church of St. Maca; but found him an intelligent and well informed man, on other subjects than that of his own profession, which, however, he had cultivated in all its departments.

LATIMER, Hugh, the son of a respectable Leicestershire yeoman, was born about the year 1470. He was initiated in school learning in the country, and making a very rapid progress in his youthful studies, he was, at the age of fourteen, sent to Chrift's college, Cambridge, where he was distinguished for his rapid proficiency in the studies of the place. Here he took his degrees, entered upon holy orders, and was at this period a zealous Papist, read the scriptures and the schoolmen with the same reverence, and held Thomas à Becket and the apostles in equal honour. He had taken alarm at the progress of Lutheranism, and inveighed with great bitterness, publicly and privately, against those principles.
inciples, of which he was hereafter to become a most zealous defender. His zeal as a Papist was so distinguished in the university, that he was elected cross-bearer in all public processions, an employment which he is said to have accepted with a high degree of reverence, and to have discharged with much solemnity. Our good divine was a Papist from conviction, and had a mind open to arguments on all sides of the question: he fortunately met with Mr. Thomas Bilney, a clergyman of great piety, and who, by the perusal of Luther's works, had become a secret favourer of the reformation. By degrees he infused into the mind of Latimer all those doubts which he had formerly felt respecting the discordance of Popery with pure Christianity. Latimer heard the arguments of his friend, and was prepared at first to dispute the ground inch by inch. At length he found the ground on which he stood absolutely untenable; and acknowledged the errors in which he had been educated. But the temper of the scholar was not like that of the master: he could not be a Protestant in secret: he must come forth boldly and declare the convictions of his heart: he had fought truth as the pearl of great price, and having, as he believed, found it, was determined not to conceal its beauty from his friends and the world. He became an active apostle in the cause of Protestantism: he preached in public, he exhorted in private, and every where enforced the necessity of a holy life, in opposition to the superstitious ceremonies and observances inculcated by the Romish religion. The soon became obnoxious to the generality of the clergy, but being contented to go through evil as well as good report, he continued on his course with more ardour in proportion to the outcry made against him. He inveighed against the ceremonies which encumbered true religion, and exposed the pride and usurpation of the Romish hierarchy: but what he most inflicted on was the right of the people to read the scriptures in their native tongue. Dr. Buckenham, one of the Black-friars, was selected to answer, from the pulpit, the arguments of Latimer: he performed the task with great pomp, but not to the complete satisfaction even of his own party, and in a short time afterwards the whole university met to hear what the reformer had to say in his defence. Mr. Latimer at first recapitulated Dr. Buckenham's arguments; placed them in the strongest light, and gave them much greater importance than the friar had been able to do: he then attacked them with so much force of reasoning, and such abundance of wit, as to render the learned doctor truly ridiculous: he next appealed to his hearers, urging them to respect their own understandings, and not to submit to be led by the priests, who had ever been accustomed to treat the people at large with contempt; and he concluded with ardently hoping, that his honest countrymen might be permitted to have the use of the scriptures, till they showed themselves to be as absurd interpreters of them as the learned friar. Latimer, by this exertion, and by an answer to Venetus, greatly increased the credit of the Protestant party at Cambridge. Bilney and Latimer were regarded as the heads of the party, and to them the students looked with respect, attachment, and even veneration. The heads of the colleges, and the seniors of the university, were alarmed, and determined to withstand the progress of heresy. Frequent convocations were held, and the [sic] injunctions were laid on all the tutors to be watchful of the opinions of their pupils: but these efforts were in vain, and the bishop of Ely was applied to, and entreated to crush, by his authority, the new opinions. The prelate, though a Papist, was not a friend to persecution: he was willing to judge for himself, and though he went to Cambridge and preached against the heretics, yet he did not scruple to attend himself the sermons of Latimer, and with much candour declared, that the reformer was the best preacher he had ever heard. Latimer's enemies next appealed to the court, and transmitted very heavy complaints respecting the incraze of heresy; and Woffley, contrary, it is thought, to his own inclination, instituted a court, consisting of bishops and other divines, to put the laws in execution against heresy. Bilney and Latimer were called to an answer for their conduct, and as the former was regarded as the most guilty, by being the first promulgator of the new doctrines, his examination was the most severe, and he was pronounced guilty; but not having a mind formed for the sufferings prepared for him, he recanted, and after some ignominious treatment was dismissed. Latimer, and others who were involved in the charge, were, by the management of the cardinal, and the merciful disposition of Tunstal, bishop of London, dismissed probably without a reproach: the cardinal even granted Latimer his licence to preach throughout England. The friends of the reformers received them with open arms; but the fate of Bilney was truly wretched: he was struck with remorse at the thought of his recantation, and the agonies of his mind deprived him for a time of his reason. In a few years he returned to a sane state, and determined to expiate his abjuration by his death. He accordingly left his friends at Cambridge, went into Norfolk, his native country, and preached most earnestly against the corruptions of the established religion; he was seized, imprisoned, and executed, at Norwich, exhibiting, at his cloathing scene, a most admirable example of composure, firmness, and Christian courage. Latimer, in the mean time, exerted himself more than ever: he was confin'd in his exertions, and once or twice he had the honour to preach before the king at Windor. Encouraged by the gracious reception afforded him by Henry, he took the liberty of writing a very bold letter to his majesty, against a proclamation which the clergy had prevailed upon the king to publish, forbidding the use of the bible in English. The king received the letter with good temper, and even thanked Mr. Latimer for his well-meant advice. When measures were taken for the establishment of the king's supremacy, Latimer exerted all his power in forwarding his majesty's designs. His zeal in the business procured him the presentation of the rectorcy of Welkinton, in Wiltshire, and, notwithstanding the remonstrances of his friends, who considered this as the first step only to higher dignities in the church, he went to reside on his living. His preaching rendered him very popular, and he was soon after appointed by the mayor of Bristol to preach on Easter Sunday. Public notice of this appointment had been given, and received by the people with great joy; but an order was suddenly issued by the bishop of Bristol, prohibiting any one to preach there without his licence. This was but the first instance of opposition which the clergy in that neighbourhood excited against him; they traduced his character, and inveighed against him with the greatest violence; and at length they drew up a set of articles, in the form of an accusation, which was laid before Stokesley, bishop of London, who immediately cited Latimer to appear before him. To this mandate he was not obedient, but on a citation from the archbishop he feignedly submitted. He met out in the midst of winter, and at a moment when he was grievously afflicted with the stone and other acute disorders. On his arrival in London he found the court sitting, but instead of being examined as to any particular charges, he was ordered to subscribe a paper put into his hand, containing the obnoxious doctrines against which he had been preaching. This he positively refused, and he was dismissed, for the present, with an exhortation to reflect upon his conduct, and submit, Frequently
LATIMER.

Frequently was he brought before the court, and as frequently he rejected the proposal. At length he renounced against their ill-treatment, and was probably rescued by the interposition of the king. In 1534, he was appointed chaplain to queen Anne Boleyn, and in the following year he was offered the bishopric of Worcester, which he accepted, and discharged the duties of the office with zeal, piety, and diligence. In 1536, he was called on to attend the parliament and convocation; and it was hoped that this feccion would bring with it many important advantages for the Protestant cause. The convocation was opened by an eloquent Latin discourse from Latimer, who had been appointed to this office on account of his great talents, and because it was known that no other person could so ably expound the corruptions of the clergy as himself, and thus lead them to an active discharge of their duty. In a short time after this, an English translation of the bible was published and recommended by authority to a general perusal. During the sitting of the convocation, an animated but unsuccessful attempt was made to excommunicate archbishop Cranmer and bishop Latimer, by some public censure. As soon as the convocation broke up the bishop repaired to his diocese; he had no title for late affairs, and he had a mind ill adapted to the manners of a court. It was the custom at that period for the bishops, at the commencement of every new year, to make presents to the sovereign, and many of them were very liberal in their donations; but Latimer, on this occasion, presented, instead of a purse of gold, a New Testament, with a leaf doubled down on this paffage, "Whoremongers and adulterers God will judge."

Attempts were frequently made to ruin the bishop, but hitherto they were unsuccessful; and he continued in favour with the king. After the passing of the bloody statute, or the act of the fix articles, the bishop protested against it by his conduct; he resigned his bishopric, and retired into the country. Here he intended to pass the remainder of his days, but an accident, which befell him, by the fall of a tree, obliged him to come to London for surgical assistance. His arrival was soon known in the metropolis, and the spies of the bloody-minded Gardiner watched him in every place. At length they obtained, or made, matter for accusation; he was charged with speaking against the statute of the fix articles, and was, without hesitation, committed to the Tower, where he suffered a cruel imprisonment during the remainder of king Henry's reign. On the accession of Edward VI. Latimer, and all the others who had been imprisoned in the same cause, were set at liberty. He might have been reinstalled in his bishopric, but he preferred a more private life, accepted an invitation from Cranmer, and took up his residence at Lambeth, where his chief employment was to hear the complaints, and to procure redress for the injuries of poor people. No man was so well qualified for an office of this kind, and he continued in it during two years, interfering very little with public transactions. It was, however, known that he assisted the archbishop in composing the Homilies, which were published, by authority, in the beginning of king Edward's reign, and intended to supply the want of preaching, which was now at a very low ebb. Being one of the most eloquent preachers of the age, he was appointed to preach the Lent sermons before the king, during the first three years of his reign. After this he retired into the country, and made use of his majesty's licence, as a general preacher, in those parts where he thought his labours might be most serviceable. He continued in this practice till Popery was re-established in the reign of queen Mary, when he was cited to appear before the council in London. He immediately obeyed, and as he passed through Smithfield, the scene of the most horrid cruelties exercised upon those who had been denounced heretics, he said, very cheerfully, to his attendants, "this place has long groused for me." The next day he appeared before the council, who, after loading him with many reproaches, committed him to the Tower. His imprisonment was rendered uncommonly severe, but he endured every evil with resignation, and true Christian humility. The weather was exceedingly severe, but no fire was allowed him, which led him to tell the lieutenant of the Tower, that, however his enemies might expect he should be burned, unless he was permitted to have a fire this frosty weather, he should be first starved to death with cold. About this time archbishop Cranmer and bishop Ridley were committed to the Tower, which became so crowded with prisoners, that the three prelates were confined in the same room, a circumstance which, no doubt, they greatly enjoyed. The pleasures, however, was but of short duration; they were hurried to Oxford under the pretence of a public disputation to be held there by the most eminent divines on both sides. At this place they were most closely confined in the common prison, and deprived of every comfort, and of almost all the necessaries of life; hence they readily inferred what kind of disputation would be allowed them. They fully expected that the argument of power was the only one that would be referred to, and having made up their minds to this, Latimer said he should give them very little trouble. "I shall," said he, "offer them a plain account of my faith, and say but little more; for I know that any thing more will be to no purpose. They talk of free disputation; but I am assured, their grand argument will be, as it was that of their forefathers, We have a law, and by our law, we ought to do."

When he was brought into court, he had a cap on his head, a buttoned under his chin, a pair of spectacles hanging at his breast, a new Testament under his arm, and a staff in his hand. He was exhausted in prying through the crowd, and was permitted to sit down; after a suffi- cient pause, he was told he must dispute against the articles brought against him; he declared he was unable, through age, to do any such thing; "I am not able to debate," said the venerable old man, "I will own my faith, and then do with me as you please." He was next enfeigned, by the artful conduct of his accusers, to make confessions which were against him, and upon this the protector arose, and exclaimed to the populace, "Here you see the weaknesses of hereby against the truth; here is a man, who, adhering to his errors, hath given up the gospel, and rejected the fathers." The good old man made no reply, but wrapping his gown about him, and taking his new testament and his staff, walked out with the greatest composure. On the following Friday he was again brought into court, was first excommunicated, and then condemned to death. As soon as the sentence was read, Latimer, lifting up his eyes to heaven, exclaimed, "I thank God most heartily, that he hath prolonged my life to this end."

No steps were taken towards putting the sentence against the prelates into execution, for nearly a year and a half; but, in 1555, new laws in support of the Romish religion having been enacted, a commission was granted by cardinal Pole, the pope's legate in England, to the bishops of Lincoln, Gloucester, and Bristol, empowering them to try bishops Latimer and Ridley for heresy. The prelates were ordered before the commissioners, and when Ridley had been examined, bishop Latimer was brought to the bar, whom the bishop of Lincoln addressed, in an eloquent, and very pathetic speech, earnestly exhorting him to accept the mercy that was offered, and to acknowledge the authority of the see of Rome. The good bishop was too firmly fixed in his opinions.
opinions to give them up through motives of timidity, and the desire of prolonging his life. He was, however, re-
manded, and on the next day judgment was passed on him 
and Ridley. Their execution was fixed for the 16th of 
October, and the place fixed on was the north side of the 
city, near Balliol college. Left the bloody scene should ex-
cite a tumult, the military were ordered to attend the place 
of execution. On the day appointed, the vice-chancellor of 
Oxford, and other persons of distinction, repaired to the 
spot which was to witness the sufferings of these worthy 
men; the prisoners, at the fixed hour, were sent for, 
and the concern of the spectators, which was apparent in 
every countenance, excepting in those who were actors in 
the scene, was greatly augmented by the striking contrast 
of their appearance. Ridley was dressed in his episcopal habit, 
flaying what they had formerly been, and bishop Latimer 
worst his priest attire, by which he exhibited the condition to 
which they were now reduced. Having heard a sermon, 
by a Popish doctor, in which they were treated with great 
inhumanity, they prepared for their last trial, and were 
chained to the stake. The fire was speedily kindled, and at 
the sight of the flames Latimer exclaimed, “Be of good 
cheer, my brethren, Ridley, and play the man, we shall this 
day light such a candle, by God’s grace, in England, as I trust 
shall never be put out.” He then recommended his soul to 
God, and a few minutes put an end to the sufferings of these 
noble martyrs. Such was the glorious and triumphant end of 
Hugh Latimer, who had been indefatigable in the discharge 
of the duties of life, and who exhibited the most astonishing 
firmness and composure in the several trials to which he was 
exposed. He was not learned in the usual sense of the word, 
for he cultivated only useful learning; and he lived rather 
what the world calls a good than a great man. He 
was eminent as a preacher, but his sermons, that are extant, 
are not patterns of good composition; his manner of 
preaching was affecting, as he spoke from the heart, and made 
depth and lasting impressions on his auditors. He displayed 
at all times a noble and apostolic zeal in the propagation of 
the truth. No one had a higher sense of what became his 
office, or was least influenced by any fainter motive; and none 
ever reproved vice with more freedom, without any regard 
to the rank of his hearers. A collection of his sermons was 
published, in 1570, by Augustus Bernhure, a Swiss, who 
dedicated them to Catherine, the duchess of Suffolk. It 
contains forty sermons, and has been frequently reprinted. 
In Mr. Fox’s Acts and Monuments, several of his letters 
are preferred, among which is the celebrated one to King 
Henry VIII. for restoring the free liberty of reading the 

LATIN, a dead language, first spoken in Latium, and 
and afterwards at Rome, and still used in the Romish church, 
and among men of letters.

Some authors rank the Latin among the number of 
original languages, but by mistake: it is formed principally 
from the Greek, and particularly from the Ἱδικὸν διάλεκτον 
of that tongue; though it has a great number of words which 
it borrowed from the languages of the Etrurians, Ofcii, 
and other ancient people of Italy; and foreign commerce 
and wars, in course of time, added a great many more.

The Latin is a strong, nervous language, perfectly suit-
able to the character of the people who spoke it. The 
Romans were engaged in wars and commotions, foreign 
and domestic, which for four hundred years engrossed 
all their thoughts. Hence, therefore, says the ingenious 
Mr. Harris, their language became like their ideas, copious 
in all terms, expressive of things political, and well adapted 
to the purposes both of history and popular eloquence.
But the Romans were no philosophers; and hence 
the unfitness of their language to this subject; a defect, 
which even Cicero is compelled to confess, and more fully 
makes appear, when he writes philosophy himself, from the 
number of terms he is obliged to invent. Harris’s Hermes, 
p. 411, &c.

The Latin is more figurative than the English, less plain 
than the French, less copious than the Greek, less pompous 
than the Spanish, less delicate than the Italian, but clearer 
and more nervous than any of them.

We may here observe, that the profody both of the 
Greeks and Romans was carried much farther than ours; or 
that they spoke with more, and stronger, inflections of voice 
than we use. The quantity of their syllables was much 
more fixed than in any of the modern languages, and ren-
dered much more sensible to the ear in pronouncing them. 
Besides quantities, or the difference of short and long, acc-
ents were placed upon most of their syllables, the acute, 
grave, and circumflex; the use of which accents we have 
entirely lost, but which, it is well known, determined the 
speaker’s voice to rise or fall. (See Accent and Prosody.) 
We may also observe, that strong tones and animated ges-
tures always accompany one another. The action both of 
the orators and the players in Greece and Rome was far 
more vehemence than that to which we are accustomed. (See 
Action and Gesture.) When the Barbarians spread them-

ourselves over the Roman empire, these more phlegmatic nations 
did not retain the accents, the tones and gestures, which 
necessity at first introduced, and custom and fancy after-
wards so long supported, in the Greek and Roman lan-
guages. As the Latin tongue was lost in their idioms, so 
the character of speech and pronunciation began to be 
changed throughout Europe. The same attention was no 
longer paid to the music of language, or to the pump of 
declamation, and theatrical action. The arrangement which 
commonly obtains in the Latin language confines in placing 
first in the sentence, that word which expresses the principal 
object of the discourse, together with its circumstances; 
and afterwards the person, or the thing that acts upon it. 
Thus Sallust, comparing together the mind and body, uses 
the following expression: “Animi imperio, corporis servitio, 
magis uti promiscuo,” in which the word renders the sentence 
more lively and striking than when it is arranged according 
to our English construction; “We make most use of 
the direction of the soul, and of the service of the body.” 
The Latin order more gratifies the rapidity of the imagina-
tion, which naturally runs first to that which is its chief 
object; and having once named it, carries it in view through 
the rest of the sentence. But though the common arrange-
ment in the Greek and Roman languages is to place that 
first which strikes the imagination of the speaker most, yet 
this does not hold without exception. Sometimes regard 
to the harmony of the period requires a different order, and 
to this the ancients attended. The Latin order is more ani-
mated; but the English is more clear and distinct. The 
Romans generally arranged their words according to the 
order in which the ideas rose in the speaker’s imagination. 
We arrange them according to the order in which the under-
standing directs those ideas to be exhibited in succession, to 
the view of another. Our arrangement, therefore, appears to 
be the consequence of greater refinement in the art of 
speech; as far as clearness in communication is understood 
to be the end of speech. The limitation of arrangement in 
the modern tongues is, in a great degree, owing to the dif-
ficulty of those differences of terminations, which, in the Greek 
and Latin, distinguished the several cases of nouns, and
tenses of verbs; and which, by means of these, pointed out the mutual relation of the several words in a sentence to one another, though the related words were disjoined and placed in different parts of the sentence. As articles contribute very much to the clearness and precision of language, the want of them in the Latin tongue is unquestionably a defect, though they recur for the supply of this defect to the use of pronouns. (See Article and Pronoun.) Blair's Lectures, vol. i.

For a while the Latin tongue was confined almost wholly within the walls of Rome; but nor would the Romans allow the common use of it to their neighbours, or to the nations they subdued. Cicero observed, that even in his time, Greek was used almost among every people, but the Latin only confined to a very narrow compass. By degrees they were brought to grant the use of it as a favour; and, in time, became sensible of the necessity there was of its being generally understood; for the convenience of commerce: and, accordingly, used their utmost endeavours, that all the nations subject to their empire should be united by one common language: so that at length they imposed that as a law, which they had before granted as a favour.

After the translation of the feast of the empire from Rome to Constantinople, the emperors of the East, being always desirous of preferring the title of Roman emperors, appointed the Latin to be still retained in use, both in their edicts and edifices, as appears by the constitutions of the Eastern emperors, collected in the Theodosian Code; but at length the emperors, neglecting the empire of the West, abandoned all care of the Latin tongue, and allowed their judges to pass sentence in Greek; and, accordingly, we find the emperor Julian's Novels composed in Greek.

Charlemagne, coming to the empire of the West, appointed the law proceedings in sovereign courts to be made in Latin; and the notaries were to draw their acts and instruments in the same tongue: this practice continued a long time through a great part of Europe; but at length it gave way, and the French took place of the Latin, not only in France, but, in some measure, in England too; and the reason given for it was, that abundance of difficulties arose about the understanding of Latin terms. See Law Language.

The Latin, however, was prodigiously degenerated and corrupted, before it came to be laid aside. The incursions of the Goths and Vandals into Italy brought an inudnation of foreign words and phrases into it; insomuch that Valla and Naud call Boethius the late Latin author. By command of Theodoric, king of the Goths, it was the hard fate of this worthy man, says Mr. Harris, to suffer death; with whom the Latin tongue, and the last remains of Roman dignity, may be said to have sunk in the western world. But that was not all; when it once got into the courts of justice, it was still worse handled; till, at last, being introduced amongst the monks, and become the common language of monastic and breviaries, it was debauched to that degree, that it was almost become scandalous to use it.

In this condition it was found at the time of the Reformation, when Vives, Erasmus, &c. began to open the way for its recovery; since which time monkish Latinity has been declining, and all endeavours have been used to retrieve the pure language of the Augustan age. It was said of cardinal Bembo, that he would never read the breviary for fear of corrupting his fine Latin.

LATIN. Bible. See Bible.
LATIN CHARACTERS. See Character.
LATIN CHURCH, is a term used for the Roman or western church, by way of opposition to the Greek church. See Church.

LATINÆ FERIE. See FERIE.

LATINI, Brunetto, in History, an early reviver of literature in Italy, was born at Florence in the early part of the fourteenth century; he was employed, about the middle of that century, by the Guelphs, in Florence, as ambassador to Alphonso, king of Castile, with the view of obtaining aid against Manfred, king of Naples and Sicily. By the prevalence of the opposite party he was driven from his country, and retired to France. At Paris he opened a school of philosophy, and wrote several books. We find him in his native country in 1284, and acting as syndic at Florence. He died in 1294. The most celebrated of his works was his "Teforo," a compilation from various authors, in history, philosophy, rhetoric, and morals. He translated into the Italian language part of the first book of Cicero de Inventione, and he was author of a moral work in verse, entitled "Il Teforetto." He is represented as a profound rhetorician and philosopher, and is said to have been the first who began to polish the language, and refine the understanding of his countrymen. Though he does not appear to have been a public inquistor at Florence, he probably gave private affilience in the studies of his friends, and he is mentioned as having been, in some measure, the tutor of Dante.

LATINI, Latino, a learned Italian, was born at Ver- terbo in 1513. He studied several years at Sienna, with a view to jurisprudence, which an ill state of health obliged him to relinquish. He then assumed the ecclesiastical habit, went to Rome, and became librarian to cardinal Rodolfo Pio, who, dying in 1564, left Latini the bequest of his copious library. He was employed in the reformation of the Decretal of Gratian, first undertaken by desire of pope Pius IV. and published under Gregory XIII. and committed to the care of many of the most learned ecclesiastics of the Roman court. He died in 1593, and bequeathed all his books to the chapter of Viterbo. He was highly esteemed for his learning and industry, though his modesty did not permit him to publish anything during his life-time. After his decease there appeared two volumes of his "Latin Letters, Poems, and other small Pieces." He communicated many emendations of Tertullian to the edition of that father published by Palmesi. His MS. annotations on the fathers, and on other authors, were given to the public in the "Bibliotheca Sacra et Profana," printed at Rome in 1657. Moreri.

LATIN, the Latin, in Ancient Geography, comprehended in general all the people of Latium, and particularly those who inhabited the territory along the Tiber from Rome to the sea. They were formed, it is said, by the union of the Aborines, or of people whose origin was not known, of the Pelagi, who had migrated from Thessaly, and of the Arcadians, brought thither by Evander, 60 years before the war of Troy.

LATION is used by some for the translation or motion of a body from one place to another.
LATISSIMUS COLLI, in Anatomy, a muscle of the neck, often called platysma noides. See DEGLUTITION.
LATISSIMUS DORSI, a muscle of the back, described under DORSI.
LATTITAT, in Law, a writ, whereby all men in personal actions are called originally to the king's bench.
It has this name, as supposing the defendant lurks, lies hid, and cannot be found in the county of Middlesex, to be taken by bill; but is gone to some other county, to the sheriff whereof this writ is directed. See BILL of Middlesex.
LATITUDE, in Geography and Astronomy. The latitude of a place on the terrestrial globe is its angular distance from
from the equator. It is measured on the meridian, being that part of it which is intercepted between the zenith of the place and the equator. See MERIDIAN.

If the place is situated to the north of the equinoctial line, it is said to have north latitude; if on the other side, its latitude is south.

When the spheroidal figure of the earth was once admitted, obvious methods, founded on astronomical principles, were immediately invented, to determine the latitude of places, or their relative situation to the equator. Previous to the establishment of this theory, nothing could be more vague and unsatisfactory than the methods employed by the ancients for determining the relative situations of the principal cities of the world to each other. But the knowledge of the true figure of the earth, not only suggested a more scientifical division of its surface by imaginary circles, supposed to be drawn on its circumference; but by referring these circles to corresponding ones in the heavens, astronomy and geography were combined, and the principles of the former were successfully applied to the improvement of the latter. Long before the apparent motion of the heavens was known to arise from the real motion of the earth, the two points which we now call the poles were referred to those two points in the heavens which were observed to be stationary; and a great circle of the terrestrial sphere, supposed to be every where equally distant from the poles, was called the equinoctial line, and assumed as a principal circle, to which geographical situations were to be referred; and as astronomers, in taking the ecliptic for their principal circle, had defined the positions of the heavenly bodies by their distances from this circle, and a perpendicular to it, calling these distances longitudes and latitudes; so, in imitation of this method, geographers assumed the equinoctial line as their standard, and taking another circle perpendicular to it, they referred all positions on the earth to these circles by the same name. Hence longitude and latitude, in geography, are not defined in the same terms as in astronomy, being in the latter always referred to the ecliptic, and on the terrestrial globe to the equator. This circumstance often embarrasses the young student in astronomy, who is naturally at a loss to comprehend why the same terms should have such different significations, when applied to the terrestrial and celestrial globe. It being once clearly understood that every point of the convex surface of the earth has at any given instant of time its corresponding point on the concave surface of the heavens, a number of methods were immediately suggested, and quite independent of actual measurement, for determining the situation of places, or their latitudes and longitudes as defined above. The most obvious method of defining the situation of points on a sphere, is to refer them to two great circles perpendicular to each other. On the celestial globe, whether we assume the equator or the ecliptic for one of these circles, we can have no hesitation in the choice of the other, because the equinoctial points are so remarkable, that they naturally indicate the advantage of making the second circle pass through them. Still, however, it must be remembered, that this choice is to a certain degree arbitrary; we might have assumed the equator or ecliptic for one principal circle, and for the other, a great circle perpendicular to either of them, which should pass through any remarkable fixed star, as Sirius, or Arcturus. The preference, however, has always been given to the equinoctial points, and, accordingly, as we assume the equator, or the ecliptic, as the principal circle, we define the situation of the different points by right ascension and declination, or by longitude and latitude. See RIGHT ASCENSION, and DECLINATION.

There is likewise another method occasionally employed by astronomers, but which relates only to their own particular situation at the moment of observation; this is by altitude and azimuth. The place of a heavenly body determined by this method is not permanent, but changes at every instant; and since no two observers can have the same zenith, no star can have the same altitude and azimuth at the same instant of time to different observers. See ALTITUDE, AZIMUTH, &c. &c.

In this latter method the principal circle assumed is the horizon, and the great circle perpendicular to it is that which passes through any two opposite cardinal points, as the North and South, or the East and West.

Let us now consider the terrestrial globe. Here the equinoctial line presents itself as the great circle, of all others the most proper for our purpose; but what is to guide our choice in the selection of another great circle perpendicular to it? We are not here afflicted, as in the celestial globe, by finding any one point possessing some remarkable property peculiar to itself; and even if there were such a point arising from local circumstances, it would have no representation in the heavens; and, therefore, would not facilitate the object of our present investigation, which is to shew by what method astronomers have contrived to determine the situation of points on the earth's surface, by finding their corresponding zenith points in the heavens.

Finding, therefore, but one great circle on the terrestrial globe indicated by nature, astronomers and geographers have been obliged to assume a second from circumstances entirely accidental. The first meridian has been differently assumed by writers of different countries. The French astronomers divide the celestial globe by two great circles; one of which is the equator, the other a great circle passing through the observatory of Paris, and to these great circles all other places are referred; hence, according to their definitions, if a great circle be conceived to pass through any place, and to be perpendicular to the equator, the latitude of that place will be the arc of this secondary circle between the equator and the place, and its longitude will be the arc of the equator, intercepted between this great circle and that which in a similar manner passes through the observatory of Paris.

English geographers and astronomers, in like manner, suppose their first meridian to pass through the Royal Observatory of Greenwich.

Having thus minutely described what is meant by longitude and latitude, both on the celestial and terrestrial globe, it remains to explain the different problems connected with the subject; and, with allude to the arrangement adopted in this work, we shall confine ourselves as much as possible to that part of the subject connected with LATITUDE, referring to LONGITUDE that which more immediately belongs to it.

The theory of finding the latitude of a place by astronomical observation is so simple, that it may be understood by merely inspecting a celestial globe. See GLOBE.

The meridian (Plate XVI. fig. 147. ASTRONOMY,) rises in our latitudes in the north point of the horizon O, passes through the pole P, through the zenith, and crosses the equator A E before it meets the southern point of the horizon. It is thus divided into four parts:

\[
\begin{align*}
PO & = \text{the latitude}, \\
PZ & = \text{the co-latitude}, \\
AZ & = \text{the latitude}, \\
HE & = \text{the co-latitude}.
\end{align*}
\]

It is evident, that if the value of either of these four arcs can be determined, the latitude is known.

The most ancient method of determining the latitude was by
by means of a gnomon; in this case the mean of the greatest
and least altitude of the sun was taken, which is always
equal to the co-latitude, or A.H. The altitude of the equa-
tor above the horizon, and the complement of this to 90, is
the latitude of the place. See GNOMON.
We shall first give the methods of determining the lati-
ditudes of fixed observatories on shore, and then describe
those which are best adapted to perform the same operation
at sea.

Method of determining the Latitude of a fixed Observa-
tory.—The best method of determining the latitude of a fixed
observatory, is by a long series of observations of the pole-star,
made with an 18-inch repeating circle of Borda. The
method of adjusting and observing with this instrument has
already sufficiently explained under CIRCLE and DECl-
NATION. But as this instrument is not in this country in very
genera/ use, we shall suppose the observer to be in possession
of an astronomical circle or quadrant, or some equivalent
instrument adapted to the determination of zenith distances
by meridional observations.

The latitude of an observatory may be determined with
very considerable accuracy by zenith distances of the sun
when near the summer solstice, as the obliquity of the
ecliptic is very correctly ascertained; but the most preferable
method is certainly by a regular series of observations on
circumpolar stars. Polaris, and $\beta$ Ursae minoris, are the
most eligible stars for this purpose. They should be ob-
served continually, both above and below the pole, and all
the observations carefully reduced to the first of January, of
the year in which the observations are made. It is evident,
that the mean of the latitudes above and below the pole, will
be the latitude of the pole itself. The accuracy of the result
will depend on the goodness of the instrument, the skill
of the observer, and the exactness with which the necessary
corrections have been applied. When the altitude of a heav-
ieny body is taken with an astronomical instrument, the
observer must first consider what correction is required from
the nature and construction of the instrument itself; such
as the error of collimation, or index error, error of division,
&c. This being properly allowed for, the observation is next
to be corrected for refraction, and here attention must
be paid to the state of the barometer and thermometer, and
the mean refraction corrected accordingly. The true al-
itude, or zenith distance, being thus ascertained, the next step
is to determine what would have been the true zenith distance
if the observation had been made on the first of January, in-
stead of the given day. For this purpose we must apply the
precession, aberration, stellar and lunar motion, and likewise
corrections arising from the proper motion of the star
whenever this can be known. By a careful discussion of a
series of observations thus corrected, the latitude is to be
obtained, and with a good two-feet circle a skilful observer
will never err above a second or two from the truth, except
from the little remaining uncertainty which still attends the
subject of astronomical refractions.

In the Philosophical Transactions for 1806, Mr. Pond
suggested a method of correcting the respective latitudes of
any two observatories, by means of the catalogues of stars
made at each of them, and applied it with success to the
correction of the latitude of Palermo. The principle of the
method is this: If the declinations of a number of stars are
observed at two observatories, subject only to the errors of
division in the respective instruments, the positive and
negative errors may be naturally expected to be nearly equal
to each other; if, therefore, the declinations of one catalogue
should be all either greater or less than in the other, it would
indicate that the error was in the ascribed latitude, which
enters as a common element of calculation, and not in the
observations themselves. Now if such a correction be applied
to the latitude of each observatory, as will make the sum of the
positive differences equal to the sum of the negative, the
lattitudes thus corrected will be much more accurately
determined than by any method that can be practised se-
parately.

Examples of deducing the latitude from observations
of the sun; taken from the Greenwich Observations of
1810.

Results.
This method is subject to whatever error may exist in the solar tables relative to the declination of the sun. The following example is taken from Dr. Bradley’s Observations, for the purpose of determining the latitude of the Royal Observatory at Greenwich.

### LATITUDE

Below is the table for calculating the latitude:

<table>

On the method of finding the latitude at sea.—The method of finding the latitude at sea by a meridional observation of the sun or star, differs so little from that above explained, and is so fully described in books which mariners are never unprovided with, that scarcely any thing need be added on the subject. Some of the nicer corrections used at land may be omitted, and others will be necessary; such as the correction for the depression of the horizon, and the index error of the sextant, all which are to be found in every book of navigation. (See DEPRESSION.) The latitude may be found either by taking the meridian altitude of the sun, moon, or fixed star. But it sometimes happens that, in the winter season, a meridian altitude cannot be taken for many days together; in that case, recourse must be had to two altitudes of the sun taken at different times, the interval between the two observations being supposed to be given by a pocket chronometer.

Many able mathematicians have successfully laboured to improve this problem, and to render it easy to mariners. Mr. Professor Lax of Cambridge presented a very valuable paper on this subject to the Royal Society in 1799, in which a method is given of finding the latitude by a double observation, with extreme precision; and Dr. Brinkley likewise constructed a set of very useful tables, which were for some time annually inserted in the Nautical Almanacs. Problems relating to the finding the longitude and latitude of the heavenly bodies, from their observed passage over the meridian, with their zenith distance.

We have already explained, under DECLINATION and RIGHT ASCENSION, how these quantities are obtained. We shall now add an example of the calculation, by which the longitude and latitude are deduced from an observed right ascension and declination.

Example.—October 2, 1811. The right ascension of the comet was obtained from observation 6° 23° 42' 13", and its declination 49° 31° 2" N.; required its longitude and latitude.

\[
\begin{align*}
\text{Dec.} & \quad 49° 31' 2'' \\
\text{A. R.} & \quad 6° 23' 42' 13'' \\
\text{A.} & \quad 71 3 40 \\
\text{Obliqu. of ec.} & \quad 23 27 41 \\
\text{O + A = B} & \quad 94 31 21 \\
\text{Cof.} & \quad 9.9975435 \\
\text{Lat.} & \quad 53 17 9 \\
\end{align*}
\]

\[

\]

When the moon's longitude and latitude are to be deduced from its observed right ascension and zenith distance, the process is much longer; and as the calculation is not given at length in any author we are acquainted with, we shall add an example, with the method of comparing it with the Nautical Almanac.

First, compute the mean time by Dr. Maskelyne's folio tables, or other equivalent solar tables. To the mean time of the transit thus found, apply the equation of time taken out of the Nautical Almanac with a contrary sign, and this will be true or apparent solar time. From the moon's horizontal equatorial parallel, taken from the Nautical Almanac, subtract the correction, page 75 of Mayer's Lunar Tables, or, still more correctly, a quantity which will be given in a table we propose to annex to the article Parallax, the remainder will be the moon's horizontal parallel. From the observed zenith distance of the \(\gamma\)'s U L or L L corrected for refraction, subtract the confluent quantity \(10'3''\), which is the angle the vertical makes with the radius, (see DEGREE and Figure of the Earth,) and add the log. fine of remainder to the log. fine of \(\gamma\)'s horizontal parallel, the sum will be the log. fine of \(\gamma\)'s parallax in zenith distance; which subtracted from the observed zenith distance, gives the corrected zenith distance. To this add \(\gamma\)'s horizontal semidiameter, (taken from Nautical Almanac,) if U L was observed; or subtract, if L L; and thus the correct zenith distance of the \(\gamma\)'s centre will be obtained. The difference of this quantity, and the latitude of the place, \(\pm\) error of collimation, will give the required declination north or south, as the first is greater or less than the second.

But if the \(\gamma\)'s zenith distance was not observed exactly at the time of the transit of the preceding or subsequent enlightened limb, this declination must be corrected by the following proportion

As 12 hours is to the interval of time between the two observations, so is the variation of declination on 12 hours by the ephemeris to the correction required, and which must be thus applied:

\[
\begin{align*}
\Delta \text{declination increasing} & = \Delta \text{declination decreasing} \\
& = \Delta \text{declination increasing} \\
& = \Delta \text{declination decreasing} \\
\end{align*}
\]

Thus the true declination will be obtained from observation.

From log. fine of \(\gamma\)'s horizontal semidiameter, subtract the log. conline of \(\gamma\)'s true declination, the remainder will be log. fine of \(\gamma\)'s semidiameter in A. R., which add, if preceding limb was observed, namely, before the full; or subtract, if \(\gamma\)'s subsequent limb was observed after the full, or from A. R. of limb; and this will give the true A. R. of \(\gamma\)'s centre.

Next with the apparent time previously found, compute the \(\gamma\)'s longitude and latitude by proportion from the Nautical Almanac, and apply the corrections for a second difference (from Taylor's Sexagesimal Tables). N. B. Compute the proportional part of the moon's motions in longitude doubly by the rule of practice, by changing the second and third terms of the proportion for each other, for greater certainty.

Then from the true A. R. and declination found above, and the apparent obliquity of the ecliptic, compute the longitude and latitude by Dr. Maskelyne's rules, annexed to the precepts prefixed to Taylor's Logarithms, and the difference between this and the longitude and latitude, found as above by proportioning from the Nautical Almanac, gives
LATITUDE.

gives the error of the tables. N. B. Compute the longitude and latitude from A. R. and declination affirmed to the nearest second over or under; and after the operation, correct it, that is, as much as the true A. R. exceeds or falls short of that found. And as much as the true declination is north or south of that assumed, so much the true latitude may be north or south of that found; which correct accordingly.

Example of the calculation of the moon's longitude and latitude, January 6, 1811, and compared with the Nautical Almanac.

In the following examples the second and third terms of the proportion are reversed by way of proof.

On the secular variation in Longitude and Latitude of the fixed stars.

We have already explained, under Ecliptic, the cause of the change of position in this circle, which produces a secular variation both in the longitude and latitude of the fixed stars. The following table by M. Zach is intended to facilitate the calculation of this quantity, and has not yet been published in this country.

The formula used for the construction of these tables are,

Sec. var. north lat = \(52°.6318\) fin. (long \(+ 853\) 13')

Sec. dmi. in long. \(52°.6318\) cof. (long \(+ 853\) 13')

tangs. lat. \(+\). See Freqeesion.

**Examples of the use of the following tables.**

Let it be required to find the secular variation in latitude and longitude of Aldebaran for 1700—1800.
**LATITUDE.**

The long. of Aldebaran for 1750 = 21° 60' 16" 0'.

Latitude south = 5° 29' 16" + 50.812

Var. in lat. by Table III. for 21° 60' = 0.079

Prop. part for 18' = + 0.079

Sum = 50.882

But the latitude being south, the sign must be changed:
the secular diminution of latitude is therefore = -50°.882.

*To find the secular variation in longitude.*—First find the subdiary angle α.

Since the latitude is south, the sign must be changed:
therefore the secular increase of longitude of Aldebaran is 1°.29.

</table>

The sum or difference of the two quantities taken from this table by the two arguments, will be the secular variation in longitude, which, when the auxiliary angle \(\beta\) is used, is to be multiplied by 10.
LATITUDE, in Ancient Geography, a considerable division of Italy, which acquired importance from its having given name to the Latins, and from its having Rome for its capital. Some authors have thought that this was a denomination given to the whole of Italy, or at least to a more considerable extent of territory, than that to which it was afterwards confined. Several of the ancients have fought the etymology of Latium, in the verb later, to conceal, and they have imagined that this name was given to the country, because Saturn retired thither in order to shelter himself from the fury of his children. M. Gellius, in his Oriental Antiquities, makes the inhabitants of the Tyrrhenian Sea, the Etruscans, the Greeks, the Latins, and the Sabines, to have been of the Sabine tribe. Hence the Latins were called Sabines, and the Sabines were called Latins. The Latins were the most ancient of the Roman people, and they were the first to settle in the city of Rome. The Latins were divided into two principal classes, the patricians and the plebeians. The patricians were the ruling class, and the plebeians were the working class. The Latins were the ancestors of the Romans, and they were the first to settle in the city of Rome. The Latins were divided into two principal classes, the patricians and the plebeians. The patricians were the ruling class, and the plebeians were the working class. The Latins were the ancestors of the Romans, and they were the first to settle in the city of Rome. LATOMOS, or LATUMUS, a mountain of Asia Minor, partly in Ionia and partly in Caria.

LATMUS, originally a village of Asia, in Clicia, on the banks of a river of the same name, which afterwards became an episcopal town of Iliria. The river had its source in mount Latmus, and discharged itself into the Latmic gulf, near the town Heraclea. The Latmic gulf was a gulf of Ionis, which commenced between the mountains Latmus and Grissus, and extended from thence towards the N.W., communicating with another gulf at the mouth of the Meander — Also, a small island situated to the S.E. of the Latmic gulf, near Tarsus and W.N.W. of Heraclea.

LATOAN, in Geography, a small island in the East Indian Sea, near the coast of Borneo. N. lat. 7° 16'. E. long. 117° 21'.

LATOMIA, Antiquias, derived from the Greek lato, flos, and epwm, I cut, properly signifies a quarry, or place where bones are dug. See Quarry.

There were anciently used as goals for criminals. Dionyus had a place of this kind dug in a rock near Syracusae, where an infinite number of people were shut up. Cicero reproached Verres with imprisoning Roman citizens in latomia; so that latomia became a general name for a prison; fore’ prisoners included in them were called latomarini.

LATOMIA, in Ancient Geography, the name of six small islands in the Arabian gulf, according to Strabo.

LATONA, a town of Egypt, upon the Nile, which was the capital of a nome called the Nomos Latopolites. Ptolemy.

LATONIA, in Mythology, a goddess of paganism, whose habitation is very obscure. Heifod makes her the daughter of Titan Coeus and Pheme, his sister. The fable adds, that Apollo and Diana were her offspring by Jupiter, and that they advanced her to the rank of a goddess in spite of Juno. According to Herodotus, she was an Egyptian deity, the nurse, and not, as the Greeks represented her, the mother of Apollo and Diana, and was worshipped at Buta, or Butos, in Egypt. The inhabitants of Delos erected a temple for her, pretending that Neptune, with a blow of his trident, had made the island of Delos to rise up from the bottom of the sea, to secure to Latona, persecuted by Juno, a place where she might, without molestation, bring forth her children; but that at Argos was the most magnificent, and celebrated for her statue, executed by Praxiteles. Latona, Venus, and Diana, were the three goddesses most in veneration among the Roman women.

LATOPOLIS, or Latopolites Nomos, a district of Egypt, the capital of which was dedicated to Latona, and situated on the left of the Nile. This nome is mentioned both by Strabo and Pliney.

LATOPOLITES Nomos, or Hermopolis Nomos, another district of Egypt, the capital of which was the town of "Latonum," according to Ptolemy.

LATORCZA, in Geography, a river of Hungary, which rises near the Carpathian mountains, and runs into the Thejla, near Tokay.

LATOUCHIE'S ISLAND, an island in the North Pacific ocean, at the entrance of Prince William's Sound, 13 miles long and three broad. N. lat. 60°, E. long. 212° 59'.

LATOVICI, in Ancient Geography, a people of Upper Pannonia.

LATOUR, in Geography, a town of Hindooslan, in the circar of Aurungabad; 25 miles W. of Aurungabad.

LATOWIC, a town of the duchy of Wallachia; 18 miles S. of Czecisk.

LATTRIA, Antiquias, in Theology, a religious worship, due only to God.

The Romanists say, "They honour God with the worship of latria; and the saints with the worship of dulia;" but the terms, however distinct, are usually confounded.

The worship of latria, besides its inner characters, has its external marks to distinguish it; the principal whereof is sacrifice, which cannot be offered to any other but God himself, as being a solemn acknowledgment, or recognition, of the sovereignty of God, and our dependence on him.

M. Daille seems to own, that some of the fathers of the fourth century allowed the distinction between latria and dulia. See Adoration and Worship.

LATRIS, in Ancient Geography, a town of Germany, at the mouth of the Vistula. Pliney.

LATRONICA, in Geography, a town of Naples, in Bafilicia; 22 miles S.W. of Turf.

LATSCHACH, a town of the duchy of Carinthia; 14 miles S.W. of Clagenfurt.

LATTANZIO, GAMBARA, in Biography, a painter of history and portraits. He was the son of a taylor at Cremona; but being more inclined to painting than the use of the needle, he spent his youthful days in covering the walls and furniture of his father's house with drawings in charcoal, and thus drew upon himself the displeasure of his parents; who envied their dissatisfaction by the unequivocal testimony of the foes.

Giulio Campo, an artist of some celebrity, refusing at Cremona, happened one day to pass by when the taylor was exerting his energies upon the back of his felt-willed son Lattanzio; hearing the caufe, he took the boy home with him, and for six years assisted and encouraged him in his pursuit of the art of painting. Such was the success accompanying this act of generosity, that according to Vafari, Gambara became the best painter of his time in Brescia, where he took up his residence; and where many ingenious artists practiced painting in conjunction or competition with him.

His principal works are in fresco, and some are still to be seen at Brescia, particularly the cloister of Santa Euphemia, wherein he painted a series of scriptural and evangelical subjects. Venice, Parma, and Cremona all possess testimonials of his skill, which adorn their churches and many of their private houses. His style is very much like that of Pordenone, an attempt to unite the colour of the Venetian with the drawing and design of the Florentine school, but it is not so powerful. He married a daughter of Romanno, but died at the early age of 32, by a fall from a scaffold while painting.
LAT

painting in the church of St. Lorenzo in Brescia, about the year 1670. Ridolli. Vafari.

LATIMO, in the Clafs Trade, a name for a fine milk-white glass. There are several ways of making it, but the best of all is this: Take four hundred weight of crystal frit, and fifty pounds of calcined tin, and two pounds and a half of prepared manganese; mix these well with the frit, and let them in a pot in a furnace to melt and refine. At the end of eighteen hours this will be purified; then cast it into water, purify it again afterwards in the furnace, and make a proof of it. If it be too clear, add fifteen pounds more of calcined tin; mix it well with the metal, and let it stand one day to purify; it will then be of a whiteness surpafling even that of snow, and is fit to work into vessels. Neri's Art. of Glasses, p. 98. See Glass.

LATTIN, or Latten, a name by which we used to call the plates of iron covered with tin, and now usually called tin, of which our mugs, and such other things, are made. The principal part of the work is to prepare the leaves, beat out to a proper thickness, so as that they shall readily receive the tin; for if there be but the smallest particle of dust on them, or only the slightest ruit in any part, the tin will never fix there.

This smoothing of the plates is effected by steeping them in acid water, till the surface is a little preyed upon by it, and then they are fowered with sand, which makes them very smooth and fine. By this means a woman cleans more plates in an hour, than the most expert workman can do otherwise in many days. M. Reaumur, to whom the world owes the discovery of this process, mentions several waters, any one of which will succeed, but the Germans themselves use nothing but common water, made eeger with rye. This they make a great secret of, but the preparation is very easy. After they have ground the rye groatsly, they leave it to ferment in common water for some time; and they are thus liable of a sharp and eager metalrum, excellently fitted for their purpose. With this liquor they fill certain troughs, or tuns, and into these they put several bundles of the plates of iron: and to make the liquor more eeger, and to act the better on them, they keep it in foves, where it has little air, and is kept warm with small charred ashes.

There are several other ways of making iron ruff, as keeping it in a moist cellar, exposing it to the dew, sprinkling it with simple water, or, which is still better, with water in which fat ammoniac has been diffus’d, several times a day: and in those countries where the pyrites is common, the vitriolic waters, which partake of it, will do it very well. This water may be prepared at little or no expence, only by heaping up large quantities of the pyrites, and letting it moulder in the air, then putting it into common water, and making a licnivum of it. Whichever method of ruffling the plates be used, it is always necessary to fower them with sand as soon as it is done; and when they are thus cleaned, they must be immediately plunged into water, to prevent their ruffling again, and they are to be left in this water till the infant in which they are to be timbered, or, in the language of the workmen, blanched. The people employed in this part of the operation are called blanchers; and the others, who assist at the cleaning of the plates, the scapers. The blancher makes as great a secret of his art, as the scaler does of his; and it was with great difficulty that M. Reaumur obtained it. The manner of doing it is this:

They flux the tin in a large iron crucible, which has the figure of an oblong pyramid with four faces, of which two opposite ones are less than the two others. The crucible is heated only from below, its upper part being luted with the furnace all round. The crucible is always deeper than the plates, which are to be timbered, are long; they always put them in downright, and the tin ought to swim over them. To this purpose artificers of different trades prepare plates of different shapes, but M. Reaumur thinks them all exceptable. But the Germans use no sort of preparation of the tin, to make it receive the tin, more than the keeping it always steeped in water till the time: only when the tin is melted in the crucible, they cover it with a layer of a sort of fuel, which is usually two inches thick, and the plate must pass through this before it can come to the melted tin. The first use of this covering is to keep the tin from burning: as if any part should take fire, the fuel would soon moisten it, and reduce it to its primitive state again. The blanchers say, this fuel is a compounded matter. It is indeed of a black colour, but M. Reaumur supposed that to be only an artifice to make it a secret, and that it is only coloured with fuel, or the flame of a chimney; but he found it true so far, that the common un prepard fuel was not sufficient; for after several attempts, there was always something wanting to render the success of the operation certain. The whole secret of blanching, therefore, was found to lie in the preparation of this fuel; and this he at length discovered to consist only in the first frying and burning it. This simple operation not only gives it the colour, but puts it into a condition to give the iron a disposition to be timbered, which it does surprizingly.

The melted tin must also have a certain degree of heat, for if it is not hot enough, it will not stick to the iron; and if it is too hot, it will cover it with too thin a coat, and the plates will have several colours, as red, blue, and purple; and upon the whole will have a call of yellow. To prevent this, by knowing when the fire has a proper degree of heat, they might try with small pieces of iron, but, in general, it teaches them to know the degree, and they put in the iron when the tin is at a different standard of heat, according as they would give it a thicker or thinner coat. Sometimes also they give the plates a double layer, as they would have them very thickly covered. This they do by dipping them into the tin, when very hot, the first time, and when less hot, the second. The tin, which is to give the second coat, must be fresh covered with fuel, and that with the common fuel, not the prepared. Philos. Trans. N. 140, p. 634. See Tin.

LATYPHOURS, in Geography, a town of Bengal; 20 miles N. of Kithanagar.

LATUS, in Ichthyology, the name of a fish of the coracinus, or umbra kind, caught in the Nile, and in the Adriatic and Mediterranean seas. It much resembles the common coracinus, but is larger, and has not the beard which hangs from the chin in that species; and its body is somewhat rounder. It is esteemed a very delicate dish. Rondelet. de Pisc. p. 130.

LATUS, in Anatomy, a name given by many authors to one of the muscles of the anus, now generally called the levator ani.

LATUS Rentum, in Conics, the same with parameter. See Conic Sections, and Parameter.

LATUS Transversulum of the hyperbola, is a right line, intercepted between the vertices of the two opposite sections; or that part of the common axis which is between the vertices of the upper and lower cone. See Hyperbola.

LATZKI, in Geography, a town of Austrian Poland; 80 miles N.W. of Lemberg.

LAVA. This word, in its strict sense, denotes only the fused flomy substance which issues from volcanoes during the time of their activity, and according to the degree of fluidity it has acquired, and the quantity in which it is discharged,
charged, either collects near the crater in amorphous groups, or extends its course to various diversities. Butler much greater latitude (as we shall see hereafter) has been given to the term lava by several authors, for not only other volcanic ejections, to which the above definition cannot be applied, have been described under that name, but even such unaltered rocks as will be allowed by unbiased observers to have fearlessly any one character in common with real volcanic productions.

Werner has divided lava into two varieties only; viz. 1. Scoriaceous or flaggy lava (Schlackige Lava), and 2. Foamy lava (Schaumige Lava.)

The colour of the scoriaceous lava is greyish-black, which passés into smoke-grey, yellowish-grey, reddish-grey, greenish-grey, and through several shades of this into greenish-black. Decomposition, sulphurous and other vapours, frequently modify the principal colours, and often produce the higher tints of yellow.

It occurs more or less knotty and vesicular, with vesicles of different size, sometimes glazed over, and empty. Internal luster between glimmering and glintening, seldom shining. Fracture imperfectly conchoidal, sometimes fine-grained, uneven. Is commonly opaque, sometimes faintly translucent on the edges. It is semi-hard, brittle, easily frangible, and not particularly heavy.

The colour of the foamy lava is generally dark greenish-grey, approaching to greenish-black. Its vesicular structure, brevilefns, and lightness are indicated by its name.

This the Wernerian school carefully distinguishes from pumice; which see.

Lava is often porphyritic, but the crystals of hornblende, augite, &c. are, according to Werner, wrapped up, not imbedded, in its basis; and when they occur in the hollows or vesicles of lava, are not in the form of druses, but generally part of the crystals projecting into the cavity, while the other is included in the lava.

Though the Neptunists professe to find characters sufficiently obvious to distinguish lava from unaltered rocks that might be mistaken for it, such as the rough aspect which it presents both internally and externally, &c.; yet their decision in dubious cases is known to be chiefly regulated by the mode of occurrence of the rock; and substances, that present regular strata, not seldom of very considerable extent and comparative thickness, and frequently conformable to all the similitudes of the older formations, can never be expected to find a place in their catalogue of volcanic productions.

The question, whether lava ever occurs in a compact state, involves the various controversies with regard to the origin of basalt, which will be treated of at large in its proper place. But as it is necessary in this article briefly to advert to the reaons that have induced Werner, and other Neptunists, to exclude compact lava from their systems, we shall extract the excellent observations given on this subject by Mr. Kirwan, in the second appendix to his Mineralogy.

"By compact lava," says this distinguished mineralogist, "volcanic writers denote an earthy substance, which, after having been fused, but not vitrified, becomes, on cooling, compact, close, and solid. Whether this degree of solidity is such as totally to exclude that evidently porous and cavernous structure, which cellular lava presents, is not perfectly agreed upon.

"Thofe who are guided by observation on modern and undisputed volcanic torrents, allow that no lava, absolutely compact and destitute of pores, in an extent of more than a few square inches, is ever found. Thus Mr. Bergman defines compact lavas to be those which, though not absolutely destitute of cavities, yet contain so few, that they may be cut into slabs with an almost entire surface, and polished like marble." (Bergm. p. 201.) To this definition, Mr. Dolomieu, in his notes on Bergman's Dissertation, makes no objection; from which we may conclude, that in a small extent, such as that of common marble slabs, they never exhibit an uninterrupted surface. This last mentioned philosopher, indeed, having unfortunately wished to comprehend, in his definition of compact lava, flinty masses, not found in modern and undisputed beds of lava, but in supposed ancient currents, found himself much embarrassed: There is, says he, such uncertainty in the characters of compact lava, that, independently of local circumstances, the most experienced eye may be deceived. (Hês Ponces, p. 171.) Yet these circumstances, not properly attended to, are those which have seduced him into the most palpable mistakes.

"Gioeni, though in many inferences misled by Dolomieu, yet acknowledges that lava, so compact as to be totally destitute of pores, is not found. (Lithol. Vefuv. p. 85.) Padre Torre, who, independently of any fyllam, has candidly and impartially examined the products of Vefuvius, expressly denies the existence of lava destitute of pores, none other but the porous being found in currents of modern date. Gioeni, in his catalogue of this lava, of Vefuvius, drawn up in 1772, hardly mentions any compact lavas. Gioeni, in his catalogue, entirely omits this distinction; and Mr. Dolomieu acknowledges that not a single specimen of compact lava is to be found in the cabinet of prince Bucari.

"Thofe, on the other hand, who, guided by fyllam, before the name of lava on flinty masses, which they fuppofe to have anciently flowed, either from real flill bubbling, or imaginary ancient extinct volcanoes, find compacts lava entirely destitute of pores, very fcarce, indeed in the fuppofed currents from modern, but in great plenty in those in which they ascribe to their fictitious volcanoes now extinct, as well as in the very bowels of thofe volcanoes.

"Gioeni, after telling us, that compact lava occupies the centre of the beds of lava, and porous lava the upper part, acknowledges that this gradation seldom takes place; fowever, however, says he, are the visible currents of lava on Vefuvius, in which we meet this gradation. It seems, he should rather have said, none; for, some lines after, he tells us, that modern volcanoes have left the power of producing any. (Lith. Vefuv. c. xii.) The detached masses that pass for compact lava, he acknowledges to have been ejected in their fold form by the explosive power of the volcano, and consequently are not real lavas, but rather natural stones, torn from the sides of the mountain. (Lith. Vefuv. i. ) Mr. Dolomieu tells us, that compact lavas are those which, after having been melted, re-assume their natural state and appearance without any change in their external or internal properties, or scarce any change; and that some are perfectly compact (that is, destitute of pores), namely, those that are buried under, not other lavas, but under an entire and immense volcano (De Prod. Vofuv. p. 162. Ponces. 170. 179.) he, therefore, gives up the idea of finding these not only in the beds of modern, but even in those of extinct ancient volcanoes. Hence he tells us, that they are much more common in extinct volcanoes; and that in Etna they do not constitute the fifth part of the whole; whereas in Vivas and Auvergne they form whole mountains. Now most of these ancient volcanoes of the Vivarais appear to me and many others, to be mere creatures of imagination, and consequently, until the substances they contain are proved to have been in fact, no definition, grounded on the appearances.
L A V A.

anes of these substances, can pass for that of real compact lava.

"In beds, however, of real undisturbed lava, some parts are
found, that, having been pressed by the super-incumbent
weight, are more compact than common porous lava; and
these, comparatively to the former, may be called compact;
but scarcely more than a few square inches of their substance
is definite of visible pores.

"Their colour is brown, yellowish, reddish brown, bluish,
or black, more rarely grey. Their lustre 0.1. Transparency 0.1.
Their fracture earthy, or fine splintery, more
rarely foliated, and presents small internal pores, if of suf-
ficient size, in some part of the substance. Hardness from
7 to 9. Specific gravity 2.75 to 2.95.
"Much circumstanced is requisite in framing a description
of compact lava, from a view of the specimens brought to us
from volcanic countries, as they are all collected by persons,
who take indiscriminately from real, and from supposed,
volcanic currents, even from mountains in which no volcano
ever existed.

"To form a true idea of these lavas we should attend to the
following circumstances: 1. That the heat of most volcanoes
(exclude those that for the most part produce only vitrified
substances) seldom reaches 100° of Wedgwood; the proof
of which is, that almost all real lavas, whether cellular or
compact, are vitrifiable at that degree. Since, therefore,
they were not vitrified in the volcanic. It is plain, that in it
they did not attain that degree; 90 or 95 degrees may then
be assumed as the average heat of most volcanoes. 2. In this
heat many stones of the argillaceous genus, as trapps, horn-
blendes, and argillites, undergo a change; for they alter
their colour, become porous, assume a porcelain grain, and
consequently begin to vitrify, as I have found on repeated
trials; but they never flow in this heat, nor consequent-
ly form a lava; but bitumen will flow in this heat, and even
in one much inferior, and be decomposed. If, therefore,
the argillaceous stones be mixed with and drowned in bitu-
men, they will be softened by it, and flow with it; and
where the air, erupting both from them and the decomposing
bitumen has molten liberty to escape, it will tumify, burst
through the liquid mass, and form cellular lava; but, where
it is more compressed, less of it will be disengaged, and the
lava will be compact, and retemble, in some degree, the or-
iginal stone of which it is formed. 3. Stones of the silicious
genus undergo no change in this heat, not even floris or
feldspar; and hence, though immersed in the fiery torrent,
they cannot with propriety be called lavas, as they are not
even softened by the mixture of bitumen, as stones of the
argillaceous genus are.

"Between silicious and argillaceous stones there are many
gradations and various mixtures, which must occasion cor-
responding varieties in the effects which heat and various
other circumstances may produce. It is sufficient here to
establish the principles on which most of them may be ex-
plained. Compact lavas abound in heterogeneous substances
which either have not been fused, or only partially fused or
mixed, or decomposed by heat, as feldspar, floris, garnets,
tourmalines &c. Every volcano has some that are peculiar to
it. Thus the lavas of Vefuvius abound in that called white
garnet, and which I call Vefuvian, those of Etna abound in
feldspar, &c.

"Hence we must exclude from the rank of lavas all stones
which do not appear, either from their external characters
or local circumstances, ever to have been softened by heat;
and consequently, all those detached pieces which are ejected
at the beginning of an eruption without fusion, and many
others which volcanic collectors enumerate among compact
lavas, merely from having found them in the vicinity of
volcanoes. Thus Mr. Dolomieu (Lapi, p. 85.) reckons
among volcanic stones one, in the interior of which he
distinctly perceived a leaf of tea-weed. Few indeed are the
stones contained in his catalogue which can be deemed really
volcanic.

"All real lavas, except those of the vitreous kind, affect
the magnetic needle, unless the iron they contain be much
oxygenated, as it often is in those of a red colour; but even
these are frequently magnetic by reason of the thorium
embodied in them.

"The component ingredients of lavas are various, accord-
ing to the nature of the original stones, and the accidents
they meet with in their liquitated state. Mr. Dolomieu
found them to contain from 40 to 55 per cent. of filxen, from 16 to
3 of magnesia, from 5 to 1 of calcium, and from 2 to 25 of
iron." Poncet, p. 184.

Though the above, and several other remarks of the same
tendency, which will be noticed under the articles TRAPP
FORMATION AND VOLCANO, have much contributed to in-
avidate the testimony of those who contend for the exis-
tence of compact lava, and the igneous origin of many other
substances apparently Neptunian, yet volcanists continue to
classify over and over again those substances which they con-
sider as belonging to their domain; and it is necessary to
be acquainted as well with their mode of viewing the subject
as with that of the opposite party. It is with this view
that we give the following abstrait of the most complete
arrangement of, so called, volcanic rocks hitherto offered
to the world, namely, that of the celebrated Faujas de
Saint-Fond, which occupies nearly a whole volume of his
"Effays de Géologie," published at Paris in 1869. It is
almost superfluous to observe that this arrangement should
be confounded con gravo falsis; as of course almost all the
rocks belonging to the flatus-trapp formation of Werner are
introduced into it, as well as other substances, which,
although ejected, have probably not undergone any altera-
tion by the agency of the fire, and are therefore to be con-
sidered as intruders into an arrangement of lavas.

CLASS I. LAVAS CONSIDERED WITH REGARD TO THEIR FORM AND
EXTERNAL MODIFICATIONS.

Div. 1. Black, homogenous, massive, compact lavas.—
1. Fine-grained; from Otathhe, Staffa, the neighbourhood
of Rome, Darmstadt, the Euganean mountains, Auvergne,
&c. 2. Var. of a coarse grain, from Meiffen, the vicinity
of Gottingen, Heife Caffel, Rochemaure in Vivaria, &c.;
3. Var. of a fealy texture; from Stolpe in Meiffen, the
isle of Bourbon, Mont Meillin in Vivaria, &c.

Div. 2. Homogeneous compact lava in prismes, with from
two to nine sides (the latter rare).—1. Prisms without joints;
Staffa, Exploy in Vivaria. 2. Var. with prisms trans-
versely divided or jointed; at the Pont de la Beanne in
Vivaria, &c. 3. Var. with jointed prisms; jointes concave at one
side and convex at the other; Giant’s Caufeway, Ireland,
left bank of the Volane, &c. 4. Var. with prisms laterally
compressed; Rochemaure in Vivaria. 5. Var. with arched
prisms; Staffa, isle of Bourbon.

Div. 3. Prismatic lava, with edges and planes so regular
as to appear the result of crystallization.—In pyramids of four
sides, flattened, &c.; in Auvergne, &c.

Div. 4. Tabular lava.—1. Var. in thick table; from
Monts Meillin, Coneron, &c. in Vivaria. 2. Var. in thin
table; Rochemaure in Vivaria, isle of France, isle of
Bourbon.

Div. 5. Globular lava.—1. Var. in solid balls; from
Teneriffe. 2. Var. in hollow balls; isle of Bourbon. 3. Var.
in balls composed of concentric layers; from Vefuvius,
Catel-
Of the A.

Cacil-Gomberto near Vicenza, Montechio Precalino, &c. These lavas are the result of a particular kind of decomposition, which takes place in extensive beds of compact basaltic lavas, in which they appear as if implanted. Some globular lavas owe their origin to the joints of basaltic pillars, whose angles and edges decay, while the nucleus remains found, and appears to issue from out the prifin.

Div. 6. Teardrop-shaped lava (lava in larnes).—Small oblong masses, imitating more or less the form of tears. They occur from the size of a hazel-nut to that of an egg, often enclosed within their centre the fragment of a foreign body, such as granite, olive, &c. Common on Vesuvius, in the crater of Mont-Brill, in Vivara, Auvergne, &c.

Class II. Porous lavas.

Div. 1. Heavy porous lava.—1. Var. with large oblong pores; from Vesuvius, Etna, Hecla, Vivara, Auvergne, &c. 2. Var. with large irregular pores; in all the above places. 3. Var. with pores less large, and generally round; in a partly porous, partly compact lava; from the Melfi-in Heffa. 4. Var. with small, round, and oblong pores; in a lava remarkable on account of its hollows or depressions, which exhibit a regular structure, and, on being broken, convey the idea of parallelograms of different sizes: arranged side by side, as well externally as on the internal surface of the lava: some of these parallelograms are more than an inch long, and the fourth part of an inch deep. The origin of this lava, which occurs in the isle of Bourbon, is thus explained by M. Hubert:—A great eruption of the volcano of that island gave origin to a vast stream of lava, which in its progress came in contact with a plantation of palm trees. The trees were immediately set on fire, but being soon covered by the lava, combustion ceased, and the wood became converted into charcoal. Incandescence long time continued, afterwards produced in the fibrous wood, thus carbonized, contractions and clefts of a certain regularity. The lava next entering the clefts formed by contraction, and moulding itself over the nucleus of the coal, produced the hollows observable, as often as the coal is purposely detached, or destroyed by some accidental cause. 5. Var. of prismatic triangular form, with oblong and irregular pores; from the neighbourhood of Rochefoucault, in Vivara.

Div. 2. Light porous lava.—1. With round pores; from Vivara, Auvergne, isle of Bourbon, Tunis, &c. Desfontaines has gathered at Tunis specimens of such a lava, which the natives employ in the preparation of their woollen stuffs, in preference to the fuller's thistle used in other countries. 2. Var. with oblong pores; from Vesuvius, Etta, Hecla, from Vivara, Auvergne, &c. 3. Var. with irregular curved or twisted pores; from Vesuvius, the isle of Bourbon, Teneriffe, Stromboli; Vulcan, Vivara, &c. 4. Var. with decinated pores; from the isle of Bourbon, Vesuvius, &c. 5. Var. with fractured pores; from Vesuvius, Etta, isle of Bourbon, and Mount Hecla.

The light flated lavas, appearing in the shape of cables, ribbands, &c. also belong to this clafs. In general, the porous lavas are nothing but the result of the more or less active or continued development of gases produced by the peculiar nature of the lavas, and by the more or less violent action of subterraneous fire.

Class III. Scoriifed lavas.

A particular modification of porous lavas, produced when, under certain circumstances, the matter of which these consist undergoes the first degrees of vitrification, and becomes covered with a kind of shining varnish, which distinguishes them from ordinary porous lavas. These scoriifed lavas are found, 1. twisted; 2. cable-shaped; 3. ribband-shaped; 4. in bunches, with round or oblong grains; 5. flataitical, short elongated knobs, separated or united. All these varieties are found at Vesuvius, Etta, Hecla, in Teneriffe, the isle of Bourbon, &c.

Class IV. Lavas considered with regard to their component parts, or to the different rocks from which they originated.

Div. 1. Granitoid lavas.—These lavas, which, according to Fauss' system, must have been elaborated at a great depth in the bowels of the earth, owe their origin to rocks analogous to our granite, except that quartz does not enter into their composition; the substance formerly considered by Fauss and others as quartzy, having proved to be feldspar.

A. Coarse-grained granitoid lava.—1. With base of a whitish-grey colour, composed of irregular whitish grains of feldspar, of aony appearance, but easily fused before the blowpipe; a great number of minute, thin, and hexagonal laminae of black mica, disintegrated among the grains of feldspar, and large crystals of this substanca, of a nearly white and parallelipedic form, are imbedded in this quartzitic granite. The grains of feldspar have suffered a little by the fire, and the crystals are slightly calcined. Some of them are even dissolved into capillary separations, and pass into a substanca like pumice. This lava, which is strongly attracted by the magnet, is found at Mont-d'Or; but a similar variety occurs in the isles of Ponza and Lipari; at Santa Fiora, in Tuscany, &c. 2. Var. with base of whitish granular feldspar, spotted with dots of black mica, and hornblende of the same colour, and in small crystals with dull surface; from the Euganean hills, &c. 3. Var. with large laminae of a fusing bronze-coloured mica, some of more than an inch in diameter, in a rough uneven purplish black mass, which is melted without being glairy, and is pervaded by large pores. It is slightly attracted by the magnet. Found near(pyrenees). 4. Var. with base of redish granular feldspar streaked black mica, and of white slightly calcined feldspar crystals, with some hexagonal laminae of brown mica, minute reddish garnets, which are partly fused, and a black glossy substanca appearing to be hornblende; it is faintly attracted by the magnet. From Santa Fiora, in Tuscany. 5. Var. with base of white feldspar, in irregular rather fealy grains, with a great quantity of needles of black hornblende, and altered garnes of a purplish hue. Very obedient to the magnet. From Teneriffe. 6. Var. of a white colour inclining to grey, composed of a multitude of very small and close grains of white feldspar; and of much larger grains of shining fealy feldspar, with rather pearly lustre, some of which grains show a tendency to crystallization. Blackish, dull dots, being common hornblende altered by the fire, are disseminated in the feldspar. Fauss mentions a specimen of this variety, from the Cantal, which is traversed by a bar of black and white granite, formed of small grains of very pure feldspar, and of small grains of black hornblende, waked by the action of the fire. 7. Var. with blueish-black base, having small brilliant points proceeding from the fealy particles of a white flony substanca, with dull fracture; purplish red, semi-transparent garnets, partly flawed, partly fused, are indistinctly imbedded both in the black and white substances. The former of these, which is compact, and fuses before the blowpipe into a black glass, has all the characters of hornblende; the latter is compact feldspar. From the Cape de Gatte, in Spain.

B. Fine-grained granitoid lava.—8. Var. formed by a mixture of small, irregular, close grains of hornblende, and small grains and scales of white, rather pearly feldspar. The hornblende being predominant in this mass, it exhibits a black surface on being broken, or cut by a saw, in which case it resembles bafalt; but when polished, small white dots and lines appear, which, though delicate, are still sufficiently visible on the
L A V A.

the black ground of the mafes; found on the summit of Mount Mezin, where, by the action of the atmosphere, it undergoes a striking alteration; for while the particles of feldspar at the surface become corrodized and disappear, the hornblende remains unaltered and fresh, projecting over the rest as black granular particles. Latas similar to this, some of them primitivistic, Mr. Fauss pretends to have seen in the neighborhood of Caffel, and near Gottingen. 9. Var. composed of white feldspar in small grains, rather mealy at the surface, and of a black substance disseminated as dots in the mafes: the latter appears to be altered hornblende. In this mixture are also imbedded large white feldspar crystals with pearly lustre. Occurs on the right bank of the Rhone, at the foot of the Seven Mountains, nearly opposite Godeberg. 10. Var. with white grains of feldspar, harder, freer, and of closer texture than those of the preceding variety, mixed with black hornblende, disposed in dots, lineaments, and even as small primitivistic crystals, more abundant, and less altered, than the hornblende of No. 9. Also garnet crystals are disseminated in it, but cannot be seen without the assistance of a high magnifier. This variety is attracted by the magnet. It takes a good polish, and is used for building. It is, together with the preceding, found at the foot of the Morvan in quantity. Large feldspar crystals have not been found in it. 11. Var. composed of small irregular white crystals, disposed in distinct lines appearing scaly, thinning, and as rather calcined when viewed through a lens; their length is about 1/4th, their width about 1/8th of an inch: they are intermixed with other primitivistic indeterminate crystals of the same dimensions, of an intense black colour, vitreous, almost metallic external lustre, but rather dull on the surface of fracture. Also particles of iron micas, (for oligite of Hauy,) and of magnetic iron-stone, are found in this mafes. Fauss has analyzed these two ores of iron; according to him they are combined with titanite, and the white crystals belong to the species of the latter, called Sphene or Titanite siliceo-calcare. This variety was found, in infusiform blocks, near the top of the Moufflier, in Heida. 12. Var. differing from the preceding only by the for oligite, it contains being in large laminae, marked with lines, the general disposition of which produces small hexagonal laminae. The fphenite, which forms the base of this mafes, is harder, white, inclining to yellowish; it consists of crystalline translucent particles; the magnetic iron intersects the fphenite in all directions, while the iron-mica is only disseminated here and there; both these iron ores are, like the preceding, combined with titanite. This variety is found near the extinct volcano of Bournieu, in the Si-devant Provence. Mr. Fauss remarks, that no similar rock is known to occur, that may be considered as the original of this, and the preceding volcanic substances. He denominates them granitic, because they have much the appearance of such a compound.

C. Schiffe granitoid lava. — 13. Var. composed of minute, reddish-brown grains of feldspar, much larger, angular grains of feldspar, and a great quantity of small fished laminae of shining micas, disposed in a similar manner as in gneises. The white feldspar is eaily separated into lamina in the direction of parallel lines observable on it, and which are produced by the action of the fire. Sometimes some dots of hornblende are seen in the mafes; but they are of rare occurrence. This is found in Lipari under the name described by Dolomieu. 14. Var. with yellowish-grey, granular, dull feldspar, intermixed with white vitreous grains of feldspar, and much black hornblende in small lensoid crystals, disposed in horizontal lines, representing thin layers, and giving this substance a fibrous appearance. Found at Vulcann.

Class V. Porphyrid lava.

Faujas' volcanic porphyries are composed of a fusible paste or base, in which more or less regular crystals of feldspar are imbedded, often accompanied by grains of quartz, hornblende, augite, &c. The base itself he considers analogous to the “traps of the Swedes.” He subdivides them as follows.

A. Porphyrid lava with feldspar crystals. — 1. Var. with black, hard, and heavy, though rather porous, base, and white feldspar crystals of loose texture. Strongly attracted by the magnet. From mount Etna. 2. Var. with more compact base, of a deep violet brown colour, with a great quantity of small greyish-white, rhomboidal, and paralleloipiedic crystals, and also grains of feldspar. It is very magnetic, and takes a good polish. Found by Dolomieu in the Isle des Salenes, near the village Amalfi, where, according to this geologist, it appears in the form of steps of flairs. Fauss adds that a similar rock is found in Auvergno, in thin tables, which are used in some villages for roofing. 3. Var. with purplish brown base, including white irregular feldspar crystals, without lustre. From Trizac, in the canton of Mauriac, Auvergno. 4. Var. with rather purplish base, abounding with large very hard and less regular feldspar crystals of a white colour. Though rather decomposed, it affects the magnetic needle. From Mauriac, and found on the mountains of Auvergno.

B. Porphyrid lava with feldspar and mica. — 5. Var. with rather purplish grey base, very white irregular feldspar crystals, and small sometimes fished laminae of an intensely black mica. It sometimes contains small crystals of siliceo-calcareous titanium. From Leonens, part of the Cantal mountains. The base of this has quite a compact feldspar appearance. 6. Var. with grey base, including white feldspar crystals and black mica, but less abundant than in the preceding. From Mont d'Or; occurs also in the islands of Ponza and Lipari, &c.

C. Porphyrid lava with feldspar and pyroxene. — 7. Var. of a deep grey base, with dots, lineaments and crystals of white feldspar and black pyroxene, in small crystals. Susceptible of a good polish. From the extinct volcanoes of Campania, the neighborhood of Rome, Santa Fiora, &c.

D. Porphyrid lava with crystals of black pyroxene and small grains of green pyroxene. — 8. Var. with deep grey, containing a great number of crystals of black pyroxene, and irregular dots of greenish pyroxene. From Chimborazo, where it was found by Humboldt at the height of 18,490 toises. Fauss so completely mistakes Humboldt, that he imagines the stratum of this substance has 18,590 toises in thickness! The same is found near Puzuoli; and in the ancient lavas of Vefuvius. 9. Var. with the same base as the preceding, and, like it, susceptible of taking a good polish, with angular grains, needles, and regular crystals of green pyroxene. Found among the ancient lavas of Vefuvius.

E. Porphyrid lava with hornblende and feldspar. — 10. Var. with purplish base, with a profusion of lineaments and more or less regular crystals of black hornblende, irregular grains of white feldspar, some of which have penetrated into the hornblende crystal. Found at Santa Fiora in Tuscany.

F. Porphyrid lava with hornblende only. — 11. Var. of a blackish-grey colour, with large crystals of very black and shining hornblende. From Mas de Puifanton, near Chambrune, in Vivarais. 12. Var. of deep reddish-brown colour, with a profusion of brilliant needles and crystals of hornblende. From the Peak of Tenerife.

G. Porphyrid lava with hornblende and olivine. — 13. Var. in which the hornblende, in irregular fragments, confinutes
more than double the weight of the mass, in which some pores are observable. The grains of olivine which it includes are indiscernible. From the Peak of Teneriffe.

H. Porphyroid lava with leucite crystals. 14. Var. with opaque white leucites, with rather pearly lustre, the largest of which have from three to five lines in diameter; they exhibit, when pieces of the lava are cut and polished, minute rents. The base in which they are imbedded is black, compact, hard, very obedient to the magnet; fusible before the blowpipe into a black, opaque glass; it takes a fine polish. From Capo di Bove, Caparola, and the neighbourhood of Naples. 15. Var. with large leucites of a dull white colour, some of them transparent, lamellar, and here and there fusible and vitrified. The enveloping lave is of an earthy-black colour; it is dry, rough to the feel, full of irregular pores, and attracted by the magnet. From the ancient lavas of Vefuvius. 16. Var. with white, opaque, dull crystals, which, though they are so friable as to be easily reddened to powder by the pressure of the nail, have still preferred their original form; they are large and closely grouped together. The lava which includes them is of a dull black colour, inclining to grey; it has lost part of its hardness, but still attracts the magnet. In the midst of these decomposed crystals are seen black lineaments and grains of a substance which appears to be that of the lava itself, and which was perhaps forcibly introduced into the body of the crystals, through the rents that were produced when the mass was still in a fluid state. Found in abundance in the vicinity of Viterbo. 17. Var. with white opaque leucites, having some black points in their centre, and with irregular crystals of black pyroxene disseminated in the lave. It is black, hard, fusible of a good polish, attracted by the magnet, and fusible into a black brilliant glass. Found in large masses, and sometimes in prisms, at Bolsena. A similar variety occurs at Civita-Caffellana, and another at Aquapendente, which latter, however, includes pyroxenes of a yellowish-green colour. 18. Var. with transparent, hard, leucite crystals, of a yellowish-white colour, accompanied with black hornblende. The including lave is black, compact, hard, and attracted by the magnet. Found at Borghetto, Bolsena, Aquapendente, and Albano. 19. Var. with very small white opaque leucite crystals, closely grouped together, and accompanied by much larger, irregular crystals of black hornblende; in a black, hard, compact and very magnetic lave, from Tivoli and Aquapendente. 20. Var. with almost microscopic white, translucent leucite crystals, so closely grouped together as to appear to be in contact with each other, intermixed with irregular black hornblende crystals. Found abundantly at Bolsena, in the neighbourhood of Civita-Caffellana and of Viterbo. 21. Var. with very small, pellicid, white, leucite crystals, and irregular hornblende crystals, of a greyish colour. In a purplish, not very hard, lave, the iron of which has acquired a degree of oxidation, whence it shews no effect on the magnet needle. From Viterbo. 22. Var. with large, white, pellicid leucite crystals, which are generally of a scaly nature and full of minute flaws, and sometimes with small lineaments of a very beautiful sky-blue colour, of a crystalline appearance. This substance, comparable to blue sapphire, or, more aptly, to lazulite, appears to be of contemporary formation with the rest. The same substance in minute particles is discriminated also in the paste of the lave, which is compact and of a blackish-grey colour. Besides these, also black shining dots are observable in this lave; they have the appearance of having been fused, and may perhaps be grains of pyroxene, or black garnets. Some grains of arfical pyrites are likewise observable in it. From Albano. Sometimes the leucite crystals, in the lavas of this division, are accompanied by some mica in small scales; and in the neighbourhood of Rome large nodules are found, sometimes of the thickness of a man's fist, and entirely composed of black crystallized mica and leucite; the latter are closely enveloped by the former, and both appear to have acquired their crystalline form at the same period. This is not considered by Faujas as a true volcanic sub fluence.

Class VI. Varies. Scoria. The pillow is the same as that of the porphyritic lavas, but instead of crystals, it includes globules of feldspar.

1. Var. with pahie of a greenish-grey colour, with numerous blackish-grey globules, of the size of pea, and of a finer and harder texture than the base; both of them fusible. When the pate is decomposed by the action of the atmosphere, the round spots exhibit themselves as projecting globules. From Teneriffe. 2. Var. with grey pahie, and very small round spots of a darker grey colour. This variety, which attracts the magnet, is, like the preceding, compact, and takes a fine polish. It has a tendency to separate into thin laminae when struck with a hammer. From Veste, in Auvergne. 3. Var. with grey pahie, inclining to greenish; spots like those of No. 1, but four times smaller. Is strongly attracted by the magnet. From Pau en Velais. 4. Var. with white orbicular spots on a grey ground; attracted by the magnet. From Pans-de-Compin, Auvergne. 5. Var. like No. 4, but with much smaller spots, grouped closer together, and less regularly orbicular. From Puy-Creux, Auvergne. 6. Var. of a bluish colour, with very small pores, and numerous white orbicular spots of about two lines in diameter. From the crater of Mon-Bruin, in Vivarais, where it often occurs in large irregular balls, which separate into concentric layers when struck with a hammer.

Class VII. Feldspar lavas; or lavas with base of compact feldspar.

Faujas remarks, after Dolomieu, that there are sometimes in the same lava two different kinds of feldspar, one of which is compact and fusible, and serves as base to the other, which is more or less regularly crystallized and refractory, so that the base may have been in complete fusion, while the crystals remained in their original state.

1. Var. Feldspar lava of a black colour, opaque, of a very fine grain and coriaceous fracture; it fuses into a white translucent glass, and is strongly attracted by the magnet. From Castel in the Euganean mountains, and from Vulcano. 2. Var. of a light grey colour, inclining to flesh red, of a fine grain, trapezoidal at the edges; fusible before the blowpipe, and faintly attracted by the magnet. From one of the Pouzailes. 3. Var. of a white colour, heavy, partly vitrified. From the Euganean mountains. 4. Var. of the same colour, but shining; rather glassy; composed of small, rather streaked, and sometimes twelled scales; and, therefore, lighter than the preceding. Is not attracted by the magnet; but is fusible before the blowpipe. From Milo, an island in the Archipelago. 5. Var. of greyish-white colour, here and there with a slight shade of red, with numerous shining scales of mica; feldspar rather calcined. Is not attracted by the magnet; but fusible into a semi-transparent glass. From the Isle of Ponza, and from Puy-de-Dôme, in Auvergne. 6. Var. white, with scales of brown shining mica, and pellicid grains of feldspar, more crystalline than the base in which they are included. From Mont d'Or, in Auvergne; similar varieties are found in the Euganean mountain, and another from Mont Mezin, in Velui.

Class VIII. Amygdaloid lavas, with base of trapp.

These are considered, by Faujas, as having originally be-
L A V A.

Longed to rocks, whose base is generally the same as that of the porphyries; and whose globules and nodules of calcareous spar, zeolites, calcodony, &c. do not owe their existence as such, to infiltration, but are of a contemporaneous origin with the base. The volcanic fire, which operated on such amygdaloid rocks, though it has rendered them soft and fluid, has but little changed their character; but all, in the opinion of that famous volcanist, bear clearly the stamp of igneous origin. They are subdivided as follows:

A. Amygdaloid lava with calcareous globules.—1. Par. with globules of translucent calcareous spar of a yellowish colour, of the size of a pea; in a black, compact mass; attracted by the magnet. From Vivara; also from Vicenza. 2. Par. with white, transluent, spathic globules, some with a thin, shining, reddish-brown, others with a green-grey coating of the same kind, in a similar mass, affecting a triangular-prismatic form. From near Roccellafuca, in Vivara. 3. Par. with white, compact, lenticular grains, transluent on the edges, the largest of them of the size of a common lea; in a black compact mass, of a very fine grain. From the island of Ascension. 4. Par. with white, spherical globules; sometimes two, three, or four of them together; sometimes single in cells that are partly empty; bafe like that of the preceding variety. From the valley of Rome, in the Venetian territory. 5. Par. with similar, very small globules, grouped closely together, and taking up the whole of the cell; in a reddish-brown, hard, compact mass, attracted by the magnet. From the same place. 6. Par. with small, perfectly orbicular, globules of equal size, in a deep-grey, compact, soft mass, containing numerous grains of olivine, with oxidized ochreous surface. From Vivara. 7. Par. with white, translucent, shining, radiated globules of aragonite; in a black, hard, compact lava; obedient to the magnet. From the island of Ascension. A similar one, but with larger globules, from near Roche-Sauve, in Vivara. 8. Par. with the same globules, but accompanied by grains and indeterminable crystals of black hornblende; in a brownish compact mass. From near Bais, in Vivara. 9. Par. with radiated globules, and irregular grains of aragonite, intermixed with grains of olivine. From the Isle of Bourbon.

B. Amygdaloid lava with globules of mafic type.—1. Par. with mafic globules of a white silky zeolite, composed of needles radiating from the centre; in a black, compact, hard mass, attracted by the magnet; including also grains of black hornblende. Between Roche-Maure and Meyrila, in Vivara. A similar variety from Staafa, and the island of Mull. 2. Par. with very small mafic globules, of a snow-white zeolite, and irregular, almost microscopic grains of the same sublimate, so numerous as to conlute half of the whole mass; the base like that of the preceding variety. From the valley of Roma, in the Venetian territory. A similar one is found near Rome, in which grains of hornblende are lodged in the very sublimate of the zeolite. 3. Par. with numerous, white, pellucid, zeolitic grains, of about the size of a millet seed, and closely grouped together; in a greyish-black compact lava. From Montecchio-Maggiori, near Vicenza. Similar varieties occur in the Lipari islands, at mount Velovius, &c.

C. Amygdaloid lava with felsite.—1. With globules of white pearly felsite, in a black compact base, attracted by the magnet. From Feroe. 2. Par. with similar globules, surrounded by a crust of a green, rather friable, sublimate, very like the green earth of Verona; in a greenish-grey mass, not attracted by the magnet. From Feroe. 3. Par. with white radiated felsite, on crystals of calcareous spar; in a black mass. From Iceland. 4. Par. with white felsite, in indeterminably-shaped nodules, in a friable, brownish mass. From Dumbarton.

D. Amygdaloid lava with analcime.—1. With irregular globules of transparent analcime, partly crystallized; in a greyish-black, lava, attracted by the magnet. From Mount Etna. 2. Par. with oblong globules of pelitic analcime, in a black compact lava, strongly attracted by the magnet. From one of the Cyclopean islands. 3. Par. with globules of white compact analcime; in a greyish-black lava, appearing rather altered. From Montecllo-Maggiori. 4. Par. with hollow nodules of white, dull, and opaque analcime, partly in the form of trapezoidal crystals; in an altered lava, as it is called by our author. From Dumbarton, Scotland. 5. Par. with small, inflated, semi-transparent, greyish, dozodecald crystals; in a light grey lava resembling triplite, and penetrated in all parts by numerous, very small, spherical grains of analcime, of a darker grey colour, and a little translucent on the edges; intermixed also with some small crystals of calcareous spar.

E. Amygdaloid lava, with facolite, (referred by Haux to analcime.)—1. Par. with globules, and sometimes irregular nodules, of a reddish yellow sublimate, similar to the facolite of Thompson; in a greyish hard, porous, but heavy lava; the red globules accompanied by analcime, white radiated zeolite, cuboid crystals of calcareous spar. From Montecchio-Maggiori. 2. Par. with radiated zeolite, trapezoidal analcime, cuboid calcareous spar, and semi-transparent crystalline calcite, or sulphate of frontal, of a light blue colour, palling, in some specimens, into white. In a similar mass, from the same place.

F. Amygdaloid lava, with chabasite.—1. White chabinas, in a porous, black, heavy mass, with small, blueish, elevated, rather mamillary spots, which are phosphate of iron. From Val di Noto. A similar sublimate is found at Clermont, in Auvergne. 2. Par. with small primitive crystals of chabasite, in the orbicular hollows of a black, hard, heavy, and compact mass. From the Peak of Tenerife. 3. Par. with small globules, and very minute crystals of chabasite, in a black heavy mass, with shining black hornblende, and numerous grains of olivine, decomposed into a yellowish earthy sublimate. From Tenerife. 4. Par. with primitive crystals of chabasite, lining the orbicular hollows of a close black lava. From Iceland.

G. Amygdaloid lava, with calcodony.—Here M. Faujas mentions several varieties of nodules of calcodony, some of them containing water, (known by the name of ehydras), others solid; found principally in the decomposed lavas of Monte Tondo, Monte Galdo, San Filomiro, Mont-Main, in the Vicentine territory. To these he adds, by way of appendix, some calcodonic and quarts sublimate, which he considers as owing their origin to infiltration, and to which he refers the hyalite of Frantfort on the Mayne. In another appendix the same author places the mafies including the granular peridot or olivine, and which he would consider of porphyritic origin, were the olivines ever found crystallized in them. He enumerates several varieties found in the basalts and lavas of Vivara, Caffeo, Isle of Bourbon.

CLASS IX. Volcanic breccias and tuffs.

A. Volcanic breccias formed of more or less rounded fragments of different kind of lavas, furred and enveloped by other lavas in a plate of fusion.—1. Par. composed of angular and blunt fragments of black, hard, compact lava, of rather porous black lava, and of grains of white feldspar; the whole intimately united by a brownish lava, with flecked pores. Peak of St. Michael, in Velay; as also near Roche-Sauve, in Vivara. 2. Par. with irregular fragments of scoriiform semi-vitrous lavas of a shining black colour, cemented by a
grey flinted lava, approaching hard pumice. From Vivarais, and the island of Lipari. 3. Var. formed of numerous angular fragments of black porous lava, and some white opaline feldspar, cemented together by grey pumice with small pores; from Lipari and Ifchia. 4. Var. with fragments of white, sometimes yellow and brownish lime-flint, in a grey hard lava, mixed with white, transparent, flawed crystral and grains of feldspar, some laminae of black hornblende, silver mica, and grains of green augite; from the vicinity of Albanu, and other parts of the Roman territory. 5. Var. composed of large fragments of white marble, fine-grained yellowish marble, and another hard irony substance formed of lime and flints; in a grey lava, including much black pyroxene; from the vicinity of Rome, and from near Vesuvius. 6. Var. composed of fragments of white and grey marble, and rounded pieces of black hornblende; others of black scaly mica; in a grey lava, mixed with particles of frefly mica, and numerous fragments of deep grey pyroxene. From Ifchia. 7. Var. with large nodules of olivine, of different colours; fragments of black compact lava, of porous, almost fcerated lava, of the fame colour, cemented by a grey mass formed of more or less comminuted detritus of several kinds of lava. From the Isle of Bourbon, of Ascension, &c.

B. Volcanic breccias formed by the sudden contact of fire and of water greatly heated.—1. Breccia formed of fragments of brown porphyry, porphyry with red bafalt, and crystalline white feldspar; of fragments of white marble, marked at their points of contact with the lava, with black lineaments that appear produced by an aqueous solution which intimately united all parts of this breccia, the base of which is a grey lava, mixed with melted grains of black pyroxene; it is attracted by the magnet. From the foot of Mount Etna. 2. Var. including angular fragments of black lava, with conoidal fracture; of grey feldspar lava, with rough surface (both attracted by the magnet); of glassy blue-black green lava, fragments of all-black pumice, fragments of a whitish, semi-transparent, volcanic glass, and a colourless glaf; the whole cemented by a blueish-grey, fiotith, coarfed-grained lava. From the Lipari islands. 3. Var. composed of fragments of black, rather porous, bafalt, including grains of olivine, of large fragments of a yellowish quartz sand-flone with red ftripes, of fragments of grey or red indurated marle, and geodes of brown iron-flone; the whole cemented together by a grey lava, composed of the more or less comminuted grains of the fubfances that form the breccia, and of some black pyroxene. From the Habichtswald. 4. Var. composed of various fragments of black bafaltic lava, intimately connected by white and fuming calcareous spar, sufficiently hard to allow the breccia to be cut and polished; sometimes the compact lava adopts the reddish colour of ochre. From Rochemauere, Vivarais; also from Monte-Bolca. 5. Var. formed of more or less large fragments of intensely black, shining, volcanic glaf, cemented by white calcarceous spar, susceptible of a good polish. From Val di Noto. 6. Var. composed of very small fragments of a compact, greenish-black, decomposed lava, some of which include grains of black pyroxene; in a hard fliceocal-carneous patte, which is but little soluble in nitric acid.

C. Volcanic tuftas, properly so called, formed by the detritus of different species of granular, pulverulent, or earthy lavas. They appear to owe their origin to various circumstances. First, they may, according to Faujas, be considered as the result of the sudden contact of water with volcanic fire; when, at the time of great subterraneous convulsions, a communication is suddenly opened between the sea and the igneous gulf. Secondly, the projected pulverulent lavas, which are sometimes carried to a great distance, such as those which buried Herculanenum and Pompei, or those which accumulate at the bottom of the sea in the vicinity of volcanoes, and may, in the progress of time, produce deposits, and some more or less regular strata, of tuftas. Lastly, under some circumstances, the tuftas that were already deposited in the sea, may have been again displaced by currents, and mixed with shells and other marine productions, and sometimes even with land productions, swept into the sea by rivers, &c. The current may, at different intervals, have deposited these tuftas, as more or less regular layers.

1. Volcanic tuftas, composed of white and grey, very light pumice, in small fragments, adhering to each other. From Pliny, near Anderchau, where it covers the quarries of traifs. 2. Var. with base of pumice reduced to fine powder, as to appear like a clayey fubfance, serving as a cement to numerous grains of a very light pumice, but less rough to the touch than that of the base, which, moreover, includes small nodules of real porous lava, of a brown colour, and sometimes colourles. From the fame place, where it forms a kind of traifs. 3. Var. formed of pumice in grains, and small angular fragments of black bafaltic lava. Scaly particles of a somewhat micaceous fchistus, cemented by a pale of pumice reduced to powder. From the same place; where it forms another variety of traifs, being of greater solidity, and forming beds of upwards of fifty feet thicknefs, in which sometimes charred wood is found. 4. Var. formed of very small grains of lava, which is partly fcerated, of some grains of black pyroxene, and other grains of rounded yellowish olivine, cemented by grey and black pulverulent lava, resembling sand-flone. It is sometimes found in beds at Carlsberg, in Hefrsia. A similar tuftas, of a dark grey colour, with white points, is found on an elevated part of the Cantal, in Auvergne. 5. Var. of a purplish-grey colour, and refembling, at first sight, a sand-flone, but in reality composed of the detritus of a purplish lava, of a less altered compact lava, and some grains of black pyroxene. Near Roche- faue, in Vivarais, where it forms thick beds, resting on other tuftas, and overlaid by basalt. 6. Var. gold yellow, dotted with white, grey, and black, composed of small fragments of bafalt, yellowish-brown flable lava, some grains of olivine, and small particles of black pyroxene; also yellow ochre nodules are found in it. This tufta forms considerable beds, one above the other, at Rochefaue, in Vivarais. 7. Var. of a purplish-brown colour, with yellow ochre, white and blackish dots, composed of small angular fragments of black compact lava, which has lost some of its hardnefs; of small fragments of a white marle, mixed with some iron; of particles of porous altered lavas of an ochrey-yellow colour; of grains of shining black pyroxene, and some olivine in grains. It is attracted by the magnet. Found at the preceding place, where it forms considerable strata, overlaid by small basaltic casufways. Also, in this tufta large nodules of ochre are found. The tuftas of the vicinity of Roche-mauere, in Vivarais, are similar to this; as likewise those of the neighbourhood of Rome, of Naples, and Campania, of the Euganean mountains, of several parts of the Vicentine territory, &c.

M. Faujas enumerates, at the end of this fectio, the various animal and vegetable fubfances, shells, madrepores, and carbonized species of wood, that have been found imbbed in volcanic tuftas. A fectio is also fet apart to volcanic pitch-flones, divided into three classes, viz. wood, converted into pitchflines, by volcanic fire; flint, which has undergone the fame change; and porphories converted into what Werner calls pitchflone porphory. The places affiliated to the firt of thefe varieties are, Affelheim, near Frankfort, and
and Upper Hungary; the locality of the second is principally Auerwye; which is also that of the specimens of volcanic pitchstone porphyry, here enumerated. To the left of these substances Faujas refers most of such "lavas infusibles," or "refusiformes" of Dolomieu, as contain crystals of feldspar, and several of which are found at Vulcano. Those are said to form a transition into

Class X. Enamels, obsidians, and other volcanic glases. — The prototypes of these are the different varieties of trapp, compact feldspar, and porphyry, which, according as they are more or less fusible by volcanic fire, are, under circumstances favourable to vitrification, converted into the several kinds of glases that are found among volcanic productions.

A. Enamels. — 1. Grey, with greyish-white, or greenish zones; opaque; some pores are visible in the paffe, and, with the help of a lens, also crystals of feldspar, or traces of them. From the isle of Aescifion. 2. Var. of dark-grey colour, bejewelled all over with small round spots of a much lighter grey, and produced from small globules in the substance of the enamel, which, in some places, displays an intense, vivid-black colour. This substance, which is from the island of Vulcano, bears distinctly the characters of a variolate lava converted into enamel. 3. Var. of a blackish-grey colour, hard, opaque, in which some dots of fused black pyroxene are still visible. From the isle of Ponza. 4. Var. of an intense black colour, approaching obsidian, but more opaque, and of a rather greyish aspect. From the Peak of Teneriffe. This enamel is sometimes covered with a dull-coloured crust. In some specimens scarcely any foreign body is observable, except some traces of white feldspar; in others the mass is rather less intensely black and more marked with spots of white feldspar, melted together with the enamal without having entirely lost their original tint.

B. Real obsidian, or volcanic glasses.— 1. Obsidian of a black colour, of conchoidal fracture, divisible into sharp fragments, of deep black colour, and translucid on the edges; thinner fragments almost completely transparent, with scarcely any traces of a fuliginous tint. It is fusible before the blowpipe into a very white, shining, translucid glass, with minute superficial vessels. From Mount Heide, Teneriffe, Aescifion, Vulcano, Lipari, Ponza, &c. 2. Var. of a globular form, black, opaque, but sometimes transparent, and faintly turbid or smoky. From Cap de Gairis. Faujas refers this substance (which has been called hydro-sapphire by some writers) to the homogeneous volcanic glases, because it easily melts before the blowpipe into a white enamel, and because the globules are sometimes found imbedded in a greyish enamel, approaching to lamellar pumices. These globules are not always spheroidal. Their size is from that of a small pea to that of a large hazelnut. They are very light, though not porous; their external lustre is muciuous. 3. Var. forming a very fine black glass, with well defined, conchoidal fracture; and fragments nearly transparent on the edges, and of a white olive-brown colour. In some parts white points and some small hollows are seen, which latter are lined with a white fused, rather vitreous, substance, which appears to owe its origin to such grains of feldspar as did not experience a sufficient degree of fusion to amalgamate with the obsidian. From Cerro de las Marejas, in Mexico. 4. Var. with intensely black ground, and well defined fracture, yielding sharp-edged fragments; the whole of the brilliant mass is filled with small, white, opaque, globular, and oblong spots, closely grouped together, and appearing like melted enamel, but rather unctuous. From the Lipari islands. 5. Var. of a black colour, inclining to olive-green, disposed in more or less elongated, rather flexible, capillary filaments, often terminated by very small, round, or oblong globules; fusible before the blowpipe into globules of a greenish-black. From the isle of Bourbon. Lava with small siliiform particles of volcanic glass have also occurred in the island Vulcano. These are by some mineralogists looked upon as siliiform crystals of augite or pyroxene; but M. Faujas says he has subjected them to closer examination, and found them to be volcanic glases.

C. Pumice stones. — The true pumice, says Faujas, which we should be careful not to confound with the lightest lavas, keeps the middle way between the volcanic glases and the enamels: it generally derives its origin from a peculiar kind of vitrification of compact feldspar, and some porphyritic rocks. Those of Lipari and Vulcano are the only known volcanoes that have produced pumice in considerable quantity; the isle of Lipari, in particular, is the very magazine that furnishes almost the whole of the immense stores of this substance, consumed for the purposes of different arts, in almost all parts of Europe. In small quantity and in inflated fragments it occurs in the neighbourhood of several other volcanoes.

1. Pumice of a white colour, porous, light, rough to the touch, and fusible. From Campó-Bianco, the Lipari islands, Valle-del-Aqua, near Otto-Jano, &c. 2. Var. of a milky appearance, fibrous, and with capillary lines. From the same place. 3. Var. of a dark grey or black, sometimes greyish-white colour, with twisted pores; fibrous, including, among its fibres, more or less indeterminable crystals of white feldspar, which, in some of the specimens, are only seen on the rifts. From Ifchia, Procida, from the neighbourhood of Naples. At Lipari, the varieties of black pumice are found in the hillock of the tomb of the Naos. 4. Var. of a whitish colour, scaly, light, fibrous, and semi-transparent. From Lipari. 5. Var. the same, but heavy. Ibid. 6. Var. of a grey colour, light, fibrous, with blackish, shining, sometimes crystalized, mica. In a pumice from Herculanenum, from the neighbourhood of Naples, from Ifchia, Procida, &c. 7. Light, porous, or fibrous variety, with more or less angular nodules, and grains of black volcanic glases. From Lipari, Stromboli, Capo di Monte, at Scutello, in the neighbourhood of Naples; from Teneriffe, &c. 8. Var. the same, but white, with small thin fragments of a silyrcy-grey chalcedony. In the tufts from Pleythi and other places in the vicinity of Andernach. 9. Var. with very small angular and irregular fragments of a vitreous, flinty substance, of a sky-blue colour (now called Latialite, or Hauyne). Among the varieties of pumice from Pleythi, &c. 10. Var. of a greyish-white colour, light, with nodules of obsidian of various sizes. From Teneriffe and Lipari. 11. Var. of a dark grey, sometimes rather brownish colour, heavier than the preceding variety, with vesicles, all of which are elongated in one and the same direction; gives out some sparks when struck with steel. From Lipari. 12. Var. of a silyrcy-white, composed of small lamelles, or scales. Found among the other varieties at Lipari; it is rather lighter than the common white pumice.

Class XI. Sulphur, and various saline substances, found sublimated in volcanoes and solfatatas.

The salts are: Glauber salt, nitre, alum, Eplom salt, mineral alkalii, rock salt, efflorescent, in filaments and cubes, talc ammoniac, in rhombic, or dodecahedral crystals, generally of a topaz-yellow colour. Also gypsum, and calcareous spar; muriate of copper, in small deliquescent crystals; red and yellow orpiment.
CLASS XII. **Volcanic iron**, viz. titaniferous iron, as sand, and in small octahedral crystals, from various places; peculiar iron from several volcanoes in Italy and France; phosphate of iron, as powder in porous lavas from Cape de Boeuf, Etna, Val di Noto; or in small limonite, from Bouche, in the department of Allier, &c.; iron pyrites, in fine grains; oxides of iron; muriate of iron, of a yellow colour, from Vefuvius and Etna; and iron-vitriol, found in volcanic grottos, in the island of Volcano.

Several interesting observations on the nature of lava, and the various phenomena it presents under different circumstances, are given by Dr. William Hamilton, father of the Torre, Boli, Tata, Birth-fach, Buch, and others, which will be more particularly noticed under the article VOLCANO.

The purposes for which the lava of Vefuvius, Etna, and other volcanoes is employed, are particularly those of building and paving. Also the ancients made use of it for their purposes, as appears from the presence of Vefuvian lava in the architectural remains and pavements found in Horaceanum and Pompei. That of Etna appears to be still more generally used for building, since, according to Ferrari, there is not a house in its neighbourhood that is not constructed of it. The rapid progress in the rebuilding of Catania was, in a great measure, owing to the facility with which the building materials were procured. Also mill-stones are made of the lava of Etna, many of which are exported to Calabria and Malta; and it has even been manufactured into cannon balls.

**LAUACA**, in Geography, a small island near the S. coast of Sardinia. N. lat. 39° 4'. E. long. 8° 36'.

**LAVACRUM**, in Botany, a name given by some authors to the common wild teasel, or _discus sulcifinis major_, Ger. Emes. Ind. 2.

**LAUADEROS.** See LAVATORY.

**LAVAGNA,** in Geography, a sea-port town of Genoa, at the mouth of a river of the same name, which rises in the Apennines; 12 miles W.N.W. of Brugnato.

**LAVAL,** a city of France, and capital of the department of the Mayenne, situated on the river Mayenne. The number of inhabitants is estimated at 14,154; the easterly division containing 6658, and the canton 15,775, on a territory of 145 square kilometres, in 9 communes; and the western division comprehending 7496, and its canton 15,000, on a territory of 122 1/2 square kilometres, in 6 communes. In the town and its environs are manufactures of linen, which yield a considerable commerce. N. lat. 48° 5'. W. long. 0° 41'.

**LAVAMUND,** a town of the duchy of Carinthia, on the Drave; the site of a bishopric, suffragan of the archbishop of Salzburg; 24 miles E. of Clagenfurt. N. lat. 46° 44'. E. long. 14° 57'.

Gen. Ch. Cal. Perianth inferior, of one leaf, ovate, obtusely toothed at the orifice, short, permanent, with a bract at its base. Car. of one petal, ringlet, revered; tube cylindrical, longer than the calyx; limb spreading; its larger lip turned upwards, cloven, spreading; the other directed downwards, in three roundish, nearly equal, segments. Stam. Filaments four, within the tube of the corolla, short, pointing downwards, two of them shorter than the rest; anthers small. Fil. German four-cleft; style thread-shaped, the length of the tube; stigma of two obtuse cohering lobes. Peric. none, except the calyx, which protects the seeds, its mouth being closed. Seeds four, obovate. Eff. Ch. Calyx ovate, obtusely toothed, attended by a bract. Corolla reversed. Staminates enclosed in the tube.

Obf. The species of Tournefort differs from his _Lavandula_, in having the flowers ranged in many rows on the spike, and the whole crowned with an ornamental tuft of floral leaves.

Six species are described in the latest edition of Linnæus, eight in Willkorn, all of them admitted into the new Hortus Kewensis, but the last in the list erroneously. The real are for the most part known and efficacious in every garden or greenhouse. All are showy, with blue or purplish, fragrant, spiked flowers, and their foliage is likewise aromatic, generally of a grey or hoary-green, narrow, either roundish or compound. The Spike is supported on a longish, naked, square stalk.

1. _L. Spicata._ Common Lavender, or Spike. Linn. Sp. Pl. 800. (Stezech; Willd. Sp. Pl. 362.)—Leaves linear-lanceolate. Spike interrupted, naked at the summit. Native of the south of Europe, hardy with us, and cultivated for the sake of its scent when dried. To be "laid up in lavender" is become proverbial for any thing stored up with peculiar care. The essential oil and distilled water are so generally used in perfumery, as to be no unimportant articles of commerce. The compound spirituous tincture, or lavender drops, is a popular cordial, very commodious for those who wish to indulge in a dream, under the appearance of an elegant medicine. This plant varies in the breadth of its leaves, from linear to lanceolate, inclining to obovate; hence the old writers describe and figure two kinds. The flowers are occasionally white, which also they have not omitted to notice.

2. _L. Stezech._ French Lavender. Linn. Sp. Pl. 800. (Stezech; Rivin. Monop. 323. f. 1. 2.)—Leaves linear-lanceolate. Spike interrupted, naked at the summit. Native of Spain, Greece, the south of France, and the north of Africa. It will not bear our winters without the shelter of a greenhouse. The leaves are much smaller than in the former, more strongly revolute. Spike unimpaired, short, and thick, on shortish stalks, their branches more or less distinctly three-lobed, purplish and woolly; those which crown the top of the spike, greatly dilated, white, thickly, divided, of a beautiful purple, much paler than the flowers; rarely wanting.

3. _L. viridis._ Madeira Lavender. L'Herit. Sert. Angl. 19. Alt. Hort. Kew. n. 3. Hoffm. and Link Laflit. v. 3. 91. t. 4. 140.—Leaves linear, revolute, rugose, villous. Spike closed, crowned with a leafy tuft. Bracteas undivided.—Native of Madeira, from whence it was sent to Kew by Mr. Moffan in 1777. It differs from the last in its rugose, green and villous, not hoary, leaves, its undivided bracteas, and its green, not purple, crown of the spike.

4. _L. dentata._ Tooth-leaved Lavender. Linn. Sp. Pl. 800. (Willd. Sp. Pl. 362.)—Leaves linear, finely pinnatifid, pectinate. Spike closed, with a leafy crown. Native of Spain, the north of Africa, and some parts of the Levant, not of Greece. The very neatly-toothed leaves distinguish this species. Its spikes stand on long stalks, and are crowded, pale, with all the bracteas large, coloured, and somewhat membranous, a few
few at the top being rather the largest, and destitute of flowers, as in the two leaf. The corolla is often white. This is one of the species that has been longest cultivated in England, having been preferred in the dwelling-house before green-houses or oves were invented.

5. L. pinnata. Pinnated Lavender. Linn. fil. Diff. 9. t. 1. Am. Acad. v. 10. 182. Curr. Mag. 401. t. 400. Jacq. Misc. v. 2. 318. IC. Rar. i. 106.—Leaves deeply pinnatifid; their segments wedge-shaped, obtuse, nearly entire. Spike linear, somewhat branched. —Native of Madeira, from whence Mr. Muffett sent it in 1777. The leaves are finely hairy, with little scent, elegantly pinnatifid, and distinguished by their obtuse wedge-like segments. The spikes stand on very long stalks, and are much more slender than any of the former, often compound. The bracteas are imbricated, uniform, ovate-lanceolate, pointed, coriaceous, not membranous, slightly coloured, and there is no leafy crown at the summit. The corolla is of a delicate blueish-purple, like the common Lavender, but larger and more flowy.

6. L. multifida. Cut-leaved Canary Lavender. Linn. Sp. Pl. 800. (L. folio multident; Rivin. Monop. Irr. t. 54. f. 3. Stutch. multifida; Ger. em. 585.)—Leaves doubly pinnatifid, hoary. Spike ovate, mostly simple. Bracteas woolly, elliptical, with dilate and unequal ribs. Native of Spain, Barbary, and the Canary isles. One of the species long cultivated in England, though it requires protection in winter. The Hortus Kewenianum marks this plant as biennial, and we have a French specimen marked annual. It has certainly more of an herbaceous than shrub-like appearance. The leaves are hoary, doubly and very deeply pinnatifid, with decurrent segments, whose extremities are acute, and in some measure elliptical. Spike ovate oblong, and with very rarely, if ever, producing a small branch or two from the bottom. Bracteas membranaceous, broadly elliptical, besprinkled with wool, furnished with three strong ribs, equally dilate from each other, and from the edge. There are no barren leafy bracteas at the top.

7. L. abrastrama. Southernwood-leaved Canary Lavender. Lamarck Dict. v. 3. 469. Willd. n. 7. (L. folio longiorti, tenuis et elegantissimis dissectis; Tourn. Inf. 198. Comm. Rar. t. 27.)—Leaves doubly pinnatifid, with linear segments, nearly smooth. Spike linear, mostly branched and interrupted. Bracteas smoothish, ovate, with approximated ribs.—Native of the Canaries, long known in gardens. The stem is hoary. Leaves with finer, more linear, and greener segments in the Hert. The narrowness and branching nature of the spikes more accord with L. pinnata than with multifida, with which latter this species has long been confounded. The bracteas also more relinque those of pinnata, but are more membranaceous, and far less hoary. Their ribs generally three, sometimes five, are always closer together than in multifida.

The eighth species of Wildenow, L. carnosus, Linn. fil. Diff. 9. t. 9. Am. Acad. v. 10. 52. t. 3. (Kattu-Kurka; Rheede Hort. Mal. v. 10. 179. t. 90.) found by Koch on dry walls and rocks at Sardina's in the East Indies, and sent to Kew in 1783 by Dr. Joseph Banks, where it is kept in the stone, being a tender biennial, is most certainly not a Lavandula, but a Plethranthus, as its habit, and the large deflexed upper segment of its calyx, both evince. See Plethranthus.

LAVANDULA, in Gardening, comprises plants of the shrubby evergreen kind, of which the species cultivated are, the common lavender (L. spica); the French lavender (L. fraxina); the tooth-leaved lavender (L. dentata); and the Canarey lavender (L. multifida).

The first fort has varieties with narrow leaves with blue flowers, and with white flowers with broad leaves, and dwarf lavender.

It may be remarked that this species is the common lavender; but the narrow-leaved variety with blue flowers is the fort cultivated for its flowers for medicinal purposes.

And that the broad-leaved fort has much shorter and broader leaves, and the branches are shorter, more compact, and fuller of leaves; it continues several years without producing flowers; and when it does, the leaves on the flowering-flalks approach nearer to those of the common lavender, but are still broader; the stalks grow taller, the spikes are hoarser and larger, the flowers smaller, and appear a little later in the season.

The second kind has varieties with white flowers, and with purple flowers.

The fourth species has a variety which rises with an upright, branching, square stalk, four feet high; the leaves longer, and cut into narrower segments than the Spanish plant; they are of a lighter green, and almost smooth; the naked flower-flalk is also much longer, and terminated with a cluster of spikes of blue flowers; at two or three inches below these are two small spikes, one on each side; the flowers are smaller than those of the first fort.

Method of Culture.—All the forts are readily increased, by planting slips or cuttings of their young shoots in the spring. With the first two forts, a quantity of slips or cuttings should be taken off in the early spring, as March or April, from three or four, to six inches long, dripping off the under leaves, then planting them in a shady border, four inches asunder, giving a good watering, and repeating it occasionally in dry weather. When the plants are well rooted in summer, they should be transplanted into the places where they are to grow early in autumn, as September or October, with balls of earth about their roots.

And where the first fort is intended to produce flowers for economical purposes, it should be planted in rows, two or three feet asunder, and about the same distance in the rows, or in a single row one or two feet asunder, along the edges of or divisions of garden-grounds, in a fort of edging or dwarf hedge; in either of which modes the plants grow freely, continuing in root, item, and branches several years, and produce abundance of spikes of flowers annually for gathering in the latter end of summer; the culture afterwards is principally to cut down any remaining decayed flower-flalks in autumn, pruning or cutting away any disorderly cut-growing branches at top and sides, and digging the ground occasionally in spring or autumn along the rows of plants.

In regard to the second fort, it may also often be raised from seeds, which should be sown in a bed of light earth in the early spring, and raked in evenly with a light hand. The plants rise in about a month, when, if there be dry weather, water should be given; and after they are three inches high, they should be thinned out in beds, half a foot apart, watering them as they require, until fresh rooted. They should stand here till the following spring, and then be thinned out, and planted where they are to remain.

The third and fourth forts may be increased by slips and cuttings, planted in pots, in the early spring months, and placed under frames, due water, and shade from the midway sun, being given till they are rooted; when a little advanced in growth, transplanted into separate small pots, and managed as other green-house exotic plants.

The two first forts are useful for their fine spikes or flowers, as well as ornamental in assemblage with other shrubby plants, in the borders and clumps of pleasure-grounds; and the two last forts in the green-house collection with
with other plants. Those designed for shrubberies or other similar places, being previously raised to some tolerable bushy growth, and a foot high or more, should be planted either in the early autumn, or in the spring, disposing them thinly at proper distances in the fronts of the clumps, borders, &c.

LAVENDER.

LAVANDULA, Lavender, in the Materia Medica. The common lavender, or lavandula officinarum, was formerly confounded, says Woodville, as a species of Narbus, and appears to be the pseude-nardus of Matthiolus and Pliny. This plant, which grows spontaneously in many of the southern parts of Europe, appears to have been cultivated in England previously to the year 1568. The fragrant smell of the flowers is well known, and to most persons is agreeable; to the taste they are bitterish, warm, and somewhat pungent; the leaves are weaker, and less grateful.

The flowers and summits of the narrow-leaved or common lavender are, in a very eminent degree, cephalic and nervine. They are often employed as a perfume, and medicinally as mild stimulants and carminatives, in palpies, vertigoes, lethargies, and tremors of the limbs, both internally and externally.

The flowers are sometimes used in the form of a conserve, into which they are reduced by beating them, while fresh, with thrice their weight of double refined sugar. Water extracts by infusion nearly all the virtue of the leaves and flowers: in distillation with water, the leaves yield a small portion of essental oil; but the flowers, in their most perfect mature state, about one ounce from sixty. Woodville observes, that in order to obtain the largest quantity of essental oil from these and most other flowers of this kind, they should be allowed to grow to their full maturity, and be dried for some time. This oil is of a bright yellow colour, a very pungent taste, and poffeifies, if carefully distilled, the fragrance of the lavender in perfection: it is given internally from one drop to five, and employed in external applications for stimulating paralytic limbs, and for destroying cutaneous infects. It is also said, that if sponge paper be dipped in this oil, and applied to the parts, it immediately kills the pediculi inguinales. Rectified spirit extracts the virtue of lavender more completely than water. The simple spirit of lavender, prepared by pouring a gallon of proof spirit on two pounds of the fresh gathered flowers, adding water sufficient to prevent empyreuma, macerating for 24 hours, and distilling a gallon by a gentle fire, is richly impregnated with the fragrance of the flowers. More compounded spirits, in which other aromatics are joined to the lavender, have been distinguished by the name of English or palsy drops: the college of London (1809) directs three pints of the simple spirit of lavender, and one pint of spirits of rosemary, to be digested on half an ounce of cinnamon, half an ounce of nutmegs, both bruised, and an ounce of red fanders wood sliced as a colouring ingredient, macerating for 14 days, and then straining; the college of Edinburgh, to the same quantity of both spirits, orders one ounce of cinnamon, two drams of cloves, half an ounce of nutmegs, and three drams of red fanders. These preparations are taken internally on fugar or in any convenient vehicle, from ten to one hundred drops, and used externally in emboctions, &c.

The medicinal virtue of lavender resides in the essental oil, which is supposed to be a gentle carminative and stimulant of the aromatic kind; and is recommended in nervous debilities and various affections proceeding from a want of energy in the animal functions. According to Dr. Cullen (Mat. Med. vol. ii.) it is, "whether externally applied or given internally, a powerful stimulant to the nervous system; and among the others of this order, named cephalics, the lavender has a very good and perhaps the best title to it."

And be further says, "it appears to me probable, that it will seldom go farther than exciting the energy of the brain to a fuller impulse of the nervous power into the nerves of the animal functions, and seldom into those of the vital. It was, however, with great propriety, that professor Murray diffused its name, where there is any danger from a filthiness applied to the languishing system. It is however still probable, that lavender commonly stimulates the nervous system only, and therefore may be more safe in palsy than the warmer aromatics, especially if the lavender be not given in a spirituous menstruum, or along with heating aromatics, which however is commonly done in the cafe of the spiritus lavandulæ compositus." The official preparations of lavender are the essental oil, a simple spirit, and a compound tincture, already mentioned.

The broad-leaved lavender, a variety of the former, to which foreign writers have given the name of spike, is stronger both in smell and taste than the other, and yields in distillation almost three as much essental oil; but the flavour of the oil and of the plant itself is much less grateful: the oil is likewise of a much darker colour, inclining to green. This oil, mixed with 5ths of rectified spirit, or oil of turpentine, was the "Oleum Spicis," formerly highly celebrated as an application to indolent tumours, old sprains, cicatricial joints, &c. See Oil of Spike.

LAVANGE, in Geography, one of the Virgin islands in the West Indies; three miles S.E. of the island of St. Thomas.

LAVANGAARI, an island of Russia, on the coast of Livonia, 80 miles from the capital, four miles and a half long, and two broad, surrounded on the N.W. side by islets and shallows, having three tolerable harbours, and occupied by about 40 families. Some patches of foil are cultivated, and in the middle of the island is a small lake.

LAVANT SEE, a lake of Stiria; nine miles E. of Neumark.

LAVARA, in Ancient Geography, a town of Hispania, in the interior of Luutania. Ptolemy.

LAVARDAC, in Geography, a town of France, in the department of the Lot and Garonne, and chief place of a canton, in the district of Nérac. The place contains 928, and the canton 9482 inhabitants, on a territory of 1824 kilometres, in 13 communes.

LAVAREUS, in Ichthyology, the name of a small fish called by some the gang-fish, and by the Roman mariscus or curritas. It seems of a middle nature, between the trout and herring kind, and is caught in salt quantities, in the months of March and April, in several of the lakes in Germany, and is pickled, and sent to different parts of the world. It seldom grows to more than four inches long.

LAVAREUS. See Salmo Lavaretus.

LAVATER, John Gasparo Christian, in Biography, was born at Zurich in 1741. He was intended for the Protestant ministry, and entered upon holy orders in 1761. He acquired an early reputation by the eloquence of his pulpit discourses, and the zeal and benevolence with which he fulfilled the duties of his functions. He felt an early propensity to read the human countenance, and frequently exercised the pencil in felctching such features as had made a particular impression on him, which he studied with great attention. Accident led him to the study of physiognomy; standing at a window with Dr. Zimmerman, he was led to make some remarks on the singular countenance of a foilder that was passing by, which induced the physician to urge him to pursue and methodize his ideas. He accordingly
In the he yet the hardy many (lyle heart-fliaped, cuttion nothing Lavaler, when fore liberty. The work is soon translatced into the French and English languages, and for a time became the favourite topic of literary discussion. The work now is rarely referred to except for the plates; the science itself is gone into utter neglect. Lavater is well known for a work entitled "Aphorisms on Man," of which an English translation was published in 1806, in the year 1788. He was a zealous Christian, and translated into the German language "Bonnet's Enquiry into the Evidences of Christianity." His popularity as a preacher and pastor was extremely great at Zurich, where the people exhibited to him tokens of the highest respect and the most affectionate veneration, and he was applied to by persons of all ranks as the arbiter of controversies among them. His moral character was exemplary, and his ardent zeal for doing good was feared at any time unfurled. No man was ever a more determined opponent to tyranny and intolerance in every shape; he had the true Swift's zeal for liberty. This noble spirit rendered him a friend to the French revolution at the outset, but when the republican rulers began to display a system of rapine and extortion, and to extend this even to Switzerland, he was the boldest of their antagonists. When Zurich was burned in 1797, he rushed into the flames, and received a severe wound in the breast from a Swiss soldier, on whom he had conferred important benefits. From the effects of this he never entirely recovered; but the activity of his mind was unabated till a short time before his death, which happened on the 2d of January 1801, when he was in the sixtieth year of his age. A warm desire to promote the honour of God, and the good of his fellow creatures, was the principal feature in his character, and the leading motive of all he did. Next to these were an indefatigable placability, and an inexhaustible love for his enemies. Monthly Mag. Ann. Registor.

Eff. Ch. Calyx double; the outer three-cleft. Capules numerous, ranged in a circle, single-seeded.

One of the most handson of the malvaceous order, at least of those found in Europe, to which quarter of the world, and the north of Africa, the whole genus is confined; for the Linn.sea L. americana is no other than Sida abutio lodes of Jacquin, and Willdenow. n. 48. Eight species, exclusive of this, are detailed in Syll. Veg. ed. 14.; Willdenow has twelve, seven of which are shrubby, five herbaceous and mostly annual.

In the first section are

L. arborea. Sea Tree-Mallow. Linn. Sp. Pl. 972. Cavan. Dift. t. 139. f. 2. Engl. Bot. t. 1841.—Stem arboreous. Leaves downy, plaited, with seven angles. Flower-stalks axillary, clustered, single-flowered.—Found upon rocky cliffs on the south-west coast of England and south coast of Scotland. As well as in other parts of Europe, flowering in July and August. It is naturally biennial, though of a shrubby habit and above six feet high, for it blooms but once, though it will, in a garden, sometimes survive many winters before that event takes place. The stem is round and thick, branching at the top chiefly, where it forms a leafy head. The leaves are alternate, flat, pliable, single, downy, of seven shallow crenate lobes. Flowers numerous, axillary, purple, very like those of the common Malva sylvestris, but rather more handson.

L. triphala. Three-lobed Tree-Mallow. Linn. Sp. Pl. 972. Jacq. Hort. Vind. v. 30. t. 74.—Stem shrubby. Leaves rounded, crenate, somewhat heart-shaped, slightly three-lobed. Stipulas heart-shaped. Flower-stalks aggregate, single-flowered.—Found on the coasts of Spain and France. With us it is a greenhouse plant, not easily kept nor much valued, being far more beautiful on its native rocks, where the light hoary green of its copious foliage, is prettily contrasted with the large, very delicate, rose-coloured flowers. The broad stipulas are remarkable.

L. maritima. Soft Single-flowered Tree-Mallow. Gouan. Illutr. 46. t. 21. f. 2. (Althaea frutescens Linn.) Gouan. 9337.—Stem shrubby. Leaves rounded, crenate, bluntly angular, soft and downy. Stalks axillary, solitary, single-flowered. Native of Spain and the south of France. Linn. maritima did not distinguish its synonyms from the last, though it differs abundantly in the reach greater totteness of the leaves, want of stipulas, and the solitary flower-stalks. The flowers are large and elegant, of a light purple with dark claws. We have seen this species blossoming in Mr. Angelina's fine conservatory at Blackheath, but it finds no place in the 1st edition of Hort. Kew. or the 5th of Hort. Cant.

Of the second section are

L. thuringiana. Great-flowered Lavatera. Linn. Sp. Pl. 973. Jacq. Dift. t. 311. Curt. Mag. t. 517.—Stem herbaceous, downy. Leaves somewhat downy; the lower onesangular; the upper three-lobed. Flower-stalks axillary, single-flowered. Native of Hungary, Tartary, Germany, &c. about hedges; a hardy perennial in our gardens, flowering from July to September, and propagated either by root or by seed; yet as Curtis observes, "it is rarely met with in any of our collections," possibly because the trimfloris is preferred. The stems are few, erect, three or four
four feet high, clothed with short soft hairs. Leaves flaked, dependent, but slightly downy. Flowers on long solitary
flats, with large, pink, veiny petals, inerly heart-shaped,
their finules "puckered" as Curtis says; but this is not re-
prented by Jacquin in his wild plant, and is perhaps an
indication of luxuriance only.

Jacq. Hort. Vind. v. 1. 15. t. 41. — Stem herbaceous, rather
hairy. Leaves acutely five lobed. Flower-flats axillary,
aggregate.—Native of Crete, cultivated by Miller in 1768,
and we believe still preferred in Chelsea garden, coming up
spontaneously from seed, the root being annual. There is
nothing to recommend it to general admiration, the flowers
being far less ornamental than the wild Malva sylvestris, which
the plant resembles in herbage. We have a specimen from
the Goettingen garden named Lavatera sylvestris of Link.

Stem herbaceous, rough with deflexed hairs. Leaves
smoothly, heart-shaped, angular; the lower ones rounded.
Flower-flats solitary, shorter than the leaves.—Native of
Spain, France, and the Levant, a yearly annual in our
gardens, where it is raised without trouble, producing
abundance of large, pink or white, very showy blossoms,
all summer long. The stem is branched, two feet high,
rough in the upper part especially, with simple deflexed
hairs. The leaves are nearly smooth on the upper side,
more or less downy beneath, all heart-shaped; the upper ones
most angular, the lower more rounded, but still rather lobed.

Flower-flats hairy, shorter than the leaves.

— Stem herbaceous, rough with flary points. Leaves
downy; the lower ones rounded, the upper halfate.
Flower-flats solitary, elongated.—Native of the country
about Nice, according to Allioni, who first, among modern
botanists, determined this very distinct species, but did not
advert to Bauhin's synonymy, which Linnaeus had referred
to the preceding, but which, from the excellent figure and
description, we have no hesitation in applying to this. L.
punctata is an annual, disdistinguished from the laft by its flary
pubescence, much more downy foliage, and much smaller
purple flowers, on longer and more slender flats. The
leaves also grow long on footflats, and differ greatly in
shape, the lower ones being heart-shaped, shorter and rounded,
loosely lobed; some higher up deeply and flarly five-lobed;
but most of the upper ones halfate; all are crenate. The
calyx is soft and downy.

LAVATERA, in Gardening, comprehends plants of the
herbaceous perennial kinds, of which the species most gen-
erally cultivated are the Crete lavatera (L. ericita); the
common annual lavatera (L. trimorh); the great-flowered
lavatera (L. thuringiaca); the tree lavatera or mallow
(L. arborea); the downy-leaved lavatera (L. olbia); the
three lobed lavatera (L. triboba); and the Portuguese
lavatera (L. hifpanica).

The first kind varies with red flowers, with white flowers,
and with purple flowers.

The second kind has likewise several varieties.

Method of Culture.—The first two, or annual kinds, are
readily increased, by sowing the seeds in a light soil in the
places where the plants are to remain, or in pots, in the
spring season, as about the latter end of March, in patches
of four or five each, giving them water occasionally when
the weather is dry. When the plants have attained a little
growth, they should be thinned out to one or two of the
strongest plants. When any are to be removed to other
places, it should be done at this period, and with a little
earth about the roots, due water and shade being given; but
they seldom succeed well by transplanting.

All the other shrubby perennial kinds may likewise be in-
creased by sowing the seeds, and managing the plants in
the same manner. Most of these kinds will not last more
than two years in this climate, unless the soil be dry, when
they continue three or four.

They in general require a warm dry situation, or to have
their roots covered by old tan, or the protection of the green-
house during the severer of the winter season.

These plants are highly ornamental in different parts of
pleasure-grounds. The annual kinds have great beauty, in
their flowers being large, numerous, and conspicuous, and are
proper where large showy-flowery plants are required.
The perennial kinds are also suitable for large borders and
shrubbery compartments, having large, bright, upright,
durable stems, terminated by leafy bushy heads, and very
large soft foliage; that form a variety in assemblage with
other plants, though their flowers are often hidden by their
large leaves.

LAVATION, in Antiquity, a feast of the Romans, in
honour of the mother of the gods, instituted in memory of
the day when the worship of Cybele was transferred from
Phrygia to Rome, and celebrated on the twenty-fifth of
March.

LAVATORY, or LAVANDERO, a name given to certain
places in Chili and Peru, where gold is got out of earth by
washing.

M. Frezier gives us the following description of the la
vatories of Chili: they dig deep into the earth, in such places
as they have reason to expect gold in; and, in order to fa
cilitate this digging, they dig a stream of water upon the
spot, loosing the earth as much as possible all the time,
that the current may have the greater effect, and tear up
the earth more strongly. When they are got to the earth they
want, they turn off the stream, and dig dry.

The earth that they now get is carried on mules, and
discharged into a bason, made somewhat in the manner of
a smith's bellows, into which a little rivulet of water runs
with a great deal of rapidity, disloving the parts of the
earth, and carrying every thing away with it, excepting
the particles of gold, which, by their great weight, precipitate
to the bottom of the bason, and mix with a fine black sand,
where they are almost as much hidden as they were before
in the earth. See History of Gold.

Sometimes they find very considerable pieces in lavatories,
particularly some pieces of 24 ounces each. There are
several lavatories where they find these pepitas, or pieces
of virgin gold, of a prodigious size. Among others, they
tell of one that weighed 512 ounces, bought by the count
de la Moncloa, viccroy of Peru.

Nineteen or ten leagues to the east of Coquimbo are the
lavatories of Andecoll; the gold of which is 25 carats fine.
Their work here always turns to great profit, excepting
when the water fails them. The natives maintain that the
earth is creative (creatrix); that is, it produces gold con
tinually; because, after having been washed fifty or eighty
years, they find it impregnated afore, and draw almost as
much out of it as at first.

LAVATRIS, in Ancient Geography, a place of Great
Britain, mentioned in Antoninus's 5th Iter, situated between
Cataractoni or Cataract, and Verticis or Douch, and sup
posed to be Bowers in Yorkshire.

LAVARUS, in Geography, a town of France, and chief
place of a district, in the department of the Tarn, before
the revolution the see of a bishop; 18 miles N.E. of Tou
louse.

Samland; 23 miles E.N.E. of Königsberg.

1. LAUD, William, in Biography, archbishop of Canteb-
bury, the son of a clothier of Reading, in Berkshire, was
born in October 1573, and having received his grammar-
learning at the school of that town, he was sent to the
university of Oxford in 1589, where he was entered of St.
John's college. Of this college he was admitted a fellow,
and at the proper periods he took his degrees. In early
life he was esteemed by all who knew him as a very forward,
confident, zealous person. He was ordained deacon in
1600, and in the following year he took priest's orders,
and read a divinity lecture in the college. It was about
this time that he maintained the constant and perpetual
violability of the church of Christ, derived from the apostles
to the church of Rome, and continued in that church till
the reformation. In 1605, he was chosen proctor of the
university, and in the same year he was appointed chaplain
to Charles Blount, earl of Devonshire. In 1604, he took
his degree of bachelor of divinity, and in the exercise which
he performed on this occasion he maintained the necessity
of baptism; and that there could be no true church without
ecclesiastical bishops. From the drift of his discourse he was
supposed to be strongly inclined to popery. Dr. Abbot
had already been his antagonist, and on this occasion he
made no scruple of charging him with being a Papist in the
most public manner, so that it was scarcely safe to be con-
fidant his friend and companion. In the year 1607, Mr.
Laud married the earl of Devonshire, his patron, to Pen-
elope, the late wife of lord Rich, who had been divorced
from him for adultery. In justification of himself, he
contended that the innocent and guilty might lawfully marry
again, after a divorce had been obtained. The part which
he took in this affair expos'd him to much censure from the
public, gave great offence to the sovereign, and made so
deep an impression on the mind of Laud, that he ever after-
wards observed the anniversary of the marriage as a day of
suffering and humiliation. His first preferment in the church
was to the vicarage of Stamford, in Northamptonshire, in
the year 1607, which led to other situations of more value
and importance. In 1611, he was elected president of St.
John's college, and very soon after was appointed one of
his majesty's chaplains. He had new great hopes of rising
with rapidity to the highest honours, but his expectations
were to completely disappointed, that in the year 1614 he
had determined to withdraw from the court. By the per-
fusion of Dr. Nell, bishop of Lincoln, he was induced to
remain there another year; to keep up his spirits the pre-
late gave him a prebend in the church of Lincoln, and, in
the following year, the archdeaconry of Huntingdon. In
1616, the king presented Dr. Land to the deanship of
Gloucester, and at the same time required him to reform
and set in order whatever was amiss in that cathedral.
He was diligent in obeying the royal mandate, and made
great alterations in the church, which being effected, he rec-
ommended, that the members of that church should make
their humble reverence to God not only at their first en-
tance into the choir, but at their approaches to the holy
place, which he had removed from the middle of the church
to the east end of the choir. These changes gave great
offence to many prelates on account of their superstitious
tendency, particularly to Dr. Miles Smith, bishop of
Gloucester, who from that moment would never enter the
church again so long as he lived. Laud now began to take
an active part against the Puritans; and he was so very de-
fectuous to bring the church of Scotland to an uniformity
with that of England; with this view he attended the king
in a journey to Scotland, but nothing was gained by the ex-
peusive tour, excepting that the king saw his commands
neglected, and his authority contemned. Upon his return
he was made a prebend of Welfington, and in the follow-
ing year he was nominated to the bishopric of St. David's,
chiefly through the interest of the lord-keeper Williams,
at the inclination of the favourite Buckingham, to whom
Laud had recommended himself. In the year 1622, bishop
Laud held a conference with Tiffer, a Jesuit, before the
marquis of Buckingham and his mother, in order to con-
firm them both in the Protestant religion, with respect to
which they were then wavering. From this time a close in-
temacy subsisted between Laud and Buckingham, who made
the bishop his confessor and counsellor; and when he went
with prince Charles into Spain, left him as his agent at
court, with whom he maintained a frequent correspondence.
In the course of this, he furnished some heavy charges
against his friend, the lord-keeper Williams. This circum-
cstance occasioned a settled enmity between the two bishops,
Williams accusing Laud of the deep ingratitude on that
account. Laud corresponded with the duke of Bucking-
ham during his journey to France, to bring about a mar-
rriage between the princess Henrietta-Maria and king
Charles I. Supported by Buckingham's favour, to whom he
is charged with having rendered himself too subservient,
bishop Laud gained the confidence of the new king, and it
was said that these two men flapped up both the king's ears
from any other doctrines in church or state, but what was
insisted by them. Laud was desired by king Charles to
make out a list of the eminent divines with their principles
and qualifications, that from this list he might select his
chaplains, and others for promotion in the church. Laud
quickly gave in his list, of whom his friends had the mark
O against their names, for "orthodox," but those whom
he did not delight to honour, he branded with a P, signifi-
ying, that they were Puritans, and, as such, ought not to
be trudled with any power whatever. At the coronation
in 1626, Laud officiated as dean of Welfington, by the
king's appointment, in the room of bishop Williams, who
was in disgrace. In the same year he was translated from
St. David's to the bishopric of Bath and Wells, and was
also appointed dean of the chapel royal. In 1627 he
was sworn a member of the privy council, and, in 1628,
transfused to the see of London. By the advice of
Laud all ecclesiastical preferments were given away, and
the whole country was almost entirely governed. Upon
the assentation of the duke of Buckingham he prevailed
on the king to send to the judges for their opinion,

Vol. XX. 

3 B

"whether,
whether, by law, Felton might not be racked:" they returned a decided opinion, "that he could not be racked by the laws of England," Bishop Laud was the most active and leading member of the high-commission court, the arbitrary and severe proceedings of which were justly odious to the nation. For an instance of the extreme rigour and cruelty of their proceedings, we refer to the article LEIGHTON, a learned Scotch prelate, who was sentenced to stand in the pillory, and to have his ears cut off, and his nose slit, and then to be imprisoned for life, on account of a book which he had written. No sooner was the savage sentence passed, than bishop Laud pulled off his cap, and gave God thanks for it. In the year 1620, bishop Laud was elected chancellor of the university of Oxford, to which he was a great benefactor. He adorned it with many noble buildings, and enriched it with books and curious MSS. in almost all the known languages of the world, procured at an immense expense. In 1631, bishop Laud undertook to repair and beautify St. Paul's cathedral, which he accomplished in a very magnificent style; but to raise the money which was expended, he resorted to so many oppressive and unjustifiable methods, that it became the common proverb, that St. Paul's was repaired with the sins of the people. Laud showed great zeal in obtaining the utmost deference to all the external rites and ceremonies of the church, and he caused the several churches, in which he took an interest, to be adorned with all kinds of pictures, images, and altar-pieces, all which circumstances led the people to suspect, that he was too much inclined to the papal religion, if he were not already a Papist in his heart. This suspicion was still strengthened by his declaration, that in the disposal of all ecclesiastical preferments, he should give a most decided preference to single men, supposing the abilities of the single and married to be otherwise equal. In 1633, he attended the king in a journey to Scotland, and was present at his coronation for that country, which ceremony was performed in the abbey church of Holyrood-house. While in Scotland, he took every opportunity of urging the clergy to conformity with the church of England, but in this he was completely unsuccessful. Almost immediately after his return, Abbot, the archbishop of Canterbury, died, and Laud was instantly appointed his successor. He was, almost at the same moment, offered a cardinal's hat, which he declined, but upon what grounds he refused the honour is not known, though various motives have been assigned. He now carried matters very high, drove many of the French and Dutch Protestants, to whose ancestors Edward VI. had given an asylum, out of the kingdom; and either imprisoned or silenced many worthy clergy men, who refused to read the king's declaration for allowing lawful sports on Sundays after divine service. He was still more severe against those who were any ways suspected of puritanical principles. Some of them, by an exertion of arbitrary power, were fined, imprisoned, and even whipped, and kept to hard labour. Laud was, in 1633, nominated to other high offices, among which was the office of a commissioner of the treasury. He now procured the lord treasurer's staff for his friend Dr. Juxton, the bishop of London, which gave great offence to the people. (See JUXTON.) We cannot give any thing like a detail of the many prosecutions in which the archbishop was almost constantly engaged, they will be found in other articles of this work. (See BASTWICK, PRYNE, &c.) It is sufficient to say in this place, that these prosecutions were cruel, illegal, and tyrannical; but they were not borne by the people without deep, though silent, complaints. Never was man more hated, or more defamed, for there still existed in the country the printing press, by means of which his proceedings and character, and the arbitrary measures of the court, were exposed to the whole nation, in a secret manner. He accordingly procured a decree to be made in the star-chamber, which ordained, that the number of printers should be limited; and those who were allowed to follow the profession, should not be allowed to print any books of divinity, law, physick, philosophy, or poetry, till they had been licensed by the archbishop of Canterbury, or the bishop of London for the time being, upon pain of very grievous penalties. These proceedings, though they might be useful to the court for a short time, created so many enemies to the existing state of things, that there was great danger of some sudden convulsion. Many of the right men in the country, to avoid persecution, retired to America for an asylum, and a multitude of others would have followed their example, had not the archbishop obtained an edict to prevent any one from leaving the kingdom without a licence for that purpose. This was a degree of severity fearfully paralleled in the Christian world, but it answered no good end, for the people took a general disgust, and almost the whole of England was filled with Puritans. Laud did not confine his arbitrary measures to England, but was equally violent in his plans with regard to Scotland, so that he drew upon his head the hatred of that kingdom, and provoked the resentment which led to the renewal of the solemn league and covenant, subscribed by king James, and the whole nation in the year 1590. The attempt made in 1637, to force on the Scotch the new liturgy, was the first step which called forth the open opposition of all ranks. The king at first raised a powerful army to reduce the covenanters to submission, but when he had marched to the borders of Scotland, he found the preparations made to receive him so serious, and he knew that his Protestant nobility and soldiers were not zealously inclined in his cause, that he found himself compelled to seek for a general pacification. It was soon discovered that the idea of war was not abandoned, but only deferred, and that the English court were resolved to subdue the spirit of the people in Scotland. Laud and Strafford were the advisers of this resolution, and to raise supplies, application was made to the English parliament, which, after an interval of twelve years, was summoned to meet at Westminster for that purpose. The commons not only refused to comply with the desires of the crown, but appointed committees to confer the grievances under which they laboured. The king wished them to commence with a subsidy bill, which they refused; he at length dissolved the parliament, in great anger, before a single act was passed. All the engines of arbitrary power were let to work to raise money for the war, and those who refused to comply with the demands made upon them were fined and imprisoned. The greater part of the odium of these oppressions fell upon the archbishop, of whom the populace expressed their detestation in the most open way that they dared. On one occasion, viz. on May 9th, 1640, a paper was posted up, exposing the London apprentices to attack the palace at Lambeth, but the archbishop having had timely notice of their intentions, frustrated their designs, and dispersed the multitude, amounting to the number of 500 persons. One of them was taken in the act of breaking the windows, and was cruelly put to death as a traitor, but this extreme severity only served to inflame the mob still more against the archbishop. Another circumstance which contributed to encrease the number of the archbishop's enemies, was his continuing the convocation of the clergy after the dissolution of the parliament, by which he obtained several subsidies granted by the clergy, which the Commons had refused till their grievances were redressed. At length the necessities of the state obliged the king to call a new parliament, and,
as soon as it met, the canons and constitutions of the late convocation came before the house of commons. These, being diffused, were declared "to contain many matters contrary to the king's prerogative, to the fundamental laws and statutes of the realm, to the rights of parliament, to the property and liberty of the commons, and matters tending to sedition, and of dangerous consequence." In the course of the debates the archbishop's character was warmly attacked, and in some of the speeches he was charged with the treasonable design of subverting the religion and laws of the country. On the next day articles against the archbishop, presented by the Scotch commissioners, were read in the house of lords, and then reported to the house of commons, in a conference between the two houses. The resentment of parliament broke out into a flame, and a motion was made and carried that he had been guilty of high treason. Upon this, Denzil Hollis, son of the earl of Clare, was immediately sent up to the bar of the house of lords, to impeach him in the name of the Commons of England, to inform their lordships, that, in convenient time, they would bring up the particulars of their charge, and to request, that in the mean time he might be committed to safe custody. His grace being now commanded to withdraw, he requested leave to say "that he was heartily sorry for the offence taken against him, but humbly defined their lordships to look upon the whole course of his life, which was such, that he was very sure not one man in the house of commons did believe, in his heart, that he was a traitor." He was now committed to the custody of the gentleman usher of the black rod; and on the 26th of February, fourteen articles were brought up from the Commons by sir Henry Vane, the younger. He was then committed to the Tower, and in his passage thither he had to undergo the loud and deep curfes of an enraged populace. One of the first steps taken against him was levying upon his property a fine of twenty thousand pounds, for his proceedings in the convocation held in 1640. In June 1641, he resigned the chancellorship of the university of Oxford, and in the following October, the house of lords fequestrated his archiepiscopal jurisdiction. His confinement in the Tower was very severe, and he began to feel in his own person such sufferings as must bring to his recollection what he, in the day of his power, had inflicted upon others. After an imprisonment of nearly three years, he was brought to trial upon the fourteen articles already mentioned, and upon ten additional ones, which were now, for the first time, brought forward. Many of the charges were ill supported, and much of the evidence was trifling and irrelevant. It sufficiently appeared, however, that he had laboured to extend the royal prerogative and the ecclesiastical power, to a degree that was utterly inconsistent with the liberties of the people; that he had been zealously in enforcing the illegal claim ofshipmoney; that he had committed pernicious to prison, and punished them without law; and that he had been guilty of many arbitrary, illegal, and cruel actions. Archibishop Laud defended himself with uncommon spirit, eloquence, and acuteness, and with extraordinary liberality of mind. His counsel in their defence endeavoured to show, that if the charges were true, they did not amount to treason by any established law of the kingdom. This justification had its weight, and the lords, who were flagrantly the plea, deferred giving judgment, till the Commons thought fit to bring in a bill of attainder, which was, after much delay, passed. To stop the consequences of this, the archbishop presented the king's pardon under the great seal, but it was over-ruled by both houses. By this bill the archbishop was condemned to suffer death, as in cases of high treason, and all the favour he could obtain was to have his sentence altered from hanging to decapitation. He met his death with great firmness on Tower hill, on the 10th of January, being then in the seventy-second year of his age. Mr. Hume, in speaking of the learning and morals of archbishop Laud, says "he was the learned, if severity of manners, and abstinence from pleasure, could deserve that name. He was learned, if polemical knowledge could entitle him to that praise." In his government of the church, it has been justly observed, he displayed a total want of charity towards those who made the least opposition to the doctrines and ceremonies established by authority; and under his countenance, the star-clamber wore all the horrors, and exercised all the cruelties, of an inquisition. In state affairs his counsels were high and arbitrary, and he was very active in promoting those measures which ultimately proved his own ruin, and that of the king. He was in some cases generous and munificent: besides what he did for Oxford in its buildings and library, he founded an Arabic lecture, which began to be read in 1636, and he invested the university with many new privileges. He procured a charter for the town of Reading, founded in it an hospital, and endowed it with a revenue of 200l. per annum. The archbishop published some single sermons, which have been reprinted since in an octavo volume. He printed a conference between himself and the Jesuit Fether. His diary has been printed since his death; and in the year 1700, was published "An historical Account of all the material Transactions relating to the University of Oxford, from Archibishop Laud's being elected chancellor, to his Resignation of that office," written by himself. His letters to Gerard John Vossius were printed in London in 1690, and some others may be found at the end of Dr. Parr's Life of archbishop Usher. Biog. Brit. Toulmin's Edit. of Neal. Hume.

LAUDA, in Geography, a town of the duchy of Wurzburg, on the Tauber; 28 miles S.S.W. of Wurzburg; 60 miles S.E. of Gnefla. It is called Laudica.

LAUDAMNAT, a town of Bengal; 12 miles S. of Natore.

LAUDANUM, a name given by the chemists to certain preparations, chiefly extracts of opium, on account of their excellent qualities; the word being derived from laudare, to praise.

The "laudanum liquidum" of Sydenham, the Baica tinctura, or wine of opium of the London Pharmacopoeia of 1809, is prepared by macerating for eight days 1 oz. of extract of opium, bruised cinnamon bark and bruised cloves, of each a dram, in a pint of wine, and straining. It is observed, that the degree of narcotic power of this preparation is nearly the same as that of the ordinary tincture of opium, from which it differs, in having the extract for its basis, in the addition of aromatics, and in the vehicle employed. The extract of opium, it is supposed, produces less consequent affection of the brain and nervous system than crude opium, and the fame effect seems to be further obviated by the aromatics which are joined to it. This is a compilation of the same articles, in different proportions, as the Tinctura thebaica of P. L. 1745, and as the celebrated laudanum of Sydenham. This is still in use, and itpossesses such advantages by the modification of opium it affords, as to justify being referred to the Pharmacopoeia. See OPIUM.

LAUDAVA, in Geography, a town of Prussia, in the palatinate of Culm; 20 miles N.E. of Thorn.

LAUDER, a royal borough, in Berwickshire, Scotland, is situated on a river of the same name, about 22 miles to the south of Edinburgh, and 24 from Berwick. It is now
now only a place of a mean appearance, and entirely desti-
tute of trade. Formerly, however, it was a place of very
considerable note. It was constituted a royal borough at a
very early period, and for many years was distinguished as
the residence of royalty, and the seat of the Scottish parlia-
ment. In the reign of King James III., when the parlia-
ment was convened to consult upon the means of repelling
the English invasion, the nobility were so enraged at the
conduct of the favourite minister, Sir Robert Cochrane, that
they hung him and his associates over Luder bridge, in
preference of the king and his army. This town has five
fire engines during the year. It joins with Haddington, Salburn,
Dunbar, and North Berwick, in sending a representative
to parliament. Near the town, on the side of the river, is
Lauderhart, built by Edward I. of England, and now the
principal seat of the earl of Lauderdale. This manion
are several noble apartments, rich in picture work. One
of them is very carefully preserved, as a curious example of the
tattoo of the age in which it was made. Many vestiges of ancient
Pictish camps can still be distinctly traced in this neigh-
bourhood. Several tumuli, also, are visible on Lader-Muir,
which has probably been the scene of some battles in ancient
times, as many fragments of swords, bows and arrows, &c.,
have been dug up from this place. On a rising ground, not
far from the town, is the remains of a Roman station, in
which a number of coins of that people have been found at
different periods. Some ancient Spanish, English, and
Scottish coins have likewise been discovered in different
fields in this vicinity. The soil in the parish of Luder is light
and sandy, and in a high state of cultivation. The coun-
try rises gradually from the river, on both sides, to hills of a
moderate height, which afford excellent pastures for sheep.
Copper ore has been discovered in different spots, but is not
rich enough to admit of being wrought with any prospect of
advantage. Slate is also in plenty, but of an inferior quality.
Additions of a new point of view, commonly called elf,
or fairy arrow, and several other names of the most fanciful
shapes, are found here after heavy rains. The whole parish,
according to the parliamentary returns in 1800, contained
349 houseties, inhabited by 1760 persons. Sinclair's Ac-
count of Scotland, vol. i. by the Rev. Dr. James Ford.

LAUDI, ITAL. the motl ancient melodies that can be found in Italy, let to Italian words. It was the
opinion of Father Mencelir (sur les Dames en Musique)
that hymns, canzoni, and mysteries, in the vulgar tongues of Europe, had their origin from the pilgrims who went to the
Holy Land. St. Francis d'Alfio, born 1182, is men-
tioned by Cremonini, and other Italian writers, among the
first pious persons of that country who exercised their genius in
composing hymns and spiritual songs, called Laudii, in
the form of canzonets. Le Landi, which were likewise
called lutes, lotti, cantari, or canzoni, are composed of
praise of God, the Virgin Mary, or the saints and martyrs.
They resemble hymns to the subject, but not the char-
acter and verisimilitude; hymns having been originally con-
ducted on Greek and Roman models; but the Laudii,
or spiritual songs, are entirely of Italian invention.

A society for the performance of these religious poems
was instituted at Florence so early as the year 1310, the
members of which were called landolfi, and landolfo. In the
fifteenth century this species of sacred poetry was very much
employed and practised, as is manifest by the various collec-
tions that were made of them, one of which was printed
1485. It the next century several volumes of them were
published, among which there are many poetical composi-
tions on sacred subjects by Politian, Bembo, Lodovico Martelli,
and other eminent poets. (Quadrato, Storia d'Ogni Poet

vol. ii, p. 465.) In the 17th century, though their favour
was somewhat diminished, yet, besides a large volume com-
posed by Seraffino Raventi, and published by the author, 1608,
there were many collections of these spiritual songs printed.

Cremonini tells us that the company of landolfi of St.
Benedict, at Florence, went to Rome during the time of the
grand jubilee, in the year 1520, and sung through the streets in
procision several landi that were written by the celebrated
Pavia. In most of the ancient collections, the melodies
were prefixed to each of these songs. They were at first
little more than chants, and without base. However,
according to the commentary on Boccaccio, by Sanfimomo,
published at Venice, 1546, they were afterwards sung in
many different parts. "There are in Florence," says he,
"several schools of artizans and mechanics, among which are
those of Orfanichele, and Santa Maria Novella. Every
Saturday after nine o'clock these assemble in the church,
and there sing five or six landi, in four parts, the words of which
are by Lorenzo de Medici, Polci, and Giamberti; and at
every loud they change the fingers, and to the sound of the
organ discover a madonna, which finishes the festival. And
these fingers, who are called landolfo, have a preceptor, whom
they denominate their captain or leader."

This company still subsists in 1770, when we frequently
heard them sing their hymns, through the streets, in three
parts, and likewise in their church, accompanied by an organ.
Of the antiquity of this institution, as a MS. volume
of Landi Spirituali, which we found in the Magliabcechi library
at Florence, is an indubitable proof, the preface, and a speci-
men of three ancient melodies, bearing date MCCCXXXVI.
have been inserted in the General History of Music, vol. ii.
p. 327.

LAUDICOENI, among the Romans, formed of lausi,
praife, and cens. fipper or entertainment, applauders, or persons
who, for a reward, attended the rehearsal of plays and orations,
in order to raise, or join in the acclamation. See Ac-
clamation and Applause.

LAUDON, Gideon Ernest, Baron, in Biography,
was descended from a respectable family, originally from
Scotland, a branch of which settled in Lcowen, and there
perchased an estate at Totzen, where the subject of the fol-
lowing article was born in 1716. He displayed, at an early
age, a strong inclination for a military life, and being
instructed with this view, he entered, at the age of fifteen,
in to the Russian army as a cadet, and, in 1733, he was at the
taking of Dantze, where the king of Poland had fought
refuge, in consequence of the disturbances which then pre-
valent in that country. He served three campaigns under
Count Munich against the Turks, and was present at the
taking of Azof, Oczakow, and Chotzim. On the refor-
mation of peace, he flared some time at Peterburgh, in hopes
of higher promotion, but being disappointed in his ex-
pectations, he went to Vienna, was appointed by the
emperor to a command in the corps of Pandour, then
raised by baron Trenk, and with these he proceeded to Ba-
varia. While he belonged to this corps he was severely
wounded, and taken prisoner by the French, but was rel-
ased by his own corps before his wound was healed. After
this he was engaged much in active service, but he employed
every leisure moment in the study of the military art, and
in preparing hymnif for the active situation in which he was
afterwards placed in the seven years' war. In 1754, he
was employed to reduce to obedience the rebellious Croats, which
he did rather by his judicious conduct than by force of arms.
During the seven years' war, which commenced in 1756, he
performed the most noble exploits, which we cannot in this
place give in detail. Towards the close of that war, he de-
termined
LAVENDER, in Agriculture. A small shrubby plant, sometimes cultivated in fields near large towns for the spikes of flowers, which are either fold in small bundles, or distilled for lavender-water, and the essential oil of the plant.

The common spike lavender is molly employed with this intention. According to some the method of cultivating it is by planting the slips or cuttings of the young shoots, after being dried, in rich sandy borders or nurseries the preceding spring, about September or October, in rows, two, three, or more feet distance from each other, and about the same distance apart in the rows, the ground being kept clean by digging or hoeing in the spring or autumn, and the plants retained in order by proper pruning. And as they decay from age or other accidents, they are replaced from the nurseries; the slips of such plants as are wearing out being made use of for the purpose. The spikes of flowers begin to get ripe and ready for gathering about the end of June or July, when it is collected by women and children by cutting off the heads and tying them up in bundles, to be sent to the distillers, or other places, in proper baskets.

When, for distilling, the lower parts of the items are then cut off and the heads put into the still.

But this plant, when cultivated in the field, should, according to others, have the ground well prepared by digging, or repeated ploughing and harrowing; after which, in the spring season, as about March or beginning of April, a proper quantity of slips or cuttings of the young shoots or branches should be provided, and planted at once by means of a dibble, in rows of not more than two and a half or three feet apart, and one and a half or two feet distant in the rows, closing the mould well about them. They afterwards require to be kept clean by means of the hoe, and to have the mould brought up to them occasionally, particularly in the autumn, and the dead items or leaves cleared away.

They will molly afford spikes of flowers in plenty in the second summer, after being thus planted out.

Lavender
Lavender succeds best where the soil is rather of a dry quality, and not too light. In some parts of the southern districts near London, it is grown in the fields with much profit.

In the Agricultural Survey of Berkshire, it is stated, that the late field-marshall Conway, about twenty years ago, formed a large lavender plantation, and erected proper apparatus for its management at Park-place, near Henley. "There are about twenty acres planted with lavender, on the side, and at the bottom of a chalky hill, with a south-western aspect. The land at the bottom is very good, but that on the slope has only a thin covering of mould over the chalk, and the difference of soil is strongly marked by the luxuriance of the plants they respectively bear."

It is of such importance to keep crops of this sort perfectly clean, that three men are constantly employed in weeding this plantation; who, occasionally, use small hand-hoes, but not much, as they are liable, without great care, to break and injure the plants. When the state of the weather will not admit of this sort of business being done, they go over the plantation with large shears, and clip off all the flanks which were left by the lavender cutters.

Hot summers are very favourable to the productiveness of plantations of this kind.

**LAVENDER, in Botany.** See **LAVANDULA.**

**Lavender Cotton.** See **Santolina.**

**Lavender, French.** See **Cassidony.**

**Lavender, Sea, Limonium.** See **STATIC.**

**Lavender, Hollow-based Sea, or Side-saddle Flower.** See **SARRACENA.**

**LAUNETRED, in Geography,** a town of Wellphila, in Calenberg, on the Wefer; 15 miles N.W. of Gottingen.

**LAVENHAM,** a market-town and parish in the hundred of Babong, and county of Suffolk, England, was formerly considerable for its manufacture of woolen clothes and calimancoes. The making of yarn from wool is now, however, the principal employment of the inhabitants. The market is held here on Tuesday, and there are two fairs during the year; one for butter and cheese on the 10th of October, and another for hores on Shrove Tuesday. Six capital burghoys, chosen for life, constitute the governors of the town, and by them all the inferior officers are appointed. The land here is of that sort called Borough-English, whereby all heritable property descends to the youngest son, or, in default of issue, to the youngest brother. The town itself is agreeably situated on the banks of the river Brell, from which it rises in a gentle acclivity, and consists of nine streets or divisions, and a market-place, with a stone ezech in the centre. At the south end stands the parish-church, one of the finest specimens of ancient ecclesiastical architecture in the county. This noble building was probably founded towards the close of the fifteenth century. Its walls are built of freestone, intermixed with very curious decorations of flint-work. On every side they exhibit a variety of arms of noble personages, who probably obtained that distinction by their benefactions towards the erection of the church. The inner roof is very finely wrought in carved wood; and there are two rows of such exquisite workmanship, as to vie with any in Henry VIIIth's chapel. This town has, likewise, a meeting-house for Dissenters, two charity-schools, and two Sunday-schools, one of which is supported by the Dissenters. In the parliamentary returns for 1800, the houses are stated to amount to 339 in number, and the inhabitants to 1776 persons.

**LAVENIA,** in Botany, a genus formed by the late Dr. Solander, and adopted from his manuscripts by professor Swartz, of the *Cotula Verbeina,* and *Verbeina Lavenia* of their common preceptor Linnaeus. The name is of unknown origin, and first used by professor Martyus to be vernacular in Ceylon. It first appears in the supplement to Ray's *Historia Plantarum,* v. 5. 217, on the authority of Shadrach, for the species last mentioned, for which it was adopted by Linnaeus as the trivial name. Whatever the derivation or meaning of this word may be, its euphony may uphold it, though, according to found principle, Swartz ought to have preferred *Adenosummma,* given to the same plant by the classical Forster, and constructed of *ade* a, a gland, and *summa,* a crown, the seed being crowned with three glands instead of the feather, hair or membrane appropriated to other genera of this family. Swartz. *Prod. 112.* Schreb. *444.* Willd. *Sp. Pl.* v. 3. 1734. Mart. *Mill. Dict.* v. 3. (*Adenosummma*; Forst. *Gen. t.* 45. *Juss.* 184.)—Clafs and order, *Synepia Polygamia-equalis.* Nat. *Ord. Compositae dicotyl.* Linn. *Corymbifera,* *Juss.*

**Eff. Ch. Receptacle naked. Seed-down of three blisters, glandular at their tips. Calyx ovate, slightly imbricated. Style divided.**

*Obf.* Forster describes the florets as bearded or downy on their upper or inner surface.

**1. L. decumbens.** Decumbent Lavenia. (*Cotula Verbeina*; *Linn. Sp. Pl.* 1528. Mant. 473. *Chryanthemum* *fylveicum repens minus,* *chamaedryos folio,* *lore luto nudo,* *femine roiltro.* *Sioane Jam* v. 1. 262. t. 155. f. 2. *Tanacetum herbaceum erectum,* *folis cordatis crenatis oppositis,* *capitulis paniculosis remotis terminalibus; Browne Jam. 316. Herb. *Linn.*)—*Stem* decumbent. *Leaves* heart-shaped, obtuse, obtusely fertilated. *Native of the inland cool and shaly woods of Jamaica.* *Root* annual. *Stem* decumbent or prostrate, from nine to eighteen inches long, throwing out roots from the lower joints, simple, except now and then a short axillary shoot or two, leafy, nearly smooth, bluntly quadrangular. *Leaves* opposite, flat-topped, an inch or more in length and almost as broad, heart-shaped, nearly smooth, blunt, unequally and bluntly fertilated, three-ribbed, often cut away close to the lateral ribs at the base. *Flowers* few, terminal, convex, yellow, scarcely so large as a pea. *On* long, slender, in some degree paniculated, flarks.

confining of the fewest than the preceding, of a palish blue colour, and externally downy.

LAVENSAK, in Geography. See Lavensart.

LAVENSTEIN, or LOEVENSTEIN, a town of Germany, in the principality of Calenberg, which is a copper-mine; 12 miles S. of Salfeld. — Also, a town of Weih- phalia, in Calenberg; nine miles E. of Hameln. — Also, a town of Saxony, in the margravate of Meißen; 18 miles S. of Dresden. N. lat. 52° 42', E. long. 13° 40'.

LAVENZA, a sea-port of Italy, in the department of the Apennines, with a harbour at the mouth of a small river; seven miles S.E. of Sarzana. N. lat. 44° 3'. E. long. 10° 1'.

LAYER, in Botany, perhaps from the verb to love, alluding to its being valued up on the shore. See ULYA.

LAYER BREAD, a sort of food made of a seed-plant, otherwise called the after-green, or sea-borough. It is said to be used in the county of Glamorgan, and other parts of Wales.

LAYER, in Scripture History, a sacred utensil placed in the court of the Jewish tabernacle, containing of a bason, whence they drew water by cocks, for washing the hands and feet of the officiating priests, and also the entrails and legs of the victims.

LAVERNIA, in Antiquity, the goddess of thieves and cheats among the Romans, who honoured her with public worship, because she was supposed to favour those who wished that their designs might not be discovered. Varro says, that she had an altar near one of the gates of Rome; hence called Porta Lavernalis.

LAVERNICK, in Geography, a town of Prussia, in the territory of Culm, on the Drebents; 44 miles E. of Culm.

LAVEZZO, a name given by the Italians to a fleecy stone, of which vessels are made; called also Lapis coronatus and Potstone, which fee.

LAUF, in Geography, a town of Germany, in the territory of Nuremberg; 8 miles E.N.E. of Nuremberg. N. lat. 49° 8'. E. long. 11° 13'.

LAUFFEN, a town of the archbishopric of Salzburg, on the Salza; 11 miles N.N.W. of Salzburg. N. lat. 47° 54'. E. long. 12° 52'.

LAUFFEN, a village and castle of Switzerland, which gives name to a bailiwick, in the canton of Zurich, near the Rhine, where is a celebrated cataract; 2 miles below Schaffhausen.

LAUFFEN AM NECKAR, a town of Wurttemburg, on the Neckar, formerly imperial; 16 miles N. of Stuttgart. N. lat. 49° 5'. E. long. 9° 18'.

LAUFFEN, a town of Prussia, in Natangen; 15 miles S. of Bartenstein. — Also, a town of Austria, where the diet was held under Frederick I.; 18 miles S. of Gemunden. 

LAUFFENBURG, a fortified town of Germany, and one of the four great-towns of the late Austrian Silesia, situated on both sides of the Rhine, over which is a bridge; and at this place there is a fall in the river, 26 miles W. of Schaffhausen. N. lat. 47° 36'. E. long. 8° 4'.

LAUFFON, a town of France, in the department of the Upper Rhine, and chief place of a canton, in the district of Démont, seated on the Barfach; 16 miles N. of Soleure. The place contains 740, and the canton 7513 inhabitants, on a territory of 1725 kilometres, in 21 communes. N. lat. 47° 32'. E. long. 7° 20'.

LAUGEON, a town of Mecklenburg; 42 miles W. of Munchypour.

Gen. Ch. Cyl. Perianth superior of one leaf, tubular, small, deciduous, unequal at the orifice. Cor. of one petal, salver-shaped; tube very long; limb in five obovate segments. Stam. Filaments five, very short; anthers linear, long, within the tube. Pfl. German nearly ovate, inferior; style thread-shaped, rather longer than the tube; stigma capitate. Peric. Drupa roundish, umbilicated with a small depression. Sow. Nut roundish, with five furrows, and from two to five cells.

Obf. Vahl fuggsells that this genus might with propriety perhaps be united to Guttae; see that article.

1. L. adorata. Limn. Sp. Pl. 276. Jacq. Amer. 64. (Edechi; Looef. I. 295. 271. 306.) — Leaves elliptic-lanceolate, pointed, nearly smooth. Stem somewhat spinous. Clusters panicked. Nut with five cells. — Native of South America; observed by Jacquin in exposed bushy places on the sea shore, about the Havannah and Carthagena. The stem is shrubby, ten feet high, erect, branching, the branches opposite and widely spreading. Leaves opposite, on short stalks, from one to two inches, or more, in length, elliptic-lanceolate inclining to obvate, pointed, entire, veiny, described by Jacquin as smooth, but a young branch bent by him to Linnaeus, from the Vienna garden, has numerous hairs on the leaves, especially at the rib and edges, and its footstalks, like the twig itself, are very hairy. Stipulas axilary, opposite, lanceolate, recurved. Clusters axilary, panicked, lax, as long as the leaves. Flowers dirty red, very fragrant at night. Fruit copious, larger than a pea, very black, soft, when ripe falling off on the slightest shaking of the bush.

2. L. lucida. Vahl Ind. Oc. v. 1. 475. Vahl. Symb. v. 3. 40. t. 57. — Leaves oblong, obtuse, membranous, flowering. Clusters forked. Nut with two cells. — Native of bushy places, in the warmer parts of Jamaica, as well as in St. Lucia and Santa Cruz. A shrub with round, smooth, spreading branches. Leaves two or three inches in length, obtuse, with a blunt point, flowering, smooth on both sides. Stipulas axillary, ovate, acute, deciduous. Clusters from the boiloms of the upper leaves, so as to appear terminal, foliary, rarely opposite, the length of the leaves, either simply forked, or twice divided, widely spreading. Flowers nearly sessile in a simple row on each branch of the cluster, with a solitary intermediate one, with, fragrant. Fruit black, its nut of two unequal cells. Dr. Swartz thinks this may be the Ipisragunapp of Looef. I. 270, with the description of which it agrees in many respects, but he never observed any spines on his L. lucida. We have, nevertheless, no doubt of its being one and the same species.

3. L. coriacea. Vahl. Eclog. v. 1. 26. — Leaves elliptic-ovate, rather coriaceous, smooth on both sides, bluish. Spikes twice divided. Flowers tetradraconus. — Found on the summits of mountains in the island of Montferrat, where it was probably found by Von Rohr. A shrub or tree, but we know nothing further concerning it.

5. L. tomentosa. Vahl Ind. Oc. v. 1. 477. — "Leaves ovate, acute; downy beneath. Clusters forked. Nut of two cells." — Native of shrubby places in the western part of Jamaica. A small tree, twice the height of a man, with...
subdivided downy branches. Leaves shining and smooth above, silky and soft beneath. Flowers white. It blooms in autumn, and resembles a *Tournesol* in habit and inflorescence. *Saurax*.

LAUGHER, a name given to a particular species of pigeon, called by Moore the Columbia ridens. It is about the size of the common pigeon, and much of the same make, but it has a very bright pearl-coloured eye, almost white, and is a mottled red, or blue. They are said to be brought from Jerusalem, and the country thereabouts. When the cock of this species courts the hen, he has a gutteral cooing, not unlike the gurgling of a bottle of water, when poured out halily, and after this he always makes a noise not unlike laughing, from the singularity of which he has obtained his name.

LAUGHI, Lb., in Geography, a chief of Piedmont, which takes its name from a mountain; formerly held immediately of the empire, ceded, in 1746, to the king of Sardinia, or duke of Savoy, and now annexed to France.

LAUGHER, an action or passion peculiar to man. Authors attribute laughter to the fifth pair of nerves, which sending branches to the eye, ear, lips, tongue, palate, and muscles of the cheek, parts of the mouth, precordia, &c., there hence arises a sympathy, or conflict, between all these parts; so that when one of them is acted upon, the others are proportionately affected.

Hence a favour thing seen or smelt, affects the glands and parts of the mouth, a thing seen or heard, that is shame-ful, affects the cheek with blushing; on the contrary, if it please and tickle the fancy, it affects the precordia and muscles of the mouth and face with laughter; if it causes sadness and melancholy, it likewise affects the precordia, and demonstrates itself by causing the glands of the eyes to emit tears.

Laughter, according to Hobbes, is "a sudden glory, arising from a sudden conception of some eminence in ourselves, by comparison with the inoffemiess of others, or with our own formerly." Dr. Campbell, on the contrary, maintains, that this emotion doth not result from the contempt, but solely from the perception of oddity, with which the passion is occasionally, not necessarily, combined. See KEDICUL.

L'AUGIER, Monsignor, in Biography, principal physician to the imperial court at Vienna in 1772; the most intelligent and well informed eritic, among musical dilettanti, with whom we ever conversed. He had been in France, Spain, Portugal, Italy, and Conjantinople, and was perfectly well acquainted with national styles of music, and the peculiar merits and defects of individual composers throughout Europe. This gentleman, in despite of uncommon corpulency, posseffed a most active and cultivated mind. His house was the rendezvous of the first people of Vienna, both for rank and genius, and his conversation was as entertaining as his knowledge was extensive and profound. Among his other acquirements he had arrived at great skill in practical music, had a most refined discriminating taste, and could give, vocally, specimens of the national melody, which he had heard with philosophical ears wherever he had been; in fine, he was a living history of music. In Spain he had been intimately acquainted with Domenico Scarlatti, who, at seventy-three, composed for him a great number of harpsichord leffons, the chief of which had never been printed. The book in which they had been transferried contained forty-two pieces, among which were several *flow* movements, with which, for want of follimino and expreffion, in the old harpsichords, he seldom enriched his works. These leffons were compos'd in 1756, when Scarlatti was too fat to cross his hands, as he used to do; so that these are not fo difficult as his more juvenile works, which were made for his pupil and patrons, the late queen of Spain, while she was infanta of Portugal. M. L'Augier used to rete, that the empress queen Theresa had been a very notable musician, and that some years ago he had heard her fing very well. In the year 1739, when she was only twenty-two years of age, and very handly, she fing a *duo* with old Senecline, at Florence, so well, that by her voice, which was then a very fine one, and graceful and steady manner, she so much captivated the old man, that he could not proceed without shedding tears of satisfaction. Her imperial majesty had long been a performer, that she one day, in pleafantry, told the old Faulina, the wife of Hassi, who was then upwards of seventy, that she thought herself the first (meaning the oldest) virtuofa in Europe; for her father, at a rehearsal, brought her on the court stage at Vienna, when she was only five years old, and made her fing a long.

Metafatho, in a letter to Farinelli, calls M. L'Augier Monignor; the physician of the pope, and we suppose the imperial physician is qualified with the title of Monignor, my lord. The imperial Laurent tells Farinelli, that Monignor L'Augier is charmed with him, with his heart, and with his conduct. And sporting with his rotundity, he says, that he often visits me, in spite of his immeasurable corpulence, and moves to the altitude: where I recline, with the lightest of the most finn dancers. I shall, with my making, embrace as much as possible of his majestic circumference.

This extraordinary proficiency, with a mind proportioned to his body, died at Vienna in 1774, to the great loss of society in that city, and of found criticism and good taste.

LAVIANO, in Geography, a town of Naples, in Principato Citera; 27 miles E. of Salerno.

LAVIJAR, a town of Spain, in Grenada; 18 miles N.W. of Almeria.

LAVIGEN, a town of Norway, in the diocese of Drontheim; 24 miles N. of Drontheim.

LAVIGNON, a name which the fishermen of the vicinity of Rochelle give to a shell-fish, which is used for food in that place, and is probably a species of Solen. It is common on the coast of Petou, and has a very thin pair of shells for its covering, and which never can shut close, in the manner of the oyster or mufcle, or other common bivalve shells: the fish, therefore, always buries itself in the mud by way of security. The shells are very smooth and polished, especially on the inside, and they are naturally white. This colour they always retain within, though their outer surface is often tinged black by the mud.

They are often barried five or six inches deep in the mud, but it is always easy to know where they are, because they must keep a free communication with the water above; by means of a round aperture, of about a tenth of an inch diameter, which opens from the surface of the mud to every shell-fish. When the shells of this fish are opened to their utmost width, it is easy to see a sort of arm with which each is furnished, in the manner of the common mufcle, for its progressive motion. This part serves them to bury themselves in the mud, and to raise themselves out of it again, when they are inclined to seek a new habitation; into which they make their way in a more speedy manner than would easily be thought.

When the creature is plunged to its proper depth under ground, it receives the benefit of the water above, by means of two pipes, or proboscides, which have each a double aperture at their ends. The fish in this manner and throw it out again, alternately, for the uses of the animal, and either of the two is indifferently qualified to answer either purpofe.

The fish has a power of lengthening, or shortening these pipes
pipes at pleasure, and, when it pleases, takes them wholly into the field. Mem. Acad. Par. 1710.

LAVIN, in Ornithology, a name given by the people of the Philippine islands to a species of hawk, a bird of great beauty, being variegated all over with yellow, black, and white. They call it also Feud.

LAVINGEN, in Geography, a town of Bavaria, in the principality of Neuburg, on the Donau, supposed to have been a Roman colony; five miles above Hocklett. N. lat. 48° 27'. E. long. 19° 22'.

LAVINGTON, East, or Market Lavington, a market-town and parish in the hundred of Swaunborough, and county of Wilts, England, is situated at the northern termination of Salisbury plain. It was formerly called Steple, or Staple, Lavington, and was a considerable town; having acquired the name of Cheaping, or Market Lavington, from its great corn market, which was established early in the fifteenth century, but is now much decreased, as the chief resort of the dealers is to Devizes. East Lavington is 89 miles from London; the markets were on Monday and Wednesday. The population, as returned to parliament in 1801, was 518; the number of houses 167. Bishop Tanner, the celebrated author of "Notitia Monastica," was born in this town in 1674.

Whf, or Bishop's Lavington, is a parish within two miles of the foregoing, but is situated in the hundred of Whorlton; it was returned in 1801, as containing 214 houses, and 958 inhabitants. Britton's Beauties of Wiltshire, v. 3.

LAVINUM, in Ancient Geography, a small town of Latium, exactly S. of Rome, and eight miles S.E. of Laurentum, near the sea-coast, on the rivulet Numicus, between the mouth of which, and the Tiber, Lavinia is supposed to have landed. According to Strabo, he built this town after the defeat of Turnus, king of Ardea; thus perpetuating his victory and the name of his wife Lavinia, daughter of king Latinus. According to the same author, he erected here a temple of Venus, the care of which he committed to the Arادات. But as this city was not strong enough to repel the assaults of his enemies, who were jealous of his power, he built another on an eminence, E. of the first. See LAVINIA.

LAVIS, a town of Tyrol, at the union of the rivers Lavas and Adige; eight miles N. of Trent.

LAVI DE ILAMAGNE, a town of France, in the department of the Gers, and chief place of a canton, in the district of Lectoure; 12 miles E. of Lectoure. The town contains 1356, and the canton 7606 inhabitants, on a territory of 195 Kilometres, in 15 communes. N. lat. 43° 57'. E. long. 1'.

LAKAS, a town of Sweden, in the government of Wafa; 124 miles E.S.E. of Wafa.

LAUKOWITZ, a town of Beshima, in the circle of Boleva; 10 miles N.N.E. of Jung-Buntzel.

LAUAY, PETER, in Biography, was born at Flins in the year 1573, and having considerable family interest, he obtained, in early life, a post under government, and was made secretary to the king. These honours he willingly renounced, in order that he might devote his time to the study of the sacred writings. His works prove how diligently he followed his new profession. He acquired the respect and esteem of the French Protestants, and he was chosen deputy to all the synods of his province, and to almost every national synod which was held in his time. He died in 1663, at the age of eighty-nine years. His works are paraphrases on the books of Proverbs, Ecclesiastes, the prophet Daniel, all the epistles of St. Paul, and the Apocalypse, which were published at different periods. He published likewise Remarks on the Bible, or an Explanation of the different Words, Phrases, and Figures of the Sacred Writings; and A Treatise on the Lord's Supper.

LAUNCH, in Ichthyology. See Ammonites.

LAUNCHGAYS, in our Old Writers, a kind of offensive weapons now diffused, and prohibited by the statute 7 Rich. II. cap. 13. Many of the commentators on our ancient laws profest themselves unable to explain what kind of weapons these were. Grose suggests, that the term launchgay may be a corruption of the words lance agitans, a sharp or pointed lance; and if the intention of the acts be considered, it will justify, in a degree, this supposition; as they were evidently framed to prevent those violent affrays that frequently arose among the gentry of that time, commonly attended by a numerous suite, who, if armed with mifehievous weapons, might have spilt much blood. A lance fit for war was, perhaps, termed sharp, or pointed, in opposition to a blunt or tilting lance. See LANCE.

LAUNCESTON, in Geography, a populous borough and market-town in the hundred of East, and county of Cornwall, England, is situated on an eminence, at the distance of one mile from the river Tamar, near the central part of the eastern side of the county. Its ancient name was Dunheved, the Swelling Hill; but the present appellation, according to Borlase, signifies the "Church of the Castle." The castle is the most important object in the town, to which, in all probability, it gave origin. Its mouldering walls surround and cover a considerable extent of ground, and prove it to have been a fortress of great strength and importance. The principal entrance was from the south-west, through a fortified passage upwards of an hundred feet in length, and ten in breadth. At the end of this stood the great gate, the arch of which was pointed, but is now in ruins. This led to a smaller gate, with a round arch, opening into the bailey court, which formed a square of 136 yards, surrounded by thick walls and fortified with a deep ditch. At the south-west angle was a very strong round tower, whence a terrace extended to the keep or castle at the south-east angle of the court. This consisted of an immense artificial hill, nearly ninety feet in perpendicular height, about 300 feet diameter at its base, and 93 at its summit. The ascent to this keep originally commenced at a semi-circular tower, and continued to the top through a covered way, seven feet wide, now in ruins. The keep consists of three wards, and is surrounded by a circular wall. The thickness of the outer wall, or parapet, is about three feet; the second wall is six feet from the former, nearly four times the thickness, and considerably higher. About eight feet within this wall is another, ten feet thick, and thirty-two feet high from the floor of the inclosed area, the diameter of which is about eighteen feet. In the bailey court formerly stood the county gaol, a spacious affize court, a chapel, and other buildings; but these have all been taken down, except the gaol, which retains its situation near the bottom of the hill. The building of this castle has been generally attributed to William, earl of Moreton and Cornwall, in the time of William the Conqueror; but this opinion is probably erroneous, as the style of workmanship exhibited in several parts of the remains, is apparently of a much earlier date. The walls of the keep, in particular, have every appearance of being considerably more ancient; and from a retrospective view of events that have occurred in this county, the conjecture appears to be fully warranted that the foundation of the castle is as remote as the time of the Britons. The era
in which the town was founded, or, at least, began to assume a regular form, is better determined; this was about the year 990. No remains of the original buildings are now extant. On the north side of the town was a priory of Augustine monks, said to have been established by Warlewalt, bishop of Exeter. As this town was a principal residence of the earls of Cornwall for many years after its foundation, its confluence continually increased, and many liberties and privileges were granted to its inhabitants. Soon after the conquest a weekly market was established on Sunday; in the reign of king John, the townsmen paid five marks for the removal of the market to Thursday, but it has since been changed to Saturday. In the reign of Henry III. Launceston was made a free borough by the king's brother, Richard, earl of Poictiers and Cornwall: he also granted the inhabitants some additional immunities, which were confirmed by several subsequent charters; and in the reign of Richard II. the affizes were ordered to be held at Launceston, and "where no else." This regulation was observed till the first year of George I. when an act was passed empowering the lord chancellor to appoint any other place in the county. Since that period the winter assizes only have been held here; those of the summer having been removed to Bodmin. By a charter of Philip and Mary, granted in 1555, which enumerates and confirms the various prior charters, the government is vested in a mayor, recorder, and eight aldermen, who, with the free burgesses, have the right of electing the parliamentary representatives. The whole number of voters is about twenty. This borough made its first return in the twenty-third of Edward I. and had a mayor as early as the time of Edward IV. Near the centre of the town is the church of St. Mary Magdalen, a handsome fabric, built with square blocks of granite, most of which are enriched with carved ornaments, executed in a very singular manner. At the western end is a lofty tower; and a figure of the Magdalen, in a recumbent posture, is placed in a niche at the east end. This church was originally only a chantry chapel; in the reign of Henry IV. it was re-edified and considerably enlarged; in Henry V.II.'s reign it was consecrated a parish church, and was again rebuilt in the time of Henry VIII. The town was formerly surrounded by a wall, of which some parts still remain. The streets are narrow; but the houses are well built; on the south side is a fortified gateway, containing an apartment used as the town gaol. The children of the poor are educated in two charity-schools maintained by voluntary subscription; and a free-school founded and endowed by queen Elizabeth. Launceston is distant from London 213 miles; has a weekly market on Wednesday, besides that on Saturday already mentioned, and six annual fairs; the return to parliament in the year 1801 stated the population to be 14,939, the number of houses 226. The houses of this town are connected with those of Newport, which is a borough, though apparently only part of Launceston. See Newport.

About two miles north of this town is Werrington, a seat of the duke of Northumberland. Polwithre's History of Cornwall, 4to. Beauties of England and Wales, vol. ii.

LAUNCH, in Ship Building, is the slip or declivity on which the ship is built, also the whole machinery used in launching.

To facilitate the operation of launching, the ship, when she is first built, is supported by strong platforms, laid with a gradual inclination to the water, on the opposite sides of her keel, to which they are parallel. Upon the surface of this declivity are placed two corresponding ranges of planks, which compose the base of a frame, called the cradle, whose upper part envelops the ship's bottom, to which it is securely attached. Thus, the lower surface of the cradle, conforming exactly to that of the frame below, lies flat upon it, lengthways, under the opposite sides of the ship's bottom; and as the former is intended to slide downwards upon the latter, carrying the ship along with it, the planes or faces of both are well daubed with soap and tallow. The necessary preparations for the launching being made, all the blocks and wedges by which the ship was formerly supported, are driven out from under her keel, till the whole weight gradually subsides upon the platforms, which are accordingly called the ways. The shores and flancions, by which she is retained upon the rocks till the time of launching, are at length cut away, and the severs applied to move her, if necessary. The motion usually begins at the instant when the shores are cut, and the ship slides downward along the ways, which are generally prolonged under the surface of the water to a sufficient depth, to float her as soon as she arrives at the farther end thereof. When a ship is to be launched, the ensign, jack, and pendant, are always hoisted, the haly being displayed from a staff erected in the middle of the ship. Ships of the first rate are commonly constructed in dry docks, and afterwards floated out, by throwing open the flood-gates, and suffering the tide to enter, as soon as they are finished. Falconer.

LAUNCHING, the act of conveying the ship into the water after she is built.

LAUNCHING-Draft of Water, the depression of the ship, when first launched below the water's surface.

LAUNCHING-Planks, form the upper surface of the platform on each side the ship, whereon the bulwarks slide in the act of launching the ship.

LAUNDER, in Mineralogy, a name given in Devonshire, and other places, to a long and shallow trough, which receives the powdered ore, after it comes out of the box, or coffers, which is a sort of mortar, in which it is powdered with iron pestles.

The powdered ore, which is washed into the launder by the water from the coffers, is always fined nearest the grate, and coarser all the way down. See Bubble and Dressing of Ore.

LAUNDRY, as if Lavandarius, Fr. the room in which clothes are washed; or, in a more restricted and appropriate sense, as the term is used in the subfolent article, it denotes the place where clothes are mangled, dried, and ironed. Under this head we shall include the coffin-house, as it is necessarily connected with the laundry. Washing and getting up linen are employments of great importance in most families, and they have engaged the attention of many ingenious mechanics, who have contrived various washing-machines for the abridgment of labour and expense in this department of domestic economy. Most of the machines hitherto used are objectionable on many accounts, but principally because they operate by friction, instead of pressure. When the linen is properly prepared for washing, it may be thoroughly cleaned by pressure only. Rubbing it with the hands, or by any machine that operates by friction, injures it more than the use it fulfills in actual use. Hence it follows that the best method of cleaning foul linen is, first, to prepare it for the operation by soaping it where necessary, and putting it into a stone for at least twelve hours. This will loosen the filth, and decompose the grime and other matter with which it is soiled, and it will then be readily removed by alternately soaking, and squeezing or prefling. The defideratum, therefore, is, to construct a machine that would, by a rotative motion, or an up-and-down stroke, (like pumping) alternately press and saturate the linen with
LAUNDRY.

the fuds, and lastly with clear water. The machine that comes nearest to this, of any that has fallen under our notice, is one invented by Mr. Gould.

We shall now describe a wash-house and laundry, constructed upon scientific principles by John Bentley, esq., the present possessor of Highbury House, near London, being the completest of the kind we have met with.

The wash-house is 24 feet long, nine feet broad, and eight feet high. It is furnished with a filtering machine, a cistern for filtered water, two copper boilers, a copper cullender, a jack with pulleys, six washing tubs, a flume, sink, a wringing machine, and a pump of hard water.

The floor is rough Yorkshire-bone, laid upon a sharp current. Over two-thirds of the roof is lead, cistern containing 40 hogsheads of rain water, supplied from the adjoining buildings. The other third of the roof is conical, surmounted with a cylinder for a steam-vent, which opens and shuts at pleasure. When open, besides emitting the steam, it admits both light and air. The cistern for filtered water holds 220 gallons, and supplies, by pipes and cocks, the copper tubs and sink.

The first copper is fixed so that the top of it is level with the bottom of the cistern, and the bottom of it is level with the top of the other copper, and the tops of the tubs and sink, all which it supplies with hot water. The tubs, copper, and sink, are supplied with cold water from the cistern. Each of the tubs has a brass plug at bottom, to discharge the foul water. A nine-inch board runs along the front of the tubs and sink on the ground, to prevent the splashing of the water when discharged. Each tub is furnished with a small wooden strainer for soap.

The second copper is for boiling the linen, and has a copper cullender to hold the linen, which is drawn up by the jack and pulleys. The jack has a pin and ratchet wheel to keep the cullender suspended, and the copper till the water is drained from the linen into the copper, which can then be turned out altogether into the rinsing-tub. By this contrivance, the usual mode of poking the linen out with a flack (which frequently damages it) is avoided. At the bottom of this copper is a large brass cock for discharging the fuds when they are done with.

Though the fix tubs are supplied with both hot and cold water, there are only six cocks to the whole, one cock supplying two tubs, by means of a screw-joint in the nozzle, which turns at pleasure to either tub. There is also a screw-joint between the key and pipe in each cock, by which means it can at any time be repaired without the assistance of the plumber.

The filtering machine performs its operation by ascent. It has three cocks in one pipe. The uppermost is for regulating the quantity of water to be filtered, which can be varied at pleasure from 50 to 220 gallons in a day. The other is for cleaning the machine when satured with filth, which is accomplished by only turning the cock; and, will, in a few minutes, be as clean as it was at first; the mud; &c., being discharged at the third or middle cock, which also serves to draw unfiltered water when required. Under the cistern is a receptacle for coals, and under the filtering machine a place for pails and mops. Both cisterns have a surplus water-pipe to prevent running over, and in which are also plugs to discharge the water when necessary.

The fable hangs to the wall, and may be put up and down at pleasure. It is for forcing and foaming the soil linen, &c.

The laundry adjoining the wash-house is 18 feet square, and 11 feet in height. It has two windows in front. The floor is level, of rubbed Yorkshire-bone, laid upon brick piers, to keep it perfectly free from damp. It is furnished with one of Baker's large mangles; an ironing-board 12 feet by three feet, two large drawers for the ironing-cloth, iron-holders, &c, with room for the clothes-baskets underneath; a stove or drying-closet, eight feet by six feet; a furnace for heating the closet and the iron, and a place for coals under the floor, close to the furnace. The closet contains four wooden horset, each with five rails or bars. Each horse runs in and out of the closet upon two small iron wheels, upon an iron rail-way. One horse holds six flaps, or a proportionable quantity of other linen, and the whole will dry off so much and as speedily as fix women can wash in succession. It hardens the linen after being ironed, and is also useful for airing feather beds, &c. The linen, whilst drying, is kept free from smoke and dust, and there never can be any fume in the room.

The furnace for heating it is similar to those under copper or in a hot-house, immediately over which, before it enters the flue to the closet, is an iron oven for heating the iron. The flue is continued round the bottom of the closet, and carried up the end of the building. The top of the horizontal part of the flue is of cast-iron plates; iron being a good conductor of heat. A few inches above these iron plates, the iron rail-way before mentioned is laid, between which and the flue there is a flooring of wire work. This prevents any accident from the fall of linen upon the flue, but does not impede the ascent of warm air. Level with the rail-way, inside the closet, there is an opening 12 inches square, communicating with the external air. The ceiling of the closet is in the form of a hopper, terminating in a funnel of the same diameter (15 inches) as the external air-vent. Both these vents are furnished with a sliding door, which opens and shuts, as required, by pulley cords.

The principle upon which it acts is by heating it to a degree sufficient to excite a strong evaporation from the wet linen, and carrying off the moisture by means of the two vents. During the time of its acquiring this heat, both the vents, and also the horset, are kept closely shut, so that the closet is nearly air-tight. As soon as the proper degree of heat is obtained, both the vents are to be opened, when a strong current of air rushes in at the lowest, carrying up all the vapour from the linen through the upper vent or funnel, when the drying will be very speedily completed. The linen is then removed, a fresh supply put in, and the operation repeated as before, beginning by closely shutting all up.

Besides the dispatch and economy attending this wash-house and laundry, the health and comfort of those employed in them are greatly promoted, by being entirely free from the pernicious effects of damp vapour, and in not being incommoded by any extra heat in hot weather.

Since this article was written, the gentleman above mentioned has made a considerable improvement in the wash-house. He has constructed an apparatus for performing the operation by steam. Although it is not yet (December 1811) quite completed, it is sufficiently so to have appeared by experiment, that every species of soiled linen may be better cleansed this way than it is possible to do it by hands, or any machine hitherto invented. We say soiled linen, because the operation proves to be so powerful, that it discharges the colour from all dyed and printed articles that have been tried with it.

At the end of the wash-house a strong iron boiler is fixed, three feet six inches long, one foot eight inches wide, and two feet nine inches deep, with fittings up the same as those for steam-engines, i.e., a feeding-pipe with regulator, a
LAU

mercury gauge-tube, a three-inch steam-tube, two observation cocks, a safety valve, and a discharging pipe. From the steam-tube, a pipe of 1 1/2 inch bore is continued the whole length of the building; and from this main steam-pipe, others of smaller dimensions, from 1/2 to 1/2 inch diameter, are laid on the different steamng vessels. These may be either of wood, tin, or copper; but the latter is certainly best, for the action of steam is so powerful, that it will soon render both wood and tin useless. They must be fitted with a loose grating in the, about two inches from the bottom; a cock at one end, to admit the steam; and another at the other end, quite at the bottom, to discharge the foul water. The process is as follows: Soap the linen where it is very dirty, and put it to soak; then place the linen upon the grating in the steam vessel; cover it up, and turn on the steam. The discharging cock must be occasionally opened, to draw off the condensed steam; and when it is found to come off perfectly clear, which it will do in half an hour, or less, the operation is finished, and the articles will come out perfectly clean, and most beautifully white.

By this simple and easy process, the drudgery of washing is entirely done away; and the saving in time, soap, and other expenses, is greater than can well be conceived. The saving of water in many situations is a matter of consequence; but what is of still more importance, the linen will last double the time it otherwise would do; for as there is neither pressure nor friction, it cannot be injured in this process.

Washing by steam has been practised, but never before by this method. The way it has been done has been by steaming the linen in the soils. Hence it is evident that the filth that is forced out of the linen is mixed with the soils, and is again dispersed equally all through the linen; so that repeated changes of soap and water must be had recourse to, before the linen is made thoroughly clean. But by this new process, the linen being put into the steaming vessels, without any other liquor than it retains on being taken out of the soaking tubs, every particle of matter which is dissolved from it instantly subdues to the bottom of the vessel, and never can again come in contact with the linen. Our readers must excuse the prolixity of this article, on account of its great importance and usefulness in domestic economy to every family.

Note.—The boiler above described also heats an hot-houfe in an adjoining garden, besides boiling a copper, and thus does the work of fix fires.

LAUN, JOHN DE, in Biography, was born at Val- de-le, a village of Lower Normandy, in 1635. He received the early part of his education at Conflant, whence he was sent to the university of Paris, where he pursued his studies with great diligence for five or six years. In 1636 he was ordained priest, and soon after was admitted to the degree of doctor of divinity at the college of Navarre. For the sake of improvement he travelled to Rome, and became acquainted with the most eminent characters; but on his return to Paris, he applied with great intenseness to his studies, and composed a vast variety of works on subjects relating to history, criticism, and ecclesiastical discipline. At his own house he formed a kind of literary school, for the discussion of topics that tended to the improvement of the mind. He was an able defender of the rights of the Gallican church, in opposition to the pretensions of Rome. He attacked several false traditions with great intrepidity; and he contended so forcibly for expunging the names of several false saints from the calendar, that he was called the banisher of saints. It was said of him, that "he was a terrible critic, formidable both to heaven and earth; that he had expelled a greater number of saints from paradise than ten popes have canonicized. He suspected the whole martyrlogy; and he examined all the saints one after another, in the same manner as they do the nobility in France." By the freedom which he exercised in his writings, he provoked against him an host of enemies; and he was obliged, at the intimation of the king, to discontinue his academic, which were held at his own apartments. He met with an excellent friend in the abbé de l'Ecluse, who presented him with a valuable presentment in the church, which he soon resigned, choosing to live contented on a small income rather than endure the cares of business. He said that it was much more difficult for a Christian to make a right use of riches, than to live without them. He died in his 75th year, in 1708.

His works are very numerous, and have been collected and published in ten volumes, folio. Of one of his pieces, viz. "De Autoritate negantis Argumentis," Bayle says, had he published nothing else, he would have established his fame as a benefactor to the republic of letters, by a thousand fine hints which it contains for distinguishing truth from falsehood in historical matters. He was a person of great simplicity, a good friend, disinterested, and laborious; an enemy to vice, void of ambition, charitable and benedictious, and ever observing the fame tenor of life. Bayle. Moreri.

LAUNY, or LAUN, in Geography, a town of Bohemia, in the circle of Sattz, on the Ligna, on the road from Leipzic to Prague; 9 miles E.N.E. of Sattz. Lat. 50° 20' E. long. 13° 54'.

LAVOISIER, ANTHONY LAWRENCE, in Biography, a distinguished chemical philosopher, was born at Paris, on the 13th of August 1743. His father, who was a man of opulence, spared no expense in bellowing upon him the advantages of a liberal education; and he displayed very early proofs of the extent and fecundity of his studies, especially in the circle of the physical sciences. In the year 1764, the French government proposed a prize question, relative to the best method of lighting the streets of a large city. Lavoisier presented a dissertation on the subject, which he differed upon the most enlarged and philosophical views. This was not only highly approved, and printed at the expense of the Academy of Sciences, but obtained for him the present of a gold medal from the king, which was delivered to him by the president of the Academy, at a public sitting, in April 1766. Two years afterwards, he was admitted a member of that learned body, of which he was constantly one of the most active and useful associates. About the same time, he was occupied in experimental researches on a variety of subjects; such as the analysis of the gypsum found in the neighbourhood of Paris; the crystallization of salt; the properties of water; and in exploring the phenomena of thunder, and of the aurora borealis; and he distinguished himself by several dissertations on these and other topics, practical and speculative, which appeared in different periodical works. In the Memoirs of the Academy for 1770 were published his observations on the nature of water, and on the experiments which had been hitherto performed to prove the possibility of its conversion into earth. He proved, by a careful repetition of these experiments, that the earthly deposit, left after repeated dilutions of water, proceeded solely from an absorption of the vessels employed. Lavoisier performed several journeys into various parts of France, in company with M. Guettard; in the course of which he collected a store of materials for a lithological and mineralogical history of that kingdom, which he ingeniously arranged in the form of a chart. These materials were the basis of a great work on the revolutions of the globe, and on the formation of the parts of the earth: two interesting sketches of which were printed
printed in the Memoirs of the Academy for the years 1772 and 1777.

In fact, M. Lavoisier devoted his whole time and fortune to the cultivation of the sciences, the boundaries of which he seemed, by such an union of zeal, talent, and wealth, to extend. About this period, a new mine of experimental research, which promised the most curious and interesting results, had been opened up by the genius of Dr. Black, and already purified with much sagacity and industry by Dr. Priestley.—We allude to the discovery of the properties of certain aeriform substances, gales, or (as they have been called) factitious airs, which had hitherto escaped the attention of chemical inquirers. M. Lavoisier, struck with the beauty and importance of these discoveries, entered into the same field of research with all the scientific ardor by which he was characterized; and here the advantage of his ample wealth was manifest; for he conducted his experiments upon a large scale, with costly instruments of the most improved construction. The result of this course of experimental inquiry he gave to the world in 1774, in his "Opuscules Chymiques," which contained not only a clear and elegant view of all that had hitherto been done, in regard to gaseous or aeriform fluids, but also several original experiments, remarkable for their ingenuity and accuracy.

The existence of a gaseous body, in a fixed or solid state, in the mild alkalies and alkaline earths, which, when expelled from these substances, assumed an aerial form, and left them in a caustic state, as well as its production during the combustion of fuel, had been demonstrated by Dr. Black; and Bergman had shewn that this air possessed acid properties. Dr. Priestley had also submitted it to various experiments in the year 1767; but no progress had been made in ascertaining the real constituent parts of this acid gas, or fixable air. The honour of this discovery was left to Lavoisier; who, in 1772, by exposing a piece of charcoal, inclosed in a glass vessel, to the action of a lens, discovered that part of the charcoal was consumed, that a diminution of air had taken place in the receiver, and that the residue possessed the properties of the fixable air:—whence he concluded that charcoal was one of the constituent parts of this gas. The combustible nature of the diamond having been already proved by Macquer, d'Arcet, and others, Lavoisier was induced to submit this substance to the same treatment as the charcoal in the former experiment; and he found that precisely the same results took place: whence he inferred that there existed a great analogy between charcoal and diamond. Both these conclusions have been amply confirmed by subsequent experiments: they were in every respect important; and seem, together with the facts previously known, of the production of acids by the combustion of sulphur and phosphorus, to have given the first hint to Lavoisier of his sublime general theory of the formation of acids.

Lavoisier now turned his experimental researches to the subject of the calcination (as it was then termed, from its apparent similarity to the processes of making lime) of metals. It had already been shewn by Rey and Homberg, that metals acquire an augmentation of weight during calcination. This augmentation was attributed by the latter to the fixation of heat and light; but was superseded by the former to proceed from the fixation of a part of the air. M. Lavoisier published the result of his investigation of this curious subject in 1774, in a memoir on the calculation of tin in close vessels, in which he demonstrated the following very important facts. He shewed, 1, that a given quantity of air was requisite for the calcination of a given quantity of tin; 2, that a part of the air is absorbed during this process, by which not only the bulk, but the weight of the air is diminished; 3, that the weight of the tin is increased during the same process; and, 4, that the weight acquired by the tin is exactly equal to that which is lost by the air.

Thus by a few simple, accurate, and well-chose experiments, Lavoisier had apparently arrived at the legitimate inference, that during the process of the formation of acids, whether with carbonaceous matter, sulphur, or phosphorus, and also during that of the calcination of metals, an absorption and fixation of air take place, and thus he gained a glimpse of principles, in the view of which his singular sagacity in devising experiments, and his accuracy in executing them, would in all probability have alone conducted him to those brilliant results, to which the active genius of Dr. Priestley so materially contributed. The synthetic proofs only of this union of air with the bale had been as yet ascertained; but Dr. Priestley first furnished the analytic proof, by differing the combination; a discovery which at once advanced the new science of Lavoisier, and, in his hands, became the source of more than one important discovery. In August 1774, Dr. Priestley discovered, that by heating certain metallic calxes, especially the calcined mercury, (the precipitate per fœ, as it was then called,) a quantity of air was separated, while the mercury assumed its metallic form; and this air, which he found was much purer than that of the atmosphere, he called, from the theory of the time, the dephlogisticated air. The succeeding winter he spent at Paris, and communicated to Lavoisier, and the other philosophers there, his recent discovery; and the importance of this intelligence to the views of Lavoisier was manifest in a memoir published by him in the following year, 1775, on the nature of the principle which combines with metals during their calcination. In this paper he shewed, in conformity with the experiments of Dr. Priestley, that the mercurial precipitate per fœ, by being heated in a retort, gives out a highly respirable air, (since called oxygen,) and is itself reduced to the metallic state; that combustible bodies burn in this air with increased brilliancy; and that the same mercurial calx, if heated with charcoal, gives out not the pure air, but fixed air:—whence he concluded that fixed air is composed of charcoal and the pure air. It has, therefore, since been called carbonic acid.

A second very important consequence of Dr. Priestley's discovery of the pure or vital air, was the analysis of the air of the atmosphere: which was accomplished by Lavoisier in the following manner. He included some mercury in a close vessel, together with a known quantity of atmospheric air, and kept it for some days in a boiling state: by degrees a small quantity of the red calx was formed upon the surface of the metal; and when this ceased to be produced, the contents of the vessel were examined. The air was found to be diminished both in bulk and weight, and to have been rendered altogether incapable of supporting combustion or animal life: part of the mercury was found converted into the red calx, or precipitate per fœ; and, which was extremely satisfactory, the united weight of the mercury and the precipitate exceeded the weight of the original mercury, by precisely the same amount as the air had lost. To complete the demonstration, the precipitate was then heated, according to Dr. Priestley's first experiment, and decomposed into fluid mercury and an air, which had all the properties of vital air; and this air, when mixed with the unrefrangible residue of the original air of the receiver, composed an metallic fluid possessing the same properties as atmospheric air. The vital air was afterwards made the subject of various experiments in respect to the calcination of metals, to the combustion and conversion of sulphur and phosphorus into acids,
acids, &c, in which processes it was found to be the chief agent. Hence it was named by Lavoisier oxygen (or generator of acids), and the unrespirable residue of the atmosphere was called azot, (i.e. incapable of supporting life.)

The new theory thus acquired further support and consistency: oxygen appeared to be one of the most active and important agents of chemistry and of nature; combustion, acidification, and calcination, (or, as it was now called, oxidation), the calces being also termed oxides, i.e. something approaching to, or resembling acids, were proved to be processes strikingly analogous to each other; all according in these points, that they produced a decomposition of the atmospheric air, and a fixation of the oxygenous portion in the substance acidified or calcined.

This alone seemed now requisite to establish these doctrines, by exemplifying them in other departments of chemical research. In the year 1777, six memoirs were communicated to the Academy of Sciences by Lavoisier, in which his former experiments were confirmed, and new advances were made to a considerable extent. Our countrymen, Black and Crawford, in their researches respecting latent heat, and the different capacities of bodies under different circumstances, had laid a solid foundation, on which the doctrines of combustion, resulting from the foregoing experiments, might be perfected, and the causes of the light and heat connected with it might be explained. The first mentioned philosopher, Dr. Black, had shown, that a fluid, when it is made to assume a liquid form, and a liquid, when it assumes the form of vapour, absorbs or combines with, and renders latent, a large portion of heat, which is again parted with, becomes free and cognizable by the sense of feeling, and by the thermometer, when the vapour is again condensed into a liquid, and the liquid becomes solid. In like manner, it was now said by Lavoisier, during the process of combustion, the oxygen, which was previously in a gaseous state, is suddenly combined with the substance burnt into a liquid or solid. Hence all the latent heat, which was essential to a gaseous state, being instantaneously liberated in large quantity, produces flame, which is nothing more than very condensed free heat. About the same time, the analogy of the operation and necessity of oxygen in the function of respiration, with the preceding hypothesis of combustion, was pointed out by Lavoisier. In the process of respiration, it was found that, although atmospheric air is inhaled, carbonic acid and azot are expired. This animal operation, said Lavoisier, is a species of flow combustion: the oxygen of the air unites with the superfluous carbon of the venous blood, and produces carbonic acid, while the latent or combined caloric (the matter of heat) is set free, and thus supplies the animal heat. Ingenious and beautiful, however, as this extension of the analogy appeared, the subject of animal temperature is still under many obscurities and difficulties.

The phenomena of chemistry, however, were now explainable upon principles more simple, consistent, and satisfactory than by the aid of any former theory; and the Lavoisierian doctrines were everywhere gaining ground. But there yet remained a formidable objection to them, which was derived from a circumstance attending the solution of metals in acids; to wit, the production of a considerable quantity of inflammable air. If sulphuric acid (formerly called vitriolic acid, or oil of vitriol) infuses only of sulphur and oxygen, it was said, and bar iron is nothing more than this metal in a fluid state, how does it happen that, when these two substances, with a little water, come in contact, they should produce a large quantity of inflammable air during their reaction? This objection was unsatisfactory, and appeared to be fatal to the whole theory; but it was most opportunely converted into an argument in its favour, by the great discovery of the decomposition of water, made by Mr. Cavendish; who resolved that element, as it was formerly esteemed, into oxygen and inflammable air. The latter has since, therefore, been called hydrogen, or generator of water. This experiment was repeated with full success by Lavoisier and his associates in 1783; and the discovery was further established by a successful experiment of the same chemists, carried on upon a grand scale, in which, by combining the oxygen with hydrogen, they produced water, and thus adding synthesis to analysis, brought the fact to demonstration.

This new view of chemical phenomena, together with the immense accession of new compounds and substances, which the labours of modern experimentalists had brought to light, appeared to demand a correspondent alteration in the nomenclature. Accordingly, a committee of some of the ablest of the French chemists, of whom Lavoisier was the most conspicuous, undertook the arduous task, and produced a regular system of nomenclature, derived from the Greek language, which, although far from being faultless, and notwithstanding much opposition with which it was at first treated, has become the universal language of chemical science and has been adopted even in pharmacy and medicine. His work, entitled “Elements de Chimie,” which was published in 1789, was a model of scientific composition.

We have hitherto viewed M. Lavoisier principally as a chemical philosopher, in which character he has founded his great claims to the respect and admiration of posterity. But the other arts and sciences are indebted to him for considerable services which he rendered them, both in a public and private capacity. In France, more than in any other country, men of science have been confided in matters of public concern; and the reputation of Lavoisier caused him to be applied to, in 1776, to superintend the manufacture of gunpowder, by the enlightened minister Thugot. By the application of his chemical knowledge to this manufacture, he was enabled to increase the explosive force of the powder by one fourth; and while he suppressed the troublesome regulations for the collection of its materials from private houses, previously adopted, he quintupled the produce. The Academy of Sciences received many services from his hands. In addition to the communication of forty papers, relative to many of the most important subjects of philosophical chemistry, which were printed in the twenty volumes of Memoirs, from 1772 to 1793, he most actively promoted all its useful plans and researches, being a member of its board of consultation, and, when appointed to the office of treasurer, he introduced order into its accounts, and economy into its expenditure. When the new system of measures was proposed, he contributed some new and accurate experiments on the expansion of metals. The national convention consulted him with advantage concerning the best method of manufacturing assignats, and of securing them against forgery. Agriculture early engaged his attention, and he allotted a considerable tract of land on his estate in the Vendome, for the purpose of experimental farming. The committee of the constituent assembly of 1791, appointed to form an improved system of taxation, claimed the assistance of his extensive knowledge; and he drew up, for their information, an extract of a large work on the different productions of the country and their cultivation, for which he had been long collecting materials. This was printed by order of the assembly, under the title of “Richesses Territoriales de la France,” and was esteemed the most valuable memoir on the subject. In the same year, he was appointed one of the commissioners of the national treasury; and he introduced
into that department such order and regularity, that the proportion between the income and the expenditure, in all the branches of government, could be seen at a single view every evening. This spirit of systematic and lucid arrangement was, indeed, the quality by which he was peculiarly distinguished, and its happy influence appeared in every subject which occupied his attention.

The private life of this distinguished person was equally estimable with his public and philosophical character. He was extremely liberal in his patronage of the arts, and encouraged young men of talents in the pursuit of science. His house became a vast laboratory, where philosophical experiments were incessantly carrying on, and where he held conversations twice a week, at which all the votaries of learning and science, foreigners as well as Frenchmen, assembled. In his manners M. Lavoisier was mild, affable, and obliging; a faithful friend and husband, a kind relation, and charitable to the poor upon his estates; in a word equally claiming esteem for his moral qualities, as for those of his understanding.

The time was arrived, however, when dissipation even by his talents and worth was too far from securing public respect, amid the tumults of the revolution, that it became a source of danger. and, when joined with wealth, was almost certainly fatal. All those especially, who had held any situation under the old administration, particularly in the financial departments, were sacrificed during the murderous reign of Robespierre, to the popular odium. Lavoisier was seized and thrown into prison, upon some charges fabricated against himself and twenty-seven other farmers-general. During his confinement he forebore that he should be stripped of all his property; but confided himself with the expectation that he would be able to maintain himself by the practice of pharmacy. But a more severe fate awaited him: he was capitally condemned, and dragged to the guillotine, on the 8th of May, 1794.

The name of Lavoisier will always be ranked among the most illustrious chemists of the present age, when it is considered what an extensive and beneficial influence his labours have had over the whole science. It has been said, indeed, that if he be estimated on the score of his actual discoveries, not only Scheele and Priestley, and Cavendish, but many more, will stand before him. But, he possessed in a high degree that rare talent of discernment, by which he detected analogies, which others overlooked, even in their own discoveries, and a sagacity in devising and an accuracy in completing his experiments, for the purpose of elucidating every speculation which he thus acquired, such as few philosophers have possessed. No one who did so much, probably ever made so few unsuccessful or random experiments. It was the singular perpsectivity, simplicity and order to which he reduced the phenomena of chemistry, that claimed for his theory the general reception which it met with, and occasioned the abandonment of those doctrines which prejudice and habit confined to support. Subsequent discoveries, however, and more especially those numerous facts which the genius of Mr. Davy has lately brought to light, through the medium of that most powerful agent of decomposition, galvanism, have rendered several modifications of the Lavoisian theory necessary, and bid fair to produce a more general revolution in the language and doctrines of chemistry.

M. Lavoisier married, in 1771, the daughter of a farmer-general, a lady of pleasing manners and considerable talents, who partook of her husband's zeal for philosophical inquiry, and cultivated chemistry with much success. She engraved with her own hand the copper plates for his last work. Mad. Lavoisier has since given her hand to another eminent philosopher, count Rumford. Gen. Biog. Hutchinson's Biog. Med.

LAVONIA, in Geography, a town of Naples, in Calabria Citra; 8 miles W.S.W. of Rosiano.—Also, a town of Calabria Ultra; 14 miles W. of Squillace.

LAVORA, or TERRA DI LAVORA, a fertile and delightful province of Naples, diversified with hills and plains, lying between 40° 36’ and 41° 45’ N. lat.; anciently Terra Laboria, Campania, and Campus Laboricis, and in the middle ages the Calcidanny of Capua. It received its present name in 1601 from Richard II., prince of Capua, on account of the fineness of the soil for every kind of cultivation. This province is populous, and abounds in corn, wine, oil, and other productions of Italy. It is bounded on the N.W. by Campagna di Roma, on the N. and E. by Abruzzo Citra and Contado di Molife, on the S.E. and S. by Principato Ultra and Prineipato Citra, and on the W. by the Mediterranean: being 90 miles from N.W. to S.E. and 30—45 in breadth; and in 1779 it contained 1,216,989 inhabitants. It is watered by the rivers Carigliano and Volturro; the former, which is a placid stream, rives in Abruzzo Ultra, and falls into the sea below Trajetto; the latter descends from the Apennines, falls by Capua, and loses itself in the gulf of Gaeta. The capital of this province is Naples.

LAUPEN, a town of Switzerland, in the canton of Berne, and chief place of a bailiwick; it is situated at the confluence of the Saanen and Sente; 5 miles S.W. of Berne. It was once imperial.

AUQUEN, called Villarica by the Spaniards, a lake of Chili, about 72 miles in circuit, with a beautiful corinic hill in the centre. From this hill springs the river Tolten, which joins the Pacific ocean.

LAUR, a town of Persia, in Chusilhan; 50 miles E. of Toftar.

LAURA, a town of Ruffia, in the government of Moscow; 36 miles N.E. of Moscow.

LAURA, a town of Hindooistan, in the circle of Nagore; 20 miles W. of Catcheswara.

LAURA, Azge, primarily signifying village, fleet, or hamlet, a name given to the residence of the ancient monks. Authors cannot agree about the difference between a laura and a monastery; some pretend, that a laura was a monastery, wherein there lived at least a thousand monks; but this is nowise credible. The more natural opinion is, that the ancient monasteries were the same with the modern, consisting of large buildings divided into halls, chapels, and cells, posseted by the monks, each of whom had his apartment; but the laura were a kind of villages, whereof each house was inhabited by one or two monks at the most; so that the houses of the Chartreux seem, in some measure, to represent the ancient laura, and those of the other monks proper monasteries. The term laura was only understood of the religious places in Egypt, and the East, where their houses stood apart from each other, and were not joined by any common cloister, the monks that inhabited them only meeting in public once a week.

LAURADO, in Geography, a town of Portugal, is the province of Estremadura, on the S. side of the Tagus; 6 miles S.S.E. of Lisbon.

LAURAGAIS, the name, before the revolution, of a small country of France, in Upper Languedoc, of which Castelnaudary was the capital.

LAURANA, a sea-port of Inisla, with a small harbour, in the gulf of Quarnero; 8 miles S of Caffua. N. lat. 45° 28’ E. long. 14° 17’.

LAURE,
LAURE, a town of Portugal, in the province of Alentejo; 30 miles W.N.W. of Évora.

LAURÉAT, Pour, is a well known office in the king's household. Sir John Hawkins observes, that there are no records which ascertain the origin of the institution of the office in this kingdom, though there are many that recognize it. It appears that as early as the reign of Henry III. there was a court poet, named Henry de Avranches, who is supposed to have had an appointment of a hundred shillings a year, by way of salary or stipend. In 1344 Petrarach was crowned with laurel in the Capitol by the senate of Rome; afterwards Frederic III. emperor of Germany, gave the laurel to Conradus Celtis; and ever since the counts palatine of the empire have claimed the privilege of solemnly investing poets with the bays. Chaucer, who was contemporary with Petrarach, and acquainted with him, when abroad, assumed the title of poet-laureat on his return to England; and in the 17th year of Richard II. obtained a grant of an annual allowance of wine. We read of perions under the same title in the reigns of Edward IV. Henry VIII. and VII. and of James I. who, in 1615, granted to his laureat an annual penion of 100 marks. In the year 1530, this pension was augmented, by letters patent of Charles I. to 100L. per annum, with an additional grant of one terce of Canary Spanish wine, to be taken out of the king's store of wines yearly. Hawkins's Hist. of Music, vol. iv. p. 13.

LAUREATION, a term in the Scottish universities, used for the act of taking up the degree of a master of arts, to which the students are admitted after four years' study in the universities.

LAUREL, in Botany and Gardening. See Laureus and Primus.

Laurel (Common or Cherry), Prunus laurocerasus, in the Mataria Medica, is a native of the Levant, and has been long cultivated in Britain. The leaves have a bitter ptyclic taste, accompanied with a flavour resembling that of bitter almonds. The flowers also have a similar flavour. The powdered leaves, applied to the nostrils, excite sneezing, but less powerfully than tobacco. The kernel-like flavour of the leaves has caused them to be used for culinary purposes, especially in confars, puddings, blanc-manges, &c. and as the proportion to the quantity of milk is inconsiderable, this has been done without any noxious effect. However, as the poisonous quality of this laurel is now indubitably proved, the public should be cautioned against its internal use. The first and principal proofs of the deleterious effects of this vegetable upon mankind were communicated to the Royal Society by Dr. Madden of Dublin, in a letter giving an account of two women being poisoned by the simple distilled water of laurel-leaves, and of several experiments upon dogs, by which it appears that this laurel is one of the most dangerous poisons hitherto known. He mentions also the case of a gentleman, who by mistake drank a quantity of this laurel water, and died in a few minutes, complaining of a violent disorder in his stomach. (See Phil. Trans. No. 418. 426. vol. xxxvii.) The case of Sir Theodorus Boughton is more recent. His death in 1780 was ascribed by an English jury to this poison. In this case the active principle of the laurerocerasus was concentrated by repeated distillations, and given to the quantity of an ounce. It has been found by the experiments of Madden, Mortimer, Nicholls, Langrill, Vater, Fontana, and others, that to brute animals this poison is almost instantaneously mortal. These experiments also shew, that the laurel-water is destructive to animal life, not only when taken into the stomach, but also on being injected into the intestine, or applied externally to different organs of the body. The most volatile is the most active part of the laurerocerasus; and from its feasible qualities we may be led to judge, that an analogous principle seems to pervade many other vegetable substances, especially the kernels of drupaceous fruits; and in various species of the Amygdalus, this rapid principle extends to the flowers and leaves. It is observable, that it is much less powerful in its action upon human subjects than upon dogs, rabbits, pigeons, and reptiles. To poison man, the effluvium of the laurerocerasus must be separated by distillation, as in the spirituous or common laurel water; and unless this is strongly induced with the oil, or given in a large dose, it proves innocent. Dr. Cullen remarks, that the sedative power of the laurerocerasus acts upon the nervous system in a different manner from opium and other narcotic substances, whose primary action is upon the animal functions; for the laurerocerasus does not occasion sleep, nor does it produce local inflammation, but seems to act directly upon the vital powers. "Although this vegetable seems to have occupied the notice of Stoeckel, its medicinal use has its advocates. From Linnaeus we learn, that in Switzerland it is commonly and successfully used in pulmonary complaints. Langrill mentions its efficacy in ague; and as Bergius found bitter almonds to have this effect, we may from analogy conclude, that this power of the laurerocerasus is well established. Bayliss found that it possessed a remarkable power of diluting the blood, and from experience, recommended it in all cases of diffeafe supposed to proceed from too dense a rate of fluid; adding particularinstances of its efficacy in rheumatism, asthma, and in febrile affections. Nor does this author seem to have been much afraid of the deleterious quality of the laurerocerasus, as he orders a pound of its leaves to be macerated in a pint of water, of which he gives from 30 to 40 drops three or four times a day." Woodville's Med. Bot.

LAUREL, Alexandriou, in Botany. See Ruscus.

LAUREL, Dewy or America. See Kalymn.

LAUREL, Sea-foil. See Phyllanthus.

LAUREL, Sun-dew or Spurge. See DPNNG.

LAUREL, Mountains, in Geography, a range of mountains W. of the Alleghany ridge, and part of the Alleghany mountains; extending from Pennsylvania to North Carolina, and giving rise to several branches of the Ohio river. The Great Kanawaha breaks through the Laurel ridge in its way to the Ohio. N. lat. 38° 30'. W. long. 81° 10'. About lat. 36', in a spur of this mountain, is a spring of water 50 feet deep, very cold, and, as it is said, blue as indigo. The lands, within a small distance of the Laurel mountains, through which the Yougheengang river runs, are in many places broken and stony, but rich and well timbered; and in some places, and particularly on Laurel creek, they are rocky and mountainous. From the Laurel mountain to Morongahela, the lands for the first seven miles are good, level, and fit for farming, interspersed with fine meadows: the timber, white-oak, chestnut, hickory, &c. Morie.

LAUREL, River, a rivulet of Kentucky, which runs into the Cumberland. N. lat. 36° 34'. W. long. 83° 50'.

LAURÉL, pieces of gold coined in the year 1619, with the king's head laureated, which gave them the name of laurels: the twenty-shilling pieces of which were marked with XX, the ten shillings X, and the five-shilling pieces with V.

LAUREMBERG, Peter, in Biography, a learned physician, was born at Rotbeck, where his father was professor of medicine and mathematics. Peter took the degree of doctor in the university of his native place, and afterwards travelled.
travelled into France, and settled for some time at Montauban, where he taught philosophy in 1611. In 1614, however, he was at Hamburg, and was professor of natural philosophy there until 1620; when he returned to Rollock, and was appointed professor of poetry in 1621. He died in this city on the 13th of May, 1639, at the age of 54.

"Anatomy corporis humani, five Collegium Anatomicum duodecim difputationibus comprehensam," Ross. 1646.

His younger son, John Lauremberg, likewise was a physician, and author of several works, on the antiquities of Greece, algebra, and arithmetic, &c. Eloy. Dict. Hiüt de la Méd.

LAUREMBERGIA, in Botany, so named by Bergius in honour of Peter Lauremberg, formerly an excellent gardener, who published a work on horticulture at Francfort in 1632, which is said to have led the way to the modern improvements in that art. Berg. Cap. 350. t. 5. f. 10. See ZEPICULA, to which the synonym of Bergius undoubtedly belongs, though cited with hesitation in Schreb. Gen. 628. Lamarck's figure of ZEPICULA, t. 758, is in fact a copy of that of Bergius.

LAURENCE, Canons of St., an order of regular canons, so called from the monastery of St. Laurence d'Oulx, in Dauphiné.

This congregation is said to have been founded by St. Benedict. It was destroyed by the Vandals, and continued uninhabited till the middle of the 11th century. In 1057, Oslo, count of Savoy, gave it to one Gerard, and his canons. This donation was confirmed in 1065, by Cumberb, bishop of Turin, who added to it above forty other churches; by which means a very considerable congregation was formed, to whom the succeeding popes, and counts of Savoy, granted a great many privileges.

It had thirty priories; the chief, who is, the prior of the congregation, bears the title of provost, and exercises a spiritual jurisdiction throughout his provostship.

LAURENCE, Bay of St., in Geography, a bay on the E. coast of Russia, at the entrance of Bear's straits. N. lat. 63° 47'. E. long. 188° 15'.

LAURENCE Creek, a river of Kentucky, which runs into the Ohio, N. lat. 38° 30'. W. long. 83° 36'.

LAURENCE Island, a small island in the gulf of Florida, near the coast of Eait Florida. N. lat. 25° 36'. W. long. 80° 23'.

LAURENCE Island, an island in the Pacific ocean, on the coast of Raffia, near Tichukotski Nofs; about three leagues in circuit. N. lat. 63° 47'. E. long. 188° 14'.

LAURENCE, Gulf of St., a part of the North Atlantic ocean, situated between the island of Newfoundland, Labra-

dor, Canada, Nova Scotia, and the island of Cape Breton; 350 miles in length, and 150 in breadth. This is the estuary of the river of the same name, and it generally frozen from December to April. This noble gulf is closed by the island of Newfoundland, and by numerous sand-banks, particularly by that which is called the Great Bank. N. lat. 47° 16'. W. long. 57° to 63°.

LAURENCE, Harbour of St., a bay on the S. coast of Newfoundland, situated N.W. of the entrance into Piacentia bay.

LAURENCE Key, a small island in the bay of Honduras, near the coast of Mexico. N. lat. 16°. W. long. 89° 48'.

LAURENCE Kirk, a town of Scotland, in the county of Kincardine, in which have been lately established manufactories of laws, cambric, &c. In 1799 it was erected into a burgh of barony, with the privilege of a market. The population in 1801 was 1215; 7 miles W. of Bervie.

LAURENCE, or Lawrence, River of St., the largest, or at least the second, river in North America, being not less than 90 miles wide at its mouth, and navigable for ships of the line as far as Quebec, a distance of 400 miles from the sea.

Near Quebec it is five miles wide; at Montreal, 560 from its mouth, from two to four miles broad. To this place it is navigable with perfect safety for ships drawing fourteen feet water. During the whole of its course to Kingston on lake Ontario, 743 miles from its mouth, it is navigable for bateaux of two tons burden, except merely at the rapids above Montreal, at the Fall of the Thicket, and at the Long Fall, where it is necessary to lighten the bateaux, if heavily laden. Mr. Weld suggests, that at each of these places it is possible to construct canals, so as to prevent the trouble of unloading any part of the cargoes of the bateaux; and that, at a future time, when the country becomes rich, such canals will, without doubt, be made. The source of this river is not precisely ascertained; but the name is generally appropriated to the stream that issues from lake Ontario. From Ontario to Montreal it has the name of Iroquois, and afterwards it assumes the name of St. Laurence. This river cannot, conformably to geographical usage, be traced beyond lake Ontario, to lake Superior; much less, with Mr. Weld, to lake Winipic, which, according to the best maps, has no communication with the sea of Canada, or the connected lakes Superior, Michigan, and Huron. The length of the St. Laurence may be reckoned about 700 British miles, its chief characteristic being its breadth. Mr. Weld has made several observations on the importance of this river to the commerce of North America.

The time required to ascend this river, from Montreal to Kingston, is commonly found to be seven days, but with a strong and favourable wind the voyage may be performed in less time; and with an adverse wind it will of course require longer time. The passage downwards is performed in four or five days, according to the wind. The current is so strong, that a contrary wind seldom lengthens the passage in this direction more than a day. The channel of this river, instead of having been impaired by time, like those of many others, and that of the Mississippi in particular, is found to be considerably better now than when it was first discovered; and there is reason to imagine that it will improve still more in process of time, as the clear water from lake Ontario comes down with such impetuosity through the floods in the spring of the year, as frequently to remove banks of sand and of loose stones in the river, and thus to deepen its bed. To this purpose, it is observed, that the channel on the N. side of the island of Orleans, immediately below Quebec, which, in the year 1720, was not deep enough to admit a
though rm LAURENTIA, even, inhabitants, Laurent a few, with a -at diversified plains. never disciple quality. Henry lancholiques, The was long lying feven lurbour fertile this that attratcd tin, trade ocean, it is sufficient for the scenery fiiflicient and portages of ulitimately of Enoree district, containing 2,809 miles. of the place containing 549, and the canton 3706 inhabitants, on a territory of 67½ kilometres, in fix communes.

LAURENT d'Egouze, St., a town of France, in the department of the Gard; 15 miles S. of Nîmes.

LAURENT d'Arce, St., a town of France, in the department of the Gironde; eight miles S.E. of Bourg.

LAURENT de Cerdans, St., a town of France, in the department of the Eastern Pyrenees; nine miles S.W. of Ceret.

LAURENT de Chamonset, St., a town of France, in the department of the Rhone, and chief place of a canton, in the district of Lyons; 15 miles W. of Lyons. The place contains 1255, and the canton 10,978 inhabitants, on a territory of 182½ kilometres, in 14 communes.

LAURENT-fur-Gorre, St., a town of France, in the department of the Upper Vienne, and chief place of a canton, in the district of Rochechouart; 15 miles W.S. of Limoges. The place contains 2313, and the canton 13,519 inhabitants, on a territory of 265 kilometres, in nine communes.

LAURENT de Médoc, St., a town of France, in the department of the Gironde, and chief place of a canton, in the district of Légras; 50 miles from Légras. The place contains 549, and the canton 3706 inhabitants, on a territory of 67½ kilometres, in fix communes.

LAURENT le Minier, St., a town of France, in the department of the Gard; six miles S.E. of Le Vigan.

LAURENT du Morat, St., a town of France, in the department of the Mayen and Loire; nine miles S.E. of St. Florent.

LAURENT des Murs, St., a town of France, in the department of the Ière; nine miles S.E. of Lyons.

LAURENT fur Oisais, St., a town of France, in the department of the Meule; 12 miles N. of Étain.

LAURENT de la Pluie, St., a town of France, in the department of the Mayen and Loire; three miles S.W. of Chatonolle.

LAURENT du Pont, St., a town of France, in the department of the Ière, and chief place of a canton, in the district of Grenoble; 12 miles N. of Grenoble. The place contains 3339, and the canton 11,551 inhabitants, on a territory of 182½ kilometres, in eight communes.

LAURENT de Rivédel, St., a town of France, in the department of the Aveyron; nine miles N. of Severac.

LAURENT de la Salbaque, St., a town of France, in the department of the Eastern Pyrenees; seven miles N.E. of Perpignan.

LAURENTALIA, or LARENTALIA, called also Larentia, Laurentales, and Larentales, feasts celebrated among the Romans on the tenth of the calends of January, or twenty-third of December, in memory of Acca Laurentia, wife of the phelephylus Faulilus, and nurse of Romulus and Remus.

Acca Laurentia, from whom the solemnity took its name, is represented as no less remarkable for the beauty of her person, than her lasciviousness; on account of which, she was nick-named by her neighbours, lupus, fie-wolf; which is said to have given rise to the tradition of Romulus and Remus being buckled by a wolf. She afterwards married a very rich man, who brought her great wealth; which, at her death, she left to the Roman people; in consideration of which they performed her these honours; though others represent the feast as held in honour of Jupiter Lataris. See Laren-

LAURENTALIA and LARES.

LAURENTIA, in Geography, a bay or gulf of the Frozen sea, on the W. coast of Nova Zembla. N. lat. 75° 15'. E. long. 55° 14'.

LAURENTIA, in Botany. Mich. Gen. 18 t. 14, received its appellation from Michell, in compliment to Dr. Mark...
Mark Anthony Laurenti, a physician and professor at Bologna, whose botanical merits have not been transmitted to posterity, and the name is now sunk in that of Lobelia, to which article we refer the reader.

LAURENTOUM, in Ancient Geography, a town of Italy, in Latium, of which it was for some time the capital; and supposed to have been the residence of king Latinus; situated upon the sea-coast, about eight miles S. of the capital.

LAUREOLA, in Botany, Spurge Laurel. See Daphne.

LAURI, Filippo, in Biography, painter of figures and landscapes. He was son of Baldassare Lauri of Antwerp, a landscape-painter of note, who settled at Rome, and died there in 1641.

Filippo was born in 1623; and became celebrated for cabinet pictures in the Flemish style of colour, but with a much more correct and refined taste of form than prevailed in that school; which most probably he acquired by residing with his father in Rome. His pictures are agreeably composed, touched with great spirit and freedom, of good colour and picturesque effect. Claude Lorraine paid him the compliment to employ him frequently to put figures in the foregrounds of his landscapes; and in some of his best pictures, the hand of Lauri is discernible in the better proportion and beauty of touch with which the figures are wrought than in those completed by Claude's own hand.

The subjects he generally selected were those of nymphs, gods, and goddesses, and the like; where he could, with propriety, introduce much of the nude. To these he gave great care in their actions, and composed them in a very agreeable manner. He died in 1694, at the age of 71.

Lauri, in Botany, a natural order of plants, to which Lauriaceae, one of the number, gives its name; (the Laurinae of Ventenat and Brown; see Prodr. Nov. Holl. v. 1. 401.)—This is the 27th order of Jussieu's system, the fourth of his fifth clads. There is nothing equivalent to it among the Ordines Naturales of Linnaeus.

The characters of Jussieu's fifth clads are—Cotyledons two; petals none; stamina inserted into the calyx.—The calyx is of one leaf, either superior or inferior, entire or divided. Corolla wanting, but there are sometimes little scales, resembling petals, borne by the calyx. Stamens penigruous, or inserted into the calyx, definite or indefinite, both filaments and anthers distinct. Germen superior or inferior, or only involved with the calyx, simple, or rarely several in a definite number; style either solitary, or several in a definite number, or wanting; stigma simple or multifid. Seed naked, superior, or pericarp superior or inferior, often containing a single seed, rarely several. The situation of the embryo is various. Sometimes the flowers are of separate sexes.—The orders of this clads are six; Elegagn, Thymelae, Protea, Lauri, Polygynae, and Atripllec. It is one of those in which botanists differ most with respect to the application of the terms calyx and corolla. In the two first orders Linnaean botanists use the term calyx for what in the third and fourth is called corolla, and in the fifth and sixth again calyx. The analogy of one clads, if truly natural, ought certainly to prescribe the use of the term throughout, for the same part; but a question will but too frequently arise how far any clads is really natural, or out of the reach of all exception; for, in every system, the leading fections, or clads, must be regulated by technical characters.

The order of Lauri is thus characterized:

Calyx divided into six parts, permanent. Stamens fix, inserted into the lower part of each segment, or double that number, fix of them being interior; anthers combined with the filament, opening from the base upwards. Germen superior, style one; stigma simple or divided. Drupa or berry of one cell, containing a nut with one seed. Embryo delticulate of albumen. Stem arborecent or shrubby. Leaves alternate, rarely opposite.

The genera are Lauris, Poroselma, Schreb. and Douglas, Schreb. to which Mr. Brown has added Endandra, Cryptocarya, Teranthera, and the Linnean genus Coffeiba:—Genera subjoined by Jussieu as allied to the Lauri are Myrificas, Viola of Aublet, which Schreber properly reduces to Myrificas, and Hernando; to which Mr. Brown adds, Gycocarpus; see that article. The excellent author last mentioned, accustomed, as has been said of Jortin and Goldsmith, to enrich every subject which he touches, has made the curious discovery of the cotyledons of the Lauri being peltate near their base. He has also remarked a strange inadvertence of Gartner, who takes the cotyledons of Coffeiba for albumen, and the pluma for cotyledons. These parts, being rightly understood, admirably prove the true affinity of the genus, notwithstanding its parallel and leafless habit.

LAURI, in Geography, a town of Naples, in Lavora; two miles S.W. of Sessa.

LAURIA, a town of Naples, in Baflìcan; 17 miles E. of Policastro.

LAURICAUCHA, a mountain of Peru, abounding in silver ore; six miles N. of Pacho.—Alto, a lake of Peru; 80 miles N. of Lima.

LAURIERE, a town of France, in the department of the Upper Vienne, and chief place of a canton, in the district of Bellac; 18 miles E. of Bellac. The place contains 1427, and the canton 6528 inhabitants, on a territory of 145 kilometres, in seven communes.

LAURINGEN, a town of the duchy of Wurzburg, on the Laur; 30 miles N.E. of Wurzburg. N. lat. 50° 13'. E. long. 10° 32'.

LAURINO, a town of Naples, in Principato Citra; 9 miles W.N.W. of Policastro.

LAURINUM. See Daphnellaon.

LAURISTAN, in Geography, a town of Persia, in the province of Irak, on the Zenderoud; 90 miles W. of Ipahan.

LAURO, a town of Portugal, on a river of the same name, in the province of Lenteio; 27 miles W.S.W. of Evora.

LAUROCERASUS, in Botany, the cherry-laured, so called, from the laurel-like appearance of its leaves, as well as from the fruit; which is truly a cherry, and, though not wholesome, eatable, notwithstanding the very dangerous qualities of the root of the plant. See Prunus and Laurel.

LAUROCTAXA, a name used by Columna, and some other authors, for the narrow-leaved kind of iucus, or butcher's broom, called by others bifugus.

LAUROW, in Geography, a town of Hindostan, in Bahar; 10 miles S.S.W. of Gayah.

LAURUS, in Botany, the ancient Linan name of the Bay-tree, for which it is retained by modern botanists, and along with which it now comprehends a great number of species, constituting one of the noblest genera in the whole vegetable kingdom. The origin of the word is lost in the obscurity of antiquity; and whether etymologists derive it from laven, to wash, or from lave, plate or honour, they give us little more satisfaction in one case than the other.—Linn. Gen. 260. Schreb. 270. Willd. Sp. Pl. v. 2. 477. Mart Mill. Dict. v. 3. Ait. Hort. Kew. ed. 2. v. 2. 477. Sm. Prodr. Fl. Grac. Sibith, v. 1. 269. Jull. Soc. Turin.

3 D 2. 1367.
Laurus.

Gen. Ch. Cal. none, unless the corolla be taken for such. Cor. in six deep, ovate, pointed, concave, erect, alternately external segments. Nectary consisting of three pointed coloured tubercles, each terminating in two brilles, surrounding the germen. Stam. Filaments nine, shorter than the corolla, compressed, obtuse, three in each row; anthers attached to the edges of each filament, in the upper part, at each side. There are two globular glands, on a very short stalk, attached to every filament of the innermost row, near its base. Pet. Germen superior, nearly ovate; style simple, of equal thickness throughout, the length of the stamens; stigma obtuse, oblique. Peric. Drupa oval, pointed, of one cell. contained within the corolla. Seed. Nut ovate, pointed, with a kernel of the same shape.

Obv. Molt of the species, including the Cinnamon and Camphor, have united, or hemaphrodite, flowers; several are dioecious, as L. nobilis, the Sweet Bay, which has mostly from 8 to 14 stamens, and a deeply four-cleft corolla. The glandular bodies attached to some of the stamens, afford a differentiating character.

Linnæus's 14th edition of Syll. Veg. has 16 species, Willdenow has 33, the increase being chiefly from the works of Swartz and Thunberg. Several illl nondonscript are in the hands of most collectors of tropical plants. The genus is extremely interesting on account of several fine and valuable aromatic species, as the Cinnamon, Calia, Camphor, Sassafras, &c. The habit of the whole is arborecent. Leaves falcate, almost without exception alternate, undivided, entire, smooth and evergreen, more or less ovate or elliptical. Flowers mostly panicled, small, pale or greenish, not ornamental, but very curious in structure. Fruit large in proportion to the blossom. Mr. Brown expresses an intention of separating Cinnamomum, as a distinct genus from Laurus, as indeed it originally flood, till Linnæus united them. It is extremely probable that other species require more accurate generic investigation than they have hitherto received, in which predicament we suspect is the Sassafras of North America, a tree with deciduous and partly lobed leaves. There appears also to be an oriental Sassafras wood, of a much more permanent though similar flavour to the American, of which we formerly procured a specimen at Venice, but of the tree that produces it we know nothing.

The following may suffice for examples of Laurus as the genus at present stands.

L. Cinnamomum. Cinnamon-tree. Linn. Sp. Pl. 528. (Cinnamomum foliis latis ovatis fragiferis; Burm. Zeyl. 62. t. 27. Caflia cinnamomea, five Cinnamomum; Herm. Lug. duse-Bot; 129. t. 655, 656.) Leaves triplicibibed near the bafe, ovate; lateral ribs vanishing near the top. Panicles repeatedly compound. Native of Ceylon, where, as well as in Amboya, its importance as an object of cultivation, for the sake of its precious bark, is universally known. (See Cinnamon.) Concerning the botanical determination of the present species, there has always been some doubt, Linnæus having defined it foliis trinervis, that is, with three ribs distinct at the base, which is only so far true, that they are united to the mid-rib at a much less distance above the base, which is rounded, than those of L. Caffa. It seems moreover that this Cinnamon, like other cultivated plants, is liable to many varieties, not only in quality, but in external configuration, and it may very possibly have originated from the Caffa, like apples from the wild crab. For a long while the true Cinnamon was scarcely to be seen in the herbarium of Europe, but we have a specimen from Amboyas, by favour of the late Mr. Christopher Smith, in which the paniculis are copious, longer than the leaves, repeatedly sub-divided, and somewhat umbellate. The flowers are silky externally, and rather small. Linnæus says they are dioecious. Another specimen, from the garden at the Mauritius, has narrower leaves, and much smaller panicles. The true Cinnamon is now not rare in the houses of curious collectors. The bishop of Winchester, many years since, raised it from seeds given in his own garden.

L. Caffa. Caffia bark-tree. Linn. Sp. Pl. 528. (Caffa; Rheede Hort. Mal. v. 1. 171. t. 57.) Leaves tripilcibibed far above the elongated bafe, elliptic-lanceolate; lateral ribs vanishing beyond the middle. Panicles corymbifo. Native of Malabar, Sumatra, Java, &c. The narrow leaves, tapering at each end, and the very different qualities of the bark, which is more mucilaginous and far less grateful aromatic, distinguishing this from the preceding, whether it be a species, or only a variety. This breed, on the back, is called camphor.

L. Camphora. Japanese Camphor-tree. Linn. Sp. Pl. 528. (Jacam. Coll. v. 4. 221. t. 3. f. 2. Kempt. Amoen. 770. t. 771. (Jacam camphoriferâ japonica; Commel. Hort. Amith. v. 1. 185. t. 95.) Leaves elliptical, pointed, tripilcibibed far above the elongated bafe. Clusters axillary, somewhat composite, shorter than the leaves. Native of Japan, often to be seen flowering in the English gardens. The curious structure of the blossoms may be seen in Jaccuin. The Japanese camphor is believed to be obtained by distillation from this tree, that of Borneo and Sumatra being the produce of one of a different species, if not genus, of whose botanical characters little is known. This latter is erroneously called Laurus Camphora in our article CAMPHOR, to which we refer the reader.

L. nobilis. Common Bay-tree. Linn. Sp. Pl. 529. (Laurus; Camer. Epit. 60. Ger. em. 1407.) Leaves lanceolate, veiny, finely reticulated, evergreen. Flowers fourcleft, dioecious, in short axillary clusters. Native of Italy and Greece, almost perfectly hardy in our climate, being one of the most defirable evergreens we have, through of slow growth. The leaves are of a rich deep green, highly and pleasantly aromatic. Flowers born by old trees only, pale yellow. Fruit black, the size of an unripe olive, strongly aromatic, never, as far as we know, perfected in England, but plentiful in Italy. This is certainly the $\alpha\delta\beta\alpha$ of Dioscorides, and consequently the classical laurel. It is still called by the same name among the modern Greeks. There is a broad-leaved variety, called $\alpha\delta\beta\alpha$ πλατυφυλλος in Dioscorides.

L. affinis, Benzois and Sassafras, three North American species, have deciduous leaves. The true Benjamin tree, or Gum Benzois (see those articles) is not, as Ray supposed, this Laurus Benzois, but a species of Styrax, as was first shown by the late Mr. Dryander in the Philosophical Transactions for 1787, p. 320. t. 12. See STYRAX.

Laurus, in Gardening, comprises plants of the evergreen and deciduous tree kinds, for borders, green-houfe, and hove, of which the species cultivated are the common sweet bay (L. nobilis); the willow-leaved bay (L. affinis); the common benzois-tree (L. benzois); the sassafras-tree (L. sassafras); the royal bay, or Indian laurel (L. indica); the broad-leaved Carolina bay, or red bay (L. borbonia); the camphor, or camphire-tree (L. camphora);
phora); the cinnamon-tree (L. cinnamomum); the cassia, or wild cinnamon-tree (L. cajia); and the alligator pear (L. persea).

The first fort has several varieties, as the broad-leaved, which is almost too tender for the open air in this climate, with leaves much broader and smoother than those of the common fort; the common, which is seldom hurt in this climate, except in very severe winters, of which there are two subvarieties, one with plain leaves, the other with leaves waved on the edges; the narrow-leaved, with very long narrow leaves, not so thick as those of the preceding two sorts, and of a light green; the branches covered with a purplish bark, and the male flowers come out in small clusters from the axils of the leaves, fitting close to the branches; of which there are subvarieties in the nurseries with variegated leaves. What is now called bay, was formerly called laurel, which has introduced some confusion.

It may be noticed, that the chief of the camphor used in Europe is prepared from this tree in Japan, by splitting the wood into small pieces, and subliming or distilling it with water in an iron retort, covered with an earthen or wooden head, in the hollow of which they fall into oil, or straw, to which the camphor, as it rises, adheres.

This camphor is brownish or white, but in very small semi-pellucid grains.

It is packed up in wooden casks, and thus sent to India and Europe, where it is purified by a second sublimation, and reduced into the solid masses as found in the shops. Native camphor, or the Capoor Baroos of the Malaya, is a production obtained in Sumatra and Borneo, by cutting down the trees, and splitting them with wedges into small pieces, the camphor being found in the interstices in the flake of the concrete crystallization. Some have asserted that it is from the old trees alone that this substance is procured, and that in the young trees, if it is in a solid state, it is called Meenio Capoor, or camphor oil; but this is a mistake: the same fort of tree that produces the fluid does not produce the dry, transparent, flaky substance, nor ever would. They are readily distinguished by the natives. Many of the trees, however, produce neither the one nor the other. The traders usually distinguish three degrees of quality, by the names of head, belly, and foot, according to its purity and whiteness. Some add a fourth fort, of extraordinary fineness, from which a few pounds only are imported to Canton, and fell there at the rate of two thousand dollars the pecul.

The common camphor will evaporate till it wholly disappears; while that of Sumatra and Borneo, called native camphor, though subject to some decrease, does not appear to lose much in quantity from being kept.

Camphor oil is obtained by the Sumatrans by making a transverse incision into the tree, to the depth of some inches, and then cutting the sap longitudinally from above the notch, till a flat horizontal surface be left. This they hollow out, till it is of a capacity to receive a quart: then put into the hollow a lot of lighted reed, and let it remain for about ten minutes, which acting as a stimulus, draws the fluid to that part. In the space of a night the liquor fills the receptacle previously made. The trees are soon exhausted.

The eighth fort has several varieties; but it is the Ceylon cinnamon that is chiefly used as a spice.

Method of Culture.—The first fort may be increased by seed, layers, and suckers. The seed should be sown soon after the berries are ripe, or early in the spring, either in beds, covering them with earth near an inch deep, or in drills half a foot apart, the same depth. When the plants are come up, they should be supplied with frequent waterings during the summer, and in winter defended from frost by the shelter of mats, or some other covering, being tender while young; and after having two summers' growth in the feed-bed, in the spring following the strongest should be removed into nursery rows, one or two feet apart, and the foot away in each row, giving water in dry weather, till they have taken root, and keeping the soil clear from weeds. When they are half a yard, or two or three feet high, they are of proper growth for transplanting into the shrubbery in autumn or spring. The berries may also be sown in pots, and plunged into a hot-bed in spring, which brings the plants forward, being careful to insure them to the full air in the summer season.

In the layer, some of the lower branches that are well furnished with young shoots, may be laid down in the early spring, or in August, but the latter is the best season; each shoot being slit-layered; they become rooted in one year, when in spring following they may be taken off, and planted in the nursery, in the manner directed for the seedlings.

Where suckers are had recourse to, they should be taken up with good roots in autumn or spring, and be planted in the nursery like the seedlings and layers.

This fort is also capable of growing by cuttings, planted in the beginning of April on a moderate hot-bed of tanners' bark covered eight inches deep with rich loofe freth earth, five inches deep, and eight or nine inches, covered with their leaves, and watering them carefully every evening, while the bed continues warm, covering the glasses with mats during the heat of the day. When the cuttings have root, they should receive all mild gentle flowers, and the evening dews. In the beginning of August, the glasses may be taken off, being replaced when the weather begins to be frosty; keeping them open every mild day.

In the beginning of the April following, or as soon as the weather becomes temperate, both glasses and frames should be removed, continuing frequent and plentiful waterings during the summer months, as the weather may require; and in the succeeding April the plants will be strong, well rooted, and fit for planting out.

At the period when the plants raised in these ways are removed to the nursery, they should have their superfluous roots and branches cut away, encouraging the leading shoots; planting them in a well sheltered quarter of light mould.

The ground should be dug over in autumn and spring, keeping it clean, loose, and mellow in summer, and the plants be annually pruned in April.

The gold-striped variety is tender, being commonly kept in pots, and housed with hardy green-house plants. When it stands in the open ground, it is sometimes much injured in severe winters. The method of increasing it is by budding it on the plain fort.

And the broad-leaved and narrow-leaved varieties are not so hardy as the common fort, being scarcely able to live abroad whilst young, in common winters, without shelter. As in severe winters the old trees are frequently killed, or at least the branches much injured, the plants are frequently kept in pots, and housed in the winter season.

The second, third, and fourth forts may be increased by seed, by layers, and sometimes by suckers and cuttings. The seeds or berries procured from America, and preferred in this instance, should be sown, as soon after they arrive as possible, in a bed of light earth an inch deep, or in large pots the same depth, plunging them in mould, in an eastern border, up to their rims, till the spring following; when they should be placed in a hot-bed, which greatly forwards the germination of the seed, and soon brings up the plants. They must be timely inured to the full air. The plants raised by either method should, while young, be watered during summer, and
and sheltered from the frost in winter, and when two years old be planted out in nursery rows, as directed for the other plants. They may also be increased by layers and suckers in the same manner as directed for the first sort; but it is sometimes long before the layers are rooted.

They are likewise sometimes capable of being increased by cuttings, by the aid of a good hot-bed.

And the fifth, sixth, and seventh sorts may be increased by layers, but they are sometimes two years before they are sufficiently rooted. They may also be raised from seeds, procured from the places of their natural growth, sowing them in pots, and planting them in a hot or back-bed; but without this aid they do not always grow freely the first season; in which case they should be placed in the open air in flumers, and in a frame, or in the green-house, near the windows, in winter; and in spring the pots be plunged in a hot-bed, which will bring up the plants, giving air daily, and frequent waterings, and inuring them by degrees to the open air as the summer advances; placing them in shelter in winter, and in the following spring planting them out in separate small pots, managing them as other green-house shrubs.

The eighth, ninth, and tenth sorts are also raised by layers and seed, town and managed as above, generally afflaited by the back-bed of the flume; the plants being planted off into separate pots, and managed afterwards as other hot-house plants.

It may be noticed that the first, second, third, and fourth sorts are highly ornamental in the borders and clumps of pleasure grounds; the three following in green-house collections; and the three last among other flume plants.

LAURUSTINE, a name often given to a fine evergreen flowering shrub. See Viburnum Tinus.

LAUS, in Ancient Geography, a town of Italy, in the territory of the Laconians; founded by the Sybarites, but afterwards taken possession of by the Lycaonians, a colony of the Samnites.

LAUS Ponteia, a town of Gallia Transpadana towards the S.E.; founded by the Boii, and afterwards belonging to the Infibrians. It was a Roman colony and municipal.

LAUS Kauera, in Geography, a peninsula of Ymamark, in the Frozen sea. N. lat. 70° 45'. E. long. 30° 24'.

LAUSANNE, a city of Switzerland, in the canton of Berne, and the largest town in the Pays de Vaud, and by the French division of 1798 the capital of the department and canton of Leman, is beautifully situated on the declivities of three hills, and in the intermediate valleys, environed by an old wall, and distant two miles from the lake of Geneva, and 37 miles N.E. from Geneva itself. The district to which it gives name was once a republic itself, but afterwards annexed to the canton of Berne, and is a considerable tract, lying below the border of Vevey and Venoge, about 13 miles in length and five in breadth. The ascent upon which the town is built is so steep, that in some places the horses cannot, without great difficulty, draw up a carriage, and foot passengers ascend to the upper part of the town by steepes. These inconveniences, however, are amply compensated by the fabulous views in nature, commanding the lake of Geneva, the Pays de Vaud, and the rugged coast of Chablais. The church is a magnificent Gothic building, having been formerly a cathedral, while the Pays de Vaud was subject to the house of Savoy. It stands on the most elevated part of the town; and contains, among many other sepulchres, the tomb of Amadeus VIII. duke of Savoy, flayed the Solomon of his age, but more known by the name of the antipope Felix V., who exhibited a singular instance in the annals of Europe of a personage twice abdicating the pomp of sovereignty, and twice retiring to a private station. The number of inhabitants, according to Coxe, is about 7000; Pinkerton states them at 9000. In the year 1536, when part of the Pays de Vaud was conquered from the house of Savoy, the bishop of Lausanne retired from the town, and the inhabitants put themselves under the direction and sovereignty of the canton of Berne, which granted to it new privileges, in addition to those which it had formerly possessed. The reformation was introduced by Pierre du Viret in the same year. The bishop's diocese formerly comprehended the greater part of the cantons of Berne, Soleure, and Früburg, the Pays de Vaud, the principality of Neufchatel, Berne and its territory, and the country of Arguel, and extended almost to Franche Comté. Since the reformation, it has been reduced to little more than the canton of Früburg and a part of that of Soleure. Lausanne chooses its own magistracy, which confines a burgomaster, five bannerets, the town council, the council of sixteen, and the great council. An academy was established here in 1537, and a college in 1540. Professors in every science are appointed by government, and there is a tolerable library for the use of the public. The bailiwick of Lausanne is extensive; the bailiff, who is chosen every six years, succeeds to the bishop, and has equal jurisdiction. The air of Lausanne is very pure and healthy; and it has plenty of excellent water, with every necessity of life in the greatest abundance. Lausanne is not only governed by its own magistrates, and has its own courts of justice; but the burghers, who possess honours in the principal street, enjoy the right of pronouncing sentence in criminal causes. The criminal is tried by the civil power; if he is found, and acknowledges himself guilty, one of the magistrates pleads in defence of the prisoner, and another against him; the court of justice gives an opinion upon the point of law, and the majority of the burghers above-mentioned determine the penalty. If the punishment is capital, there is, according to the letter of the law, no pardon, unless obtained within twenty-four hours from the sovereign council of Berne, although it generally happens that eight days are granted for that purpose. When the criminal is feised within the jurisdiction of the town, the fact is tried, and the burghers pronounce sentence in the town-hall; in this case there is no appeal. But when he is taken within the district of the bailiff, they assemble in his house, and an appeal lies from their determination to Berne. Lausanne is 41 miles S.W. of Berne. N. lat. 46° 33'. E. long. 6° 28'. Coxe's Travels in Switzerland, vol. ii.

LAUSSIG, a town of Saxony, in the circle of Leipzig; 13 miles S.E. of Leipzig. N. lat. 51° 7'. E. long. 12° 36'.

LAUSSNITZ, a town of Saxony, in the margravate of Meissen; 13 miles N. of Dresden.

LAUSZA, a town of Samogitia; 46 miles N.W. of Miedniki.

LAUT. See Pulo Laud.

LAUTAKARI, a small island in the N. part of the gulf of Bothnia. N. lat. 65° 35'. E. long. 24° 34'.

LAUTENBURG, a town of Prussia, in the territory of the circle of Culin; 48 miles E. of Culin.

LAUTER, a town of Germany, in the county of Henneberg; 11 miles N.E. of Meinungen.

LAUTERBACH, a town of Bohemia, in the circle of Saaz; 65 miles W. of Prague. N. lat. 50° 2'. E. long. 12° 45'.-Also, a town of Upper Hesse; 13 miles N.W. of Fulda.—Also, a town of Saxony, in the circle of Erzgebirge; five miles N.W. of Zwickau.

LAUTERBERG, a town of Westphalia, in the Hartz.
LAU

Lauz, forest, near which are mines and forges of copper and iron; 14 miles S. of Golfar.

Lauterbourg, a town of France, in the department of the Lower Rhine, and chief place of a canton, in the district of Wiesbaden, situated on the Lauter. The place contains 1944, and the canton 9782 inhabitants, on a territory of 1890 kilometres, in 10 communes; 324 kilometres by road, 395 by river.

Lauterbrunnen, a valley of Switzerland, in the canton of Berne; 6 miles S. of Interlachen, and about 15 miles in circuit, embosomed in the midl of the Alps, and celebrated for its picturesque and romantic scenery. The western boundary, from which the Staubbach falls, forming a cata
d, would, in any other country, be called an enormous mountain; it here appears only a trilling hill, in comparison with the opposite chain, of which the highest point is the beautiful Jungfrau-horn, that stretches in a semi-circular direction, and, towering above the adjacent peaks, rises to a tremendous height. At the extremity of the vale, there are some noble points of view, and glaciers which stretch from the foot of the Breithorn and Grotta-horn. In this delightful valley, many streams of the clearest water gush from the earth like small rivers, and numberless torrents precipitate themselves from the mountain. From this circumstance the valley derives its name; Lauterbrunnen signifying, in German, many springs. One of the peaks, adjoining to this valley, which is called the Grotta-horn, is of a pyramidal shape, and capped with frozen snow; another, the Breithorn, is conical, and seems crowned with an enormous mass of transparent ice, from which the reflection of the fun-beams is inexpurably beautiful. But the most elevated and the most majestic of the whole group, is the Jungfrau-horn. (See Jungfrau.) The hollows between the mountains are filled with large valleys of ice, broken into various shapes, and several torrents, burling from the snow, and uniting in their course, form the Weis-Lutunie, a river which rolls rapidly through the valley of Lauterbrunnen, joins the Schwartz-Lutunie, which flows from Grindelwald, and swells the Aar. This valley is bordered by calcareous rocks to its utmost extremity. Wengenalp is the last of a group of calcareous and schistous mountains between Lauterbrunnen and Grindelwald, which there joins the Jungfrau, the summits of which appear to be of granite. Coxe's Travels, vol. i. and ii.

Lautereken, a town of France, in the department of Mont Tomerre, and chief place of a canton, in the district of Kaiserauerlauern; 24 miles N. of Deux Ponts. The place contains 627, and the canton 4594, inhabitants, in 21 communes. N. lat. 49° 30'. E. long. 5° 35'.

Lauterhofen, a town of Bavaria; 12 miles S.W. of Sulzbach.

Lautern, a town of Prussia, in the province of Ermeland; 14 miles S.S.E. of Hellberg.

Lautershauen, a town of Germany, in the principality of Anpach, on the Altmhal; 8 miles W. of Anpach.

Lauterstein, a town of Saxony, in the circle of Erzgebirge; 17 miles S.S.W. of Freyberg.

Lautrec, a town of France, in the department of the Tarn, and chief place of a canton, in the district of Carcassonne; 12 miles N.N.W. of Carcassonne. The place contains 3248, and the canton 7548 inhabitants, on a territory of 1472 kilometres, in 12 communes.

Lautte, a town of Prussia, in Oberland; 16 miles E.S.E. of Marienwarder.

Lavuns, a town of France, in the department of the Lower Pyrenees; 15 miles S.E. of Oleron.

LAUZERTE, a town of France, in the department of the Lot, and chief place of a canton, in the district of Montauban; 17 miles N.W. of Montauban. The place contains 3608, and the canton 123176 inhabitants, on a territory of 2371 kilometres, in 16 communes. N. lat. 44° 15'. E. long. 1° 13'.

LAUZES, a town of France, in the department of the Lot, and chief place of a canton, in the district of Cahors. The place contains 444, and the canton 7139 inhabitants, on a territory of 2371 kilometres, in 11 communes.

LAUZET, a town of France, in the department of the Lower Alps, and chief place of a canton, in the district of Barcelonnette; 10 miles W. of Barcelonnette. The place contains 857, and the canton 5038 inhabitants, on a territory of 295 kilometres, in seven communes.

LAUZUN, a town of France, in the department of the Lot and Garonne, and chief place of a canton, in the district of Marmande; 14 miles N.E. of Marmande. The place contains 1089, and the canton 12852 inhabitants, on a territory of 220 kilometres, in 17 communes. N. lat. 44° 38'. E. long. 0° 32'.

LAW, Edmund, in Biography, a learned English prelate, the son of a clergyman, in the neighbourhood of Carmel, in Lancashire, was born in the year 1701. He received the greater part of his classical learning at the free grammar school of Kendal, from which place he was sent to St. John's college, Cambridge. He was admitted to the degree of B.A. in 1723, and soon afterwards was elected fellow of Christ's college. During his residence in this college, he became known to the public by a translation of Aelian's King's "Effay upon the Origin of Evil," with notes. To this work was prefixed "A preliminary dissertation," by the Rev. Mr. Gay of Sidney college. In the controversy which took place in consequence of Dr. Clarke's "Demonstration of the Being and Attributes of God," Mr. Law took a part, and among other things published his "Enquiry into the Ideas of Space, Time, &c." In the year 1735, a new and improved edition of Robert Stephens' "Theaenum Lingvum Latinum," was given to the public, and in the preparation of this valuable work, Mr. Law had a considerable share. In 1737, he was elected by the university to the living of Graytock, in the county of Cumberland, worth about 300l. per annum. In 1743, he was promoted by Sir George Fleming, bishop of Carlisle, to the archdeaconry of that diocese, and, in 1746, went from Graytock to reside at Salkeld, a pleasant village upon the banks of the river Eden, the rectory of which is annexed to the archdeaconry. During his residence at this place, he published his "Considerations on the Theory of Religion," to which he added "Reflections on the Life and Character of Christ," and an appendix concerning the use of the word "Soul and Spirit." In 1749, Mr. Law proceeded doctor of divinity; in his public exercises for which degree, he defended the doctrine of what is usually denominated "The sleep of the soul." In 1754, he was elected master of Peter-houes, in Cambridge, and in the following year appointed head librarian of the university; a finecurse place, with a salary of fifty pounds a-year. He received almost every year some additional preferment, which were rather honourable expressions of regard from his friends, than of much advantage to himself; in 1761, he obtained a stall in the church of Durham, and in 1769, on the recommendation of the duke of Grafton, he was nominated bishop of Carlisle, and was permitted to hold, in connexion with the bishopric, the mastership of Peter-houes, and the rectory of Graytock. In 1774, he published a very valuable tract, entitled "Considerations on the Theory of Religion,"
LAW

Religion," which has passed through at least eight editions. The object of this work was to shew that arts and sciences, natural and revealed religion, have upon the whole been pro-
gressive, from the creation of the world to the present time; as also that they have been suited to each other, as well as to the circumstances of mankind, during each eminent period of this their progression. In 1777, Dr. Law gave the public a handsome edition, in four vol. 4to. of the works of Mr. Locke, with a life of the author, and a preface. In the edition of the "Considerations," published at Carl-
lisle in 1784, he made such alterations as showed that he had given up the doctrine of the pre-existence of Christ, a fact which he noticed to a friend in pretty strong language. Dr. Law died in August 1787, in the 84th year of his age. The life of Dr. Law was a life of incessant reading and thought, almost entirely devoted to metaphy-
ical and religious enquiries. The leading peculiarity of his religious sentiments is, that "Jesus Christ will, at his second coming, by an act of his power, restore to life and con-
sciousness the dead of the human species, who, by their own nature, and without his intervention, would remain in the state of infensibility, to which the death, brought on mankind by the sin of Adam, had reduced them." Dr. Law published, besides the articles already mentioned, some fingle sermons; a tract on "The Nature and Necessity of Cate-
chesing;" "A Defence of Mr. Locke's Opinion concerning personal Identity;" and "Observations occasioned by the Conturb to literary Property." See life prefixed to an edition of his Reflections printed by Johnson in 1803.

LAW, JOHN, a famous projector, the son of a goldsmith in Edinburgh, was born about the year 1681. It appears that he was not brought up to any profession, but having a turn for calculation, he made himself a proficient in numbers, and in the speculations depending upon them. He obtained, while very young, the confidence of the king's ministers for Scotland, and was employed by them to arrange the revenue accounts, which were at that time in great disorder. To remedy the want of a circulating medium he proposed the estabishment of a bank, which, according to his plan, might supply paper-money to the amount of the value of all the lands in the kingdom. This was not adopted. At the death of his father he succeeded to a small estate, and commenced the line of gentility, supplying the deficiency of his income by gaming. In consequence of a duel in which he killed his antagonist, he was obliged to leave the country. He visited Venice and Genoa, from which cities he was banished as a sharper; he wandered through Italy, supporting himself by his wits, chiefly by the success of singular wagers, in which, by his skill in calculation, he always took care that the chances should be in his favour. He proposed his financial scheme to Louis XIV., who listened to his plans. A bank was established, composed of 1200 shares of 3000 livres each; to this was annexed a Missisippi company, who had grants of land in Louisiana, and was expected to realize an immense sum by planting and commerce. To this were afterwards joined the trade of Senegal, and the privilege of the old East India company. In 1718, it was declared a royal bank; and by a number of advantages arbitrarily con-
ferred upon it, such were the extent of its business, and the magnitude of its funds, that its shares rose to twenty times their original value. All France was feized with the rage of gambling in the funds. Money and valuables of all kinds were brought to the market and invested in bank paper, and those thought themselves truly happy who could slip them-
seives of every thing for a participation in this imaginary wealth. In 1720, Law was made comptroller-general of the finances. Regarded as the Plutus of the kingdom, he law at his levee dukes, peers, and marshals of France. At

LAW, WILLIAM, a learned and pious divine of the church of England, was born at King's-Ciffe, Northampton-
shire, in 1686, and educated at Oxford, where he took his degrees. He entered into holy orders, but it does not appear that he ever had the eure of souls, owing probably to his adherence to non-juring principles, which he maintained to the close of his life. He was some time a private tutor in a gentleman's family at Putney, after which he chiefly resided in a very retired way at the house of Mrs. Heifer Gibson, aunt of the celebrated historian, in Northamptonshire, where he died in 1761. He was author of a great many theological publications, of which the most important is "The Fer-
rious Call to a devout and holy Life, adapted to the State and Condition of all Orders of Christians." His "Prac-
tical Treatise on Christian Perfection" was likewise very much esteemed. He entered the lists against bishop Hoadley; and was a zealous disciple of the doctrines of Jacob Behmen, whose works he published.

LAW, in its most general and comprehensive sense, signifies a rule of action; and is applied indiscriminately to all kinds of action: whether animate or inanimate, rational or irrational; in which sense it is used when we say, the laws of motion, of gravitation, of optics, or mechanics, as well as the laws of nature and of nations. Accordingly law is a command or precept, constituting a rule of action, and coming from some superior authority, which an inferior is obliged to obey; or, according to some, law is a command, or mandate of some person, or power, whose precept carries with it the reason of obedience: or, it is a rule of action, that obliges by virtue of its being the will of a superior. See OBLIGATION.

The word is formed from the Saxon lawa, size, which signi-

fies the same.

Thus, the commands of God with respect to men, of a city with respect to the citizens, and universally of all powerful beings in respect to those who cannot resist, are called their laws.

The nature of a law will be most clearly discovered by shewing wherein it differs from covenant, counsel, and right or equity, with all which it is frequently confounded.

Law is confounded with covenant, or compact, by those who take laws to be nothing else but agreements, or forms of living determined by the consent of mankind: among whom is Aristotle, who defines a law, "a declaration deter-

mined by the common consent of a city, shewing in what manner things are to be done:" which is not so much the definition of a law, as of a civil law; nor yet properly of a civil law; for this common consent is no more than a mutual covenant, which does not oblige any person, and consequently is not any law, till some supreme power be constituted with a power to compel, and to make it penal to transgress it. Here then the covenant is confounded with the law, which leads into absurdities; for a covenant or compact is a promise proceeding from us; a law, a command directed to us.

The.
The difference between a counsel and a law is this: A counsel is a precept, wherein the reason of obedience is taken from the thing itself preferred; a command is a precept, wherein the reason of obedience depends on the will of the prescriber; for we cannot properly say, *se volo, se jubeo, unilex flet pro ratione voluntas.* A law comes from a person who has a power over those whom he commands; a counsel, from him who has no such power. To do what is enjoined by a law, is an act of duty; what by a counsel, an act of choice, or freewill. Counsel is only matter of persuasion, law is matter of injunction; counsel acts only upon the willing, law upon the unwilling also.

Law is confounded with right or equity, by those who pervert in doing what is permitted by the divine law, though prohibited by the laws of the country. What is prohibited by the divine law, cannot be permitted by the civil law; nor what is commanded by the divine law, be prohibited by the civil law; but what is permitted by the divine law, may, notwithstanding, be prohibited by the civil law: for the inferior laws have a power of restraining the liberty left by the superior laws, though they cannot enlarge it. Now right or equity is a natural liberty, not constituted by laws, but free of them; for take away laws and liberty is complete.

This liberty is first restrained by the natural and the divine law, the reit restrained by the civil laws; and what remains unrestrained by the civil law, may be again restrained by the constitution of particular cities and societies. There is a great difference, therefore, between law and right, lex & jus; for law is a chain; but right a liberty; and they differ as two contraries. See Civil or Municipal Law, infra.

Law may be divided, with respect to its different original, into divine and human.

**Law, Divine,** may be considered as twofold, with respect to the two different manners in which God notifies or anounces his will to man; viz. natural (or moral), and positive.

**Law, Natural,** is that which he has made known to all mankind, by an innate light, called natural reason.

Natural law may be divided into that natural law of men, which, in a peculiar sense, is called the Law of nature; and the natural law of countries, commonly called the Law of nations. (See each of these articles.) The precepts are the same in both the; but because, when societies are once instituted, certain personal properties become yielded in men; that law, which, when we speak of the duties of men severally, we call the natural law, when transferred to cities or countries, we call the law of nations.

M. Regis says, that the laws of nature are the dictates of right reason, which teach every man how he should use his natural right; and the laws of nations, the dictates, in like manner, of right reason, which teach every state how to act and behave themselves toward others.

**Law, Positive,** is that which God has revealed by his prophets, or by persons supernaturally commissioned and inspired and found only in the holy scriptures: such are those laws delivered to the Jews, relating to the divine worship and polity, which may be called divine civil laws, as being peculiarly directed to that people. As the matter of natural laws is something in its own nature good and necessary, these laws are founded in the immutable natures and relations of things, carry with them their own recommendation, and if it were not for the depravity of mankind, would not need a supernatural light for the discovery of their reasonableness and obligation. Whereas positive laws differ from the former, both with regard to the matter of them, as well as the manner of their publication. These may be distinguished into such as are purely positive, or partly so. The matter of purely positive laws is indifferent; so that the positive decree of the legislator alone makes them to be laws, mere reason being then silent. Such were the ceremonial laws of the Jews, and such are the sacraments of the Christian religion. Nevertheless, every positive law is founded in reason, though reason may not be able, antecedently to their promulgation, to discover their necessity and utility. But the reasons that recommend them, when they are actually promulgated, would not give them the authority and sanction of a law, without the express institution of the supreme lawgiver. Laws that are partly positive may be resolved into the law of nature, or the moral law as revived, improved, and enforced by revelation. Several particulars of this law derive a greater degree of evidence from this new mode of promulgation, and also a stronger enforcement. The law concerning the Sabbath is in a peculiar sense a law of this kind, the matter of it being of a mixed nature. That some part of our times should be consecrated to the worship of our creator, the light of nature dictates; but that it should be a seventh part rather than any other, or the left seventh rather than the first, or the third, is not natural but positive.

**Law of Nature,** as it respects intelligent, moral, and accountable beings, is the will of God, relating to human actions, grounded in the moral differences of things; and because it is, in some measure, discoverable by natural right, it is obligatory upon all mankind. It is thus defined by Cicero (De Legibus, lib. i.) "Lex est ratio fumma in nulla quae judet ea quae facienda sunt, prohibitque contraria." It is called the law of nature, on account of the manner of its promulgation, which is by natural reason; on account also of its source or foundation, this law resulting from the respective natures of beings and things, of beings, as God and man, and of things or actions, as morally good or evil. and having different physical effects; and, moreover, because it is the law of God. Nature is but a fictitious thing; and all that is said of the wisdom of her designs and operations, of her power, or her laws, is to be ascribed to him who is the author of nature, "Quid enim est alius natura, quam Deus et divina Ratio, toti mundo, et partibus eis inferta?" Seneca de Benef. l. vi. c. 7. The demonstration of this law of nature has been attempted by several learned men, who commonly urge the content of the more civilized nations, as a good argument for the existence of this law. "Omnia autem in re conueniunt omnium gentium lex natura putanda est," says Cicero; i. e. "as to any point, the agreement of all nations in it is to be esteemed a law of nature." Others have erroneously alleged, as a proof of the law of nature, innate ideas or practical principles, impressed on the soul of man by its creator; but of such ideas and principles we have no evidence. A more direct and conclusive demonstration of the law of nature may be deduced from the consideration both of the divine and human nature; which, having in one view and in the relation they bear to each other supply unequivocal evidence of the existence and obligation of this law. To this purpose we shall avail ourselves of some appropriate reflections and reasonings of the learned judge Blackstone in immediate connection with this subject. "As God," says this learned writer, "when he created matter, and endowed it with a principle of mobility, established certain rules for the perpetual direction of that motion; so, when he created man, and endowed him with freewill to conduct himself in all parts of life, he laid down certain immutable laws of human nature, whereby that freewill is in some degree regulated and restrained, and gave him also the faculty of reason to discover the purport of those laws."

Considering the Creator only as a being of infinite power,
he was able unqualifiedly to have prescribed whatever laws he pleased to his creature, man, however unjust or severe. But as he is also a being of infinite wisdom, he has laid down only such laws as were founded in those relations of justice, that existed in the nature of things antecedent to any positive precept. These are the eternal, immutable laws of good and evil, to which the Creator himself in all his dispensations conforms; and which he has enabled human reason to discover, so far as they are necessary for the conduct of human actions. Such among others are these principles: that we should live, honestly, should hurt nobody, and should render to every one his due; to which three general precepts Justinian has reduced the whole doctrine of law.

But if the discovery of these first principles of the law of nature depended only upon the due exertion of right reason, and could not otherwise be obtained than by a chain of metaphysical disquisitions, mankind would have wanted some inducement to have quickened their inquiries, and the greater part of the world would have rested content in mental indolence, and ignorance its inseparable companion. As therefore the Creator is a being, not only of infinite power, and wisdom, but also of infinite goodness, he has been pleased to contrive the constitution and frame of humanity, that we should want no other prompter to inquire after and pursue the rule of right, but only our own self-love, that universal principle of action. For he has so intimately connected, so inseparably interwoven the laws of eternal justice with the happiness of each individual, that the latter cannot be attained but by observing the former; and, if the former be punctually obeyed, it cannot but induce the latter. In consequence of which mutual connection of justice and human felicity, he has not perplexed the law of nature with a multitude of abstracted rules and precepts, referring merely to the fitness or unfitness of things, as some have vainly affirmed; but has graciouly reduced the rule of obedience to this one paternal precept, "that man should pursue his own true and substantial happiness." This is the foundation of what we call ethics, or natural law. For the several articles into which it is branched in our fyllems, amount to no more than demonstrating, that this or that action tends to man’s real happiness, and therefore very justly concluding that the performance of it is a part of the law of nature; or, on the other hand, that this or that action is destructive of man’s real happiness, and therefore that the law of nature forbids it.

This law of nature, being coeval with mankind and dictated by God himself, is of course superior in obligation to any other. It is binding over all the globe in all countries, and at all times; no human laws are of any validity, if contrary to this; and such of them as are valid derive all their force, and all their authority, mediatly or immediately, from this original.

But in order to apply this to the particular exigencies of each individual, it is still necessary to have recourse to reason: whose office it is to discover, as was before observed, what the law of nature directs in every circumstance of life; by considering, what method will tend the most effectually to our own substantial happiness. And if our reason were always, as in our first ancestor before his transgression, clear and perfect, unruled by passions, unclouded by prejudices, unimpaired by dilfease or impenetrap, the task would be pleasant and easy; we should need no other guide but this. But every man now finds the contrary in his own experience; that his reason is corrupt, and his understanding full of ignorance and error.

This has given manifold occasion for the benign interposition of divine providence; which, in compassion to the frailty, the imperfection, and the blindness of human reason, hath been pleased, at sundry times and in divers manners, to discover and enforce its laws by immediate and direct revelation. The doctrines thus delivered we call the revealed or divine law, and they are to be found only in the holy scriptures. These precepts, when revealed, are founded upon comparison to be really a part of the original law of nature, as they tend in all their consequences to man’s felicity. But we are not from hence to conclude that the knowledge of these truths was attainable by reason, in its present corrupted state; since we find that, until they were revealed, they were hid from the wisdom of ages. As then the moral precepts of this law are indeed of the same original with those of the law of nature, so their intrinsic obligation is of equal strength and perpetuity. Yet undoubtedly the revealed law is of infinitely more authenticity than that moral system, which is framed by ethical writers, and denominated the natural law. Because one is the law of nature, expressly declared so to be by God himself; the other is only what, by the assistance of human reason, we imagine to be that law. If we could be as certain of the latter as we are of the former, both would have an equal authority; but, till then, they can never be put in any competition together.

Upon these two foundations, the law of nature and the law of revelation, depend all human laws; that is to say, no human laws should be suffered to contradict them. There are, it is true, a great number of indifferent points, in which both the divine law and the natural leave a man at his own liberty; but which are found necessary for the benefit of society to be restrained within certain limits. And herein it is that human laws have their greatest force and efficacy: for, with regard to such points as are not indifferent, human laws are only declaratory of, and act in subordination to, the former. To infiance in the cause of murder: this is expressly forbidden by the divine, and demonstrably by the natural law; and from these prohibitions arises the true unlawfulness of this crime. Tho’ human laws that annex a punishment to it, do not at all increase its moral guilt, or superadd any feign obligation in furo conscientie to abate it from its perpetration. Nay, if any human law should allow or join us to commit it, we are bound to transgress that human law, or else we must offend both the natural and the divine law, with regard to matters that are in themselves indifferent, and are not commanded or forbidden by those superior laws; such, for instance, as exporting of wool into foreign countries; here the inferior legislature has scope and opportunity to interpole, and to make that action unlawful which before was not fo.

We might further add, that, as there is a natural and necessary difference between virtue and vice, and the several actions and dispositions which are denoted by these two opposite terms, natural reason discoveres it to be the will of God, that every man should look upon this difference in the nature of things and actions, as a law or rule, which he is religiously to observe, under pain of his Maker’s displeasure. Among those writers who have alleged arguments in proof of the law of nature, some have founded it upon the reason and fitness of things, others, on our moral sense, and social affections; and others, again, on the good effects of virtue, and evil effects and consequences of vice; but, however they may differ in the principles upon which they have founded their reasoning, they have ultimately arrived at the same conclusion. These principles are illustrated under their proper heads in the course of this work. The names and works of the different writers are cited by Grove,
in his "System of Moral Philosophy," vol. II. p. ii. n. 5.

The law of nature, says the author last cited, is eternal and necessary; so that it always did, and always could not but exist. It is universal, inasmuch that all mankind are born the subjects and objects of this law, notwithstanding the difference of climate, of government, of language, and of opinions and customs that have prevailed in different parts of the world. Moreover, the law of nature is immutable, for the divine nature is immutable. The first principle, or law of nature, according to Hobbes, is self-preservation. Thomasius will have it to be our own happiness, which falls in at last with the sentiment of Hobbes. Puffendorf maintains it to be sociability. Valentine Alberti, the belief that we are the image of God. Henry and Samuel Cocceius, the will of God. Grotius, right reason. Veltheimus, the intrinsic decency or turpitude of actions. Strumeius and Janus, that we are to love God, ourselves, and our neighbour.

Laws, Human, comprehend all those rules of conduct, which originate in the wisdom of man, individually or collectively considered, and which are designed to regulate their behaviour to one another in more limited or more enlarged societies, and which are enforced by human authority and worldly functions. Human laws are necessary as a remedy, partly to the generality, and partly to the ineffectiveness of the divine. The laws of God are too general to ascertain all the duties of society, without some additional interpretations of men. That no man by fraud or violence injure another, and take his property, is a divine law; which notwithstanding, human laws are in many cases needful to settle the bounds of property, and assign every member of the community his rights and duties; what he may expect from others, and what he is to do to them. "Salus populi suprema lex esto." "To secure the welfare of the society be the supreme law" is really a divine precept; but the genius and interests of nations are so various, yea, so liable to change are the interests and circumstances of the same people, that different laws are necessary to suit this diversity of tempers, occasions, and emergencies. Nor is it any reproach to the divine law that it is no more particular; since it must be infinite to reach all the particular circumstances of mankind; and God hath given men reason, by which they may build upon the foundation that he hath laid such further laws and constructions, as the course and posture of human affairs shall require. Nor is the inefficacy of the law of God, which is the other thing that makes human laws necessary, any more a diabolion to it. For what is the cause of this inefficacy, but the willful corruption of men? It was most fit, that the chief rewards and punishments annexed to the divine laws should be unseen and future; that the trial of human virtue might be more conspicuous. And were not mankind sunk into an extreme degeneracy, the prospect of an eternal world would make all other considerations useless. But as it is now, the torments of an after-life are not a bribe strong enough upon the lusts and passions of men. It is therefore necessary, that every society, to secure its own peace, should inflect as much of the divine law into their respective constitutions, as concerns the welfare of the body politic: and inforce these laws, not as divine, but as laws of the state, with civil functions; that they who will not be made honest by the fear of God, may be so by the fear of the laws of their country. The difference between the philosophers and others was said to be this, "Natu"r eoniam exaequar or t ivum cunxxii or λαόν, "that they praetificd from choice that honesty and virtue, which others observed through fear of the laws," agreeably to that of the apologist, "that the law is not made for a righteous man, but for the lawless and disobedient." All human laws are of the nature of those called civil; and these, with regard to the difference of their subject matter, may be subdivided into the law of nations, civil law, and canon law.

Law of Nations, Jus Gentium, is that rule, or measure, which all or several nations, either by a tacit or express agreement, are obliged to observe towards one another, whether in peace or war. If, indeed, men were to live in a state of nature, unconnected with other individuals, there would be no occasion for any other laws, than the law of nature, and the law of God. Neither could any other law possibly exist: for a law always supposes some superior who is to make it; and in a state of nature we are all equal, without any other superior but him who is the author of our being. But man was formed for society; and, as is demonstrated by the writers on this subject, is neither capable of living alone, nor indeed has the courage to do it. However, as it is impossible for the whole race of mankind to be united in one great society, they must necessarily divide into many; and form separate states, commonwealths, and nations, entirely independent of each other, and yet liable to a mutual intercourse. Hence arises a third kind of law, to regulate this mutual intercourse, called "the law of nations:" which, as none of these states will acknowledge a superiority in the other, cannot be dictated by any; but depends entirely upon the rules of natural law, or upon mutual compacts, treaties, leagues, and agreements between these several communities: in the construction also of which compacts we have no other rule to resort to, but the law of nature; being the only one to which all the communities are equally subject: and therefore the civil law very judiciously observes, that "quod naturalis ratio inter omnes homines constitut, vocatur jus gentium."" Law, Civil or Municipal, is the rule by which particular districts, communities, or nations are governed; being thus defined by Juftinian, (Inf. i. 2. 1.) "Jus civile est quod quiq w ifi a publicus constitut." Judge Blackstone calls it "municipal" law, in compliance with common speech; for though, strictly speaking, that expression denotes the particular customs of one single municipal, or free town, yet it may with sufficient propriety be applied to any one state or nation, which is governed by the same laws and customs. Accordingly, municipal law, thus understood, is properly defined to be "a rule of conduct prescribed by the supreme power in a state, commanding what is right and prohibiting what is wrong." It is a "rule," not a transient order from a superior to or concerning a particular person, but something permanent, uniform, and universal. It is thus distinguished from advice or counsel, and also from a compact or agreement. (See the beginning of the article Law.)

It is a rule of "civil conduct," by which it is distinguished from the natural or revealed law. (See Law of Nature.) The municipal or civil law regards man as a citizen, and bound to other duties towards his neighbour than those of mere nature and religion; duties in which he has engaged, in consequence of enjoying the benefits of the common union; and which amount to no more than that he do contribute, on his part, to the subsistence and peace of the society. It is likewise a rule "prescribed," because a bare resolution, confined in the breach of the legislator, without manifesting itself by some external sign, can never be properly a law. This resolution must be notified to the people who are to obey it. This may be done by universal tradition and long practice, which suppose a previous publication, and is the case of the common law of England. It may be notified, via voces, by officers appointed for that purpose, as is done with regard to proclamations, and such acts of parliament.
parliament as are appointed to be publicly read in churches and other assemblies. And, lastly, it may be notified by writing, printing, or the like; which is the general course taken with all our acts of parliament. This notification, however, should be made in the most public and perspicuous manner; and not like the mask of Caligula, who (according to Dion Cassius) wrote his laws in a very small character, and hung them up on high pillars, the more effectually to enfringe the people. That, without doubt, can never be a rule to any person, which is not liable to his cognizance, or which he neither does nor can know. Agreeably to this circumstance, some have derived "lex" and "legenda" because the law was to be publicly read, that it might be known to all and observed by all. The matter of divine laws being usually of great importance, and the author a sovereign who has an absolute propriety in us, and on that ground an unquestionable right to the most entire devotedness, and zealous concern to please him; we ought to use all the means in our power to come at the knowledge of his will. But as human laws proceed from the will of those who, by nature, are upon a level with the rest of mankind, and have the consent of others to govern them purely for their temporal or political good; such a provision ought to be made for their publication, that by an ordinary care, and without taking up much of their time and thoughts, which are to be spent in their private callings, people may be able to know the pleasure of their governors. There is another circumstance, which is worse than the non-promulgation of a law; and that is the making of laws "ex post facto;" when after an action (indifferent in itself) is committed, the legislator then for the first time declares it to have been a crime, and inflicts a punishment upon the offender who has committed it. All laws should be made to commence "in futura," and be notified before their commencement. When the laws or rules of conduct are properly notified or prefixed, it is the business of the subject to be thoroughly acquainted with them; for if ignorance, of what he might know, were admitted as a legitimate excuse, the laws would be of no effect, but might always be eluded with impunity. On this head we shall only add, that it is requisite to the very essence of a law, that it be made by the supreme power. Sovereignty and legislature are convertible terms; one cannot subsist without the other. That the law may answer the purpose of a complete rule, "commanding what is right and prohibiting what is wrong," it is necessary that the boundaries of right and wrong be established and ascertained by law; and it is then the business of the law, considered as a rule of civil conduct, to enforce those rights, and to redress those wrongs. For this purpose every law may be said to consist of several parts: one, declaratory, whereby the rights to be observed, and the wrongs to be excused, are clearly defined and laid down; another, directory, whereby the subject is instructed and enjoined to observe those rights, and to abstain from the commission of those wrongs; a third, remedial, whereby a method is pointed out to recover a man's private rights, or redress his private wrongs; to which may be added a fourth, usually termed the "sanction," or vindicatory branch of the law, whereby it is signified what evil or penalty shall be incurred by such as commit any public wrongs, and transgress or neglect their duty. (Blackst. Comm. book i.) For the interpretation of the law, see Interpretation.

Civil laws, considered with regard to the two offices of the legislator, viz. to judge and to compel, may be divided into two branches; the one distributive, the other vindicatory and penal.

LAW, Distributive, is that by which every man has his right; or, it is that which constitutes the rules and measures of things, whereby we know what belongs to us, and what to others; so as we may not disturb or interrupt others in the enjoyment of their own, nor be interrupted by them; and what each man may lawfully do or not do.

LAW, Vindicative, is that branch by which the punishments to be inflicted on those who violate the laws, are determined.

The distributive and vindicative are not two species of laws, but two parts of the same law. For if a law say no more than "Whatever you catch in your net, in the sea, shall be your's," it is in vain; for though another take from you what you have caught, it is still your's; in regard, in the state of nature, where all things are common, your's and another's are the same thing. So that what the law defines to be your's, was your's before that law, and will be your's after it, though polluted by another. A law, therefore, is but an empty sound, unless it determines the thing to be your's in such a sense as to forbid every body else from disturbing you in the possession of it. But such prohibition will be vain, unless there be a penalty annexed to it. A law, therefore, must contain both these parts, that which prohibits, and that which punishes. The first whereof, which is called distributive, is prohibitory, and speaks to all; the latter, called vindicatory or penal, is mandatory, and speaks only to the public officers. Whence it follows, that to all civil laws there is annexed a penalty, either implicitly or explicitly; and where that punishment is not ascertained, either by writing or by example, it is supposed to be arbitrary, and to depend on the pleasure of the legislator; for that is no law, which may be violated impunitively.

Civil laws, considered with regard to the different manners of promulgating them, are of two kinds; scripta and non scripta, or written and unwritten.

Laws, Written, are those which require either the voice, or some other sign of the legislator's will to become laws. The written laws of England consist of statutes, acts, or edicts, made by the king's majesty, by and with the advice and consent of the lords spiritual and temporal, and commons, in parliament assembled. The oldest of these now extant is the famous "magna charta," as contained in parliament 9 Hen. III. See Magna Charta and Statutes.

Laws, Unwritten, are such as need no other promulgation besides the voice of nature, or natural reason; of which kind are all natural laws.

Hence it appears, that though the natural laws be described in the writings of the philosophers, they are not therefore to be called written laws; nor are the writings of lawyers, laws, for want of the supreme authority; nor the "response prudentium, or opinions of judges, laws, excepting so far as they are allowed by the supreme power to pass into use; and then they are called leges scriptae, written laws; not because of their use, but because of the will of the supreme power, which is argued from their passing into use.

The unwritten law of England includes not only "general customs," as the common law, properly so called; but also the "particular customs" of certain parts of the kingdom; and likewise those "particular laws," that are by custom observed only in certain courts and jurisdictions. When these parts of the municipal law of England are called "leges non scriptae," we are not to understand that these laws are at present merely oral, or communicated from the former ages to the present solely by word of mouth. Indeed, during an age of profound ignorance of letters, all laws were entirely traditional, because the nations among which they prevailed had but little idea of writing. Thus the British
as well as the Gallic Druids committed all their laws, as well as learning, to memory; and it is said of the primitive Saxons here, as well as their brethren on the continent, that "leges sola memoria et ufu retinebant." But with us, at present, the monuments and evidences of our legal customs are contained in the records of the several courts of justice, in books of reports and judicial decisions, and in the treatises of the learned fages of the profession, preferred and handed down to us from the times of highest antiquity. But these parts of our law may be fitly styled "leges non scriptae," because their original institution and authority are not set down in writing, as acts of parliament are, but they receive their binding power, and the force of laws, by long and immortal usage, and by their universal reception throughout the kingdom. In like manner as Aulus Gellius defines the "ius non scriptum" to be that, which is "tacito et illiterato hominum conferent et moribus expressum." See Common Law and Custom.

Having considered the civil law in its more general acceptance, as denoting the statutes and ordinances of every state for its own good government, we shall refer for the statement of its more special acceptance to the article Civil Law.

Laws, Canon or Ecclesiastical, in a more extensive sense, denote laws relating to the worship, discipline, and government of the church. For an account of that which is by way of eminence called canon law, see Canon Law.

There is another division of the law of England besides that which we have above stated, more large and particular; as into the prerogative or crown law; the law and custom of parliament; the common law; the statute law; reasonable customs; the law of arms, war, and chivalry; ecclesiastical or canon law; civil law, in certain courts and cases; forest law; the law of marque and reprisal; the law of merchants; the law and privilege of the gathers, &c. But this large division may be reduced to the common division; and all is founded on the law of nature or reason, and the revealed law of God, as all other laws ought to be. 1 Co. Inft. 11.

Law is also applied to the several policies of states and people, or the maxims and rules they have agreed upon, or received from their magistrates, whereby to live in peace and mutual society.

The laws of the twelve tables were the ancient laws of the Romans, for which the Decemviri were sent into Greece, and which served for the ground-work of all their jurisprudence.

The celebrated laws of the more modern days, are those of the Angli, the Wirini, or Thruringi; of the Boi, or Bavarians; those of the Burgundi, Germans, Danes, and Norwegians; of the Franks, the Frifons, the Lombards, the Gothic laws, the Martina, or Mercian law; the laws of the Saxons, Scots, Sicilians, Frigidi; the laws of Ocron, the Moimarin law, and the Saic law.

Law, Lex, among the first Romans properly signified an ordinance of the people, made at the request of a magistrate, particularly a confid. These ordinances differed from the plebificita and senatus consultia, and even from other ordinances made at the request of any other magistrate beside a confid, though those too bore the name of laws.

Thus, though Aquilius and Faldcidius were only tribunes when they made their requets, yet we still say, the Aquilian law, the Faldcidian law, &c.

The several laws of the Romans are distinguished, 1. By the name of human at whose request they were passed; as the Cernlichen law, the Julian law, &c. 2. By the matter or subject of the law; and hence came the terms, testamentary laws, as the Furian, Vociarian, &c. judiciary laws, Agrarian laws, &c.

3. Sometimes by the crimes against which they were made. For instance: the laws touching poifting, parricides, &c. the laws of concussion, peculat, &c.

The Codek and Authentick are the laws and constitutions of the Roman emperors; and the Digest is a compilation, made by the emperor Justinian's order, of the several opinions and judgments of the most learned in the Roman law; to which he gave the fation of laws, as appears by the epistle prefixed to the work; and it is this that properly constitutes the Roman law. See Civil Law.

The lex talionis, or law of like for like, is the most ancient and equitable law in the world. It was observed by the Hebrews.

Law has also a more special signification, wherein it is taken for that which is lawful with us, and not elsewhere: as "tenant, by the courtesy of England." Thus we also lay, to wage law (vundire legem), and to make or do law (facere legem). See Wager, and Make.

Law of Arms, is that law which gives precepts how rightly to proclaim war, to make and observe leagues, to attack the enemy, and to punish offenders in the camp.

Common things concerning arms and war are under the cognizance of the constable and marshal of England.

Law, Frank. See Frank.

Law of Honour, denotes a system of rules, constructed by people of fashion, and calculated to facilitate their intercourse with one another; and for no other purpose. Nothing is adverted to by the law of honour but what tends to inconvenience this intercourse; and hence it only prefers and regulates the duties between equals, omitting such as relate to the Supreme Being, as well as those which we owe to our inferiors. For which reason, profaneness, neglect of public worship or private devotion, cruelty to servants, rigorous treatment of tenants or other dependants, want of charity to the poor, injuries done to tradesmen by insolvency or delay of payment, with numberless examples of the same kind, are accounted no breaches of honour; because a man is not a less agreeable companion for these viciss, nor the worst to deal with, in those concerns which are usually transacted between one gentleman and another. Again, the law of honour, being constituted by men occupied in the pursuit of pleasure, and for the mutual convenience of such men, will be found, as might be expected from the character and design of the law-makers, to be, in most instances, favourable to the licentious indulgence of the natural passions. Thus it allows of fornication, adultery, drunkenness, prodigality, duelling, and of revenge in the extreme; and lays no stress upon the virtues opposite to these. Paley's Principles of Moral and Political Philosophy, vol. i.

Law Language was formerly, in this kingdom, Norman or law French; and in this barbarous dialect were all public proceedings written and recorded. Nothing could be more humiliating and ignominious badge of tyranny and foreign servitude; being introduced under the auspices of William the Norman, and his sons; and thus the ironical observation of the Roman satirist came to be literally verified, that "Gallia
for

and

the

Gallia
caucidicos
docuit
facunda
Britannos.)

(Juven. xv.

iii.)

This continued till the reign of Edward III., when

by

stat. 36

Ed. III. c. 15, it was enacted, that for the future

all pleas, &c. should be conducted in the English tongue;

but entered and enrolled in Latin. The practitioners,

however, being used to the Norman language, which was

more familiar to them, continued to take their notes in law French;

and when these notes were published, under the denomination

of reports, they were printed in that barbarous dialect;

which, joined to the additional terror of a Gothic black letter,

has occasioned many students to throw away their Plowden

and Littleton, without venturing to attack a page of them.

But in reality, says Blackstone, on a nearer acquaintance,

they would have found nothing formidably in the language;

which differs in its grammar and orthography as much from

the modern French, as the dictum of Chaucer and Gower

does from that of Addison and Pope. Besides, as the Eng-

lish and Norman languages were concurrently used by our

ancestors for several centuries, the two idioms have naturally

affiliated, and actually borrowed from each other; for

which reason the grammatical construction of each is so very

much the same, that an Englishman (with a week's pre-

paration) would understand the laws of Normandy, collected

in their "grand coutumier," as well, if not better, than a

Frenchman bred within the walls of Paris.

The Latin, which succeeded the French for the entry and

enrolment of pleas, and which continued in use for four

centuries, answers so nearly to the English, that it has been
generally imagined to be totally fabricated at home, with

little more art or trouble than by adding Roman termina-

tions to English words. Whereas, in reality, it is a very

universal dialect spread throughout all Europe at the irrup-
tion of the northern nations, and particularly accommodated

and moulded to answer all the purposes of the lawyers with

a peculiar exactness and precision. These northern nations,
or rather their legislators, though they resolved to promulge
their laws in the Latin tongue, have frequently intermixed
in it some words of a Gothic original; which is more or
less the case in every country of Europe, and ought not,
to be imputed as any peculiar blemish in our English legal
Latinity. The truth is, that which is generally denominated
law Latin, is in reality a mere technical language, calculated
for eternal duration, and easy to be comprehended both in present and future times; and on those
accounts best suited to preserve those memorials which are
intended for perpetual rules of action. As to the objec-
tion of locking up the law in a strange and unknown
tongue, this is of little weight with regard to records,
which few have occasion to read, but such as do, or ought
to, understand the rudiments of Latin. The learned Black-
stone suggests, that the terms of the "law are not more
numerous, more uncouth, or more difficult to be explained
by a teacher, than those of logic, physics, and the whole
circle of Aristotle's philosophy, nay even of the politest
art of architecture and its kindred studies, or the science
of rhetoric itself." The technical Latin continued in use from
the time of its first introduction till the time of the sub-
version of our ancient constitution under Cromwell, when,
among many other innovations in the law, the language of
our records was altered and turned into English. But,
at the restoration of King Charles, this novelty was no
longer continued; the practitioners finding it very difficult to
express themselves so concisely or significantly in any other
language but the Latin. Thus it continued without any sen-
fible inconvenience till about the year 1730, when it was
again thought proper that the proceedings at law should
be done into English; and it was accordingly so ordered

by statute 4 Geo. II. c. 26. This provision was made,
according to the preambles of the statute, that the common
people might know and understand what was alleged or
done for and against them, in the process and pleadings,
the judgment and entries in a cause. Several incon-
veniences arose from this alteration; so that in two years
it was found necessary to make a new act, 6 Geo. II. c. 14,
which allows all technical words to continue in the usual
language, and has thereby almost defeated every beneficent
purpose of the former statute. Blackf. Com. b. iii.

LAW, Marine, denotes that law which serves to regulate
the interests of navigation and maritime commerce. (See
Navigation, and Commerce.) This law has undergone
several alterations and improvements, in consequence of the
extension of naval intercourse between different nations for
the purposes of commerce. Several codes have been formed
by different states primarily for the regulations of naviga-
tion, and for defining the authority of the masters and
other officers of ships, and the duty and rights of the
seamen; and afterwards for the regulation of maritime con-
tracts. The earliest syllab of marine law, which history
records, was that compiled by the Rhodians, after they had,
by their commerce and naval victories, obtained the fore-
renity of the sea, about 900 years before the Christian era.
These laws exist at present only in a detached and imperfect
state, as they have been preferred and incorporated in other
subsequent institutions of a similar nature. It has been sup-
pofed by some that the Rhodian laws were adopted by the
Romans during the first Punic war, when they first became
a naval power; but others affirm that they were incorporated
with the Roman law by Justinian and others. As for the
Phoc-
icians, Carthaginians, Athenians, Corinthians, and other
maritime states of antiquity, it does not appear whether they
had any marine laws of their own institution. If they had
any, they have not been transmitted to our times. The
first code of modern sea-laws was compiled, says ferjant
Marshall, about the time of the first crusade, towards the end
of the 11th century, by the people of Amalfi, who had then
become considerable for their commerce and maritime power.
It is not improbable that the code confided principally of
the Rhodian institutions, which were found full in force in
the countries bordering upon the Mediterranean; and being
collected into one regular system, were generally received,
for a considerable time, as law in those countries. In pro-
cesses of time, other states, as they acquired importance
and distinction, formed new collections of marine laws, in
which the old institutions were altered and modified to suit
the improvements of the times, or their own particular in-
terest. But when inconveniences were found to arise from a
diversity of rules pertaining to a subject that had been
long regulated by one general system, which was regarded
as part of the law of nations, it became necessary for the
different maritime states to form a new code out of all these
discordant materials, which was done, as Grotius informs us,
(De Jure Bell. l. iii. c. 1 § 5. n. 6), by the authority of
almost all the sovereigns of Europe. This new digest was
denominated "Confolato del Mare." It was first published,
by order of the ancient kings of Aragon, in the Catalan
tongue, and therefore probably composed at Barcelona, the
capital of Aragon. In the 13th century this code was
revived as law in Italy, the Greek empire, France, and Ger-
many; and Vinius says, that most of the marine laws in
Spain, Italy, France, and England are borrowed from it.
It seems to have been considered as a branch of the public
law, and its regulations are still of very high authority in
every maritime state of Europe. The next collection of sea-
laws in point of time, as well as of celebrity, is that of
Oleron,
Oleron. (See Oleron.) This was succeeded by a collection of the ordinances made by the "Merchants and masters of the magnificent city of Wibulbry, in the island of Gothland, formerly very famous for its commerce, but now reduced to an obscurc and inconsiderable town." Many of the regulations contained in this code of laws are precisely the same with those of Oleron. These laws were for some ages, and indeed still remain, in great authority in the northern parts of Europe. In 1597, the deputies of the Hanseatic league, in a general assembly at Lubeck, drew up a system of laws relating to navigation, for the use of their confederacy, to which, in 1614, they added several new ordinances. But the most complete and comprehensive system of this kind is the famous ordinance of the marine of Louis XIV. published in 1681. This excellent code was compiled and arranged by a very masterly hand, under the inspection of Colbert, the celebrated minister of that prince, upon an attentive revision of all the ancient sea-laws of France and other countries, with the assistance of the most learned men of the time, and upon consultation with the different parliaments, the courts of admiralty, and the chambers of commerce in France. It forms a system of whatever experience and the wisdom of ages had pronounced to be most just and convenient in the marine institutions of the maritime states of Europe. Notwithstanding new regulations, suggested by motives of national interest, it has hitherto been esteemed a code of great authority upon all questions of maritime law. From this ordinance, and from the elaborate and useful commentary of Valin, Lord Mansfield is said to have derived much of his extensive and accurate acquaintance with the principles of marine. Marshall's Law of Insurances, vol. 1. See INSURANCE.

Law of Marque, a law by which those who are driven to make use of it, take the goods, or shipping of the party that has done them wrong, and of whom they cannot get ordinary justice, whenever they can take him within their own bounds or precincts. 27 Edw. III. cap. 17.

Law, Martial. See MARTIAL.

Law Merchant, a summary sort of law, originally differing from the common law, though now adopted, and become a part of the laws of the kingdom. This decides the causes of merchants on the general rules which obtain in all commercial countries; and that often, in matters relating to domestic trade, as, for instance, with regard to the drawing, the acceptance, and the transfer, of inland bills of exchange. (Co. Litt. 172. Lord Raym. 181. 1562.) One point of it confines it, that if there be two joint merchants of wares, and one of them dies, his executor shall have the moiety; which is not allowed in the case of others, not merchants. See CUSTOM.

The law of merchants not being founded in the particular institutions, or local customs of any particular country, but consisting of certain principles which general convenience has established to regulate the dealings of merchants with each other in all countries, may be considered as a branch of public law.

Law is also used figuratively in speaking of the rules or order wherein any thing is performed.

Thus we say, the laws of motion, the laws of mechanics, the laws of fluids, the laws of chance, of a game, &c. laws of friction, of resistance, of decent of bodies, &c. laws of elasticity, rarefaction, refraction, reflection, &c.; all which see under their proper heads.

Law, in Scripture History, one of the three divisions of the Old Testament, comprehending Genesis, Exodus, Leviticus, Numbers, Deuteronomy. See CANON.

Law-Day, Laggedayum, in our old Law Writers, was any day of open court, and commonly used for the courts of a county or hundred. It is also called view of frank-pledge, or court-leet. "Et quieti finis de seftis comitatum & hundredorum norttorum, de vilu franci pledgi & laudavorum, &c."

LAWA, in Geography, a town of the island of Borneo, situated on a river of the same name. N. lat. 0° 40'. E. long. 116° 42'.

LAWEND, in the military language of the Ottoman empire, the appellation of cavalry, called also Delibaches. (See DELIBACHES.) From Lawend we have formed Laweni. Their arms are short sabres, pikillos, muskets, and lances. They wear a kind of cap, which is a long cylinder of black felt, nine or ten inches high, and without any projecting rim. Their faddles are made in the English manner, of a single skin, stretched upon a wooden tree; in the rest of their accoutrements and clothing, they resemble the Mamlouks. Their ragged clothes, their rusty arms, and their horses of different sizes, give them the appearance of banditti more than of soldiers; and, in reality, they have first distinguished themselves under the former character, nor have they much changed their habits by adopting their second occupation. Almost all the cavalry in Syria are Turkmans, Curds, or Caramanians; who, after exercising the trade of robbers in their own country, seek employment, as well as an asylum, near the perfon of the pacha. Throughout the empire, their troops are, in like manner, formed of plunderers, who roam from place to place. From want of discipline, they retain their former manners, and are the scourge of the country, which they lay waste, and of the peasants, whom they often pillage by open force. Volney's Travels, vol. ii.

LAWER KIRK, in Geography, a town of Scotland, in the county of Perth; 15 miles S.E. of George Town.

LAWES, WILLIAM, in Biography, the eldest son of Thomas Lawes, a vicar-choral of the cathedral church of Salisbury, and a native of that city, was placed early in life under Copernic, for his musical education, at the expense of the earl of Hertford. His first preceptor was in the choir of Chichester, but he was soon called to London, where, in 1602, he was sworn a gentleman of the chapel royal; which place, however, he resigned in 1611, and became one of the private, or chamber-musicians, to Charles, then prince, and afterwards king. Fuller says, "he was respected and beloved of all such persons as cast any looks towards virtue and honour," and he seems well entitled to this praise. He manifested his gratitude and loyalty to his royal master by taking up arms in his cause against the parliament.
iallament. And though, to exempt him from danger, lord Gerrard, the king's general, made him a commissary in the royal army, yet his activity of his spirit disdaining this intended security, at the siege of Chester, 1645, he lost his life by an accidental shot. The king is said, by Fuller, to have been so affected at his loss, that though he was already in mourning for his kinsman lord Bernard Stuart, killed at the same siege, his majesty put "on particular mourning for his dear servant William Lawes, whom he commonly called the father of music."

His chief compositions were fantasies for viols, and songs and symphonies for masques. Though his brother Henry, in the preface to the Choice Psalmes for three voices, which they published jointly, boasts that he composed more than thirty several sorts of music for voices and instruments, and that there was not any instrument in use in his time but he composed for it as aptly as if he had only studied that," in Dr. Aldrich's Collection, Christ-church, Oxon, there is a work of his called Mr. William Lawes's Great Confort, "wherein are fix sets of muficke, fix books." His Royal Confort for two treble viols, two viol da gambas, and a thorough-bafe, which was always mentioned with reverence by his admirers in the 17th century, is one of the most dry, awkward, and unmeaning compositions we ever remember to have had the trouble of forscing. It muft, however, have been produced early in his life, as there are no bars, and the passages are chiefly such as were used in queen Elizabeth's time. In the music-school at Oxford are two large manuscript volumes of his works in feore, for various instruments; one of which includes his original compositions for masques, performed before the king, and in the ins of court.

His anthem for four voices, in Dr. Boyce's second volume, is the best and moft solid composition that we have seen of this author; though it is thin and confused in many places, with little melody, and a harmony in the chorus, p. 201, which we are as unable to understand, or reconcile to rule, or to our own ears. He muft have been considerably older than his brother Henry, though they frequently composed in conjunction. We are, however, unable to clear up this point of primumgeniture: Henry's name is placed first in the title to Choice Psalmes, published in 1648, in the preface to which he says, "as to that, which is my part in this composition, it takes precedence of order only, not of worth." And yet he says of his own tunes just before, "they had their birth at the same time as his." Besides the psalms at the end of Sir William Davenant's masque, called "The Triumphs of the Prince d'Amour," 1635, it is said, that "the musicke of the fongs and symphonies were excellently compos'd by Mr. William and Mr. Henry Lawes, their majesty's servants."

Several of the fongs of William Lawes occur in the collection of the time, particularly in John Playford's Musical Companion, part the second, containing of dialogues, mambles, and airs, the words of which are in general coarse and licentious. The dialogue part, which he furnished to this book, is a species of recitative, wholly without accompaniment: and the duet at last, which is called a chorus, is infipid in melody, and ordinary in counterpoint. His bested canons, published by his brother Henry at the end of their psalms, as proofs of his great abilities in harmony, when recited, appear to far from finished compositions, that there is not one of them totally free from objections, or that bears the stamp of a great master.

Lawes, Henry, the brother of William, was likewise a disciple of Coperario. By the cheque-book of the chapel royal, it appears that he was sworn in Pitseller, in January, 1625, and, in November following, gentleman of the chapel; after this, he was appointed clerk of the cheque, and one of the public and private musicians to Charles I. William and Henry Lawes were at this time in such general favour, that though the kingdom was divided into factions, and were not only varied more in their principles, but disputed them with more violence than at any other period of our history, there was but one opinion concerning the abilities of these musicians. Yet as the reputation of Henry was still higher, and more firmly established than that of his brother, it seems to require more ample discussion. We have examined with care and candour all the works which we could find of this composer, which are still very numerous, and are obliged to own ourselves unable, by their excellence, to account for the great reputation which he acquired, and the numerous panegyrics bestowed on him by the greatest poets and musicians of his time. His temper and conversation must certainly have endeared him to his acquaintance, and rendered them partial to his productions: and the praise of such writers as Milton and Waller is durable fame. Tallis, Bird, or Gibbons, who were all infinitely superior to Lawes, never had their abilities bazoned by contemporary poets or historians of eminence. Fenton, the editor of Waller's works, tells us, that "the boldest of his time were ambitious of having their verses set to music by this admirable artist;" and, indeed, he not only set some of the works of almost every poet of eminence in Charles I.'s reign, but of young noblemen and gentlemen who seem only to have tried their strength on the lyre for his use, and of whose talents for poetry no other evidence remains than what is to be found in Lawes's publications.

Waller has more than once bestowed his fragrant incense on this musician. Peck says, that "Milton wrote his Masque at the request of Lawes;" but whether Milton chose Lawes, or Lawes Milton for a colleague in Comus, it equally manifests the high rank in which he stood with the greatest poets of his time. It would be illiberal to cherish such an idea; but it does sometimes seem as if the twoflffers, Poetry and Music, were mutually jealous of each other's glory: "the less interesting my hitter's offspring may be," says Poetry, "the more admiration will my own obtain." Upon asking some years ago, why a certain great prince continued to honour with such peculiar marks of favour an old performer on the flute, when he had so many musicians of superior abilities about him? We were answered, "because he plays worse than himself." And who knows whether Milton and Waller were not secretly influenced by some such consideration? and were not more pleased with Lawes for not pretending to embellish or enforce the sentiments of their songs, but setting them to founds less captivating than the flute? But bad as the music of Lawes appears to us, it seems to have been namely admired by his contemporaries in general. It is not meant to intimate that it was pleasing to poets only, but that it was more praised by them than any other music of the same time. Though that of Laniere, Hilton, Simon Ives, Dr. Child, and others, seems preferable; and the poets, whose praise is fame, perhaps taught others to admire.

The time was now come for simplifying harmony and purifying melody in England, as well as in Italy; and the beginning of this enterprise was not fortunate here any more than in that country: harmony and contrivance were relinquished without a compensation. Simplicity, indeed, was attained; but devoid of accent, grace, or invention. And this accounts for the superiory of church music over secular at this period in every part of Europe, where canon, fugue, rich harmony, and contrivance, were still cultivated; while the first attempts at air and recitative were awkward, and the baes thin and unmeaning. Indeed, the composers of this kind
kind of music had the single merit of boast of affording the finger an opportunity of letting the words be perfectly well understood; and their melodies, in general, confided of no more notes than syllables, while the treble acconpainment, if it subsisted, being in unison with the voice-part, could occasion no embarrassment or confusion.

But there seems as little reason for sacrificing music to poetry, as poetry to music; and when the sentiments of the poem are neither enforced nor embellished by the melody, it seems as if the words might be still better articulated and understood by being read or declaimed, than when drawn out in such psalmodic ayres as those of Henry Lawes and his contemporaries. It has, however, been asked "whoever reads the works of a song but the author?" And there are certainly many favourite songs, which nothing but good music and good singing could ever bring into notice. There are, however, poems, we will not call them songs, on subjects of wit and science, which must ever be embellished by music; while others, truly lyric, and confided to passion and sentiment, travel quicker to the heart, and penetrate more deeply to the soul by the vehicle of melody, than by that of declamation. But we want not to set up one art against another, or to give a preference to singing over declamation; but to allot to each its due place and province. There are passages in our bell plays which could never be sung by the finest performer that ever excelled, to so much effect as they have been spoken by a Garrick or a Siddons; while in Metastasio's charming dramas, there are lines and stanzas, by which an audience has been often more completely enraptured, when well set and well sung by a mellifluous and touching voice, than by the most exquisite declamation of the greatest actors that ever excelled. Though Henry Lawes feverishly cursettes the admirers of Italian music in his preface, yet his first cantata, "Theuseus and Ariadne," is both in poetry and music, an imitation of the famous scene in Monteverde's opera of "Arianna," which was afterwards formed into a single heroic song, entirely like this, in flflo recitative, without any air from beginning to end. After the opera of Rinuccini, which had been set by Jacopo Peri, Giulio Caccini, and Monteverde, in that manner, at the beginning of the 17th century, had met with such universal applause in Italy, from the lovers of poetry and simplicity, and enemies to madrigals and music of many parts, this kind of composition had many imitators, not only in Italy, but throughout Europe. All the melodies of Henry Lawes remind us of recitative or psalmody, and scarce any thing like an air can be found in his whole book of Ayres. As to his knowledge and resources in counterpoint, we are certain that they were neither great nor profound. His works were chiefly publish under the title of "Ayres and Dialogues," of which he printed three several books, the first in 1653; the second in 1653; and the third in 1658. Besides these, many of his songs and dialogues were publishd by Playford in collections, entitled "Select Musical Ayres and Dialogues," by Dr. Wilton, Dr. Charles Colman, Nicholas Laniere, and others. Though most of the productions of this celebrated musician is languid and insipid, and equally devoid of learning and genius, we shall point out one or two of them that seem the most meritorious.

Book the First, p. 11.

Careless of love, and free from fears, &c.

Vol. XX.
The usual situations of lawns are those just mentioned; yet if the nature of the ground admit, or in cases where there is a good slope of ground, they may be continued more or less each way; but always the most considerable on the principal fronts, which, if they be to the south, or any of the southerly points, they are the most definable for the purpose.

With respect to the dimensions, they may be from a quarter of an acre, or less, to fix or eight acres, or more, according to the extent and situation of the ground. Sometimes lawns are extended over ha-has, to ten, twenty, or even to fifty or sixty acres, or more. But in these cases they are not kept mown, but eaten down by live stock.

The form must be directed by the nature of the situation; but it is commonly oblong, square, oval, or circular. But in whatever figure they are designed, they should widen gradually from the house outward to the furthest extremity, to have the greater advantage of prospect; and by having that part of them within the limits of the pleasure-ground, bounded on each side by plantations of ornamental trees and shrubs, they may be continued gradually near towards each wing of the habitation, in order to be sooner in the walks of the plantations, under shade, shelter, and retirement. The terminations at the farther ends may be either by ha-has to extend the prospect, or by a shrubbery or plantation of stately trees, arranged in sweeps and concave curves. But where they extend towards any great road, or distant agreeable prospect, it is more in character to have the utmost verge open, so as to admit of a grand view from and to the main residence.

But the side-boundary verges should have the plantations rurally formed, airy, and elegant, by being planted with different sorts of the most ornamental trees and shrubs, not in one continued close plantation, but in distinct separated compartments and clumps, varied larger or smaller, and differently formed, in a somewhat natural imitation, being sometimes separated and detached less or more, by intervening breaks, and open spaces of short grass, communicating both with the lawns and interior districts; and generally varied in moderate sweeps and curves, especially towards the lawns, to avoid stiff, formal appearances, both in the figure of the lawns and plantations. In planting the trees and shrubs, which should be both of the deciduous and evergreen kinds, where intended to plant in distinct clumps, either introduce the deciduous and evergreens alternately in separate parts, or have some of both interpersed in assemblage; in other method, placing the lower growth of shrubs towards the front, and the taller backwards, in proportion to their several figures, so as to exhibit a regular gradation of height, that the different sorts may appear conspicuous from the main lawns. They may be continued backwards to a considerable depth, being backed with trees and shrubs of more lofty growth. The internal parts of the plantations may have gravel or sand walks, some shady, others open; with here and there some spacious short grass openings, of different dimensions and forms.

It is seldom that extensive lawns in parks or paddocks, &c., have any boundary plantations close to what may be considered as a continuation of them beyond the pleasure-ground, but are sometimes dotted with noble trees, dierfed in various parts, at great distances, so as not to obstruct the view; some placed singly, others in groups by two, three, fives, &c., and some placed irregularly, in triangles, sweeps, straight lines, and other different figures, to cause the greater variety and effect, each group being diversified with different sorts of trees, all suffered to take their natural growth. Where small, these kinds of openings should always be kept perfectly neat, by being often pedled, rolled, and mown, but where they are of large extent, this is scarcely ever the case. See Grass, Ground, and Turfing.

LAWS, in Commerce. See CAMPBELL.

LAWROW, in Geography, a town of Austrian Poland; 24 miles W. of Lemberg.

LAWRENCE, Peter Joseph, in Biography, an engineer, was born in Flanders in the year 1715. He distinguished himself, when he was only eight years old, by a considerable turn for mechanics. Cardinal Peligrane being shown a machine that he had at that early age contriv'd, predicted that he would one day arrive at eminence in the science of practical mathematics. Before he had attained to manhood, he had executed drains in different parts of Flinders and Hainault, which till that time had been impracticable. He contriv'd many curious and very ingenious flues and locks for rivers and canals; and he invented machines that were found of great utility in fortification, and a carriage on which the colossal statue of Lewis XV. was brought to Paris with great ease. He contriv'd engines, which at once cleared mines of their water, and, at the same time, raised the metallic ores. He formed a junction of the Scheldt and the Somme, which he effect'd by a subterraneous canal, three leagues in length, the level of which was 45 feet above the source of the Scheldt, and 15 feet below the bed of the Somme. The various mechanical inventions and undertakings of M. Lawrence have been celebrated in a poem by Déléile, intitled, "The Treasury of Paraffus."

I. A W

Eff. Ch. Calyx four-crested. Petals four, regular. Stamens approaching each other in four pairs. Berry dry, inferior, of four cells, with many seeds.

1. L. inermis. Henna, or Smooth Lawsonia. Linn. Sp. Pl. 498. (L. abla; Lamiack. Dict. v. 3. 110; L. spinosa; Hasselq. It. 464. Alkēnus, five; Henna. Arabum; Walch. Hort. 3. 1. 114. Rauwolf. It. 60. t. 75.)—Thorns none. Leaves obovate, acute. Segments of the calyx as long as its base.—Native of various parts of the Levant. Miller is said in the Hortus Kewensis to have cultivated it in 1759, but it is never preferred long, even in a flower, by our gardeners. The writer of this article obtained seeds in 1785 at Paris, from Mr. Desfontaines, who had brought them from Barbary. These vegetated at Chelsea, and in some other gardens, producing thorny plants of a humble stature, which in the ensuing autumn and winter were laden with flowers, whose delicate aspect, and exquisite scent, attracted the admiration of all who saw them. The habit of this species is not unlike Privet, but the leaves are more obovate, and of a lighter green. The flowers are yellowish-white, with purplish stamens, and grow in opposite clusters about the tops of the branches. Hasselquist in his travels, English edition 246, says, "the leaves are pulverized, and made into a paste with (hot) water. They (the Egyptians) bind this paste on the palms of their hands and (foles of their) feet, keeping it on all night. This gives them a deep yellow, which is greatly admired by the eastern nations. The colour lasts for three or four weeks, before there is occasion to renew it. The custom is so ancient in Egypt, that I have seen the nails of the mummies dyed in this manner. The powder is exported in large quantities yearly, and may really be reckoned a valuable commodity. The Egyptians call it Cehna. The dried flowers afford a fragrant smell, which women who have conceived cannot bear."

2. L. spinosa. Prickly Lawsonia. Linn. Sp. Pl. 498. (Cyprus, Acalca; Rumph. Amboin. v. 4. 42. t. 17. Mail-anfchi; Rheede Hort. Mal. v. 1. 73. t. 40. Pluk. Phyt. t. 220. f. 1.)—Branches becoming spinous. Leaves obovate, with a small point. Segments of the calyx as long as its base.—Native of the East Indies. It differs from the former, of which many have not unjustly thought it a variety, in having the permanent lateral branches hardened into a spine at their extremities. The fruit answers to Gärtner's description of a dry berry rather than a valvar capsule. The leaves seem to vary in shape. Rumphius says they are used to dye the nails in the island of Celebes, &c., and that the Malay women are particularly fond of the flowers, with which they deck their person and hair their beds. Hasselquist's own specimen, called in his travels, by Linnaeus, L. spinosa, proves not to be this plant but the former. Indeed, as we have before hinted, they are most probably one and the same species.

3. L. coccineum. Scarlet Lawsonia. Branches becoming spinous. Leaves elliptic-obovate, acute. Segments of the calyx twice as long as its base.—Sent from Banda by the late Mr. Christopher Smith, as "a Lawsonia with scarlet flowers." It is very nearly related to the last, and we find nothing to discriminate this, our specimen being but imperfect, except a difference in the relative proportions of the parts of the calyx, of the certainty or conformation by which we have some doubt.

One might suppose this plant to be the L. purpurea, Lamark. Dict. v. 3. 107, Wildenow's n. 2; but on turning to the Poutaliste, Rheede Hort. Mal. v. 4. 117. t. 57; cited for it, which Linnaeus very erroneously quotes for L. inermis, the plant of Rheede will be found widely different from every Lawsonia, as Jussieu well observes, p. 342. The flowers are monopetasal and tetradrous, with an inferior germen, and this great French botanist suspects it may be a Pitsia. Of its belonging to his order of Rubiaceae there can be little doubt. The L. purpurea, therefore, of which Lamark had seen only leaves, and Willdenow nothing, falls to the ground.

4. V. Acropychia. Broad-leaved Lawsonia? Linn. Suppl. 219 Forl. Prodr. 27. (Acropychia lavis; Forl. Gen. 27. t. 27.)—Leaves obovate, on long stalks. Petals inflexed at the point. Stamens fringed.—Gathered by the Forsters in New Caledonia. A smooth shrub, with round branches. Leaves opposite, an inch or two long, obovate, obtuse, entire, slightly revolute, veiny, smooth. Foottuffs half an inch long, straight, channelled, smooth, united to the leaf by a joint. Clusters axillary, forked, much shorter than the leaves. Calyx with very small, rounded, pale-edged segments. Petals linear-oblong, hooked inward at the point. Stamens fringed at the base, scarcely so long as the corolla. The fruit is positively described by Forster as "an inflatd capsule of four valves." This character, and the totally different form of the petals and calyx, persuade us that the species in question ought to stand as a genus by itself, as Forster originally made it.

Lawsonia, in Gardening, contains plants of the exotic tree kind for the flower, of which the species are the smooth Lawsonia (L. inermis), and the prickly Lawsonia (L. spinosa).

Method of Culture.—These two plants may be raised by fowing the seeds in pots of light mould, in the early spring, and plunging them in the bark bed of the flower. When the plants have acquired a few inches growth, they should be removed into separate small pots filled with light sandy earth, replanting them in the bark-bed, and giving a little water, with proper shade. They afterwards may be placed so as to have pretty free air, but be constantly kept in the flower at all seasons.

They afford a variety among other flower plants.

LAWYER, (legistis, legiferius, jurifonfulius), by the Saxons called labman, is a counsellor, or one learned in the law; and lawyers, such as counsellors, attorneys, &c. are within the act 3 Jac. 1. against extortion; but it has been held only to extend to officers. See COUNSELLOR, ATTORNEY, &c.

LAX, in Geography, a town of Switzerland, in the Va-

LAXA, a town of the island of Lewis, situated on a bay, on the east coast; 9 miles S.S.W. of Stornamay.—Alfo, a town of Peru, in the diocese of La Paz; 20 miles S.W. of La Paz.

LAXATIVE MEDICINES, are those purgative or cat-

LAXATOR, in Anatomy, a name applied to two muscles of the officula auditus. The laxator tympani major is the externus mallei of Albinus; the laxator minor is simply laxator tympani of that anatomist. The existence of the latter muscle is doubted by some. See the article EAR, where they are described by the names of Albinus.

LAXEMAURI, in Geography, a town of Auftria; 7 miles S. of Vienna.

LAXEY BAY, a bay on the east coast of the Isle of Man, in the Irish sea, which affords a shelter from westerly winds,
lies, in about 7 to 10 fathom water. The cape at the southern extremity is called "Laxey Point."

LAXIOR TOCA. See Toca.

LAXMANNIA, in Botany, a name originally given by Forster, in his *G. end. t. 47, to a tegumentous tree of St. Helena, which Solander considered as a Bidens, but which George Forster in his *Planta Atlan tica,* 56, subsequently referred to *Spilanthus.* We have not discovered it in Wil denow, nor can we ascertain what Schéber decided concerning this plant; but the latter has adopted the name for ano her genus, of which we are now to speak. It is designed to commemorate the Rev. Eric Laxmann, a native of Finland, Professor at Peter burg, who made many botanical discoveries in Siberia, and died in 1796. — Schreb. 800. Mart. Mill. Dict. v. 3. (Cuminofma; Gärtn. t. 58.) — Clafs and order, *Hectandra Monogynia.* Nat. Ord. *Auranti ca:* Juss.

1. L. Cuminofma. Globose *Ankenda.* (Cuminofma Ankenda; Gärtn. Sem. v. 280. f. 178. f. a—H.) — Fruit globose, slightly depressed. Petals twice the length of the calyx. — Native of Ceylon. Of this we know nothing but from Gärtn, who confounds its synonyms with the following, though he distinguishes it as a species by the shape of the fruit, and relative proportions of the calyx and petals.

Mr. Dryander in Tr. of Linn. Soc. v. 2. 232, has well illustrated the synonymy of this plant, which Linnæus had confounded with the Jambolana, or Jambolains of Acosta, a species of *Calpytandra;* see that article. This mistake is supputed to have arisen from the tickets of *Madan* and *Ankenda* in Hermann's herbarium having been changed.

LAY, Allampi, or Amlampi, in Geography, a town of Africa, in the kingdom of Niumo, on the Gold Coast.

Lay, or Lai, the title of the most ancient kind of fongs in the French language. It was not till the reign of Philip Augustus that fongs became common in that country. Gautier de Coiney, an ecclesiastic of St. Medard de Soffons, composed a considerable number, which are still preserved in MS. among his other writings. "Lays were a kind of elegies," says M. l'Evêque de la Ravoilere, (An-

cént de des Champs, tom. i. p. 255.) "filled with amorous complaints. The origin of this species of composition is such as rendered it necessarily plaintive: as the word *lai* is imagined to have been derived from *lyius,* Latin, which sig- nifies complaints and lamentations. However there are some lays which describe moments of joy and pleasure more than sorrow or pain; and others upon sacred subjects.

Chaucer, who frequently uses the word lay, confines it, wholly to fongs of complaint and sorrow:

"And in a litter wrote he all his forwe
   In maner of a complaint or a lay,
   Unto his faire frethe lady May."—

Cant. Tales, v. 9754.

"He was dispeire, nothing dorit he say,
   Sain in his fongs some what wold he wray
   His wo, as in a general complaining;
   He fayd, he loved, and was beleue nothing.
   Of wiefe materre make he many layes,
   Songes, complaintes, roundels, virelays—"

Tran. t. 11255.

"Thus end I this complaining or this lay.

Ibid.

In. Spencer's time, however, its acceptance was more general, and as frequently applied to fongs of joy as forrow:

"To the maiden's founding timbrels sung
   In well attuned notes, a joyous lay."—

Fairy Queen.

Shakspere and Milton use it likewise indiscriminately for every kind of fong.

Lai seems a word purely Francic and Saxon: it is neither to be found in the Armorick language, nor in the dialect of Provence. The French poetef Mair, who in the time of St. Louis, about the middle of the thirteenth century, translated several fables from the Armorick language of Bretagne, calls them lais; but the term is of much higher antiquity. After its adoption by the English poets, it soon became a generical term in poetry for every species of verle, as fong is now: but both these words still retain their particular acception as well as generical; for by a fong is understood a short poet fit to a tune, and this was the particular meaning of lay, in the last century, among our musical writers.

Tales and fongs, says the editor of ancient Fabliaux et Contes Francois, were the most common and ancient species of poetry. The French, naturally gay, cheerful, and sportive, were more attached to this species of composition than any other nation, and communicated this love for lyric poetry to their neighbours. They must have been in possession of a great number of these fongs and tales, because in all social meetings the custom was for every one present either to sing a fong or tell a story, as appears by the end of the fable of the prief, "qui ot Mere a force," where we read these verses:

"A celt mots fenit cis fabliaux
Que nous avons en rime mis,
Pour conter devant nos amis."

And according to John II Chapelain, in his ditty of the Sacristian of Clugny, it was customary for a bard to pay his reckoning with a story or a fong.

"Usage est en Normandie,
Que qui hebergiez eul, qu'il die"—
L A Y

Table ou chanzon aJon olte
Celle coustume pas n'en olte
Sure Johns li Chapelains."

"In Normandy a song or tale
Is current coin for wine or ale;
Nor does the friendly host require
For bed and board a better hire."

In the thirteenth century, the songs in vogue were of various kinds; moral, merry, and amorous: and at that time, melody seems to have been little more than plain-song, or chanting. The notes were square, and written on four lines only, like those of the Roman church, in the clef of C, without any marks for time. The movement and embellishments of the air depended on the abilities of the singer. The compas of modern music is much extended since by the cultivation of the voice; for it was not till towards the end of St. Lewis's reign that the fifth line began to be added to the stave. The finger always accompanied himself on an instrument in unison. Poëie du Roi de Navarre, tom. ii.

LAY, in Agriculture, a term applied to such land as is in the state of graps, or sward. This sort of ground is frequently tilligienhied into such as has been long in the state of sward, and such as is newly laid down to graps, or into old and new lays. The proper method of managing the latter is of great importance to the farmer, and which, Mr. Young thinks, should be by keeping them perfectly free from all sorts of flock for the following autumn and winter after their being laid down, when, in the spring, they will afford a flow of young graps highly valuable for heep, with which they should only be well focked, and kept down then, and during the whole of the summer: "nothing," in his opinion, "being more pernicious than mowing a new lay, as directed by certain authors. They may," he supposes, "have succeede in spite of such bad management, but never by it." The most fitul method of managing these new lays, under different circumstances, will be described in speaking of laying lands down to the state of sward or graps. See Laying down to Graps.

It may be observed, that the treatment necessary for old lays must vary much, according to their nature and the particular circumstances under which they are placed, as will be shown under the management of meadow and pasture lands, as well as in considering the nature of graps. See Grass-Ground, Meadow, and Pasture.

It has also been observed, that, on many farms, there are often "tracts of barren lays, from moils, poverty, neglect, and bad herbage, upon which a very great improvement may be made by a single ploughing in August. For this purpose, a strong four-horse plough must be used with a skim-couler; then going over it twice, in different directions, with the scairier, so as not to disturb the flag; harrowing it once, and immediately sowing a quarter of a peck of clole-seed, two bushels of cock's foot, and one bushel of Yorkshire white per acre; adding some of whatever seeds may be procured at the moment cheaply." It is then advised to be left "unfed and untouched till the March following; in which month, and through April, it should be loaded well with sheep: the ufe will then be very great. Keeping sheep feeding it heavily through the year, the cole will be killed, and you will have a pasture worth treble what it was before. The expense is said to be smail, and the improvement rapid."

Various modes of improving land, in the states here described, will be explained under the heads above mentioned.

And the same writer also thinks, that, by December, old lays will be wet enough to begin to break them up; "a work that should not be done while the land is dry; for it will not then turn up in clean well-cut fowrs. Ploughing gras-land is, it is laid, a very good piece of husbandry, when they are worn out and over-run with mos and other rubbish, or hide-bound. To keep land under such unprofitable turf is bad management. It should, by all means, be broken up, and kept in a churfe of tillage for three or four years, and then laid down again; by which conduct, four times the profit will arise that could be gained from keeping it in lay."

Lay-Brother, among the Romanists, a pious, but illiterate person, who devotes himself, in some convent, to the service of the religious.

The lay-brother wears a habit different from that of the religious, nor ever enters into the choir, or the chapter. He is not in any orders, nor does he make any vows, excepting of conflagy and obedience.

These lay-brothers make the three vows of religion.

In the nunneries are also lay-sisters, who never enter the choir, &c. and who are only retained for the service of the convent.

The institution of lay-brothers began in the eleventh century. The persons on whom this title was conferred were such as were too ignorant to become clerks, and who therefore applied themselves wholly to bodily labour.

It seems to have taken its rise from hence, that the layy in those days had not, for the generality, the leaf tinture of learning; whence also those came to be called clerks, by way of distinction, who had studied a little, and were able to read.

In some orders they are only retained by a civil contract, which, however, binds them for life; in other orders they are to pass through four years of probation, as among the Jacobitis; or seven, as among the Feuillants. The Capuchins admit none before nineteen years of age. The Jefuits call them condivitors.

Lay-Canons. See Canon.
Lay-Communities. See Community.
Lay-Corporation. See Corporation.
Lay-Fees, freedum lacium, land held in fee from a lay-lord, by the common services to which military tenure was subject, as tilligienhied from the ecclesiastical holding in frank-almsign, discharged from those burdens.

Lay the land, in Sea Language. See Land.
Lay-patronage. See Patronage.
Lays, late. See Side-lays.
Lay, count. See Vaunt-lay.
LAYAU, in Geography, a town of the island of St. Vincent, on the W. coast, in a bay at the mouth of a river, to both of which it gives name. N. lat. 13° 8'. W. long. 61° 18'.

LAYBACH, a town and capital of Carniola, on a navigable river of the same name, dividing it in such a manner, that part of the town lies in Upper, and the other in Lower Carniola. The citadel is ancient and has a church; it is inhabited by a contable, who has the title of burggrave, and 12 souldiers. Laybach is the fee of a bishop, who is a prince of the empire. The town contains, besides the cathedral, several churches, and about 500 houses; 28 miles N.E. of Trigla. N. lat. 46° 12'. E. long. 14° 35'.

LAYCOCK, or LACOCK, a parish, formerly a market-town of Wiltsire, England, is seated in a fine, fertile valley, on the western bank of the river Avon, three miles from Chippenham, and 95 miles of London. In the year 1808 this place contained 147 houses, and 1408 inhabitants. Here was formerly an abbey of large extent, and rich endowment. A large pile of the old buildings still remains in their former monastic.
LAY

monastic style; particularly the cloister, kitchen, cellars, gallery, &c.; with the fish-ponds and terrace walk. At the S.E. angle of the building is a tower, which contains, among other records, an original copy of the Magna Charta. See Blacklone's "Dissertation on Magna Charta," &c.

Some account of the abbey, with a view of the cloisters, is published in "The Architectural Antiquities of Great Britain," vol. ii., and a full description of the place, and other objects in the vicinity, will be found in Britton's " Beauties of Wiltshire."

LAYDE, a town of Africa, in the country of the Foulis, on the Senegal; 45 miles S.E. of Goulou.

LAYERS, in Building. See Course.

Layer, in Gardening, the young shoot or branch of such trees as are capable of being raised by being laid into the ground. It is the part which is placed in the earth in order to strike root, and from the new plant layers are made from different kinds of shoots and young branches, according to their natures and habits of growth.

LAYERING, the act of placing layers into the ground. This is performed in different ways, as may be seen under the proper head. See Laying.

LYES, or LEVES, a term used in many parts of England for such pasture ground as has been formerly tilled and fown.

LAYING, in Gardening, the process or operation of placing layers in the soil. It is a method adapted to most forts of trees and shrubs, and many herbaceous plants. It is effected by laying branches and young shoots of trees and plants in the earth, from two or three to five or six inches deep, leaving their tops out, that the part laid in the earth may emit roots, and become a plant. The layers, when well rooted, should be separated from the parent, and planted in the nursery, or other proper place, to acquire due strength and size, for the purposes for which they are designed. And they require different lengths of time for becoming rooted, from a few months to two or more years.

There are great numbers of shrubs and trees that are capable of being increased by layers, but the practice is more particularly applicable to the shrubby kind; as their branches grow near the ground, convenient for being laid down. It may, however, be practiced with success on fruit-trees and forest-trees, when their branches are situated low enough for being laid, though the varieties of many fruit-trees are better propagated by grafting and inoculation. The vine and fig, however, often admit of being increased by layers; and forest-trees, for the continuance of varieties; as the plants raised in this method continue exactly the same as the parent plant from whence they were raised. This is a certain method to continue any approved variety, as well as to increase such shrubs or trees as do not produce seeds freely, and which cannot be easily obtained. It is likewise an expedient and easy mode of propagation, as by it many new plants are often raised in a few months, which would take two or three years to bring them to the same size from seed. In many forts it is so easy that all the shoots of any branch situated near the ground, or convenient for laying down, may be made distinct plants.

It may be noticed that, for all forts of the tree or shrub kinds, it is generally performed on the young shoots of the preceding summer, which should be laid down in spring or autumn; but sometimes on shoots of the same year, in summer, especially in the hard-wooded evergreen trees and shrubs, that do not strike root readily in the older wood. Many forts of trees that have their wood of a loose soft texture often grow pretty freely by layers of them, of two or several years growth.

But in herbaceous plants capable of being propagated by layers, such as carnations, pinks, double sweet-williams, &c. the young shoots of the same year, laid down in June and July, are commonly the most successful.

In regard to the season for performing this sort of work, in most forts of trees and shrubs, it is autumn and spring, though it may be performed at almost any time of the year.

Many kinds of under-shrubby and herbaceous plants also succeed, if laid any time in spring or summer till the end of June; though that and the following month are the most successful for the herbaceous tribe, as carnations and others usually propagated by laying, as they then root the same season in from three or four to five or six weeks, so as to be proper for transplanting.

When it is intended to lay trees or shrubs that naturally run up to stems, without furnishing any considerable quantity of lower branches for laying, a sufficient number of strong shoots should be set in the nursery, at proper distances, and headed down in the autumn or spring after, within a few inches of the ground, that they may throw out a good quantity of young shoots the following summer, near the earth, so as to be convenient for laying down in the succeeding autumn; or, by waiting another year many more shoots for the purpose of layers will be provided, by the first shoots throwing out many lateral ones, each of which when laid will form a plant. And on the layers being rooted, and all cleared away, the stool remaining will furnish another crop of shoots for laying next year, and the fame in succession for many years.

Where layers are wanted from trees that are grown up, and whose branches are at a distance from the ground, a temporary stake or scaffold is erected, on which pots or tubs of mould are placed to receive the layers.

The general method of merely laying the branches or shoots in the earth, is practiced for all forts; but previous to laying, they are often prepared in different ways to facilitate their rooting, according to the trees of different natures require; as by simple laying, twining, flitting, cutting the bark, piercing the stool, wiring, and other modes.

Simple Laying.—This is merely laying the shoots in the earth, as directed below, without any previous preparation of twining, flitting, &c. and is sufficient for a great number of trees and shrubs of the soft-wooded kinds; but for such as do not readily root by this simple method, recourse must be had to some of the following ways.

Twining the Layer.—By giving the shoot a gentle twist in the part designed to be laid in the ground, it greatly promotes and facilitates the emission of fibres from the bruised part.

Slitting or tonguing the Layer.—This is the most universal and successful mode, where any preparation of the shoot is necessary to promote its rooting; it is performed by slitting the shoot at a joint underneath, up the middle, half an inch or more long, according to the size and nature of the layer, forming a sort of tongue nearly the same as directed for carnation layers, laying that part in the earth, and raising the top upright, or rather pointing inwards, so as to separate the tongue of the slit from the other part, and keeping the slit open, as directed below.

Cutting the Bark of the Layer.—This is performed by cutting the bark all round at a joint, taking out small chips all the way below the cut, and laying that part in the earth, by which it readily emits roots.

Piercing the Layer.—This is done by thrusting an awl through the shoot, at a joint, in several places, laying that part
part in the ground, by which it will emit fibres from the wounds more readily.

*Wiring the Layer.*—This is by twisting a piece of wire hard round the shoot at a joint, and prickling it with an awl on each side of the wire in several places, laying it in the earth, by which it breaks out into roots at the confined and wounded parts; often proving successful in such trees and shrubs as do not readily emit fibres by the other methods.

It may be observed that by some of these methods almost all sorts of trees and shrubs may be propagated.

*Method of Laying.*—The general method of laying all sorts of trees or plants, either by simple laying, or any of the other methods, is the following.

The ground about each plant must be dug for the reception of the layers, making excavations in the earth to lay down all the shoots or branches properly situated for the purpose, pegging each down with a hooked fitch, laying also all the proper young shoots on each branch or main shoot, fixing each layer from about three or four to six inches deep, according to their length, though some shorten their tops down to an eye or two only above the earth, raising the top of each layer somewhat upright, especially the flat or tongued layers, to keep the flat part open. As all the layers of each plant or cfiool are thus laid, all the mould should be levelled in equally in every part, close about every layer, leaving an even smooth surface, with the top of each layer out.

It sometimes happens that the branches of trees are so inflexible as not to be easily brought down for laying; in which case they must be plashed, making the gaff or cut on the upper side; and when they are grown too large for plashing, or the nature of the wood will not bear that operation, they may be thrown on their sides, by opening the earth about the roots, and loosening or cutting all those on one side, that the plant may be brought to the ground to admit of the branches being laid down into the earth.

Where layers are to be made from green-house shrubs, or other plants in pots, the work should generally be performed in pots, either in their own, or others placed for that purpose.

After laying in either of the above methods, there is no particular culture necessary, except in the heat of summer giving occasional waterings to keep the earth moist about the layers, which will greatly forward them, and promote a good supply of roots against autumn, when those that are properly rooted should be taken off and transplanted.

The laid branches or shoots should be examined at the proper season, October and November, and those that are rooted be cut from the mother plant, with all the root possible, planting them out in nursery rows a foot or two aunder, according to their nature of growth, there to remain till due use for their several purposes; but those of the tender kinds must be potted, and placed among others of similiar nature and growth.

When the layers are all cleared from the fiools or main plants, the head of each fiool, when to be continued for furnishing layers, should be drenched; cutting off all decayed and scraggy parts, digging the ground about them, working some fresh mould close about their heads, to refresh and encourage their producing a fresh supply of shoots for the following year's laying down. This sort of care preserves them many years.

*LAYING-DOWN TO GRAFS.*—In Agriculture, the means of bringing such land as has been under the plough into the state of grafs or sward. This is a part of husbandry which is of much importance to the farmer, and which requires much care and attention to accomplish it in a proper manner, under different circumstances of soil, climate, situation, and preparation of the ground. It is well known by practical farmers that some sorts of grafs are much more difficult to be brought into the state of good grafs or sward than others, and that, when this point has been accomplished, some are much more profitable and advantageous than others, as affording a much better, and more lasting herbage. In some places, too, the business of bringing the land into the state of sward, after it has been in that of arable cultivation, is effected with the greatest care and facility: the ground, on being left in an unploughed condition, from its natural tendency to the production of herbage, returns to the state of sward, almost without trouble, feed, or expense; while in others, all the art of the most careful agriculturist is found insufficient for accomplishing the purpose. It has been stated by Mr. Davis, that "after twenty years fruitfulness expectation and expense, the landholders have frequently been obliged to restore the land again to a state of tillage." But besides this disposition or tendency in soils for taking on the growth and establishment of grafs crops, there are other circumstances to be attended to in bringing them to the state of grafs or sward, after they have been under the plough; such as thefe of their poiffelling neither too much nor too little moisture, and that of their having a sufficient staple or depth of mould for the full and secure establishment of the grafs plants. As where the soils are too wet, or too retentive of moisture, they will suffer much injury, if not be wholly destroyed, during the winter season, when there is much rain and frost, as well as be quickly superceded by plants of the coarse aquatic kind, such as the rush, &c. And where they are too dry, the grafs will be liable to be destroyed by heat during the summer months, by the little moisture which they contain being thus carried away, and of course leave their places to be supplied by other sorts of coarse plants, such as those of the moss, fern, and heath kinds, according to the nature of the ground. A good depth of mould or soil is likewise requisite, in order that the roots of the grafs plants may penetrate or run down to such a depth below the surface, as to be in a great measure out of danger from the effects of heat and evaporation in the summer season. On these as well as other accounts, it is therefore better that the lands intended for grafs, especially where they are to be kept in a permanent state of sward, should incline in some measure to a state of moiture, or be in such a degree retentive of it, as to preserve that state of humidity which is necessary for the healthy and vigorous growth of the plants, withou't endangering the destruction of their roots by putrefaction, from its flagrating in too large a proportion about them. It is chiefly on this principle, it is added, that the more light, thin, dry, descriptions of soil are better suited for the production of grafs, or the occasional practice of convertable husbandry, than for that of permanent grafs or sward.

And there are still other circumstances connected with the nature of the soils, which are necessary to be particularly attended to in the laying of lands down to the state of grafs, as those of properly adapting the grafs plants to their qualities, some sorts of grafs being much more impatient of wet than others, consequently more proper for the drier sorts of lands; some more capable of refilling the effects of heat and drought, and of course more suitable for the thinner and more porous kinds of soil: while others delight in a moist or wet soil, and are incapable of being grown with any success, on such as are of a dry quality. They likewise differ much in respect to their hardiness; some refilling the effects of cold much more effectually than others, and of course more adapted to high exposed situations. Besides these,
LAYING.

thence, they vary in other respects, some succeeding to the most advantage in soils of the clayey kind, others in those of a loamy quality, while others delight in those of a sandy nature, a few in those of the calcareous kind, and some in those which partake much of the nature of peat.

In addition to these different natural propensities, there are some grasses that have the property of rising to a great height in the field, and of course affording a large coarse produce, while others are more limited in this respect, but spread and extend themselves more in a lateral direction, affording a less proportion of produce, but which is of a finer quality. The former, with certain restrictions, would seem better adapted to the purpose of hay, though the latter may be applied to the same use, where the fineness of quality is preferred to quantity of produce. There are likewise some sorts of grasses that contain much larger proportions of fascarine matter in their compositions than others, as well as more leaves and fewer flower stems; and which, from the avidity with which they are fed upon by different sorts of live stock, and the success that attends their being thus consumed in the improvement of such stock, would appear to possess the largest proportion of nourishment; and of course to be the most proper for being introduced where the lands are intended for the purpose of grazing, or fattening animals by means of vegetable food in its gross state. And further, there is another property of grasses in which they differ considerably; and which is of so much consequence as to require being regarded in the laying of lands to the flate of fward. This is that of early growth, which is a circumstance of great importance in a grazing point of view, as there is in general a great deficiency of grass for the support of stock in the early part of the spring. See Practical Agriculture.

It is the opinion of Mr. Curtis, that in the forming of good meadows, or other grass-lands, there should be a combination of these different circumstances, as it is chiefly by the first, or the quantity of produce, that the cultivator is enabled to support his live stock, and pay his rent; or of course no expense in labour or manure is spared to obtain it by the prudent farmer. It does not, however, follow, that this should be solely regarded, or that to attain it the coarsest sorts of plants should be cultivated; nor will the grasses that are recommended merely for their being relished by cattle, or for the sweetness of their foliage, if they are found to be deficient in the quantity of produce, fully answer the views of the farmer or grazier, as, to constiute a good meadow or pasture, an abundant produce is necessary. And that, though animals prefer some sorts of food to others, it is not possible to indulge the live stock that is to be supported conffantly with the finest and most delicate hay or herbage. Besides, it is not improbable that the productive grasses may in some cases be highly nutritious, or that cattle may eat as eagerly the herbage or hay made from the coarse as the fine grasses. And cattle are frequently known to thrive on food to which they are habituated by necessity, though at first they could scarcely be prevailed on to eat it. It is suggested, that in making experiments, perfons are apt to conclude too hastily from the appearance which a plant affumes on its being first planted or sown; as the most insignificant plant or vegetable will often make a great show, when its fibres have fresh earth to shoot into. But the trial comes when the object of the experiment has been in a meadow or pasture several years, when its fibres, from long growth, are matted together, and it meets with powerful neighbours, to dispute every inch of ground with it: if "it then continue to be productive, it must have merit." It is well known, that "lucern, when left to itself, is soon overpowered; and if broad-leaved clover, which is undoubtedly a perennial, the first year be sown, a great crop is produced; but let the field be left to itself, and the clover, like the lucern, will yearly diminish,—not because it is a biennial, as has been often supposed, but because plants harder, or more congenial to the soil, usurp its place; this shews, "that at the same time that a good plant is introduced, it should be a powerful one, and such as is able to keep possession, and continue to be productive." Further, that "in respect to the property of cattle's thriving on the food they eat, it is unquestionably of great consequence; and it is to be regretted, that our knowledge of the most nutritious kinds of herbage is so confined: but of those plants which have been in cultivation, we are enabled to speak with some certainty: it is well known, that "clover, lucern, fainftoin, thore, and several other similar plants, have a great tendency to fatten cattle; but what natural grasses, or other plants, which have not been subjected to separate culture, have this particular tendency, and in what degree, remains to be ascertained by the test of experiment." But, "that as leguminous plants are in general found to agree with cattle, it may be reasonably concluded, that a certain quantity of them may be proper and beneficial in pastures. It is well known that certain pastures are more disposed to fatten animals than others: but how far this depends on situation, and their particular produce, remains to be ascertained." With respect to the property of early growth, it is suggested that the "want of early herbage in the spring is the general complaint of farmers and graziers in all the belt grass districts of the kingdom: those plants, therefore, which are found to shoot at an early period, and to put forth early foliage, especially when it is such as is grateful to cattle, must be deserving of great attention. As far as grasses have to do in this business, tho' mentioned hereafter may affect all that can be expected in this way: much must, however, depend on season; if the winter should be severe, or north-easterly winds prevail in the spring months, grassy herbage will be back,ward, in spite of all that can be done; but in order to counteract the bad effects of such seasons as much as possible, pastures and grass-lands should be warmly situated, and not drenched too much with moisture, being sheltered by thick hedges, and divided into small inclosures." But where early pasturage is the great object of the farmer, there are other plants that may deserve a place among them, such as those mentioned below. And that "though early herbage is highly valuable for pasturage, it is not less so for the purposes of hay; as by the middle of May at the latest, a meadow of this sort would be fit for cutting; and the second hay-making begin by the time that hay-making usually takes place in other cafes; and by this means the double advantage be obtained, of a larger produce, and less risk in securing or making it."

It is stated in a late work on Practical Agriculture, that "on the principles that have been already explained, there can be little doubt but that by a judicious and due attention to the different circumstances and uses for which grass-lands are intended, as well as to the feeding and mixing of the beet and most proper grass-feeds, and adapting them to the particular nature and circumstances of the soils, after they have been brought into a suitable condition for receiving them, those grounds which have been in a state of tillage may be laid down to the state of sward, in a much better and more beneficial manner than has been the case under the indiscriminate use of such as were in, or which have sworn themselves on the lands from the contiguous pastures." It has "been long since remarked as extraordinary, by Mr. Stillingley, that cultivators should have neglected
to make a proper advantage of plants of such importance, and which, in most situations, constitute the principal food of live stock, from the want of properly distinguishing and selecting such as are the most advantageous and useful under different circumstances of the land." Some have likewise contended, that "the best grafts-feeds cannot be collected at too high a rate; as it is possible, by such means, to render lands, which are fabled for the production of grafts, much more valuable than can be done by the common modes of laying them down."

It cannot, however, but be confessed that much difficulty has been thrown in the way of introducing the most proper sorts of grafts, in laying lands down to sward, from their near resemblance to each other, in many instances, requiring the nicest discernment to distinguish them, and from the want of other means of procuring them.

It has been flated by Mr. Curtis, in his tract on Grafts, that "if grafts-lands, such as downs, pastures, and meadows, be carefully examined, they will all, except such as have been recently laid down with rye-grasts or clover, be found much in a state of nature, replete with the most indiscriminate mixture of plants, some of which produce cattle food of a good kind, others such as is of a very indiftenent description, some affording good crops, while others fearely yield anything at all." And in the System of Practical Agriculture it is fuggled as sufficiently obvious, "that by a careful attention to the procuring of the beet and most fuitable sorts of grafts-feeds, and applying them according to the principles which have been given above, much superiority may be attained in the formating of pasture, or other sorts of grafts-lands." See Grass.

Method of Preparation of the Land.—The proper preparation of land for grafts-feeds is a part of management, according to the same writer, "that is of vast importance to the success of forming good grafts-lands, but which has been much neglected in the practice of laying them down. From the same frefs of the feeds, and the fibrous nature of the roots of the grafts-plants in moist cafes, it is evident that lands which are intended for being laid down to the sward, whatever their quality may be in respect to soil, should constantly be brought into as fine a state of pulverization and mellowifs as possible, before the feeds are put in: as where the contrary is the cafe, from the lumpiness of the surface mould, the feeds can neither be sown with fo much regularity, vegetate in fo equal a manner, or extend their roots, and establish them at first so perfectly in the land, they are of course more liable to be destroyed by hot fasons coming on afterwards. It is probable that in this way much new laid down grafts-land is greatly injured the first fummer, especially when it turns out to be hot and dry. The necifary finenes of mould may be obtained in different modes, according to the nature of the lands. In the more fuffif and heavy ones, by ploughing before winter, and leaving them to be expoed to the action of frofts and other causes during that feaon; having recourfe to severe harrowung, and occasional rolling, in the early fpring months; and by the frequent interpoftion of fuch forts of crops, in the courifes that precede thofe of grafts, as have a tendency, from the peculiar nature of their roots, to loofen and render the foils fine, fuch as thofe of the bean, cabbage, rape, and clover kinds. The lighter forts of land may be brought into a proper condition for the reception of grafts-feeds, by repeated ploughing and harrowing, or fcullifng, and the frequent introduction, in the previous crops, of fuch forts of green fawf crops as have a power, by the great degree of shade and figation which they afford, as well as by the culture which they require while growing, of bringing the foil into a fine friable flate. These are turnips, potatoes, tares, faifonifs, and others of a fimilar defcription." It has been contended by Mr. Clofe, "that where the grafts-feeds are to be put into the ground with grain crops in the spring, the tillage should be performed with more than ordinary attention; which, in the cafe of turnips, will depend greatly upon their being conformed at fuch an early period as will admit of the ground being thoroughly broken down and reduced; for if there be much delay, and the feafon prove unfavourable, a bed of mould, sufficiently loose and mellow, will not be procured for the reception of the feeds: and when grown with spring corn, the lands should be ploughed over three times; and where the first of these earths can be given early enough to be influenced by the veinous frofts, it will be found to be much more beneficial." The ufe of the harrow and the roller will be occasionally neceffary, after the different ploughings, according to the nature and flate of the land. "But when the fowing is executed in Auguft, the fame degree of attention is not believed by the Rev. Mr. Young to be necessary, as the time and feafon afford fo full an opportunity of bringing the ground into fuitable order, that the moft inattenfive cultivator can scarcely experience any other difficulty than what originates from an unfual wetness of feafon."

In the System of Practical Agriculture notice above, it is mentioned that, "besides this finenes of preparation in the soils, it is neceffary that the method of cropping and the application of manure in the preceding courufes be fuch as to leave them in a flate of high fertility and riches; as no good grafts-land can be fuppofed to be produced, where the lands have been worn out and exhausted by the previous crops; a practice which has, however, been too general in the re-turning of arable lands to the condition of grafts. Mr. Marshall has, he fays, indeed very juftly observed, that the want of proper condition in the lands at the time of their being laid down to sward, added to thofe of improper forts of grafts and bad feeds, is the chief caufe of their not fucceeding." According to fome cultivators, "manure ought to be applied with every other crop, and always with that which immediately precedes the grafts. This is," he fays, "a practice that fhould be adopted as much as poifible." And "in order to have grafts-lands of the beft kind, it is likewise of great utility to have them fo managed in the preparation, as to be rendered perfectly clean and free from all forts of weeds; as by their rife with greater rapidity than the fown grafts-plants, they are often liable to fhade and defroy them, or greatly injure their growth."

And it has been advised by Mr. Billingsley, "in reforing old worn out lands to the flate of good pasture, to clear the land from injurious weeds by means of a full winter and fummer fallowing; or, inftead of the latter, by a crop of potatoes, well manured for, and kept in a perfectly clean flate by attentive culture while growing, succeeded by winter vetches fed off in the early fpring. And in all the more light forts of soil, it is unquestionably the moft beneficial practice to bring the ground into that for of fine tift, which is proper for the reception of grafts-feeds, by a judicious mixture of green crops of different forts with thole of the corn kind, according to the nature of the foil." The moft proper methods of combining and intermixing these with each other are fully explained in confidering the modes of cropping different forts of ground. See Course of Crops, and Rotation of Crops.

Further: "when the lands have been, by fome methods, brought into a good flate of fertility, and reduced into a sufficiently mellow and friable condition of mould, the surface fhould be made as fine, loofe, and even as poifible."

Vol. XX.
And that "where the grounds are much inclined to moisture, the ridges may be preferred, which should be of considerable breadth, with very light furrows; but in the more light and porous descriptions of land, the whole should be laid as even as possible, without any ridges or furrows. In the former cases, in some districts, they prefer making the ridges fix, eight, or more yards in breadth; which, when the land is to be under the scythe, is in a much better state for being mown; and if for pasturage, there will be less danger of the animals being injured by being cast in the furrows. But in the latter, the surface will not only be more agreeable in its appearance, but be more advantageous for all the purposes of grass management," when thus laid down.

Most proper natural grasses.—In respect to the kinds of natural grasses, the circumstances that have been observed above render it sufficiently plain, that the proper choice and application of grasses must be a matter of great consequence, in the laying down lands to the state of sward or herbage. In fact, it is, according to the author of Practical Agriculture, "a business attended with uncommon difficulty, from the number of trials that have been yet made being very inadequate for affording the means of fully deciding upon their properties, advantages, and uses, in many cases, as well as from their habits, and the soils to which they are the best suited, being very imperfectly known; and also from the great trouble and inconvenience of obtaining their seeds genuine, and in a proper state of healthy vegetation."

But it is suggested that the plants of the natural grass kind, which have been found by experienced cultivators most useful in the different intentions already mentioned, are "the sweet-scented vernal grass, meadow fox-tail grass, smooth-stalked meadow grass, rough-stalked meadow grass, meadow fescue grass, hard fescue grass, tall fescue grass, crested dog's-tail grass, ray or rye grass, Yorkshire white, cock's-foot grass, tall oat grass, timothy grass, yarrow, burnet, white clover, trefoil, cow grass, rib grass, and a few others;" most of which will be found useful in laying lands to grass, under different circumstances of soil, situation, moisture, and dryness. See Grass, and these several heads.

The Rev. Mr. Young, in the third volume of Communications to the Board of Agriculture, advises the varying of grass-seeds, according to the nature of the soil, in this way:

<table>

With regard to the proportions or quantities which are necessary per acre, it is hinted, that "in situations where women and children are fully employed, it may be difficult to procure large quantities gathered by hand; in such places a man must be content with what can be bought. Crested dog's-tail is so very generally to be thus procured, that he cannot but suppose it in a good measure at command.
LAYING.

Seeds. Substitutes.

White clover - 10 lb. Yorkshire white grass 6 pecks.
Dog's-tail - 10 lb. Rib 5 lb.
Ray - 1 do. Cow-grass 4 lb.
Foxtail - 2 do. Timothy 1 do.

Method of sowing Grazes-seeds.—In respect to the time and manner of sowing grass-seeds, they are different in practice according to the preparation and the particular circumstances of the land. The most usual period of putting in grass-seed is the spring; at the time the grain crops are sown; but where the land has been brought to a suitable state of preparation by means of green and other fallow crops, the latter end of the summer, as about Aug., has been the more general time. In the former case they are most commonly put in with the grain crops; but in the latter without any other sort of crop. The author of the System of Practical Agriculture remarks, that there has been much diversity of opinion among agricultural writers with regard to the superior utility of these different seasons of introducing the seeds, as well as with regard to their being sown with or without other sorts of crops. The advantages of the autumnal over those of the vernal sowings are contended to be, those of the grass-plants being less exposed to danger from the shade, clover, and chinking, that must necessarily occur at the latter season; there being less risk of stockling the ground with noxious weeds in case of the seeds of hay-chambers being indiscriminately sown; their being put in upon a better preparation and more mellow and fertile state of the land; their growth being more strong and vigorous from their not being robbed of their proper nourishment by other exhausting crops, and the greater superiority of the hay produce: while, on the contrary, it is maintained in support of the vernal sowings, that besides their being less precarious, shade is necessary in the early growth of the grass-plants to protect them from the effects of heat; the moiture is better preserved in the soil for their support; small annual weeds more effectually prevent it from rising to injure them; and the loafs the farmer must sustain from the want of grain crop guarded against.

But in regard to the objection on the ground of weeds being produced, Mr. Clof has remarked, that sowing rubblish in Aug. is not of so great importance as in the spring. In the former season all the annual seeds vegetate, and if the beginning of the winter be mild, they will blossom; but they cannot perfect their seeds, and thus slock the land with noxious weeds.

Upon which the first of these writers observes, that though some of the arguments urged on both sides of this controverted point may be objected to, the autumnal sowings not preventing the perennial weeds from rising and seeding their seeds in the following summer, nor the great clover of grain crops being without injury to the growth of the young grass-plants; there are facts which render it probable that each method may have advantages under particular circumstances. In the more Southern districts, where the severity of the winter season is later in its approach, the autumnal season may frequently be made use of with advantage, after fallow crops, for sowing grass-seeds, especially in fields where the lands are in too rich a condition for the successful growth of corn. But in the more northern parts of the kingdom, and exposed situations, where the frost sets in at an early period, it may be in general the most advisable practice to put the seeds in, in the vernal months, with suitable crops of the grain kind. And the Rev. Mr. Young has observed, that "gras-feeds answer almost equally well in either method; he prefers, however, the August sowing without corn, though the success of his trials in the different seasons has not justified any decisive conclusion." It is even admitted, that "in moory and mountainous situations, where the snows come early, autumnal sowings are not advisable, as to be performed later than the very early part of August; the vernal feation with oats, for being cut young for nothing or hay, is constantly to be preferred." Mr. Dalton, in Yorkshire, after trying other methods, also recommends the autumnal sowing without corn as the most advisable. And the Rev. Mr. Clof, in Yorkshire, after trying other methods, also recommends the autumnal sowing of hay-chambers. The barley was a good crop, and the clover and rye-grasses were probably equal to the first year's cut of hay. The second year the artificial grasses began to fail; worse the third, fourth, and fifth; the sixth year, after having received two dressings, the spontaneous product of the foil began to give a fleece over the surface of the land. About ten years after these lands were sown, Mr. Clof saw this field, when the part sown in Aug. was worth at least fifteen fillings per acre more than the part which had been sown with artificial grasses in the barley. Thus from actual experiments, numbers of which he could adduce, he concludes that sowing the sweepings of hay-chambers in Aug., is preferable to sowing any artificial grasses in the spring with any crop of corn. Suppose the corn worth five pounds per acre, the difference in the produce of hay or feed in the second, third, fourth, and fifth years, would more than counterbalance this; and the proprietor would find a permanent improvement in his land of from ten to twenty fillings per acre. Mr. Young thinks, the beet feation in the whole year for this purpose is Aug., and the only one admissible for it on strong, wet, and heavy soils, in forty years' experience having never failed at that period. It is stated in the System of Practical Agriculture already noticed, that "on comparative experiments being made with corn in the spring months, and without it in Aug., the latter was found by much the best mode by different cultivators." But that in the experiment of an accurate agriculturist, mentioned by the Rev. Mr. Young, in his paper in the communication to the board, in comparing different methods of vernal sowings, in which four acres were sown with seeds alone, on peafe and buck-wheat ploughed in the preceding autumn; five acres with barley, and five more with the seeds put in alone without corn or manure: the portions sown alone were over-run with weeds, and only preserved from being smothered and destroyed, by being eaten down by a dairy of cows. And others, after repeatedly trying the experiment of sowing in the spring with corn, and the autumn without, and from long and extensive practice, conclude, that, even if we were to have no regard to any other circumstances, except the grass crop alone, it would be always best to sow it with some kind of grain; but when we consider likewise the loafs that the farmer thus sustains for want of a crop of grain, the practice of sowing alone must be looked upon as highly pernicious to the farmers."
LAYING.

And he supposes, that it is probably in this last respect that the greatest disadvantage of the practice consists, as without it the farmer can derive no immediate recompense for his great expence of tillage and preparation of the land.'

In cases where the vernal sowing with other sorts of crops is had recourse to, barley is that, according to Mr. Cartwright, which is most usually recommended, and "there seems to be no question that barley is in general the fittest grain to be sown with grass-feeds. The same tillage which answers for one is requisite for the other. Barley has a disposition to loosen the texture of the ground in which it grows; a circumstance highly favourable to the vegetation of grass-feeds, which require a free and open soil to extend their roots in; the tender and delicate fibres of which have much difficulty in contending with the resistence of a flubborn soil. And this points out the reason why grass-feeds so frequently fail on strong land not in a proper state of cultivation. In the choice of barley, that sort should be preferred which runs least to straw, and which is the soonest ripe."

But the writer of the System of Practical Agriculture observes, that as from the grassy nature of the ftem, and the large size of the ear in this sort of grain, a considerable degree of cloveness and flake mutt constantly be kept up, it should never be sown so thickly as in other cases where there are no grafs-feeds. Some object to sowing grafs-feeds with barley on other principles, as those of its drawing its nourishment from the surface, which is also the case with the grafs-plants, and that in consequence they must be greatly retarded in their growth from the want of due support. Where the land is in a proper state of preparation and tillage, if sown with oats, they will be apt to become so luxuriant as to greatly injure, if not wholly destroy, the young grafs-plants by the cloveness of their flake.

In some cases they, however, succeed tolerably with this sort of crop. On the stronger kinds of land the sowing of grafs-feeds has been found to answer well with thin crops of beans. In an experiment of this kind, it is stated that Mr. Dalton found that the beans did not "rob, but sheltered and nourished the grafs-plants, the plan answering beyond expectation."

It is suggested, that in order to effect the purposes of distribution and perfect vegetation in the most complete manner, the seedman should "be accustomed to the busses, and the seeds, as being of different weights, 1. as little mixed with each other as possible. It is much better to have more costs than to blend the seeds together for the sake of dispatch. For all the smaller sorts of seeds, it has been supposed by the Rev. Mr. Young, preferable to deliver them by means of the Norfolk turnip trough, which has lately been adapted to clover and ray-grsaffles. And this operation should always be performed as soon after the land has been ploughed as possible, as under such circumstances the seeds vegetate in a much more quick and vigorous manner. But it should never be attempted in such a wet state of the land as produces any great degree of tenacity or adhevenes in the mould, as in such circumstances the seeds would be apt to come up in a tufty unequal manner. Nor for the same reason should the lighter sorts of grafs-feeds ever be sown in windy weather; as the delivering them in an equal and regular manner is a point of consequence to the forming of good grass-land. In the covering in of the seeds, the author just mentioned observes, that care should be taken that there none are left in an exposed state on the surface of the ground, as where that is the case many of them will be destroyed or picked up by birds, and the fward appear patchy. This business is executed in the most complete manner by a pair of light short-tired harrows at one time.

The practice of employing bush-harrows is improper, as in that way the seeds are liable to be drawn into a heap. In all the lighter and more porous descriptions of land, it may be advantageous to put a light roller over the surface immediately after the seeds have been well harrowed in."

And in cases where the tenants and not the proprietors of the land are to lay them down to grass, it may be the most ad- vantageous practice for the latter to procure the seeds, but at the expense of the former, especially where they have a sufficient interest in such lands; as, without this precaution, from their general propensity to keep the ground under the plough, and their indifference in respect to the obtaining of the most proper sorts of seeds, there may be danger of the business being improperly performed."
open, porous, and left firm quality, sheep, by their eating too closely, may do much harm, especially in the first years of the new lay, by pulling up the young and imperfectly established grass-plants. Several instances of this kind have been noticed in such soils. In lands that are more inclined to moisture, the contuming of the produce by neat cattle must constantly be liable to do mischief, except in very dry seasons; they must of course be principally fed down by sheep. And in all cases where the new lay is chiefly constituted of the more coarse forage of grasses, sheep would seem to be the most proper kind of flock, as the grasses are thereby constantly becoming more fine and sweet. Many facts of this nature have been noticed by cultivators. The sweetest of the pasturage on many sheep-downs has been remarked to depend more on their being kept closely fed down than any other circumstances, as on being neglected in this respect it becomes coarse, and is rejected.

**System of Practical Agriculture.**—It has been well observed by the Rev. Mr. Young, in a valuable paper, in the third volume of Communications to the Board, that "sheep-feeding not only ameliorates by enriching the soil, and fining the herbage, but also by destroying weeds." And Dr. Dickson has "been ascertained by a very extensive and experienced cultivator in Somersetshire, that under this form of management, not only many coarse grasses, but other sorts of plants become fine, and eagerly fed upon by animals."

It is still farther stated, that "Dr. Wilkinson, who has been much in the habit of comparing different practices, advices the grazing constantly with sheep, and for the first six years never to permit the scythe to touch the lays;" but this is certainly longer than is necessary to precede the scythe in many sorts of soil. And the Rev. Mr. Young has remarked in addition, "that it is not merely the first year that feeding with sheep is the best practice on new lays, but it may be so managed the second, and if it extend to the third it is the better; and though there is not any necessity for adhering to it any longer, it has been found to answer well in his practice, four, five, or even six years; and in general it may be concluded, that the more the land is fed with sheep, the greater the improvement will be. But in this management the impoverishing absurd system of removing the animals to be folded in other places, is not to form any part of the practice."

In the Agricultural Report of the North Riding of Yorkshire it is suggested, that "it has been long the practice in that district, with the most improved cultivators, to have recourse to the method of sheep-feeding for some time after laying the lands down to grass, as two years or more. Where ray grass and white clover are intended to remain many years, it is found by some advantages to eat them the first year by the sheep, in cloving, thickening, and rendering them more permanent." These facts are all in evidence of the great propriety and utility of the practice of feeding new grass-lands. It must, however, be observed, that in order to render the practice perfectly safe and beneficial, the new lays should not be fed during the autumn, or the flock turned into them at too early a period in the spring. "Nor should they be too heavily flocked, or the flock kept upon the pastures too long; especially when it contains principally the clover, as they may do much harm by paring and eating the plants to closely down as immediately to kill them, or expose their roots too much to the destractive effects of drought. And in cases where the grasses have run up much to them, if the lands be sufficiently stocked with plants, it may be an useful method to cut them over, by means of a strong scythe, before their seeds are formed, as by this means they will become more strong and vigorous; but, in the contrary circumstances, they are better left for the purpose of providing a more abundant supply of young grasses, as the benefit obtained in this way will more than counterbalance the injury sustained by the running up of the old plants." But the author of the System of Practical Agriculture states, that "though the practice of feeding new laid grasses in the first years appears to be the most advantageous and proper mode of management, especially for lands intended for pasture, there are many cases in which they may be mown with great success. This practice is perhaps always the most beneficial and proper, and indeed the only one that can be adopted, in such soils as possess any great degree of moisture; as, under such circumstances, the feeding them down with any sort of live flock milt, in moff seasons, be injurious to the fward. And, besides, where the object and intention of the farmer is chiefly hay, the grass-plants, by being kept closely eaten down by live flock for a considerable length of time before the scythe is applied, may, from the becoming thereby infected to a lower and lateral spreading growth, be afterwards more unfit for the production of hay crops. Several facts of this nature are related by writers on husbandry. In one case, where different divisions of land of the same kind were laid down in the same manner, on one of them being kept in the state of pasture, and the other alternately mown and pastured; after some years, both being cut up for hay, that which had been pastured afforded a much inferior produce to the other. The same thing has happened in other cases of old pastures being converted into hay lands, even when the most favourable season prevailed." It is consequently concluded, that "on these principles, it may be a more judicious practice to manage lands designed for hay, without having them for any great length of time, previously to their being mown, fed down closely with stock; as in this way a larger produce of hay may be afforded." And it is supposed, that "where the new lays are mown the first year after being laid down, which is not a method to be recommended, it is an excellent practice to apply a moderate coat of manure over them in the autumn, especially when the state of the land and the season is such, in respect to dryness, as to admit of its being done without injuring the surface fward; as by this means the grass-plants not only become more strong and vigorous, but better established in the soil, and of course bear cutting with much less injury."

But as it may be the case sometimes, though seldom, where these modes are fully attended to, that the farmer may fail either in part or wholly of producing a good lay; it has been observed, that, "in the first case, it is the best practice to have recourse to sowning fresh seeds, which should be performed in the early part of the spring, when the weather is in a mott state; the seeds being sowed by some to be trodden in by putting sheep upon the land, either indiscriminately, or by very open folding, as the ufe of the roller will not be effectual, and that of harrowing cannot be practiced without injury." It is stated that a large cultivator at Enfield found advantage from putting the seeds in before the manure was applied in the new lays, which are sometimes too hastily plunged up. By either method, the fward of such lays may often be much thickened, as well as improved in other respects. And that, in cases where the grasses have run up much to them, if the lands be sufficiently focked with plants, it may be beneficial to cut them over, by means of a sharp scythe, before their seeds are formed; as by this means they will become more strong and vigorous, and the lands be less injured; but, under the contrary circumstances,
LAYING.

flances, they are better left for the purpose of providing a more abundant supply of young graves, as the benefit obtained in this way more than counterbalances the injury sustained by the old plants being left upon the land. But that where there is a complete failure from particular causes, the most advisable method is, where the seeds have been put in, in the spring, with grain crops, to take off these crops as soon as they admit of it; and, after giving the land one ploughing, to harrow in directly fresh feeds, which should be accomplished as early in the beginning of August as it can be performed; and a roller may be applied over the land, when in a suitably dry condition, about October. But that where the latter end of summer has been the time of flowering, it is advised "that the land should have three ploughings performed upon it in the early spring months, when the weather is sufficiently dry, and the grass-feeds be again put in with the crop of buckwheat in May, which, though it is not a suitable crop for the heavy wet ferts of land, sometimes answers well in dry season; and in wet ones, as affording but little feed, may be mown when in blossom as green food for the cows." From the land not being now robbing of its fertility in this way, it may be a beneficial practice.

The application of manure to new laid down grass lands is seldom absolutely necessary: yet where they have not been returned to the state of furred under that degree of fertility and preparation which has been inculcated, it may, in many instances, he recours to with great advantage and improvement: as it is perhaps one of the best methods of preserving a good close state of grass or sward, when properly employed. Mr. Maxwell states, in the third volume of Communications to the Board, that "though in general no manure will be wanted till the land has been sown for hay, there can be no doubt but that great additional improvement will be produced, where manure of any sort can be applied;" and that "the oftener the land is manured, the greater will be the improvement." Where lands have been laid to sward or grass with grain crops, the application of flight dressings of manure in the following autumn may be of much utility in fixing and encouraging the growth of the young grass-plants, as has been seen; but in other cases, the latter end of the summer following, or very early in the autumn, are suppos'd by some to be the most beneficial and proper periods for the purpose: "but as at these times, in many instances, much loss of manure may be sustained both by evaporation and the washing of heavy rains and snows, it may be a better and more advisable practice to perform the dressings in the early spring months, especially where the lands are to be conducted under the sythe; as in this way the enriching material will be ready to exert its influence at the moment the young plants begin to send forth their new shoots, and thus not only afford more abundance in thickening and invigorating the new sward, but be less in danger of being uselessly dilipated and wasted." But "where manure cannot be spared for repeatedly dressing new grass lands, as the grasses are often, especially on lands not fitted to their growth, liable to decline and become thin, in some instances, it is suppos'd, from the town graves disappearing before the spontaneous ones have attained sufficient vigour and strength; but more generally, probably, from the grounds not having been in a proper state of fertility, or deficiencies of surface mould, at the time the feeds were put in; or the particular unfavourableness of the season, about the close of the third summer after their being sown. It is believed by the Rev. Mr. Young, to be a better practice to defer the use of manure till that time, on such lays as are patured; and when they are under the sythe, till the hay crop has been taken from the ground. We have no doubt of the success of the application of dung top dressings at these periods, though they must evidently be made use of in a less economical manner than at a later season in the autumn, or an earlier one in the spring. And it is the most common opinion, that all the finer and more soluble kinds of top dressings are applied with the greatest benefit in the very early spring months, as about the latter end of February, or the beginning of the following month. The differences in the effects of these sorts of manure have perhaps not yet been fully ascertained, under different circumstances of application."

With the view of encouraging and supporting the growth of the natural graves, when the town ones decline, as about the third year, an experienced cultivator at Enfield, who seems to favour the opinion of manure being the most usefully laid on land early in the autumn, or on hay lands immediately after the crops have been taken off, states that "he has used coal ashes with great success, to the amount of three chaldrons per acre. He has laid of this manure on grass land above fifty chaldrons in a year. About eight years ago, he laid down a field of twelve acres with broad clover principally, intending it to stand only for two years. In the summer it was mown twice; next year it was grazed: the clover was but weak. As he had particular reasons for altering his mind, and for wishing to continue it in grass, he resolved to try the effects of grazing it with sheep. On the fourth year it looked so very bad, the clover almost entirely disappearing, that he was tempted to plough it up. He, however, resolved to continue the grazing, and to give it a dressing of three chaldrons per acre of coal ashes. The next year he observed the white clover and natural graves beginning to form a close turf; and the field is now an excellent piece of sward, without the aid of any hay-feeds." And it appears from the further trials of the same cultivator, that the following substances have much effect, not only in promoting the growth and rendering the herbage more fine and sweet, but in renovating the sward:--the leavings of the road, sand drift, fold-yard liquor, and watering; and that the effects of other manures would seem to be chiefly in promoting the luxuriance of the graves, and of course to be principally advantageous in increasing the quantity of produce; such as "tafflow-chanders" graves, when used in proportion of a ton an acre; and night-foil, when laid on about three horse cart loads the acre. And that in fixing, producing, and rendering the white clover more permanent, marle, or strong cold land, and coal-ashes, on wet soils, have been highly beneficial. On the drier clayey lands in Cornwall, "sea-land has been found to mellow the clay, and make them hold the graves." And on what are termed stone braise lands. the use of marle is often found of great utility, when applied in the latter part of the summer of the first year of the lay. But it is necessary, to the success of this sort of application, that the ground be well covered with grass before it is applied; and where the surface is much exposed, the marle is liable to flake and cake together, and the young graves-plants to be, in consequence, exposed to much injury from the heat of the summer. This substance seems to bring up the best sort of natural graves, but in time it sinks below the reach of vegetation. About thirty cart-loads are sufficient for the acre. And chalk, on the deep loamy clays, was found by Mr. Davis an useful application the first year on new lays, in the proportion of about twenty loads to the acre. On the more sandy sorts of land, clayey marle may be of great advantage in elevating the
and on peaty or moozy lands, marle and other similar materials will be found of advantage in rendering them more compact, and better suited for preserving the grases; as well as sand and road-duff, for fining the herbage, and rendering it more palatable to the flock.

Though "foot" has been much used as a top-dressing, it has not been found that its effects last beyond the first year. It has been tried to the amount of sixty bushels per acre, at 8d. per bushel; perhaps it should be used in larger quantity. Lime is nearly as dear, and of that 150 bushels have been used per acre on arable land. Soot should perhaps be laid on to that amount. Sugar-bakers' scum has been used with great success to the amount of two loads an acre, at a half a guinea per load, which has been found a strong warm manure, highly serviceable on cold land, its effects being permanent. Lime is also found useful on the more friable red loamy soils, by fixing and rendering them more close, to keep the vegetation more to the surface, as well as to promote the growth of the natural grases, and prevent their roots from being injured by the heat of the sun. And woollen rags, though not generally used as manure on grases-land, when chopped small, have been spread with advantage on young clovers before winter, to the amount of about 10 cwt. per acre," being useful in protecting and nourishing the young grases-plants in their more tender growth, but they are slow in producing their beneficial effects.

On applying, in order to compensate for an immediate crop of hay, and to thicken the sward on one part of a field, rotten dung about eight tons to the statute acre, on another part woollen rags chopped at the rate of 1-0 felines to an acre; and on a third a rich marle in the proportion of about 80 tons to the statute acre; Dr. Campbell found, on comparing their effects two winters afterwards, that "the dung had produced a greater luxuriance. The woollen rags had a superior verdure, a deeper green; but as they had not yet been properly incorporated with the land, by the grases growing over them, their ultimate produce could not be ascertained."

An acre of land may, it is supposed, "be manured by this means for about 3f. effectually, should they be found to answer the purpose." The fame is the case with "the marle, which having covered the ground into which it is not yet carried down by the rains, and the grases not having grown through, it has at present rather done harm than good." On this account, he supposes that "we are long in producing its beneficial effects, and the return of which cannot be looked for in less than two or three years."

It is evident from these facts, that different effects may be produced on grases-lands by the application of different sorts of substances or materials to them in the manner of top-dressings after they have been laid down to grases; and that "where fine herbage is the principal object in view, coal ashes and composts of the earthy kind formed from sand, mud, scrapings of roads, and other similar materials, intimately blended and incorporated with suitable proportions of well rotten dung, may be the most beneficial applications;" also that "the liquor of fold yards and waterings may be useful in the same intention as well as those of reparing the grases-plants or swards, and promoting the luxuriance of the crops."

But that "where the increase of produce is chiefly aimed at, good dung in a well reduced state, tal- low-chandlers' graves, night-fish, chopped rags, foot, scum of fugar, and other substanccs of the more animal kind, are the most effectual and proper." While in the intention of "establishing, preserving, rendering durable the different grases, marle, lime, chalk, the folding of sheep, and other substanccs and practices of the same sort, will be the most proper for producing such effects." And that in "rendering the lands more firm and solid, the three last substanccs may perhaps be employed with the greatest success and advantage." See MANURE and Grass Land.

LAYING-out Homesteads. See Homestead and Farm Buildings.

LAYING-out Lands, the manner of distributing the land of a farm or an estate. See Farm.

LAYING-out Roads, in Rural Economy, the mode of planning and laying out the lines of roads. See Roads.

LAYING-down, or Laying-off, in Ship Building, delineating the ship to its full size from the given draught upon the mould-loft floor, for the purpose of making the moulds by which the several parts of the ship is provided.

LAYING, in Repotting, the closing of the plants together, to compose the rope.

LAYING-hob, the hook on which the plants are all hung together for laying or closing.

LAYKAN, in Geography, a small island in the East Indian sea, near the S.W. coast of Celebes. S. lat. 5° 52'. E. long. 119° 51'.

LAYMAN, a person not engaged in any order of ecclesiastics: accordingly, in the distribution of the people, laity is opposed to the clergy, and may be divided into three distinct classes, viz. the civil, the military, and the maritime.

LAYMANS, among Painters, a little stature, or model, either of wax or wood, whose joints are so made, that it may be put into any attitude, or posture. Its chief use is for the casting and adjusting draperies, for the clothing of figures.

Some call it, after the French, mannequin, q. d. a little man.

LAYMABAMBA, in Geography, a town of Peru, in the jurisdiction of Chachapayas.

LAYMOU, a town on the S. coast of the island of Ceram.

LAYR. See LAR.

LAZA, in Geography, a town of Spain, in Galicia; 18 miles E.S.E. of Orenie.

LAZANILLA, a town of the island of Cuba; 40 miles E.N.E. of Spiritu Santo.

LAZARE Eube, a town of Spain, in New Castile; eight miles from Toledo.

LAZARETTO, a small island in the Mediterranean, near the N. coast of the island of Candy, formerly used by the Venetians as a lazaretto, but now deserted.

LAZARETTO Vecchio, Ill, a small island in the neighbourhood of Venice, formerly called "St. Maria of Nazareth," from a church of that name built by Augustin Hermits in 1249. Since the year 1423, all ships coming from the Levant, are to perform quarantine in this island, for which purpose it was provided with the necessary inns, which were rebuilt and enlarged in 1567. Here all the ships and merchandise are closely inspected, under the direction of a deputation of the Senate.

LAZARETTO, or Lazar-house, a public building, in manner of an hospital, for the reception of poor sick.

LAZARETTO, in some countries, is an office appointed for persons coming from places suspicious of the plague, to perform quarantine. See Quarantine.

This is usually a large building, at a distance from any city, whose apartments are detached from each other, &c. where ships are unladen, and their crew is laid up for forty days, more or les, according to the time and place of their departure.

We are indebted to John Howard, esq., the most distinguished philanthropist, who has appeared in this or any other country, and whose services in the cause of humanity can
The lazaretto, a name given to a hospital ship, which is for the reception of the sick, or persons supposed to be infectious. It is also the name of a place parted off at the fore part of the lower deck in some merchant ships, for the convenience of laying up the provisions, stores, &c. necessary for the voyage.

Lazarettos, the principal lazaretos in Europe, with the outlines of a proper lazaretto, and an engraved sketch of a plan for its construction. He has also subjoined, in minute detail, various pertinent remarks respecting quarantines and lazaretos in general; together with observations on the importance of a lazaretto in England, in its connection with the advantages which our commerce might derive from it. See "An Account of the principal Lazaretos in Europe, &c." by John Howard, F.R.A.S. Warrington 1789, 4to.

By 29 & 42 Geo. III. c. 80, § 23, it is enacted, that if any person shall enter any lazaret, he shall perform quarantine; and if he shall return from thence (unless duly licensed), or shall escape, or attempt to escape, he shall be guilty of felony without benefit of clergy. See Quarantine.

He has also subjoined, in minute detail, various pertinent remarks respecting quarantines and lazaretos in general; together with observations on the importance of a lazaretto in England, in its connection with the advantages which our commerce might derive from it. See "An Account of the principal Lazaretos in Europe, &c." by John Howard, F.R.A.S. Warrington 1789, 4to.

By 29 & 42 Geo. III. c. 80, § 23, it is enacted, that if any person shall enter any lazaret, he shall perform quarantine; and if he shall return from thence (unless duly licensed), or shall escape, or attempt to escape, he shall be guilty of felony without benefit of clergy. See Quarantine.

A particular account of all the principal lazaretos in Europe, with plans of the buildings, a detail of their chief regulations, and very important and useful hints for their improvement. With this view he determined, towards the end of the year 1785, notwithstanding the expense and danger which he thus incurred, to visit them in person. Accordingly, the first lazaretto which he inspected was that at Marselles, which is situated on an elevated rock near the city, at the end of the bay, fronting the south-west, and commanding the entrance of the harbour. This is a spacious building, and its situation renders it very commodious for the great trade which the French carry on in the Levant. Within the lazaretto is the governor’s house, a chapel, in which divine service is regularly performed, and a tavern, from which persons under quarantine may be supplied with necessaries. In order to prevent any communication, that is not allowed by the regulations of the establishment, there is a double wall round the lazaretto; and at the gate there is a bell for calling any person within this inclosure; and by the number and other modifications of the freshers, every individual knows when he is called. At Genoa, whither Mr. Howard next proceeded, the lazaretto is situated on the sea-shore, near the city, detached from other buildings, and encompassed by a double wall. Another lazaretto, belonging to the Genoese, stands on a rising ground at Varignano, near the gulf or noble port of Specia. At Leghorn there are three lazaretos; one of which is new, having been erected in the year 1778. The lazaretto at Naples is very small; that at Messina lies on an island near the city. At Naples there are two kinds of quarantine performed; one by ships with clean bills of health, and the other by ships with foul bills. The first, called the petty quarantine, lasts 18 days, and the ships which perform it lie at the entrance of the port near the health office. The other, called the general quarantine, is performed at a lazaretto, situated on a peninsula near the city. The health-office at Zante is in the city at the water side. The old lazaretto is distant about half a mile from the city, and situated on a rising ground near the sea. There is another called the new lazaretto, which is appropriated to a numerous body of peacocks, who pass over to the Morea to work in harvest time; on their return, they perform here a seven days’ quarantine; and other persons perform 14 days’ quarantine in the old lazaretto. The lazaretto at Corfu is situated on a rock surrounded with water, about a league from the city. The lazaretto of Callas Nuova, in Dalmatia, is on the shore, about two miles from the city; at the back of it there is a delightful hill, which belongs to a convent of friars. Persons in quarantine, after a few days, are allowed to walk there, and divert themselves with shooting, &c. In order to obtain the most complete and satisfactory information by performing the strictest quarantine, our author determined to go to Sinysra, and there to take his passage to Venice in a ship with a foul bill. He was thus enabled to give a particular account of his reception and accommodation in the new lazaretto of this city, which is chiefly afloat at Turks and fielders, and the crew of these ships which have the plague on board; and this he thought to be the more necessary, as the rules and orders of the other lazaretos in Europe have been evidently formed from those established at Venice. The city of Venice has two lazaretos, appropriated to the expurgation of merchandise susceptible of infection, coming from suspected parts, and for the accommodation of passengers in performing quarantine; as also for the reception of persons and effects infected in the unhappy times of pestilence. The old lazaretto is two miles, and the new about five miles distant from the city, both on little islands, separated from all communication, not only by broad canals surrounding them, but also by high walls; they are of large extent, being about 400 geometrical paces in circumference. Of these Mr. Howard has given a particular description, with an account of the regulations, and mode of government to which they are subject, and a plan of the old lazaretto. At Treacle there are two lazaretos; one new, but both clean, and a contrast to those which our author had seen at Venice. Of the new one he has given a plan. It is surrounded, at the distance of about 20 yards, by a double wall, within which are separate burying places for Roman Catholics, Greeks, and Protestants. Mr. Howard describes his account of the principal lazaretos in Europe, with the outlines of a proper lazaretto, and an engraved sketch of a plan for its construction. He has also subjoined, in minute detail, various pertinent remarks respecting quarantines and lazaretos in general; together with observations on the importance of a lazaretto in England, in its connection with the advantages which our commerce might derive from it. See "An Account of the principal Lazaretos in Europe, &c." by John Howard, F.R.A.S. Warrington 1789, 4to.

By 29 & 42 Geo. III. c. 80, § 23, it is enacted, that if any person shall enter any lazaret, he shall perform quarantine; and if he shall return from thence (unless duly licensed), or shall escape, or attempt to escape, he shall be guilty of felony without benefit of clergy. See Quarantine.
at the same time, to pollute penums charged upon ecclesiastical livings. The badge of this order is a cros (like that of Malta) of eight points, made of pure gold, edged with white enamel; the middle, or nucleus, of the cros is enamelled crimfon, and on it is the image of the blessed virgin and child proper; the reveree has the middle enamelled green, on which is the figure of St. Lazarus; between the rays of the cros are four fleurs-de-lis, and on each of the points a small gold ball. The cros is fastened to a broad crimfon ribbon, and is worn either on the breast or scarf-wlile.

Lazarus, Fathers of St., called also Lazarets, a name to certain regular clerks of a congregation instituted in France, in the seventeenth century, by M. Vincent. They take the denomination from a houfe in the Faucesbouf St. Denis of Paris; they have a leminary in Paris, called the leminary des bons enfans. The vows they make are simple, and may be dispensed with on occasion.

Lazica, in Ancient Geography, a country of Afa, S. of the Phæs, and N. of Armenia. This country was inhabited by a tribe of people called Lazi, who have to this day preferred their name, and are known among the Turks under the denomination of Lazis, and their country is called the country of the Lazas, or the province of Trebizond. In the time of Pliny, Arrian, and Ptolomy, the Lazi were a particular tribe on the northern shores of Colchos. In the age of Justinian, they spread, or at least reigned, over the whole country. At present they have migrated along the coast towards Trebizond, and compose a rude fea-faring people, with a peculiar language. As the strength of the Roman empire was gradually impaired, the Romans stationed on the Phæs were gradually withdrawn or expelled on the beginning of the 24th century of the Christian era; and the tribe of the Lazi, whole polity (as we have said) speak a foreign dialect, and inhabit the sea coast of Trebizond, impaled their name and dominion on the ancient kingdom of Colchos. Their independence, however, was soon invadad by a formidable neighbour, who had acquired, by arms and treaties, the sovereignty of Iberia. The independent king of Lazica received his sceptre from the Persian monarch, and the succéssors of Condantin acceded in his injurious claim, which was proudly urged as a right of immemorial prescription. In the beginning of the sixth century (A.D. 532.) their influence was restored by the introduction of Christianity. After the decease of his father, Zathus was exalted to the regal dignity by the favour of the great king; but the pious youth abhorred the ceremonies of the Magi, and took, in the palace of Constantinople, an orthodox baptism, a noble wife, and the alliance of the emperor Justinian. The king of Lazica was solemnly invested with the diadem, and his new patron footed the jealousy of the Persian court, excurring the revolt of Colchos, by the venerable names of hospitality and religion. The common interell of both empires imposed on the Colchians the duty of guarding the pass of mount Caucasus, where a wall of 60 miles is now defended by the monthly service of the musquefets of Mingrela. But this honourable connection was soon corrupted by the avarice and ambition of the Romans. Degraded from the rank of allies, the Lazi were incessantly reminded, by words and actions, of their dependent state. At the distance of a day's journey beyond the Aparus, they beheld the ring forts of Petra, which commanded the maritime country to the four of the Phæs. Instead of being protected by the valour, Colchos was insulted by the licentiousness of foreign mercenary; the benefits of commerce were converted into base and vexatious monopoly; and Gubazes, the native prince, was reduced to a pagant of royalty by the superior influence of the officers of Justinian. Disappointed in their expectations of Christian virtue, the indignant Lazi repiled some confidence in the justice of an unbeliever, and after a private assurance that their ambassadors should not be delivered to the Romans, they publicly solicited the friendship of Chofroes. The fagacious monarch discerned the use and importance of Colchos, and mediated a plan of conquest. His ambition was fired by the hope of launching a Persian navy from the Phæs, of commanding the trade and navigation of the Euxine sea, of defolating the coast of Pontus and Bithynia, of diftreffing, perhaps of attacking, Constantinople, and of perfuring the barbarians of Europe to second his arms and counsels against the common enemy of mankind. Accordingly he led his troops to the frontiers of Iberia; they were conducted by Colchian guides through the woods and along the precipices of mount Caucasus; and a narrow path was formed into a safe and fracious highway, for the march of cavalry and even of elephants. Gubazes laid his person and diadem at the foot of the king of Peria; his Colchians imitated the submiffion of their prince, and after the walls of Petra had been shaken, the Roman garrison prevented, by a capitulation, the impending fury of the lait affault. But the Lazi soon discovered that their impatience had urged them to choose an evil more intolerable than the calamities which they strove to escape. The monopoly of salt and corn was effectually removed by the loss of those valuable commodities; the authority of a Roman legislator was succeeded by the pride of an oriental despot, who beheld, with equal diction, the flames whom he had exadted, and the kings whom he had humbled, before the footstool of his throne. The adoration of fire was introduced into Colchos by the zeal of the Magi; their intolerant spirit prohited the favour of Christian people; and the prejudice of nature or education was wounded by the impious practice of expropriating the dead bodies of their parents, on the summit of a lofty tower, to the crows and vultures of the air. The Lazi were also apprized that Nuthervan had given secret orders for afflictiong their king, for transplanting them into some distant land, and for fixing a faithful and warlike colony on the banks of the Phæs. In these circumstances the Colchians, apprized of the ruin that awaited them, solicited the clemency and succour of Justinian; who, from motives of policy, determined to expel the Persians from the coast of the Euxine. The siege of Petra (which fee) was immediately undertaken. Thus commenced the Colchian or Lazic war, A.D. 549. Notwithstanding some splendid advantages obtained by the troops of Justinian, the Persians occupied the passes of Siberia; Colchos was enslaved by their forts and garrisons; they devoured the scanty suffurance of the people; and the prince of the Lazi fled into the mountains. At length, the prudence of Chofroes relinquished the prosecution of the Colchian war, under a persuasion that it is impossible to reduce, or at least to hold a distant country against the wishes and efforts of its inhabitants. The fidelity of Gubazes sustained trials of the most rigorous kind; he patiently endured the hardships of a savage life, and rejected, with disdain, the specious temptations of the Persian court. The king of the Lazas had been educated in the Christian religion; his mother was the daughter of a tenant; he had served 10 years a silenary of the Byzantine palace; and the aures of an unfitted salary were a motive of attachment and of complaint. The lieutenants of Justinian prejudiced the emperor against him; perfused him that a second defection was meditated; an order was issued to lend the king prisoner to Constantinople, and a treacherous edict was inferred in it, that he might be law-
fully killed in caae of resistence; and Gubazes, without arms, or sfipcioc of danger, was stabbed in the security of a friendly interview. In the first moment of rage and despair, the Colchians would have sacrificed their country and religion to the gratification of revenge: but the counsel of the wiser men among them prevailed; and the emperor, anxious to avoid the imputation of so foul a murder, commissioned a judge of senatorial rank to enquire into the conduct and death of the king of the Lazi; and some satisfaction was granted to an injured people by the sentence and execution of the meaner criminals. After 20 years of destructive though feeble war, Chosroes was persuaded to renounce his claim to the possession or sovereignty of Colchos and its dependent states. Gibbon's Decl. &c. of Rom. Emp. vol. vii. See Colchis, Mingrelia, and Trebizond.

LAZISE, in Geography, a town of Italy, in theVenetia, on the E. bank of lake Garde, with a harbour, a custom-house, and a castle; five miles W. of Verona.

LAZIVRAD, in Natural History, one of the oldest names by which we find the lapis lazuli expressed in authors.

LAZULI LAPIS, or LAPIS LAZULI; Azure Stone, Jam.; Lapis Lazuli, Wern.; Lapis-ultramarine of Haüy and Delameth. (not of Werner); Pierre d'Azur, Broch.; Lapis-ultramarinum, Bong.; Lazur or orientalis, Lin.

The colour of this mineral is azure blue, generally perfect, but also palting into Berilo blue and, smalt, blue, feldom into sky blue; some varieties shew a cottage tint of greenish-blue.

It occurs generally massive, in rolled pieces and diffeminated; also indiffimeently crystallized. The regular crys-
tal form mentioned by Lhernina, and other French mineralologists, is that of the garnet dodecahedron; but whether this is the primitive or a secondary form, or whether it belong at all to the true azure flone, is as yet undecided.

Its internal luster is glimmening and glimmering. Fracture uneven, fine-grained.

Fragments indeterminately angular, more or less sharp-edged, and slightly translucent on the edges.

It (=cratches glass, and is easily frangible.

Specific gravity of the Persian, (according to Brillon and Blumenbach) 2:771; 2:896, (Kirwan) of the Siberian 2:945, (Brillon).

It is infusible before the blowpipe; but at a still higher degree of heat its natural colour gives way to a bluish-grey, and it runs into a whitish enamel. Klaproth obtained a dark-coloured, semi-transparent, glassy globule, covered with grains of iron. If previously calcined it forms a jelly with acids. This latter observation was first made by Marggraf, who, as early as the year 1758, published an analysis of the lapis lazuli, in which he shewed that its colour is by no means produced by copper; his analysis has been confirmed by Klaproth, who found also alumine as a constituent part, which had been overlooked by his celebrated predecessor. Its composition, as determined by Klaproth, is the following:

They consider these constituents as essential, and look upon the 0.024 of lime, and the 0.015 of iron, which they have sometimes found, as accidental ingredients. These chemists have also observed some peculiarities in the characters of the earth, mentioned as pure silica in the above analysis. This discrepancy in the results of the analyses points out the necessity of submitting the lapis lazuli to new chemical examination, which may throw light on the nature of the matter that produces the vivid and intense colour of this substrate.

But little is known respecting the geographical situation of this mineral. We see it disseminated in, and mixed with, a clayey crystalline lime-flake; also with quartz, and most frequently with iron pyrites. The Siberian azure flone (which is distinguished from that called the Persian by its lustre vivid colour) is said to be the production of a vein near the lake Baikal in Siberia, where it is accompanied with feldspar, garnet, and pyrites.

The finest azure-flone is found in China, Great Bucharia, and Siberia. The true lapis lazuli has not yet been found in Europe, except buried under the ruins of Rome. That mentioned by Tournefort, as occurring near Ergeron in Armenia, is probably a blue copper-ore; and that, which, as Mr. Pennant states, is found in great quantities in the isle of Hainan, in the Chinese sea, (whence it is sent to Canton, where they employ it in china painting,) may likewise turn out to be different from the true lapis lazuli.

M. Patrin was informed by a dealer in flones, whom he met at Ekaterinburg in Siberia, and who had been in Bucharia, that the lapis lazuli occurred there in granite; not in veins, but disseminated in all parts of proportion; that it was extremely rare to find mafsles, as thick as one's head, in which the blue generally predominated over the white and the grey. The blocks examined by Patrin had the appearance of being rolled; but he informed they were taken from the quarry, and that their roundness was owing to their friction against each other in the carriage; though sometimes they were found by chance as boulders in torrents, and that these were of the most vivid blue.

According to Laxmann, who resided several years in Eastern Siberia, rolled pieces of lapis lazuli are found on the shore of the lake Baikal, in a kind of gulf to the southward, called the Koulouk; but he searched in vain for the mountains from which these blocks had been detached, and he could obtain no information on this subject from the Buret Tartars who inhabit that savage country. Patrin.

We have omitted mentioning Persia among the countries that furnish this valuable substrate, because a traveller well versed in the study of precious flones denies its ever having been found there. "In the copper-mines of Persia," says Tavernier, "veins of lazur have been found; which colour is much used in the country for painting flowers on the ceilings and roofs of apartments. Before these were discovered, the Persians had no other lazur than the real kind which comes from Tartary, and is exceedingly dear. The Persian lazur is a sort of copper-ore, which, when pounded and sifted, forms a fine paint, which appears very bright and pлеasant."
After this discovery, the Persians were no longer permitted to purchase the Tartarian lapis lazuli; and Mahomet Beg issued an order that painters should not use any but Perian blue. This prohibition, however, did not long continue: for the Persian pigment would not withstand the effects of the atmosphere like the real kind, but, in the course of time, became dark and of a dimflm colour. Sometimes it was full of flakes, and would not adhere to the end of a soft hair brush; on which account it was soon neglected as a pigment, and the lapis lazuli of Tartary again introduced.

The lapis lazuli is susceptible of taking a good polish, and is therefore used for various ornamental and other purposes, such as the engraving of gems: (See GEMS.) The variety containing disseminated pyrites, which the ignorant frequently mistake for gold, is preferred for mosaic and other inlaid work, &c. Most profusely it was used for the last-mentioned purpose, in the magnificent marble palace which Catherine II. built at Petersburg for Orlof, her favourite, and which has some apartments completely lined with lapis lazuli brought from Great Bucharia.

Mafses that contain much quartz are left esteemed by the lapidaries, and particularly by those who prepare from it the ultramarine, a beautiful blue colour, so called because it was originally brought from the trading towns of the Levant. See ULTRAMARINE.

Pline diligently describes the lapis lazuli, but as a variety of fapphire.

The lapis lazuli was formerly reckoned of some use in medicine: it was prepared by calcining and wafting it several times; which done, it made a ingredient in the famous confecion of alkarmes.

The alchimical writers have given us proceffes for magiftries, tinctures, and elixirs of lapis lazuli, but they are wholly out of use.

The method of making the Venetian counterfeit lapis lazuli is this: melt in a pot, in a glafs-house furnace, equal quantities of the fafret lattimo, and the whitiflcr safrolime glafs; when this is in fusion, mix it into, by small parcels at a time, the blue smalt used by the painters; make frequent proofs of the colour, and when it is right let the whole stand twelve hours, and then work it. If the metal rife in the pot, put in a piece of leaf gold to keep it down. This makes a fine pale blue substance, representing the plain blue parts of the natural lapis lazuli. Neri's Art of Glaas, p. 117.

A counterfeit lapis lazuli may be also made by fusing ten pounds of either of the compositions for hard glafs (see Colouring of Glass) with an ounce and a half of falfet, and half an ounce of magnefia, till a very deep transparent blue glafs be produced. When the mafs is cold, powder it, and mix with it three quarters of a pound of calcined bones, horn, or ivory, by grinding them together: then fuse this mixture with a moderate heat, till the ingredients are thoroughly incorpolated, and form the melted mafs into cakes by pouring it on a clean bright plate of copper or iron. In order to give it veins of gold, mix gold powder with an equal weight of calcined borax, and temper them with oil of spinke: let the cakes be painted with this mixture with fresh veins as are defired, and then put into a furnace of a moderate heat.

LAZULITE, or LAZULITE of Werner (not that of Hailly, for which see the preceding article) ; Azurite, Jamefon; Siderite, Tromfhorff.

Colour indigo blue, from which it passes into fmalalt blue. It is found massive, disseminated, and crystallized, as it would appear, in four-fided and six-fided prifms. Mr. Bernhardt observed the same forms in the variety from Salzburg, but also the regular octahedron with truncated edges, paffing into the regular rhombic dodecahedron. In general, the cryftals are very indiflinct and small; and they occur always imbedded.

It is ghtening and thinning, and of rather refrusus luftre. Longitudinal fracture imperfectly foliated, crofs fracture uneven. Fragments indeterminately angular. Its hardnefs is inferior to that of common feldspar.

It is brittle, easily frangible, and not particularly heavy. The chemical characters of lazulite, which differing from blue iron earth, are, according to Klaproth, firft, its crumbling before the blowpipe into a whitifl earthy mafs; fecondly, its giving a clear light wine yellow, glaffy pearl, with borax, and a transparent white pearl with falt of phosphon; and, laftly, its not being operated upon either by acida, or caufic alkali.

Klaproth found the variety from Vorau, near Wiennich Neufadt, in Stiria, to be composed of filex, alumine, and iron, but could not, from the fmalnefs of the quantity he operated upon, ascertain their proportions. An analysis of the fame, by Heim, gave 0.65 alumine, and 0.39 iron.

Tromfhorff's analysis of the variety from Salzburg has given the following reffults:

100 Gehlen's Journal.

Mr. Tromfhorff thinks that alumine and magnesia must be confidered as the effential parts of this mineral fubfance; hence Mr. Bernhardt is inclined to refer it to the fpinelle ruby, with which Hailly has already united the ceylanite, or pleonaf, and which the lazulite resembles alfowith refpect to its cryftallization. But is not the hardnefs of the latter much inferior to that of fpinelle?

To the above two localities where the lazulite has been found, we may add that of Krieglach; for, indeed, the fubfance known by the name of blue feldspar of Krieglach appears to agree in all its characters with thofe of Stiria and Salzburg. In all thofe places it is found in, and grown together with, white quartz, imbedded in a kind of mica flate.

LAZZI, a denomination given by the Saxons to that rank of people who were born to labour, and being of a more fervile flate than our fervants, becaufe they could not depart from their service without leave of the lord, but were fixed to the land where born and in the nature of faffles: hence the word lazzi, or lazy, signifies thofe of a fervile condition. See Edhling.

        Le roy l'advefta, {
LEA, in Ancient Geography, a small ifland of the Egean fea. Pliny.
LEA, in Geography, a river of England, which rises in Bedfordshire, paffes by Hertford, Ware, &c. and falls into the Thames a little below London.
LEA of Tarin, is used in some parts of England for a certain quantity of yarn. At Kidderminifter it ought to contain two hundred threads, on a reel four yards about. Stat. 22 & 23 Car. 11.
LEACH-BRINE, a word used by the English salt-workers to express the brine which runs out from the fall, when it stands in the basin to drain, immediately after being taken out of the pan; and also the liquor left in the pan, when no more salt will shoot. This is also called the mother-brine, and bitter. In the German salt-works they always throw this liquor away. In our brine-falls works in Cheshire they always prefer it, and add it to the next boiling; and in the Newcastle, and other sea-water salt-works, they save it for the making the bitter purging salt, called Epsom salt.

LEAD, in Mineralogy, Plumbum, Lat.; Plomb, Fr.; Bly, Germ.; Saturnus, Alchem. The colour of lead is of a blueish-white; when tarnished, it becomes yellowish-white, then blue, and at last blueish black. Lufure, when untarnished, 3 hardnesses, 5; and specific gravity somewhere between 11 and 12. According to Brillon, it was 11.352; and a specimen tried by Gellert, which was found at Freyburg, was estimated at 11.443. Next to gold, platinum, and mercury, it is the heaviest metal, being upwards of eleven times heavier than an equal bulk of water. (See Specific Gravity.) The heaviest is reckoned the best. It flakes paper and the fingers. Next to tin, it is the most fusible of all the metals. It is soluble in most of the acids, though more readily so in the nitrous diluted than the others. By exposure to the moist atmosphere, it dulls or oxides. It is malleable and malleable, and its oxide is easily fusible into a transparent yellow glass. Having given this general description, we shall now consider the several combinations under which it is found in nature.

Ores of Lead.

Sp. 1. Lead Glance. Bleiglanz. This species contains two subspecies: (1) Common lead-glance, the colour of which is of a lead-grey, of different kinds of intensity; in some varieties it inclines to a blackish cast. The lead-grey frequently contains the greatest proportion of silver. It sometimes presents superficially an iridescent tarnish. It occurs malleable, diffamitated, in membranes, in angular pieces, and in grains; sometimes it is met with reticulated, specular, corroded, and amorphous; seldom cylindrical, but often crystallized. The crystalline form exhibits several varieties: 1. in the shape of a cube, in which the planes are either straight or spherical convex; 2. the cube having angles more or less deeply truncated; 3. the cube having its edges and angles truncated at the same time; 4. rectangular four-sided prisms, acuminated on both extremities by four planes, which are let on lateral edges; 5. five-sided prisms, acuminated by four planes; 8, three-sided tables, in which the terminal planes are bevelled. The crystals are usually small, or at most middle-sized, either grouped on another, implanted, or solitary. The planes of the crystals are sometimes smooth, sometimes cloudy, and sometimes rough. Internally it alternates from specular splendent to glinting; on the external surface it is less bright, but its lustre is metallic. Its fracture is more or less perfect foliated, and its fragments are cubical. In masts it is often composed of granular, and rarely of lamellar distinct concretions, which are much grown together, and whose fracture has a radiated aspect. It is felt, perfectly flexible, easily frangible, and the specific gravity is from 6.2 to 7.5 nearly. Before the blowpipe it flies to pieces, and emits a sulphurous odour. It is easily fusible, and may be readily reduced on coal before the blowpipe. When it is alternately heated and cooled, it at length disappears entirely; and if it contain silver, a globule of that metal remains behind. According to Vauquelin, lead-glance contains the following ingredients:

<table>

Dr. Thomson gives the following as the result of his experiments:

| Lead                                 | 85.13      |
| Sulphur                              | 13.02      |
| Oxyd of iron                         | 0.5        |
|                                      | 98.65      |

Hence, as is evident from the above tables, the proportion of lead varies from 54 to rather more than 85 per cent. The proportion of silver varies considerably also; and it appears to have an effect on the external aspect of the varieties. It sometimes also contains a small portion of iron; and gold has even been found in lead-glance. It is, next to pyrites, the most common of metallic ores, and is found in beds and veins in primitive, transition, and secondary mountains. It occurs almost always with blende and calamine, with which it appears to have a strong geognostic affinity. It is frequently accompanied with silver ores, and sometimes with copper ores. To mention all the places in which it is found, would be to mention almost all the known mineral districts in the world. It is very abundant in Germany, and also in many places in our own country. The lead-mines in Britain are situated in Cornwall, Devonshire, and Somersetshire, in Derbyshire, Durham, Lancashire, Cumberland, and Westmoreland; in Shropshire, in Flintshire, Denbighshire, Merionethshire, and Montgomeryshire; at the lead-bills in Scotland, on the borders of Dumfriesshire and Lanarkshire, in Ayrshire, and at Strontian in Argyleshire. Lead-glance is also found at Königberg in Norway; in various parts of Lapland, and in Denmark and Sweden; in several districts of Saxony, Hungary, Transylvania; in France, Italy, and Spain. Most of the lead of commerce is procured from this ore; it is also used without further preparation in the potteries for coarse work, and also in the melting of silver ores. Lead-glance is now generally used as a scientific name, in preference to the less significant but common one galena, on account of its lustre, which forms a striking feature in the external aspect of this mineral. (2) The second subspecies
is compact lead-glance. The colour of this is very similar to that of the common lead-glance. It occurs in mafs, disseminated, and specular. The latter is externally smooth, shining, and spiky; internally it is glimmering, and its luster is metallic. Its fracture is even. It acquires a polish by friction; its fracture is shining, almost spiky; not so easily frangible as the preceding subspecies; but agrees with it in the other characters. Its specific gravity is about 7.4.

It occurs in veins, and is usually accompanied with the common lead-glance. When the two subspecies occur together, the compact always forms the sides of the vein, and this probably owing to its having been in a less perfect state of solution. It is accompanied with black blende, common iron pyrites, copper pyrites, quartz, and heavy spar. It is found in the lead-hills in Lanarkshire, and in Derbyshire; in divers parts of Germany, and in the valley of Chamouni in Switzerland.

Sp. 2. Blue lead ore. Bleu bleus, Wern. Mine de plomb bleus, Broch. The colour of this species is intermediate between dark indigo blue and lead-grey. It occurs massive, and crystallized in perfect flat-fided prisms, which are usually small, low, sometimes bulging, with a surface rough and dull. Internally it is feebly glimmering, and its luster is metallic. The fracture is even, passing into the fine-grained uneven and flat conchoidal. Its fragments are indeterminately angular. It is opaque, gives a shining metallic streak, is soft, brittle, and easily frangible. Its specific gravity is 5.46. It easily melts before the blowpipe, burns with a weak blue flame, emits a strong sulphurous vapour, and is reduced to pure lead. It is conjectured to be a compound of lead, oxyd of lead, and sulphur; and is supposed by Werner to be intermediate between lead-glance and black lead ore. Klaproth discovered it in phosphoric acid.

It occurs in veins, accompanied with black lead ore, white lead ore, malachite, radiated copper azure quartz, fluor spar, and heavy spar. It is not often to be met with, and has hitherto been found only at Zschopau in Saxony, at Schenmizit in Hungary, and Brittany in France.

Sp. 3. Brown lead ore. Braun bleyer, Wern. Mine de plomb brune, Broch. Its colour is hair-brown, of different degrees of intensity, sometimes very pale, approaching to grey, and sometimes it passes into a clove-brown. It occurs massive, and is crystallized in fissile prisms. The surface of the crystals is blackish and rough. Internally it is glintening, and its luster is resinous. The fracture is small and fine-grained uneven, and sometimes passes into splintery. It is soft, not very brittle, but easily frangible. Its specific gravity between 6.60 and 6.98. It melts easily before the blowpipe, without being reduced; and, during the cooling, foists into acicular crystals. It does not effervescence with acids. According to Klaproth, a specimen from Brittany contained,

- Oxide of lead - 78.58
- Phosphoric acid - 19.73
- Muriatic acid - 1.65

Lofs - 99.96

It is found at Mifs in Bohemia; also in parts of Hungary, Saxony, and Lower Brittany. In Bohemia it is usually found accompanied with lead-glance, white, black, and green lead ores, copper pyrites, blende, quartz, heavy spar, &c. It occurs in veins.

Sp. 4. Black lead ore. Schwarz bleyer, Wern. La mine de plomb noire, Broch. The colour of this species is greyish-black, of different degrees of intensity. It occurs in mafs, disseminated or cellular, or crystallized in fised prisms. It is externally splendent, and internally only shining. Fracture small grained uneven, which sometimes passes into imperfect conchoidal and splintery. Fragments indeterminately angular; fresh greyish white; rather brittle; easily frangible. Specific gravity about 5.8. Before the blowpipe it decomposes, and is quickly reduced to a metallic globule. According to Lampadius it consists of,

- Lead - 72
- Oxygen - 7
- Carbonic acid - 18
- Carbon - 2
- Lofs - 99

100

It occurs in veins, and is almost always accompanied with white lead ore and lead-glance, and usually in the upper part of veins, and in new lead-glance formations. It very frequently encrofts lead-glance, and is covered with white lead ore, and sometimes by green lead ore. It is found in the lead-hills of Scotland; in different parts of Bohemia, Saxony, Salzburg, Lower Brittany, and in Siberia. Previously to the analysis of Lampadius, Haiiy supposed it was a phosphatic of lead; and Werner supposed that it was a compound of lead, carbonic, and sulphur acids.

Sp. 5. White lead ore. Weisser bleyer, Wern. Mine de plomb blanc, Broch. This is a carbonate of lead; its colour is a greyish or yellowish-white, with very many different shades. It occurs massive, disseminated, but most frequently in a crystallized flat. The chief varieties are, 1. the cubic octahedron; 2. the pyramidal dodecahedron; 3. the preceding, with a fissile prism interpolated between the pyramids; 4. the same as variety 3, with fumruits of the terminal pyramids replaced by a fissile plane; 5. a fissile prism, with fumruits composed of four planes; 6. the same, with fumruits composed of five planes. The crystals are usually small. Externally, it is peculiar splendent, seldom glintening; internally, it alternates from highly splendent to glintening, and its luster is adamantine, inclining sometimes to metallic, and sometimes to resinous. The fracture is commonly small conchoidal, but it frequently passes into fine-grained uneven, and even into fine splintery. Fragments indeterminately angular. It alternates from translucent to transparent, and is duplicating. It is soft, brittle, and easily frangible. Its specific gravity ranges from 6 to 7.24, according to the different specimens that have been analysed. Before the blowpipe it flies to pieces, becomes red, yellow, and lastly melts into a globule of metallic lead. It makes a strong effervescence with acids. Its surface becomes black, when exposed to the vapour of sulphuret of ammonia. Its conchoidal parts are as follows:

It is almost always accompanied with lead-glance, and occurs in a kind of repository. It occurs in veins that traverse transition rocks; though it is found with different minerals, in different parts of the world. It is not a rare mineral, but is seldom found in sufficient quantities to make it worth while to separate it from the adhering matter, for the purpose of finetuning. The finest specimens of this ore that are found in Britain come from the mines of Derbyshire, the Lead-hills in Scotland, and Minera in Denbigshire. It is also found on many parts of the continent.

Sp. 6. Green lead-ore. Grün Bleyzer, Wern. La mine de plomb verte, Broch. The colour of this mineral is of a greenish-blue, sometimes inclining to aurora, or morning red. It occurs more commonly crystallized in broad four-sided prisms, and but rarely massive, disintegrated, or in membranes. The crystals are middle-sized: the surface of the crystals is usually smooth, sometimes longitudinally streaked. Both externally and internally it is splendid, and its lustre is intermediate between adamantine and resinous. The fracture is foliated, and the fragments indeterminately angular. It sometimes inclines to transparency. It is soft, and in the intermediate state between very brittle and fleshy easily fracture, and its specific gravity is somewhere between 5.6 and 6.0. It melts before the blow-pipe into a blackish scoria, and may be partly reduced with borax. Specimens have been analyzed by

This mineral occurs in veins in gneiss and mica slate, where it is accompanied with lead-glance, green lead-ore, iron pyrites, brown iron-oxide, native gold and quartz. It is found in Siberia; at Annaberg, in Austria; and at Upper Fauvigny, in Savoy. It is much used as a pigment, on account of its beautiful colour, its durability in the atmosphere, and its mixing readily with oil.

Sp. 8. Yellow lead-ore. Gelbes Bleyzer, Wern. Yellow lead-ore, Kirwan and Hatchett. Plomb molbdlate, Hâuyi. La mine de plomb jaune, Broch. In this species, which has long been known to mineralogists, the lead is mineralized by a particular metallic acid, called the molbdic acid. It occurs sometimes massive, more commonly crystallized in small crystals; the forms of which are rectangular tables of four sides, or of eight sides, bevelled; the cube, octahedron, equiangular eight-sided table, and double eight-sided pyramid. The tables are usually broad and thin, and alternate from small to very small, but are seldom middle-sized.

They...
They are sometimes united, frequently interfuse one another, and form thus the cellular external shape. Its colour is wax-yellow, and its lustre distinctly waxy; it is translucent, soft, and easily frangible. Its specific gravity is rather more than 5. It decrepitates before the blowpipe, then melts into a globule of a grey colour, in which are differentiated particles of metallic lead. It gives a blueish-white colour to borax; it occasionally produces a glas, which is greenish-blue, and sometimes deep blue. Its constituent parts are, according to

It occurs on compact lime-flour which is much traversed by veins of calc-fspar, and is accompanied with molybdena and yellow lead-earth; sometimes, also, with lead-glance, white, black, and green lead-ore, calamine, blende, the calc and fluor fspars. It is found principally in Carinthia; though it is met with at Annaberg, in Austria; also in Hungary, Silexia, Saxony, Burgundy, in France, and other places.

Sp. vi. Lead vitriol, or sulphate of lead. Bliť vitriol, Werner. Natür vitriol of lead, Kirw. Plomb falkhaté, Häuy. Le vitriol de plomb natif, Broch. The colour of this mineral is yellowish grey, passing to the grey-white; the lighter varieties incline much to white. It occurs only in crystals, the form of which is rectangular octahedrons with obtuse pyramids. The pyramids are often variously truncated. Externally it is shining; internally it is splendent. The fracture is compact; it is more or less transparent; it is soft, rather brittle, and its specific gravity is about 6.3. It is easily reduced, when exposed to the flame of the blowpipe; and is insoluble in the nitric acid. Specimens have been analyzed by Klaproth; the constituent parts are as follow: viz. of that from Anglesea

It occurs in lead-glance veins at Wanlock-head, and in brown iron-flour in the island of Anglesea. It has also been found in lead-glance veins in Andalusia in Spain.

Sp. 10. Lead-earth. Bleyerze, Wern. is divided into two sub-species; 1, the coherent; and 2, the friable. 1. The coherent, or indurated, named Verhärtinge blieerze by Werner, and Le plomb endurez by Brochant, is of a yellowish or greenish-grey colour. It is sometimes of a smoky-grey, and sometimes of a light brownish-red. It occurs in mats. Internally it is glimmering, passing into glittening, and its lustre is resinous. Its fracture is fine-grained, uneven, passing into fine splinter and earthy, also into flat conchoidal. It is opaque, or, at most, slightly translucent on the edges. It gives a brownish streak, is soft, passing into friable, not brittle, but inclining to brittle, and heavy. It is easily reduced before the blowpipe, effervesces with acetic acid, and becomes black with sulphuret of ammonia. It does not appear to have been hitherto analyzed, but is supposed to be in intimate combination with white lead ore, alumine, and lime. It occurs with the other ores of lead, and is usually accompanied by iron pyrites, malachite, and quartz. The yellow varieties are found in Derbyshire, in some parts of Germany, at La Croix in France, and at Nertshinck in Siberia. The other varieties are to be met with at Wanlock-head, in the Lead-hills in Scotland, in Saxony, Silexia, Poland, &c. 2. Friable lead-earth. Zerätliche blieerze, Werner. Le plomb terreux friable, Brochant, is of a yellowish-grey, approaching to sulphur-yellow. It occurs friable; sometimes malleable and disintegrated. It is composed of dull dusty particles, which are more or less cohering, and foil a little. It has a rough feel, and is heavy. It occurs on the surface, or in the hollows of other minerals, and is usually accompanied with lead-glance, and other ores of lead, and is found at Wanlock-head, and the Lead-hills of Scotland, at Zellerfeld in the Hartz, near Freyberg, in the electorate of Saxony, in the mountains of Cracow, Poland, at La Croix in France, and at Bereafsky in Siberia. It is in some instances observed passing into solid lead-earth, and is probably formed by the decomposition of lead-glance, as it is frequently met with as a crust upon it.

Sp. 11. Another species is designated a triple sulphuret of lead. Its colour is dark-grey inclining to black. It occurs crystallized. Its primitive figure is a rectangular tetrahedral prism, besides which it presents the following varieties. 1. The primitive crystal with solid angles by triangular planes. 2. The same with lateral edges replaced by rectangular planes. 3. The same terminated by a very low and deeply truncated tetrahedral pyramid. 4. Four prisms with deeply truncated dihedral summits joined together at their bases, forming a rectangular crosst. The crystals are large and middle-sized, with a splendid metallic lustre both externally and internally. Its fracture is coarse-grained and uneven. It is brittle and easily frangible. It leaves a faint black trace when rubbed on paper. Specific gravity 5.8 nearly. When suddenly heated before the blowpipe it crackles and splits; but if gradually heated it melts, and on cooling forms a globule of a dull metallic grey colour. According to an analysis made by Mr. Hatchett, it consists of

It is found in a mine at Huel-Boys in Cornwall.
The existence of native lead, which has been maintained by several mineralogists, is extremely doubtful. What has been regarded as a native oxyd of the metal, appears to be rather an earthy carbonate.

**Assay and Analysis of Lead Ores.**—The most common lead ore, galena, is very easily analysed, since it is in general composed of sulphur and lead only. Those ores in which the lead is combined with other metals, such as silver, copper, antimony, bismuth, or arsenic, are attended with more difficulty in their analysis. If the analysis be made with a view to smelt the ore, it will be proper to make the assay in the dry, as well as the humid way. The latter will not only give the proportion of lead, but its other constituents, by which the smelter is directed to use the most proper fluxes. When, however, the analysis is made for publication, it should be made by the humid process only, and with the greatest accuracy.

The common galena may be analysed by dissolving 100 grains in dilute nitric acid: the lead will be dissolved, and the residuum will be sulphur, which may be separated by washing. The solution of lead may now be treated with sulphat of soda. The lead will be precipitated, with the sulphuric acid in the flake of sulphat of lead. The precipitate being collected, and dried at the temperature of 212, must be weighed, allowing for every 100 grains of the sulphat 69.82 of lead. The lead may be precipitated from the nitric acid, in the metallic, by means of a plate of zinc. The metallic lead will adhere to the plate, and may be scraped off and squeezed into lumps, after being washed in clean water. The lead obtained by this process is supposed to contain a small portion of the zinc. It will, therefore, be proper to digest the metallic precipitate, for a short time, in very dilute sulphuric acid, and then wash the lead with warm distilled water.

A specimen of galena containing fleck was analysed by Vaquelin.

By slowly roasting a portion of this ore, he found it lost 12 per cent. of sulphur. Another portion was treated with dilute nitric acid, which dissolved the lead. The residuum was heated to redness, by which the sulphur was volatilized, leaving behind 16.76 of sulphur. To the solution in nitric acid was now added sulphat of soda, when the lead was precipitated in the flake of sulphat. He obtained 63.1 per cent. of lead, allowing 10.0 of sulphat to contain 75.72 of metallic lead. He then separated the liquor with ammoniac, which threw down 3.3 per cent. of oxyd of iron, and obtained from the remaining liquor, by carbonate of potash, 3 per cent. of carbonate of lime.

A specimen of lead ore from Cornwall, consisting of lead, sulphur, antimony, and copper, was analysed by Mr. Hatchet. To 200 grains of the ore, in a matrass, he added 2 oz. of muriatic acid. While the mixture was heated, he added, from time to time, small quantities of nitric acid, just to keep up the effervescence, till the metals were oxydized and dissolved. After being gently heated for an hour, the solution was complete, and of a green colour, owing to the presence of the copper. The sulphur was separated and floated on the liquid, which being collected was digested in muriatic acid. When dried it weighed 34 grains.

The above solution, and the muriatic acid in which the sulphur was digested, were mixed together, and diluted with six pints of distilled water. The mixture became turbid and milky, and on being filtered while hot, the pure oxyd of antimony was left on the filter, which being washed with more boiling water, was dried, and found to weigh 62 grains.

When the liquid, which had passed through the filter, including the washings, was cold, some muriat of lead was deposited in crystals, owing to the sparing solubility of that falt. The whole was evaporated to a small quantity of liquid, sufficient to hold the copper in solution. This liquid, being separated from the solid muriat of lead, contained a small portion of that falt. A few drops of sulphuric acid were added, however, separated it in the state of sulphat of lead.

The muriat of lead left by evaporation, was now re-dissolved in boiling water, and decomposed by sulphat of soda. The sulphat of lead here formed was added to that produced from the separated liquid, which, on being washed and dried on a sand bath, weighed 120.3 grains. The green liquid containing the remainder of the mineral was now filtered with ammonia and an excess added, which redissolved the oxyd of copper, forming a vivid blue solution. A quantity of oxyd of iron now separated, which, when separated, weighed 24 grains.

The solution of copper was now evaporated nearly to dryness, and boiled with pure potash, when the black oxyd of copper was left at the bottom of the vessel, which being washed, separated, and dried, weighed 32 grains.

In this analysis the sulphur is the only substance separated in a state of purity. The 63 grains of oxyd of antimony, allowing it to contain 23.08 per cent. of oxygen, would afford 48.46 of antimony. The 120.3 grains of sulphat of lead, allowing 70.9 to the 100, will give 85.22 of metallic lead. The 32 grains of oxyd of copper, reckoning the black oxyd of that metal to contain 25 in the 100, will yield 24 grains. If we reckon the 24 grains of iron at 1.2 of metal, the analysis will stand as follows, when reduced to 100.

If silver had been a constituent of the ore, the above processes would have been a little varied. In the first operation the ore would have been dissolved in dilute nitric acid, the antimony would have been in part dissolved, and left at the bottom of the vessel in the state of white oxyd. When the sulphur and the antimony, by dilution with water, are separated, muriatic acid must be added. The lead will be in part, and the silver entirely precipitated. The muriat of lead may be separated, by boiling water, from the muriat of silver. The weight of silver may be rated at 77.52 in the 100 of muriat. The other metals may be separated as in the last processes. Arseninated lead ore requires a still different treatment. It was analysed by Vaquelin as follows: 100 parts of ore were roasted for half an hour, occasionally adding a little tallow, which served to reduce the arsenic and facilitate its escape. By this treatment it lost 38 parts, which was presumed to be oxyd of arsenic; the remaining muriat was boiled with strong muriatic acid for an hour. A quantity of oxymuriatic acid escaped, the liquid assumed a red colour, and white needle-formed crystals of muriat of lead were deposited. The lead by this means was converted into a muriat, which being dissolved in boiling water, and treated with sulphat of soda, afforded sulphat of lead. This precipitate, being separated and dried, weighed 25 parts, which gave 20.3 of lead, allowing 80.8 to the 100 of sulphat. The liquid thus freed from lead being treated with pure ammonia, afforded a precipitate equal to 39 grains, containing of oxyd of iron and arsenic. The circumstance of oxymuriatic acid being given out, when the oxyd of lead was digested...
gelled with muriatic, induced Vaquelin to conclude that it
was in a state of peroxyd.

In this account the last part of the process appears incom-
plete, in the circumstance of the oxyds of arsenic and iron
being mixed together. The former of these may be sepa-
rated, boiling the two in nitromuriatic acid, which will
convert the oxyd of arsenic into arsentic acid, and which may
be separated by washing.

Carbonat of lead was analysed by Klaproth by the fol-
lowing process. He introduced 100 grains of this ore into
200 grains of nitric acid, and diluted it with 300 of water. The
nitric acid escaped in the form of gas, making a loss of
weight equal to 16 grains. Into this solution was suspended
a cylinder of zinc. In 24 hours the lead was precipitated
in the metallic state, which weighed 77 grains, equal to 82
of oxyd.

Sulphat of lead has been analysed by the same chemist: 100
grains of the ore were first roasted at a red heat, and
lost two grains, supposing to be water. The remainder
was then heated to redness in a platina crucible, with 400
grains of carbonat of potash. By this treatment a yellow
reddish mafs was obtained, which, on being digested in water
and filtered, afforded 72 grains of oxyd of lead. This was
next dissolved in nitric acid, leaving a residuum of one grain
of oxyd of iron. A cylinder of zinc was introduced into
the solution, which precipitated the lead in the metallic form,
in quantity equal to 662 grains.

The alkaline matter which passed through the filter con-
tained the fulphuric acid of the fulphat of lead, with ex-
cess of alkali; this excess was saturated with nitric acid, and
the liquid acetat of barytes was added, which caused a pre-
cipitation of 73 grains of fulphat of barytes; this allows
containing 25 grains of real fulphuric acid. Hence the re-
result is

| Oxyd of lead | 72 |
| Sulphuric acid | 25 |
| Oxyd of iron | 1 |
| Loss by roasting | 2 |
| **100** |

We have also the analysis of phosphat of lead by the same
ingenious experimenter.

One hundred grains of this native salt were dissolved in di-
lute nitric acid, and into this solution nitrat of silver
was dropped till it ceased to precipitate: the insoluble sub-
stance, which was muriat of silver, weighed 11 grains, indicating
17 grains of muriatic acid. Sulphuric acid was now added
to precipitate the lead. The fulphat of lead weighed
106 grains, which contained 78.4 of oxyd of lead. The
excess of fulphuric acid was separated by adding nitrat of ba-
rates, and then nearly neutralized with ammonia. On adding
acetat of lead, 82 grains of phosphat of lead were precipi-
tated, containing 18.27 of phosphoric acid: muriatic acid
was now added to the solution, and evaporated to dryness.
The dry masses were digested with alcohol, which dissolved the
muriat of iron, the presence of which was detected by pru-
flatis of potash, and was found equal to 27th of a grain of the
oxyd.

Molybdat of lead was analysed by Mr. Hatchett. He
boiled a quantity of the ore in fulphuric acid, till it would
diffuse no more. This formed fulphat of lead, while the
molybdcic acid was dissolved in the fulphuric acid. The
fulphat of lead was boiled with carbonat of soda, and was
afterwards washed: this appeared to be carbonat of lead.
The nitric acid dissolved all but a small quantity, which was
found to be flex. The lead was next precipitated by ful-
phuric acid. The solution of the molybdcic acid in the ful-
phuric acid was diluted with 16 parts of water, and satu-
rated with ammonia; when a little oxyd of iron was precipi-
tated. The solution was now evaporated to dryness, and
a strong heat given to sublime the fulphat of ammonia.
The remaining mafs, when boiled with nitric acid to dry-
ness, afforded molybdic acid of a yellow colour.

Although the analysis of the different ores may have
pointed out general methods for the separation of lead from
other metals, some hints may, nevertheless, be necessary for
the analysis of the alloys of lead. Lead is most frequently
alloyed with tin, silver, antimony, or bismuth. The alloy
of tin and lead may be dissolved in dilute nitric acid.

The lead will be entirely taken up. Most of the tin will be pre-
cipitated in the state of white oxyd, by the addition of water.
If fulphuric acid be now dropped into the solution till the
precipitates ceases, the lead, in a state of fulphat, will be
obtained, while the remaining tin will be diffused, which
may afterwards be precipitated by an alkali. Lead may be
separated from silver, when both those bodies are dissolved
in pure nitric acid. The silver may be precipitated in the state
of muriat, by adding muriat of soda. The lead may be
afterwards precipitated by fulphuric acid.

To separate lead from bismuth, diffuse the alloy in nitric
acid, then add a large quantity of water, which will pre-
cipitate the greatest part of the bismuth in the state of white
oxyd. The lead must then be precipitated by fulphat of soda,
and the remainder of the bismuth by potash.

The separation of lead from antimony may be performed by
the same process used for separating tin.

It may be here noticed, that in all cases where sulphur is
present in the ore or substance to be analysed, if the nitric acid
be employed, it must be very dilute, otherwise the sulphur
will combine with its oxygen, forming fulphuric acid. In
order to know when this takes place, the solution must be
treated with nitrat of barytes. If, however, lead be present,
will it combine with the fulphuric acid as it is formed, and
fall to the bottom of the vessel.

Reduction of the Ores, or smelting of Lead.—Two processes
are employed for the smelting of lead, the one by means
of a blaff furnace, called an ore-earth, and the other by
means of a reverberatory furnace. The latter is used
throughout Derbyshire and North Wales, and is doubt-
edly the best, where coal is not very scarce. In the former
of these methods the ore and the fuel are mixed together,
and exposed to the blast. The heat diffuses the fulphur,
The ore being the common fulphurit of lead or galena.

A portion of the lead is oxidated, which facilitates the vitri-
fication of the earthy parts of the ore, and of the fuel.

These together constitute the flag or scoria. The metallic
lead falls into the lower part of the hearth, and is defended
from the oxygen of the blast by the scoria, which is fluid
upon its surface. The liquid lead is let off from time to
time, always retaining a portion for the scoria to float upon.
When the whole of the lead is to be drawn off, the blast
must be stopped, and some lime thrown upon the liquid
scoria, which renders it concrete, while the lead, being still
liquid, can be run off.

The reverberatory furnace employed for smelting lead is
made on the same plan with those commonly used for
muddling iron, differing in size, and a few other particulars.
The fire is made at one end, and the flame plays over the
earth, entering an oblique chimney at the end, which
terminates in a perpendicular one, of considerable height.

The length of the hearth, from the place where the fire
enters, to the chimney, is 11 feet; two feet of this length
next the fire constitutes the throat of the furnace; the width
of the fame is four feet, and its depth about 1/8 inches, the
length of the fire-place is four feet, equal to the width of the throat; its width two feet, and depth three feet, from the grate up to the throat of the furnace. The rear of the hearth is a concave surface, nine feet long, four and a half feet wide at the throat of the furnace, seven feet four inches wide at the distance of two feet from the throat, seven feet two inches in the middle of the hearth, five feet eleven inches at two feet distance from the chimney, and two feet ten where the flame enters the chimney at two apertures, each ten inches square. These apertures terminate in the oblique part of the chimney, the section of which is 16 inches square, which communicates with the main chimney, the section of which is twenty inches square, supposing a straight horizontal line, drawn from the lower plane of the throat of the chimney to the opposite side of the furnace; the lowest part of the concave hearth, which is in the middle of this cavity, is nineteen inches below this line, the roof of the furnace being seventeen inches above the same line: the rest of the hearth is conformably concave.

On each side of the furnace are three openings, each about ten inches square, provided with iron doors, to be removed as occasion may require. They are arranged at equal distances from each other, between the commencement of the hollow hearth and the entrance into the chimney. The lower part of these apertures is on a level with the horizontal line above alluded to, being for the purpose of stirring and raking the ore, &c. Besides the larger openings there are two small apertures, one below the large middle opening, and nearly on a level with the bottom of the furnace; the other under that next to the chimney, at some distance above the first aperture. The first is a tapping hole for the lead, and the second for the scoria. The ore is introduced by a vessel in the shape of a hopper, placed in the roof of the furnace.

Previous to the ore being smelted, it requires to be separated as much as possible from the earthly matter in which it is imbedded. Although galena, which is the ore used for smelting, is most frequently accompanied by sulphate of barytes, floats and carbonat of lime, it is found to exist in crystallized distinct masses, and can be separated from it by mechanical means to a tolerable extent. The whole of the ore, with the earthly matter, is pounded to a certain degree with hammers, and is chiefly performed by women. In some places, however, it is broken down by passing it through iron rollers pressed together by great weights. After the ore has been thus reduced, the earthly matter is separated by washing. The powder to be washed is introduced into a sieve or riddle, and placed in a large tub full of water. By a certain motion given to the riddle, the lighter or earthly parts are thrown over the edge of the same, while the galena, by its greater specific gravity, is retained. This process requires great dexterity, which can be acquired by experience only. There are, however, some impurities which cannot be separated by this mechanical process, and are generally smelted with the ore. These are, blind, or black-jack, called by the smelters black ore; pyrites, or sulphuret of iron, named Brazil by the workmen. When the ore abounds much with these substantiae, the process of smelting is more difficult, and requires an extra abundance of flux to reduce it.

In the plate above described, the ore is introduced at the hopper in the middle of the roof of the furnace, and spread upon the concave hearth, to expose it as much to the flame as possible, in order to facilitate the escape of the sulphur. This should be performed by a long continued heat which is not violent, in order that the sulphuret itself may not be volatilized; an effect which, more or less, always takes place. The moment the sulphur has left the lead it begins to combine with oxygen. The oxyd of lead, thus formed, combines with the earthly matter, which it renders so fusible as to become liquid upon the sulphur of the melted lead, and defends it from the future action of the oxygen. At this stage of the process the fire is raised too separate as quickly as possible the melted lead from the liquid scoria. The latter is now let off at the upper tap hole, leaving a small portion still upon the lead to preserve it from the air. The fire at this period is lowered, and a quantity of coal-flack thrown in upon the melted mass. This serves as well to facilitate the cooling, and to enable the reduction of some oxyd of lead, which also tends to soften the melted scoria. This left effect, however, is not produced sufficiently, till a quantity of powdered lime is thrown into the furnace. By this treatment the remaining scoria becomes concrete, and is then broken to pieces and pushed to the opposite side of the furnace by means of a rake, and taken out of the furnace at the different openings on the same side. The liquid lead is now let out, at its proper aperture, into a large iron pan, or cistern, from whence it is laded into moulds to cast into pigs. The furnace is now ready to be charged again. When the ore abounds with much impurity, the oxyd of lead is not sufficient to give the proper degree of liquidity to the scoria. In this case a certain quantity of flux of lime is added, which has the property of forming a very fusible compound with sulphur of barytes, an ingredient very common in the ore.

This flux has been used from time immemorial for the same purpose, and has no doubt derived its name from its properties as a flux. See Flux of Lime.

The concrete scoria, which is taken out of the furnace, is found to contain some lead, independent of that in the flake of oxyd, and chemically combined. This is generally lodged in the cavities of the spongy mass. These masses are broken to a kind of borax flakes, called a flag-hearth. By this second fusion of the scoria, the lead drops through the liquid mass into the lower part of the hearth, where it is not acted upon by the blast, and from thence is let off and cast into pigs. This lead is said to be of an inferior quality. Some ores of lead contain silver. The great affinity of lead for that metal is such, that the whole of it is found in the lead (see Silver), from whence it is afterwards separated.

**Physical and chemical Properties of Lead.**—Lead is of a bluish-white colour, when made as bright as possible. This polish it soon loses by exposure to air.

Its softness is such, that a cylinder of one inch in diameter and twelve inches long, may be easily bent by a person of ordinary strength; indeed, it is the most soft and flexible of the metals. Its specific gravity, according to Blisson, is 11.5573, and this, from being increased by the hammer, agrees closely with the change in other metals by the same effect. Mufchenbroeck asserts that it is diminished. It may be here proper to observe, that those metals which are susceptible of the most perfect crystalization, will undergo the greatest condensation by the hammer, provided the metal be sufficiently malleable. Hence we find this property the most conspicuous in brass, and in blistered lead. See Metal.

Lead, in common with its softness, is the least elastic of the metals, to which also may be attributed its little tenacity. Its hardness is increased by hammering, and its tenacity in a proportionate degree.

Lead is exceedingly malleable, which connected with its excessive softness, admits of its being rolled into thin sheets with little power. Its tenacity, according to Dr. Thomson,
Thomson, is such, that a wire of \( \frac{1}{120} \) of an inch will support only 18.4 pounds. Lead fuses at about 600° of Fahrenheit, and if raised to a much higher temperature, will be found to diminish by evaporation. If lead be melted and poured into an iron mould, it will be found to cement on the sides next the mould, while the middle part will be liquid for a short time. If this liquid part be poured off, or let out at a plug-hole at the bottom, the interior surface of the solid part will exhibit a crystalline form. The crystals will be larger and more distinct as the cooling is slower.

Lead is much employed in the arts, particularly for buildings and cisterns. For this purpose it has many advantages. It is easily worked into any shape on account of its great softness, and is sufficiently malleable to fold two edges over each other, so as make it water-tight without folding. This is a great advantage, since, when the pieces are folded together, the expansion and contraction, by a change of temperature, soon breaks it to pieces.

Although it is at present in general use for water-cisterns, pumps, and pipes for conveying water, serious objections have been made to it by different philosophers, particularly Dr. Lambe, so far as regards its effects on the human economy.

A very ingenious paper was some time ago published by Morveau, in which he shews that the water exposed to the leaden vessels would frequently be pernicious, if some sulphuric acid were not present, which never fails to precipitate lead from any of its solutions. Thus we see that lead is the least objectionable for mineral waters containing the sulphuric acid, which is very general in almost all springs.

Great mischief has been produced by the use of lead in dairies; although we lament to say that this practice is still followed up to a certain extent. If the milk runs into the flighted acidity, we must expect some lead to be dissolved, and its probable consequences if taken into the human body.

The disease called the Devonshire colic, was proved by Sir George Baker, in several excellent papers written by him, and published in the Philosophical Transactions of that time, to be occasioned by lead dissolved in the curd, and which had been furnished from the curdy presels, which were lined with that metal; but was in consequence of this valuable discovery laid aside.

We have heard of a similar disease in the West Indies, acquired by drinking new rum. The rum was found to contain lead, which had been taken from the leaden worm used for the condensation of the spirituous vapour. What, however, is very singular, the rum lost its deleterious property by keeping about twelve months. This fact was not explained at the time, but it has lately been cleared up by a series of experiments made by the writer of this article. The new rum is generally put into oak casks, from whence the liquor extracts a quantity of tar and gallic acid. These substances combine with the lead in solution, forming a perfectly insoluble substance, which falls to the bottom of the cask. These facts shew that lead should not be used in any situation where fermented liquors are present, since in every stage of their existence, they contain more or less acetic acid. And it must not be forgotten, that all distilled spirits will contain the same acid, from the circumstance of its being volatile and coming over with the spirit.

We have, however, abundant satisfaction in knowing that the existence of lead and gallic acid in spirits, wines, or other fermented liquors, are incompatible: and that all liquors which have been kept in oak casks for a certain time must be freed from lead. If we find the presence of gallic acid by a solution of iron, we may pronounce such liquid free from lead.

These observations, which may appear out of place, are given with a view to guide those who may be making or using vessels of lead, which, under some circumstances, are attended with deplorable consequences.

**Alloys of Lead formed with other Metals.**—One part of tin and two parts of lead form an alloy, fusible at about 350° of Fahrenheit, and used by tinmen and others under the name of soft solder. See **Solder**.

Lead forms an imperfect alloy with copper. The metal used for common brazes-cocks is an alloy of these two metals. The lead is so imperfectly combined with the copper, that when a piece of the metal is exposed to a certain heat, the lead separates from the copper in bright globules of the former.

The alloy of antimony with lead is not uncommon. Sixteen of lead and one of antimony form the printers' type metal.

Lead easily combines with mercury, forming an amalgam. This is effected either by putting mercury into melted lead, or by putting lead, in small particles, to the mercury. See **Amalgam**.

An alloy of silver and lead is easily formed. Indeed lead is frequently used to take silver from plated iron, which is afterwards got from the lead by cupellation.

We are indebted to Mr. Hatchett for some valuable facts relative to the alloys of lead and gold. One part of lead to eleven of gold forms a very brittle alloy, having a fracture of a pale brown colour, deliquescent of metallic lustre.

The alloys in any proportion have the singular property of being of less specific gravity than the metal, the very contrary of which is observed in most other compounds of metals. The following is a table given by Mr. Hatchett exhibiting these facts.

*When*
When lead is exposed to the air for a little time, it soon appears of different colours, not unlike the prismatic colours. By a longer exposure, ascribed with moisture, it becomes covered with a white powder. This is the oxyd of lead combined with carbonic acid. This change is facilitated by heat, and still more by the fumes of acetic acid or vinegar. It is by this means that the white lead of commerce is made, of which we shall treat hereafter.

If melted lead is exposed to the oxygen of the atmosphere, a greyish-yellow powder begins to form upon the surface. By keeping it exposed for some time, the powder becomes more yellow. In this state it is called mafficet, or yellow oxyd of lead. It contains about 6.88 per cent. of oxygen.

This oxyd is made, in the large way, in a furnace not unlike a baker's oven. The middle of the heath contains a reces for exposing the melted lead. On each side, and a little below the level of the hearth, is a fire, the flame of which passes slowly over the hearth, giving sufficient heat to keep the lead melted, and passes up a chimney near the mouth of the furnace. As soon as the lead is melted, a person is constantly employed to agitate it, in order to expose greater surface to the air. This manual operation is performed by a rake suspended from a chain, so that the perpendicular part of the rake dañes through a portion of the melted lead, by merely moving it backwards and forwards. By the same motion, the oxyd which is formed is pulled away from the surface of the lead, leaving it free to the action of fresh oxygen. This proceeds being kept up, the lead is at length converted into a greenish-yellow powder, mixed with lumps of metallic lead. This powder is ground in a mill and then washed, by which means the metallic lead is separated, and the powder becomes of a more bright yellow. The green colour was therefore owing to a mixture of the blue particles of lead, mixed with the yellow oxyd. The yellow oxyd here produced is called mafficet; which see.

This oxyd appears capable of combining with more oxygen by a second exposure. For this purpose the yellow powder, after being washed and dried, is returned into the furnace above-mentioned, or one of similar construction, kept for this second process only. The heat is kept uniform but not great, and the oxyd raked about to expose as much surface as possible. It gradually changes colour, and ultimately affumes a splendid red. In this state it is called minium; which see. Although during this process the oxyd appears gradually to pass through all the shades of orange colour from yellow to red, the two latter can only be considered as distinct oxyds, the intermediate tints being mixtures of the two.

If we consider the yellow as the first or protoxyd, the red will be the second, and the brown, yet to be treated of, the third and the peroxyd. Proust, however, has given some reason to believe that the yellow is not the first. The oxyd which is precipitated from the nitric acid when heated to redness, to drive off the water and carbonic acid, is found to be the yellow oxyd in a very perfect state. The author above-mentioned informs us, that if crystals of the common nitrate of lead be boiled with some pieces of metallic lead, scaly yellow crystals are formed. This fact, decomposed by potash, affords an oxyd which Proust supposes to contain less oxygen than the yellow. Dr. Thomson repeated his experiment; he found the oxyd not to differ in appearance from the yellow, and makes it to consist of lead, 91.4 lead, and 8.5 oxygen. This appears to be rather less oxyd than, according to his own analysis, is contained in the yellow. But there is reason to believe, that in Dr. Thomson's analysis of the yellow oxyd, the oxygen is rated too high. The fame oxyd, according to Bucholz, is composed of 100 lead and eight of oxygen, equal to 7.4 per cent. This analysis appears to have been made under such circumstances as to entitle it to much credit. From the average of three analyses of the yellow oxyd, obtained from acetate of lead, the writer of this article made the oxyd 7.4 per cent. Hence we have abundant reason to doubt the existence of an oxyd below the yellow oxyd, since it appears, from Dr. Thomson's own account, that the oxyd, failing to consist of less oxygen than the yellow, contains 8.5 per cent., being 1.1 more than Bucholz makes the yellow oxyd.

If nitric acid in sufficient quantity be added to the red oxyd of lead, nearly the whole will be dissolved; 1/10th of the oxyd will remain at the bottom of the vessel, which, when collected and dried, is of a dark brown colour, and is called the brown oxyd of lead. The following process is given by Vanquelin: Mix a quantity of the red oxyd of lead with water in a Wouff's apparatus, and let the oxyd in the agency gas pass through the mixture. The oxyd gradually becomes of a deeper colour, and at last diffuses. From this solution the brown oxyd is precipitated by potash. From every 100 parts of the red oxyd 68 of the brown may be obtained.

This oxyd is of a fleas-brown colour, having no smell or taste. It is insoluble in any of the acids. It converts the muriatic into oxyd in the mixture, by giving up a portion of its oxygen. When rubbed briskly in a mortar with powdered sulphur, the sulphur inflames, producing a strong smell of sulphuric acid. According to the analysis of Proust, this oxyd is composed of 79 lead and 21 oxygen. Dr. Thomson makes it 81.6 lead and 18.4 oxygen.

It appears highly probable that we have only three oxyds of lead, namely, the yellow, the red, and the brown. The first, according to Proust, contains 9 per cent.; Thomson, 10.3; Bucholz, 7.4; the writer of this article, 7.4; the average of all these being 8.5. The red oxyd, by Dr. Thomson's analysis, contains 12 per cent.; the brown, according to Proust, contains in the 100, 21 oxygen; Dr. Thomson makes 18.4; the mean of these is 19.7.

Agreeable to the average results of these different analyses, we cannot help being forcibly struck with the beauty of Mr. Dalton's hypothesis relative to the limited proportions with which bodies combine. He makes the atom of lead to weigh 95, or to be 95 times heavier than an atom of hydrogen; the atom of oxygen being 7 times heavier. In referring to the doctrine advanced by this ingenious chemist, it will be seen that he holds the necessity of bodies combining atom to atom, or in some multiple of the same; as, 2 to 1, 3 to 1, &c. The first oxyd of lead, agreeably to the above data, must be 1 to 1, or 64 to 1; the second oxyd, 95 to 1; and the third, 95 to 21. Hence these proportions reduced to 100, will stand as follows: $\frac{95 + 7}{7} = 100 \div 6.86$, or 6.86 in the 100, for the first oxyd. Then, for the second, $\frac{95 + 14}{14} = \frac{100}{12.84}$, or 12.84 in the 100.

Lastly, for the third or peroxyd, $\frac{95 + 21}{21} = \frac{100}{18.1}$, or 18.1 in the 100. The proportions by analysis give, for the first, 8.5; second, 12; and the third, 19.7. By theory, 6.86, 12.84, and 18.1.

The second and third oxyds of lead give out oxygen, by exposure to heat in a crucible, and are reduced to the state of the first oxyd. If the heat be raised a little above redness,
Lead combines with sulphur and phosphorus.

Sulphuret of lead may be formed by projecting sulphur into melted lead, or by stratifying thin plates of the metal with the sulphur. The compound is very brittle, of a dark grey colour. It may be crystallized by slow cooling; under which form it exhibits a brilliant fracture, resembling the native sulphuret, or galena. This sulphuret, according to Dr. Thomson, consists of 86 lead and 14 sulphur. According to Dalton's hypothesis, it consists of one atom of lead to one of sulphur: the former atom being 95, and the latter 13, will give $\frac{95 + 13}{13} = \frac{100}{12}$, or 12 to 100; which agrees with several other analyses very nearly.

Lead appears capable of combining with a second dose of sulphur, constituting a compound, which is more brilliant, and of a lighter colour. It may be easily distinguished from the common kind, by its burning in the flame of a candle.

It is called the super-sulphuret of lead, and, according to Dalton's hypothesis, must consist of one atom of lead and two atoms of sulphur, which would give $\frac{95 + 2 \times 13}{26} = \frac{100}{21.5}$, or 21.5 per cent. Dr. Thomson makes it 25 per cent.

It is to this chemist we are indebted for our knowledge of this substance.

Phosphuret of lead may be formed by mixing together equal parts of filings of lead and phosphoric glafs; the mixture being fucned in a crucible. It is of a silvery blueish-white colour. It poifflesfes flight malleableness, and may be cut with a knife. It is composed of 88 lead and 12 of phosphorus. Dalton makes the atom of phosphorus to weigh 9:

hence this compound of 1 to 1 will give $\frac{95 + 9}{9} = \frac{104}{8.6}$

Salts of Lead.—Most of the acids combine with the yellow oxyd of lead, forming peculiar compounds. By far the greatest proportion of these compounds is insoluble in water. All those which are soluble have a sweetish taste, attended with a roughness which it leaves on the tongue, familiar to that of red port, and some other wines. This property has caused it to be used for the villainous purpose of mixing with four wine, which does not only take up the acid, but adds a roughness and sweet vinous flavour, exceeding imposing upon the palate. Some have fupended bags of it in the cafs of wine; others have added common white lead.

Mankind are now so well acquainted with the different tests for lead, that it is very seldom found in thoce liquors. Water impregnated with sulphuretted hydrogen gas will instantly turn wine muddy and black, which contains lead. If a solution of iron be dropped into wine, and it turns black, the presence of gallic is indicated: and from what we before obferved, the existence of lead and that acid are incompatible in the same liquid.

Sulpht of Lead.—Lead is scarcely acted upon by the sulphuric acid, in the cold. If the acid be boiled with the lead, fumes of sulphurous acid will be given out, and a portion of the lead oxydated, which combines with the acid, forming a whitish palty compound. If the acid be in excess, and the mass washed in water, the sulphate becomes divided into two portions, namely, the sulphate of lead, which is insoluble, and the superphosphate, which is slightly soluble, and will be deposed in crystals.

It is from the circumstance of the insolubility of the sulphate of lead, that the metal can be used with such advantage for the lead-houses, used in making sulphuric acid, and for making vessels which have to hold this acid. The sulphate which first forms upon the surface defends the lead not only from the action of this acid, but from any other solvent of this poisonous metal. Sulphate of lead may be best formed by adding sulphate of soda to the acetat of nitrate of lead. A dense white precipitate is formed, which is sulphat of lead. This salt is produced in great abundance by the calico-printers, in making acetam alumine, with alum and acetat of lead. It forms an excellent paint with oil, forUand the action of acids.

Kirwan gives the proportion of this salt at 23.37 acid, 75 acid yellow oxyd, 1.63 water in the 100; Bucholz, 24.72 acid, 75.28 oxyd; and Klaproth, 26.5 acid, and 73.5 oxyd: the mean of these is 24.86 acid, and 75.14 base. Calculated by Dalton's theory, the atom of sulphuric acid weighs 34: therefore, $\frac{95 + 7 + 34}{34} = \frac{100}{25}$; or, the acid is 25 in the 100: then, 100 - 25 = 75 the base.

Sulphite of Lead.—The sulphurous acid has no action upon lead: but it combines with the yellow oxyd, forming an insoluble compound, having no remarkable properties. When exposed to a red heat, the acid is difengaged, in the form of gas.

When the sulphurous acid is added to the red oxyd of lead, the acid takes oxygen from the oxyd, reducing it to the state of yellow oxyd. The acid is converted into the sulphuric, and combines with the oxyd, forming the sulphate of lead.

Dr. Thomson gives the proportions at

$$\begin{align*}
\text{74.5 oxyd} & \quad \text{25.5 acid.} \\
\end{align*}$$

Nitrat of Lead.—When the nitric acid is a little diluted, it acts with considerable rapidity upon lead. If it be a little assifled by heat, the whole will become speedily dissolved, forming nitrat of lead: This consists of the yellow oxyd of the metal united to a portion of the acid. If the solution be evaporated, it affords crystals of tin, in fix-sided pyramids of a silvery white colour. This salt dissolves in $\frac{1}{2}$ of boiling water. When the crystals are heated, they undergo a slight detonation: the fame takes place when they are rubbed with sulphur in a hot mortar.
According to experiments of Dr. Thomson, this salt consists of,

- 66 oxyd,
- 34 acid.
- 100

When the crystals of the last salt are boiled with metallic lead, yellow fealty crystals are formed, constituting, according to Dr. Thomson, a subnitrat, containing of

- 81.5 oxyd,
- 18.5 acid.
- 100

By Dalton's theory the weight of an atom of nitric acid is \(19\) : in mols of the nitrats he supposes one atom of the base to unite with two atoms of acid. The nitrat of lead, already described, should, according to the above analysis, consist of at least two atoms of acid to one of base, for

\[
\frac{102 + 2 \times 19}{38} = \frac{100}{27.14} = 27.14 \text{ of acid, and } 72.86 \text{ of base.}
\]

The acid here falls considerably short of that in the analysis of Dr. Thomson. The latter salt, which we have called the subnitrat, should have one atom less of acid.

Hence \(25 + 7 + 19\) \(\frac{19}{15.7}\), which gives \(27.7\) acid, and

84.3 of oxyd = 100.

**Muriat of Lead.** — Muriatic acid has a very feeble action on lead, but it readily dissolves the yellow oxyd, forming the muriat of lead. This salt may be also formed by adding muriat of soda to nitrat of lead. The precipitate which is formed is the salt in question. It dissolves in 22 parts of cold water. This is the fact only when no excess of this acid, or when no other acid is present; since the salt is soluble in most acids to a greater extent than in water. When this salt is mixed with the sulphat of lead, it may be separated from it by its solubility in the acetic acid. Muriat of lead is much more soluble in hot than in cold water. Hence, when a saturated hot solution is suffered to cool, the salt is deposited in crystals of a silvery-white colour. When heated they readily melt, and on cooling assume a slight transparency, from which it has been called *Plumbum corneum*.

On the application of greater heat some of the salt evaporates in a white smoke, leaving behind a subnitrate, which is said to be a submuriat of lead.

The composition of muriat of lead is, according to Klaproth,

**Acid** 13.5

**Oxyd** 86.5

</table>

The weight of the atom of muriatic acid being 22, we shall have by Dalton's theory \(\frac{25 + 7 + 22}{22} = \frac{100}{17.74}\), by which we have \(17.74\) acid, and \(82.26\) of oxyd, which comes very near to Kirwan. When the muriatic acid is poured on the red oxyd of lead, the lead gives up a part of its oxygen to the muriatic acid, constituting the oxymuriatic acid. The muriatic acid then unites with the yellow oxyd thus formed, while the oxygen is returned to the remaining red oxyd, forming the brown oxyd.

The substance above-mentioned, said to be a submuriat, appears rather ambiguous, and may, perhaps, be a mere mixture of the common muriat with the yellow oxyd of lead. There is, however, one argument in favour of its being a proper compound. It is said not to be soluble in water, or that the excess of oxyd is attached to the muriat, so as to prevent its being separated by the affinity of the water for the salt.

The common way of forming this substance is by adding to the muriat of soda a much larger quantity of litharge than would be necessary to saturate the acid of the salt. We are indebted to Vauquelin for the bell account of the nature of this anomalous decomposition. At the same time the muriat of lead is decomposed by soda. We have the fact before our eyes, that an oxyd of lead will completely decompose the muriat of soda. If we take the experiment of Vauquelin we shall be better able to give an opinion. To one part of muriat of soda he added seven of litharge in fine powder, with as much water as made the mixture of the consanguinity of thin four. This was frequently stirred for several hours. The litharge gradually lost its colour, and ultimately became white. It increased in bulk, and so much water was absorbed as to make it necessary to add more. At the end of four days the chemical action had entirely subsided, when the result was examined. The liquid part, when separated by the filter, had a strong taste of soda, with a taint of muriat of lead, but no muriat of soda was present. The liquid afforded crystals of carbonat of soda by evaporation. The substance from which the liquor had been separated, when walled and dried, was of a dirty white colour, and was found to have increased in weight \(\frac{7}{12}\)th of the whole oxyd employed. When this substance was heated to a certain degree it assumed a fine yellow colour, by which it lost \(\frac{3}{4}\)th of its weight. This was, perhaps, carbonic acid and water.

Some caustic soda was added to a part of this substance, which changed its colour to that of a dirty yellow, and the reductum was found to be a mass of crystals of muriat of lead. By the test of an alkaline hydro-sulphuret, the soda appeared to hold a great quantity of the oxyd of lead in solution.

The one part of muriat of soda, used in this experiment, consisted of \(0.44\) of acid, and \(0.56\) of soda. The \(0.44\) acid would combine with \(2.4\) of the yellow oxyd to form \(3.84\) of muriat of lead, leaving \(7 - 2.4 = 4.6\) of oxyd of lead. This is supposing the true muriat to be formed; but if a submuriat were formed, it must consist of more than one atom of lead united to one of acid. Suppose it one of acid to two of oxyd, then \(0.44 + 2 \times 2.4 = 4.48\) of submuriat, filling in the space of oxyd left. But the author tells us that the yellow submuriat was insoluble in water, or that the water would not take the muriat from the excess of oxyd, although the nitric acid, as well as the soda, was capable of that effect. If there were no free oxyd when two atoms of lead were to one of acid, let us suppose them three to one, we shall then have \(4.4 + 3 \times 2.4 = 10.4\) of a second submuriat. If, therefore, we are to rely upon the fact, that the muriat of lead could not be dissolved, leaving the excess of oxyd, we must regard this
L E A D.

This yellow substance as a legitimate compound. If the contrary be the case, we must regard it as a mixture of the true muriatic mixed with the yellow oxyd of lead. This substance has been manufactured under a patent by Mr. Turner, of Newcastle-upon-Tyne, and is deemed a valuable pigment for painting.

Phosphat of Lead.—The phosphoric acid does not act upon lead in the cold, but very feebly by heat. The result of this action is the formation of an insoluble compound, which is the phosphat of lead.

This salt may be more easily formed by adding together the solutions of phosphat of soda and the nitrat, or acetat of lead. A dense white powder subfides, which is the salt in question. This salt is insoluble in water, but it diffuses readily in nitric acid, and also, when diffused by heat, in the muriatic acid. On the latter solution cooling, cryftals of muriatic of lead are deposited; a proof that a partial decomposition takes place. It is also decomposed by the fulphuric acid, by the affinity of heat.

When this salt is heated it melts, and on cooling affumes a cryftalline appearance.

It is from this salt that phosphorus is generally obtained; for when it is exposed to a great heat, in an earthen retort, with charcoal, both the lead and the phosphorus lose their oxygen, the latter being diffused over.

Mr. Dalton makes the atom of phosphoric acid to weigh 23, then \( \frac{95 + 7 + 23}{23} = \frac{100}{18.4} \); so that this salt, from these data, consists of 18.4 of acid, and 88.6 of oxyd, which is very near the proportions of the native salt.

Carbonat of Lead.—Carbonic acid does not act upon leads but it combines with the yellow oxyd of lead, forming an insoluble white powder, which is manufactured under the name of white lead.

This salt may be formed by adding a carbonat of potash to the acetat or nitrat of lead. The precipitate, being washed and dried, is snowy-white powder, appearing to the eye we've calculated to make a much finer white paint than that made in the common way. Although the carbonat formed by precipitation is, no doubt, chemically the same with the manufactured, their difference, in point of density, is very remarkable.

The proportions of the constituents of this salt are, according to Bergman, 16 acid, 84 oxyd; to Chenevix, 15 aci, 85 oxyd; Prout, 16.15 acid, 83.85 oxyd; and Klaproth, 16.33 acid, 83.67 oxyd in the 100.

The manufacture of white lead has been known long before any idea was entertained of its composition, or the theory of the procés; and it is rather singular that no more improvement has been made in the common procés, which has long appeared to chemists as clumsy and uneconomical.

The procés consists in exposing thin sheets of lead to the fumes of vinegar at a certain temperature. The lead is cast into sheets about two feet long, five or six inches broad, and about 3/4 of an inch thick. These are coiled up, rather spirally, into a cylindrical shape, about five or six inches diameter. The vinegar is placed in the bottom of earthen pots, which are different in size at different manufactories; some holding three pints and others five or six. There is a ledge round the pot, in the inside, about an inch deep, for the purpose of supporting the cylindrical coil of lead, which stands upon it like a chimney. The pots thus fitted, with the lead and vinegar, are arranged in rows, upon a stratum of horfe-litter, or, what is now used as being cheaper, the refuse bark of tanneurs. The ends of all the cylinders of lead are covered with a plate of the same metal, to confine the whole as much as possible to the action of the vapour. The pots thus placed are covered over with litter or bark, and a new stratum of pots arranged in a similar way over them. Several tons of lead are sometimes exposed in this manner at one time. The heat arising from the fermentation of the vegetable or animal matter keeps up a certain temperature, by which the vinegar is slowly evaporated. The vapour oxydates the lead, and the oxyd combines with carbonic acid. This latter subftance was formerly thought to be furnished by the fermenting substance in which the pots were imbedded: it is now, however, known, that the vinegar is decomposed, and furnishes the carbonic acid. White-lead works are at present carried on, both on the continent and in this country, in which the heat is furnished by artificial means only; and of course the carbonic acid can come from no other source than that of the vinegar.

After the lead has been exposed to the vapour of the vinegar for about six weeks or two months, the pots are withdrawn, and the coils of lead are found corroded to a considerable thickness. The white carbonat thus formed is very brittle and very hard. The sheets are now paffed through rollers for the purpose of breaking the white lead from the uncorroded metallic lead. The powder is now taken to a pair of stoves, and ground in a manner similar to corn. After this it is levigated to get it of the greatest possible fineness, and it is then gradually dried in stoves for the purpose.

Densit and whitenefs are the most valuable properties of white lead. These properties do not depend upon the proportions of its elements, but upon the mechanical treatment. The densit in all probability will be greater, as it has been longer forming, by the action of the vinegar being flower. Some of the pieces of white lead, as they are separated from the sheet, are much harder than others, even in the same bed. This hardnes and densit are sometimes so great as to render the pieces incomparably. In this state it is the most valuable. Hence the whitest and denser pieces are selected for making the beautiful substance called flake white.

The value of white lead is easily afeertained by the painters, from the quantity of oil required to give it proper conftency. The greater the proportion of lead to the oil, the greater is the amount of the body of the paint, and the greater will be its whitenefs. The carbonat of lead made by precipitation, when in a dry state, is much whiter than the bell white lead, made in the common way. If, however, equal weights of the two be mixed with oil to make them fit for painting, the precipitated specimen will be found to take a much greater quantity of oil than the other, and its whitenefs much diminished. The common white lead will have lost so little of its whitenefs, that the contrast will be very striking in favour of the latter. This fact is exceedingly apparent, on mixing together transparent media of different densities. The whitenefs of snow depends upon the mixture of small particles of ice with air; for when the snow is mixed with water, the whitenefs disappears. All colourless transparent bodies become white on being reduced to powder. This is observed in powdered glass and in salts which lose their water of crystallization. Whitenefs may therefore be said to arise from a confused refraction of light, rather than from reflection. See Light.

Fluit of Lead.—Fluoric acid does not oxydize lead; but it is capable of combining with the yellow oxyd, forming this salt, which is an insoluble compound. It may be formed.
formed better by adding the fliat of ammonia to nitrat of lead, the fliat of lead falling down in a flate of powder.

Borat of Lead.—Boracic acid does not act upon lead. This falt, however, may be formed by aolution of borat of foda to nitrat of lead. The borat of lead will be precipitated in the formation of an infoluble white powder. This falt, from a vitreous flate which the acid is capable of af-suming, melts into a colourless glafs before the blow pipe.

Acetat of Lead.—Acetic acid has little or no action upon lead when the metal is immerfed in it; but the fumes of the acid in contact with air is capable of oxydating lead, as we have shewn in the manufacture of white lead. The oxyd thus formed is easily taken up by the acetie acid, forming a soluble compound of a sweetish and astringent taste. If the folution be evaporated, an excess of the acid being preent, the falt is obtained in needle-formed cryftals, and of the luftre of satin. It difolves in about four times its weight of water at 60°. It is fingular that this falt is decompoied by the carbonic acid. It is from this circumftance that we always find it decompoied in some degree, by dif-foled in water, which generally contains more or lefs of that fubftance. This falt is used in medicine, uncrystallized, under the name of Goulard's extrait.

The acetat of lead is an article of extensive manufacture in England, France, and Holland.

Common diffilled vinegar is firft faturated with the yellow oxyd of lead, which is fometimes from the carbonat or white lead, and frequently from litharge: the latter, however, is the cheaft and procefs. The folution should have a little excess of acid, elfe it does not form the real falt. By flow evaporation this folution cryftallizes, in which state it is used in abundance in the arts, particularly by the calico printers, for the purpose of getting the acetat of alumine, by double decompoifition with alum.

The analyfis of this falt, according to Dr. Thomfon, is

\[
\begin{align*}
\text{Acid} & = 26 \\ 
\text{Yellow oxyd} & = 58 \\ 
\text{Water} & = 16 \\
\hline
\text{Total} & = 100
\end{align*}
\]

From the combinations of the acetic acid, the earths, and alkalies, it appears that the weight of its atom is about 36.

We have hence \( \frac{102 + 36}{36} = \frac{100}{26} \), which gives 26 of acid and 74 of yellow oxyd = 100.

Subacetat of Lead.—When the falt is boiled for some time with the yellow oxyd of lead, a peculiar falt is formed, confifiting of two atoms of oxyd, and one of acid. It is lefs folute in water than the acetat. It was firft noticed by Thenard, to whom we are indebted for the following analyfis:

\[
\begin{align*}
\text{Acid} & = 17 \\ 
\text{Oxyd} & = 78 \\ 
\text{Water} & = 4 \\
\hline
\text{Total} & = 100
\end{align*}
\]

If it confiis of two atoms of base to one of acid, its analyfis, according to the data in the acetat, will be \( \frac{2 \times 102 + 36}{36} \), which gives 15 acid, and 85 oxyd = 100.

Oxalat of Lead.—This falt is formed by diffoled the oxyd of lead in oxalie acid. In all probability there are two farts of this fpecies. That given by Dr. Thomfon is formed with the second oxyd, and an excess of acid, and is the superacetat. According to Bergman’s analyfis it contains

\[
\begin{align*}
41.2 & \text{ Acid} \\
58.8 & \text{ Red oxyd} \\
\hline
100 & 
\end{align*}
\]

The weight of the atom of oxalic acid appears to be 39, and an atom of the oxyd in this falt 95 lead + 14 oxygen

\[
= 100, \text{ therefore supposing it the super falt } 95 + 14 + 39 \times 2 = \frac{39 \times 2}{100}, \text{ which gives } 41.7 \text{ acid, and } 58.3 \text{ red oxyd } = 100.
\]

The proper oxalat of lead may, no doubt, be formed by an alkaline oxalat being added to the nitrat of lead, the falt being precipitated in a flate of infoluble powder. From the above data it ought to confift of 27.7 and 72.3 yellow oxyd.

Tartrat of Lead.—The tartaric acid does not act upon lead; but this falt may be formed by adding an alkaline tartrat to the acetat, or nitrat of lead. The tartrat of lead falls down in the form of white powder. Dr. Thomfon gives the analyfis of this falt at 37.4 acid, and 62.56 yellow oxyd.

Citrat of Lead.—This is an infoluble compound, formed by adding an alkaline citrat to a folute falt of lead.

Malat of Lead.—Malic acid has no action on lead; but the acid combines with the oxyd, forming a compound infoluble in water, but folute in acetic acid. Cyder, which contains an abundance of malic acid, would never contain lead, but from the prevalence of acetic acid. If aecat of lead be dropped into cyder, a copious precipitate falls down, but if free acetic acid be added, the precipitate is diffoled.

Arsenieat of Lead.—The arfenic acid is capable of oxydating lead, and then combines with its oxyd, forming arfeneat of lead, which is completely an infoluble compound. It may also be formed by adding the arfeneat of potafli to a folute falt of lead. From the analyfis of Chenexis it confiis of 33 acid, 63 yellow oxyd, and 4 of water. According to Thenard, it is compoied of 35.7 acid, and 64.3 of oxyd. See the native arfeneat of lead under the mineralogical part of this article.

Molybdat of Lead.—The artificial falt of this fpecies has been little examined. See the native falt.

Chromat of Lead.—This falt may be formed by adding an alkaline chromat to a folute falt of lead. The falt is precipitated in the form of powder of a reddifh-yellow colour. It is folute in potafli and foda, from which it may be precipitated without changing its properties. It is folute in nitric acid, but it is decompoied by the muriatic and fulphuric acids. See native falt.

The other fpecies of the farts of lead are not of importance. The alkalies and some of the earths diffole the oxyd of lead.

Potafli and foda, when pure, diffole the greatest proportion. By exposure to the air, however, the carbonic acid of the atmosphere combines with the oxyd of lead, as well as the potafli. The lead is precipitated in a frate of carbonat.

These alkaline folutions of lead have the property of staining hair, wool, and horn. The tint commences with a light fawn colour, and ultimately becomes of a deep and beautiful reddifh-brown. These colours are not permanent, being quickly faded by exposure to the light and the air.

Lime
Lime water, and probably solutions of barytes and fritter, diffuse the oxyd of lead, but in smaller quantity. A liquid formed by boiling lime and lathyrus water, has also the property of thinning wool, but the colour is somewhat different from the brown given by the alkaline solution. The brown colour has left of the red and more of the yellow tint. A composition of common pearl-ash, red lead, and quick lime, is used to give horn the appearance of tortoise shell. In effect, this composition is a solution of the oxyd of lead in potash.

Lead, as we have already seen in the preceding part of this article, is much used in buildings, particularly for covering, gutters, pipes, and in glass windows. For which use, it is either cast into sheets in a mould, or milled; which latter, some have pretended, is the lead serviceable, not only on account of its thinness, but also because it is so exceedingly fretted in milling, and rendered so porous and spongey, that when it comes to lie in the hot sun, it is apt to shrivel and crack, and consequently will not keep out the water. Others have preferred the milled lead, or flatted metal, to the call, because it is more equal, smooth, and solid.

The lead used by glaziers is first cast into slender rods, twelve or fourteen inches long, called canes; and these, being afterwards drawn through their vice, come to have a groove on either side for the panes of glass; and this they call turned lead.

The method of paling or folding lead for setting on of imbossed figures, &c., is by placing the part wherein the figure is to be paled horizontal, and drawing on it some pulverized resin; under this they place a chafing-dish of coals till such time as the resin becomes reddish, and rifes in pimples; they apply the figure, and rub some soft folder into the joints; when this is done, the figure will be paled on, and as firm as if it had been cast on.

Lead is much used in varnishes and painting with oil, both as a colour and as a dryer. It is also used in the preparations of enamels and of porcelain as a flux, and makes the basis of the glazing of almost all pottery wares, and by means of lead the most perfect metals are refined and alloyed.

**LEAD, in Medicine.** This metal is celebrated by some chemical writers for its great medical virtues; but after all it seems to be a metal which ought to be given internally with the greatest caution, and to be rather calculated for outward application. Its ore is so poisonous, that the flame arising from the furnaces where it is worked, infects the grafs of all the neighbouring places, and kills the animals which feed on it. The poisonous quality of this ore is such, that the people who live in the countries where it is dug, and near the places where it is washed, can keep neither dog nor cat, nor any kind of fowl, but all die in a short time, and it has been known that a little house, in which lead ore had been kept for some time, though afterwards made very clean, and bedded with fern, infected calves which were put into it, so that all died in a very short time; and it is a too melancholy observation, that children often die strangely and suddenly about these places. Philosophical Collections, N. 2. p. 6.

Its best preparation is *fasciunum saturni,* or the super-acceptate of lead; which, though capable of doing great good in hemorrhages, and some other cases, is apt, however, to bring on colics of fo violent a kind, that the remedy often proves worse than the disease.

The internal use of lead is dangerous, on account of the colics and pallsies that are occasioned by it. Culinary vessels, lined with a mixture of tin and lead, which is the usual tinning, are apt to communicate to acid foods pernicious qualities, and require to be used with great precaution. The same thing has been also said of liquors kept in glazed ware, and of cyder made in vessels, where lead is used, and of wines adulterated with lathyrus, &c. See the article Lead, *fascia,* and Colica Pictauna.

M. Navier has lately discovered that the liver of sulphur, and particularly liver of sulphur of Mars, is an excellent antidote against the poison of lead; and he advises patients laboured under its pernicious effects to drink largely of acidulated liquors, to make afterwards the liver of sulphur the principal part of the cure, and to finish the cure with gentle purgatives.

The Dutch have been charged, correcting the more offensive expressed oils, as that of rape, feed, so as to sublimate them for oil olive or oil of almonds, by impregnating them with lead, in order to detect this abuse, mix a little of the fulpected oil with a solution of opium made in lime-water: on shaking them together, and suffering them to reft, the oil, if it has any fatal taint, will appear of an orange-red colour: if pure, of a pale yellowish. The lead is discovered in wines by the same fulphureous solution, which changes the colour of wines impregnated with this metal to a brownish red or a blackish hue. However, the various preparations of lead are applied externally with safety and great benefit, on account of its sedative, drying, and repellent qualities. The vinegar and sugar of lead, and all the ointments and plasters which contain cerussa, minium, or lathyrus, eminently poifie the qualities. See the following articles and references.

For the laws relating to lead, and the dealing of it, see 27 Ed. III. stat. 2. c. 1. 3. 15. 38 Edw. III. stat. 1. c. 6. 4 Geo. II. c. 32. 29 Geo. II. c. 30. See Larceny.

**LEAD, Black.** See Plumbago.

Black lead in fine powder may be readily mixed with melted sulphur, and though the compound remains fluid enough to be poured into moulds, it looks nearly like the coarser sorts of black lead itself. This was probably the method by which prince Rupert is said to have made black lead run like a metal in a mould, so as to serve for blacklead again. Birch's Hist. Royal Soc. vol. iii.

The German black-lead pencils, and those which are hawked about among us, are prepared in this manner: their melting or softening, when held in a candle, or applied to a red-hot iron, and yielding a blueish flame, with a strong smell like that of brimstone, discovers their composition. Pensils of this kind are hard and brittle, and cut or scratch the paper or wood instead of marking them. The true English pencils are formed of black lead alone, fawed into slips, which are fitted into a groove made of the softest wood, as cedar, and another slip of wood glued over them. These pencils, however, are of different quality, on account of different sorts of the mineral being fraudulently joined together in one pencil, the fore-part being commonly pretty good, and the reit of an inferior kind. To avoid these inconveniences, some take the finer pieces of black lead itself, which they saw into slips, and fix for use in port-crayons. Lewis's Commerce of Arts, p. 328.

By our laws, entering mines of black lead, with intent to steal it, is made felony. See 25 Geo. II. c. 10. See Larceny.

**LEAD, for the manufacture of, see Plumberry.**

There are various preparations of lead, serving for various purposes, some of which are now dispersed, and others, under one form and name, or another, still continued.
LEAD. Balsam of, an external medicine, formerly famed for its effects in old and sharp ulcers. It is made by mixing one ounce of sugar of lead with two of oil of turpentine, and setting this mixture in a sand-heap till the salt is dissolved. By this means the oil acquires a red colour, and is called balsam of lead.

Lead, Burnt, plumbeum a/burn, is a chemical preparation used in medicine, made of plates of lead, melted in a pot with fulphur, and reduced by fire into a brown powder.

Lead continued in fusion and fired, so that dry surfaces may be exposed to the air, will gradually change into a powderly dulky-coloured calx, bearing this name.

Burnt lead is only intended for external use. It has the same virtues ascribed to it, in ointments and plasters, like litharge or minium. Mixed into an unguent with lard alone, it makes a good ointment for the piles.

Lead, Butter of, is a kind of liquid, yetungent made of vinegar and lead, incorporated with rofae oil, and commended for the cure of titters. It is called butyrum saturni.

Lead, Calcinis, or calx of lead. See Calx, Cerussa, Glass of Lead, Litharge, Massicot, Minium, &c. and Alloys of Lead, supra.

Lead, Casting of. See Casting.

Lead, Cerat of Super-acetate. Ceratium plumbe super-acetatis, the Unguementum cerusae acetatis of P. L. 1787, is prepared in the following manner: Take of super-acetate of lead two draehms, while wax, two ounces, and olive oil, half a pint. Dissolve the wax in seven fluid-ounces of oil, then gradually add to it the super-acetate of lead, separately rubbed down with the remaining oil, and stir the mixture with a wooden file, until the whole has united.

Lead, Compound cerate of. See Ceratum lithargyri acetatis composition.

Lead, Colofen of. See Cohesion.

Lead Dust is a preparation used by the potters; made by throwing charcole dust into melted lead, and stirring it a long time together; to separate the coal again, they only wash it in water, and dry it after. Its use is, to give a varnish and gloss to their works.

Lead, Extract of, or Saturn, is prepared by simmering together as many pounds of the litharge of gold as quarts of vinegar for an hour and a quarter, and often stirring them; then taking it from the fire, and as soon as it is cool enough, pouring the clear liquor into bottles to be kept for use. If this liquor be made into the common confidence of an extract, it must boil yet longer after its separation from the mafs, and will acquire a reddish colour. This is Goulard's extract (see Lead, supra), and the basis of all his preparations of lead. It evidently differs in no respect from fugar of lead, and vinegar of litharge, but in the degree of concentration. The only circumstance in which the extract seems to have the advantage of sugar of lead, appears to be in the greater quantity of the acceous acid contained in it, which proves an excellent effiant in many cafes, and the furger of lead, when once crystalized, cannot be brought back to that state of solution in vinegar in which it was before; yet where a large quantity of watery membrain is added, as in Mr. Goulard's faturnine water, it is as well to make a solution of furger of lead in the water, and add the vinegar afterwards, as to mix them both together in the form of extract. Aikin's Obs. on the external Use of Preparations of Lead, &c. p. 2. See Vinegar of Lead.

In the London Pharmacopeia of 1787, this was denominated "Aqua lithargyri acetati," and in the last edition it is called "Liquor plumbi acetatis," or "solution of acetate of lead," and it is directed to be prepared by mixing two pounds four ounces of semi-vitreous oxyd of lead, with a gallon of acetic acid, and boiling down to six pints, continually stirring; then setting it by, that the feculences may subside, and draining. This is a dense liquor, of a deep brown colour, and consists of a satureted solution of subacetate of lead. It was restored in the last Pharmacopeia, in consequence of the celebrity it had obtained under the name of "Goulard's Extract." The "Aqua lithargyri acetati composta" of P. L. 1787, called in the last edition "Liquor plumbi acetatis dilutus," or "diluted solution of acetate of lead," is prepared by mixing a drachm of solution of acetate of lead, a pint of distilled water, and a fluid-drachm of weak spirit. When this mixture is made, even with distilled water, some precipitation takes place; and when, as is more common, ordinary water, containing any muriates or sulphates, is used, this is much more abundant from double decomposition, and gives the liquor a milky appearance when diffused through it. To this it owes its common name of "white wash."

Lead, Glue of. See Glass of Lead.

Lead, Magister y of, is the cals of lead purified and sublilated. It is made of lead dissolved in aquafortis, pouring filtrated salt water into it; whence extractus a magister extremely white, which, when softened by several lotions, is mixed with pomatums for the face and complexion.

Lead Mine. See Mining.

Lead, Mock, a name given to a glittering substance found in lead-mines. See Galena inans, and Blinde.

Lead, Naive. See Lead, supra.

Lead, Ointments of, Preparations of. See Unguent.

Lead Plunger. See Emplastrum Commun.

Lead Pipes, Manufacture of. The common method used for making lead pipes, consists in casting the lead upon a smooth flled mandril placed in a mould, also of metal, to form the outside. These pieces are about 18 inches long. They are afterwards joined together by a process called lining.

A very great improvement has been made in the manufacture of lead pipes, by drawing them in a manner similar to wire. The lead to form the pipe is cast upon a mandril of the diameter of the inside the pipe, but of such a thickness as to equal the whole pipe in weight: it is then fastened upon one end of a cylindric steel mandril, and the lead is pulled through different sized holes, till the pipe is of sufficient length and thickness. These pipes can be drawn to the length of eight or ten feet. The power required, however, is very great, which is one objection to the method. They are also liable to flaws; for, if the casting happen to be imperfect, the imperfection is much increased and extended by the process of drawing.

This manufacture has been much improved by passing the lead upon the mandril, through grooved rollers of different sizes, following each other in succession. The power required is much less than that required for drawing; and the pipes are said to be superior in other respects. For a more particular account of this manufacture, see Lead Pipes.

Lead, Red, a preparation of mineral lead calcined and rubbed; used by painters, potters, and surgeons. See Minium, and Oxyd of Lead.

Lead, Salt or Sugar of, Saccharum saturni, Superacetatus plumbi, superacetate of lead, is an essentlial salt of vinegar, incorporeated with the proper substance of lead, or cerusses, dissolved in spirit of vinegar. See Saccharum Saturni, and Lead, supra.
LEAD

LEAD, Tincture of. See TINCTURA SATURNIA.
LEAD, Vinegar of, or of Libarge. See VINEGAR.
LEAD, Water of, Aqua Saturni, is called by Mr. Gouard vegeto-mineral water, which makes it by dropping into a quart of pure water a hundred drops of the extract of Saturn, and then adding to them four tea-spoonfuls of brandy. This is his specific in external inflammations, particularly of the eye, for washing ulcers, cancers, scrofulas, contusions, phlegmons, erysipelas, piles, chillblains, tetter, garrigrenes, &c. But a solution of the faccharum saturni will have the same effect.

LEAD, White. See CERUSE, and LEAD, supera.
LEAD Nails. See NAILS.
LEAD, in the Flanges, is a term used to express the part that begins any motion first. A horse going in a straight line always leads, or cuts the way with his right foot. This is called in French intemер le chemin.

LEADWORT, in Botany. See PLUMBAGO.
LEADERS, in the Military Art. See FILE-LEADERS.
LEENA, the lioness. See LIONESS.

LEAF, (FOLIUM), in Botany and Vegetable Physiology, is a very general, but not universal, organ of the herbage of plants, of the first importance to vegetable life, being, in many respects, equivalent to the lungs of animals; inasmuch that when leaves are not present in the usual manner, their office must be performed by some other part, which is generally the stem. Leaves are, for the most part, remarkable for their expanded form, in which the object of nature is manifestly to present to the atmosphere as wide an extent of surface as possible, greatly exceeding that of all the rest of the plant. "Their colour is almost universally green, their internal substance pulpy and vascular, sometimes very succulent, and their upper and lower surfaces commonly differ in hue, as well as in kind or degree of roughness."—How great a share the foliage of plants has in contributing to the beauty of the vegetable creation, and how widely their utility extends, in the usefulness they afford to the animal world, not to mention their various economical uses to mankind, is too evident to require much illustration. Their curious structures, and their real use to the plant that bears them, has not till lately been properly understood or fully appreciated. The science of chemistry was, for a long time, not sufficiently advanced to throw the necessary light upon this subject; and even at the present day, when applied to the physiology of vegetables, it serves rather to help us to conceive what may be, than to see clearly what is, translated in their apparently simple, but truly elaborate, frame.

The first who attempted to reason upon the uses and properties of leaves was Cæsalpinus, who merely supposed them a sort of clothing, or protection against cold and heat. It is not worth stating to consider his reasons, for an opinion which is so inadequate to what it attempts to explain. This writer conceived the foliage of plants to originate from, or to be, a sort of expan'sion of their bark.

Some of the first practical observations that tended to discover the importance of leaves, were made by gardeners, who, in their various treatment of fruit trees, soon found they were not to be stripped of their leaves, even partially, without caution, and that a general injury to the foliage insensibly ruined the fruit. They have also universally discovered, by experience alone, the benefit of removing decayed or sickly leaves; which all books on gardening have never failed to inculcate, though the writers had no idea of the manner in which the morbid secretions, or corrupted exhalations, of these bodies, might injure the growing plant.

LEAF

When gooseberry or currant bushes are stripped of their leaves, by the voracity of caterpillars, every body knows that the fruit, if not withered, is altogether tasteless. We cannot even yet precisely trace the mode in which this effect is produced, except that it evidently arises from a great, though only temporary, injury to the constitution of the shrub, caused by its premature and violent defoliation. This injury is repaired in the ensuing season.

The absorption and perspiration of leaves could not long remain unobserved, with these organs came to be considered with any philosophical attention. Hales and Bonnet have made the best and most numerous experiments on this part of their functions. The former first suggested the probability of their imbibing air as well as moisture, nor did the action of light upon them escape his sagacity, though frequent chemists and physiologists have pursued these subjects to a far greater extent. The fading of a leafy branch of any plant when gathered, and its revival, on being immersed for a short time in water, sufficiently evince the perspiring and absorbing powers of the leaves. Dr. Hales first determined the proportion of each, by experiments upon the great annual sun-flower, the vine, cabiag, &c. On the first-mentioned plant he bestowed particular attention, and the result of his observation was that it lost 1 lb. 14 oz. weight in the course of a hot dry day, but in a dry night only three ounces. In a rainy night it gained two or three ounces by abstraction. The surface of the plant, compared with that of its roots being, as nearly as could be calculated, in the proportion of five to two, it follows that the daily abstraction by the roots was so much the more rapid, in order to make up the loss which took place in the herbage. Compared with the ordinary insensible perspiration of the human body, that of the sun-flower is only as 15 to 50; but the bulk or solid substance of the two being extremely different, that of the vegetable being so much more diluted, it is found the latter perspires seventeen times more, in proportion to its bulk, than the human frame. These proportions of course vary in both, according to circumstances. If the roots be plentifully watered, the evaporation by the leaves is the more copious and rapid. In newly removed plants, the abstraction by the leaves supplies the wants of the vegetable body, till the roots have shot forth new fibres in order to obtain moisture in that their natural direction; but if such plants be immoderately watered, they may be killed by excess of moisture; for no evaporation by the leaves being allowed to take place, nothing can be imbibed by the roots. In certain states of the atmosphere, some plants are frequently exhausted by their perspiration, and drop for want of adequate supplies from the roots; while others are so constructed as to perspire very slowly, and therefore to resist the effects of the most parching air or sun. Such is the nature of the cuticle that covers the leaves of aloes, and of all succulent plants, more or less, that although they perspire but very slowly, they absorb with great facility. Hence these plants are admirably adapted to the arid dry rocks, or amid the soil and sandy deserts of Africa, where the rare and trivial supplies of rain which fall to their lot during a great part of the year, prove sufficient for their support in consequence of their tardy perspiration. It is truly worthy of remark, that this difference, in their powers of imbiving and giving out moisture, exists only while these plants retain their living principle. When killed by the application of great heat or cold, their leaves dry as quickly as any bodies of equal thickness. Evergreens are found to perspire much less than other shrubs, while the Cornus masula, or Cornelian cherry, a plant with a thin dry leaf, was found...
found by Du Hamel to perspire to the amount of twice its whole weight in 24 hours.—See Perspiration of Plants.

The best observations on the absorbing power of leaves, and its difference in different plants, have been made by Bonnet, and are recorded in his book entitled Recherches sur l'Usage des Feuilles. By laying good, healthy, full-grown leaves of various herbs or trees upon the surface of water, some with the upper, and others of the same species with the under, side applied to the water, he observed in which situation they continued longest in health and vigour; and also how far different species differed from each other in this respect. In general, herbaceous plants swallowed the liquid this continued and copious application of wet to their upper surface, while various trees on which the same experiment was made, decidedly preferred absorption by their under side.

The absorption and evaporation in the leaves of aquatic plants, whether, like many species of Potamogeton, as well as the Zannichellia, the Chara, and all the submersed Algae, they are entirely under water; or whether, like the Nymphaea, they float on its surface; appear in general to be very rapid; such plants, however juicy, drying with great rapidity when taken into the air. They are, for the most part, highly vascular, and, no doubt, have an equal facility in imbibing and in giving out water.

Although most leaves are so formed as to have decidedly an upper and under surface, the sword-shaped plants (see ENSETE) are an exception. Their foliage is vertical, and has little or no upper surface, except where it embraces the stem; what is analogous to the under side of ordinary leaves, being in fact so circumstanced in these, as to constitute their whole surface. Other leaves are so cylindrical that no difference of sides can be traced. In all these the absorbent vessels and the periphoring ones must be dispersed alike over the whole expansion of the leaf; as they are over stalks, and especially over the stems of plants that have no leaves at all, in which nevertheless all the known functions of leaves necessarily take place. This latter is the case in the whole genus Stapelia, and in many species of Calotis, as well as in several rush-like plants, and those singular productions the Caffica and Caffiola.

There are, in a very few instances, strange aberrations of configuration in leaves, delined to the accomplishment of some particular purpose. Thus, those of the Dionisus, (see that article,) bear an appendage like a rat-trap, the toothed lobes of which, when immolated, clove upon each other, and imprison any insect that may have happened to alight upon them. The leaves of the Sarracenia are tubular, and those of the Nephenthes bear each a tubular appendage with a lid. These are found for the most part full of water, that seems to be secreted or poured out by the vessels of the leaf, rather than received, as has commonly been fancied of the Sarracenia, from the atmosphere. This water is the retort of insects, who mostly perish in it, and the materials of their decomposing bodies are furnished to minifier to the health of the plant. The Drosera, found in our bogs, eat up insects by the viject and irritate hairs of their leaves, apparently for a similar purpose.

This leads us to consider the effects of air and light upon vegetables, through the medium of their foliage, which, in this point of view, is transcendentally important.

Grew and Malpighi, independent of each other, but about the same period, detected, in the leaves of plants, abundance of vessels full of air, as also the spiral-covered tubes or vessels of the film, considered by their discoverers, as well as by subseqent physiologists to till very lately, in the light of air-vessels likewise, because, like the arteries of the animal frame, they appeared, on division, to be empty, or at least not occupied by the sap or juices of the plant. On the detection of these vessels, physiologists theoretically supposed leaves to imbibe air, "which the spiral vessels were believed to convey all through the plant, in order that it might act on the sap as it does on the animal blood."

The analogy thus underlaid was not correct, because air is conveyed no further than the lungs of animals; but without this hypothesis no use could be found for the supposed longitudinal air-vessels." Now it is proved that these longitudinal spiral-coated tubes do really transmit the sap from one part of the vegetable frame to another, finally conveying it into the leaves, where it is acted upon by the air, either of the above-mentioned vessels, or of the atmosphere. The analogy with animal respiration holds good, therefore, much more correctly than the authors of the above hypothesis imagined. On this subject we need not repeat what is said under the article Circulation of the Sap.

Dr. Hales's experiments with the air-pump, to prove the transmillation of air through the vegetable body, are to be regarded with caution, as merely showing that air will pervade their longitudinal vessels, when a branch is cut, and its vital principle probably in some degree injured; at least when the natural movement of its sap is by no means going on, nor that fluid remaining in its natural situation. Air is obtained in abundance, by means of the air-pump, from every part of the vegetable body, as well as from recently extracted sap; and plants are found to perish very soon in an exhausted receiver. Hales rightly remarked, that air is not only taken in by plants very copiously along with their food, but also imbibed by their bark, as well as through the surface of their leaves. Yet we cannot follow him when he adds, "especially at night, when they are changed from a perispire to a strongly imbibing state." Such a difference between night and day seems merely to regard the watery absorption and perspiration of leaves, the introduction of air, or rather its action upon them, being doubtless carried on chiefly in the light, that body having a principal share in the result. Nor did this escape the sagacity of Hales, who, after concluding that "one great use of leaves is to perform in some measure the same office for the support of the vegetable life, that the lungs of animals do, for the support of the animal life; plants, very probably, drawing through their leaves some part of their nourishment from the air," adds two pages further; "and may not light also, by freely entering the expanded surfaces of leaves and flowers, contribute much to the enabling the principles of vegetables?"

Bonnet's experiments and enquiries, respecting leaves, principally elucidate their absorbing powers, proving them to be "furnished with a system of cuticular absorbents, which carry fluids into their sap-vessels, so as to enable them, in some degree, to dispense with supplies from the root." This philosopher has not improved upon the ideas of Hales, respecting the effects of air or light upon plants. He does not appear to have had any conception of leaves imbibing air and giving it out again; still less of their effecting any change in its properties. He was not aware that the bubbles he observed clinging to leaves, whether dead or living, when placed under water, and exposed to a bright sun, were separated, by the action of light, from the water itself; so that he has no right to be considered as the discoverer of the expiration of plants.

The great Dr. Priestley first pointed out a property in growing
LEAF.

growing vegetables, of absorbing carbonic acid gas, deno-
minated by him fixed air, by the upper surface of their
leaves, and of giving out by their under surface oxygen
gas, or pure respirable air. Dr. Ingenhousz improved upon
this important discovery, by observing light to be necessary
to these functions, remarking that in the dark leaves give
out a bad or carbonic air, and that fruits and flowers almost
invariably give out the lost-mentioned kind of air, at all
times, but especially in the dark. Aquatic or bog plants,
as the Epilobium and Nymphea, were found by these philo-
sophers to excel remarkably in this faculty of purifying air,
or of changing it from a carbonic to an oxygenous nature.
This operation is, in most cases, performed very quickly.
A vine-leaf in an ounce phial of carbonic acid gas, that
immediately extinguished a candle, being set in the fun,
without water, changed it to pure respirable air in an hour
and a half. Dr. Priestley found some of the bog-plants to
alter even unmixed inflammable air, or hydrogen. Succe-
quent leaves afford most of the purified air in question, becau-
se of the abundance of their cellular parenchymatous sub-
stance, in which the chemical operations of leaves are per-
formed, and in which their green colour chiefly refines.
This colour therefore does not exist in leaves never ex-
posed to the light, in which consequently no such chemic-
al operations ever take place. The fickle white observ-
able in that part of celery stalks, or of the sprouts of al-
paragus, indeed of all plants, which is under the surface
of the ground, is entirely owing to the absence of light;
for when exposed to light such parts become green like the
reft of the herbage. It is found that exposing plants to
the action of hydrogen gas will produce the same green
colour, even if they are kept in the dark.
Every person attentive to the growth of plants must
have observed the constant direction of the upper surface
of their leaves towards the light. When the situation of
branches naiied to a wall is altered, and the position of their
leaves disturbed, the latter refuse their natural posture in a
day or two, and the more speedily in proportion to the
brightness of the weather. It has long been known that
light acts beneficially upon the upper surface of leaves, and
hurtfully upon their under side; for if the latter be re-
peatedly turned to the light, or forcibly kept in the un-
natural position, the leaves grow fickle, black, and disco-
roured spots appear about the veins at their backs, and the
cuticle lefles off. Thus we have the Magnolia grandis-
flora, whose rigid leaves do not readily change their posture,
very materially injured, by nailing it to a wall in hot and
bright weather. The under surface of its foliage became
decayed, and the colour of the other side fickle.; the leaves
fell prematurely, and the plant was long in recovering its
health. One great use of footstalks to leaves appears to be
to facilitate their turning to the light, and varying their
position as the sun pursues its course; as may be seen in
clover and other papilionaceous plants more especially.
Leaves separated from their parent branch, and furnished
deliberately by a fine thread, turn to the light as effectually
as if in their natural situations. This power, however, of
turning to the light, is not equally obvious in all leaves.
Such as are very much folded or plaited, necessarily prefer-
ing, on that account, about an equal portion of their
surface to the sun in every position, arc often less moveable;
and this may account perhaps for the insensibility observed
by Bonnet in the mallow. Sword-shaped leaves are always
vertical, and do not alter their position. Those of the pa-
pilionaceous tribe are, as we have already hinted, among
the most sensible. Light feeds, in many influences, the foli-
cafe of their expansion, for when it is withdrawn, they
fold together and droop as if dying; such a state of relaxa-
tion being very elegantly, and indeed, as it appears, very
correctly, termed by Linnæus the sleep of plants, on which
subject he has left us a curious dissertation in his Amo- 
natiaes Academicæ, v. 4. p. 333. He there justly remarks
that the general aspect of a field, a garden, or a hot-house, is
wonderfully changed during a summer's night in Sweden, so
as to puzzle the most experienced botanist, owing to a general
alteration in the posture of the foliage of plants. Some
fold the two sides of the leaf together; others turn their
leaves upward, so as to enclose the flowers, which they thus
shelter from nocturnal dews that might interfere with their
impression; and many press their foliage downwards,
close to the stem or branch, whose buds they thus perhaps
protect from cold. Such movements evince a portion of
that irritability, dependent on life, which is more strikingly
displayed in the sensibility of some leaves to the touch of
any extraneous body. Several species of Mimosa, ca-
led for that reason sensitive plants, as well as a few others
of different genera, fold up their leaves when any concussion
is given to the plant. If any of their leaflets be shaken or in-
jured, the irritation is communicated to the neighbouring
ones, and thence, with accelerated velocity, to the reft,
even to other leaves on the same branch or root. The leaves
of the Hedyarum gymnæs of Bengal are remarkable for a
spontaneous movement, apparently independent of external
stimulation. They are tender, and their small lateral leaf-
lets move frequently, but irregularly, up and down, inde-
pendent of light, requiring only, for the performance of this
action, a warm and still air. This, like all other move-
ments of leaves, is most conspicuous in such as are young.
In consequence of the observations of Priestley and Ingen-
housz, confirmed, variously extended, and explained upon
the principles of improved chemistry by succeeding philo-
sophers, the effects of light, heat, and atmospheric air
upon leaves, and, where these are wanting, upon the green
flews of plants, are now, as far as concerns all vegetables in
common, tolerably well understood. It is agreed that in
the day-time the parts in question imbibe from the atmo-
sphere carbonic acid gas, which they decompose, absorbing
the carbon as matter of nourishment, which is added to the
fap, and emitting the oxygen. Plants absorb the same gas
from water, when by the action of light it is separated from
that fluid. Air contaminated with this gas by the burning
of a candle, or the breathing of animals, serves therefore
as food for vegetables, who in their turn purify it again,
and render it fit for the support of animal life, by the oxy-
gen given out from their leaves under the influence of light.
Hence arises a mutual and essentzal dependence of the animal
and vegetable kingdoms on each other, for the discovery of
which, one of the most curious and beautiful in natural philo-
sophy, we are principally indebted to Dr. Priestley, that
great name from which fanaticism would gladly tear, if it
could, even the laurels of science.

The above view of the functions of leaves exactly coin-
cides with Mr. Knight's theory of vegetation, of which we
have given an outline in our article Circulation of the Sap.
That gentleman has proved, that very little albumen, or
new wood, is secreted when light is kept from the leaves.
We are also thus enabled to understand how essentzal oils
may be produced, which, as well as sugar, are known to be
composed of oxygen, hydrogen, and carbon in different pro-
portions. The various modifications of mucilage, detected
and distinguished in the vegetable body by modern chemistry,
are perhaps, as more dependant on the vital principle for
their
their formation, more inexplicable by chemical laws. It is perhaps in vain to attempt to explain how any particular secretion is elaborated. Still less can we comprehend how different tribes of plants, growing in the same soil, even vegetating in the same distilled water, should regularly produce, as far as the health of the individuals under experiment will allow, their own peculiar secretions, ever preserving the most essential qualities of their species in this respect. How the nutritious sap, originally similar in these different plants, can be so operated upon, by the very same agents, in the thin and tender structure of the different leaves, as to produce substances so totally unlike each other as we meet with in plants, whence their various flavours and qualities originate; all this is inexplicable in our present state of knowledge, though transmitted every moment before our eyes. The different secretions in various organs of the same individual vegetable body; the acrimony of the leaf, the bitter of the bark, the perfume of the blossom, the sweetnens and acidity of the fruit; all these are not less wonderful. We understand enough indeed to conceive how the reflux may be accomplished, and may congratulate ourselves on being allowed even a glimpse of those mysteries of nature, which our finite powers are inadequate fully to comprehend.

Having said so much on the physiology of leaves, it is necessary to consider them in another point of view, for the purposes of scientific botany. In differentiating the species of plants a knowledge of the various forms of leaves is of the utmost importance, nor are they entirely useless in the discrimination of natural tribes or orders. It is universal with grasses and the orchis family to have simple and undivided leaves; it is nearly as general for the papilionacees or leguminous tribe to have compound ones. In some orders they are always opposite, in others alternate; in some genera evergreen, in others deciduous; but these latter circumstances are liable to various exceptions. Trees and shrubs of North America, and even those of Europe, generally related to them, have a general tendency to assume very brilliant colours in their foliage, as it verges towards decay. Grasses, on the other hand, are very uniform and constant in their green colour, which is seldom changeable. Evergreen leaves are commonly darker coloured, though more shining than others, and will often thrive with a less proportion of light than is necessary for other trees. The lower leaves of herbs that grow in lofty and windy situations, are frequently much less divided than the upper ones, while the reverse is the case with most aquatic plants, whose lower leaves, immerged in the water, are sometimes quite capillary, while the uppermost are broad, and float on its surface; witness the Ranunculus aquatilis, whose white flowers arrange our ponds in summer. The action of a running stream appears to elongate the leaves of this, as well as of many other plants. The dilated form of leaves in general, by which they present so large a surface to the atmosphere, causes them to be the more easily diffused by autumal storms, when their connection with the branch or stem has already become gradually loosened by their approaching decay. See DIESEOUS, and FALL OF THE LEAF.

Leaves are, in the first place, to be considered as to their situation and position.

Folia radicalia, radical leaves, springing from the root, as in the Primrose and Cowslip; caudina, item-leaves, grow on the item, as in the White Lily; ramea, branch-leaves, if different from those of the main item, require to be distinguished from them, as in Purple Cow-wheat, Melampyrum arvaevae.

Alterna, alternate leaves, stand solitary on the item or branches, as in Willows and many common plants; opposita, opposite ones are found in the Lilac, and many others equally common; sparsa, are scattered without any order, as in the Orange and White Lilies; confluenta, are crowded together, as in the Rhododendron and Azalea.

Bina, are only two upon a plant, like those of the Lily of the Valley; terna, stand three together, as in the sweet Verbenatriphylla, and often in the Fuchsia; quaterna, quinua, fema, &c. are when four, five, fix, or more, surround the item in a whorl, as in some kinds of Heath; verticillata, whorled leaves, used without any reference to the number, expresses this mode of growth, as exemplified in the Wood-ruff, Madder, and many plants of the same as well as different families.

Pectinata, tufted leaves, are seen in the Larch and Cedar; imbricata, lying like tiles upon a house, in the Common Ling; decussata, stand in pairs crossing each other, as in the Cape Spurge, Euphorbiæ Lathyris; difficila, two-ranked, spread in two directions, yet are not regularly opposite at their origin, as in the Yew; secunda, are unilateral, leaning all toward one side, as in the Solomon's Seal.

Adpressa are closely pressed to the item, as in some kinds of Xeranthemum and Spurge, in which case the back of each leaf only is presented to the light; verticillata, stand perpendicularly, with both sides equally at right angles with the horizon, like the Lathyrus Scariola, but such a case is rare, except in sword-shaped leaves; erecta, are such as grow nearly upright, forming a very acute angle with the item; patens, spread more in the usual manner; horizontalia, or potentilla, spread in the greatest possible degree; reclinata incline downward, the extremity of each being lower than the base, or point of infection; recurvata, are curved backward, as in Erica retorta; incurvata, turn inward, as in E. empetriformis; obliqua, are twisted, so that one part is vertical, the other horizontal; refusinata, are so completely turned or reversed that the upper surface is become the under, as in Affremeria palmerina; depressa, are radical leaves pressed close to the ground, like the Hoary Plantain, Plantago media, or any succulent ones that are vertically flattened, in opposition to comprimata, flattened laterally; natantia, float on the surface of water; demersa, immeris, or submera, are plunged beneath it; emerita are raised above the water, others upon the same plant being sunk below its surface.

The inflection of leaves means the mode in which they are connected with the parent plant.

Petiolata, stand on footstalks (petiole) either long or short, simple or compound; pelletata, have the footstalks inflected, not into the base as usual, but into the middle of each leaf, like the arm of a man holding a shield, as in the Common Nasturtium or Tropæolum; sejalis, sejilis leaves, sprigging immediately from the item, branch or root, without any footstalk, of which examples are frequent; amplexicaulis, clasp the item with their more or less dilated base, being usually alternate; connata, or connato-perfoliata, are opposite leaves, united at the base, so that the item runs through them; perfoliata, have the item running through them in any way whatsoever, as Bupleurum perfoliatum, called Thorow-wax, from way to grow, in allusion to this circumstance; vaginata, are such as sheath the item, or each other, with their base, which is exemplified in most grasses, and many liliaceous plants that have no item; equinata, embrace each other with their comprifed base, while they spread upwards in two ranks, of which the genus Iris affords many examples; decurrent, fur.
Leaf.

run down the stem or branch in a leafy border or wing, as in many Thistles, and the Great Mullein; _florifera_, bear the flowers out of their disk or margin, as in _Rafius_ and _Xylophylla_.

With regard to form, the first thing to be considered is whether leaves are simple (_simplicia_ or compound (_composita)). Of the former kind are those of gramineous and Orchis tribes, which are not only simple but undivided, while those of the Vine and Mallow are simple, but lobed; the Hop bears some leaves lobed, others undivided, as _Laurus Sylvestris_, and the Paper Mulberry. Compound leaves are observable in the Rose, Jasmine, and the Unbelliferous tribe in general, and consist of leaflets, or partial leaves, (_foliata_), connected by a common stalk, and falling off along with it. In compound leaves the footstalk is either simple, as in the Jasmine and Rose, or compound, as in Parsley, Hemlock, and Fumitory. "In simple leaves the footstalk, if present, must of course be simple, while in compound ones it must always be present, though not always subdivided."

The following are the principal forms of simple leaves, considering their outline only:

* Orbiculatum*, nearly circular, is not uncommon.

* Subrotundum*, roundish, is not uncommon.

* Ovalum*, the shape of an egg cut longitudinally, a very common form of leaves.

* Ovatum*, is the same figure reversed, the little end being downward.

* Ellipticum*, oval, of an equal breadth at each end.

* Oblongum*, of an indeterminate oblong shape, three or four times longer than broad.

* Spatulatum*, roundish, or obovate, with a long taper base, like a surgeon's spatula.

* Coniiforme*, like a wedge, broad and abrupt at the extremity.

* Lanceolatum*, lanceolate, of a narrow oblong figure, tapering towards each end, very common, as in Willows, and _Plantago lanceolata_, or Ribwort.

* Linearis*, linear, narrow, with the sides as nearly parallel as possible, such as the leaves of most gramineous; the various species of _Narcissus_, the Rosemary, and many different plants. Linear-lanceolate leaves are of an intermediate shape between this and the last, or but slightly lanceolate, of which the gradations are numerous, often upon the same plant.

_Acteris_, needle-shaped, linear and evergreen, mostly acute and rigid, almost peculiar to the Fir and Juniper tribe. Such leaves have usually a joint where they unite with the branch, at which they separate from it when they fall.

* Triangularis*, having three prominent angles, of whatever measurement or direction, as in Goosefoot, and some leaves of Ivy.

* Quadrangularis*, having four angles, as in the _Liriodendron_, or Tulip-tree, a very peculiar kind of leaf.

* Quingualangularis*, with five angles, like the Cyclamen, and Ivy.

* Deltoides*, deltoid, or trowel-shaped, having three angles, of which the terminal one is much further from the base than the other two lateral ones, as in _Chenopodium Bonus-Henricus_. Linnaeus in his _Philosophia Botanica_, p. 43, cites his fig. 58. of that work as an example of this leaf, which is a mitre, that figure being a representation of the succulent three-edged leaf, (_fol. trigonium_), of _Melembryanthemum deltoides_.

* Ribonemum*, rhomboid or diamond-shaped, approaching to a square, though the sides are fearfully ever equal. This is seen in _Trapa natans_, and the Stinking Goof-foot.

* Retiforme*, kidney-shaped, a short broad rounded figure, hollowed out at the base, as in _Arabacea_.

* Cordatum*, heart-shaped, ovate hollowed out at the base, according to the vulgar idea of a heart; a form very frequent in leaves.

* Lunatatum*, crescent-shaped, like a half-moon, whether the points be directed backward, as in _Sagittaria obtusifolia_, when its leaves are shorter than usual, or forward, as in _Lafissora lanceolata_. Sm. 1c. Pict. 1.

* Sagittatum*, arrow-shaped, like _Sagittaria sagittifolia_, and several species of _Sorrel_, _Rumex_. In the Great White Bindweed, _Convulvulus sepium_, the posterior angles are abrupt or lopped.

* Hofatum*, halberd-shaped, triangular, hollowed out at the base and sides, the lower lobes spreading horizontally, at right angles with the footstalk, as in _Sheep's Sorrel_, and the upper leaves of the Woody Nightshade, _Solanum Dulcamara_.

* Pandaliforme*, saddle-shaped, oblong, blunt and dilated at each end, hollowed out at each side, of which remarkable figure the _Fiddle Dock_ is a striking, and almost singular example.

* Runcinatum*, runcinate or toothed, that is _re-uncinata_, hooked backward, being cut into many transverse acute segments, whose points are directed backwards, like the Dandelion.

* Lyrieum*, lyrate, so named in allusion to the antique lyre, but reversed. This leaf has a broad rounded extremity, with several transverse rounded segments, gradually lessening towards its base, as in _Eryngium Barbae_. It is most frequent in the Cruciform and Compound clafes, and by an occasional deep separation of the segments, often becomes a compound or lyrate-pinnate leaf.

* Fissum*, cloven or split, when the margins of the _serrae_ and segments are straight, not rounded, as in the _Ginkgo_ or Maidenhair-tree. _Bifidum_, _trisidum_, _multisidum_, &c. express the number of the segments, but these terms are also used with less limitation; to indicate the number of divisions, of whatever shape, when the latter circumstance does not come under consideration.

* Lobatum*, lobed, when the margins of the segments are rounded, as is most generally the case; witnesses the _Heptacodium_. _Bifidum_, _trisidum_, &c. indicate the number of the lobes.

* Sinuatum*, sinuate, cut along the margin into deep, rounded, or wide openings, like _Stellae sinuata_, _Methylbryanthemum pinnatifidum_. Curt. Mag. t. 67, and the Common Oak.

* Partitum*, deeply divided, almost to the base, like the _Milk Mallow_. _Bipartitum_, _tripartitum_, _multipartitum_, expresses the number of divisions.

* Laciniatum*, laciniate, cut, or as it were torn, into numerous irregular portions, which may be seen in various species of _Senecio_, denominated on that account Ragwort.

* Incisum_ and _Difsectum_, cut or jagged, are nearly synonymous with the last, but express a less deep division of the whole leaf.

* Pulmatum_, palmate or hand-shaped, cut into several oblong, nearly equal or uniform segments, about half way, or rather more, towards the base, leaving an entire space there, like the palm of the hand, as in the common _Blue Passion-flower_, whose leaves however are frequently filled more deeply divided, and the fig.

* Pinnatifidum_, pinnatifid, or wing-cut, cut transversely into several oblong parallel segments, like several species of _Thistle_, _Cardatus_, and on a smaller scale, though more deeply,
Leaf.

depth, Lepidium petraeum and alpinum; as well as Cucurbita
Then of L. Brit.
Bilimbi, doubtfully divided, as in the Long Rough-
headed Poppy, Papaver Argemone, and Eriocaulon major; see
that article.
Pectinatum, pectinate, a fine and elegant form of pinna-
tild leaf, whose segments are so narrow and so regularly
parallel, that they resemble the teeth of a comb, exemplified
in the Water Violet, Hottonia palustris.
Inequale, unequal, sometimes called oblique, is when the
two halves of a leaf are manifestly unequal in dimensions,
especially at the base, where they are not at all parallel.
This is the case with most species of Eucalyptus and Begonia,
but it is hardly observable in any British plants, except in a
small degree.
Integrum, undivided, expresses a leaf or leaflet being de
tinue of all segment, division or lobe, without any reference
to its margin, whether toothed or not.

The various terminations of leaves are thus distinguished.
Folium truncatum, an abrupt leaf, has the extremity cut
eff, as it were, transversely, by a straight line, as the Tulip-
tree, Liriodendron tulipifera.
Pterocarpum, bitten, or jagged-pointed, is blunt with va-
rious irregular notches, a very unusual termination, but
characteristic of Dr. Swartz's genus Ardisia, a tribe of
Indian Orchids. Hibiscus pterocarpus, Linn. Suppl. has a
more dilated leaf with a familiar termination.
Refinum, retuse, blunt with a broad shallow notch, like
the Mountain Sorrel, Rumex digynus.
Emarginatum, emarginate or notched, having a small acute
notch at the summit, which is not uncommon.
Obtusum, blunt, terminating in a segment of a circle, like
the Primrose leaf, and many others.
Acutum, sharp, ending with an acute angle, as is still more
usual.
Acuminatum, pointed, having a taper point, like many
graffes, and various other plants.
Obtusum cum acuminis, blunt with a small point, like the
Sea Lavender, Statice Limonium.
Macronatum, or Cyphadatum, sharp-pointed, tipped with a
rigid or pungent spine, like the Thistle tribe.
Trilobatum, three-toothed, when there are three terminal,
nearly equal, points.
Triquetrum expresses the same thing.
Cirratum, cirrate, tipped with a tendril, as in Gloriosa
and Ficus, glabra, two Indian plants.
The different margins of leaves are defined as follows,
and are very important to be well understood, and correctly
applied, in forming specific characters of plants.
Folium integrerrimum, an entire leaf, is defilite of all mar-
ginal teeth, notches or incisions, as in the Orchis and Lily
tribes. This term, alluding solely to the margin, has no
reference to, or comparison with, integrum, which concerns
the general figure, or bulk, of the leaf.
Spinosum, spiny, beset with prickles, though otherwise
perhaps entire, as in Thistles, and Eryngos. The veins and
ribs are spiny in some kinds of Solanum, and many Roses
and Brambles.
Icercus, unarmed, is opposed to spinosus.
Glandulosum, glandular, bordered with pores that exude
some peculiar fluid, as in Salix petandra, the Bay-leaved
Willow, and some others.
Ciliatum, fringed, bordered with soft parallel hairs, as in
Ribes adstringens bifolium.
Carpellaginosum, carpellaginous, having a hard or horny edge,
like several species of Saxifrage.
Dentatum, toothed, beset with directly projecting teeth,
LEAF.

from a scaly kind of mealiness, as in Atriplex, and some species of Alyssum.

Glaucum, glaucous, clothed with a fine mealiness, of a sea-green colour, which easily rubs off, as in the Cabbage, the Chlora, and many others.

Maculatum, spotted, besprinkled with spots or flains of a different colour from the prevailing green of the leaf. In Lamium maculatum these spots are white, in Hypochaeris maculata they are of a dark purple.

Coloratum, coloured, is used when a leaf, or any part thereof, is of any other colour than green, as in Amaranthus caudatus.

Punctatum, dotted, either superficially, as in Rhodoedendrum punctatum, Andr. Repof. t. 36, or with pellicular cells filled with an essential oil, like Hypericum perforatum, and the whole natural order of Jussieu’s Darnel.

Rugosum, rugged, having the veins thicker than the intermediate spaces, so that the latter become tupid, as in the Garden Clary, and many other species of Salvia.

Bulbium, blitely, a more remarkable degree of the latter, frequent in the Garden Cabbage.

Picatum, plaited, when the disk of the leaf, especially towards the margin, is acutely folded up and down, as in Malvaceae, and Ladies’ Mantle.

Undulatum, undulated, when the disk near the margin is waved obloquely up and down, in consequence of being more ample than the adjoining part, as in Cyamus Nelumbi; or than the ribs, as in Refecta beta and alba.

Crispum, curled, when the border is so much more dilated than the disk, that it necessarily becomes curled and twisted, which is the case with the Curled Mallow, and some varieties of Mint, for this mode of growth is justly susceptibility of Linneas, to be but a variety, or preternatural luxuriance.

Concavum, hollow, depressed in the centre, owing to a tightness in some part of the circumference, as in Cyamus Nelumbi.

Conicalatum, channelled, having a longitudinal depression, like several species of Naricius.

Vernum, veiny, when the veins by which the fluids are conveyed through the leaf, are branched, subdivided, and more or less prominent, frequently forming an elegant network, in which case the leaf is said to be reticulated, either on one or both of its surfaces.

Nervosum, or Cleftatum, (see the latter article,) ribbed, when the roots extend in simple lines from the base to the point, or towards it. The greater clusters of veins are generally called nervi or eges, nerves or ribs, the smaller venules, veins, whether branched or simple.

Avenium, veined, and Enec, rilbeles, are opposed to the last-mentioned terms.

Trinerve, three-ribbed, is a leaf with three great or principal ribs, all alike distinct and separate from the very base, as well as remote from the margin, like the beautiful Blakes trinervia.

Bif trinervia, three-ribbed at the base, has the base cut away, as it were, close up to the lateral ribs, as in the Burdock, and Great Annual Sunflower.

Triostrineve, tripityl-ribbed, is when the side-ribs branch off from the middle one, at some distance above the base, as in Laurus Cinnamomum and Camphora, and many species of Sunflower. The five and ample South American genus Melolomus, is remarkable for the conspicuous ribs of its leaves, which are usually five, seven, or more, the lateral ones either branching off from the central, or all of them distinct to the base.

Nudum, naked, implies that a leaf is destitute of all kinds of clothing or hairiness, as in the Orchis.

Variegatum, variegated, is a sort of variety or diffebite, in which it differs from coloratum, the latter being natural, and proper to the species. Variatio of leaves consists in white or yellow irregular blotches, as in the Elder, Round-leaved Mint, Holly, and Aucuba japonica. Such plants are usually more tender, and difficult of increasen, than when in their natural state, as gardeners experience in Geraniums.

The following terms express the substance, peculiar configuration, or some other circumstance relating to leaves, not included in the foregoing lists.

F. luma teres, or cylindraceum, cylindrical, is seen in Conchilium gibbosum, and some others of that genus. See Conchilium.

Semiylindraceum, semicylindrical, flat on one side, which is generally the upper, like Salsola fruticosa, and Chenopodium maritimum.

Subulatum, awl-shaped, tapering from the base to the point, like Salsola kali.

Tubuliform, tubular, hollow within, as in the Onion, and some other species of Allium, some Ruffes, Sc. The tube is double in Lobelia Dortmanna.

Coriolum, fleshy, of a thick pulpy substance, as in all those called succulent plants, belonging mostly to the genera of Sedum, Crassula, Aloe, Mesembryanthemum, &c. Of the fudgular power in such leaves of resisting drought, we have already spoken. When bruised they soon dry or corrupt.

Gibbus, gibbous, swelling on one side or both, as in Aloe retusa.

Compressum, compressed, flattened laterally.

Depressum, depressed, flattened vertically, as already mentioned. Various kinds of Mesembryanthemum exemplify this.

Carinatum, keeled, when the back is longitudinally prominent, like the keel of a boat.

Enfiforme, sword-shaped, compressed, tapering to a point, slightly convex at each side, neither of which is properly the upper or lower surface; as in Iris and its allies.

Anecone, two-edged, is nearly synonymous with the last.

Acinaciformes, cimitar-shaped, and Dolabriformes, hatchet-shaped, are two kinds of succulent leaves appropriated to two species of Mesembryanthemum, that bear the same names.

Trigonum, three-edged, has three longitudinal sides and as many angles, like Mesembryanthemum deltoides, Linna. Phil. Bot. t. 58.

Triquetrum differs from the last only in being more precisely applied to a three-sided awl-shaped leaf.

Tetragonum, four-edged, has four prominent angles, as in Iris tuberosa.

Lingulatum, tongue-shaped, is a thick oblong blunt figure, generally cartilaginous at the edges, as in Saxifraga Cotyledon, and some of its near relations.

Membranaceum, membranous, expresses a thin pliable sort of leaf, the reverse of succulent.

Coriaceum, leathery, is thick and tough, without being pulpy or succulent, like Magnolia grandiflora, Aucuba, Laurel, and many others.

Scupervirens, evergreen, permanent through one, two, or more winters, so that the branches are never stripped.

Deciduum, deciduous, (see that article,) such as falls off at the approach of winter, as in most trees and shrubs of cold climates.

Alienatum, alienated, when the first leaves of a plant give place to others totally different from them, as well as from the natural habitat of the genus, as in many Miners of New Holland.

Circinatum, hooded, when the edges meet in the lower part
part and expand in the upper, forming a sheath or hood, of which the genus *Sarracenia* is a curious example. The Common Lime, *Tilia europa*, is liable to a variety in which the same thing takes place accidentally. A tree of this kind, of which we have a specimen, in the church-yard of Zedlitz in Bohemia, is vulgarly supplied to bear such hooded leaves, in consequence of a parcel of monks having once been hanged upon this tree. It is seldom we can so clearly trace the cause of any variety. Some might think the experiment worth repeating.

*Appendiculatum*, furnished with an appendage, or additional organ, for some purpose not essential to a leaf, as the irritable lobes at the end of the foliage of *Dianthus factitius*; and the pouch with a lid, upon that of *Nepenthes distillatoria*; of both which we have already treated. *Aludravoenda* and *Utricularia* bear numerous bladders on their leaves under water, which seem to secrete air for the purpose of floating the plants, especially perhaps at their flowering season.

*Folius compositum*, compound leaves, consist of two or any greater number of partial leaves, connected by a common footstalk, whether simple or branched. Such partial leaves are termed *foliola*, leaflets.

*Folium articulatum*, a jointed leaf, consists of one leaflet, or pair of leaflets, growing out of the summit of another, with a foot of joint, as in *Fagara trigona*.

*Digitatum*, fingered or digitate, has several leaflets at the top of one common stalk, as in many *Potentilla*.

*Binatum*, binate, consists of a pair of leaflets only on one footstalk, as in *Zygophyllum*, some *Mimosa*, the Great Everlasting Pea, and other species of *Lathyrus*.

*Ternatum*, ternate, has three leaflets, like the Trefoil and Strawberry.

*Quinatum*, quinate, has five.

*Pinnatum*, pinnate, a very common kind of leaf, is formed of several leaflets, ranged laterally along one footstalk, either with or without partial stalks, and in an opposite or alternate manner. There is usually a terminal leaflet, as in *Roses*, *Frasinus*, and *Elder*, which mode of growth is called *folium pinnatum cum impari*, and is that always understood, when nothing is particularized; *abruptum pinnatum* means that there is no such terminal or odd leaflet. Sometimes its place is supplied by a tendril, as in *Vetches* and *Peas*, and such a leaf is termed *pinnatum cirosum*. *Interruptum pinnatum*, interruptedly pinnate, is when the principal leaflets are ranged alternately with one or more intermediate series of smaller ones, as in our English *Spirea*, and *Potentilla anserina*. *Articulatum*, jointed, is when there are apparent joints in the common footstalk, as in *Winnemanna pinnata*. In the Japanese shrub *Nandina domestica* the leaflets all separate by a joint at their base, very soon after the leaf is gathered. *Dregea*, decurrently, is when the leaflets run down the footstalk at their base, like *Erysimum campestre*. *Lyrate*, in a lyrate manner, has the terminal leaflet largest, the rest gradually smaller, often with intermediate leaflets, as in *Geranium*, and the *Turnip*. This and the true lyrate leaf often vary into each other, in the same plant or species. *Verticillatum*, in a whorled manner, has the leaflets cut into fine divericated segments, embracing the footstalk, of which the curious *Stum verticillatum*, Fl. Brit. is an instance.

*Auriculatum*, an auricled leaf, bears a pair of leaflets at its base, that often indeed unite with it, as in the *Dipsacus pilosus*, and *Salvia triola*. *Hedysarum gyros*, the Mowing Plant, mentioned above, has properly an auricled leaf, rather than a ternate one, the auricles being what move up and down spontaneously.

*Conjugatum*, conjugate or yoked, consists of one pair of leaflets, and is much the same as binatum. *Bipinatum, trinatum, quadrijugum, multijugum*, expresses particular numbers of pairs of leaflets, as is sometimes necessary in the specific characters of *Mimosa*.

*Pedatum*, pedate or foot-like, is in the first instance ternate, but the two lateral leaflets are compounded in their fore part, which may be seen in *Helloborus satitus* and *H. niger*. "There is an affinity between a pedate leaf, and those simple ones which are three-ribbed at the base."

The different degrees in which leaves are compounded are thus distinguished, without any reference to the mode.

*Folium compositum* is a simply compound leaf, as in *Roses*. *Discompositum*, doubly compound, is exemplified in the *Globe-flowered* (*Euphorbia*), and many other umbelliferous plants. *Duplicis-compositum*, more than twice compounded, is seen in some common umbelliferous plants, as the *Hemlock*, and in many *Mimosa*.

The following terms express not only the degree but the mode.

*Bipinnatum*, twice paired, and *Ternipinnatum*, thrice paired, are found in some *Mimosa*.

*Ternaratum*, twice ternate, is seen in *Euphorbia*, and *Triternatum*, thrice ternate, in *Punica indica*.

*Bipinnatum*, doubly pinnate, *Trippinnatum*, triply pinnate, are found in many exotic leguminous plants.

Some botanists, among whom *Forster* seems to have taken the lead, use the word *laminula* for the expanded part of a leaf, that is, for the leaf itself, so that the term is entirely superfluous, and is besides appropriated to the border of the petals in a polyshalous corolla. (See *Lamina*.) What is not a *footstalk* (*factitius*), the part which usually supports the leaf, and which different kinds will be explained under the article *Petiolus*. Another appendage to leaves, but not always present, any more than the footstalk, is the *Stipula*. See *Fulcrum* and *Stipula*.

In the use of the various terms above explained, it is often found necessary to combine two of them; in order either to express some intermediate figure, or to provide for that variety or mutability of shape, very frequent in the foliage of many plants. Thus *ovato-lancifolaturn* indicates a lanceolate figure, somewhat dilated towards the base, so as to approach towards *ovate*; as *elliptico-lancifolaturn* implies a dilatation about the middle. Or such compound terms may express, that the foliage, generally lanceolate, occasionally verges towards either of those broader forms. But we must be careful not to combine terms which are incompatible, as *conjugato-pinnatus*, and *digitato-pinnatis*, employed by some writers in defining *Mimosa*; whereas their meaning is *conjugata*, or *digitata*, in the first instance, and *pinnata* as regarding the secondary divisions. *Sub* is commodiously prefixed to many terms, when our application of them is doubtful, or not precise, as *subrundifolius*, *rounded*, *subulatus*, *narrowly*; but it should be sparingly used. It too often indicates a want of decision or periphrasis in the writer, rather than any uncertainty in his subject. An acute observer can generally seize what is essential, in parts that are the leaf variable, in each particular tribe; passing over what is doubtful, and above all, not dwelling on too many particulars in his definitions, when a few are sufficient. The leaves of plants afford, on the whole, the most commodious specific distinctions, as being obvious, most generally present, and independent of the parts of fructification, from which the generic characters are taken. In few cases are the leaves of any genus so uniform or similar in all the species, as to not exhibit abundance of clear specific differences, especially when their stipules and footstalks are taken likewise into consideration.

The *Leaves of Plants* have, in one instance only, as far as we know, been referred to for the purpose of forming a *fylem*. 
The word comes from leuca, or leuga, an ancient Gaulish word, for an itinerary measure, and adopted in that sense by the Romans. Some derive the word leuca from Latin, cubite; because the Gauls, in imitation of the Romans, marked the spaces and distances of their roads with white stones. The Gallic leuca was \( \frac{1}{4} \) Roman mile = 2415,532 yards.

A fea-league is usually reckoned 3000 geometrical paces, or three English miles; the large leagues of France are usually 3000, and in some places 3500 paces; the mean or common league is 2500 paces, and the little league 2000. Chorier observes, that the ancient Gaulish leagues were but 1500 paces; and the modern French league is = 2500 toises = 5328,755 English yards. The term league, or league, is applied in different parts of France to very different distances. The astronomical league of 25 to a degree measures 4865 English yards. The legal leagues, of two French miles, by which the highways were measured, contain each 4263 English yards. The marine league of 20 to a degree measures 6081 English yards.

The Spanish leagues are larger than the French, 17 Spanish leagues making a degree, or 20 French leagues, or 69 1/2 English statute miles. The league of Spain is = four ancient Roman miles = 6441,392 yards. The large league of Spain is = five ancient Roman miles = 8051,74 English yards. On roads made since 1766, the distances are laid down at the rate of 8000 varas to the league; that is, 7416 English yards; so that five such leagues = 21 English miles nearly. But the juridical league is 5000 varas, or 4635 English yards; so that eight of these are equal to 21 English miles. Marine leagues are reckoned at the rate of 20 to a degree. But in different parts of Spain, the leagues are very different. The leagues of Germany and Holland contain four geographical miles each. The German league, or that of Scandinavia, is = 5662,886 English yards. The mile or league of Germany is = 200 Rhenish yards = 8239,846 English yards.

The Persians mark their leagues by trees, as the ancient Romans did by fiones, lapidas; for which reason they are also called sagg, a Turkish word signifying a tree. In Japan, the league consists of 1860 fathoms. There are all distinguished by little hillocks, raised on purpose by the roadside. See the leagues of most countries reduced to the Roman foot, under Mile. See also Measure.

LEAGUE also denotes an alliance or a confederacy between princes and states for their mutual aid, either in attacking some common enemy, or in defending themselves. The word comes from liga; which, in the corrupt Latin, was used for a confederacy: "Quia quis cumulo ligatur." There have been several holy leagues entered into by the Christians, against the Saracens and Infidels; called also crusados, or croisades.

The League, by way of eminence, denotes that famous one on foot in France, from the year 1572 to 1593. Its intent was to prevent the succession of Henry IV., who was of the Reformed religion, to the crown; and it ended with his abjuration of that faith.

The leaguers, or confederates, were of three kinds: the zealous leaguers aimed at the utter destruction, not only of the Huguenots, but also of the ministry. The Spanish leaguers...
Leagurers had principally in view the transferring of the crown of France to the king of Spain, or the infant his daughter. The moderate leagurers aimed only at the extirpation of Calvinism, without any alteration of the government.

LEAGUE, in Geography. See GRISONS.

LEAGUE of God's House. See GOD'S HOUSE.

LEAGUE, Gray. See GRAY LEAGUE.

LEAGUE of the Ten Jurisdictions, one of the three leagues into which the Grisons are distributed. This league ought properly to be called, and is not unfrequently denominated in Switzerland, the league of the ten jurisdictions, from the number of communities that compose it; but as on its first union it was formed of ten only, the original appellation is still retained, although one of the jurisdictions has been since that period divided into two. This territory was formerly under the dominion of the Vats, whose authority was limited, as the people possessed very considerable privileges. On the death of Donatus, the last baron, the count of Toggenburg, who married his eldest daughter, succeeded to his possessions; and Frederic, one of his descendants, dying in 1436, without issue, the communities united, formed an offensive and defensive alliance, and erected themselves into a league. After some vicissitudes, the communities became free, and their independence was solemnly ratified by the emperor Ferdinand III., soon after the peace of Westphalia. For further particulars, see GRISONS.

LEAGUE, Solomon. See COVENANT.

LEAK, in Sea Language, is a chink or breach in the decks, sides, or bottom of a ship, through which the water comes in. A ship is said to spring a leak when she begins to leak, or let in the water.

The manner of stopping a leak is to put into it a plug wrapt in oakum, and well tarred, or in a turpentine cloth, which keeps the water out; or nailing a piece of sheet-lead on the place. See CAULKING, and FORTERING.

Seamen sometimes stop a leak by thrusting a piece of salt beef into it. The sea-water, says Mr. Boyle, being freer than the brine imbibed by the beef, penetrates into its body, and caustic it to swell so as to bear strongly against the edges of the broken plank, and thereby stops the inlux of the water. Works, 4to, vol. i. p. 147.

A ready way to find a leak in a ship, is to apply the narrow end of a speaking trumpet to the ear, and the other to the side of the ship where the leak is supposed to be; then the noise of the water issuing in at the leak will be heard distinctly, whereby it may be discovered. See Philos. Trans. No. 201.

LEAKAGE, the rate of a vessel that leaks; that is, lets water, or other liquid, ooze in or out.

LEAKAGE also denotes an allowance of three barrels in thirty-six, both of strong beer or table beer and ale, and after that rate for any greater or less quantity, out of the excise, 43 Geo. III. c. 69. f. 12. The said allowance is the eur son breue of three upon every thirty-six barrels of beer or ale, shall be in full compensation for all waife or other losses whatsoever. f. 13.

LEAKE, John, M.D., in Biography, was born of Scotch parents in Cumberland, and received his education at the grammar-school at Bishop-Auckland. This being finished, he set off for London, intending to engage in the military profession; but finding some promises, with which he had been flattered, were not likely soon to be realized, he turned his attention to medicine. After attending the hospitals, and being admitted a member of the corporation of surgeons, an opportunity presented itself of improving himself in foreign schools; he embarked for Lisbon, and afterwards visited Italy. On his return, he established himself as a surgeon and accoucheur in the neighbourhood of Piccadilly; and about that time published "A Dissertation on the Properties and Efficacy of the Lisbon Diet-drink." Where he obtained his doctor's diploma is not known; but he became long a licentiate of the College of Physicians, and removed to Craven-Breet, where he began to lecture, as well as continued to practice, the medical art. In 1755, he purchased a piece of ground on a building leaf, and afterwards published the plan for the institution of the Westminster Lying-in-Hospital; and as soon as the building was raised, he voluntarily, and without any consideration, assigned over to the governors all his right on the premises, in favour of the hospital. He enjoyed a considerable share of reputation and practice as an accoucheur, and as a lecturer; and was esteemed a polite and accomplished man. He added nothing, however, in the way of improvement, to his profession, and his writings are not characterized by any extraordinary acuteness, or depth of research; but are plain, correct, and practical. He was attacked, in the summer of 1793, with a disorder of the chest, with which he had been previously affected, and was found dead in his bed on the eighth of August of that year. He published, in 1773, a volume of "Practical Observations on Child-bed Fever"; and, in 1774, "A Lecture introductory to the Theory and Practice of Midwifery, including the History, Nature, and Tendency of that Science, &c." This was afterwards considerably altered and enlarged, and published in two volumes, under the title of "Medical Injunctions towards the Prevention and Cure of various Diseases incident to Women, &c." The work passed through seven or eight editions, and translated into the French and German languages. In the beginning of 1793, a short time before his death, he published "A Practical Essay on the Diseases of the Viscera, particularly those of the Stomach and Bowels." Hutchinson, Biog. Med.

LEAKE, Richard, was born at Harwich in the year 1629, and was bred to the ten-service. At the restoration he was made master-gunner of the Princes, a frigate of fifty guns; and in the first Dutch war distinguished himself by his skill and bravery in two very extraordinary actions, in one against fifteen sail of Dutch men of war, and another in 1667, against two Danish ships in the Baltic, in which, the principal officers being killed, the command devolved on him, though only master-gunner. In 1669, he was promoted to be gunner of the Royal Prince, a first rate man of war. In 1673, he was engaged, with his two sons Henry and John, in the battle against Van Tromp, when the ship had all her masts shot away, nearly four hundred men killed and disabled, and most of her upper tier of guns dismounted. As the lay like a wreck, a Dutch man of war and two fire-ships came down upon her, and captain Rook, afterwards Sir George, conceiving it impossible to defend her, defied the men to save their lives, and like the colours. Mr. Leake hearing this, ordered the lieutenant, or the quarter-deck, and took the command, saying "The Royal Prince shall never be given up to the enemy, while I am alive to defend her." The undaunted spirit of the brave gunner inspired the small residue of the ship's company with resolution, they returned to the fight, and, under the direction of this valiant gunner and his two sons, funk both the fire-ships, and obliged the man of war to sheer off, and having thus saved the Royal Prince, he brought her into Chatham. Mr. Leake's joy in obtaining this victory was pitifully damped by the loss of his eldest son Henry, who was killed by his side. Mr. Leake, in consequence of his great merit, was made, in 1677, master-gunner of England, and storekeeper of the ordnance at Woolwich. He invented, among other things, the cuisse-piece;
piece; and contrived a new method of firing a mortar. He
died in 1685. He had a surprizing genius for all inventions
relating to gunnery, and also in the composition of fire-
works. He left a son.

Leake, John, who was but sixteen years of age when he
was engaged in the battle just referred to, and in which
he took a conspicuous part. He was shortly after made
captain, and performed many prodigies of valour, and,
among others, he executed a desperate attempt of convey-
ing some victuallers into Londonderry, which obliged the
enemy to raise the siege; he was also at the battle of the
Hooge. In 1703, being commodore of a squadron, he
destroyed the French trade and settlements at Newfoundland,
and restored the English to the possession of the whole isle.
On his return he was made rear-admiral, and, in a short time
afterwards, he was created vice-admiral of the blue, and
received the honour of knighthood. In 1705, he saved
the important fortresses of Gibraltar from the combined attacks
of France and Spain, and was engaged in the reduction of
Barcelona. In the course of the following year he relieved
that same city, when it was reduced to the last extremity,
and obliged king Philip to raise the siege. Soon after this
he took the cities of Cartagena, Alicante, and Joyce, and
concluded the exploits of the year with the reduction of the
city and island of Majorca. On his return home, he was
presented by prince George of Denmark with a valuable
diamond ring, worth 400l., and from the queen he received
1000l. as a reward of his important services. On the death
of admiral Sir Cloudy Shovel, in 1707, he was made admiral
of the white, and commander-in-chief of her majesty's
fleet. In the following year he surprized a convoy of the
enemies corn, sent it to Barcelona, and thus saved the city
and the confederate army from the danger of famine. He
reduced the island of Sardinia to obedience to Charles king
of Spain, and assisted lord Stanhope in the conquest of Mi-
norca. Returning home, he was appointed one of the coun-
cil to the lord high admiral, and in 1709 he was made rear
admiral of Great Britain. He was several times chosen
member of parliament for Rochester, and in 1712 con-
ducted the forces to the possession of Dunkirk. On the
accession of George I. he was superseded, and allowed a
penion of 400l., upon which he lived in a private manner
till his death, which happened at his house in Greenwich, in
1720. He left no children, but was succeeded in his property
by

Leake, Stephen Martin, who was son of captain
Martin, the brother-in-law of admiral Leake. Inheriting
the property of the admiral, he took his name in addition
to that of his own. He went through the different ranks in
the Herald's office, till he came to be Garter. He was the
first person who wrote profusely on English coins. He
published a history of British coins, under the title of
"Nummi Britannici Historia:" he wrote also "The Life of
Sir John Leake," of which only 50 copies were printed:
and in 1766 he printed 50 copies of "The Statutes of the
Order of the Garter." He died in 1773.

Leam, a term sometimes used for a cut or canal.

Leam, in Geography, a high mountain of the county of
Galway, Ireland, situated on the south side of Lough
Corrib, near the small town of Oughterard.

Leam-Kien-Sam, a town of Chinese Tartary; 42
miles S. of Poro.

Leam-Yom-Hotun, a town of Corea; 600 miles
E.N.E. of Pekin. L. lat. 42° 26'. L. long. 128° 46'.

Leander, in Biography, a French Capuchin friar, was
born at Dijon, where he died, in the year 1667. His writings
are numerous, and by these he acquired a high reputation;
he is frequently referred to by Dupin, in his "Nova Bibli-
otheca Authorum Ecclesiastic." One of his works is en-
titled "The Truths of the Gospel," in two volumes folio.

Leao, in Geography, a river of China, which runs into
the sea; 12 miles W. of Lai-cheou.

Leao, or Leun, a river of Chinese Tartary, formed
by the union of several rivers, of which no one bears this
name till it has passed the barrier between Leao-tong
and Tartary. It runs into the gulf of Leao-tong, about 12
miles W. of Yen-tseu.

Leao, in Natural History, a mineral substance, approach-
ing to the nature of the lapis lazuli, found in the East
Indies; and of great use in the Chinese porcelain manufac-
ture, being the finest blue they are polished of. This stone
is found in the strata of pit-coal, or in those of a yellowish or reddish
earth, in the neighbourhood of the veins of coal. There
are often found pieces of it lying on the surface of the ground,
and these are a sure indication, that more will be found on
digging. It is generally found in oblong pieces of the size
of a finger, not round, but flat. Some of this is very fine,
and some coarse, and of a bad colour. The latter is very
common, but the fine sort is scarce, and greatly valued. It is
easy to distinguish them at sight, but they are found by
experiment, and the trying one piece is generally sufficient
for judging of the whole mine; for all that is found in the
same place is usually of the same sort.

Their manner of preparing it for use is this: They first
wash it very clean, to separate it from the earth, or any
other foulest it may have; they then lay it at the bottom
of their baking furnaces; and when it has been thus calcined
for three or four hours, it is taken out and powdered very
fine in large mortars of porcelain, with pebbles of stone
fixed with iron. When the powder is perfectly fine, they pour
in fume boiling water, and grind it with the roll; and when
it is thoroughly incorporated, they add more, and finally
pour it off, after some time settling. The remainder at the
bottom of the mortar, which is the coarser part, they grind
again with more water, and so on, till they have made the
whole fine, excepting a small dirt or grit. When this is done,
all the liquors are mixed together, and well filtered. They
are suffered to stand two or three minutes after this, and then
drawn off, with the powder remaining in them. This is
sufficient to dissolve gradually, and is the fine blue they use
in their beet works, our common snail serving for the blue
of all the common low-priced China-ware. Observat. sur
les Coûtumes de l'Afri, p. 326.

It is plain that this stone is a sort of lapis lazuli; and the
ultramarine blue, used by our painters, is made in a manner
not wholly unlike this. It is much to be wished that
England were well searched for such a stone as this leado,
since our mines in Derbyshire afford many blue substances,
which have not been sufficiently considered; and if it should
be found that either this, or any other European nation,
produces it, it will be a fine discovery, as we should not only
have the means of giving a fine colour to our own manufactur-
es of this kind, but we might trade with it in China to a vast
advantage. If England does not possess it, it is very probable
that Germany does, the mines there affording an almost
inexhaustible store of coloured stones; and this being cer-
tainly no other than the stoney matter of some crytalline
nodules, accidentally tinged with some particles of copper.
See Lapis Lazuli.

Leao-Tong, in Geography, a province of Chinese
Tartary, more usually called Chen-yang, or Mongden.
(See Chen-yang.) The province is extremely fertile;
but it is too far distant from Peking, and from the centre of
the empire, to send its provisions thither. Besides, carriage is altogether impracticable, except in winter; in this season, great quantities of game, and fish, preserved, or inoculated in ice, according to the Chinese expression, are carried from that country to the capital.

LEA-TONG, Gulf of, or Yellow Sea, is a large bay or gulf of the Chinese sea, between the peninsula of Corea and China; about 400 miles from N. to S., and from 100 to 250 from E. to W. N. lat. 34° 45' to 41°.

LEA-COU-HOTUN, a town of Corea, on the S. side of the Va-lou river; 370 miles E. of Peking. N. lat. 40° 0'. E. long. 125° 24'.

LEAP, in Agriculture, a measure of capacity, signifying half a bushel, sometimes termed lip.

LEAP, in Music, is when the song does not proceed by conjoint degrees. For instance, when there is an interval of a third, fourth, fifth, &c. between two notes, the Italians call it a lep, falto.

It is to be observed, that there are two kinds of leaps, regular and irregular, called by the Italians sali regolari & irregolari.

The regular leaps are those of a third major or minor, whether natural or accidental, fourth, fifth, sixth minor, and octave, and these either ascending or descending.

Irregular leaps are the triton, fifth major, seventh major, the ninth, tenth, and, in general, all beyond the compass of an octave, at least in vocal music.

Befides these, there are others which may be used, but with discretion; such as the diminished fourth, the falla fifth, and flat seventh. The difference between the regular and irregular leaps is, that the former are performed by the voice, without any great difficulty or effort; whereas, the latter require more attention and pains to execute.

LEAP, in Flying, is used for a net, engine, or wheel, made of twigs, to catch fish in. Stat. 4 & 5 Will. & Mary, c. 23.

LEAPING-HORSE, in the Measure, is one that works in the high measure, or one that makes his leaps with order and obedience between two pillars upon a bright line, in volts, caprioles, balates, or croupades. Ufe includes a gallop a terra a terra, and corsets from the number of leaps; because the horse does not rise so high in these. Each leap of the horse ought not to gain, or make above a foot and a half of ground forward.

LEAP-YEAR, the name with Biftembe : which see.

It is thus called, because, in the common year any fixed day of the month changes successively one day of the week; but in the leap-year, it flips or leaps over one day.

The common year hath three hundred and sixty-five days in it, but the leap-year three hundred and sixty-six days; and in this case February hath twenty-nine days; which, in the common year, hath but twenty-eight.

To find the leap-year, the rule is,

"Divide by 4, what's left shall be,  
  For leap-year, 0: for part, 1, 2, or 3."

For example; is the year 1812 a leap-year, or common-year.

\[ 4 \div 12(453) \]

There is 0 remainder, so that it is leap-year.

LEASBROOK, in Geography, a town of America, being the capital of Caswell county, in North Carolina: containing a court house, gaol, and a few houses.

LEASE, from the French leier, diminut, to let, in Law, a demesne, or letting of lands, tenements, or hereditaments, unto another for term of years, or at will, for a rent reserved.

A contract for the possession of lands or tenements, for some determinate period, is an effate for years (see Estate); and it takes place where a man letteth them to another for the time of a certain number of years, agreed upon between the lessor, or person who granteth a lease, and the lessee, the person to whom it is granted, and the lease enters thereon. (Litt. § 58.) If the lease be but for half a year, or a quarter, or any left time, this lease is reputed as a tenant for years, and is so styled in some legal proceedings; a year being the shortlent term which the law takes notice of in this case. A year is a determinate and well-known period, consisting commonly of 365 days. (See Minister.) A month, (see Month) in law, is a lease month, or 28 days, unless otherwise expressed; and, therefore, a lease for "twelve months" is only for 48 weeks; but if it be for "a twelve-month" in the figurative number, it is good for the whole year. (6 Rep. 61.) These estates for years were originally granted to mere farmers or husbandmen, who every year rendered some equivalent in money, provisons, or other rent, to the lessors or landlords; but, in order to encourage them to manure and cultivate the ground, they had a permanent interest granted them, not determinable at the will of the lord. Their poiffession, however, was deemed of so little consequence, that they were rather considered as the bailiffs or servants of the lord, who were to receive and account for the profits at a settled price, than as having any property of their own; and, therefore, they were not allowed to have a freehold estate; but their interest expired after their deaths in their executors, who were to make up the accounts of their tettator with the lord, and his other creditors, and were entitled to the stock upon the farm. The lessee's estate might also, by the ancient law, be at any time defeated by a common recovery suffered by the tenant of the freehold (Co. Litt. 46.) which annihilated all leaves for years then subsisting, unless afterwards renewed by the recoveror, whose title was suppos'd superior to his by whom those leaves were granted. Estates for years, whilh they continued precarious, were usually of short duration, like our leaves upon rack-rent; and we are told (Mirror. c. 2. § 27. Co. Litt. 45, 46.), that by the ancient law, no leaves for more than 40 years were allowable, because any longer poiffession (especially when given without any livery declaring the nature and durance of the estate), might tend to defeat the inheritance. This law, if it ever exis'ted, was soon antiquated; for, in Madox's "Collection of Ancient Instruments," some leaves for years, of a pretty early date, occur, which considerably exceed that period; and long terms, for 500 or 1000 years, were in use in the time of Edward III., and probably of Edward I.

But when, by the statute 21 Hen. VIII. c. 15, the termor (that is, he who is entitled to the term of years), was protected against these fictitious recoveries, and his interest rendered secure and permanent, long terms began to be more frequent than before; and were afterwards extensively introduced, being found extremely convenient for family settlements and mortgages; continuing subjecto, however, to the same rules of succession, and with the same inferiority to freeholds, as when they were little better than tenancies at the will of the landlord.

Every estate which must expire at a period certain and prefixed, by whatever words created, is an effate for years; and, therefore, this estate is frequently called a term, terminus, because its duration is limited and determined; for every such estate must have a certain beginning and certain end. (Co. Litt. 45.) But "id certum est, quod certum reddi potest;" therefore, if a man make a lease to another, for
LEASE.

so many years as J. S. shall name, it is a good lease for years (6 Rep. 35.) ; for though it is at present uncertain, yet when J. S. hath named the years, it is then reduced to a certainty. If no day of commencement is named in the creation of this estate, it begins from the making, or delivery, of the lease. (Co. Lit. 46.) A lease for so many years as J. S. shall live, is void from the beginning (Co. Lit. 45.) ; but a lease for 20 or more years, if J. S. shall live long live, is good, for a certain period is fixed, beyond which it cannot fail, though it may determine sooner, on the death of J. S. An estate for life, even if it be pur aiter vie, is a freehold; but an estate for 1000 years is only a chattel, and reckoned part of the personal estate. A lease for years may be made to commence in future, though a lease for life cannot. Because no livery of seisin is necessary to a lease for years, such lease is not to be seised, or to have true legal seisin of the lands. Nor, indeed, does the bare lease vest any estate in the lessee; but only gives him a right of entry on the tenement, which right is called his "interest in the term," or interesse termini; but when he has actually so entered, and thereby accepted the grant, the estate is then, and not before, vested in him, and he is possess, not properly of the land, but of the term of years (Co. Lit. 46.) ; the possess, or seisin, of the land remaining still in him who hath the freehold. Thus, the word "term" does not merely signify the time specified in the lease, but the estate also and interest that pass by that lease; and, therefore, the "term" may expire during the continuance of the "time," as by surrender, forfeiture, or the like. See TENEANT.

Estate at will, another species of estates not freehold, are those where lands and tenements are let by one man to another, to have and to hold at the will of the lessor; and the tenant by force of this lease obtains possession (Lit. 568.) Each tenant hath no certain indefeasible estate, nothing that can be aliquot by him to another; because the lessee may determine his will, and put him out whenever he pleaseth. But every estate at will is at the will of both parties, landlord and tenant; so that either of them may determine his will, and quit his connection with the other at his own pleasure. If, indeed, the tenant at will fowls his land, and the landlord, before the corn is ripe, or before it is reaped, puts him out, yet the tenant shall have the emblements, and free ingross, egrets, and regreves, to cut and carry away the profits. (Co. Lit. 56.) But it is otherwise, when the tenant himself determines the will; for in this case the landlord shall have the profits of the land. (Co. Lit. 57.) And if rent be payable quarterly, or half-yearly, and the lessee determines the will, the rent shall be paid to the end of the current quarter or half-year. (Salk. 344. 1 Sid. 339.) Upon the same principle, courts of law have of late years leaned as much as possible against continuing demises, where no certain term is mentioned, to be tenancies at will; but have rather held them to be tenancies from year to year for so long as both parties pleaseth, especially when an annual rent is reserved, in which case they will not suffer either party to determine the tenancy even at the end of the year, without reasonable notice to the other, which is generally understood to be six months. For another species of estates at will, see COPYHOLD. See also SUFFERANCE.

A lease is either written, called an indenture deed-poll, or lease in writing; or by word of mouth, called lease-parol. See PAROL.

All leases, interests of freehold, or terms for years in lands, &c. not put in writing and signed by the parties, shall have no greater effect than as leases at will; unless it be of leases not exceeding three years from the making; wherein the rent reserved shall be two-thirds of the value of the things demised. (Stat. 29 Car. II. cap. 3.) Leases exceeding three years must be made in writing, and if the subsistence of a lease be put in writing, and signed by the parties, though it be not sealed, it shall have the effect of a lease for years, &c. Wood's Inl. 266.

But a lease in writing, though not under seal, cannot be given in evidence, unless it be signed. (1 Term. Rep. 735.) Articles with covenants to make a lease to let and make a lease of lands, for a certain term, at so much rent, hath been adjudged a lease. (Civ. Eliz. 486.) In a covenant, with the words "have, profits, and occupy lands, in consideration of a yearly rent, without the word demise," it was held a good lease; and a licence to occupy, take the profits, &c. which paffeth an interest, amounts to a lease. (3 Bull. 204. 3 Salk. 223.) An agreement of the parties, that the lessee shall enjoy the lands, will make a lease; but if the agreement hath a reference to the lease to be made, and implies an intent not to be perfected till then, it is not a perfect lease till made afterwards. (Bridg. 13. 2 Slepe. Abr. 374.) If a man, on promise of a lease to be made to him, lays out money on the premises, he shall oblige the lessee afterwards to make the lease; the agreement being executed on the lessee's part, where no such expense hath been, a bare promise of the lease for a term of years, though the lessee hath paffion, shall not be good without some writing. A lease for years may begin from a day past, or to come, at Michaelmas next, Christmas next, three or four years after, or after the death of the lessee, &c. though a term cannot commence upon a contingency which depends upon another contingency. (1 Inl. 5. 1 Rep. 155.) If one makes a lease for a year, and fo from year to year, it is a lease for two years; and afterwards it is but an estate at will. (1 Mod. 4. 1 Litt-w. 213.) And if from three years to three years, it is a good lease for six years; also, if a man make a lease for years, without specifying the number, it may be good for two years, to answer the plural number. (Wood's Inl. 267.) Of all kinds of powers the most frequent is that to make leaves. In the making of such leases all the requisites specified in the power must be strictly observed; and such leaves must contain all such beneficient clausules and reservations as ought to be, for the benefit of the remainder-man; the principle being, that the estate must come to him in as beneficial a manner as the ancient owners held it. By lat. 29 Geo. II. c. 31. infants, lunatics, and personages in covert, may apply to the courts of chancery or exchequer, or to the courts of equity of the counties palatine of Chester, Lancaster, and Durham, or to the courts of great fession of Wales, by petition or motion in a summar way, and by the order of those courts respectively, such persons may by deed only, without levying a fine, surrender leases for lives or years, and take new leases for lives or years of the premises comprized therein. Joint-tenants, tenants in common, and coparceners may make leaves for life, years, or at will, of their own parts, which shall bind their companions; and in some cases, persons who are not feoffed of lands in fee, &c. may make leaves for life or years, by special power enabling them to do it; when the authority must be exactly purified. (Wood's Inl. 267.) But there is a difference, where there is a general power to make leaves, and a particular power. (8 Rep. 69.) If joint-tenants join in a lease, this shall be but one lease, for they have but one freehold; but if tenants in common join in a lease, it shall be several leases of their several interests. 3 Rol. Abr. 64. Com. Dig. title Estates (G. 6.) Bac. Abr. Leases (1. 5.) A lessee may take dummies on the tenements: let for the rent; or may have action of debt for the arrears, &c. Tenants suffering houses to be uncovered, or in decay, taking away windwoc,
wainfoot, &c. fixed to the freehold, unless put up by the
lessee, and taken down before the term is expired; cutting
down timber trees to fell, permitting young trees to be
destroyed by cattle, &c. ploughing up ground that time out
of mind hath not been ploughed, not keeping banks in re-
pair, &c. are guilty of waste. (1 Init. 52. Dyer 37.
2 Salk. 568.) Leases are bound to repair their tenements,
except the contrary be mentioned in the lease. Although a
lease for years is not obliged to repair the house let to him,
which is burned by accident; if there be not a special cov-
enant in the lease, that he shall leave the house in good repair
at the end of the term; yet if the house be burnt by negli-
gence, the lease shall repair it, although there be no such
covenant. (Parch. 24 Car. B. R.) A lease will at will is not
bound to sustain or repair, as tenant for years is. A lease
who covenants to pay rent, and to repair, with an excep-
tion of casualties by fire, is liable upon the covenant for rent,
though the premises are burnt down, and not rebuilt by the
lessee after notice. (1 Term Rep. 310.) A proviso in a
lease for two years, that the landlord shall re-enter, on the
tenant’s committing any act of bankruptcy, on which a
commission shall issue, is good. (2 Term Rep. 13.) An
assignee of a bankrupt, a devisee, and a personal represen-
tative, are assignees in law to the purpose of being liable
to actions on a covenant for rent in a lease to the bankrupt,
deviser, or intestate. (Dongl. 184.) Perfons for whose
lives eftates are held by lease, &c. remaining beyond the,
or being absent seven years, if no proof be made of their being
alive, shall be accounted dead. (See 19 Car. II. c. 6.)
Where the term of a lease is to end on a precise day, then,
there is no occasion for a notice to quit; because the lease
of course is at an end, unless the parties come to a fresh
agreement. In the case of a tenancy from year to year,
there must be half a year’s notice to quit, ending at the
expiration of the year. Six calendar months’ notice is not suf-
cient. And there is no distinction between houses and lands as
to the time of giving notice to quit. 1 Term Rep. 54 1590.
Lease by statute. There are three kinds of persons, who
may make leases for three lives or twenty-one years, and not
exceeding this term, by statutes, that could not do so here-
tofore, viz. tenants in tail, binding their issue in tail, but not
in remainder or reversion; husband and wife, of the wife’s
land; and persons settled of an estate in fee simple in right of
the church, except parsons and vicars; by the Statute 32
Hen. VIII. c. 28. called the “enabling statute.”
But this statute specifies several requisites in order to
render the leases binding: they must be by indenture, and
not by deed-poll, or patent. They must commence from the
day of making, and not at any greater distance of time; the
old lease, if there be any, must be first absolutely surrendered,
or be within a year of expiring: it must be either for twenty-
one years, or three lives, and not for both; it must not ex-
cede the term of three lives, or twenty-one years, but may
be for a shorter time; the lease must be of corporeal hered-
taments, and not of such things as be merely in grant; for
no rent can be reserved out of these by the common law, as
the lessor cannot refer to them to detain: though now by
5 Geo. III. c. 17, a lease of tithes or other incorporeal hered-
taments alone, may be granted by any bishop or eccle-
siastical or clematory corporation, and the successor shall
be entitled to recover the rent by an action of debt, which,
in case of a freehold lease, he could not have brought at the
common law. The lease must also be of lands and tenements
commonly letten for twenty years past; and the customary
rent for that term reserved; and leases must not be made
without impemel of wale.
By 1 Eliz. c. 15, called the “disabling or restraining a-
tute,” it is enacted, that all grants by archbishops and bi-
shops, other than for the term of twenty one years or three
lives from the time of making, or without reserving the
usual rent, shall be void: but this statute did not extend to
grants made by any bishop to the crown; however, these,
as well as those made to any subject, were comprehended in
the prohibition of the statute 1 Jac. I. c. 3. The restric-
tions of this statute were extended by 13 Eliz. c. 10. ex-
plained and enforced by 14 Eliz. c. 11. and 14. 18 Eliz.
c. 11. and 43 Eliz. c. 29. to certain other inferior corpo-
pions, both sole and aggregate. From all these it is col-
cluded, that all colleges, cathedrals, and other ecclesiastical
or clematory corporations, and all parsons and vicars, are
restrained from making any leases of any kind of their land,
unles under the following regulations: 1. They must not ex-
ceed twenty-one years or three lives from the making.
2. The accustomed rent, or more, must be yearly reserved
upon them. 3. Houses in corporations or market-towens
may be let for forty years; provided they be not the man-
agement-houses of the lellars, nor have above ten acres of ground
belonging to them, and provided the lessore be bound to
keep them in repair; and they may also be aliened in fee-
simple for lands of equal value in recompense.
Where there is an old lease in being, no concurrent lease shall
be made, unles where the old one will expire within three years.
5. No lease by the equity of the statute shall be made with-
out imprisonment of wale. (Co. Litt. 45.) 6. All bonds
and covenants tending to frustrate the provisions of the
statutes 13 and 18 Eliz. shall be void. The 13 Eliz. c. 20,
together with all explanations, &c. of the same by 14th,
18th and 43d of Eliz. and much of 3 Car. I. which made them
perpetual, are repealed by 43 Geo. III. c. 84.
f. 10.
If a bishop have two chapters, as there may be two or
more to one bishopric, both chapters must confirm leases
made by the bishop. (1 Init. 131.) A lease made by a
bishop to begin precipitantly for twenty-one years, when there
is an old lease in being, is good, notwithstanding the flat.
of 1 Eliz. c. 19. (Moor. Cafl. 541.) But if such a lease is to
commence at a future day, it will be void. (1 Leon 44.)
Lease for three lives by a bishop of tithes is void against the
successor, although the usual rent be duly received. (Moor
Caf. 1778.) Leases of a dean and chapter are good, with-
out confirmation of the bishop. (Dyer, 273.) Nelf. Abr.
1096.) Where there is a chapter and no dean, they may
make grants, &c. and are within the statute. (1 Mod. 204.)
A prebendary’s lease confirmed by the archbishop, who is
his patron, is good, without confirmation of dean and chap-
ter. (3 Bulltr. 290.) But where a prebendary made a lease
for years of part of his prebend, and this was confirmed by
dean and chapter; because it was not confirmed likewise by
the bishop, who was patron and ordinary of the prebend,
the lease was adjudged void. (Dyer 6.) If a prebendary
hath recorries in two several dioceses, belonging to his pre-
bend, and his lease of them is confirmed by the bishop, dean
and chapter of the diocese of which he is prebend, it is
good, though not confirmed by the other. (Litt. 75.) A
chancellor of a cathedral church may make a lease, and it
is said it will be good against the successor, though not
confirmed, &c. (Litt. 138.) If a parson or vicar makes a
lease for life or years, of lands usually letten, reserving the
cumulatory rent, &c. it must be confirmed by patron and or-
dinary, for they are out of the statute 32 Hen. VIII. c. 28.
And if the parson and ordinary make a lease for years of the
glebe to the patron; and afterwards the patron assigns the
lease to another, such assignment is good, and is a confirma-
tion
tion of that lease to the assignee. (5 Rep. 15.) A lease for years of a spiritual person will be void by his death, if it is not according to the statute; and a lease for life is voidable by entry, &c. of his successor. (2 Cro. 173.) If a bishop be not the bishop de jure, leases made by him to charge the bishopric are void, though all judicial acts by him are good. (2 Cro. 353.) And where a bishop makes a lease, which may tend to the diminution of the revenues of the bishopric, &c. which should maintain the successor, there the deprivation or translation of the bishop is the same with his death. 1 Inst. 324.

There is another restriction with regard to college leases, by stat. 18 Eliz. c. 6, which directs, that one-third of the old rent, then paid, should for the future be reserved in wheat or malt, reserving a quarter of wheat for each 6s. 8d. or a quarter of malt for every 5s.; or that the leesees should pay for the same according to the price that wheat and malt should be sold for, in the market next adjoining to the respective colleges, on the market-day before the rent becomes due. This money arising from corn rents is, communitus annis, almost double to the rents referred in money.

But when a quarter of wheat is worth 50s. and the colleges receive one-third of their rent in corn, i. e. a quarter of wheat, or its value for every 13s. 4d. which they are paid in money, it follows that the corn rent will be in proportion to the money rent nearly as four to one. But these rents united are very far from the present value. Colleges, therefore, in order to obtain the difference, generally take a fine upon the renewal of their leases.

The leases of beneficed clergymen are farther restrained, in case of their non-residence, by statutes 13 Eliz. c. 20. 14 Eliz. c. 11. 18 Eliz. c. 11. 42 Eliz. c. 9. which direct, that if any beneficed clergymen be absent from his cure above fourcore days in any one year, he shall not only forfeit one year’s profit of his benefice to be distributed among the poor of the parish; but that all leases made by him of the profits of such benefice, and all covenants and agreements of like nature, shall cease and be void; except in the case of licensed pluralists, who are allowed to demise the living, on which they are non-resident, to their curates only, provided such curates do not absent themselves above forty days in any one year. Blacklt. Com. b. ii.

An assignment differs from a lease only in this; that by a lease one grants an interest less than his own, referring to himself a reversion; in assignments he parts with the whole property, and the assignee stands to all intents and purposes in the place of the assignor.

If a leffer accepts of rent from an assignee, knowing of the assignment, it bars him from action of debt against the leffer; for the privity of contract is extinguished: but after such acceptance, the leffer or his assign may maintain an action against the first leffer upon his covenant for payment of the rent. (1 Saund. 241. 3 Rep. 24.) But acceptance of rent from the assignee has been adjudged a sufficient notice of the assignment, so that the leffer could not refer to the first leffer. 2 Bulltr. 151.

Leases of the King. Leases made by the king, of part of the duchy of Cornwall, are to be for three lives, or thirty-one years; and not to be made dishonorable of waftle, wherein the ancient rent is to be reserved; and estates in reversion, with those in poecifion, are not to exceed three lives, &c. 13 Car. II. c. 4.

Leases from the crown of lands in England and Wales, and under the seal of the duchy of Lancaster, &c. for one, two, or three lives, or terms not exceeding fifty years, are allowed time for enrollment, &c. by Stat. 9 Ann. c. 18. Leases made by the prince of Wales of lands, &c. in the duchy of Cornwall, for three lives, or thirty-one years, on which is reserved the most usual rent paid for the greatest part of twenty years before, shall be good against the king, the prince, and their heirs, &c. and the conditions of such leases be as effectual as if the prince had been seized of an absolute estate in fee-simple in the lands. Stat. 10 Geo. II. c. 29.

Lease of Land, in the Economy of Agriculture, a kind of contract or agreement for the letting of lands, tenements, &c. either for life, or a certain term of years, under a reserved rent. It has been stated by Mr. Marshall, that the different modes of holding land are distinct from that of "the tenant holding at will, or until the customary notice be given, by either party to the other,—without any legal contract of written agreement,—the only tie between the owner and the occupier being the custom of the estate, or of the county in which it lies,—and the common law of the land." This, he conceives, may be considered as "the simple holding which succeeded the feudal or copyhold tenure; but which is now going fast into disuse." The second mode is that of "holding from year to year, under a written agreement, with specified covenants." This, which is a more modern fable, is, on the contrary, he thinks, becoming more and more prevalent; even where leases for a term of years were formerly granted. The third, is that of a "lease for a term of years; as seven, fourteen, twenty-one, or a greater number of years certain; but without the power of assignment, unless with the consent of the lessor." And the fourth, that of a "lease for lives; as one, two, three, or more, without the power of assignment, which he believes now are rarely granted in England, but in Wales they are still prevalent; the rent being there settled according to the value of the land at the time of letting, as on granting a lease for a term. And, in the western extremity of England, what are termed life leases are still common. But that they are in fact rather pledges for money taken up, or deeds of sale for lives, than leases; as nearly the whole of the estimated sale value of the land, during the life term, is paid down at the time of purchase, the seller referring only a quit-rent or annual acknowledgment." It is conceived by the farm writer, that life leases may be considered in different points of view; as "to a tenant who holds at a moderate rent, a lease for life is gratifying, his farm becoming a fortune of life estate, in which he is fixed for life; but that unless he is a prudent or a fortunate man, it may prove a source of misfortune to his family, who in the moment of their distress for his loss, may be liable to be turned out, penniless, to a hovel and home; a circumstance which can rarely happen, under holdings for certain terms of years." These sorts of leases have a much better effect, it is supposed, on agriculture than annual holdings; and that it is more than probable that life tenancy heretofore has assisted in the advancement of the art. "It is, however, a well ascertained fact, that the manifold and great improvements which have taken place in English agriculture, during the last half century, have not been effected in Devonshire nor in Wales, but in Norfolk, and in the midland counties under leases for terms of years." And that in a political light, life leases have a favourable appearance, as tending to fill up a space between ordinary tenants and yeomanry or small proprietors, and giving their holders better stakes than less certain occupiers have, in the established order of things. But that "here it is the light in which life-holds appear to land proprietors that is entitled to the
LEASE.

It may be noticed, that those farts of holdings which are only for the year, "are, to a tenant, most discouraging; and to improvement in agriculture most unfriendly. In a public view they are of course highly imployable, while to a proprietor they are most convenient, as he may be fail to be in constant possession of his estate. He can lay out and execute general improvements, as embankments and drainage, extensive works of irrigation, the alteration of water-courses, roads and fences, and complete the arrangement of tenements without control. It would be unwise, therefore, on an estate under this fort of tenancy, to alter it, until the requisite improvements were planned, and put in a train of being performed." It has, however, been further judiciously remarked, that "whatever discourages agriculture cannot be permanently profitable, either to a proprietor or the community." And in regard to present profit they must be highly disadvantageous to the proprietor or owner.

With respect to the third holding of land, as that of leafes for terms of years, as "for twenty-one years, though they may be profitable at their commencement, they have, it is supposed, been found much otherwise before their expiration; owing to the great rise in the value of farm produce, during the terms. And while proprietors who were letting their lands from year to year, were profiting by this circumstance; the income of those whose lands were under long leaves (whether of lives or years) were stationary; and this while the expences of living were advancing with the value of lands; which circumstances, added to their being controlled in the required arrangement, and perhaps annoyed during a length of years, by the improper conduct of ignorant, ill-disposed, purse-proud tenants (enriched by these very circumstances) have determined many persons in different parts of the kingdom to discontinue the practice of granting leaves; giving written agreements from year to year only; which is much to be lamented for the intereft of agriculture and the community in general." While others have shortened the terms of their leaves to fourteen years. But such "has been the rapid depreciation in the value of money, and the nominal increase of the value of lands, that even this term has been found serenely inconvenient to a landlord; and the term of seven years (without a covenant of remuneration) is, it is believed, of little use to a tenant." These fixed leaves are liable, it is conceived, to another objection. As "although a man of spirit and worth will not only give an advanced rent, in the first instance, but will, through the improvements he has made, be able and willing to give a still greater advance at the end of the term; yet, when a lease of this nature has been unfortunately or improvidently granted to a poor, an ignorant, an insoucient, a restless, or a dishonest man, the farm thus let may be left at the end of the term in a much worse condition than it was in at the commencement." This renders it highly necessary for the manager of an estate to be careful in the choice of tenants. Where great and expensive improvements are required, it will be constantly necessary, however, to have long leaves.

This may be remedied, in a great measure, by the renewal of leafes before their terms are expired.

The above writer considers it useful, for owners or proprietors to come to clear understandings with their tenants, three years previously to the terminations of their respective leafes. "For it is conceived, that, until about that period, a skilful tenant continues to keep his land in cultivation and condition, for his own interest; which, until then, may be fail to go hand in hand with that of his landlord. And if, at that period of a leafe, a fresh agreement were entered into, the ruinous consequences of an expiring term might be avoided. And that from proprietors objecting to give leafes for long terms, "it occurred to him, that agreements for holding from three years to three years, instead of from year to year, would be an eligible species of tenancy. Or, which is precisely the same thing, granting leafes for five years certain; with a condition, that if neither party give notice to quit before the expiration of the first three years, then the term to be prolonged to nine years; and so on, from three years to three years, (or in effect from six years to six years,) until three years after notice has been duly given by either party to the other," as by these means room is given for a tenant "to turn his hand in. He has, in reality, a fresh leaf of six years granted him every third year. And this is sufficient to encourage him to keep his lands continouly in the most husbandlike state. And if he execute any of the higher improvements, it is but reasonable that he should have, whenever he may quit his farm, an equitable remuneration for the remainder of such improvements. Thus the tenant is placed on sure ground; he may still manage and improve with much the same confidence, as if the lands in his occupation were his own property." And "in return for such advantages, the tenant cannot be justi, it is supposed, to covenant, that, during the last three years of his term, he will manage his farm in a husbandlike manner, and at the end of the term leave it in such a state of cultivation and repair, as will induce a good tenant to take it at a full rent; or suffer the proprietor to put it in such a state, as his (the out-going tenant's) expense. An estate which is under leafe on these principles, and under attentive management, cannot, it is conceived, be let down to an unprofitable state. It must continually remain under a regular course of husbandry, and in a state of cultivation and repair; and the more permanent improvements be kept up. If the acting manager do his duty, even the changing of tenants cannot interrupt its prosperity," while "the incoming tenant (under active management) steps into his farm, with the advantages that he would have enjoyed, had it been under his own direction, for the three preceding years." But "with a leafe on this principle, and with a proper choice of tenants, removals can rarely happen. What proprietor, who knows the difficulty of procuring a good tenant, would wish to discharge him? And no such tenant would readily leave the farm he is settled upon, if he find proper treatment. Even should notice be given in consequence of any misunderstanding between the parties, three years allow time for reflection; and, before they expire, retentment may die away, and cordiality be restored. If, however, either party be dissatisfied, he has an easy way of dissolving the connection. Or if a proprietor is desirous to make fresh arrangements on his estate, or to regulate his rent-roll by the exil-
LEASE.

ing value of money, he need not wait many years to fulfil his dege; for if the tenant in occupancy will not agree to pay a fair rent, the owner has three years before him to choose one who will.” It is thus evident, that “a lease on this principle has a decided preference, by a proprietor, to long leaves. And its advantage over annual holdings is not less considerable. The lands of an estate are well worth from five to ten per cent. more to a tenant, under the former, than under the latter tenancy. So that beside the conveniences mentioned, a proprietor may be immediately adding very considerably to his income, by this principle of management.

This has been proved in many cases in different parts of the kingdom.

Covenants of Leaves.—It is suggested, that the necessary covenants, — the reservations, restrictions, obligations, penalties, and remunerations, that the lease (or form of a lease) of any landed estate contains, are (or ought to be) a code of private restraining laws, suited to the circumstances of that particular estate, in order to protect it from injury, and to promote its prosperity; an honest tenant considers the covenants of his lease merely as instructions to direct his steps, but which ought to restrain him no farther than to protect the farm or the estate from injury. But a worthless tenant, as a thief, is ever ready to break the laws which bind him; and the proprietor of an estate ought to have some means of punishing him for his fault. Penal covenants in leases are of course of the greatest importance to proprietors. But on account of the great difficulty with which a general law of this nature would be framed, owing to the great diversity of soils, situations, and modes of culture, every estate, strictly speaking, requires its own peculiar code to govern and defend it, (and of course the great difficulty which a court must find to decide with any fort of accuracy in cases of this kind,) one would naturally imagine, it is said, that courts of law would rather be thankful to proprietors of estates, for furnishing them with ready and safe means of doing justice, than let their faces against any covenants, which have been formerly entered into, and legally confirmed by the parties before them. If penalties are excessive or oppressively severe, or have been perpetually amended, it undoubtedly belongs to a court of law to mitigate or remove them. But severe restrictions, and excessive penalties, are highly impolitic, and altogether improper to be introduced into the lease or law of an estate, insomuch as they tend to depress its character, and may prevent good tenants from settling upon it; or drive away those whose it may already possess; and of course militating against one of the first principles of good management. But where, by judicious restrictions and reasonable penalties, designing men are kept aloof, a general good is gained to the estate.

The particular covenants that are necessary, must be determined by the existing circumstances of the estate, or the particular farm for which it is intended; the modes of culture, cropping, &c. as it is obvious, that “a grazed land farm requires a set of covenants differing from those which are proper for a farm under mixed cultivation. And an arable farm, situated near a great town, should have covenants differing in some respects from those of another, which lies in a reclusive district; while every part of an estate, and all estates on which hedge timber can be profitably raised, call for a series of regulations, which an unimproved estate, or one on which grown timber only is to be protected, does not require.” And that, “much depends on the time of changing tenants. A spring and autumnal removal require very different stipulations respecting the dates in which the lands of a farm are to be left; how the crops in the ground, and the produce on hand are to be disposed of; and by whom the crops of the succeeding year are to be put in. Every district has its customary time or times of removal, and it can seldom be prudent in an individual to alter it (even though very improperly fixed) as he might thereby diminish his choice of tenants. Nevertheless, it is in the power of proprietors conjointly, to effect, in time, the required alteration. Michaelmas and Lady-day may be considered as the ordinary times of changing tenants in England. The former is not an ineligible time for removing in autumn, but the latter is extremely improper, as being in the middle of spring feed time, and falling at a time when the winter fodder is partially expended, and the crops of the preceding year are partially thwarted out.” Mr. Marshall states, that “in the north of England (Cleveland, in Yorkshire, being the most southern district in which he has observed it,) a far more rational plan of removal is established. There, the arable lands are quitted at Candlemas; the pasture grounds (Cleveland being much of a dairy district) at Lady-day; and the mowing ground and the home-hall at old May-day. While, in Scotland, similar regulations prevail; but with a well judged difference, which naturally arises out of the different climates of the two situations. There, the premises are finally quitted at what is termed Whitmaside, namely, the fifteenth of May old style.” And it is the opinion of this writer, that, “for the more southern provinces of England, the first of May, new style, would be a proper time for removals in the spring.”

Forms of Leaves.—In respect to the forms of leases, those which are good do not, it is stated, “merely require a judicious selection of covenants, but that the several clauses should be properly digested; and be arranged, worded, and lettered in such a manner, as to be intelligible to plain countrymen,—to men for whose guidance and good government they are intended.” And the plan, which experience entitles the above writer to recommend, is that “of printing leaves on large folio sheets of firm paper, or sheets of parchment, folded in the folio manner; each page containing two columns, and each clause composing a distinct paragraph; with a blank page, or half page, to receive the title, or rough plan of the farm described, as well as a particular, or schedule, of the different parcels of land which it is composed: with the number name, and measurement of each arranged in the column manner; in order that no doubt may at any time arise respecting their identity.” It is useful to have a book in which all these, and some other circumstances, are regularly arranged and marked down.

Mr. Kent, in his “Hints to Gentlemen of Landed Property,” states, that the ancient feudal tenures had undoubtedly a strong tendency to enflave mankind, by subjecting them to the control and power of an arbitrary lord; but, like most other things, there were some advantages to be found in the system. Every man who held land had a certainty in it, as the tenant generally held his possession for life. When these tenures were discomfited by the more liberal spirit of modern law, some new compact became necessary, and terms of years were substituted in lieu of the former; for, as land properly managed requires great expense, and seldom answers that expense in one year, it was but reasonable that the man who applied his judgment, devoted his labour, and ventured his capital, should have some reasonable time allowed him to reimburse himself, and derive some proportionate reward for what he had done. In the course of time, this term began to be reduced into a certain number of years; and as most of the land was formerly under the regulation of two crops and a fallow, the time allowed was from three to twenty-one years. And the latter in the end became the most general limitation,
and is the most prevalent term for leafes at the present period.

There can be no doubt, it is suppos'd, but that leafes are the first, the greatest, and most rational encouragement that can be given to agriculture; yet of late years there are very strong prejudices entertained against them.

Let any impartial man take a view of two districts, where it is the custom to grant leafes, and where it is not; in the former he will generally find a respectable yeomanry, and a well cultivated country; in the other, an indigent spiritless race; following a contracted fyllem of husbandry, calculated to answer no permanent purpose of advantage to themselves or landlords. Yet, there are many gentlemen who, to have such people at immediate command, prefer the continuance of a slovenly unproductive style of husbandry, to neatness and fertility. In some parts of England, the prejudice against leafes is so strong, that some landlords will be tempted almost as soon to alienate the fee simple of their estates, as to grant a tenant a reasonable term in them. It is very unfortunate for a county where this abhorrence of leafes prevails, as it keeps back an immense fume of improvement, which otherwise would take place, and robs the indigent occupier of a deal of comfort which might be bestowed upon him; and it can produce no other conflagration to the owner than that of having the country more at command, and forcing a certain degree of respect from it, which is absurd to the full degree; for a landlord may, it is conceived, enforce as much real respect from a tenant on leaf, as from a tenant at his immediate will and pleasure, and at the same time secure his property better, and stipulate for improvements to the extent of his inclination or desire.

It is noticed further, that in the eastern counties, where it is more the custom to grant leafes than in the midland parts of England, agriculture is upon the most respectable footing; and that within half a century there are many estates more than doubled in their value; which, without leafes, where the means of improvement were heavy, could not have carried a third of the advance that has been put upon them. In short, it seems to him unreasonable to expect a man to employ the whole of his capital, and to devote the best part of his life upon an estate which, on the death or mere caprice of the landlord, he is liable to be turned out of at six months, or perhaps a shorter notice.

It is not, however, meant to imply, that leaves ought not in any case to be withheld; there are certainly some exceptions against the practice he wishes to see established: for instance, if lands are situated very near a gentleman's house, part of which it may, perhaps, be an object, on some future occasion, to take into hand, or where a minor is very near coming of age, or where there is any immediate view of sale; in such cases, it would be imprudent to grant leafes. But where none of these contingencies stand in the way, and where estates are under an entail, or in a family that has no idea of parting with them, leasing is unquestionably the most effectual means of raising the value of an estate, as it enables the owner to stipulate for improvements in what way and proportion he pleases, which he cannot do so well in any other manner.

And the author of the "Treatise on modern Agriculture" contends, that nothing gives such a spring to industry as the conviction, founded on the experience of ages, that in this country the fruits of the labours of the industrious man are secured to him. Hence, a farmer will be more or less active in proportion to the security he holds of reaping the fruits of his industry, skill, and capital.

And it is still further stated, that leafes are certainly necessary and proper, as a compact between man and man; and though the mode of cropping and general tenor of the leafe must vary according to times and circumstances, yet no man who has thought seriously on the subject will deny that they are for the benefit of both parties, as they secure to the landlord the proper management of the land so leafed, and to the tenant the additional profits which may be expected to arise from his superior cultivation of such lands or farms.

But as it is necessary to impose some degree of restraint upon tenants, the means of doing it in such a way that they may not be so fettered as to be prevented from making useful improvements, or left so much at liberty as to do mischief; are the points that forms the principal difficulty. Hence the circumstance to be chiefly guarded against by restrictive penal covenants, are those of preventing the breaking-up of old meadows, postures, or other lands, the removing away hay, flax, or other materials convertible into manure; and the improving or destroying of timber trees. To enforce the leaving of green winter food; the keeping up of all forts of fences; the cleaning of water-courses, ponds, pools, &c. and the preventing of buildings, gates, pens, and saddle roads in proper repair. To prevent the forming of rabbit-warrens, and the committing of waste of any kind. And, finally, to regulate the circumstances of the out-going and in-coming tenants with propriety.

But although it is not possible to form any particular leaf, so as to include clauses that can apply to every kind of soil, mode of cropping, and general management; yet, as he has had opportunities of perusing a great variety of leafes in different parts of England; and as he is in possession of one which is the most perfect of the kind he has seen, it is suggested that it may convey more information of the subject than any explanation that could be otherwise given of it.

**Form of Leaf.**

"This Indenture, made the day of in the year of our Lord one thousand eight hundred and between A. B. of in the county of esquire of the first part, and C. D. of in the county of yeoman of the second part: Witnesseth, That for and in consideration of the rents and covenants, provisos and agreements, hereinafter reserved, expressed, and contained, and which, on the part and behalf of the said C. D., his executors and administrators, are to be paid, done, and performed, he the said A. B. hath demised, leafed, fetten, and to farm letten; and by these presents doth demise, leaf, fet, and to farm let unto the said C. D., his executors and administrators, all those messuages, tenements, or farms, situated in the parish of and county of now or late in the possession of together with all and singular houses, out-houses, edifices, buildings, barns, cow-houses, cattle-heds, stables, yards, garths, flakt-garths, gardens, lands, feedings, ways, waters, esements, privileges, and appurtenances whatsoever, to the said demised premises belonging, or in anywise appertaining, except and always reserved out of this present demise, unto the said A. B., his heirs and assigns, all mines, minerals, and quarries, of what nature or kind forever the same may be, as well opened as not opened, lying, being, and remaining within or under the said premises, or which can or may be obtained, or gotten forth, or out of the same, or any part thereof, with liberty to dig brick-earth, and room to work, mow, dry, and burn the same into bricks, in and upon the said hereby demised premises, or any part thereof: And all and every full and free liberty, power, and authority, to and for the said A. B., his heirs or assigns, and his and their agents, servants, and work.
LEASE.

men, at reasonable times in the year, in the day-time, to search for all and every such mines, minerals, quarries, and brick-earth, and to sink pits or shafts, and to make trenches, grot ves, drifts, water-gates, canals, water-courts, and to direct or turn any water-course, brook, or river, for the winning and working such mines, minerals, and quarries, within the said demised premises, with sufficient ground-room and heap-room for laying the ores, metals, minerals, coals, flumes, clay, earth, materials, and rubbish, to be obtained, or be obtained or gotten forth out of the same or any of them; together with full liberty and power to build and erect engines, machines, houfes, bowels, lodges, stables, cabins, and other edifices and erections whatsoever, for the effectual winning and working the same: And also full and free liberty of way, leave, and passage in, through, and over the said premises, or any part thereof, and, from and from the said mines, minerals, quarries, and brick-kilns whatsoever, with carts, wains, waggons, and any other carriage or carriages necessary for loading ores, metals, minerals, coals, flumes, enclaves, bricks, lime, timber, or any other matter or thing whatsoever, and to make, lay, and place through, over, and upon the said premises, any road or roads, waggon-way or waggon-ways, rail-ways, or any way or ways, canal or canals, for the purpose aforesaid, and from time to time to repair the same, and to do all other acts and things needful or necessary for the winning, working, managing, and carrying on the said mines, quarries, and brick-making, as he or they shall think proper, with liberty to demife or grant to any person or persons such liberties as herein before-mentioned: And also, except and referred unto the said A. B., his heirs and assigns, all timber and other trees, woods, underwoods, and plantations, and the ground and soil thereof, now standing, growing, or being, or which shall happen after any time during the continuance of this demise, fall, grow, or be upon the said premises, with liberty to fell, cut down, or lop such timber trees, or other trees, woods, underwoods, and plantations, and to carry away the same, by any means whatsoever: He, the said proprietor, his heirs or assigns, or his or their grantees orleeves respectively, making reasonable satisfaction to the said tenant, his executors or administrators, for the damage or spoil of herbage or ground, to be occasioned by the use or exercise of all and every or any of the liberties aforesaid, such satisfaction to be from time to time fixed and ascertained by two indifferent persons, one to be named by and on the part of the said A. B., his heirs or assigns, and the other by and on the part of the said C. D., his executors or administrators: And also, except and referred full power and authority for the said A. B., his heirs or assigns, and his and their heirs and agents, with workmen in their company, or without, in the day-time twice, or oftener, in every year during the term hereby demised, to enter in and upon the said premises, or any part thereof, to view the state and condition of the same: And also, except and referred unto the said proprietor, his heirs and assigns, free liberty to hunt, course, hawk, shoot, and fish, in, upon, through, and over all and every the said hereby demised premises, or any part thereof; to have and to hold the said meallage, tenement, or farm-held, lands, grounds, and all and singular other the premises hereby demised, or mentioned, or intended so to be, with their and every of their appurtenances (except as before excepted), unto the said C. D., his executors and administrators, from the twelfth day of May, in the year of our Lord one thousand eight hundred and , for and during and unto the full end and term of twenty-one years, from thenceforth next ensuing, and fully to be complete and ended; yielding and paying yearly, and every year during the said term of twenty-one years hereby demised unto the said A. B., his heirs or assigns, the clear yearly rent or sum of of lawful money of Great Britain, by equal half-yearly payments, at two days or times in the year, that is to say, the twenty-second day of November, and the twentieth day of May in every year, by even and equal portions; the first half-yearly payment of the said yearly rent to begin and he made upon the twenty-second day of November next ensuing, and the commence ment of the said term hereby demised: And also yielding and paying yearly and every year unto the said A. B., his heirs or assigns, on the several days and times aforesaid, over and above the said yearly rent of the further rent or sum of pounds an acre, for every acre of the said demised premises, that he the said C. D., his executors or administrators, shall, at any time or times during the continuance of this demise, break up, tear out, or convert into tillage, or have, or use, or employ in any course of husbandry, contrary to the covenants hereafter contained, without the licence and consent of the said proprietor, his heirs or assigns, in writing for that purpose first had and obtained, and in proportion for a greater or less quantity than an acre; the first payment of the said additional rent to be made on the first of the aforesaid half-yearly days of payment, which shall happen after the ploughing, breaking up, tearing out, converting into tillage, or having or using, or employing in any course of husbandry, contrary to the covenants hereafter contained, any part of the said hereby demised premises, which said two several and respective rents are to be paid as above expressed and referred, free and clear of all taxes, affemitions, charges, and impositions whatsoever, as well parliamentary as parochial, or otherwise, which the said premises now are, or may hereafter be liable to answer for payment: Provided always, and upon condition, and it is the true intent and meaning of these presents, that if it shall happen that the said yearly and other rents herein and above referred, or any of them, or any part thereof, be behind or unpaid, by any of the said executors or administrators, or by the heirs or assigns thereof, then the said A. B., shall, or shall, or do, at any time or times during the term hereby demised, alien, let, or assign over the said premises, or any part thereof, unto any person or persons, without the licence and consent of the said A. B., his heirs or assigns, in writing for that purpose first had and obtained, that then, and in any of the said fares, it shall and may be lawful to and for the said A. B., his heirs or assigns, or such person or persons as shall be by him or them appointed for that purpose, into and upon the said demised premises, or into and upon any part thereof, in the name of the whole, wholly to re-enter, and the same to have again, re-poffess, and re-enjoy, as in his and their first and former estate, and from and immediately after such re-entry made, the said term hereby demised shall cease, determined, and become utterly void and of none effect, any thing in these presents contained to the contrary thereof in any wise notwithstanding: And the said A. B., or himself, his heirs and assigns, doth hereby covenant, promise, and agree to, and with the said C. D., his executors and administrators, that it shall and may be lawful to and for the said C. D., his executors and administrators, (he and they paying the rents and performing the covenants and agreements herein referred and contained, on his and their parts.
LEASE

parts, and to be paid, done, and performed, according to the true intent and meaning of these presents, peaceable and quietly to have, hold, use, occupy, possess, and enjoy all and singular the said premises, with their appurtenances hereby demised (except as before excepted), for and during the said term of twenty-one years, without the lawful let, luit, trouble, demis, hindrance, molestation, eviction, or interruption of him the said A. B., his heirs or assigns, or any other person or persons, claiming by, from, or under him, them, or any of them: And also, that it shall and may be lawful to and for the said C. D. his executors or administrators (he and they paying the rents and performing the covenants and agreements as aforesaid), in the harvest season next after the expiration of the said term hereby demised, peaceably and quietly to have, cut down, reap and lead the crop of corn or grain by him, them, or any of them, sow and then growing upon two-third parts of the lands then in ploughing or tillage (according to the covenants hereinafter contained, and the true intent and meaning of these presents), commonly called the way-going crop; and the same corn or grain to set in the back-yards, and thaf to the same in the barn or barns of and belonging to the said demised premises: And that he the said C. D. his executors or administrators, shall, for the purposes aforesaid, have the use of all the back-yards, barns, and granaries of and belonging to the said demised premises, until the twelfth day of May next, after the determination of this demise; and the same corn and grain so thafed (after payment of rents and arrears of rents then unpaid), shall and may carry away, sell, and dispose of, to and for his or their proper use and benefit, leaving and delivering all the straw of the said way-going crop, as soon as the same is thafed (as hereinafter mentioned), in and upon the said premises, unto and for the use and benefit of the said A. B., his heirs and assigns, or his or their next succeeding tenant or tenants: And the said A. B., his heirs and assigns, or his or their next succeeding tenant or tenants, shall and will lead the said way-going crop from the lands where it grew to the barns or back-yards, and fork the same from the loaded carts to the stacks: And also shall and will bear and pay one-half the expense of making and erecting new quick fences upon the said premises, and of clearing, rearing, and preferring the same for seven years, after being first planted: And also, &c. [Here follow any other covenants on the part of the lessor for new buildings, &c. &c.]

And the said tenant, for himself, his heirs, executors, administrators, and assigns, do covenant, promise, and agree to and with the said A. B., his heirs and assigns, by these presents, in manner following, that is to say, that the said C. D., his executors or administrators, shall and will well and truly pay, or cause to be paid, unto the said A. B., his heirs or assigns, the said yearly rent or sum of

[The rest of the text is not fully legible due to the quality of the image. However, it appears to continue with details regarding the lease, including covenants, conditions, and disputes related to the property and its uses.]

* Rape for green food is allowed.
the said premises, and of cleaning, rearing, and preferring the fame for seven years after being first planted. [Here follow any other particular covenants that circumstances may require.]

In addition to this general form of lease, others with particular covenants become necessary for each particular fort of farm.

**Lease, Valuation of**, the mode of finding out and ascertaining the value of leaf-hall property, in which the circumstances that are to be more particularly attended to are those of the peculiar nature or conditions of the leaf, and the difference between the leaf rent, and the full or actual rental value; as all sorts of leaves, where the rent payable is not equal to the just or true rental value at the period of their being sold, lessen the value of the land, and are obviously an incumbrance in different points of view. The mode of managing this business with propriety, according to a late writer, is, after ascertaining the difference between the leaf rent and the full rental value (incumbranced with the fame outgoings and repairs as the leaf rent), to multiply it by the number of years that are unexpired, deducting the product in full from the value of the land free from such incumbrance; and from the product thus found, to further deduct half the interest thereof during the said number of years, together with that of one-half year over, where the rent is payable half yearly, and one year where it is payable annually; as all that a purchaser of this sort of property has a right to expect, is that of receiving the full rent for his land during the continuance of such lease or engagement. See *Valuation of Loaded Property*.

**Lease, in Agriculture**, a provincial term that implies grassy ground, meadow-ground, or any unploughed ground kept for the use of cattle.

**Lease and Release, in Law**, is a conveyance of the fee-simple, right, or interest in lands or tenements, under the statute of Uses, 27 H. VIII. cap. 10. giving the possessor, and afterwards the interdict, in the estate conveyed. This species of conveyance was first invented by Sir Francis Moore, in the statute of Uses, and it is now the most common of any, and not to be shaken. Though the deed of feoffment was the usual conveyance at common law; yet since the Stat. of 27 Hen. VIII. of uses, the conveyance by lease and release has taken place of it, and is become a very common assurance to pass lands and tenements; for it amounts to a feoffment, the use drawing after it the possession without actual entry, &c. and supplying the place of livery and feisin, required in that deed: in the making of it, a lease, or bargain and sale for a year, or such like term, upon some pecuniary consideration, is first prepared and executed, to the intent that by virtue thereof the lessee may be in actual possession of the land intended to be conveyed by the release, and thereby by force of the statute 27 Hen. VIII. c. 10. for transferring of uses into possession, be enabled to take and accept a grant of the reversion and inheritance of the said lands, &c. to the use of himself and his heirs for ever. Upon which the release is accordingly made, reciting the lease and declaring the uses; and in these cases a pepper-corn rent in the lease for a year is a sufficient reservation to raise an use, to make the lessee capable of a release. (2 Vent. 35. 2 Mod. 262.) This is held to supply the place of livery of feisin; and to a conveyance by lease and release is said to amount to a feoffment. (Co. Lit. 270. Cro. Jac. 204.) Black. Comm. b. 11. Tomlin's Jacob Dict. vol. ii. tit. Lease and Release. See Bargain and Sale, and Conveyance. The form of this conveyance is originally derived to us from the common law; and it is necessary to distinguish in what
What respect it operates as a common-law conveyance, and in what it operates under the statute of Uses. At the common law, where the usual mode of conveyance was by feoffment with livery of seisin, if there was a tenant in possession, so that livery could not be made, the reversion was granted, and the tenant attorned to the reversioner. As by this mode the reversion or remainder of an estate might be conveyed without livery, when it depended on an estate previously existing, it was natural to proceed one step further, and to create a particular estate for the express and sole purpose of conveying the reversion; and then by a surnerreder or release, either of the particular estate to the reversioner, or of the reversion to the particular tenant, the whole fee vested in the surrenders or releasee. It was afterwards observed, that there was no necessity to grant the reversion to a stranger; and that if a particular estate was made to the person to whom it was proposed to convey the fee, the reversion might be immediately released to him, which release operating by way of enlargement, would give the releasee (or releasor as he is sometimes termed) a fee. In all these cases the particular estate was only an estate for years; for at the common law the ceremony of livery of seisin is as necessary to create even an estate of freehold, as it is to create an estate of inheritance. Still an actual entry would be necessary on the part of the particular tenant; for without actual possession of the fee the fee is not capable of a release, operating by way of enlargement. But this necessity of entry for the purpose of obtaining the possession, was superseded or made unnecessary by the statute of Uses (27 Hen. VIII. c. 10 above alluded to); for by that statute the possession was immediately transferred to the<i> eff uel quo ufe;</i> so that a bargainee under that estate is as much in possession, and as capable of a release before or without entry, as a leasee is at the common law after entry. All, therefore, that remained to be done to avoid on the one hand the necessity of livery of seisin from the grantor, and to avoid on the other the necessity of an actual entry on the part of the grantee, was, that the particular estate (which, for the reasons above-mentioned, should be an estate for years) should be so framed as to be a bargain and sale within the statute. Originally it was made in such a manner as to be both a lease at the common law, and a bargain and sale under the statute; but as it is held, that where conveyances may operate both by the common law and statute, they shall be considered to operate by the common law, unless the intention of the parties appears to the contrary, it became the practice to insert, among the operative words, the words bargain and sale (in fact, it is more accurate to insert no other operative words); and to express that the bargain and sale, or lease, is made to the intent and purpose that thereby, and by the statute for transferring uses into possessions, the leasee may be capable of a release. The bargain and sale therefore, or lease for a year, as it is generally called, operates, and the bargain is in the possession, by the statute. The release operates by enlarging the estate or possession of the bargainee to a fee. This is at the common law; and if the lease be declared to the releasee in fee-simple, it continues an estate at the common law; but if the lease is declared to a second person, the statute again intervenes, and annexes or transfers the possession of the releasee to the use of the person to whom the lease is declared. It has been said, that the possession of the bargainee under the lease is not properly merged in, as enlarged by, the release; but at all events it does not, after the release, exist distinct from the estate paid by the release. 1 Thurs. 271. b. m n.

As the operation of a lease and release depends upon the lease, or bargain and sale; if the grantor is a body corporate, the lease will not operate under the statute of Uses; for a body corporate cannot be seised to an use, and therefore the lease of possession, considered as a bargain and sale under the statute, is void; and the release then must be of no effect for want of a previous possession in the releasee. In cases of this nature, therefore, it is proper to make the conveyance by feoffment, or by, a lease and release with an actual entry by the leasee previous to the release; after which the release will pass the reversion. It may also be observed, that in exchanges, if one of the parties die before the exchange is executed by entry, the exchange is void. But if the exchange be made by lease and release, this inconvenience is prevented, as the statute executes the possession without entry; and all incidents annexed to an exchange at common law will be preserved. 1 Thurs. 271. b. in n.

When an estate is conveyed by lease and release, in the lease for a year there must be the words, bargain and sale for money, and five shillings or any other sum, though never paid, is a good consideration, whereupon the bargainee for a year is immediately in possession on the executing of the deed, without actual entry; if only the words <i>demesne, grant and to farm, &c.;</i> are used, in that case the leasee cannot accept of a release of the inheritance, until he hath actually entered, and is in possession. (2 Thurs. 425.) But where Littleton says, that if a lease is made for years, and the lessor releases to the lessee before entry, such release is void, because the lessee had only a right, and not the possession; and such release shall not ensue to enlarge the estate, without the possession; though this is true at common law, it is not so now upon the statute of Uses. (2 Mod. 270, 271.) And if a man make a lease for life, remainder for life, and the first leasee dieth, on which the lessor releases to him in remainder, before entry; this is a good release to enlarge the estate, he having an estate in law capable of enlargement by release, before entry had. 1 Thurs. 270.

No person can make a bargain and sale, who hath not possession of the lands; but it is not necessary to reserve a rent therein; because the consideration of money raises the use. If a lease be without any such consideration, the lessee hath not any estate till entry, nor hath the lessor any reversion; and therefore a release will not operate, &c. (1 Thurs. 270. 278. Cro. Jac. 169. 1 Mod. 263.) On lease at will, a release shall be good by reason of the privacy between the parties; but if a man be only tenant at sufferance, the release will not inure to him; and as to the person who hath the reversion it is void, for such tenant hath not any possession, there being no estate in him. Lat. § 461, 462. Cro. Eliz. 21. Dy. 251.

In a lease and release, to make a tenant to the <i>prenip</i> to suffer a recovery, where the release is made to A. B., and his heirs (viz. the tenant to the <i>prenip</i>), it must be also paid to the use of him the said A. B. and his heirs and assigns for ever; for the releasee must be absolute tenant of the freehold. (2 Vent. 312. Lit. Conveyance, 275.) And a release made on trust, must be to A. B., his heirs and assigns, to the only use and behoof of the releasee, his heirs and assigns for ever; in trust for C. D., who is to be a party to the deed, and the purchase-money to be paid by the <i>eff uel que truif.</i> If the words to the use, &c., are not inserted in the release, the estate doth not execute by the statute of Uses, and the truth is void. Lit. Conv. 231, 251. See Recovery and Trust.

A lease and release make but one conveyance, being in the nature of one deed. 1 Mod. 251. See Release.

LEASEHOLD Tenure of Lands, in Agriculture, is that fort of tenancy which is held under lease or special agreement for any definite term, whether of lives or years; which also admits of several distinctions, as, where the term is for
LEA

for a great length of time, as a thousand years, and where it is for life, of which there are different kinds, as where the fine is certain, or under certain limitations on renewal, with an uncertain fine; payable to a proprietor or other superior, who has merely reserved a conventional rent, the tenant having given a sum of money to obtain the lease and the right of alienation; this is a practice common in the western counties; with an uncertain fine payable to a proprietor, who receives the full rent of the land at the time of granting the lease, the landlord having a power of alienation; this is a practice common in Wales, and some parts of this country; and where it is for an ordinary term, (as for less than 100 years,) with the power of alienation. They are all tenures, which give a fort of temporary property or interest in the lands, by which they are rendered liable to bargain or sale as other sorts of property by the holders of them. See TENANT and TENURE.

LEASH, or LEASING. See GLEANING.

LEAT, or LEASING. See GLEANING.

LEATHER. In Commerce, the skins of several sorts of beasts dressed and prepared for the use of various manufacturers, whose bullocks is to make them up, according to their different employments. The butcher and others, who flay them off the carcasses, dispose of them raw or salted to the tanner and taver; they to the shamoy, morocco, and other kind of leather-dressers, who prepare them according to their respective arts, in order to vent them among the curriers and leather-cutters, gloves, harness-makers, coach-makers, faddlers, breeches-makers, gilt-leather-makers, chair-makers, shoe-makers, book-binders, and all in any way concerned in the article of leather.

Leather has divers names according to the flate wherein it is, and according to the different kinds of skins of which it is prepared, and its peculiar qualities when so prepared. 1. The skin is raw as it comes off the animal. 2. Some are salted with sea-salt and alum, or with natron, which is a species of salt-petre, or white salt-wort, to prevent corruption in keeping, or fending to distant tanneries during hot seafons.

Skins dried with the hair on, are commonly thofe of oxen and cows, or buffaloes, either tame or wild. Most of thofe in France come from foreign countries. The places which furnish the largest quantity, are Peru, the ifle of St. Domingo, Barbary, Cape Verde Ifles, the river Senegal in Africa, Mufcovy, Ireland, the ifland of Cuba. Thofe of this latter place are the molt esteemed; they are called Havanah skins, from the name of the capital city of that ifland, whither they are carried in order to be fent to Spain, and from thence into other parts of Europe. After these skins are dryed of their hair, they are fold to the tanners. See CURRYING, TANNING, and SKINS.

The three principal oflafforts of leather are tanned or rawed, and oil and alum leather, all which are dressed in fome yards.

The art of drefling leather in oil confifts in firft foaking the skins; then throwing them into the lime-pit; and when they are taken hence, pulling them and delivering them to the frierer; they are then truck with the oil, and fent to the mill; when they are milled sufficiently; they are thrown into the ditch to be fecured, and by some feduced, and afterwards hung upon the hooks to dry. When they have been weighed and marked by the proper officers, in order to fix the excife duty, they are fit for fale. The forts of skins drefled in oil are thofe of deer, sheep, and lambs, and fome few of goat, and the oil used for this purfće is Newfoundland, or cod's liver oil. The alum leather-dressers' art confifts in properly foking, liming, wringing, (an operation fometimes omitted,) and drying them in a liquor composed of water, falt, and alum, and then drying them properly. The forts of skins drefled in alum are thofe of sheep and lambs, and a large quantity of kid. Poftleth. Dict. Com. art. Leather.

There are feveral statutes relating to leather; the 27 Hen. VIII. c. 14 directs packers to be appointed for leather to be transported; but the 18 Eliz. c. 9, prohibits the flipping of leather on penalty of forfeiture, &c. Though by 20 Car. c. 5, transportation of leather was allowed to Scotland, Ireland, or any foreign countries paying a custom or duty; which statute was continued by divers fubfequent acts.

No perfon shall ingrofs leather to sell again, under the penalty of forfeiture. None but tanners are to buy any rough hides of leather, or calves' skins in the hair, on pain of forfeiture; and no perfon shall forefale hides, under the penalty of 6s. 8d. a hide. Leather not sufficiently tanned is to be forfeited. In London, the lord mayor and aldermen are to appoint and swear searchers and fealers of leather out of the company of cordwainers, &c. and also triers of the sufficiency of leather; and the fame is to be done by mayors, &c. in other towns and corporations; and searchers allowing insufficient leather, incur a forfeiture of 40l. Shoemakers making shoes or boots of insufficient leather are liable to forfeit for every pair 3d. and the value thereof. (1 Jac. I. c. 22.) Red tanned leather is to be brought into open leather markets, and searched and fealed before it be exposed to fale, and on fale is to be registered, or shall be forfeited; and conpts for fale otherwise to be void. (13 & 14 Car. II. c. 7.) Hides of leather are adjudged the ware and manufacture of the currier, and subject to fearch, &c. All perfon dealing in leather may buy tanned leather, searched in open market, and any perfon may buy or sell leather, hides, or skins, by weight. 1 W. & M. c. 33.

The firft statute concerning leather, which it is neceffary for us to refer to in this article, is the 1 Jac. c. 22, which reduces all preceding acts relating to that commodity into one; and therefore to this we shall have a refpect in the progress of this article; premising that all forfeitures by this act, not otherwise specially directed, shall be divided, one-third to the king, one-third to him that shall fue, and one-third to the city, town, or lord of the liberty. By 9 Ann. c. 11, any two juflices near the place where the forfeitures are incurred, or offence committed, may hear and determine the fame. All forfeitures, by the act of 13 & 14 Car. II. c. 7. shall be recovered in any court at Welfminster, or in any court of record in the city, &c. where the offence shall be committed; to be distributed half to the king, and half to the informer. By 39 & 40 Geo. III. c. 66. it is enacted that proper places and times for inspecting all raw hides and skins of cattle, sheep, hores, and hogs, shall be fixed by the mayor, bailiff, or head-officer of any city, town corporate, borough, or market-town, or any two magistrates acting for the fame, or any two juflices acting for the division within or nearest to such city, &c. The manner of appointing inspectors is also prescribed by the faid acts. And by the fame, butchers, &c. who are chargeable with wilfully or carelessly injuring hides, to act to make them lefly valuable, are liable to penalties, not exceeding 5l. (4* Geo. III.) nor lefs than 1s, for the raw hide of every ox, 3 N bull,
LEATHER.

...and one-half shall be equally divided between the inspectors, acting at the respective markets, and the remaining half-part shall be paid weekly to the arbitrator of the market, in respect to which they are received, and paid monthly by the bail arbitrators to the respective persons appointed by the courts of affiants to receive the same. There is a penalty for impeding inspectors, not exceeding 5l. nor less than 10s. for each offence, and also a penalty not exceeding 20l. on inspectors receiving and perrons offering bribes. Salemen are required to deliver an account of hides or skins sold, under a penalty for every offence of 10l. The lord-mayor of London is empowered to incafe the fees of the inspectors, under the representation of the courts of affiants of the companies concerned, to any sum not exceeding 1l. for every hide, 4d. for every calf, hog, pig, sheep, or lamb. The respective courts of affiants are required to appoint annually four arbitrators, to settle disputes arising in any of the markets above-mentioned; and these arbitrators are empowered to fine inspectors, and alfo butchers and salemen, for frivolous decisions and exorbitant impositions. Inspectors and arbitrators are liable to be dismissed for misconduct in their respective offices, or to a fine not exceeding 5l. nor less than 1s. Buyers and sellers of untapped hides or skins are liable to a forfeiture not exceeding 20l. nor less than 5l. for every hide; and not exceeding 5s. nor less than 1s. for every skin of hogs, pigs, or calves; and not exceeding 1s. nor less than 6d. for every sheep or lamb-skin. The treasurers are appointed by the respective courts of affiants to receive the sums collected by the arbitrators; one-half of which shall be paid to the treasurer appointed by the company of butchers, one-fourth to the officer of the company of curriers, and one-fourth to the officer of the company of cordwainers; which sums shall first of all be applied for the execution of the acts, and to the use of the poor of the said companies.

For particular regulations concerning tanners and curriers of hides, see these articles respectively. The mayor and aldermen of London (on pain of 40l. for every year they make default, half to the king and half to him that shall sue) shall yearly appoint eight freemen of some of the companies of cordwainers, currier, faders or girdlers, of whom one shall be a sealer, and keep a seal for the sealing of leather; they shall be sworn to do their office truly; and they shall search and view all tanned leather brought to market, whether it is thoroughly tanned and dried; and if it is, shall seal the same. Four of these officers shall be changed every year; no officer shall be continued above two years together, nor be re-elected till after the end of three years, on pain of 10l. a month. A similar regulation extends to other places. The wardens of the curriers shall search and seal curried leather, for which they are entitled to fees, to be paid by the currier; on pain of forfeiture for every hide not searched and sealed, 4s. 6d. If any person shall fail to seal his or her hide, he shall forfeit 5l. if he shall take a bribe, or exact a fee not appointed, he shall forfeit 20l.; and if he shall refuse to execute his office, he shall forfeit 10l. If any person shall hinder the sealer in the execution of his office, he shall forfeit 5l. (1 Jac. c. 22.) The mayor of London (on pain of 5l. half to the king, and half to him that shall sue) shall, within six days after notice given of any seizure of any leather, red and unwrought, appoint six triers, two of the cordwainers, two of the curriers, and two of the tanners, using Leadenhall market, who, upon their oaths taken before him, shall, on the second or third market-day for leather, try the same, whether it be sufficient or not. The same regulation extends to other places. Triers not doing their duty shall forfeit 5l. The offering for sale of unsearched and
and unfealed leather incurs a forfeiture of the same, or its value, and for every hide or piece 6s. 8d.; and for every dozen of calves’ skins, 3s. 4d.; but no person shall incur any penalty for selling or buying any sheep-skins, unfealed or unfealed. (1 Jac. c. 22. 4 Jac. c. 6.) All red tanned leather shall be bought only in the open fair or market, and not in any house, yard, shop, or other place, on pain of forfeiting the same, or its value, and rendering the contract void: and such leather shall be searched and sealed before sale, and on sale shall be registered, on pain of forfeiting the same, or its value. (19 & 14 Car. II. c. 7.) Searchers and sealers shall keep a register of all bargains made for leather, during the fair or market, with the prices; taking for searching, sealing, and registering of every ten hides, or butts, of the feller 2d., and so in proportion; and for every five dozen of calves’-skins, or sheep-skins, 2d.; and of the buyer after the same rate. Red tanned leather, brought into London, or within three miles of it, shall be brought to Leadenhall, to be viewed and registered by the searchers, with half such fees to be paid for tanned leather brought out of London, or within three miles, and searched and sealed before it be brought within the city; on pain that every person houling, or not bringing his leather to Leadenhall, shall forfeit for every hide or skin 6s. 8d. No person shall buy any tanned leather, unwrought, but who shall work the same into wares, on pain of forfeiting the same, or its value. (1 Jac. c. 22.) But by 12 Geo. II. c. 25, all persons who deal or work in leather may buy all sorts of tanned leather in open fair or market, whether curried or uncurried, being first searched and sealed, and may cut and sell the same in any small pieces in their open shops. (See also 1 W. & J. II. c. 33.) Within London, or within three miles, no person shall sell any wares appertaining to the mystery of any artificer cutting leather, but only in open shop, common fair, or market, whereby the wardens may have search thereof: on pain of forfeiting the same, and also 10s. 1 Jac. c. 32.

No shoemaker shall make any boots or shoes, or any part of them, except of leather, well and truly tanned and curried, or of leather well and truly tanned only; nor put into any part of any shoes or boots, any leather made of a sheep-skin, bull-hide, or horse-hide, &c. &c., on pain of forfeiting every pair of shoes or boots 3s. 4d., and the value. And if any artificer using leather do make any wares of any tanned leather insufficiently tanned, or of tanned and curried leather, not sufficiently tanned and curried, he shall forfeit the same, and the value. If any shoemaker or cobbler within London, or three miles of it, shall put any tanned leather into any boots or shoes, or other things made of tanned leather, which shall not be well and properly tanned, or do put any curried leather into boots or shoes, or any things made of leather, which shall not be sufficiently tanned and curried, and also sealed; he shall forfeit the same, and the value. 1 Jac. c. 22.

All sorts of leather and skin, tanned or drest, may be exported. 20 Car. II. c. 5. 9 Ann. c. 6.

By 43 Geo. III. c. 69, a duty is laid upon all hides and skins, vellum and parchment, imported; and drawbacks allowed on the exportation of them. Other duties are also imposed by 49 Geo. III. c. 98, for which we refer to the act, feched A. After the duty on importation shall be paid, the officers of the customs shall cause every hide or skin to be marked, to denote the payment of the duty. (9 Ann. c. 11.) But by 15 Geo. III. c. 35, raw or undressed goat-skins may be imported for five years, duty free; and this act was made perpetual by 31 Geo. III. c. 43. The several duties for and upon all hides and skins, and parts and pieces of hides and skins, tanned, tawed, or drest, to be paid by the tanners, tawers, and dresters of hides and skins respectively, and the duties upon vellum and parchment, to be paid by the respective makers thereof; and certain drawbacks are allowed on the exportation thereof. By tanned hides or skins, or pieces thereof, are meant only such as are tanned in wool, made of the bark of trees, or huck-mack; and by hides and skins, dressed in oil, are meant such as are made into leather in oil, or with any materials, of which the chief ingredient shall be oil; and by tanned hides or skins, are meant such as are dressed or made into leather, in alum and salt, or meal, or other ingredients properly used by tawers of white leather. 9 Ann. c. 11. 3.

By 43 Geo. III. c. 69, every tanner shall take out a licence annually, for which he shall pay, if within the bills of mortality, £1, elsewhere 2l. 10s., on pain of 20l. (24 Geo. III. c. 41. Serf. 2. § 1.) And every tawer shall take out a licence annually, for which he shall pay 1l. on the penalty of 10s. And every dresher of hides in oil shall take out a licence annually, for which he shall pay 2l. on the penalty of 20l. And every maker of vellum or parchment shall take out a licence annually, for which he shall pay 1l. on the penalty of 10s. And every person who shall take out such licences shall renew them annually, ten days before their expiration, on the penalties above stated. Collar-makers, glowers, broad-cutters and others, who dress skins or hides, or pieces thereof, in oil, alum, and salt, or meal, or other ingredients, and who cut and make the same into wares, shall be accounted tawers, or dressers. (2 Ann. c. 11. § 25.) Any hide or skin, which hath once paid the duty, shall not be charged under any other denomination. (9 Ann. c. 11. § 3.) The commissioners of these duties, appointed by the commissioners of the treasury, shall have the same power as the commissioners of excise. Tanners, tawers, curriers, or dressers of hides or skins, and makers of vellum or parchment, are required to give notice in writing to the officer, of their names and places of abode, and of their tan-houses, yards, work-houses, mills, or other places where they intend to tan, taw, or dress hides or skins, or make vellum or parchment, before they use the same, on pain of 50l. Those who use such places without entry of them, shall forfeit 20l., and the goods found in them, or their value, shall also be forfeited. The officers, at all seasonable hours, shall enter and survey these places, and if the owner or occupier refuse them entrance, he shall forfeit 10l. And if any hide or skin, tanned, tawed, or dressed in oil, be found in any place not entered, without a search warrant to the duty that has been charged, the same shall be forfeited and seized; and the persons whose possession it shall have been found, shall for each offence forfeit 10l. (41 Geo. III. c. 91. § 10.) Tanners and others shall give two days notice to the proper officers of the removal of goods to the dressing place, that an account of them may be taken; and before they are carried away from the dressing place, two days notice shall be given; and they shall be entered with the officer with respect to their number and quality, and verified on oath before a justice of peace, collector or supervisor; and shall they be removed, till the duty be first charged, entered and marked. The penalty for neglect is 20l. and forfeiture of the goods, or their value. Concealment of any hide or skin, vellum or parchment, in order to avoid the duty, incurs a forfeiture of 20l. and the goods or their value. If any tanner or other person shall have any hide or calf-skin, before the same be thoroughly tanned, so as to impair it and diminish the duty, the same or its value shall be forfeited. Tanners or other such persons keep
jull scales and weights; and the penalty for neglect or not allowing the use of them, shall be a forfeiture of 50l. The use of false scales incurs a forfeiture of 100l. (10 Geo. III. c. 44. 28 Geo. III. c. 37.) Cheating or obstructing officers subjects to a forfeiture of 100l. (26 Geo. III. c. 77.) When the duties are ascertained, the officer shall enter them in a book, and return them to the commissioners, or a person appointed by them; and when the duty is settled, the officer shall cause every hide or skin, and every piece of both, and all vellum and parchment to be marked. And if the goods be removed before the duty is charged, and they are marked, the penalty is a forfeiture of 50l. and the said goods; and any person counterfeiting the stamps, or knowingly selling any of the said goods with a counterfeit stamp, is chargeable with felony without benefit of clergy. (9 Ann. c. 11. 5 Geo. II. c. 3. 33 Geo. III. c. 54.) Stamped and unlamped goods shall be kept separate, on pain of 10l. (5 Geo. c. 2.) And those that have been stamped shall not be removed for 24 hours after stamping, &c. under a forfeiture of 20l. (5 Geo. III. c. 43.) Scales and weights shall be kept for reweighing them, and affidavit given to the officer, on pain of 50l. Persons within the bills of mortality shall pay off the duties within 14 days to the commissioners, and in other places in 6 weeks, after the goods have been marked. (9 Ann. c. 11.) Those who do not pay in this manner shall forfeit double duty; and they shall not be delivered out till the duty be paid, on pain of double value. Every tanner, and other such person, shall balance their accounts with the officers once in three months, on pain of 50l. Any two justices residing near the premises may hear and determine offences, and order the penalties to be levied by duifters and false, if not redeemed in six days.

Foreign manufactured gloves imported shall be forfeited, and may be searched for and seized by any officer of the customs or excise; and every person importing or vending the same, shall also forfeit 200l. with double coals. 6 Geo. III. c. 19.

Leather, blacking for. See BLACKING.

Leather, buff. See BUFF.

Leather, jaffis, allita montana, is a foliated amianthus, containing of folt fibres interwoven together and frequently containing sparly crysals inclosed in it.

Leather, gilt. See JAPANESE GILDING, and LACQUER.

Leather mills. See MILL.

Leather money. See MONEY.

Leather-mouthed, in Ichthyography, a term used as the English for malacolomous, the distinctive epithet of such fishes as have thick lips and no teeth in their jaws; as the carp, tench, bream, roach, &c.

Leather-dyers, company of. See COMPANY.

Leather, blesnes, or bloomy. See SHAMMY.

Leather, Turkey, method of preparing, &c. See TURKISH LEATHER.

LEATHERHEAD, in Geography, a large parish, formerly a market-town of Surry, England, is 12 miles E.N.E. from Guildford, and 19 S.W. by S. from London. In the year 1800, the town confisted of 200 houses, and contained 1097 inhabitants. This place is chiefly remarkable for a large fair, held here on the 10th of October, for cattle, horeses, pigs, toys, &c. The river Mole passes through this parish, and emerges to day here, after having been hidden in a subterraneous channel from the foot of Boxhill. This is a singular character of the Mole. At this place it is croffed by a bridge of 14 arches. In the vicinity of Leatherhead are severall seats; some of which are particularly noted for the picturesque and beautiful character of their contiguous scenery, and fine prospects. The principal of these is Norbury-park, the seat of William Lock, Esq.; a very interesting description of which, and its painted room, by Barret, will be found in Gilpin's "Observations on the western Parts of England," 1800. 1798. See also Manning and Bray's "History and Antiquities of Surry."

LEATHERWOOD, in Gardening. See DEREA.

LEAU, in Geography, a town of France, in the department of the Dyle, and chief place of a canton, in the district of Louvain. The place contains 775, and the canton 2624 inhabitants, on a territory of 97½ Kilometres, in 15 communes.

LEAVE and TAKE. See TAKE.

LEAVEN, any thing that will make a body swell and ferment.

The word is formed of the French levain, which signifies the same, of the verb lever, or Latin levare, to raise.

Beer, ale, wine, and cider, only work by means of the leaven in them. Sour pales, barm, rennets, &c. are leavens used in baking bread, brewing beer, making cheeese, &c.

LEAVER. See LEVER.

LEBA, in Geography, a town of Pomerania; 16 miles N. of Lauenburg.

LEBACH, a town of France, in the department of the Sarre, and chief place of a canton, in the district of Sarresbruck. The place contains 506, and the canton 8392 inhabitants, in 66 communes.

LEBADEÆ, Livadiæ, in Ancient Geography, a town of Greece, in Boetia, built on a plain upon the small river Hercya. The inhabitants at a former time occupied a town on an adjoining eminence, and their town was called Midea; but an Athenian, named Lebados, persuaded them to build another on the plain, which was called after his name. On the banks of the Hercya was a temple dedicated to Herceya. The sacred grove of Trophonius was near this town, in which was a temple of this name, with a statue made by Praxiteles. Ceres, surnamed Europa, had a temple here, and Jupiter Pluvius had a statue. Near this place was a temple of Proserpina confervatrix, and another of Jupiter Jovis. The statue of Trophonius at Lebadeæ is said to have been the work of Dædulus. Paulinus, l. ix. Boetica, c. 40.

LEBÆA, a town of Macedonia, anciently the capital of this kingdom, the prefic description of which cannot be ascertained.

LEBANON, or LIBANUS, a celebrated mountain of Asia, situated on the borders of Palestine and Syria. It takes its name, as some say, from the Hebrew labun, on account of the whiteness of its summits, which appear covered with snow a great part of the year. Others derive it from the Greek libanos, frankencene, alleging, without sufficient reason as Reland observes, that it furnishes this or any other aromatic gum. The antilabanus, or antilibanus, is so called from its parallel course in opposition to the other. Some ancient fathers, as St. Jerom and Eusebius, have described the libanus and antilibanus as one continued ridge, winding about in the form of an horse-shoe, which begins about three or four leagues from the Mediterranean, a little above Smyrna, and running southwards towards Sidon, takes an eastern course towards Damascus; winding thence northwards towards Laodicea Cabofo. The western ridge is that which is properly called Libanus; the eastern is Antilibanus, and the hollow between is Culeyria. (See ANTILIBANUS AND CULEYSRIA) St. Jerom represents Libanus as by far the loftiest hill in the whole land of promife, as well as the molt woody and thick-let, and
and Theodore also rates it to be the highest of all Palestine. Modern travellers concur in the account of its great height. "Scarcely," says Volney, "do we depart from Larnaca in Cyprus, which is 36 leagues distant, before we discover its summit capped with clouds. This is also distinctly perceivable on the map, from the course of the rivers. The Orontes, which flows from the mountains of Damascus, and loses itself below Antioch; the Kefmian, which, from the north of Balbec, takes its course towards Tyre; the Jordan, forced by the declivities towards the south, proves that this is the highest point." Although the height of this mountain has not been determined by the barometer, Volney deduces it from another consideration. In winter the tops of the adjoining mountains are entirely covered with snow from Alexandria to Jerusalem; but after the month of March it melts, except on mount Lebanon, where, however, it does not remain the whole year, except at the highest cavities, and towards the N.E., where it is sheltered from the sea-winds and the rays of the sun. Since it is well known that snow in this latitude requires an elevation of 15 or 16 hundred fathoms, we may conclude, says Volney, that to be the height of Lebanon, and that it is consequently much lower than the Alps, or even the Pyrenees. Mount Blanc, the loftiness of the Alps, is estimated at 2488 fathoms above the level of the sea; and the peak of Olym, in the Pyrenees, at 1900. Lebanon, which gives its name to the whole extensive chain of the Kefraouen, and the country of the Druzes, presents us every where with majestic mountains. At every step we meet with peaks, in which nature displays either taille or grandeur, sometimes singularity, but always variety. When we land on the coast, the loftiness and steep aspect of this mountainous ridge, which seems to include the country, these gigantic masts, which float into the clouds, inspire astonishment and awe. Should the curious traveller then climb these summits which bounded his view, the wide extended space which he discovers becomes a fresh subject of admiration; but completely to enjoy this majestic scene, he must ascend the very point of Lebanon, or the "Sannin." There, on every side, he will view an horizon with boundless breadth, while, in clear weather, the sight is lost over the desert, which extends to the Peulian gulf, and over the sea, which bathes the coasts of Europe. He contemplates, besides rocks, woods, torrents, hills-plies, villages, and towns, which are nearer and more distinct objects, the valley obscured by stormy clouds, and smiles at hearing the thunder, which had so often burst over his head, growing under his feet; while the threatening summits of the mountains are diminished till they appear only like the furrows of a ploughed field, or the steps of an amphitheatore, and he feels himself flattered by an elevation above so many great objects, on which pride makes him look down with a secret satisfaction. Such is the picturesque description of Volney, which he pursues more in detail. Mount Lebanon is computed at about 100 leagues in compass, and is bounded by Melopotamia on the E., Armenia on the N., Palestine on the S., and the Mediterranean on the W. It consists of four ridges of mountains, which rise one above the other; the first of these is very fertile in grain and fruit; the second is barren and rocky, producing nothing but briars and thorns; the third, though still higher, is said to enjoy a coolant verdure and spring; its gardens and orchards producing such a variety of herbs, fruits, &c. that it has been styled an earthly paradise; the last and loftiest is uninhabitable, by reason of its excessive coldness, being covered with deep snows almost all the year. It is mostly inhabited by the Maronites below, and by the wild Arabs, called Amades, of the feet of Hail, every where else but on the top. Here are several churches, convents, and chapels, and caverns cut into the rock. The Monks that inhabit it are very poor, but courteous to travellers, from whom they expect some token of beneficence. The convent, or cloister, where the Maronite patriarch resides, lies almost in a bottom; the descent to it is very steep, narrow, and winding, and it has only that one avenue, which makes it so much the safer, as well as the more retired. It chiefly consists of sundry grottos, cut into the rock; of which the church is one of the largest. A river which empties itself at Tripoli, runs a little below it, and supplies it with water. Near the grot of St. Marina, who is reputed to have lived here as an hermit, in man's clothes, are some vines, which afford excellent wine; and fine young mulberry trees, as well as cedars, and other curiosities. Of the boasted cedars of Lebanon, there are no very magnificent remains; four or five of them only deferving notice: but the number of fir, oaks, bramble, mulberry trees, figs, and vines, is much more considerable. The wines of Lebanon have been much extolled by the Grecian and Roman epicures. It is probable, that the inhabitants of this territory have made no change in their ancient method of making wines, nor in the culture of their vines. They are disposed on piles of six or eight feet in height. They are not pruned as in France, which must certainly, says Volney, greatly injure both the quantity and quality of the crop. The vintage begins about the end of September. The convent of Mar-Banna makes about 150 roba, or earthen jars, containing about 110 pints each. The price current in the country is about seven or eight fols (fourpence) the French pint. Of the numerous kinds of wine made in Syria, the chief is the Vino d'Oro, or "golden wine" of mount Lebanon. This is not boiled, as is the case in the preparation of other wines, but left to purify itself by keeping; the quantity produced is small. It is, as its name implies, of a bright golden colour, and is highly prized even on the spot. Several considerable rivers have their source in this mountain, viz. the Jordan, Rocham, Nahar-Roffian, and Nahar-Cadicha; besides many lesser streams, that run between the valleys; particularly that of Ahmohall, which flows down into the "Romantic valley," so called, because it is surrounded on all sides with high rocks. These rivers, rushing down from such heights, form several beautiful cascades, like those of the Nile. This mountain has been, and is still to this day, a place of retreat and refuge for a great number of robbers, and other desperate people. The stone which composes the mountains of Lebanon and Anti-Lebanon, and those of Syria in general, is a hard calcareous stone of a whitish colour, ponderous like free-stone, and disposed in strata variously inclined. Of this stone the inhabitants build their houses, and make lime. Lebanon, a post-town of America, in York county, Maine, on the east side of Salmon-Fall river; 100 miles N. of Bolton. It was incorporated in 1767, and in 1790 contained 1275 inhabitants.—Alfo, a post-town in Windham county, Connecticut, settled in 1697. The soil is equal to almost any in the state, and the inhabitants are generally farmers, of whom many are rich. The number of inhabitants is 3653; 9 miles N. of Norwich.—Alfo, a post-town in Grafton county, New Hampshire, on Munceury river, and on the east side of Connecticut, 2 miles below Dartmouth college; incorporated in 1761, and in the year 1800 containing 1574 inhabitants.—Alfo, a post-town of Pennsylvania, situated on the south side of Quachphilla creek, in Dauphin county; containing about 300 houses regularly built,
built, many of them of brick and stone, a German Lutheran and a Calvinit church; 82 miles N.W. by W. from Philadelphia.

LEBANON, New York, a village in Canaan, New York, pleasantly situated, partly on the declivity of a hill, and partly in a vale, and containing medicinal springs next in celebrity to those of Ball-town, Saratoga.

LEB, a town of Germany, in the lordship of Lauenburg, in a lake near the Baltic; 15 miles N.W. of Lauenburg. N. lat. 52° 40'. E. long. 17° 29'.

LEBEDIAU, a town of Ruffa, in the government of Tambouv; 100 miles W.N.W. of Tambouv. N. lat. 53° 28'. E. long. 48° 5'.

LEBEDIN, a town of Ruffa, in the government of Charkow; 66 miles N.W. of Charkow.

LEBEDIN, in Ancient Geography, a town of the Ionians, situated in Lydia, upon an isthmus, north of Colophon, distant 120 miles from this city. Lydymachus demolished it, and transported the inhabitants to Ephesus.

LEBEDIS, in Some Medical Writers, a word used to express the exuviae of serpents, or the skins which snakes cast off every year. These are by some greatly recommended for taking off freckles and sun-burns from the face.

LEBIALNA, in Geography, an island of Ruffa, in the Caffian sea. N. lat. 45° 55'. E. long. 53° 50'.

LEBIAR, a forest of Africa, in the country of Zenaga, affording great quantities of gum; 100 miles E.N.E. of Porto Duc.

LEBIDA, or LEBDA, a sea-port town of Africa, in the country of Tripoli, on the coast of the Mediterranean; 30 miles S.E.E. of Tripoli. N. lat. 32° 40'. E. long. 13° 56'.

LEBIDA, a town of Lithuania, in the palatinate of Wilna; 10 miles S. of Lida.

LEBIEDZIOH, a town of Lithuania, in the palatinate of Wilna; 56 miles E.S.E. of Wilna.

LEBLANC, Michael, in Biography, born at Dijon in the year 1653, entered into the order of the Jefuits, and was one of the fourteen mathematicians whom Lewis XIV. sent to the king of Siam in 1687. Leblanc went and resided with the priests of the country, to learn their language; but the revolution taking place, which deprived the king of his crown, put an end to the hopes of the missionaries, and he was obliged to return to Paris. He had the misfortune of being taken prisoner by the Dutch, and thrown into prison at Middelburg, in Zealand. In the year 1690 he was set at liberty, and returned to Dijon, where he was employed as professor of mathematics in the Jefuits' college. In 1661 he joined a new mission for China, and embarked at Liffon. During the voyage he met with an accident, which put an end to his life at Mozambique, in the year 1693. As a writer he is principally known by "A History of the Revolution of the Kingdom of Siam in 1688, and of the present State of the Indies," 2 vols. 12mo. Moreri.

LEBNA, in Scripture Geography, a strong city of Palæstine, in the tribe of Judah, situated on a narrow neck of land, which ran northwards between the tribes of Dan and Benjamin. Joshua took it and gave it to the Levites of this tribe, and it became a city of refuge. This had been an encampment of the Israelites in the Desert.

LEBNEK, in Geography, a town of Transylvania; 15 miles S.E. of Schelburg.

LEBNI, in the Materia Medica of the Ancients, a name given by some to florax. Avicenna has treated of this drug in three separate chapters. The Greeks were very nice in distinguishing the several kinds of florax, and the Arabians seem to have followed their example; nay, they have even borrowed some of the terms, by which they called the particular sorts. The soil, or liquid florax of the Greeks, seems to have been very common among thee people; and they have called it mel khan, the honey of florax. This was a common word with them to express any thing bright.

LEBO, in Geography, a river of Chili, which runs into the Pacific ocean, S. lat. 37° 50'.

LEBRILLA, a town or village of Spain, in the province of Murcia, containing about 1000 inhabitants; almost divided into two by a fort of long, broad, and deep bog, formed by rains, over which is a bridge; 11 miles from Murcia.

LEBRIXA, or LEBRILA, a town of Spain, in the territory of Seville, situated formerly on a branch of the Guadalquivir, but now, in consequence of its being choked up, 6 miles from the river. It has a castle; and the environs produce olives, which afford feme of the best oil in Spain; 20 miles S. of Seville.

LEBESKOI, a town of Ruffa, in the government of Archangel, near the union of the rivers Mezen and Pezna; 168 miles E. of Archangel.

LEBUS, a town of the Middle Mark of Brandenburg, situated on the Oder, containing about 14,000 inhabitants. Its feite is low, and among hills, which intercept the view of it; 5 miles N.W. of Franckfort on the Oder. N. lat. 52° 26'. E. long. 14° 44'.

LECA, a town of the island of Samos.

LECANOMANTIA, Acanthia, in Antiquity, a kind of divination performed in a bain with wedges of gold or silver. See HYDROMANCY.

LECASELLO, in Geography, a town of the Ligurian republic; 20 miles N.E. of Genoa.

LECCE, or LECIUM, a city of Naples, the capital of the province of Otranto, and sometimes giving name to the province. It is a large, well-built town, the fee of a bishop, full of churches. The wool produced in its environs was formerly much celebrated; and the adjacent country yields abundance of almonds and olives. It contains, besides the cathedral, three parish churches and several convents.

It is the residence of the governor, and the number of inhabitants is estimated by some at 30,000, by others at 40,000; 24 miles from Brindisi, and as far from Otranto, and 8 miles from the eastern shore. N. lat. 40° 40'. E. long. 18° 8'.

LECCI, a town of the island of Corfu; 5 miles N. of Porto Vecchio.

LECCO, a town of Italy, and capital of the department of the Montagna, on the lake Como, whence a branch of the lake is called "the lake of Lecco; 14 miles E.N.E. of Como. N. lat. 46° 5'. E. long. 9° 23'.

LECETA, a town of Spain, in Navarre; 17 miles N.N.W. of Pamplona.

LECH, in Metallurgy, a term used by the miners to express the gold ore which has been powdered and washed, and afterwards run with the saltpetre of lime-stone. The lech is afterwards burnt in a fire of charcoal, in order to render it fit for the separation of the metal, by means of lead, which absorbs and scorifying the extraneous matter, renders the gold pure.

LECHÆUM, in Ancient Geography, a town and monitory of Greece, on the gulf of Corinth, which served as a port to Corinth. It had a temple of Neptune, in which was a bronze statue of this deity. Venus had also a temple here.
LECHEA.

Gen. Ch. Cal. Perianth inferior, of three ovate, concave, spreading, permanent leaves. Cor. Petals three, oblong, narrower than the calyx, but about as long, concave. Stam. Filaments three, sometimes four or five, capillary, longer than the petals, lying over the pistil, equal; anthers roundish. Pif. Germen superior, ovate; styles none; stigmas three, feathery, spreading. Peric. Capsule ovate, slightly triangular, of three cells, and three valves, cohering at their base, with three central linear receptacles. Seeds solitary, ovate, angular at the inner side, where they are attached to each receptacle.

1. L. minor. Lecher Lechea. Linn. Sp. Pl. 133. Am. Acad. v. 3. 10. Lamarck. t. 52. f. 17. (L. major; Michaux n. 1, by the description.)—Hairs of the stem and branches spreading. Lower leaves whorled, elliptical, with a small point; upper alternate, lanceolate, acute. Flowers panicled, somewhat corymbose.—Gathered by Kalm in the dry sandy fir woods of Canada.—The root is perennial and woody. Stems several; the barren ones about a span long, lax, and spreading, with numerous, ternate or quaternate, short, leafy branches, all clothed with long, white, spreading hairs; flowering stems much taller and flowered, from one to two or three feet high, panicked, leafy, round, clothed with rather less spreading hairs. Leaves of the barren stems three or four in a whorl, on short stalks, spreading, a quarter of an inch long, broadly elliptical, entire, with a short point, the margin and rib fringed with long white spreading hairs; those of the flowering ones scattered, longer, and narrower.

Flowers numerous, small, terminating the lateral branches, in small corymbose clusters, whose flowers are hairy, and more or less furnished with lanceolate bracteae. Calyx-leaves broad, keeled, very concave, smooth. Capsule polished.

This is certainly what Linnaeus originally intended for Lechea minor, though he afterwards confounded other still smaller species with it, and the name being opposed to his major, which is a nonentity, is unmeaning, if not false. Lechea inconvenience, however, must arise from retaining than from changing it, unless we were furnished with more ample and certain materials for new modelling the whole genus. Our aim here is to correct such errors as we can, for the use of those who may take up the subject hereafter.

2. L. major. Greater Lechea. Linn. Sp. Pl. 133. Am. Acad. v. 3. 11. f. 4. 4; copied in Lamarck, f. 2.—"Leaves ovato-lanceolate. Flowers lateral, facted."—Native of dry situations in Canada. Linnaeus, in his manuscripts and Syll. Veg. quotes for this, Memandria trinervis, Gron. Virg. ed. 2. 20, that is, An Camararia species, foliis laticarbus oblongis, foliis argenteis, caule rubro, capsula ampla tribulucari of Clayton, who found his plant, flowering in August, on sandy hills at point Comfort, in the county of Gloucester, Virginia. It is described as thrifty, with the aspect of Cifrus helianthemum or of Vaccinium Oxyseus, two plants between which it is difficult to find any point of resemblance; the leaves alternate, oblong, and entire. Corolla none. Stamin four, as long as the calyx, the uppermost springing from the same point of the receptacle, the two lateral ones opposite. Style none. Stigma hispid. The rest of the account accords with the generic character. It must be observed that when Clayton guessthis plant to belong to Camararia, he means that of Dillenius, which is the Linnaean Montia. Linnaeus, in the Annenates, describes his L. major thus. "Stems purplish, round, with simple, alternate, diffusert branches. Leaves alternate, oval-lanceolate, rough above, downy beneath, reflexed at the margin, scarce perceptibly flaked. Flowers two, three or four from the small uppermost branches." Now it happens that the specimen in the Linnaean herbarium is no other than Cifrus camadenis, with the numerous flaesns proper to that genus, and totally foreign to Lechea. The capsule also has imperfect partitions from the middle of the valve. The seeds indeed appear to be but one in each cell, and large, the only circumstance which could induce a reference of this Cifrus to Lechea. Yet there can be no doubt of the description in the Annenates having been made from this plant, though the figure is unlike it, and more resembles L. minor, for which indeed, as well as for the major, it is quoted by Linnaeus in Sp. Pl., and being in itself too imperfect to convey a precise idea of anything, it can determine nothing in the present case. What is L. major of Kalm we know not, nor that of Hort. Kew. That of Michaux appears clearly to be our minor, whose lower leaves are indeed so much like oscyremnus, that its upper are not very unlike helianthemum, that Clayton might possibly have that species in view when he made the above description, but the "large capsule with three cells" agrees best with the above Cifrus. Amid all this uncertainty we would rather strike out L. major, and give a new name, perhaps heterophylla, to our minor.

3. L. racemulosa. Many-cluttered Lechea. Michaux Boreali-Amer. v. 1. 77. (Menandra ramis ternis; Gron. Virg. ed. 2. 21.)—Hairs close-pressed. Leaves linear-lanceolate, acute, hairy beneath. Flowers in numerous slender clusters. Calyx hairy.—Gathered by Clayton in the same place, at point Comfort, with the last. Specimens from him are in the Linnaean herbarium, answering to the account of Michaux, who also gathered his plant in Virginia. We have others, probably of the same species, from Kalm, and from the Rev. Dr. Muhlenberg of Lancaster in Pennsylvania. Those of Clayton have a panicked stem, a foot or two high, clothed with close-pressed, somewhat silky, hairs; the branches either ternate, opposite, or scattered. Leaves of the stem lanceolate; those of the branches linear, gradually smaller upwards, and often accompanying the flowers, but sometimes the clusters are leafless; they are elongated, slender, hairy or silky. The calyx also is hairy, and greatly resembles that of a little annual Cifrus.

4. L. thyrsifolia. Thyme-leaved Lechea. Michaux Boreali Am. v. 1. 77; excluding the synonym. (Caparia folis intergenris; Gron. Virg. ed. 1. 75. Herb. Linn. from the author.)—Hairs close-pressed. Leaves lanceolate. Stem panicked. Clusters leafy. Bracteae linear, much longer than the flowers.—Gathered by Clayton in Virginia; by Michaux in dry exposed situations in North and South Carolina. Stem a foot high, round, reddish, rough with close-pressed hairs; simple and naked below; panicked and leafy above. Leaves opposite or scattered, various in size, slightly.
L. vorni, a. — Stemii, buhny, decumbent, acdescendg, with spreading branches. Leaves linear-awl-shaped. Flowers ranged alternately, and rather remotely, along the branches. On sandy hills near the Santee river, flowering in April and May. We know nothing of this species but from Michaux, who describes it as of humble and bushy growth, with capsules rather larger, in proportion to the plant, than is usual in this genus.

6. L. verticillata. Whorled Lechea. Willd. n. 3. — Leaves elliptical, serrated. Flowers whorled. — Sent by Dr. Rottler from Madras. The root feets, as in all the former, to be perennial. Stemii ferial, spreading or decum- bent, simple or branched, a span long, round, leafy, clothed with soft spreading hairs. Leaves opposite, stalked, half an inch long, elliptical, acute, finely and sharply serrated, hairy, tapering to the base. Flowers numerous, in dense axillary whorls, sufficiently agreeing with the character of the genus, to which Willdenow has judicially referred it. The serrated leaves, however, are very peculiar.

Another species, L. chloenii, is mentioned in Lecompt, 62; but this, though adopted by professor Martyn, cannot, in our opinion, have any right to a place here, the author's description shewing it evidently to be nearly allied to Comenina, consequently more remote, if possible, than even the above Cyclus canadensis from Lecompt. 5.

Obs. The grains of pollen, in all the species, are composed of four combined globules, which mark, though minute, is esteemed by Mr. Brown very essential to distingus- ugh this genus from all the rest of its natural order, and especially from its near ally Anthotium.

The species are generally shrubs of humble growth, rarely herbaceous, and are smooth, with narrow entire leaves. Flowers axillary or terminal, molly solitary.

2. L. tubifera. Flowers nearly terminal, solitary, slightly flattened. Corolla tubular, curved, with a closed limb. Leaves awl-shaped, with a small pellucid point. — Native of the same country.

3. L. expana. Corms axillary, of few flowers. Stalks with a pair of bracts each. Corolla with one lip, in fringed segments. — Native of the same country.

Sect. 2. Herbaceous. Flower opposite to a leaf. Cap-
the mouth of the Duero. N. lat. 41° 43'. E. long. 8° 25'.
LECUM, a city in Hindoo land, in Bahar; 30 miles S. of Bahar.
LECK, a town of Denmark, in the duchy of Slefwick; 14 miles N. of Bredtedale.
LECKNESS, a town of Norway; 22 miles W. of Christianand.
LE CLERC, DANIEL, in Biography. See CLERK, DANIEL.
L'ECLUSE, in Geography. See ECLUSE.
LE COQ, ANTHONY, in Biography, a Pariuan physician, graduated in the faculty of that city, and practised there with great reputation until his death, which took place on the 28th of March, 1550. He was elected dean of that faculty in 1538; and in the following year was called, in consultation with Ferme, to visit the French king, Francis I., who had contracted the venereal disease. He showed his knowledge of the nature of the disease, by insisting, in opposition to Ferme, who was not disposed to employ any other remedy than his antivenereal opiate, that mercurial frictions were necessary; but his mode of proposing it evinced that he was a novice in the manners of a court. He observed to Ferne, speaking of the king, "C'est un villain qui a gagné la vérole; frôtter comme un autre, et comme le dernier de son roy auce, pulque il se' dét de la même maniere." This was reported to the king, who laughed, and was pleased with his frankness. Le Coq left two works: 1. "De Ligno lac yano non permiscendo in imperios fauc toque medicos," Paris, 1543. 2. "Conflitia de Arthritis," Francfort, 1540. The latter comprehended also some other treatises on the gout, especially those of Sylvius and Ferme; in conjunction with whom, Le Coq had been consulted on the subject by Louis of Flanders, and by Eleonora, queen of France. Elyon, Dict. Hist.
LECTICA, among the Romans, a litter, or vehicle, in which people were carried. The silla differed from the lectica, as being higher, and because people always sat in it; on which account the silla, from the time it was first brought into use, was esteemed the more honourable carriage of the two.
LEC. See LITTER.
LECTICARII, among the Romans, servants who carried the lectica.
LECTICARIUS, was also an officer in the Greek church, whose business it was to bear off the bodies of those who died, and to bury them. These were otherwise denominated decani and epiteche.
LECTIO, READING. Considered in a medicinal view, it is said by Cellus, lib. i. cap. 4. to be bad, especially after supper, for those whose heads are weak; and in lib. i. cap. 8. he recommends reading with an audible voice, for such as have weak stomachs. It is also directed by Paulus Arginetius as an exercise, lib. i. cap. 19.
LECTISTERNIUM, a religious ceremony among the ancient Romans; being a festival prepared, and solemnly served up, in a temple, at a time of public calamity and danger.
And because, according to the customs of those times, they placed beds around the tables, and set the statues of the gods on those beds, in the same manner as men sat at meals, they called the solemnity lectisternium, from lectus, bed, and sternorum, of sterno, to spread, prepare.
In this ceremony the Sibyline decrees were prefixed, till the year of Rome 558, and afterwards the Epulones. See EPULI.
Cafabon has observed, from a passage in the scholiast of Pindar, that the Greeks had also a sort of lectisternium in use.
Livy observes, that the first lectisternium seen in Rome, was that which held for eight days successively, in honour of Apollo, Latona, Diana, Hercules, Mercury, and Neptune; on occasion of a contagious disease which killed almost all their cattle, in the year of Rome 354; though Valerius Maximus mentions one before that.
LECTORES, among the Romans, servants in great men's houses, who were employed in reading while their masters were at supper. They were called by the Greeks anagnolhe.
LECToure, in Geography, a town of France, and principal place of a district, in the department of the Gers, feated on a mountain, having access only on one side, near the Gers, and well defended. Before the revolution it was the residence of a governor, and seat of a bishop. The place contains 5433, and the canton 15,655 inhabitants, on a territory of 265 kilometres, in 17 communes; 16 miles S. of Agen. N. lat. 45° 56'. E. long. 0° 22'.
LECTUM, in Ancient Geography, Cape Baba, a promontory of Afia Minor, belonging to the Troades, situated between the ile of Lesbos to the south, and that of Tenedos to the north, at the extremity of Mount Ida. To the north it terminated the gulf of Adramyttium.
LECTURES, in England, are an order of preachers in parish churches, distinct from the rector, vicar, and curate. They are chosen by the vestry, or chief inhabitants of the parish, supported by voluntary subscriptions and legacies, and are usually the afternoon preachers in the Sunday service. The term is also more generally applied to those who preach on Sunday, or on any fixed day of the week, in churches, or other places of public worship. By 13 & 14 Car. II. cap. 4, lecturers in churches, unlicensed, and not conforming to the liturgy, shall be disabled to preach, and shall also suffer three months' imprisonment in the common gaol; and two justices, or the mayor, or other chief magistrate, in a town corporate, shall, upon certificate of the offence from the ordinary, commit them accordingly. Where there are lectures founded by the donations of pious persons, the lecturers are appointed by the founders, without any interposition or consent of rectors of churches, &c., though with the leave and approbation of the bishop; such as that of lady Moyer's at St. Paul's. But the lecturer is not entitled to the pulpit, without the consent of the rector or vicar, who is possest of the freehold of the church.
LECTURES. See Boyle's Lectures.
LECTURES of Divinity, &c. in the universities. See REGIUS Professors.
LECTUS IGNUS, among the Romans, a kind of instrument of torture first invented by Decius. The bottom of it was set with serrated teeth or spikes, and fired with fuel; while melted tallow was poured from above on the unhappy tortured person.
LEYTHIS, in Botany, so denominated by Linneus, from the Greek word λευκος, an oil jar, or large pot. He confounds it with λυκος, the yolk of an egg. The latter has been used for the pea, alluding to the yellow colour of its internal substance: λυκος applies to the form of the seed-veffel, which is that of a great pot with a cover. Linn. Rr. 189. Linn. Gen. 268. Schrep. 359. Willd. Sp. Pl. v. 2. 1172. Mart. Mill. Dict. v. 3. Jacq. Amer. 168.
LEC.
LECITHIS.

Gen. Ch. Cal. Perianth superior, of six roundish, concave, permanent leaves. Cor. Petals six, very large, oblong, obtuse, flat, the two uppermost widely spreading. Nectary petal-like, of a single tongue-shaped leaf, flat and perforated at the base to admit the germen, bordered; its oblong part bent inwards and upwards from the bottom of the flower, linear, externally convex, thicker and ovate at the extremity, covering the pistil with the filaments. Stam. Filaments very numerous, inserted upon the disk of the base of the nectary at the inner side, very short, swelling upwards; anthers oblong, small. Pet. Germen inferior, depressed, pointed, encompassed and connected with the receptacle of the flower, style very short; stigma blunted, conical. Peric. Capsule woody, roundish at the base, abrupt at the top, encompassed with the remains of the calyx, cut round, and opening by a circular lid, imperfectly divided into four, sometimes two or six cells. Seeds few, polished, with rough edges.

1. L. alvis Linn. Sp. Pl. 734. Loc. It. 189. (Jaca-petala; Margr. Br. 138. Pit. Br. 135.)—Leaves small, ovate or oblong, somewhat heart-shaped, nearly entire. —Native of Brazil and the Caracas. This, according to Loddington, is a valve tree, with large unequal branches, bent in various directions, and a rough bark. Leaves about the ends of the branches, alternate, small, ovate inclining to heart-shaped, firm, smooth, nearly entire, slightly waved, of a brownish green. Flowers in terminal clusters, slightly drooping, on alternate, sometimes horizontal, angular stalks, with ovate, concave, soon deciduous bracteae. Corolla white, with a yellow nectary. —Marcgravay says the leaves are ferrated, the fruit like a pot with its cover, as big as a child's head, containing seeds like chestnuts, eatable either raw or roasted, and that the bark of the tree serves to make ink.

2. L. minor Linn. Syn. Veg. ed. 14. 494. Jacq. Amer. 168. t. 169. —Leaves stalked, lanceolate, ferrated. —Observed by Jacquin in woods near Carthagena, South America, flowering in June and July, ripening fruit in December. An elegant branching tree, 60 feet high. Leaves numerous, six inches long, alternate, spreading in two directions, lanceolate-oblong, pointed, ferrated, smooth. Spikes terminal, each often accompanied by a smaller axillary one below, shorter than the leaves; the flowers nearly sessile, slightly faceted. Petals and nectary white. Stamens yellow. Fruit very hard, brown, two inches wide. Seeds about eight. Jacquin thought he experienced a giddiness and sickness after eating one of them, though its taste proved very agreeable. Some persons told him these seeds were eatable, others reported them to be poisonous. Monkeys are said to be fond of them. The flowers are infested with a kind of black wasps, very troublesome to those who attempt to gather any.

3. L. grandiflora Aubl. Guian. v. 2. 712. t. 283—285. (L. Ollaria; Linn. Am. Acad. v. 8. 258; Herb. Linn.)—Leaves stalked, ovate, entire. Clusters many times longer than the footstalks. Petals obtuse. —Native of Guiana and Surinam. A large tree. Leaves from four to seven inches in length, and two or three broad, ovate-oblong, with a little point, entire, slightly wavy, smooth, with one rib and many parallel transverse veins. Footstalks an inch long. Clusters about the ends of the branches, axillary, pendulous, of numerous large rofe-coloured flowers, whose entire stalks are an inch long, bearing a pair of blunt bracteae, and whose blunt concave petals are nearly an inch and half in length. Calyx-leaves rounded, obtuse, flat. Fruit about seven inches long, and four wide; the opening about 2½. Seeds, according to Aublet, very good to eat. The flowers appear in January, the fruit is ripe in April.

4. L. amara Aubl. Guian. 716. t. 286 and 285.—Leaves elliptic-oblong, pointed, entire. Clusters axillary and terminal, twice the length of the footstalks. Petals acute.—Found in the woods of Guiana, by Aublet, whose figure and description afford all the knowledge we have of this species. He says the trunk is 10 feet high, bearing at the top many straight and horizontal branches, whose subdivisions are pendulous and leafy. In his French description, which will generally be found the most original and authentic throughout his work, he says this is a very lofty tree. The flowers are small, yellow, with two or three scales upon their footstalks. Fruit the size of an egg, its coat thin though hard. Seeds bitter, but eaten by monkeys.

5. L. zollineri Aubl. Guian. 718. t. 288.—Leaves elliptic-oblong, pointed, entire. Clusters terminal. Petals obtuse. Calyx-leaves lanceolate. —Gathered by Aublet in the desert woods of the interior of Guiana, flowering in March, and bearing fruit in July. We have from Sir Joseph Banks a specimen of this species, gathered in Dutch Guiana by Mr. Alexander Anderson, which agrees well with Aublet's description, and helps us better to understand the distinctive characters, than professor Willdenow was able to do from his incorrect figure. The professor rightly expunges the quotations of Piso, which belong to the first; but it is unlucky that the specific name belongs to them, or rather perhaps is common to many species. This is a valley tree; its trunk 60 feet, or more, in height. Wood white, red in the centre. Leaves stalked, from six to ten inches long, and two or more in breadth. Clusters at the ends of the branches, pendulous. Partial flowering stalks an inch long, swelling upward. Calyx-leaves broadest at the base, tapering, concaee, sharpish from the inflexion of their edges at the summit, fleky, one-third of an inch in length, reddish when fresh. Petals large, rounded, fleky, white bordered with rose-colour, two of them much bigger than the rest, being equal to those of L. grandiflora. The fruit is about four inches in diameter. Seeds sweet, eatable, preferable to our almonds.

6. L. Idatemon Aubl. Guian. 721. t. 289.—Leaves elliptical, pointed, entire. Clusters axillary. Stalks glandular. Calyx-leaves ovate, acute. Petals obtuse. —Native of wild forests in Guiana. A tree agreeing with the height in height, and in the general aspect of its leaves. Clusters axillary, with zigzag, glandular red stalks. Flowers rose-coloured, not half the size of the last, with broader calyx-leaves. Fruit little more than an inch in diameter. Aublet observed what he deemed a variety only, with yellow flowers.

8. L. multiflora.—Leaves .... Clusters terminal, panicled. Petals obtuse. Calyx-leaves broader than long, rounded, blunt, downy. —A native of Guiana, communicated by E. Rudge, c.f. as a new species of Lecithis, which
LED

which it really appears to be. The leaves are wanting in our specimen. Clusters, terminating the little branches at the ends of the main ones, bearing many flowers, which are of a moderate size, and seem to be yellow; their petals rounded and blunt. The partial flanks are an inch long, swelling upwards, downy or glandular, naked. German hemispherical, downy, crowned with the fin calyx-leaves, which are very short, rounded or heart-shaped, blunt, minutely fringed, very like those of a Myrtus or Eugenia.

9. *L. bracteata.* Wildn. n. 8. (Conopopa guianensis; Aubl. Guian. 708. t. 282; Pekia fructu maximo globofo; Barrere France Equinoxiale, 92.),—Leaves stalked, obovate, pointed, entire. Clusters lateral. Calyx with a pair of acute bractea at its base. Fruit of fix cells.—Native of Cayenne, where the fruit is known by the name of the cannon ball. This is a large tree, with a thick rugged bark, and white soft and indiflerent wood, red in the middle. The shade of the leaves seems most to approach those of *L. grandi flora,* and these two species agree also in having a pair of bractea on each partial flank, just below the calyx. These are acute in the present, blunt in the former. Both also have a deciduous bractea at the base of each partial flank. All this confirms the propriety of reducing them to one genus, though the frui of that now under consideration has fix cells, and its coats are separated by an intermediate pulpy and fibrous substance, which may also be the cause of its lid not falling off, as in all the above-described. *L. bracteata* is in flower and fruit nearly all the year round. Its corolla is of a full rose-colour, beautiful and fragrant. The fruit is as large as a cannon ball of 16 pounds, and Aublet remarks that its weight is such as to render it dangerous in falling. The pulp is red, acid, and not disagreeable, diffused, as the fruit ripens, through all the internal part, among the seeds.

**LEYTHUS,** in Ancient Geography, a town of Greece, in Euboea. Thyacydies.

**LECEZAGA,** in Geography, a river of Africa, which runs into the Mozambique gulf. S. lat. 17° 20'.

**LEZNA,** a town of Poland, in the palatinat of Chelm; 24 miles N.W. of Chelm.

**LEDAG,** a town of Abysinia, in the province of Gojam; 120 miles S.S.W. of Gondar.

**LEDIAH,** a town of Hindoosan, in the circuit of Gangpur; 20 miles S. of Gangpur.

**LEDHUR,** an ancient borough, and market town in the hundred of Radlow, and county of Hereford, England, is situated on a declivity within a small valley, formed by the Dog-hill and other eminences, about one mile west from the river Leddon, from which it derives part of its name. The town consists chiefly of two streets, crossing each other at right angles; the principal street runs north and south, and has a middle row near the old market house. This building is elevated on strong oak pillars, and composed of timber and lath plastered and white-washed; the beams being coloured black. This mode of building is prevalent in the more ancient parts of the town; and many of the houses have projecting stories: the modern houses are of red brick, and of a respectable appearance. The pavement, even in the high street, is very bad, and full of inequalities; the small stones that form it being pressed into the stiff clay, which is the general soil of the country. Ledbury formerly belonged to the fee of Hereford; and bishop Bohun procured the charter of a market from king Stephen, to be held on Saturdays; but this having fallen into disuse, queen Elizabeth granted a new charter for a Tuesday market, and two annual fairs; the tolls arising from which were to be given to the poor. This borough had once the privilege of sending two members to parliament, but surrendered the right, on the plea of inability to support them. The church, which is a large edifice, of Saxon origin, consists of a nave, side aisles, and chancel; a chapel called St. Catherine's, and a detached tower, terminated by a finely proportioned spire, about sixty feet high. Bishop Foliot founded an hospital in this town in the year 1322 for the maintenance of poor men and widows; it was refounded and further endowed by queen Elizabeth. The hospital is a very ancient timber and plater building. Here are also a free-school, a charity-school, and several almshouses. The clothing trade was, at one period, very flourishing in this town; but the principal business now carried on is the manufacture of ropes, lines, and facks. The cider trade is very considerable; great quantities being made in the vicinity. Ledbury is distant from London 121 miles; the inhabitants, as ascertained under the act of 1820, amounted to 3058; the number of houses being 618. The bishops of Hereford formerly had a palace here.

On the Dog-hill, to the north of Ledbury, is Hope End, the seat of Sir Harry Vane Tempeft, bart. About two miles south of the town is the Vineyard camp; the works of which have been almost defaced by the plough, and the area is cultivated. Beauties of England.

**LEDERS,** a lake of the county of Tyrol; 18 miles W. of Trent.

**LEDENI,* an ancient town of Spain, formerly called Bibijia, in the province of Leon, situated four or five leagues from the mouth of the Torones, and defended both by nature and art. In its jurisdiction are 380 villages, which have about 16,000 houses. To the E. of Ledesma and near it is a medicinal bath, made by a Moor for the use of the public. The water is moderately warm, and is reckoned good for the cure of different diseases, particularly the itch; 18 miles W. of Salamanca.

**LEDENICH,** a town of Bohemia, in the circle of Czaflan; 13 miles S. of Czaflau. N. lat. 49° 40'. E. long. 15° 15'.

**LEDETZ,** a town of Bohemia, in the circle of Boleslaw; seven miles S.E. of Jung-Buntzel.

**LEDGER.** See Book and Book-keeping.

**LEDGERS,** among Builders. See Putlogs.

**LEDGES,** in a Ship, oak or fir scantling, used in framing the decks, which are let in the carlings athwart the ship. Those for gratings arch upwards, agreeable to the head ledges, which form the hatchways, &c.

**LEDIANIA,** in Geography, a bay or gulf of the Frozen sea, on the coast of Nova Zembla. N. lat. 76° 40'. E. long. 59° 14'.

**LEDIANO,** a cape on the N. coast of Nova Zembla. N. lat. 78°. E. long. 73° 24'.

**LEDIGNAN,** a town of France, in the department of the Gard, and chief place of a canton, in the district of Ales. The place contains 666, and the canton 3905 inhabitants, on a territory of 1025 kilometres, in 13 communes; 15 miles N.W. of Nimes.

**LEDON,** in Gardening. See Cistus.

**LEDONG,** in Geography, a town on the E. coast of the island of Bornoe. N. lat. 4° 33'. E. long. 116° 42'.

**LEDORAN,** a small island on the W. side of the gulf of Bothnia. N. lat. 63° 12'. E. long. 20° 50'.

**LEDWEIRA,** a town of Spain, in Galicia; 12 miles N.E. of Santiago.

**LE DRAI, Henry Francis, in Biography,** a celebrated surgeon of the 18th century, was a native of Paris, where his father practised the same profession with considerable reputation, and was deemed the first operator of his time.
time. He soon equaled his father in reputation; and uniting with great dexterity, an excellent judgment and much acuteness of mind, learning, and experience, he not only practised with great success, but was the author of several works, which gave him a high rank among the surgeons of France. There are, "Paral!lele des différentes manières de tirer la pierre de la vellèle," Paris, 1730. "Observations de Chirurgie, auxquelles on a joint plusieurs Réflexions en faveur des Étudians," Paris 1731, two vols. 12mo. Both these works were translated into other languages, and passed through several editions. "Traité des Operations de Chirurgie," ibid. 1731, 8vo. This was also a valuable work, was translated into English, and several times republished. "Réflexions sur les plans d'armes à feu," ibid. 1731, &c. 12mo. A short treatise, but full of judicious and interesting observations, the result of the author's practical observation during several campaigns, in which he accompanied the French armies. "Suite du paral!lele de la taille," ibid. 1756, 8vo. "Conflations sur la plupart des maladies qui font du ressort de la Chirurgie," ibid. 1765; another judicious and valuable work, which contributed to support the eminent character of the author. But his last work, "Traité économique de l'Anatomie du corps humain," ibid. 1768, was inferior to the rest. His genius seem'd to partake of the debility which age had now occasioned in his frame. Eloy. Dict. Hiff.

LEDUM, in Botany, a name adopted from the Greeks, whose Ἀδεος is generally believed to be a species of Cilfus. Linnaeus, in applying it to designate a not very diffimilar genus of shrubs, whose scent is so powerful as to be unpleasant and hurtful, offers an etymology expressive of that circumstance, a ledendo; but such explanations have scarcely more than the merit of a pun, and none in this case was wanting. Linn. Gen. 218. Schreb. 204. Willd. Sp. Pl. v. 2. 602. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 2. v. 3. 46. Suff. 159 Lamarck Ill. 180 t. 303. Gartn. t. 112. Clas and order, Decandria Monogynia. Nat. Ord. Bicorneis. Linn. Rhododendra. Juff.

Gen. Ch. Cal. Perianth inferior, minute, of one leaf, with five teeth, permanent. Cor. of one petal, wheel-shaped, regular, in five deep, ovate, concave, rounded segments. Stamin. Filaments ten, thread-shaped, spreading, as long as the corolla; anthers ovate-oblong, vertical, opening by two terminal pores. Pifl. German superior, roundish; fylle thread-shaped, the length of the flaments; stigma obtuse. Peric. Capsule roundish-oblong, of five cells, and five valves, separating from the base, their infixed margins forming the partitions. Seeds numerous, oblong, narrow, their extremities acute and very thin, attached to five linear pendulous receptacles, proceeding from the central column.

Eff. Ch. Calyx five-cleft. Corolla flat, in five deep regular segments. Capsule of five cells, splitting from the base; partitions from the margin of the valves.

1. L. palustris. Marsh. Linn. Linn. Sp. Pl. 561. Fl. Lapp. ed. 2. 127. Ehrl. Arb. 113. Fl. Dan. t. 1031. (L. sale elucidum; Chuf. Pann. 69. Hitt. v. 1. 83. Ger. em. 1238. Rofmarum etilfvea; Camer. Epif. 546) — Leaves linear, revolute, woolly beneath. — Native of lumpy bogs in the north of Europe, very plentiful in Lapland. With it flowers in April and May, being cultivated in bog earth, like the shrubs of North America. The flern is shrubby, erect, much branched in a determinate manner, about two feet high; the young branches woolly. Leaves scattered, numerous, falked, an inch or more in length, linear, obtuse, entire, revolute; dark green and smooth above; clothed with dense rusty wool beneath. Flowers numerous, in dense, simple, terminal, brae$tated corynbs, white and very pretty. The whole plant, especially when bruised, has a strong aromatic oppressive scent, somewhat like hops, instead of which the inhabitants of Dalecarlia are said by Linnaeus sometimes to make use of it, but the confidences are a most pernicious kind of intoxication, with obfolute head-aches. The Swedes wash their ozen and wien with a decoction of it, to kill lice, and the settlers in Lapland wear its branches among their grain to drive away mice.—A procumbent variety, a span long, is said to be found at Hudson's bay, just as the birch grows humble, and almoft prolate, in the upper parts of Lapland.

3. L. Iuxifitum. Box-leaved Ledum. Bergius in Ait. Petrop. for. 1777, part 1. 213. t. 3. f. 2. Dryand. Leaves elliptical, smooth on both sides, nearly flat. Native of Carolina and New Jersey. Introduced to our gardens by the celebrated Peter Collinson in 1736. It is a much smaller shrub than either of the foregoing, with leaves resembling those of Azalea procumbens at first sight. They are about a ¼ of an inch long, elliptical or ovate, smooth on both sides, most shining above, their edges scarcely revolute, their midrib prominent underneath. Flowers white, about a quarter of the size of the first species.

LEDUM, in Gardening, comprehends plants of the hardy evergreen kind, as the marsh cillus, or wild rosemary. The species cultivated is the marsh ledum, (L. palustris.)

It has varieties with erect and decumbent branches.

Method of Culture. — These plants are increased by fowing the seeds in pots filled with boggy earth, or in shady borders of the same kind of mould, in the spring season. But the best method is to take up the plants in their native situations, with balls of earth about their roots, and plant them in borders of the above kind, keeping them well watered.

It is also found that layers of the young shoots will sometimes grow.

These plants afford variety in shady situations, where the soil is of the boggy kind.

LEDYARD, in Biography, a native of America, who seems from his youth to have indulged an invincible desire of acquainting himself with the unknown, or imperfectly discovered regions of the globe. His history is so extraordinary, that a detail of some of its leading particulars cannot be unappalling to our readers. Having lived for several years with the Indians of America, he had studied their manners, and had practised in their school the means of obtaining the protection, and of recommending himself to the favour of savages. In the humble situation of a corporal of marines, to which he submitted rather than relinquish his pursuit, he had made with captain Cook the voyage of the world; and feeling on his return an anxious desire of penetrating from the north-west coast of America, which Cook had partly explored, to the eastern coast, with which he himself was perfectly familiar, he determined to traverse the vast continent from the Pacific to the Atlantic ocean. His first plan for the purpose was that of embarking in a felief, which was then preparing to sail, on a voyage of commercial adventure, to Nootka found, on the western coast of America; and with this view he expended in sea-flores the greatest part of the money with which he had been supplied by the liberality of
Sir Joseph Banks, who has eminently distinguished himself in this way on other occasions for the promotion of every kind of useful science. But this scheme was frustrated by the incapacity of a custom-house officer; and therefore Mr. Ledyard determined to travel over land to Kamtchatka, from whence the passage is extremely short to the opposite coast of America. Accordingly, with no more than ten guineas in his purse, which was all that he had left, he crossed the British channel to Ostend, towards the close of the year 1786, and by the way of Denmark and the Sound, proceeded to the capital of Sweden. As it was winter, he attempted to traverse the gulf of Botnia on the ice, in order to reach Kamtchatka by the shortest course; but finding, when he came to the middle of the sea, that the water was not frozen, he returned to Stockholm, and taking his course northward, walked to the Arctic circle, and falling round the head of the gulf, defended on its eastern side to Petersburg, where he arrived in the beginning of March 1787. Here he was noticed as a person of an extraordinary character; and though he had neither fockings nor shoes, nor means to provide himself with any, he received and accepted an invitation to dine with the Portuguese ambassador. From him he obtained twenty guineas for a bill, which he sold the liberty, without being previously authorized, to draw on Sir Joseph Banks, concluding, from his well-known disposition, that he would not be unwilling to pay it. By the interest of the ambassador, as we may conceive to have been probably the case, he obtained permission to accompany a detachment of flares, which the emperors had ordered to be sent to Yakutsk, for the use of Mr. Billings, an Englishman, at that time in her service. Thus accommodated, he left Petersburg on the 21st of May, and travelling eastward through Siberia, reached Irkutsk in August; and from thence he proceeded to Yakutsk, where he was kindly received by Mr. Billings, whom he recollected on board captain Cook’s ship, in the situation of the astronomer’s servant, but who was now enfranchised by the emperors in accomplishing her schemes of discovery. He returned to Irkutsk, where he spent part of the winter; and in the spring proceeded to Oczakov, on the coast of the Kamtchakan sea, intending, in the spring, to have passed over to that peninsula, and to have embarked on the eastern side in one of the Russian vessels that trade to the western shores of America; but finding that the navigation was completely obstructed, he returned to Yakutsk, in order to wait for the termination of the winter. But whilst he was amusing himself with these prospects, an express arrived, in January 1788, from the emperors, and he was seized, for reasons that have not been explained, by two Russian soldiers, who conveyed him in a sledge through the deserts of Northern Tartary to Moscow, without his clothes, money, and papers. From Moscow he was removed to the city of Moiafo, in White Russia, and from thence to the town of Tolochin, on the frontiers of the Polish dominions. As his conductors parted with him they informed him, that if he returned to Russia he would be hanged, but that if he chose to go back to England, they wished him a pleasant journey. Diliried by poverty, covered with rags, infelched with the usual accompaniments of such clothing, harried with continual hardships, exhausted by disease, without friends, without credit, unknown, and reduced to the most wretched state, he found his way to Konigberg. In this hour of deepest distress, he resolved once more to have recourse to his former benefactor, and fortunately found a person who was willing to take his draft for five guineas on the president of the Royal Society. With this assistance he arrived in England, and immediately waited on Sir Joseph Banks. Sir Joseph, knowing his disposition, and conceiving, as we may well imagine, that he would be gratified by the information, told him, that he could recommend him, as he believed, to an adventure almost as perilous as that from which he had just returned; and then communicated to him the wishes of the Association for discovering the Inland Countries of Africa. Mr. Ledyard replied, that he had always determined to traverse the continent of Africa, as soon as he had explored the interior of North America, and with a letter of introduction by Sir Joseph Banks, he waited on Henry Beaufoy, esq., an active member of the fore-mentioned association. Mr. Beaufoy spread before him a map of Africa, and tracing a line from Cairo to Senamar, and thence westward in the latitude and supposed direction of the Niger, informed him that this was the route by which he was anxious that Africa might, if possible, be explored. Mr. Ledyard expressed great pleasure in the hope of being employed in this adventure. Being asked when he would set out? "Tomorrow morning" was his answer. The committee of the society addressed to him, at his own desire, as an enterprise of obvious peril and of difficult success, the task of traversing from east to west, in the latitude attributed to the Niger, the wildest part of the continent of Africa. On the 30th of June, 1788, Mr. Ledyard left London; and after a journey of 36 days, seven of which were consumed at Paris, and two at Marly, he arrived in the city of Alexandria. On the 14th of August, at midnight, he left Alexandria, and sailing up the Nile, arrived at Cairo on the 19th. From Cairo he communicated to the committee of the society all the information which he was able to collect during his stay there; and they were thus sufficiently apprised of the ardent spirit of inquiry, the unwearied attention, the persevering research, and the laborious, indefatigable, anxious zeal with which he pursed the object of his mission. The next dispatch which they were led to expect, was to be dated at Senamar: the terms of his passage had been settled, and the day of his departure was appointed. The committee, however, after having expected with impatience the description of his journey, received with great concern and grievous disappointment, by letters from Egypt, the melancholy tidings of his death. By a bilious complaint, occasioned probably by excessive delay at Cairo, and by too free an use of the acid of vitriol and tartar emetic, the termination of his life was hastened. He was decently interred in the neighbourhood of such of the English as had ended their days in the capital of Egypt. Mr. Ledyard, as to his person, scarcely exceeded the middle size, but he manifested very remarkable activity and strength; and as to his manners, though they were unpolished, they were neither uncivil nor unpleasing. "Little attentive to difference of rank," says his biographer, "he seemed to consider all men as his equals, and as such he respected them. His genius, though unpolished and irregular, was original and comprehensive. Ardent in his wishes, yet calm in his deliberations; daring in his purposes, but guarded in his measures; impatient of control, yet capable of strong endurance; adventurous beyond the conception of ordinary men, yet wary and considerate, and attentive to all precautions, he appeared to be formed by nature for achievements of hardship and peril."—They who compare the extent of his pilgrimage through the vast regions of Tartary with the feats of his funds, will naturally ask, by what means he obtained a subsistence on the road? All that I have ever learned from him on the subject was, that his sufferings were excessive, and that more than once he owed his life to the compassionate temper of the women. This remark is strongly confirmed by the following extract from his account of his Siberian tour: "I have always remarked, that women, in all countries, are civil, obliging, tender, and humane:
humane: that they are ever inclined to be gay and cheerful, timorous and modest; and that they do not hesitate, like men, to perform a generous action.—Not haughty, not arrogant, not supercilious; they are full of courtesy, and fond of society; more liable, in general, to err than man; but in general, also, more virtuous, and performing more good actions than he. To a woman, whether civilized or savage, I never addressed myself in the language of decency and friendship, with out receiving a decent and friendly answer. With man it has often been otherwise. In wandering over the barren plains of inhospitable Denmark, through bonny Sweden and frozen Lapland, rude and cheerless Finland, unprincipled Russia, and the wide-spread regions of the wandering Tartar, if hungry, dry, cold, wet, or sick, the women have ever been friendly to me, and uniformly so; and to add to this virtue (to worthy the appellation of benevolence), these actions have been performed in so free and so kind a manner, that if I was dry, I drank the sweetest draught; and if hungry, I ate their coarse morsel with a double relish.

Similar to this was the experience of Mr. Park. (See Afric.) Nevertheless, the Mr. Park’s frequent relief and assistance from female attention and kindnesh, he seems on many occasions to have endured the utmost pressure of distress. “I am accustomed,” said he, in his last conversation with the writer to whom I am indebted for this account of him, “to hardships. I have known both hunger and nakedness to the utmost extremity of human suffering. I have known what it is to have food given me as charity to a madman; and I have at times been obliged to shelter myself under the miferies of that character to avoid a heavier calamity. My distresses have been greater than I ever owned, or ever will own to any man. Such evils are terrible to bear; but they never yet had power to turn me from my purpose. If I live, I will faithfully perform, in its utmost extent, my engagement to the society; and if I perish in the attempt, my honour will still be safe, for death cancels all bonds.”

LEE, Nathaniel, son of a clergyman, was educated at Welfington school under Dr. Bubbry. He was admitted a scholar of Trinity college, Cambridge, in 1668, but quitted the university without a fellowship, and attempted to push his fortune at court. In this he was unsuccessful, and then began to write for the stage. His first piece was the tragedy of Nero, produced in 1675, and from this time, till 1681, he produced one tragedy every year, all which appear to have had temporary success. He made a trial of his talents as an actor, but did not succeed in the attempt. About the year 1684, he was bereaved of his understanding, an affection which proved so severe as to baffle the powers of his medical friends, and which oblied his relatives to obtain for him an asylum in Bedlam. Here he remained about four years, during which he was able to write two tragedies. He died, in 1690, so poor, as to have been buried by the parish of St. Clement Danes. According to Addison, Mr. Lee was equal to any of his contemporaries in a natural genius for tragedy, but his impetuosity led him into a turbulent style, approaching to bombast, and he was apt to bury his thoughts in such a cloud of words, that it was difficult to discern their beauty. He is reckoned to excel in representing the passion of love, which he sometimes touched with exquisite tenderness and force. Two of his pieces only are, at this time, ever brought on the stage, viz. his “Theodolinda,” and his “Rival Queens.”

Lee, in Geography, a river of Ireland, which rises in the mountains, on the western border of the county of Cork, and having passed Longs Gouane-barra and Allun, flows eastward through the barony of Mulkey. It receives in its way the rivers Sullivan, Dripsey, Blarney, and Bride, with several smaller streams, and below the city of Cork, which is built chiefly on islands formed by it, it expands into that capacious and beautiful harbour, called Cork harbour. (See Cork.) There is also a small river of this name, which runs into Tralee bay, in the county of Kerry.

Lee, a county of Virginia in the S.W. corner of the state, bounded S. by North Carolina, and W. by Kentucky; its form is triangular, two sides being 60 miles long, and the other about 30. In this county is Powel’s Fort Valley, but a third part of the county is mountains. It contains 4,795 free inhabitants, and 245 slaves. The chief town is Jonesville.—Allo, a small town in Strafford county, New Hampshire, about 12 miles N. of Exeter; formerly part of Dover, and in 1777, and containing 207 inhabitants. Horfatonick river runs towards the fourth through this town.

Lee, a term variously used at sea, though its general use be to signify the part towards, or opposite to the wind. This expression is chiefly used when the wind crosses the line of a ship’s course, so that all on one side of her is called to windward, and all on the opposite side, leeward. Hence,

Lee-Shore is that on which the wind blows, so that to be under the lee of the shore, is to be close under the weather-shore, or under wind; or at a short distance from the shore which lies to windward.

A-Lee the Helm. See A-Lee.

Lee, Hard a. See HARD.

Lee-Heave, take care of the, is a word of command to the man at the helm, to take care that the ship do not go to the lee-ward of her course.

To Lee-ward, denotes towards that part of the horizon which lies under the lee, or whither the wind bloweth.

Lee-ward Ship, is one that is not fall by the wind, or which doth not sail so near the wind, nor make so good way as the ship; or which is much to leeward of her course, when falling close hauled.

Lee, To lay a Ship by the, or to come up by the Lee, is to bring her so, that all her sails may lie flat against her masts and shrouds, and that the wind may come right upon her broadside.

Lee-Fangs, are ropes reeled into the cringles of a yacht’s or hoy’s falls.

Lee-Larches, signify the sudden and violent rolls which a ship often takes to the leeward in a high sea, particularly when a large wave strikes her on the weather-side.

Lee-Side, denotes all that part of a ship or boat, which lies between the main and the side farther from the direction of the wind; or that half of a ship which is pressed down towards the water by the effort of the sails, as separated from the other half by a line drawn through the middle of her length; that part of the ship, which lies to the windward of this line, is accordingly called the weather-side. Thus, if a ship sails south, with the wind at call, she is her larboard, or right side, the lee-side; and the larboard, or left, the weather-side.

Lee-Way, or Lee-ward Way of a Ship, is the angle made by the line on which the ship should run according to her course, or the point of the compass fleeced upon, and the real line of the ship’s way occasioned by contrary winds, and a rough sea.

All ships are apt to make some lee-way; so that in casting
up the log-board, something must be allowed for lee-way. But the lee-way made by different ships, under the same circumstances of wind and falls, will be different; and even the same ship, with different lading, and having more or less sail abroad, will make more or less lee-way. The ordinary rules of allowing for it are these: they were given by Mr. John Buckler to the late Mr. William Jones, who first published them about the year 1702.

1. When a ship is close-hauled, has all her sails set, the water smooth, and a moderate gale of wind, she is then supposed to make little or no lee-way. 2. Allow one point, when it blows so fresh, that the small fails are taken in. 3. Allow two points, when the top-fail must be close-reeded. 4. Allow two points and a half, when one top-fail must be hoisted. 5. Allow three points and a half, when both top-fails are to be taken in. 6. Allow four points, when the fore-course is hoisted. 7. Allow five points, when trying under the main-fail only. 8. Allow six points, when both main and fore-courses are to be taken in. 9. Allow seven points, when the ship tries a-hull, or all sails are hauled. When the wind has blown hard in either quarter, and shifts across the meridian into the next quarter, the lee-way will be lessened. But in all these cases, respect must be had to the roughness of the sea with the trim of the ship; and hence the mariner will be able to correct his course.

Gen. Ch. Cal. Perianth inferior, of one leaf, coriaceous, bell-shaped, five-toothed, permanent. Cor. of one petal; tube the length of the calyx; limb in five ovate, acute, recurved segments. Nectary attached to the inside of the tube, erect, pitcher-shaped, shorter than the tube, with five notched lobes. Stam. Filaments five, connected with the nectary, between the lobes, a little way down, incurved; authors ovate, valvate, cohering together before impregnation and covering the stigma. Pfj. Germen superior, nearly globular; style simple, shorter than the nectary; stigma capitate. Peric. Berry orbicular, deprest, with five prominences, of one cell. Seeds five, gibbous at the outside, angular at the inner.

Eek. Ch. Corolla of one petal; limb in five segments. Nectary of one leaf attached to the tube, five-cleft, erect, bearing the flaminis. Berry inferior, with five seeds.

1. L. jambeina. Elder-leaved Lecce. Wild. n. 1. (Aquilegia jambeina; Linna. Mant. 2. 211. Cavan. Diff. 327. 218. Lamarck. Dict. v. 1. 217. Stephylea? indica; Burn. Ind. 75. t. 24. f. 2. Frutex aquosus femina; Rumph. Ambon. v. 4. 109. f. 45. Naluni; Rheede Hort. Mal. v. 2. 43. t. 26.)—Stem furrowed and angular, smooth. Leaves smooth, doubly pinnate; the terminal leaflet large.—Native of the East Indies, from whence it was procured for the Kew garden, by Sir Joseph Banks, in 1790. It is a smooth shrub or small tree ten or twelve feet high, with the aspect of Elder; the branches tumid at the junction of the leaves, dilated and more or less angular. Leaves alternate, large, doubly pinnated; leaflets falked, opposite, elliptical-oblong, pointed, veiny, strongly ferrated, very smooth, paler beneath; the odd ones large. Panicula cymose, opposite to the leaves, pubescent. Flowers small, white. Berries rather acrid, the size of a pea, depressed, black, purplish internally. A decoction of the roots or wood feems, by the accounts given of its uses, to be a valuable tonic medicine.

2. L. equata. Downy Lecce. Linna. Mant. 124. (Cajoe toca of the Malays.)—Stem round, downy. Leaves doubly pinnate, rough.—Native of the East Indies, from whence Mr. Lee received and cultivated it before the year 1777. We find no notice of this species. Linnaeus did not distinguish it from the former, but they are very different. In both the leaves are bipinnate, or rather ternate in their first division, pinnate in the second; but in this species the terminal leaflet is not larger than the rest, except in some of the lateral divisions, and all the leaflets, as well as their stalks, are rough with minute rather rigid pubescence. The serratures are less strong than in L. jambeina.

3. L. cripta. Wing-talked Lecce. Linna. Mant. 124. Meerburgh. Ch. v. 1. t. 50. (L. pinnata; Andr. Repof. t. 355.)—Stem angular, with criped wings. Leaves simply pinnate.—Native of the East Indies, not, as Linnaeus supposed, of the Cape of Good Hope. The roots are tuberous. Stem scarcely shrubby, remarkably bordered, as are the leaf-stalks, with parallel, partly criped, wings. Leaves pinnate, generally of two pair, with an odd one, of elliptical, pointed, strongly ferrated and cipiously veined leaflets, roughish to the touch when dry, but not pubescent. Flowers much as in the former, with channelled, angular, or winged stalks. Each segment of the corolla, according to Andrews, is hooded at the point. We have seen one leaf imperfectly bipinnate.

It appears, from the Linnaean herbarium, that Linnaeus originally defined the name of Hippia for his Lecce; but he afterwards applied the term to a very different genus. (See Hippia.) From the same source the identity of his Lecce and Aquilegia was first discovered, and the latter name gives place, as being the more recent, to lay nothing of the claims of the former respecting the peron it commemorates.

LEEYRAN, in Geography, a small island in the East Indian sea, near the north-east coast of Borneo. N. lat. 6° 1'. E. long. 118° 12'.

LECH, in Zoology. See Hirudo.

The history of this animal, and the structure of its parts, by means of which it becomes useful to us, in supplying very happily the place of the lanceet, with every other particular circumstance of its life and food, have been very accurately given by Mr. Morand, in the Memoirs of the Academy of Sciences, in the year 1779.

The more vulgarly known particulars of this animal are briefly mentioned by this gentleman; such are the cutaneous annules of its outer coat, the beautiful arrangement of the several rays, the colours, the pyramids, and points, with which it is ornamented; the avidity with which this creature feizes the flesh of animals; the manner of its applying its mouth; the vermicular motion observed within it whileucking, which resembles the common motion of deglutition; the time they have been known to live in the water without
without any visible food; and the faculty they have, in common with many other animals, of moving when cut into several pieces: thele the author supposes already sufficiently known, and paffes on to what is less fo, the structure of its inner parts.

The part of this animal, by which it pierces the skin of any creature to get at its blood; is generally called, simply, its mouth; but it really consists of five different parts, which are confounded under that general name. These are two regular lips, a cavity, which is properly the mouth, certain instruments to pierce with, others which serve it for fucking, and finally a fort of throat, or æsophagus, through which it swallows the blood. When the leech is in a state of rest, its upper lip forms a regular semicircle, and the lower a portion of a much larger circle.

When the creature lengths its head to move, the semicircle of the upper lip becomes two oblique lines, the junction of which makes a salient angle, which the creature applies to whatever it would fix itself to. That angle is marked by a regular black spot on the outer edge of the lip. The extreme softness of the fibres of this part makes it very serviceable to the animal, in that it readily assumes any figure, according to the occasion of seizing any thing solid, in order to move the rest of its body; or, on the flesh of an animal, to give opportunity to the piercing instruments to exert their force and action.

Whether it be for either of these purposes, that the creature fixes its mouth, the two lips regularly fix, and make in this state a fort of acetabulum, like the hollow of the tail. This may be seen in their fixing on the sides of a glass-vessel in which they are kept, and the mouth, or aperture between the lips, is distinctly seen. This mouth is formed, like the lips, of such extremely supple fibres, that it takes the figure of the part to which it is applied, and fixes perfectly close to it. When the lips are fixed on the flesh, in order to suck, this little mouth continues moveable under them, and searchs over the compass of flesh, inclosed in the larger circle of the lips, for the spot where it will be easiest to draw much blood.

Within this mouth is placed the instrument for piercing the skin, which is more than the mere fucker of the gnat, or the like kind of flies; since the quantity of blood to be sucked by the leech, is much larger, and the aperture of the vellum mouth therefore also be larger. The shape of this weapon may be discovered by examining the wound it leaves. This is composed of three cuts, making three rays, and uniting in a centre, under equal angles. This structure of the wound is most distinctly seen when the swelling is gone down, and the skin is clean; and this is usually on the fourth day after the application. The three openings are then plainly seen not to be punctures, but absolute wounds, or cuts, as if made by a fine lancet. In examining the creature, the organ, destined for making the wound, is found to be placed between the aperture of the lips and the bottom of the mouth; and on cutting up the animal, and drawing the finger carefully over this part of it, there is felt a roughness like that of a fine file, which evidently is owing to some rough substance, of the hardness of bone. This is, in reality, a number of fine and sharp teeth; and when examined by a microscope, they are found to be disposed in three series on three ribs, or, as they may be called, jaws; each of which is placed along the middle of a strong muscle of its own length; and these corresponding regularly to a triangular opening, which the creature has in its mouth. When that has seized on a proper part for the getting blood, and is fixed, these muscles exert their action, and strike in the teeth through the skin.

There are the instruments which pierce the vellum which is to afford the blood; and for the receiving it into the body of the animal, there is between these rows of teeth, or in the common centre of the mouth, a small aperture; and within this there is a little body to be discovered, which by its motion seems very plainly to be a tongue, and which probably acts as a piston to take up the blood flowing from the triple wound, in the centre of which it naturally flows, while the larger circle of the lips, &c. perform the office of the body of the pump, and the blood is easily, by this means, conveyed into the body of the animal. Finally, between the root of the tongue and the beginning of the flomach, there is a space of two lines in length, in which it is easy to discover two different arrangements of fibres; the one set are flat and plain, the others are circular. These evidently have a power of widening or contracting the cavity of the pump, and by that means facilitate its office; the plane ones contracting in length, to enlarge the capacity, and the circular ones determining the blood towards the flomach, by their power of contracting the hollow, when the blood is received. The blood from hence enters into a membraneous fort of sack, which serves the animal for the flomach and guts, and occupies the greatest part of the body of the creature. If the air is admitted into the body by the mouth, it may be seen to make its way down a longitudinal canal, and fill, as it goes, a number of sacks, or little bags, which are on each side. These vessels receive the blood, and becoming filled with it, swell out the body of the animal to a great size. It remains here many months, and nourishes the creature; and if any thing is excreted from it, it must be merely by an inefable perpiration; since the creature has no anus, so far as can be yet discovered, nor any aperture which can supply the place of one.

Leeches are able to live in oil; and when removed out of this liquor into water again, they throw off a tender skin, or film, of the regular shape of their body, and resembling the skin of an eel in miniature. Their living in oil seems a proof, that their organs of respiration are not placed on the outside of their bodies, as they are in many small animals, which therefore die on being only rubbed over with oil. But the leech seems to respire by the mouth; and this may be the more plainly discovered, if the water, in which it is kept, be gently heated; for then the animal, being uneafy, breathes hard, and very visibly.

If a leech be kept in an eight-ounce glass phial, about three-fourths filled with water, it will indicate the changes of the weather, in the manner of a weather-glafs. Thus, if the weather continues serene and beautiful, the leech lies motionless at the bottom of the phial, rolled in a spiral form: if it rains either before or after noon, it is found at the top of its lodging, where it will remain until the weather be settled: if we are to have wind, the leech gallops about its limpid habitation with amazing swiftness, and seldom rests until it begins to blow hard: if a remarkable form of thunder or rain is to succeed, for some days before, it lodges almost continually without the water, and discovers great uneafines, in violent throws and convulsive like motions. In frost, as in clear summer weather, it lies confinedly at the bottom; and in snow, as in rainy weather, it dwells at the very mouth of the phial.

The phial should be covered at the mouth with a piece of linen rag, and the water should be changed once a week in the summer, and once a fortnight in the winter. Gent. Mag. vol. xxiii. p. 28.

Leech, Sta. See Hirudella marina.
Leech is also a name given by Boecon to a very particular water-animal, which he found sticking to the sides of the xiphias, or sword-fish.

He calls it hirudo, or acus castus utringle penata, and observes, that it is slightly mentioned by Celsus, and by Johnfon, in their books of fishes. It is about four inches long; the belly is white and cartilaginous, and transparent; there is no regular head to be seen, but only a hollow fnout in the place of the head; this covered with a very hard membrane, and differs extremely from the skin of the belly; this snout it thrusts up to the end into the body of the fish, and sucks its blood with it; it has a tail shaped like a feather, and under it two slender filaments of fibres, longer than its whole body. By means of these, when it is not fastened to the body of the fish, it clings to the leaves of the sea-plants, to prevent its being carried away by the motion of the water; and when it is on the body of the fish, these serve it to hold much more fairly with, than it otherwise could do. This creature miterably afflicts the sword-fish, but it is itself as much tormentèd by an animal that presys on its blood and juices. This is a sort of loofe, which is always found upon it; it is of a brownish colour, and is generally found fastened toward the tail of the creature, Ricking as firmly as a limpet to a rock; it is nearly of the bigness of a pea, and when bruised a little, will thrush out severall slender filaments. This leech is not found, as far as has yet been observed, on any other fish but the sword-fish; nor this loofe among other creatures, besides this leech. Phil. Trans. N. 102.

Leeches. Utility of. In the Cure of Diseases. — Bleeding, or, the taking away of blood, for the alleviation and cure of diseases, especially when the disease is great, is frequently one of the most powerful means to which the physician and surgeon can recourse for the relief of their patients. It is divided into general and topical; the first signifying the evacuation, as made from a large vein in the arm, or the temporal artery, the external jugular vein, &c; the second denoting the evacuation of blood directly from the vessels of the part affected, or its vicinity, by incisions, cupping, or leeches. In the article BLEEDING are described most of the surgical methods of taking away blood, with the exception of that by leeches, which more properly belongs to the present place, and of CUPPING and SCARRIFICATIONS, for an account of which the reader is referred to those respective terms.

The hirudo medicinalis, as the term denotes, is the proper kind for medical purposes; and, when it has been caught in a clear piece of water, it is not full of blood, and is hungry, in consequence of being kept for some time in a vessel of pure water, it is in the best condition for use. According to Schmucker, even the medicinal leech, if taken out of unclear, muddy, stagnant water, will cause pain, swelling, and inflammation, after being applied. Vermifex Chir. Schriften, vol. i. p. 86. edit. 2.

With respect to the art of collecting medicinal leeches, the best time for taking them is when they are found in the earliest warm weather of the year. June and July are accounted favourable months, if there is a good deal of sun, and the wind is either very full, or blows gently from a southerly point. It would be in vain to endeavour to catch them in cold weather attended with northerly winds. The hirudo medicinalis inhabits clear lakes and ponds in warm situations, and streams flowing through, valleys. In cold and woody countries, the horfe leech can only be met with. The warmer the situation of the water is, and the fatter the foil, the thicker and larger are the leeches. Those which are caught in waters abounding with fish, do not bite and suck too well, as others taken out of poorer places. From lively leeches bite the most readily; but when they have been kept a long while, or have been put out of temperate into very cold water, they generally bite with less avidity.

With regard to the mode of applying leeches, the part on which they are to be put may first be washed with some clean water and well dried. The leeches are then to be placed on it with the fingers, either one by one, or all of them together, by putting them first into a tumbler, and then applying this to the skin, in the manner of a cupping-glas. The leeches should generally be full-red to fall off the part spontaneously, which they commonly do, as soon as they are well distended. But when the patient's weakneshs, or any other circumstance, requires them to be more speedily removed, they may easily be made to drop off by sprinkling them with a little salt or nuff. For the purpose of inducing leeches to bite with greater facility, some practitioners first wet the part on which they are to be put with a little milk, or milk and sugar.

On some occasions, the application of leeches will procure as copious an evacuation as phlebotomy itself. The quantity of blood which may sometimes be taken away by twelve leeches, would surplifie the inexperienced. When the bites are expofed to the stream of warm water, or fomented after the leeches have dropped off, the bleeding may often be kept up for an extraordinary length of time. The writer of this article has known infinences, where surgeons have been detained for nearly twenty-four hours, in employing means to suppresse the continuance of the bleeding from the bites of leeches on inflamed parts. In cafes of herna humoralis, where the fcrum has been much reddened and inflamed, he has often seen the hemorrhage, from the application of leeches, last a very unpleasant length of time. Indeed, the records of surgery prove, that the bleeding from the bites of leeches may even continue to a dangerous extent. Pelletan mentions a cafe, where an infant, four months old, bled to death, in consequence of the application of fix leeches to the chest, some women who were in attendance having contented themselves with merely wiping away the blood with cloths, as fast as it flowed out. (See his Clinique Chirurgicale, tom. ii. p. 245.) In general, however, the bleeding, after leeches have dropped off, readily ceases, either of itself or on cold being applied; and it is only when the part is highly inflamed, or excessively vascular, as we know the skin of a very young infant to be, that the subsequent hemorrhage is disposed to continue long. In many infinences, the continuance of the bleeding a certain time is a most definable circumstance, as by this means a more effectual quantity of blood can be taken away than could otherwise be accomplished.

We learn from Galen, that Hippocrates was acquainted with the medical utility of leeches. (De Hirudinibus eum communt. Sebii.) In inflammation of the liver, they were preferred by Aretaeus, of Cappadocia, to cupping-glass; and they are made frequent mention of in the writings of Dioscorides, Celsus, and Paulus Aegineta. Pliny thought, that leeches might be employed with several intention, as, in phlebotomic cafes, they extract the blood like cupping-glass, and, according to his conjectures, also opened the pores. (Hist. Natural. i. xxxii. c. 10.) Horace has taken notice of these useful little animals in the following line of his farries.

"Non mulula cutem ni plena cruoris hirudo."

The Arabian physicians well knew the usefulness of leeches, and were in the habit of directing them to be applied in melancholic and hypochondriacal cases. Rhazes, in particular, recites numerous cures which he effected with their affiil-
L. E. E.

Paracelsus used to apply them in cases of jaundice. By the chemical practitioners of medicine, leeches were not at all employed, because they were accustomed to reprobrate all evacuations of blood as useless and hurtful; and Van Helmont would not suffer them to be applied to an hemorrhoidal swelling.

The use of leeches, in the practice of physic and surgery, appears to have been revived by Sennertus and Zacatus Lusitanus.

It would be almost an endless task to enumerate the great variety of medical and surgical cases in which leeches may be used with advantage. We may state, indeed, that in all inflammatory affection, they are frequently of considerable service. In inflammations about the throat, in the abdomen, thorax, or cranium, or in the limbs and more superficial situations, the benefit derived from the application of leeches, can often be obtained by no other means. The great good which they often do in inflammatory diseases of the eye, joints, and teeth, is acknowledged by every practitioner, as well as the relief which they speedily afford in cases of inflamed hemorrhoidal tumours. Their utility in inflammations of the breast, and in alleviating the pain, and even retarding the progress of febrile swellings of the same part, deserves also to be mentioned. That they sometimes prove even capable of curing and reducing many indurations of the breast, is a fact proved by daily experience. Nor must we forget the beneficial effects, frequently arising from the application of leeches in various examples of buboes, scrofulous and sympathetic swellings, as well as vesicular.

In the majority of cases, however, we are not to imagine that one application of three, four, or even a dozen leeches, is enough to try their efficacy; in general their application must be repeated from time to time, and, in some instances, once or twice a day, according to the urgency of the symptoms.

In infants of tender years, and persons who have a particular dread of venefection, leeches may be used for the relief of all diseases which require blood to be taken away; and this method of bleeding has the advantage of not being likely to induce fastness, debility, and languor, by the blood being drawn too suddenly.

In many cases, where the practitioner is fearful of venturing upon general bleeding, the employment of leeches may often be tried with greater safety.

In painful affections of the ear and teeth, in inflammations and swellings of the gums, and in numerous inflammatory diseases affecting the parts about the neck and throat, topical bleeding with leeches proves of infinitesimal service, either alone, or in conjunction with general bleeding, according to the nature and circumstances of the case.

In numerous instances of extravasations of blood under the skin, ecchymoses, contusions, &c. leeches are frequently applied with great benefit to the patient.

In cases of quinny, when deglutition has been quite obstructed, and repeated venepunctures have proved availing, Schmucker assures us, that he has found the application of leeches attended with an extraordinary degree of efficacy. The same experienced practitioner also observes, that in pleurisy, he has found topical bleeding with leeches even more useful than blisters.

Whitlows, which can so feldom be cured without suppuration, Schmucker has sometimes resolved, by applying to them leeches and the faturene lotion in an early stage of the complaint.

This distinguished surgeon likewise confirms, how superiorly useful the application of sixteen or twenty leeches to the perineum frequently proves in cases of retention of urine, when venepunction, the warm bath, and other means alone are ineffectual. Vermiculine Chirurgische Schriften, vol. ii. art. 2.

Leech, or Leech of a Sail, in a Ship, the outward edge or skirt of the sail from the caring to the clow, or rather the middle of the sail between these two.

The leeches of all sails, whose tops and bottoms are parallel to the deck, and at right angles with the masts, are denominated from the ship's side, and the sail to which they belong, as the starboard leech of the main-fail, the lee-leech of the fore-top-fail, &c. But the fails which are fixed obliquely upon the masts, have their leeches named from their situation with respect to the ship's length; as the fore-leech of the mizen, the after-leech of the jib, or fore-top-fail, &c. Falconer.

Leech, or Leech-line, are certain ropes fastened to the leeches of the main-fail and fore-fail, and communicating with blocks under the opposite sides of the top, whence they pass downwards to the deck, serving to truss up those fails to the yard, as occasion requires. See Braid.

Leech-ropes, is a name given to that part of the bolt-ropes, to which the border of a fail is fewed. In all fails, whose opposite leeches are of the same length, it is terminated above by the earing, and below by the clew. Falconer.

Leechman, William, in Biography, a learned and excellent Scotch divine, was born at Dolfinhout, in Lanarkshire, in the year 1706. He was initiated in grammar-learning at his native place, from whence he removed to the university of Edinburgh. Here he distinguished himself by his great proficiency in different branches of learning. He began his theological studies in 1724, and in 1727 he was introduced into the western part of Scotland, which was defined hereafter to be the principal scene of his usefulness.

He undertook the education of a young gentleman at Caldwell, in Renfrewshire, where he resided in the summer months, but during the remainder of the year he lived at Glasgow, and was honoured with the friendship of professors Hutchison and Dunlop. About the beginning of 1731 he was licenced as a preacher, but it was not till the year 1736 that he had any prospect of preferment. He was now ordained minister of Beith, and remained in the discharge of the duties attached to that office during seven years.

In 1740 he was elected moderator of a meeting of the synod at Irvine, and opened the assembly at Glasgow on the 17th of April, 1741, with a sermon to the clergy: "On the temper, character, and duty of a minister of the gospel." This is thought to be one of the ablest charges ever delivered from the pulpit: it has passed through many editions, and is still in very high reputation. In 1743 he published a much longer discourse on "The Nature, Rea-sonableness, and Advantages of Prayer; with an Attempt to answer the Objections against it." This sermon, as well as that just noticed, excited great attention at the time of the publication, and it has been frequently reprinted since.

He was, about this time, invited to settle with a congregation at Belfast, in Ireland, with the promise of a better salary than that which he enjoyed at Beith. This offer, upon due deliberation, he declined, and he was shortly after elected to the professorship of theology at the university of Glasgow; an honour which he obtained only by the calling vote of the president. The opposite party did all in their power to prevent his being fixed in the situation; they even commenced a process of hereby against him, which had a direct tendency to injure his reputation and usefulness, and to expel him to general odium. The charge was founded on the sermon on prayer, which his enemies considered as having laid too little stress on the atonement and intercession of Christ.
LEE

Christ. A paper of remarks was produced, confuting of eight articles, of what they deemed heretical omi-

nents. To each of the remarks the professor gave in written an-

swers, which were neither deemed satisfactory to the com-

mittee nor to the presbytery, under whole authority they

acted. Mr. Leechman appealed to a higher court, viz. the

synod, the members of which, after hearing all that could

be adduced on both sides of the question, almost uni-

mously determined, that there was no reason to charge him

with any unfounded in the pacilings of the sermon com-

plained against. “Mr. Leechman’s character, both as a

preacher and professor, shone out the brighter after this

cloud was dìsipated. Some of those who had appeared his

keenest adherents in the church processes, lived with him

afterwards on terms of sincere friendship; even the pre-

judices of the common people in Glasgow gradually sub-

sided; so that he came to be considered there, as he had al-

ways been in every other place, a very acceptable preacher.”

Soon after he had been established in the professorship, he

took the degree of doctor in divinity. He continued in

the theological chair seventeen years, vindicating and es-

tablishing the grand truths of natural and revealed religion,

in answor to the principal objections made to them by Mr.

Hume, lord Bolingbroke, and other sceptical writers. He

had, in his lectures, a remarkable talent of felecting what

was most important and striking on every subject that he

handled: his arguments were bold, founded on indubitable

facts; and they were urged with a degree of warmth which

carried his auditors along with him; for they were addressed

equally to the judgment and the heart. Dr. Leechman’s

fame extended far and wide, the Divinity-hall at Glasgow

crowded, in his time, with a greater number of scholars than

any other in Scotland; and his numerous scholars, however

they might differ in their sentiments on speculative

theology and church government, were all cordially united

in their affection and veneration for their master. In the year

1761, Dr. Leechman was raised to the office of principal

of the university of Glasgow by a presentation from the

king. He had previously to this been in a very bad state

of health, and this change in his avocations was probably

the means of proloning his valuable life for five-and-twenty

years. Though released from the more fatiguing part of

his duties, he could not remain inactive, but entered warmly

into every scheme for the benefit and improvement of the

society, proposed by other professors, and prosecuted some

schemes of his own suggestion. He gave a lecture, for

some time, once a week, to the students in divinity, and

weekly lectures to the whole university. Dr. Leechman’s

faculties remained in full vigour amidst the increasing

infirmities of old age, and his taste for valuable knowledge

continued as acute as ever. His mind seemed to be in a great

measure independent of all bodily infirmities and con

nitions. In September, 1787; he experienced a violent paralytic

stroke, from the effects of which he speedily recovered;

but a second shock of the same kind in the following month

deprived him of the power of his whole left side. Still he

continued in the full possession of his mental faculties, and was

as intelligent, just, and even as acute as ever. Another

attack carried him off on the third of December, 1787,

when he was almost eighty years of age. Dr. Leechman

committed nothing to the press, except nine sermons, which

went through several editions during his life-time. These

were re-published, with others, forming together two vol-

umes, in the year 1789. To the first of these volumes is

prefixed an account of the author, to which the reader is

referred for more particulars relating to Dr. Leechman.

LEEDS, in Geography, a populous market-town in the

wapentake of Skyrack, in the West Riding of the county

of York, England, is situated on the north side of the

river Aire, over which is a handsome stone bridge. It is

a place of great antiquity, and its name is registered in the

Domesday survey. Here was formerly a strong caple, pro-

bably built by Eber de Lacy, which was bequeathed by

king Stephen in 1139; and here the unfortunate Richard II.

was confined about the year 1399. No vestige of this for-

tress remains; but its site is said to have been at a place

called Mill-hill. Leeds has long been distinguished as

a clothing town; though the pre-eminence it now enjoys is

not of a very remote date. Leland says it is "a pretty

market-town, subfitted chiefly by clothing, reasonably well

built, and as large as Bradford, but not to quick as it."

Its growth, however, probably soon became considerable,

as it was incorporated by king Charles I. At the com-

 mencement of the troubles of that reign, it was held for

the king by Sir William Saville; but after a sharp action, its

fortifications were stormed by the forces which marched out

of Bradford under Sir Thomas Fairfax. A second charter

was granted on the 13th of Charles II., under which the

town is now governed. The trade in woollen cloth, which

has raised Leeds to its present consequence, is carried on

here to an extent unequalled in any place in the kingdom.

The cloth-markets are held only on Tuesdays and Satur-

days, and then only for an hour and a half each day; and the

merchants are not allowed to buy, or even to look at cloth,

but at these appointed hours. At fix in the morning in

summer, and four in winter, the market-bell rings; and in

a few minutes, without the least disorder, the whole market

is filled, and all the benches are covered with cloth, each

proprietor at the same time standing behind his own cloth.

As soon as the bell has ceased the buyers enter, and having

fixed on certain lots, or pieces of cloth, they proceed in a

very expeditious and secret manner to bargain for the same.

(A particular account of the modes of transacting busi-

ness, &c. is given in the Monthly Magazine, vol. III. p. 123,

and vol. IV. p. 174.) In these places it is related that from ten

to twenty thousand pounds worth of cloth, and sometimes

more, is sold with a whisper only; the laws of the market

are certainly more strictly observed than in any other place

in England: the time of sale is terminated by another bell;

and any merchant delaying in the hall after the bell has ceased

forgets five shillings. This extensive business, which used

formerly to be carried on in the open street, is now con-

ducting in two halls, which have been built for the accom-

modation of the clothiers. The Mixed-cloth Hall, which

is the principal, was erected in 1758; it is a quadrangular

building, inclining an open area of about an hundred yards

square, and is divided into seven partitions or rooms, each

of which contains four rows of stands; and these are the

freehold property of separate manufacturers. The whole

number of stands is 1970. The White-cloth Hall, built in

1755, is partitioned in a similar manner, and contains 1120

stands. Over the former building is an assembly-room, and

over the latter a music-hall. The manufacture of broad

cloth is now almost wholly performed by machinery, which

has occasioned a considerable reduction in the price. By

this means, very few hands are wanted in the first stages of

the manufacture, particularly in carding and spinning the

wool, and in spinning it. This circumstance, on the first

introduction of machinery, deprived great numbers of peo-

ple of their customary employment.

Previous to the reign of Charles I. Leeds had but one

church: here are now, however, several ecclesiastical edifices,

appropriated to the established religion, and to different sects

do the Differents. The church of St. Peter, the original, is built

in

3 P 2
in the form of a cross, with a tower in the middle; and has a painting in fresco of the Ascension, by Parmentier, who prefixed the town with this specimen of his genius. -St. John's church was erected in 1634, at the sole expense of Mr. Harrington, who also built a free-school and a market-cross, and was in other respects a great benefactor to the town. The church of the Holy Trinity, which is an elegant structure, with a spire, was built in the eighteenth century. Eight other places of worship are appropriated to the several denominations of dissenters. Here are three alm-houses, a charity-school, and an extensive work-house, in which children are taught the easy branches of the woollen manufacture. A spacious infirmary was built by subscription in the year 1786. The streets, in the upper part of the town, are narrow; but in the other parts they are broad, and the houses are mostly uniform, and many of them elegant. Here are several large open squares, the areas of which are in some cases planted, and in others used as tenter grounds. The buildings are chiefly of brick, and covered with white slate; and every street has a flagged foot-way on each side. The civil government of the town is vested, by the charter of Charles II., in a mayor, twelve aldermen, and twenty-four common-council men.

Leeds is 192 miles distant from London, and 25 miles from York. In the year 1800, it contained, according to the return made to parliament, 11,599 houses, and 53,162 inhabitants: of the latter, 20,367 were flatted to be employed in trade and manufacture, particularly that of woollen cloth. Two fairs are held annually; and two weekly markets, on Tuesdays and Saturdays, are well supplied with all kinds of provisions. A considerable pottery is established here, which furnishes large quantities of earthenware, both for home consumption and exportation. By means of the river Aire and Calder, and the Canal Navigation, Leeds has communication with Wakefield, York, and Hull; from which latter place the woolen goods are usually shipped to foreign parts. The carriage of coals from the interior of Yorkshire is also a great source of traffic: these are carried in vehicles from 45 to 60 tons burthen, to Selby, York, Howden, Hull, Beverley, and all the intermediate towns situated on the rivers Ouse and Humber. Three miles from this town are the grand and picturesque ruins of Kirkstall Abbey, seated on the banks of the river Aire. For an account of these, with an interesting print, see Day's "Town and Boroughs" in Yorkshire, 8vo. 1835. -West of the town is an ancient seat of the Vavasor family. Aikin's Description of the Country round Manchester, 4to, and Monthly Magazine.

Leeds, a county of Upper Canada, bounded on the east by the county of Grenville, on the south by the county of Queen's, on the west by the boundary line of the late township of Pittsburg, running north until it intersects the Ottawa or Grand river; and thence descending until it meets the north-westernmost boundary of the county of Grenville. This county comprehends all the islands in the river St. Lawrence that are near it. The greater part of it lies fronting the St. Lawrence.—Allo, a township in the county of Leeds, being the twelfth township in ascending the river St. Lawrence. It is watered by the Gananoque river, which has a good harbour at its entrance. There is a port of entry on the west bank of the Gananoque, near its mouth in the St. Lawrence.—Allo, a town of America, in the eastern part of Gloucester county, New Jersey; 4 miles west of the mouth of Mullica river.—Allo, a town in Kennebec county, on the east bank of Arogooggin river, opposite to the mouth of Twenty miles stream, in the town of Turner, in Cumberland county.—Allo, a town, or rather village, of Richmond county, Virginia, on the north bank of Rappahannock river; 70 miles N.E. of Richmond; near which is a famous course for horse-racing.

LEEDSTON, a post-town of Westmoreland county, Virginia; 105 miles from Washington.

LEEELLAN, a small island in the East Indian sea, near the east coast of Borneo. N. lat. 4° 10'. E. long. 118° 40'.

LEEHY, a small island nearly north-east of Borneo. N. lat. 6° 9'. E. long. 118° 16'.

LEE, in Botany, Gardening, and the Materia Medica. See Allium.

LEE, in Geography, a small island of Pennsylvania, in Delaware river.

Leek-Hea'd, in the Manse. See Warf.

Leeke, or Leek-in-the-Moorlands, formerly called Lee, in Geography, a market-town and parish in the hundred of Tetmanlow, and county of Stafford, England, is seated at the northern extremity of that county, at the distance of 154 miles from London, and 51 from Manchetter. Here are a weekly market on Wednesday, and seven annual fairs. In the year 1800, this parish contained 780 houses, and 3,459 inhabitants. Many of them are employed in the manufacture of ribbons, silk-twist, and buttons; which may be considered the staple articles of the place. But of late years this latter branch has very much diminished, and at present the chief trade is in silk, and the manufacture of bandana and other handkerchiefs. The cotton bounties has also been introduced, within these few years, into this town. The church here is a large building, with a lofty square tower. In the church-yard is an ancient stone-croft, the shaft of which is about ten feet in height. It has been called Danith, from "the imagery and fret-work," as Mr. Gough observes, with which it is ornamented. Near the town was formerly a Cistercian abbey, called Delacres, or Diculacres, which was founded in the year 1214 by Ramulph, earl of Cheffer; to whom the lordship of this town formerly belonged. In the vicinity of Leek are some lofty bare crags, called Leek-rocks and Henclouds. Blue-hills, in this neighbourhood, abound with coal-mines; and a salt-spring issues from one of these hills. Eight alms-houses were endowed here in 1696, by Mrs. Elizabeth Allen, for as many widows.

Leer, in Glass-making, a sort of third furnace, intended to anneal and cool, by proper means, the vessels when made. See Furnace and Glass-House Furnace.

Leer, Lehr, or Lier, in Geography, a town of East Friesland, on a river of the same name, which from after joins the Ems; 11 miles S. of Emden. N. lat. 50° 12'. E. long. 7° 20'.

Leerdam, a town of Holland, on the river Linge, which gave title of count to the noble house of Egmont, and afterwards to that of Nassau; 11 miles S. of Utrecht. N. lat. 51° 55'. E. long. 4° 59'.

Leersia, in Botany, a genus of grasses, received its appellation from Dr. Swartz, in order, with peculiar propriety, to honour the memory of John Daniel Leers, an apothecary at Herborn in Nassau, author of the "Flora Herbornensis," published in 1775. This little octavo volume, now very rare, contains sixteen plates, in which all the grasses are engraved by the hand of the author, with such exquisite and minute precision, that they will bear inspection with a magnifier, almost like the plants themselves, and are unrivalled in natural history. A life of the author by his son is prefixed to this book, by which we learn that he died December 7, 1774, aged 47. The narrative contains few striking particulars, but the effusions of filial piety, with which

Gen. Ch. Calce none. Cor. Glume of two cloven, boat-shaped, concave, compressed valves, often fringed with prickles at the back, and nearly equal in length; the outer one larger, oblong, pointed; inner half as broad, linear, acute. Nectary of two lanceolate acute leaves. Stam. Filaments three, in some cases one or six, capillary, shorter than the corolla; anthers oblong. Pll. Germen superior, ovate, compressed; styles two, capillary, short: stigmas feathery. Peric. none except the permanent closed corolla. Seed solitary, obovate, compressed.

Obvl. Homaloenceurus, the name given to this genus by Mieg. was justly, as compounded of another, thought exceptional by Wiggers, who therefore preferred Ebharta; but the latter is now otherwise employed. (See Erharta.) Dr. Solander it seems originally distinguished this genus from Phalaris, and the name applied to it by Swartz, was adopted from his manuscripts. We cannot account for the error of Wiggers, who affirms it to be gynandrous, the stamens growing out of the top of the germen.

We find no traces of any such insect, which would be truly singular in a graps.

1. L. oryzoides. Swartz. Prodr. 21. Wildl. n. 1. (Phalaris oryzoides; Linn. Sp. Pl. 81. Swartz. Obs. 34. Schreb. Gram. fasc. 2. 6. t. 22.)—Panicle spreading. Flowers spreading, triandrous; their glumes fringed at the keel.—Native of watery places in Germany, France, Switzerland, Austria, Italy, and Perú. Solander says it is frequent in the rice-fields about Verona, "in weeding which this grass is detected, in its youngest state, by its glaucous foliage, and, at a more advanced period, by the minute prickles at the edges of its leaves." The roughness arising from these prickles seems the origin of the Italian name, Afipatra. The roots are perennial with long runners. Stems four or five feet high, leafy, erect, smooth, with hairy joints. Leaves linear-lanceolate, pointed, fringed, rough, especially at the edges, flatly glaucous; with long, fringed, roughish sheaths; and a short notched stipe. Panicle at first enveloped in the upper sheath, then spreading, a fan high, with numerous, drooping, compound, zigzag branches. Flowers light green, very much resembling those of rice, but smaller.

2. L. virginica. Wildl. n. 2. (L. oryzoides; Michaux Boreali-Amer. v. i. 39. Oryza glumis carina hierfidos; Grosos. Virgin. ed. i. 153. Phalaris oryzoides; ed. 2. 11.)—Panicle loose. Flowers mostly triandrous, erect, close-preffred, their glumes fringed at the keel.—Found in Kentucky, Pennsylvania, and Carolina. Michaux. In marshes in Virginia, amongst Salines and Rabi, flowering in August. Clayton. Michaux thinks this is not specifically different from the former; but Willdenow, who has observed them both in a garden, says that, "though much alike, they are constantly different. The present has shorter and broader leaves; a shorter panicle, whose branches are not zigzag but straight, and whose flowers are closely preffred to the flanks. The glumes are smaller, narrower, sparingly fringed. The panicle of this is never covered by a leaf, but always exposed and spreading." We have seen no specimen of this L. virginica. Willdenow enquires "whether the Jamaica species be the same with it?" By this he seems to mean, whether L. oryzoides of Swartz, which he had already quoted with a doubt under the former, be this L. virginica. But Swartz no where mentions the oryzoides as a West Indian plant. He merely gives its character in italics, as usual in his Prodrontus, to contrast it with his own new species, and thereby indicates it not to be a native of the West Indies.

3. L. hexandra. Wildl. n. 4. Swartz. Ind. Occ. v. i. 131.—Panicle nearly erect. Flowers alternate, close-preffred, hexandrous; their glumes fringed at the keel, roughish.—Native of watery places in the southern part of Jamaica, where it was gathered by Browne and Swartz. Stem two feet high, nearly erect, with hairy joints, but otherwise smooth, slender, leafy, sometimes a little branched. Leaves rather glaucous, lanceolate, acute, spreading, fringed, rough at the edges. Stipula point, bearded. Panicle nearly erect, the branches a little spreading in every direction, by no means inclined to droop; the flowering part zigzag. Flowers alternate, crowded, erect, so as to approach the flaks, purplish, smaller than in L. oryzoides, but otherwise much like that species. The glumes however are constantly fix. It flowers in the spring.

4. L. australis. Brown Prodr. Nov. Holl. v. i. 210.—Panicle loose, with alternate branches; the lower ones divided. Flowers hexandrous; their glumes fringed at the keel, finely toothed at their ribs; smooth at the sides. Gathered by Mr. R. Brown at Port Jackson, as well as in the tropical part of New Holland. He thinks it very near the last, as to be doubtful of their being distinct.

5. L. lenticularis. Michaux Boreali-Amer. v. i. 39.—Branches of the panicle nearly solitary, their secondary divisions spikeled. Flowers imbricated; their glumes orbicular, fringed. Native of marshes in the country of the Illinois. Michaux describes the glumes as rather large, lenticular, and conspicuously fringed.

6. L. monandra. Wildl. n. 3. Swartz. Ind. Occ. v. i. 130.—Panicle simple, loose. Spikes remote, lax. Flowers monandrous, somewhat imbricated, single-ranked; their glumes roundish, smooth.—Observed by Swartz in chalky groves in Jamaica. Flowering in the spring. He describes it as very different from all other the species known to him. The stem is two or three feet high. Leaves long, upright, smooth, of a bright green. Flowers the size of Millet-seed, green, smooth, with only one lamine in each.

LEE, H. J. Jd. Fund. v. 2. 88. See Encalypta.

LEESTRAND, in Geography, a town of Norway; eight miles S.W. of Drammen.

LEE, the groffest and thickest parts of wine, oil, and other liquors; or the sediment found at the bottom of the vessel. See Linium.

The word comes from the French le, and that either from limus, mud, or from Lycus, one of the surnames of Bacchus; or, according to Du Cange, from lâ, a corrupt, Latin word, signifying the flame. A kind of potash, called carbonis clavellatis, is made with the lees of wine burnt, and prepared, used by dyers, &c., which ought to be remembered by people troubled with the flux, &c.

The vinegar-makers make a great trade of the lees of wine dried, and made into cakes, after having squeezed out the remains of the liquor in prebels.
LEE

All the various kinds of lees, such as those of wine, beer, ale, oil, &c. may be made use of as manures, when they can be had in sufficient quantities for the purpose.

LEESBURG, in Geography, a poll-town of Maryland, in America; 25 miles from Fredericktown.—Also, a poll-town of Virginia, and the capital of Loudon county; situated six miles S.W. of the Patowmac, and containing about 60 houses, a court-house, and gaol; 20 miles from Salisbury.

LEESNITZ, or LEEGNIKA, a town of Silesia, in the principality of Oppeln; 18 miles S.E. of Oppeln.

LEET, James, in Biography, was born at Geneva in 1560. He received the early part of his education at home; studied law under Cujas, and, through the influence of Beza, obtained a chair in that faculty at Geneva in 1583. In the following year he was made counsellor of state, and the zeal and intelligence which he displayed in the public service caused him four times to be appointed to the syndicate, or first office in government, and likewise to be employed in important negotiations; one of which was with Elizabeth, queen of England, in order to obtain some pecuniary aid for the republic. He was employed upon a similar mission to Holland, and obtained a sum from the prince of Orange, and the states general, upon the condition that the academy of Geneva should be re-established. Leet supported this measure, and delivered an oration "De fudibus liberalibus publica ob mala non deferendis." He was employed to defend the rights of the republic with his pen against the duke of Savoy; and he vindicated the Protestant religion in opposition to the attacks of the president Favre. He was author of various publications in juriprudence, and in polite literature. He died in 1611, highly respected by his countrymen as the model of a good citizen and magistrate. His principal works are, "Theaurus Juris Romani, continens rario rerum Interpretum Opuscula," five vols. folio. His other publications consist chiefly of poems, orations, pieces of biography, &c. Gen. Biog.

LEET, Letas, (lēth, lathe, lathe,) a term of Saxon original, and seems to be no other than the court of the lathe; as the county court is the court of the county. For in ancient times the counties were sub-divided into lathe, rapes, wapentakes, hundreds, and the like; and the sheriff twice a year performed his tour or perambulation, for the execution of justice through the county. Afterwards the power of holding courts was granted to divers great men, within certain districts. And from hence, these courts, held within particular parts of the county, have descended unto us without variation, under the name of the leet, lēth, or lathe courts. See Court-leet, and Frank-pledge.

LEETAKO, in Geography, a large and populous city of Africa, the capital of a tribe of Kaflers called "Boo-hooanaz," and the residence of their chief, situated at the distance of 16 days' journey beyond the Orange river in the direction of N.E. from the Cape of Good Hope. The palace of the chief, like the other houses in the town, was built in a circular form, being about 16 feet in diameter. The lower part, to the height of four feet from the ground, was stone laid in clay, and wooden spars erected at certain distances. On the east side of the circle, about the fourth part of the house was open, the other three-fourths entirely closed. A round pointed roof covered the whole in the form of a tent, well thatched with long reeds, or with the straws of the holcus. From the centre to the back part of the house, a circular apartment is made off, with a narrow entrance into it, where the head of the family takes his nightly rest; the other members of the family sleep in the top part, or between the large and small circles of the house. All the houses are enclosed with palisades; and the space between the dwelling serves for a granary, and store for their grain and pulse. The granaries are constructed in the form of oil-jars, of baked clay, the capacity of each being at the least 200 gallons; and they are supported on tripods, composed of the same material, which raise them about nine inches above the ground. They are covered with a round straw roof erected on poles, and sufficiently high to admit an opening into the jars, the upper edges of which are from five to six feet from the ground. Within and without the town are plantations of that species of Mimosa, which confitutes the principal food of the camelopardalis. The city in its circumference is estimated as large as Cape Town, with all the gardens of Table valley; but it is impossible to ascertain the number of houses, by a general survey, on account of the irregularity of the streets, and lowness of the buildings; but they are supposed to amount to between two and three thousand, of the same kind, but not so large, as that of the chief. The whole population, including men, women, and children, were estimated at between ten and fifteen thousand persons. The situation of Lëtakoo was calculated to be S. lat. 26° 30', and E. long. 27°.

LEEUEWE, or LEEUWEN, a town of France, in the department of the Dyle, called by the Flemings "Sout. Leeuwe," situated on the river Geets, in the midst of a marsh; formerly a place of strength, to which perfons condemned to banishment were sent; 20 miles W.N.W. of Liege.

LEEWARD ISLANDS, so called in contradistinction to the Windward islands, an appellation given to them from their situation in a voyage from the ports of Spain to Carthagea, or Porto Bello. The place that lie to leeward extend from Porto Rico to Dominica.

LEFCA, a town of the island of Cyprus, the residence of an aga and a cadi. It was one of the four cities that bore the name of Arfino; 28 miles N.E. of Bafia.

LEFKEH, a town of Asiatic Turkey, in the province of Natalia; near it is a convent, which is the residence of a Greek bishop; 16 miles S.E. of Ifnik.

LEFOOGA, one of the Friendly islands in the South sea, near Hapaee; in reality forming with three other islands, viz. Haano, Foa, and Holoavu, a group distinguished by the general name Hapaec. Each is about fix or seven miles long, and of a similar height and appearance. Lefooga is joined by a reef to Foa. Lefooga is in several respects superior to Annamooka; its plantations were more numerous and more extensive. Towards the sea, indeed, on the east side, the country is still wafte, which is probably owing to its sandy soil, as it is much lower than Annamooka and its surrounding isles. Towards the middle of the island the soil was better, and here were exhibited conspicuous marks of considerable population, and improved cultivation. The plantations were regularly fenced, and the fences, in a manner running parallel to each other, formed spacious public roads, not only convenient but ornamental. Large spots were covered with the paper mulberry trees, and the plantations were generally fenced with such roots and fruits as are the natural produce of the island. At one place was a house, four or five times as large as those of the common fort, to which, it is supposed, the people resort on certain public occasions. Near the landing place was observed a mount, two or three feet high, covered with gravel; and upon it stood four or five small huts, in which, as the natives said, the bodies of some of their principal people had been interred. This island is not above seven miles long; and, in
some places, not above two or three broad. The reef on the
cas t side, considerably broad, and on which the sea breaks
with great violence, is a continuation of that which join
Lefogoa to Foo, not above half a mile distant; and at low
water, the natives can walk on this reef, which is then
partly dry, from one island to the other. The shore itself
is either a coral rock, fix or seven feet high, or a sandy
beach; but higher than the well side, which is not, in ge-
eral, more than three or four feet from the level of the sea,
with a sandy beach through its whole length. S. lat. 19°
47'. E. long. 15° 40'.

LEGACY, Legaturn, in the Civil Law, a donation by
testament; answering to what in common law is called a
deed of; and the person to whom it is given is flyiled the
legatee.

Legacy is usually defined some particular thing given by
a last will and testament; because if a man thus dispose, or
transfer his whole estate to another, it is called hereditas;
and he to whom it is given is called heres. Though in com-
m en low law, the distinction is this: that he to whom all a man's
lands and hereditaments descent by right of blood, is heres
natus; the other, to whom it is bequeathed, is called heres
futus.

This bequest transfers an inchoate property to the legatee;
but the legacy is not perfect without the assent of the execu-
tor; for if I have a general or pecuniar legacy of 1001.; or a
specific one of a piece of plate, I cannot in either case
take it without the consent of the executor. (Co. Litt. 111.
Aley. 39.) For all the chattels are vested in him; and it is
his business first of all to see whether there is a sufficient
fund left to pay the debts of the testator; the rule of equity
being, that a man must be just before he is permitted to be
generous, or, as Bracton expresses the sense of our an-
cient law, "de bonis defuncti primo deducens fina ea
sive funt necessitatis, et pollentque sive mutabilitatis, et
ulterius quae sive voluntatis." In case of a deficiency of
affets, all the general legacies must abate in due propor-
tion to pay the debts; but a specific legacy, as of a
piece of plate, a horse, or the like, is not at all to abate,
unless there be not sufficient without it. A specific legacy
is where, by the assent of the executor, the property of the
legacy will vell. As in one way there is a benefit to a speci-

 LEG

ficate, that he shall not contribute, in case of a deficiency,
to pay all the legacies, so there is a hazard in another way;
\( e.g. \) if such specific legacy, being a leaf, be injur'd;
or being good, be loot or burnt; or, being a debt, be loot by
the insolvency of the debtor; in all these cases, such speci-
ific legatene shall have no contribution from the other legatene,
and therefore shall pay none towards them. (1 P. Wms.
539.) Hence a question of some importance has arisen,
viz. whether a legacy was specific or general? A specific lega-

 ture of a particular chattel, specifically de-

fined and distinguished from all other things of the same
kind; or, in other words, an individual legacy. Money,
sufficiently distinguished, may be the subject of a speci-

cific bequest; as money in a certain chett, or a particular debt.
So a bequest of a part of a specific chattel may be equally
a specific legacy. (3 Atk. 103.) Legatees, however, of
specific parts, though not liable to abatement with general le-

 gatees, must nevertheless abate proportionally among them-

selves, upon deficiency of the specific thing bequeathed
(2 Vez. 563.) or on deficiency of the general affets for
payment of debts. (1 P. Wms. 423.) And specific lega-
tees of distinct chattels shall abate proportionally on a
deficiency of general affets. 2 P. Wms. 382.

On the other hand, a mere bequest of quantity, whether of
money or any other chattel, is a general legacy; as of a quan-
tity of flock (1 Atk. 414. 2 Vez. 562.) and where the
testator has not such flock at his death, it is a direction to
the executor to procure so much flock for the legatee.
(Tabl. 227.) The purpose to which a general legatene is to
be applied will not alter its nature. (1 P. Wms. 539.) Per-
sonal annuities given by will are general legacies.
3 Atk. 693. 2 Vez. 417. See Executor and Legatee.

With regard to the payment of legacies, if a legacy when
due be paid to the father of an infant, it is no good pay-
ment; and the executor may be obliged in equity to pay it
again; and where any legacy is bequeathed to a femen-
covert, paying it to her alone is not sufficient, without her
husband. 1 Vern. 261.

Executors are not bound to pay a legacy without security
for refund; and if sentence be given for a legacy in the eccle-
siastical court, a prohibition lies, unless they take security
for refund. (2 Vent. 358.) As an executor is not obliged
to pay a legacy without security given him by the legatee to
refund, if there are debts, because the legacy is not due
till the debts are paid, and a man must be just before he
is charitable; so in some cases, the executor may be com-
pelled to give security to the legatee for the payment of his
legacy; as where a testator bequeathed 10001. to a person,
to be paid at the age of 21, and appointed an executor, and
died; afterwards the legatee exhibited a bill in equity against
the executor, setting forth that he had waited the estate, and
praying that he might give security to pay the legacy when
it should become due; and it was ordered accordingly.

1 Ch. Rep. 136. 257.

If a legacy is devised, and no certain time of payment is
fixed, and the legatee is an infant, be shall have interest
for the legacy from the expiration of one year after the testator's
death; but if the legatee be of full age, he shall have no
interest but from the time of the demand of his legacy.
Where a legacy is payable at a day certain, it must be paid
with interest from that day. (2 Salk. 415. 2 Nelf. Abr.
1111.) (See Lapsed Legacy, and Interest on Legacies.)
It has been decreed in equity, that although a legacy may
be devised to be paid at a certain time, it carries interest only
from such time as it is demanded. A person having a lega-
cy, of which he was unapprized till a great while afterwards,
when the executors published it in the gazette; here chan-
cery would allow no interest, but the bare debt. Pr. Chanc.
11.

As legacies are gratuities, and no duties, action will not
lie at common law for the recovery of a legacy; but remedy
must be had in the chancery or spiritual court. (Allen. 38.)

If a legacy is payable out of the land, or its profits, an ac-
tion on the case lies at common law; but the usual remedy
is in chancery. (Sid. 44. 3 Salk. 223.) By chief justice
Holt, a legatee may maintain an action of debt at common
law, against the owner of land, out of which the legacy is
to be paid; and since the flatus of Wills gives him a right
by confecution he shall have an action at law to recover it.
(2 Salk. 415.) It is now, however, positively determined,
that no action at law lies for a legacy; the court of chan-
cery being the proper jurisdiction for that purpuse. (5 Term
Rep. 600.) An executor being in equity considered as a
trustee for the legatee, with respect to his legacy, and as a

10
trustee in certain cases for the next of kin as to the undisposed surplus, we hence derive the true ground of equitable jurisdiction in enforcing the payment of a legacy, or distribution of personal estate. (1 P. Wms. 544. 575.) The spiritual court administers redress in the case of frustration, or the withholding or detaining of legacies, as a consequent part of their testamentary jurisdiction; but in this case the courts of equity exercise a concurrent jurisdiction, incident to some other species of relief required; and as it is beneath the dignity of the king's courts to be merely auxiliary to other inferior jurisdictions, the cause, when once brought there, receives there also its full determination. Blackft. Com. b. iii.

Where a telleator gives his debtor a legacy greater than his debt, it shall be taken in satisfaction of it; though where the legacy is less, it shall not be deemed as any part thereof; but as a legacy is a gift, the legatee has been sometimes decreed both. (1 Salk. 155. 2 Salk. 508.) If a greater legacy is given by a codicil, to the same person that was legatee in the will, it shall not be a satisfaction, unless so expressed. (1 P. Wms. 424.) Although a legacy is a gift, yet upon a principle already stated, that a man should be just before he is kind, a bequest of the same sum by the legatee to the creditor, shall be applied in satisfaction of the debt. (Pr. Ch. 394. 2 P. Wms. 130. 3 P. Wms. 354. 1 Ves. 123. 4 P. Wms. 616.) Yet when there are allets, and the telleator intended both, it may be as good equity to consider him as both just and kind; and the construction of making a gift a satisfaction has, in many cases, been carried too far. (1 Salk. 155. 4 P. Wms. 410. 2 P. Wms. 616.) Cofes of this nature depend upon circumstances; and where a legacy has been decreed to go in satisfaction of a debt, it must be grounded upon some evidence, or at least a strong presumption that the telleator did intend it; for a court of equity ought not to hinder a man from discharging of his own as he pleases; and therefore the intention of the party is to be the rule; for where he pays a legacy, the court cannot contradict him, and yet he pays a debt. (Treat. Eq. lib. 4. p. 1. ch. 5.) Jacob's Law Dict. by Toms. iii. tit. Legate. See WILL.

LEGG, Contingent. See Contingent.

LEGACIES, Interests on. See Interest.

LEGG, Lapsed, is where the legatee dies before the telleator, in which case the legacy shall fall into the residuum. (See Contingent.) A legacy to be paid, when he attains the age of 21 years, is a vested legacy; an interest which commences in possession, although it be subsequent in futura; and if the legatee dies before that age, his representatives shall receive it out of the telleator's personal estate, at the same time it would have become payable, in case the legate had lived. But if such legacies be charged upon a real estate, they shall lapse for the benefit of the heir; for in regard to devises affecting lands, the ecclesiastical court hath no concurrent jurisdiction with chancery. And yet where 1000l. was given by a person out of lands to his daughter, and interest to be computed from his death, &c. here, though the legatee died before the time appointed for paying the same, it was held the legacy should be raised notwithstanding, and the lord chancellor said that this legacy was a vested one. (2 Vern. Rep. 617. Barnardf. 326. 330.) In case of a vested legacy, due immediately, and charged on land, or money in the funds, which yield an immediate profit, interest shall be payable thereon from the telleator's death. See Interest on Legacies, and Legatee.

LEGACIES, Subtraction of. See Subtraction.

LEGACY, in an Ecclesiastical Sove, was a foul-feat, a bequest to the church, or accoustomed mortuary; which was to hold good, even though the testament itself were declared null and invalid.

LEGAL, Column, Economy, Subrogation, and Tuteurage. See the several subheads.

LEGALIS, Homo, in Law, a person who stands resiens in curia, not outlawed, nor excommunicated, nor infamous. And in this sense are those words so often used, pro bi legatx hominis.

Hence, also, legality is taken for the condition of such a man.

LEGATA, fem. Legate, plu. in Music. See Notes and Synopsis.

LEGATE, a prelate, whom the pope sends as ambassador to any foreign prince.

The term legate comes from legatus, which Varro derives from legere, to choose; and others from legare, delegate, to send, or delegate. Wiechfort.

There are three kinds of legates; viz. legates a latere, legates de latere, and legates by estate, or legati nati.

Of these, the most considerable are the legates a latere; such are those whom the pope commissions to take his place in councils; who are thus called, because the pope never gives this office to any but his greatest favourites and confidants, who are always at his side, a latere; that is, to the cardinals.

A legate a latere may confer benefices without mandate, legitimate bailiffs to hold offices, and has a cross carried before him as the ensign of his authority.

The legates de latere are those who, not being cardinals, are yet entrusted with an apostolical legation.

Legates by office, legati nati, are those who have not any particular legation given them; but who, by virtue of their dignity, and place in the church, become legates. Such are the archbishops of Rheims and Arles. But the authority of these legates is much inferior to that of the legates a latere. The power of a legate is sometimes also given without the title; some of the nuncios are invested with it.

LEGATE, Court of. See Court.

LEGATEE, or Legatary, in Law, the person to whom a legacy is left; which every pereson is capable of being, unless particularly disabled by the common law or statutes, as traitors, and some others.

Formerly Papists were under several disabilities, both as to purchasing lands, and taking them by descent or devise; but in these more liberal and enlightened times. Such disabilities are removed, and Papists, as of we should rather call them, Roman Catholics, are rendered capable of purchasing and devising lands, and having them by descent, purchase, and devise, on taking the oath prescribed to them by 18 Geo. III. c. 66.

It seems to be necessary that a legatee should be born at the time of making the will; and it has been adjudged, where legacies were given to a man's children, that those who were born afterwards should have no share. (1 Bull. 153.) But it has been otherwise decreed in chancery. (1 Ch. Rep. 301.) The general rule with regard to legates is, that if the legatee die before the telleator, or before the condition upon which the legacy is given be performed, or before it be vested in interest, the legacy is extinguished. (Treat. Eq. lib. 4. part 1. c. 2.) But a bequest may be so specially framed as to prevent the death of the legatee from occaioning a lapse of the legacy. (3 Atk. 572. 570.) Nor will the rule extend to a legacy bequeathed to two or more; for though, by the civil law, there is no furvivorship among legatees, yet it is settled that a legacy to two or more is not extinguished by the death of one, but will vest in the survivior. (Gilb. Rep. 137. 2 Atk. 220.) Nor will

LEG
the rule extend to those cases where the legacy is given over after the death of the first legatee; for in such cases the legatee in remainder shall have it immediately. (1 And. 33. pl. 82. 2 Vern. 207. 1 P. Wms. 274. 3 P. Wms. 113. Pr. C. 37. Mofch. 319. 2 Vern. 378.) Nor will a legacy lapse by the death of the legatee in the testator's life-time, if he be to take as a trustee; (See 2 Vez. 140. and 2 Vern. 468.) in which latter case the point is doubted. When a father makes provision for a child by his will, and afterwards gives to such child, being a daughter, a portion in marriage; or, being a son, a sum of money to enable him in life, (such portion or sum being in amount equal to, or greater than, the legacy,) it is an implied ademption of the legacy; for the law will not intend that the father designed two portions to one child. (1 P. Wms. 686. 2 Ch. Rep. 85. 2 Vern. 115. 257. 3 Atk. 216. Amb. 325. 2 Bro. C. R. 307.) But this implication will not arise, if the provision by the will be by bequest of the residue (2 Atk. 216.); or if the provision in the father's life-time be subject to a contingency (2 Atk. 391.), or be not eiusdem generis with the legacy (1 Bro. C. R. 425.); or if the testator be a stranger (2 Atk. 516. 2 Bro. C. R. 1499.) and such implication is always liable to be refuted by evidence. 2 Atk. 516. 2 Bro. C. R. 165. 519.

A bequest of money to one at the age of 21, or day of marriage, without paying, to be paid at that time, the legatee dying before the term, is a lapsed legacy; and so it would have been, if the devise had been to her when the shall marry, or when a son shall come of age, and they die before. (Godsb. 182. 2 Vent. 342.) But a devise of a sum of money, to be paid at the day of marriage, or age of 21 years, if the legatee die before either of these events happen, shall go to the legatee's administrator, because the legatee had a present interest, though the time of payment was not yet come; and it is a charge on the personal estate which was in being at the testator's death; and if it were discharged by this accident, then it would be for the benefit of the executor, which was never intended by the testator. (2 Vent. 366. 2 Lev. 207.) If the legacy be to the legatee payable to him at a certain age, and the legatee die before he attain that age, this is a vested and transferrable interest in the legatee. (2 Vent. 342. 2 Ch. Car. 155. 3 Vern. 462. 3 P. Wms. 138. 2 Vern. 199.) Otherwise, if the legacy be to the legatee generally, at or when he attains such age. (2 Vent. 342. 2 Salk. 415. 1 Eq. Ab. 259. 6. 1 Bro. C. R. 119.) If the legacy be made to carry interest, though the words to be paid or payable are omitted, it is a vested and transferrable interest. (2 Vent. 342. 2 Ch. Car. 155. 2 Vern. 673. 2 Vern. 263. 3 Atk. 645.) So if the bequest be to A. for life, and after the death of A. to B, the bequest to B. is vested upon the death of the testator, and will not lapse by the death of B. in the life-time of A. (2 Vent. 347. 1 P. Wms. 506. 2 Vern. 376. Amb. 167. 1 Bro. C. R. 119. 181.) A person by will, &c. gives a portion or legacy to a child, payable at 21 years of age, out of a real and personal estate, and the child dies before the legacy becomes payable; in that case, so much of it as the personal estate will pay, shall go to the child's executors and administrators; but so far as the legacy is charged upon the land, it is said that it shall sink. (2 P. Wms. 615.) Jacob's Law Dict. by Tomlin, vol. ii. See Legacy and Executor.

**LEGATINE Constitutions.** See Constitutions.

**LEGATIS Tenementis.** See Tenementis.

**LEGATO, Ital., in Music, bound, tied, connected, sustained.**

**LEGATORY, or Legaty, a term used in speaking of the government of the ancient Romans: Augustus divided the provinces of the empire into confular, legatory, and prefidial. The legatory provinces were those of which the emperor himself was governor, but where he did not reside, but administered affairs by his lieutenant, or legatus.**

**LEGATORY, or Legaty, the name with legate of a will. (27 Eliz, cap. 10.) It is derived from the Latin legatio, an embassy.**

**LEGATUM, in an Ecclesiastical Sense, was a legacy given to the church, or accustomed mortuary.**

**LEGATURA, Ital., in Modern Music, implies a binding note; as when the bar goes through the middle of the note, or two notes of the same kind are tied together by a semicircle.**

---

In old church music, before the use of bars, and when the notes were chiefly square, such as the large, the long, and the breve, the laws of ligature constituted the most difficult and tedious part of a practising musician's study. The value or length of a note, in the fifteenth or sixteenth centuries, was changed, by the position of the tail being upwards or downwards, on the left or right side of a note, or in the middle of a measure. In the music-school at Oxford, a set of masses books is preserved, containing compositions by Dr. Fairfax, Taverner, and other old English masters, of Henry VII.'s and Henry VIII.'s time, that are totally unintelligible, except to very curious and industrious professors, who have made the ligatures their peculiar study.

Ligatures were used by the early contrapuntists, in vocal music, to connect such sounds as were to be sustained or sung to one syllable, as is done at present by semicircular marks, called binding-notes, and slurs. The rules for these are too numerous and vague to be explained without a long discussion, and their powers will perhaps be best comprehended in the examples of ancient composition of different parts, in partition, and barred. However, it may be useful to those who undertake to decipher such music, to remember that all the square notes in ligature, with tails on the right hand, descending, are longs; on the left, breves; and all with tails on the left, ascending, are semibreves. Square notes, without tails, in ligature, are in general breves, though there are some exceptions to this rule, for which it is not easy to affix a cause.
L. E. G

I. E. G. A. T U S, among the Romans, a military officer, who commanded as deputy of the chief general.

Of these there were divers kinds; \textit{viz.}, a legatus in the army under the emperor, or general, answering to our lieutenant-general; and a legatus in the provinces, under the proconsul, or governor.

When any considerable person among the Roman citizens had occasion to pass through any of the provinces, the senate gave him the title of legatus; that is, of envoy from the senate, to the end that he might be received with the greater respect, and that the cities and towns, through which he travelled, might defray his expenses. This they called a \textit{free legation, libera legatio}; because the person was not encumbered with any trust, and might lay it aside as soon as he pleased.

LEGAU, in Geography, a town of Bavaria, belonging to the abbey of Kempten; 2 miles N.N.W. of Kempten.

LEG', a town of France, in the department of the Lower Loire, and chief place of a canton, in the district of Nantes; 21 miles S. of Nantes. The place contains 2893, and the canton 5277 inhabitants, on a territory of 1671 kilomètres, in 5 communes.

LEGEM, \textit{ad communem, entry}, in Law, a writ of entry which lies where tenant for term of life, or for term of another's life, or by courtesy, &c. aliens and dics, when he in the reversion shall have his writ against any one that is in possession of the land. New Nat. Brev. 461. See Entry.

LEGEM facere, to make law, or oath; and legem habere, is to be capable of giving evidence upon oath. "Minor non habet legem." Selden's Notes on Eng. 133.

LEGEND, LEGENDA, was originally a book used in the old Romish churches, containing the lefions that were to be read in divine service.

Hence also the lives of saints and martyrs came to be called legends; because the chapters were read out of them at matins, and in the refecatories of the religious houses.

The first Greek legend which is known is that of Simon Metapharius of the tenth century, who wrote the lives of saints adapted to every day of the year. The first Latin legend is,

\textit{Legend, Golden, or a collection of the lives of the saints,} compiled by James de Veraga, better known by his Latin name of J. de Voragine, vicar-general of the Dominicans, and afterwards archbishop of Genoa, who died in 1268.

It was received into the church with great applause, which it maintained for two hundred years; but, in effect, it is so full of ridiculous and romantic accounts, that the Romans themselves are now generally ashamed of it. The word legend itself is, in that account, come into disrepute.

LEGEND is also used by authors to signify the words or letters engraved about the margins, &c. of coins.

Thus, the legend of a French crown is, \textit{Sit Nomen Domini Benedictum}; that of a moindre, \textit{In hoc Signo Vincit}; on those of the last emperors of Constantinople, we find \textit{Iesus Christus Basileus Basileon,} \textit{Iesvs Christus Vincit.} For a brief historical account of the legend on coins, and the method of engraving it; see the article \textit{COINAGE.}

Legend is also applied to the inscription of medals, which serve to explain the figures or devices thereof.

In strictness, the legend differs from the inscription; this last properly signifying words placed on the reverse of a medal, in lieu of figures. When the letters or words of a medal occupy the field, they are called an \textit{inscription}; but when they run round the margin, on either side of the figures, or on the obverse, they are denominated a legend.

It seems as if the ancients had intended their medals should serve both as images, and as enblems: the one for the common people, and the other for persons of taste and parts; the images to represent the faces of princes; and emblems to represent their virtues, and great actions: so that the legend is to be looked on as the soul of the medal, and the figures as the body.

Every medal has properly two legends; that on the front, and that on the reverse. The first generally serves only to distinguish the person by his name, titles, offices, &c.; the latter is intended to express his noble and virtuous sentiments, his good deed, and the advantages the public has reaped by him. This, however, does not hold universally; for sometimes we find the titles shared between both sides, and sometimes also the legend.

In the medals of cities and provinces, as the head is usually the genius of the place, or, at least, some deity adored there, the legend is the name of the city, province, or deity, or of both together; and the reverse is some symbol of the city, &c. frequently without a legend; sometimes with that of one of its magistrates.

The ordinary subjects of legends are, the virtues of princes, the honours they have received, coronations, signal events, public monuments, deities, public vows, privileges, &c.

Legends and inscriptions of medals are either in Latin or Greek. The Greek character, confining of majuscule, or capital
capital letters, appears uniform on all the medals; no change or alteration being found in confronting the several characters; though it is certain there was in the ordinary use and pronunciation. All we observe on medals is sometimes a mixture of Greek and Latin letters.

Upon many of the coins struck in the Greek cities, we find the legend of the obverse in Latin, while that of the reverse is in Greek. The reason of this, suggested by Mr. Pinkerton, seems to be, that the magistrate of such country mint, not having any portrait of the emperor, sent to Rome for one, which was returned in a die ready cut with the legend. To this a reverse was made by the Greek artists; the magistrate inclining to save the expense of cutting another reverse. This opinion is confirmed by the fact, that few or no coins occur with Latin legends on the reverse, and Greek in front: besides, the dies are hallowed done, and after the manner of different mints.

The character was preferred in all its beauty till the time of Gallienus.

From the time of Constantine, and for the space of five hundred years, the Latin tongue was alone used in the legends of medals, even in those struck at Constantinople. Michael began the first, whose legend was in Greek; and from his time the language, as well as the characters, began to alter for the worse. See Medal.

The Latin legends are all read from the left to the right; but the legends of some Greek medals are written the contrary way, from the right to the left. The letters of the circular legends are commonly placed with the bottoms inward; but sometimes with the bottoms towards the edge.

It is observed by Mr. Pinkerton in his excellent "Essay on Medals," that the legends of the earlist Greek writers are very brief, reiterating only the initials of the city or prince; as ΑΘΕ, money of Athens; ΣΥ, money of Sybaris, &c.; afterwards, Α, money of Archelaus, king of Macedon; Φ, money of Philip. Afterwards the name was put at full length; as ΣΙΛΙΠΙΝΟΣ, coin of Philip of Macedon; and Alexander the Great has the title of ΒΑΣΙΛΕΩΣ, or king. In process of time, the Syrian and Egyptian kings, the successors of Alexander, added some epithet of praise, as ΑΥΕΡΡΕΤΙΚΟΣ, beneficent, or the like, together with the year of their era in which the coin was struck. In this state the Greek coinage remained, till the Roman empire swallowed up all the kingdoms and cities which used that language. "Under the dominion of the Roman emperors, the Greek mint assumed more of the Roman form, then more perfect, as to legend, than their own. On the face they gave the Roman emperor or empress, with their titles; the founder of their city, with his name; the senate or the people of Rome, who had protected them; or the ideal bust of the genius of their city: while the reverse presents us with a legend indicative of the name of the magistrate under whom the money was struck; and of some treaty entered into with one or more neighboring states; of the river or city represented, and the like." The Greek artists, as the same ingenious writer observes, to their honour, even when their mint was depressed by the Roman power, seldom or never explain by their legends the reverses of their coins; commonly, and almost universally, putting for the legend of the reverse the name of the city, frequently adding that of the magistrate. The symbols of their deities were familiar, and needed no explanatory legend. Periphrases, rare on Greek coins, except of their cities and rivers, are commonly accompanied by an illustrative legend; and the Egyptian coins have also similar legends. The Grecian coins of cities seldom express more in their legends than the name of the town, generally contrived till the Roman times. When the Roman empire swallowed up the Grecian, the legends on Greek coins were as much distinguished by their length as they had before been by their brevity. The titles of the emperors are translated from the Latin as literally as possible, as ATTOKPATIR for Imperator, KAIEAP for Caesar, &c. In order to express Latin founds, the Greeks were often obliged to put their own enunciation of the same word, in characters very different from the Latin, as ΜΟΥΝΤΟΣ for Quinatus. On the reverses of Greek imperial coins, the legends are very various; such are KOYON, the community; OMOGOS, the alliance; ATTOKONOS, living by their own laws; ΚΑΙΡΗΣΟΠΟΣ, free, &c. Inscriptions filling the whole field of the reverse are not uncommon in Greek coins. Some few, however, occur, particularly upon thole of Smyrna. Our author further observes, that the noted S. C., signifying Senatus Consulto, by decree of the senate, and expressing the authority of the senate of Rome for striking any coin, never appears upon those of gold or silver, in the fame fence as when it occurs upon those of brass. He suggests, that the Roman emperors had the sole disposal of the gold and silver coinage, but left that of brass entirely to the senate. The Roman legends resembid, for some time, in their simplicity those of the Greeks; but gradually proceeded to more explicit length, and in time from elegant and simple veracity degenerated into flattery. This remark is strictly applicable to the legends of the obverse; whereas those of the reverse began to flatten as soon as there was a prince, "as a idol upon whose altar to burn the cloudy perfume." Clemency and moderation are found upon the medals of Tiberius, and equivalent virtues upon those of Titus. The reverses of the first imperial coins are not, however, wanting in adulation; which, says Mr. Pinkerton, is not to be wondered at, "when we consider that Virgil and Horace, men of the most enlightened minds, whatever may be decided of their claim to genius, were yet capable of even forgetting the found dignity of poetry, and profiting it at the bloody footstool of a tyrant. What Montesquieu says of the English, that if ever they were reduced to be slaves, they would prove the meast of all slaves, was exemplified in the conduct of the ancient Romans." In process of time, "a succession of virtuous monarchs authorized the reverses fo foreign to most of their predecessors. S. P. Q. R. OPTIMO PRINCIPI, so common on the coins of Trajan, is not flattery, but glory. All the virtues appear without impropiety on the medals of Nerva, Trajan, Hadrian, and the Antonini. But in proportion as the empire declined, the more common are flat-ter and gross impropiety in the legends of the Roman coin." The Greeks also even usurped the Romans themselves in the base art of adulation. "The legends of the Roman imperial coins are deftately celebrated for their beautiful simplicity, and emphatic brevity, so as to be accounted models of the kind." Mr. Pinkerton has added several instances to this purpose. The compass of a coin is so small, that artists have always been obliged to use abbreviations in the legends and inscriptions. This circumstance occasions considerable difficulty in interpreting them. Mr. Pinkerton, in the appendix to his valuable work, has furnished an explanation of those that most commonly occur.

Dr. Coningham, in his Essay on Modern Medals, cited by Mr. Pinkerton, enumerates five kinds of improper legends on modern medals; viz. poetical, impious, jingling, intricate, and abusive. Of the first kind he instances a French medal, struck on occasion of some advantage over the English at sea, Maturate Regam, which, he says, reminds us of Virgil and not of the action. Mr. Addition, in his third dialogue on medals, vindicates poetical legends. But Mr. Pinkerton...
L E G

justly observes, that medals are certainly meant to be historical, and that poetry has in it something alien to history and destractive of its reality; and he adds, that the ancients do not afford a single example of a poetical legend on a medal. Of the jingling kind of legend is that of Francis Morozini, Jupiter with his urn, GAUDIT FLUMINE NON FLUMINE, and also that of Richard Cromwell, NON DEPICIENT OLIVES, confounding the olive-tree with Oliver Cromwell. To the intricate kind is referred the chronological coin of Galliarnus Aldolphus, king of Sweden, ChristVs. DVX, EPG TrzV MusVs, the numeral letters making the year 1632. Of the abufe kind is the Dutch medal on theirstadholder, QUANTUM DUM TUTVS AB ILLO, and Louis XIV., VIRTU IMMORTALEM PENTILLAS IN ANO. To these long legends might be added. The ancient legends are remarkable for simple brevity and energy; and the best of the modern clas are formed on their model.

For further particulars we refer to Mr. Pinkerton's "Essay on Medals," 1789, vol. i. § 12. vol. ii. § 18. See Medals.

LEGER, Anthony, in Biography, a learned Piedmontese, was born in the year 1594. After pursuing his studies at Geneva, he entered the work of the ministry, the duties of which he discharged many years with great punctuality. In 1628 he went to Conflantinopole, as chaplain to the ambassador of the States-general in the Ottoman Porte, and there became intimately connected with the celebrated Cyrus. On his return to Piedmont in 1637, he was chosen pastor of the church of St. John, a situation which he retained five years; during which he displayed much talent and learning in the defence of the Protestant faith. In 1643, he was professed by the duke of Savoy, and was obliged to seek for safety in Geneva, where he not only exercised his profession, but was elected professor of the Oriental languages, and of divinity. He died in 1661, at the age of sixty-seven. He published at Geneva an edition of the New Testament in two vols. 4to, in the Greek and French languages. He left a son of the same name, celebrated as an eloquent preacher, who died in 1710, and after his death five volumes of his sermons were published. Moreri.

LEGER, John, nephew of Anthony, was born in 1615, and educated for the profession of the ministry, was chosen to succeed his uncle when he was obliged to fly for his life to Geneva. In this church he continued his labours till the year 1652, when the persecution of the Waldenses (which fee) broke out with great rage. Leger made his escape to France, and from thence he transmitted an affectionate account of the cruelties perpetrated on the Protestants to Oliver Cromwell, who sent an extraordinary ambassador to the duke of Savoy, to remonstrate with him on those proceedings. Leger likewise applied to the king of France, and to the Protestant states, soliciting their interference in behalf of his countrymen. A treaty, now agreed on, seemed to promise future security and toleration. Leger was at the signing of this treaty, which being very shortly broke, and new oppressions and persecutions let loose on the inhabitants of the vallies, he was appointed deputy general to several Protestant powers to abate again their mediation with the duke of Savoy. This gave such offence to the court of Turin, that Leger was proclaimed a traitor, and his house ordered to be razed to the ground. He now became pastor of the Walloon church at Leyden, and in 1664 he visited secretly the vallies, carrying with him considerable sums of money collected from the Protestants, for the relief of his persecuted countrymen. He was author of a valuable history of the Evangelical churches in the vallies of Piedmont. Moreri.

LEGREMENT, Fr. in Musae, indicates a movement more lively than gay; it is the mean between gay and quick, answering nearly to vivace in Italian.

LEGRE. LINE, used to signify a line added to the staff of five lines, when the ascending and descending notes run very high or very low. We often meet with several of these lines both above and below the staff.

LEGGE, George, in Biography, baron of Dartmouth, and an eminent naval commander, was born about the year 1647. The family derive their origin from Italy, but have for several centuries been resident in this country. Thomas Legge, from whom George descended, was lord mayor of London in the years 1346 and 1353. The subject of this article, being intended early for the sea-service, was brought up under admiral Spraggge, and at the age of twenty obtained the command of a ship. In 1673 he was appointed governor of Portsmouth, master of the horse, and held an office under the duke of York. In 1682 he was raised to the peerage, and in the following year was sent to raze the fortifications of Tangiers. By James II. he was appointed master of the horse, general of the ordnance, and constable of the Tower. He had also the command of the fleet at the time of the prince of Orange's invasion, but was prevented from acting by contrary winds. At the revolution he was committed to the Tower, where he died in 1691, at the age of 44. English Peerage.

LEGG, Elizabeth, the eldest daughter of Edward Legge, eq., an ancellor of the preceding, and also of the present earl of Dartmouth, was born in 1580. She studied the ancient and several of the modern languages, and had a fine poetical genius, but became blind by much study. She lived chiefly in Ireland, and died unmarried at the age of 105. Her family were remarkable for longevity. One of her brothers lived to 109, one father to be more than 100, and another died in her 112th year.

LEGGIADRO, LEGGIADRAMENTE, Ital. in Musæ, implies gayly, lively, briskly. See Allegro.

LEGHEA, in Geography, a town of Nubia; 16 miles W.N.W. of Dongola. N. lat. 20° 6'. E. long. 29° 30'.

LEGHENICH, or LECKNICH. See Legknich.

LEGGH, a town of Arabia, in the province of Yemen; 56 miles E.N.E. of Aden.

LEGHORN, or Liveorno, a considerable, regular, well-built, fortified and flourishing city and sea-port of Tuscany (formerly the grand duchy of Tufcany); and, on account of its canals, called the New Venice. It is a bishop's see, defended by a castle, two small forts, and a broad ditch, situated in a marshy and infalubrious territory on the sea-coast, opposite to Malora, a small island, and distant about 14 miles from Pisa. The canals that intersect its environs have rendered the marsh fit for culture, and in some degree contributed to its greater salubrity. Its streets are straight, uniform, and spacious; and many of the buildings are not infelicitous. The town is of a square form, and 12,790 feet in circuit, and contains a ducal palace, many religious houses, and from 40,000 to 50,000 inhabitants, of whom 15,000 are Jews, who live in a particular part of the city, are allowed a handsome synagogue, and though subject to heavy imposts, are in a prosperous state, as the greatest part of the commerce of the city is conducted by them. The Greeks and Armenians have each their peculiar church, most of them acknowledging the pope's supremacy. The free Turks and Turkish slaves have a mosque; but the Protestants are not permitted the public exercise of their religion, the English excepted, who are allowed to have a chaplain, because of all foreign nations they are the best customers to Leghorn. Other Protestants make use of chaplains of ships. Proligates are

LEG

Every and at the foremost, the inhabitants carry on an extensive trade, which is much promoted by the freedom of the port; every Hale of goods, great or small, paying only two piastres or feudi.

The harbour, which is secure, is divided into the outward and inward; the latter serving merely for four or five galleys, which are sometimes sent to sea against the corsairs, under the command of a knight of St. Stephen. In the open place before this harbour stands a marble statue of Ferdinand I., and at the angles of the pedsil are four brazen statues, of a gigantic size, representing four Turkish slaves in chains.

The outward harbour is formed by mole or dam, 600 common paces in length, well paved, with a partition in the middle, that serves to shelter the shipping from the wind on one side. The mole serves also for an occasional promenade. The harbour has not sufficient water for large ships, which therefore lie out of the mole, moored to pillars and large iron rings; and they are thus safer than if they were in the harbour.

The road, for a mile or two, is good, but not secure against winds and corsairs. Without the harbour a rock is a light-house, where 30 burning lamps are contained in one lantern, and on the shore, not far from it, is a lighthouse, where quarantine is performed by persons and goods, that come from suspected places. (See Lazaretto.) The power of the inquisition at Leghorn extends only to Roman Catholics, and comprehends only canes of religion. In June 1796 the French took possession of this town, and destroyed the fortifications. N. lat. 43° 32'. E. long. 16° 10'.

The principal monies of account at Leghorn are the lira and pezza; the former being chiefly used in domestic trade, and the latter in foreign commerce and exchanges. Each of these is divided into 20 parts called foldi, and the foldo is subdivided into 12 parts called denari. The pezza of Leghorn was originally the Spanish pezo, and hence it is called the pezza de otto reali by the Italians, the piastra by the French, and dollars by the English. This pezza, valued in silver, is worth 40/2. sterling; but valued in gold, it is worth 40/3. sterling; which is the intrinsic price between London and Leghorn, as bills in the latter place are paid in gold. The lira is either the lira moneta longa, or the lira moneta buona; the former being an imaginary money of account, and the latter the real money of all Tuscany. The lira is, as in Florence, according to the rate of coinage, worth about 8d.

Accounts on Leghorn are underfoot to be in moneta longa; and 24 lira moneta buona are worth 24 lira moneta longa. The lira has its subdivisions. The pezza is worth 4 1/2 moneta buona, or lira moneta longa. Foreign bills in Leghorn, unless particularly excepted, must be paid in gold, that is, in Florence lira or rupeni, by weight. No days of grace are allowed; but bills are paid three times a week at the "Stanza," a place where merchants meet on Mondays, Wednesdays, and Fridays. In freighting ships at Leghorn, 20 cheviots of fruit, 26 barrels of oil, 44 barrels of wine, 500 lbs. of alum, are reckoned one lira, or two tons. See Kelly's Universal Cambiff, vol. i.

LEGNAI, a town of Prussia, in the province of Ermland; 22 miles S.E. Holshberg.

LEGION, a kind of regiment, or body of forces, of a number of which the Roman armies were chiefly composed.

The word comes from the Latin leger, to choose; because when the legions were raised they made choice of such of their youths as were the most proper to bear arms.

The number of officers and officers of which the legion consisted, was different at different times; but it is impossible to determine the precise time and manner of their alteration. In the time of Romulus, the inquisitor of this corps, each legion contained three thousand foot, and three hundred horses, or horfe; these were divided into three bodies, which make as many orders of battle; each body, consisting of ten companies, or manipulating, ranged at some distance from each other, though in the same front. Each body had two general officers to command it, called tribunes; and each manipule, two centurions.

Under the confuls, the legion consisted of four thousand, or four thousand two hundred foot soldiers, who made four bodies, commanded by a conful, or one of his lieutenants; and each legion had its share of cavalry, which was three hundred horse.

About the year of Rome 412, it was composed of five thousand foot; which was the number of a legion during Julius Caesar's wars with the Gauls. Under Augullus, each legion consisted of five thousand one hundred foot, and seven hundred and twenty-fix horse. After his death, they were reduced to five thousand foot and six hundred horses.

Under Tiberius, the legion was raised again to five thousand foot and six hundred horse. In the time of Septimius Severus, the legion was composed of five thousand men; under the following emperors, it was the same as it had been under Augullus.

In the time of Marius, those four divisions of the legion which had taken place under the confuls, were united into one, and augmented; and cohorts were appointed from five to fix hundred men, each under the command of a tribune. Each cohort consisted of three companies of manipules, each manipule of two centuries, and the legion was divided into ten cohorts, who made as many distinct battalions, disposed in three lines; so that the legion, then, consisted of five thousand men.

Ididore tells us, that the legion consisted of six thousand men, and was divided into sixty centuries, thirty manipules, twelve cohorts, and two hundred troops. According to the French academy, the legion consisted of six thousand foot, and seven hundred and twenty-five horse. The legion consisted of four forts of soldiers, who differed in their age, arms, and names; they were called Velites, Helfati, Principes, and Tripus. (See Anars.) Till the destruction at Carthage, there were citizens of Rome, but after the Social War, the freedom of the city was granted to other towns in Italy, and legionary troops were raised which were called Roman, because as they shared the privilege of Roman citizens, they were incorporated in the republic.

The legions were by far the most considerable part of the Roman army; their number, in the time of Augullus, was thirty-three; they were composed wholly of Roman citizens. The allies formed a body of auxiliary forces. See the sequel of this article.

The standard borne by the legions was various; at first, a wolf, in honour of that which suckled Romulus; afterwards an hofe; by reason, says Pliny, war is only undertaken with a view to peace, which was concluded by sacrificing a horse. Sometimes they bore the minotaurs, to remind their generals, that their designs were to be kept secret, and inaccessible as the minotaur in the labyrinth. They also bore a horse, a boar, &c. Pliny tells us, that Marius was the first who changed all these standards into eagles. See Eagle.

The different legions were distinguished, according to the order.
order in which they were raised, into first, second, and third, &c. by the names of the emperors who formed them into legio Augula, Claudia, Flavia, Trajana, &c. by the provinces where they had served, as legio Pannonia, Macedonica, &c. and by some famous exploit or display of valor.

We shall here further some particulars relating to the constitution and military services of the imperial legion. It was composed of infantry and cavalry. The heavy-armed infantry, which composed its principal strength, was divided into ten cohorts (see Cohort), and fifty-five companies, under the orders of a correspondent number of tribunes and centurions. The first cohort, which always claimed the point of honour, and the cullody of the eagle, was formed of 1105 soldiers, the most approved for valour and fidelity. The remaining nine cohorts consisted each of 555, and the whole body of legionary infantry amounted to 6100 men. Their arms were uniform, and admirably adapted to the service which they were required to perform; they consisted of an open helmet, with a lofty crest, a breast-plate, and coat of mail; greaves on their legs; and an ample buckler on their left arm. The buckler was of an oblong and concave figure, four feet in length, and two and a half in breadth, formed of a light wood, covered with a bull's hide, and strongly guarded with plates of brass. Besides a lighter spear, the legionary folder grasped in his right hand the formidable pilum (which see); and as soon as he had darted this from his hand, he drew his sword, and rushed forward to close with the enemy. His sword was a short well-tempered Spanish blade, that carried a double edge, and was alike adapted to the purpose of thrusting or striking; but the folder was always instructed to prefer the former use of his weapon, as his own body remained less exposed, while he inflicted a more dangerous wound on his adversary. See Veget. de Re Milit. l. iii. c. 1. Livi B. de Militia Romana. l. iii. c. 2—7.

The legion was usually drawn up eight deep; and the regular distance of three feet was left between the files as well as ranks.

The cavalry, which was necessary for perfecting the force of the legion, was divided into ten troops or squadrons: the first, as the companion of the first cohort, consisted of 132 men; whilst each of the other nine amounted only to 66. The entire establishment formed a regiment, according to the modern expression, of 726 horse, naturally connected with its respective legion, but occasionally separated to act in the line, and to compose a part of the wings of the army. The cavalry of the emperors was not composed, like that of the ancient republic, of the noblest youths of Rome and Italy, who, by performing their military service on horseback, prepared themselves for the offices of senator and confidant, and solicited, by deeds of valour, the future suffrages of their countrymen. Since the alteration of manners and government, the most wealthy of the equestrian order were engaged in the administration of justice and of the revenue; and whenever they embraced the profession of arms, they were immediately intrusted with a troop of horse, or a cohort of foot. Trajan and Adrian formed their cavalry from the same provinces, and the same class of their subjects, which recruited the ranks of the legion. The horses were bred, for the most part, in Spain or Cappadocia. The arms of the Roman troopers consisted in a helmet, an oblong shield, light boots, and a coat of mail. A javelin, and a long broadsword, were their principal weapons of offence. The use of lances and of iron maces they seem to have borrowed from the barbarians. Considerable levies were regularly made by the Romans among the provincials: and many dependent princes and communities, dispersed round the frontiers, were permitted, for a while, to hold their freedom and security by the tenure of military service. Even select troops of hostile barbarians were compelled or persuaded to confine their valour in remote climates, and for the benefit of the state. All these were included under the general name of auxiliaries; and their number was seldom inferior to that of the legions themselves. By this influence each legion, to which a certain proportion of auxiliaries was allotted, contained within itself every species of lighter troops, and of Miller weapons; and was capable of encountering every nation, with the advantages of its respective arms and discipline. Nor was the legion destitute of what, in modern language, would be styled a train of artillery. It consisted in ten military engines of the largest, and 55 of a smaller size; but all of which, either in an oblique or horizontal manner, discharged stones and darts with irresistible violence.

The camp of a Roman legion presented the appearance of a fortified city. See the description of it under Camp. In their march, the legionsaries carried their arms, and also kitchen furniture, infrums of fortification, and provision for many days. Thus laden, they advanced by a regular file, to which they were trained, near twenty miles in about six hours. On the appearance of an enemy, they threw aside their baggage; and by easy and rapid evolutions converted the column of march into an order of battle. The slingers and archers skirmished in the front; the auxiliaries formed the first line, and were seconded or sustained by the strength of the legions: the cavalry covered the flanks, and the military engines were placed in the rear.

As to the number of the legions, we may compute, that the legion, which was itself a body of 6831 Romans, might, with its attendant auxiliaries, amount to about 15,000 men. The peace establishment of Adrian and his successors was composed of no less than 30 of these formidable brigades; and most probably formed a standing force of 375,000 men. As to the position of the legions, they were encamped on the banks of the great rivers, and along the frontiers of the barbarians. As their stations were, for the most part, fixed and permanent, the troops may be considered as distributed in the following manner. Three legions were sufficient for Britain. The principal strength lay upon the Rhine and Danube, and consisted of sixteen legions, in the following proportions: two in the Lower and three in the Upper Germany; one in Raetia, one in Noricum, four in Pannonia, three in Moesia, and two in Dacia. The defence of the Euphrates was entrusted to eight legions, six of which were planted in Syria, and the other two in Cappadocia. A single legion maintained the domestic tranquility of each of the large provinces of Egypt, Africa, and Spain. Italy was not left destitute of a military force. About 20,000 choicest soldiers, distinguished by the titles of "City Cohorts" and "Pretorian Guards," watched over the safety of the monarch and the capital.

Under Constan tin and his successors, the legions were very considerably reduced. When seven legions, with some auxiliaries, defended the city of Amida against the Persians, the total garrison, with the inhabitants of both sexes and the peasants of the defeated country, did not exceed the number of 20,000 persons. Hence we may infer, that the constitution of the legionary troops, to which they partly owed their valour and discipline, was dissolved by Constantine; and that the bands of Roman infantry, which till affirmed the same names and the same honours, consisted only of 1000 or 1500 men. Nevertheless, the successors of Constantine indulged their love of ostentation, by infusing their orders to 132 legions, inscribed on the muster-roll of their numerous...
Legion

Pythagoras, for scarcely the ffgma and Nicodorus 22 Xanomysis, Charoidas, Is'.

Parmenides created Draco, whole idols, from legion and Indians numerous legion's timate concubinage. With the emperor's legitimate his emperor's provided the laws of a kingdom or state founded by him. The principal ancient legislators are—Moies, legislator of the H-brws; Mercurius Trimegetitus, and Boccherys, of the Egyptians; Itius, of the Ænotrians; Thefeus, Draco, and Solon, of the Athenians; Zoroaster, of the Bactrians; Charodas, of the Cappadocians; and Charodas, or Phales, of the Carthaginians: Androdamas, of the Chalidians: Eudoxus, of the Cnidians; Phido, of the Corinthians; Minos, of the Cretans; Pythagoras, of the Crotoniates, and most of the cities of the Graccia Major: Parmenides and Zeno, of Elea, in Lucania; Xamolxis, of the Getae: Phoroneus, of the Greeks; Baecius, of the Indus; Saturn, of Italy; Macarius, of the Isle of Lefbos; Zaleucus, of the Locris; Nicodorus Athleta, of the city of Mutina; Hippodamia, of Miletus; Charodas, of Rhageio; Lycurgus, of the Lacedemonians; Archytas, of Tarentum; Phales, of the Thebans.

At Rome the people were in a great measure their own legislators; though Solon may be said, in some sense, to have been their legislator, as the deceiver, who were created for the making of laws, borrowed a great number from those of Solon.

With us the legislative power is lodged in the king, lords, and commons assembled in parliament; which see.

Legitimate Child, a child born in lawful wedlock, or within a competent time afterwards. "Pater eff quem nuptias demonstrat" is the rule of the civil law; and this holds with the civilians, whether the nuptials happen before, or after, the birth of the child. With us in England the rule is approved; for the nuptials must be precedent to the birth. See bastard.

Legitimate Delivery. See Delivery and Labour.

Legitimate Territor. See acre.

Legitimation, an act by which natural or illegitimate children are rendered legitimate. See Bastard, &c.

By the French law, the father and mother, by marrying, render their children, begotten before marriage, legitimate; and this is called legitimation per sub sequens matrimonium.

The right of legitimation was a thing unknown to princes till the time of Constantine; but, since his time, has been executed by most of them. The Greek emperors invented several kinds of legitimation.

Anastasius put it in the power of the father to legitimate his natural children by a bare adoption, provided he had no legitimate children. But Justin, by his constitution, and Julianus, by his Novel 74, abolished this legitimation, as fearing the too easy access to legitimation should encourage concubinage.

In lieu of this, he established a way of legitimation by the emperor's letters. This rendered bailiffs capable of attaining to honours, and even of succeeding to inheritances, provided the persons were legitimated with the consent of their father and mother; which is agreeable to the canon law.

Legiuncara, in Geography, a town of Naples, in the province of Bari; 21 miles N.W. of Mataro.

Legna, among the Ancients, a name given to the borders of the toga and pallium, that were on each hand; the extremities above and below being called ora.

Legnano, in Geography, a town of Italy, in the Veronese, on the Adige. The two divisions of this place are connected by a drawbridge; the eastern part is called Porto, and the western Legnano. It has several monasteries, and a playground. It is a populous town, and carries on a considerable trade by means of a corn-market held every Saturday, and a canal, running from Legnano to Olgilva, in the territory of Mantua. This was formed in 1762, between the Adige and the Po; and for the better security of its navigation, sluices have been constructed at both its ends. The French took possession of it in 1799; 22 miles E.S.E. of Verona. N. lat. 44 50. E. long. 11 18'.

Gen. Ch. Cal. Perianth inferior, of one leaf, bell-shaped, four or five-eleven half way down; permanent ovate, acute, erect. Cor. Petals four or five, longer than the calyx; claws slender, almost as long as the calyx, inserted into the receptacle; borders ovate, very much fringed, villose. Stam. Filaments fifteen or twenty, thread-shaped, equal, the length of the calyx, inserted into the receptacle; anthers oblong, erect. Pfr. Germanus feminum, roundish, style cylindrical, as long as the stamens; stigma capitato. Peric. Capsule large, elliptical, triangular, with three cells and three valves. Seeds solitary, convex on one side, angulated on the other.

Obf. Sometimes the number of cells and valves in the fruit is liable to variation.

Eff. Ch. Capsule superior, of three cells. Petals inserted into the receptacle, very much fringed or torn.

1. L. elliptica. Swartz. Prod. 84. Wildl. n. 1.—Leaves elliptical. Flowers on footstalks.—A native of lofty mountains in Jamaica, flowering in May and June.—This is a tree from ten to thirty feet in height, having a smooth, brown bark. Branches determinately subdivided, erect, smooth; the smaller ones slightly compressed. Leaves on footstalks, opposite, ovate-acuminat, or oblong-lanceolate, entire, scarcely nerved, smooth on both sides, somewhat rigid; footstalks short, flat above, roundish underneath. Stipulas small, ovate, membranaceous, downy, deciduous, between the footstalks. Flowers footstalks axillary, from three to five, simple; scarcely so long as the leaf-alks, with a few minute scales at their base. Capsule smooth, white and downy within. Flowers flesh-coloured, villose with white hairs.

Obf. The downy style becomes elongated to twice the length of the calyx, after flowering.

A middle-sized tree with a grey bark, about five feet in height, branched at the summit; smaller branches opposite, knotty. Its wood is white. Leaves fusing from the knobs, ovate, acute, smooth, entire, nearly fimbriate, accompanied at their base by two very minute stipulas. Flowers axillary, in tufts, white, fimbriate between two opposite bristles.

Legouzia, Jull. 450, a name defined by M. Durand.,}
LEGRAD, in Geography, a town of Croatia, at the
union of the Neret and Drave; 15 miles E. of Varazdin.
Lat. 46°30', E. long. 16°54'.
LE GRAND, a considerable river of America, in the
state of Ohio, which rises within a few miles of the W.,
extremity of lake Erie, and pursueth a N.N.W. course
for nearly 100 miles, and then turning to the W., discharges
itself into lake Michigan. At its confluence with the lake
it is about 250 yards wide.
LEGRENZI, DON GIOVANNI, in Biography, an able
master and fertile Italian composer of the seventeenth
century. He was a native of Bergamo, and produced for
the different theatres of Venice fifteen operas between the years
1664 and 1684. He was likewise a favourite composer of
cantatas, of which he published at Venice two books: one
ten, in 1674; and a second book containing fourteen,
in 1679. During his youth he was some time organist of Santa
Maria Maggiore, in his native city of Bergamo; then maestro
di cappella of the church Dello Spirito Santo, in Ferrara;
and lally of St. Mark's at Venice, and maister of the
Conservatorio de Mendicanti. He was the master likewise of
the two great musicians, Lotti and Francesco Galparsi,
both of whom are said to have resided in his house at
Venice in the year 1684, in order to receive his instructions.
He was also an instrumental composer, and among the
most early trios for two violins and a bass, may be numbered,
"Suonate per Chiefe," by Legrenzi, published at Venice,
1657; "Suonate da Chiefe e Camari," 1656; "Una
mata di Suonate," 1664; and "Suonate a due Violini e
Violone," 1677. Of this last work we are in possession, and
upon viewing it, find, that though Legrenzi has introduced
into these pieces some of the bell melody of the times, and
there is considerable merit in the texture and contrivance of the
parts, yet, for want of the knowledge of the bow, and the
particular energies and expressions of the violin, these
compositions have been long since jutly superceded and
effaced by superior productions of the same kind.

LEG, the lower extremities of the bodies of moit ani-
mais, serving them for support and motion. See EXTREM-
ITIES. See also references under Leg.

Legs, in the MANAGE, the members that support a horse's
body, and perform the motion when he goes. Of the four
legs, the two before have severalf parts, each of which has a
peculiar name; so that by the name of fore-legs, we com-
monly understand that part of the fore-quarters that extends
from the hough to the pattern-joint, and call it the flank;
the part that corresponds to this in the hind-quarters is
called the ilip. But in common discourse we confound the
fore and the hind-quarters; and without any distinction say
the four legs of a horse. The French call a horse droit fur les
jambes, i.e. straight-membered, or straight upon his legs,
when the fore-part of the pattern falls perpendicularly upon
the coronet, and the flank and the pattern are in a straight
line. See STRAIGHT AND LONG-JOINTED. See also HORSE.

The horsemans legs are likewise of singular concern in
the manage, for the action of these given leasonably, and
with a little judgment, conffutes one of the principal aids,
which consists in approaching more or less with the calf of
the leg to the horse's flank, and in bearing it more or less
off as there occasion. This aid a horsemans ought to give
very nicely, in order to animate a horse: and it is so much
the finer, that it is hidden and private: for in stretching the
ham he makes the horse dread the spur, and this aid has as
much effect as the spur itself. See AID.

LEGS, in Rural Economy, are the extremities that form
the support of animals. In horseshoes they should have a due
proportion to that of the body. The fore-legs are subject
to many infirmities, as being the parts that suffer most, and
are commonly the weakest. It is a mark of bad legs when
they appear altogether straight, or, as if they were of one
piece. A horse is said to be straight upon his legs, when
from the knee to the fore-part of the coronoet, the knees,
flank, and coronet descend in a straight or plumb-line, and
the pattern joint appears more, or at least as much advanced
as the rest of the leg; such legs are like those of a goat,
making a horse apt to trip and fall; so that in time the pattern
is thrall quite forward out of its place, and the horse
becomes lame and liable to stumble.

Horses which are straight upon their legs are quite con-
tinuous to those that are long-jointed, that is, whose patterns
are fo long and flexible, that in walking, they alomost touch
the ground with them. And it is a greater imperfection
than the former, because some remedy may be applied to
them; but there can be none for those: besides it is a sign
of little or no strength, such horses not being fit for much
fatigue. Some horses, though they be long-jointed, do not
bend their patterns in walking: such horses gallop and run
with greater ease to their riders than such as are short
jointed.

In the language of the stable a horse is said to want the
fifth leg when he is tired, and, bearing upon the bridle, lies
heavily upon the riders hand, so as to produce much fatigue.

LEGS, Arched. See ARCHED.

LEGS, Compasses of three. See Compasses.

LEGS, Hyperbolic. See HYPERBOLIC.

LEGS, Long, in Natural History. See TIPULA.

LEGS of the Marintees, in a Ship, are used for those small
ropes which are put through the bolt-ropes of the main
and fore-sail, in the keech of each. They are above a foot
in length, and at either end are spliced into themselves; they
have also a small eye, into which the martinetts are fastened
by two nitches, and the end is feized into the standing part
of the martinetts.

LEGS of a Triangle.—When one side of a triangle is taken
as a base, the other two are called legs. See TRIANGLE.

LEGUEVIN, in Geography, a town of France, in the
department of the Upper Garonne, and chief place of a
canton, in the district of Toulouf; nine miles W. of it.
The place contains 6689, and the canton 95,49 inhabitants,
on a territory of 117 1/2 kilometres, in 10 communes.

LEGUIGNO, a town of the duchy of Parma; 18 miles
S.S.E. of Parma.

LEGUME, in Botany, legumen, the pod proper to the
pea or papilionaceous tribe of plants, thence termed, by some
writers, leguminous. (See LEGUMINOSES.) The Latin word
legumen is laid by the ancients themselves to be derived from
lego, to gather; because such fruits are gathered or plucked
from their stalks, not reaped nor mown. They are termed
in English pulse.

This sort of seed-veil is always solitary and simple,
formed of two mostly oblong, equal, more or less coriaceous,
parallel valves, without any distinct longitudinal partition, and
bearing the seeds along one of its margins only. The top
is terminated by the remains of the style, which is short, and
placed obliquely, or out of the axis; the base is somewhat
contracted towards the stalk. One of the margins, where
the seeds are inserted, is generally rather shorter than the
other, and externally more furrowed, the other being often
rounded
LEG

rounded or wavy, and more compressed. There are, however, various shapes of legumes, some of which are peculiar to certain genera, as the spiral ones of different species of *Medicago* and *Scorpiurus*; the cylindrical, prismatic, or rhomboid ones of other genera. Such differ essentially from that kind of feed-vessel termed a *filicaea*, or pod properly so called, in having the seeds at one margin only, whereas the *filicaea* has them arranged along both. The furrowed edge of the legume, which bears the seeds, is called the future.

The capsules of *Helloborus*, and some other plants allied thereto, termed by Linnaeus rather incorrectly *multisiliquae*, are fully indicated by Gærtner as approaching to the definition of legumes. They differ, however, in conforming each but one of a vase, and in not being solitary or single in each flower, except the inflorescence of a few species of *Larkspur*, *Delphinium*, which differ from the natural character of their genus, in having one instead of three merens and feed-vessels; but analogy here teaches the true nature of the part in question. We are, indeed, obliged to have recourse to the same guide in a few papilionaceous genera, whose feed-vessel, otherwise a true legume, contains but one seed, as in moss species of *Teophila*, or whose valves do not separate, but become thickened and hard, as in *Pierocarpus*, or leathery, as in *Viminaria*.

When a legume is divided into several cells, it is either by an inflexion of its valves, as in *Aframalus* and *Mribelia*, or by transverse partitions, as in *Vicia* and *Genista*, or even membranous transverse partitions, as in *Securidaca* and *Caffeia*. Some, however, are still more distinctly divided, separating as they ripen into distinct joints, each of which contains a single feed, and does not in general burst till that feed forces its way by vegetating, as in *Hedysarum*, *Scorpiurus*, and *Hipocrepis*. This latter kind of legume has lately been considered as a peculiar sort of pericarp, and called *lomentum*; but the gradations leading to it are so imperceptible, that unless a multitude of other distinctions were made, we do not see the eligibility of this.

Several legumes are internally spongy, leathery, or pulpy, in which respects they vary greatly in the progress of their growth, as the bean (*Vicia Faba*), the *Tamarind*, the *Ceratonia*, the *Hymenea*, &c.

Amid all the diversities of structure in this kind of pericarp, it is most difficult to admit as a legume the three-valved feed-vessel of Gærtner's *Moringa*; our *Hyperanthera*.

**LEGUMINOSÆ**, a natural order of plants, so called from the nature of their fruit. (See **Legume**.) It is the 93d order of Jussieu’s system, the 11th of his 14th classes, and embraces the Linnaean *Papilionaceæ* and *Lomentaceæ*.

For the detailed character of Jussieu’s 14th class, see *Ficoideæ*. It has two cotyledons, many petals, and stamens inserted into some part of the calyx.

The **Leguminoæ** are thus defined.

Calyx of one leaf, variously divided. Corolla of many petals, rarely either wanting or monopetalous, inserted into the upper part of the calyx, below its divisions. Petals sometimes five, rarely fewer. regular and nearly equal; but more frequently four, and irregular, all together imitating the shape of a butterfly, whence the term papilionaceous flower; of these the upper and outer one is the standard, *veixillum*, half embracing the rest, and mostly exceeding them in dimensions; the next two are the wings, *ala*, which are lateral; the lower and innermost is the keel, *carina*, which is either simple or divided. Stamens ten, rarely more or fewer, inserted into the calyx under the petals, their filaments sometimes distinct, or slightly united at their base, or more frequently diadelphous, (see *Diadelphia*), that is, consisting of nine united into a tube, which is slit lengthwise under the standard, with a tenth applied close to that fissure, or the whole are really monadelphous, the tube being undivided and decandrous; the anthers are distinct, often roundish and small, sometimes oblong and incumbent. Germs simple, superior; style one; stigma undivided. Fruit in a few inflorescences capulular, of one cell, with scarcely more than one seed, either of two valves, or not burbling at all; in most it is leguminous, as the name of the order implies, longish, of two valves, (of three in *Moringa*, or *Hyperanthera*, of four in one species of *Mimosa*), the feed affixed to one of the lateral futures; sometimes it is of a single cell, with one feed or several, sometimes of many seeds separated by transverse partitions, each cell containing one feed, and all being occasionally pulpy. In the polypetalous irregular genera the radicle of the corculum or embryo inclines towards the lobes, and there is no perisperm or *albumen*; in those with more regular flowers the radicle is straight, and there is a perisperm, or thickish membrane, enclosing the embryo; the seeds of the feed are mostly changed into fowmle leaves, according to the usual mode of dicotyledonous vegetables, but the future remain distinct below the first leaves. The item is either herbaceous, shrubby or arborescent, branched for the most part in an alternate manner. Leaves furnished with (fipulas, alternate, in a very few inflorescences imperfectly opposite, sometimes simple, but often tarnate, or fingered, or once or more pinnate. The flowers are variously disposed.

The fections are eleven.

1. Corolla regular. Legume of many cells, mostly of two valves, with transverse partitions, the feeds solitary in each cell. Stamina separate. These are trees or shrubs, with abruptly pinnate leaves. The section contains *Mima*, *Gladiola*, *Gynacolus*, *Macrolobium of Schreber, Ceratonia*, *Tamarindus*, *Parkinsonia*, *Scotia of Jacquin*, and *Caffeia*.—To these may be added *Afzelia*, Smith Transf. of Linn. Soc. v. 4. 221.

2. Corolla regular. Legume of one cell, and two valves. Stamina ten, separate.—Trees or shrubs, with abruptly pinnate leaves. (In *Hyperanthera* they have terminal leaflets, and the legume has three valves.) This comprehends *Hyperanthera*, (Moringa of Jussieu), *Prosopis, Hamatoxyllum, Dimorpha of Schreber, Cnema of the same, Adenanthera, Poinciana, Caffolpini* (the two last being really one genus) and *Gulmania*.

3. Corolla somewhat irregular. Stamina distinct, or only connected at their base. Legume of one cell and two valves.—Trees or shrubs, with leaves either abruptly pinnate, or merely conjugate, or quite simple.

Here are *Dipteryx* and *Dimorpha* of Schreber, with *Cymometra*, *Hymenea* and *Baubinia* of Linnaeus, and *Ginannah* of the former. Jussieu admits *Vouga* of Aublet, which Schreber unites to *Outea* of the same author, 1st owns *Macrolobium*; see sect. 1.

4. Corolla irregular, papilionaceous. Stamina distinct, or rarely connected at their base. Legume mostly of one cell, and two valves.—Trees or shrubs; their leaves either simple, or tarnate, or pinnate, with an odd leaflet.

Jussieu here enumerates only *Cercis, Rittera* of Schreber, *Anagallis, Sophora*, *Mullera*, and *Coublandra* of Aublet, the character of which last is very puzzling. But to this section belongs a numerous tribe of New Holland genera, exalted by Dr. Smith, in the Annals of Botany, and in the Annals of Linnean Soc. v. 3. 245. These are *Puttana*, *Asus, Gompholobium, Chorozema*, *Daranja*, *Viminaria* (though the legume of this last does not burst), *Spaerobium, Dillwynia, Mirbella* (though the legume has two cells), and *Calyp- tachya*. --3 R
Corolla irregular, papilionaceous. Stamens ten, didymous. Legume of one cell and two valves.—Shrubs or herbs; their leaves simple or ternate, or rarely fingered; the stipules sometimes scarcely discernible, sometimes conspicuous, either attached to the bottom of the footstalk, or distinct from it.

This ample fection contains Ulex, Affallatoth, Barbania, Liparia, Genista (the latter including Spartium of Linnæus). Cytisus, Cratoxylon, Lupinus, Oenon, Astracry, Dalea, Pterocarya, Trijuncta, Medicago, Medicago, Triguma, Lotus, Dysosa, Phalera, Erastria, Ochres, and Glyceria. Here are to be added Phatochlo, Bocca, and Porcellae of Smith in Tr. of Liv. Soc. v. 9, 1811, also inata of König and Roxburgh, and Hallis of Thumberg, with doubles many more.

6. Corolla, Stamens, and Legume as in the last. Herbs or shrubs, or small trees, whose leaves are pinnate with an odd leaflet. In a few the legume has two cells.

Abras, Amorpha (remarkable for wanting both wings and keel), Pitcédina, Robinia, Caragana, Afragulus, Phacst, Biocura, Colutea, Glyceria, Galera, and Indigo is.

7. Cor. Stam. and Legume as in the two last.—Herbs, with pinnate, or conjugate, or sometimes fearly any, leaves, the common footstalk ending in a tendril; stipules distinct from the footstalk.

Lotthys, Pflum, Orbeus, Vicin, Faba, Erorn, and Cicer.

8. Cor. Stam. and as in the three last. Legume composed of single-seeded joints.—Herbs or shrubs, rarely trees; leaves simple or ternate, or more frequently pinate with an odd one; stipules distinct from the leaf-stalk.

9. Corolla as before. Stamens mostly ten, didymous. Legume capular, of one cell, often not biruding, with scarcely more than one seed.—Trees or shrubs; leaves generally pinnate with an odd one; stipules distinct from the footstalk, soon falling.

Dalbergia, Amorpha of Browne's Jamaica, Galetophora of Lamark, Anica of the fame, Geoflora, Deyhia of Lamark, Myrciaria, Dipsacus of Schreber, Acorus of Ablatt, and Pterocarya, are the genera classed here by Luff, which have all a general affinity to each other.

10. Corolla irregular (sometimes wanting). Stamens ten, distinct. Legume capular, of one cell, generally not biruding, containing a single seed.—Trees or shrubs; leaves either pinnate with an odd one, or simple; stipules distinct from the footstalk, soon falling.

Crucia of Schreber, Detarium of Luff, Capuschera, and Myrtus.—According to the definition of this fection, Viminaria belongs to it; but it is too unlike the red, and too closely allied in habit and character to the plants with which we have placed it in fect. 9, to be separated from them.

11. Luff concludes here with four genera, termed by him "akin to the leguminosa." These are Securidaca, which seems to belong properly to fect. 9, Brownea, Zygia of Browne's Jamaica, and Aruna of Schreber.

It will easily be perceived that this arrangement requires much correction and reformation, in consequence of discrepancies subsequent to its publication. The whole order is to natural, that its subdivisions are proportionately difficult to be devised, and the name may be laid of its generic distinctions. If Linnæus was obliged, by the laws of his artificial system, to offer great violence to this order, as Jussieu and others have not failed to observe, his class Diadaphia does honor to his penetration, and to the comprehensive systematic powers of his mind.

LEGUMINOUS FLOWERS. See Flower.

LEGUMINOUS PLANTS, in Gardening, a term applied to all such as are of the pulsa kind, as those of the pea, bean, and other similar descriptions.

LEHE, in Geography, a town of the duchy of Bremen; 32 miles N. of Bremen.

LEHEIM, a town of Hesse-Darmstadt; 8 miles W. of Darmstadt.

LEHI, in Scripture Geography, a city of Palestine, in the tribe of Dan, near E fractional or Elkas. This was a provincial city, given to the sons of Cohath. Here Samson flew a thousand Philistines with the jaw-bone of an ass.

LEIM, Leybly, or Leiba, in Geography, a river of America, which rises in Hampton county, Pennsylvania, about 20 miles E. of Wyoming Falls, in Susquehanna river, and flowing, by a circular course, through the Blue mountains, discharges itself into Delaware river, on the S. side of Euton, 11 miles N.E. of Bethlehem. Its course is about 75 miles, and it is navigable 50 miles.

LEHMUKHLEN, a town of Holstein; 8 miles S.W. of Lübeck.

LEHRBERG, a town of Germany, in the margrave of Anspach, on the Unter Retzat; 5 miles N.W. of Anspach.

LEHSO, a town of Arabia Doferta; 140 miles S. of Cathem.

LEHSTEN, or LEHSTEN, a town of Saxony, in the principality of Altenburg, celebrated for its quarries of flint; 45 miles S.S.W. of Altenburg. N. lat. 50° 25'. E. long. 11° 35'.

LEHTIMAKI, a town of Sweden, in the government of Vasa; 105 miles E.S.E. of Vasa.

LEIBEN, a town of Austria; 10 miles W.N.W. of Crum. Also, a town of Austria; 14 miles S.W. of Crum.

LEIBLING, or LEPPING, a town of Germany, in the lordship of hatteberg; 6 miles E. of Tutbingen.

LEIBNITZ, GODFREY WILLIAM DE, in Biography, an eminent German philosopher and mathematician, was born at Leipzig in the year 1646. He lost his father when he was very young, and of course the care of his education devolved upon his mother. She placed him under able masters, who had been colleagues to his father in the university, of which he had been professor of moral philosophy, and secretary. The son made a very rapid progress in the different branches of science and learning. He not only became a deep philosopher, but availed himself of the advantages of a large and well chosen library, which his father had left him, and read all the books which it contained in regular order, as the poets, orators, historians, civilains, philologists, mathematicians, and divines. Such was his application, that he could repeat the works of the principal poets, and featious was his memory, that even in old age he could, without hesitation, run through the whole of the Senecia, without missing a line or a word. He had a talent for making verses, and is said to have composed three hundred in one day. When he was fifteen years of age, he became a student in the university of Leipzig, where he prosecuted, with great success, the various studies of the law, medicine, philosophy, and theology. Having finished his studies at Jena, the principal
principals of his attention were history, law, and the mathematics. He was particularly attached to the writings of Plato and Aristotle, and is said to have spent whole days in meditation, in a forest near Leipsic. He principally devoted himself to the study of the law, and took his degree of bachelor in 1665, and in the following year he supplicated for his degree of doctor, which was refused, under the pretense that he was too young, being then only in his twentieth year, but it was imagined that the real cause was his having abandoned the tenets of Aristotle and the schoolmen. Offended at this treatment, he went to Altdorf, where he maintained a thesis, "De calibus perplexis," and in the disputations on this occasion, he displayed such uncommon abilities, that he had the degree of doctor instantly conferred upon him, and was even offered a professorship extraordinary in law, which he declined. He about this period published a work, entitled "Ars Combinatoria," intended to shew in what manner universal arithmetic may be applied to other sciences. This was accompanied with "A Mathematical Demonstration of the Existence of God." From Altdorf Leibnitz went to Nuremberg; to visit the learned men in that university. He was at this place initiated in the mysteries of Alchemy. From Nuremberg he went to Mentz, and published, in 1668, "Nova Methodus Discendae Difcentque Jurisprudentiae," which gained him great applause. He next shewed himself as a politician, and wrote a treatise to induce the Poles to choose the elector-palatine their king, which pleased the elector, that he invited the author to reside at his court, which invitation he would have accepted, had he not at the same time obtained the office of counsellor of the chamber of review in the chancellorcy of Mentz. In 1670 he reprinted, with a preface and notes, the treatise of Maris Niccolis de Berfello, "De veris Principiis, et vera ratione Philosophandi contra Pseudophilosophos," to which he subjoined a letter, "De Arisotole's recentioribus reconciliabili." In the year 1672, Leibnitz went to Paris, to manage some affairs at the French court; here he became acquainted with the greatest mathematicians in that metropolis, and made further and considerable progress in the study of mathematics and philosophy. Here also he met with Pascal's arithmetical machine, into the defects of which he soon discovered, and to obviate these he invented a new one, which was highly approved by the minister Colbert, and the Academy of Sciences. He was offered a seat in this body with a pension, and had the prospect of many other advantages if he would settle at Paris, but to attain this eminence he must embrace, or be forced to embrace, the Catholic religion, which neither his hours nor emoluments could induce him to do. In 1673 he came to England, and became acquainted with Mr. Oldenburg, the secretary, and Mr. Collins, a distinguished member of the Royal Society; from whom it was said he received some hints of the method of fluxions, which had been invented in 1664, or 1665, by Mr. Isaac Newton. Leibnitz improved these hints, and under the name of "calculus differentialis" he gave the same method of analysis with fluxions. (See Keil and Newton.) While Mr. Leibnitz was in England he lost his patron, the elector of Mentz, and with him a pension which that prince had allowed him. He returned to France, whence he wrote to Frederic duke of Brunfwic Luneburg, informing him of his circumstances. This prince immediately appointed him a member of the Anlie council, with a regular salary, but he permitted him to remain at Paris, till his arithmetical machine should be perfected. When he entered upon his office at Hanover, one of his earliest cares was to furnish the prince's library with the best books in the various branches of science and literature. In 1677 he first mentioned his mathematical invention of differentials to Newton, who had previously to this written to Leibnitz an account of his invention of fluxions; about the same period, he gave an account of some discoveries in optics and mechanics, describing a new method of polishing glases. He became a confiant contributor to the "Acta Eruditorum" of Leipsic, and among other pieces he published in this work "Thoughts on Knowledge, Truth, and Ideas," He next undertook a history of the house of Brunfwic, and to render himself more competent to the task, he travelled over Germany and Italy, collecting materials. In passing from Venice to Mofol, a terrible storm arose, during which the pilot, imagining that he could not be understood by a German, whom, as a heretic, he regarded as the cause of the tempest, proposed to strip him of his clothes and money, and throw him overboard. Leibnitz, hearing the conversation, without the least emotion, drew a set of beads from his pocket, and began turning them over with great seeming devotion. The artifice succeeded; one of the sailors observing to the pilot, that since the man was not an heretic, he ought not to be drowned. Leibnitz returned to Hanover in 1690, where he pursued with great industry several objects of very different kinds. In a theological dispute he appeared the friend of toleration, and in 1693 he published a work on the law of nations, entitled "Codex Juris Gentium Diplomaticus." He next wrote his treatise "De ipsa natura, five Vi initia," which was intended to improve and correct the philosophical notion of subsistence: and he likewise conceived the idea of a new science of forces, in which the laws of mechanics, and the measure of living forces might be clearly defined. This science he denominated "Dynamics" (which he), and inferred a specimen of it in the "Acta Eruditorum." He published "Thoughts on Locke's Essay on the Human Understanding," in which he contended that philosopher's opinions on innate ideas, subsistence, a vacuum, and other subjects; communicated to the world his ingenious invention of binary arithmetic; and wrote a reply to Bayle in defence of his doctrine of pre-established harmony. Without attempting to follow our author in all his publications, which were very numerous and important, we may observe that he spent much time in the invention of an universal language; but did not live to complete his design. In 1710 he published "A Dissertation on the Goodness of God, the Liberty of Man, and the Origin of Evil." The writings of Leibnitz had long rendered his name famous in every part of Europe; he had honours bestowed upon him by several other princes, besides the elector of Hanover and Brandenburg, and in 1713 he was made Ausse counsellor to the emperor, and at the same period the czar Peter the Great appointed him privy counsellor of justice, with a pension of a thousand ducats. In 1714 his patron, the elector of Hanover, was raised to the throne of Great Britain, and in a short time Leibnitz sailed over to England, where he received new marks of favour and friendship; and frequently made his appearance at court. It was during this visit, that, at the desire of the princes of Wales, afterwards queen Caroline, he engaged in a dispute with the celebrated Dr. Samuel Clarke, upon the subject of free will and other important metaphysical topics. This controversy continued till the death of Leibnitz, which event took place in 1716. He was author of many other works besides those already mentioned. His intellectual abilities and attainments entitle him to be ranked among those universal geniuses which at once surprize and benefit the world. With great strength of understanding, an excellent faculty of invention, and a most capacious and retentive memory, he united an uncommon degree of industry. Hence he was enabled not only to acquire much general knowledge, but to become eminent in
attainments of various kinds. The improvements which he made in the higher geometry and algebra, rank him among mathematicians of the first clafs. He thoroughly understood the doctrines of philosophy, both ancient and modern, and cast new light upon almost every branch of knowledge. In theology he was well read in the writings of the Christian fathers, and in the controversies of his own times. On history and jurisprudence he wrote in such a manner as might lead a reader to suppose that these subjects were his chief or only study. The philosophy of Leibnitz is a system formed partly on the Carteian, and partly in opposition to the Newtonian theory. After the dispute respecting the discovery of fluxions, he became the violent opposer of our great philosopher. He even charged his system with having an impious tendency, because it asserted that the fabric of the universe, and the course of nature, would not continue for ever in its present state, but would require, in process of time, to be re-established, or renewed by the hand of its former. According to his own principles, deduced, as he thought, from the wisdom and goodness of the deity, and his principle of a sufficient reason, he concluded the universe to be a perfect work, or the being that could possibly have been made; and that other things, which are evil or incommodious, were permitted as necessary consequences of what was best; that the material system, considered as a perfect machine, can never fall into disorder, or require to be set right; and that to suppose that God interferes in it, is to deflower the skill of the author, and the perfection of his work. Among many other of his notions (for an account of which see LEIBNITZIAN PHILOSOPHY) we may add this, that the acts of the soul and body proceed by necessary laws: the soul in its perceptions and volitions, and the body in its motions, without affecting each other; but that each is to be considered as a separate independent machine. The volitions of the mind are followed instinctly by the defined motions of the body, not in consequence of those volitions in the least, but of the nice and well-adjusted machinery of the body. The impressions produced in the fensoy have no effect on the mind, but the corresponding idea arises at that precise time, in consequence of a chain of causes of a different kind. Moreri, Maclaurin, &c. See LEIBNITZIAN PHILOSOPHY.

LEIBNITZ, in Geography, a town of Saxony, in the margravate of Meifen ; 4 miles S. of Dresden.—Also, a town of the duchy of Stiria, on the Sulm; 16 miles S. of Grazs.

LEIBNITZIAN PHILOSOPHY, or the philosophy of Leibnitz, is a system of philosophy formed and published by his author in the 17th century, partly in emendation of the Carteian, and partly in opposition to the Newtonian. The basis of Mr. Leibnitz's philosophy was that of Des Cartes; for he retained the Carteian subtle matter with the universal plenitude and vortices; and represented the universe as a machine that should proceed for ever, by the laws of mechanism in the most perfect state, by an absolute inviolable necessity, though in some things he differs from Des Cartes. After Sir Isaac Newton's philosophy was published in 1687, he printed an essay on the celestial motions (Act. Erud. 1689), where he admits of the circulation of the ether with Des Cartes, and of gravity with Sir Isaac Newton; though he has not reconciled these principles, nor shown how gravity arose from the impulse of this ether, nor how to account for the planetary revolutions and the laws of the planetary motions in their respective orbits. That which he calls the harmonical circulation is the angular velocity of any one planet, which decreases from the perihelion to the aphelion in the same proportion as its distance from the sun increases; but this law does not apply to the motions of the different planets compared together; because the velocities of the planets, at their mean distances, decrease in the same proportion as the square roots of the numbers expressing those distances. Besides, his system is defective, as it does not reconcile the circulation of the ether with the free motions of the comets in all directions, or with the obliquity of the planes of the planetary orbits; nor resolve other objections to which the hypothesis of the plenum and vortices is liable. Soon after the period just mentioned, the dispute commenced concerning the invention of the method of fluxions (which see), which led Mr. Leibnitz to take a very decided part in opposition to the philosophy of Sir Isaac Newton. See LEIBNITZ.

The perfection of the universe, by reason of which it is capable of continuing for ever by mechanical laws in its present state, led Mr. Leibnitz to distinguish between the quantity of motion and the force of bodies; and, whilst he owns, in opposition to Des Cartes, that the former varies, to maintain that the quantity of force is for ever the same in the universe, and to measure the force of bodies by the squares of their velocities. See Force.

This system also requires the utter exclusion of atoms, or of any perfectly hard and inelastic bodies; the advocates of it allege, that, according to the law of continuity, as they call a law of nature invented for the sake of the theory, all changes in nature are produced by infinitely small degrees; so that no body can, in any case, pass from motion to rest, or from rest to motion, without passing through all possible intermediate degrees of motion; whence they conclude that atoms or perfectly hard bodies are impossible; because if two of them should meet with equal motions, in contrary directions, they would necessarily stop at once, in violation of the law of continuity.

Mr. Leibnitz proposes two principles as the foundation of all our knowledge; the first, that it is impossible for a thing to be, and not to be, at the same time, which, he says, is the foundation of speculative truth: the other is, that nothing is, without a sufficient reason why it should be so, rather than otherwise: and by this principle, according to him, we make a transition from abstracted truths to natural philosophy. Hence, he concludes, that the mind is naturally determined, in its volitions and elections, by the greatest apparent good, and that it is impossible to make a choice between things perfectly like, which he calls indiscernibles; from whence he infers, that two things perfectly like could not have been produced even by the Deity: and he rejects a vacuum, partly because the parts of it must be supposed perfectly like to each other. For the same reason also he rejects atoms, and all similar particles of matter: to each of which, though divisible in infinitum, he ascribes a monad (Ac. L. p. 1698, p. 435), or active kind of principle, endured, as he says, with perception and appetite. The essence of subtances be places in action or activity, or, as he expresses it, in something that is between acting and the faculty of acting. He affirms absolute rest to be impossible, and holds motion, or a fort of nifas, to be essential to all material substanacies. Each monad he describes as representative of the whole universe from its point of sight; and after all, in one of his letters he tells us, that matter is not a substance, but a substantiation, or phenomenon bien fondé. (See Monad.) He frequently urges the comparison between the effects of opposite motives on the mind, and of weights placed in the scale of a balance, or of powers acting upon the same body with contrary directions. His learned antagonist Dr. Clarke denies that there is a similitude between a balance moved by weights, and a mind acting upon
upon the view of certain motives; because the one is entirely passive, and the other not only is acted upon, but acts also. The mind, he owns, is purely passive in receiving the impression of the motive, which is only a perception, and is not to be confounded with the power of acting after, or in consequence of, that perception. The difference between a man and a machine does not consist only in volition and intelligence; but in this power of acting also. The balance for want of this power, cannot move at all, when the weights are equal; but a free agent, he says, when there appear two perfectly alike reasonable ways of acting, has still within itself a power of choosing; and it may have strong and very good reasons not to forbear. Collection of Papers which passed between Mr. Leibnitz and Dr. Clarke in 1715 and 1716, &c. 8vo. 1717, p. 121. See Liberty.

The translator of Mosheim's Ecclesiastical History observes, that the progress of Arminianism has declined in Germany and several parts of Switzerland, in consequence of the influence of the Leibnitzian and Wolffian philosophy. Leibnitz and Wolf, by attacking that liberty of indifferency, which is supposed to imply the power of acting not only without, but against motives, he says, at the very foundation of the Arminian system. He adds, that the greatest possible perfection of the universal, considered as the ultimate end of creating goodness, removes from the doctrine of predestination these arbitrary procedures and narrow views, with which the Calvinists are supposed to have loaded it, and gives it a new, a more pleasing, and a more philosophical aspect. As the Leibnitzians laid down this great end as the supreme object of God's universal dominion, and the scope to which all his dispensations are directed; so they concluded, that, if this end was proposed, it must be accomplished. Hence the doctrine of necessity, to fulfill the purposes of a predestination founded in wisdom and goodness; a necessity, physical and mechanical, in the motions of material and inanimate things, but a necessity, moral and spiritual, in the voluntary determinations of intelligent beings, in accordance of propitious motives, which produce their effects with certainty, though these effects be contingent, and by no means the offspring of an absolute and essentially immutable fatality. These principles, fays the same writer, are evidently applicable to the main doctrines of Calvinism; by them predestination is confirmed, though modified with respect to its reasons and its end; by them irresistible grace (irresistible in a moral sense) is maintained upon the hypothesis of propitious motives and a moral necessity; the perseverance of the saints is also explicable upon the same system, by a series of moral causes producing a series of moral effects. Mosheim's Eccl. Hist. by Dr. Maclaine, vol. v. p. 464. 8vo. edit.

For an account of Leibnitz's famous doctrine of a pre-established harmony, we refer to that article; and for his account of monads to monads.

See on the subject of this article Maclaurin's View of Sir Isaac Newton's Philosophical Discoveries, &c. book i. chap. 4. or p. 79. &c. 40th edit. Brucker's History of Philosophy, by Enfield, vol. ii. p 356. &c.

Leicester, commonly pronounced Leicester, in Geography, the county town of Leicestershire, England, was formerly written Lege-ceæter, Legesceotre, and in the Saxon Annals Leger-ceæter; and during part of the heptarchy it was a city. Without referring it to a British origin, or entering into a discussion respecting the derivation of its name, and of its civil privileges from King Leir, it will amply satisfy every rational enquirer to commence its history at that period when the Romans had settled themselves in this island, and held the natives in military subordination. As those conquerors marched from the south-east, towards the central and northern parts of the country, they could not have obtained possession of this district, till the intermediate places between it and the sea were subjugated, and competent garrisons established. Having accomplished this, and overpowered the Coritani, they took possession of the chief town of that people. This town, or strong hold, was the scene of the present Leicesters, and, at the time of its conquest, was denominated Rathe in the Itineraries of Richard, Antonius, and Ravennas; but Ragine in some other writings. "The real name, therefore," says Mr. Whitaker, "must be equally Rathe and Ragine; the former implying the town to be fixed upon the currents, the latter importing it to be the capital of the kingdom." That the Romans had a permanent station here is unequivocally manifested by the tessellated pavements, and other remains that have been discovered at different periods; and, according to Antoninus, Rathe was one of their stipendiary towns. The fols-road in its way from London, to Lincoin, Lincoln, came by Vennone; whence to Rathe was twelve miles, and thence to Veromæum thirteen miles; and these distances very nearly correspond with those between Claycovel, Leicesters, and Willoughby. That this station was formed on the northern bank of the Soar, that an artificial channel was cut for the water to flow up to, and confute one boundary of the station, and that the Romans were settled here for some length of time, are circumstances easily proved, as ample evidences remain, and are recorded in support of these inferences. Many tessellated pavements, coins, urns, and other domestic and military relics of the Romans, have been discovered at different times; some of which are still carefully preserved as memorials of ancient art, but many of the most interesting objects must have been destroyed during the ravages of war which Leicesters experienced under the Saxons, Danes, and Normans. Of the Mosaic pavements, that which was found in a cellar nearly opposite the town-prison, in the year 1675, is the most worthy of notice. But the most curious relic of antiquity, and one that has provoked the most copious dissertations, is the military, or Roman mile-stone, which was discovered in 1771, on the side of the Foss-road, at the distance of about two miles north of the town, and thence removed into the town at the expense of the corporation; by this it is the Flate of Rathe is clearly defined. In different parts of the town, and at distant periods of time, a great number of Roman coins have been found; among which were several with the names of Titus, Trajan, Dioecletian, Constantine the Great, Constantine Junior, Constantius, Hadrian, Theodosius, Honorius, &c. Here is also a curious fragment of Roman architecture, commonly called the Jewry wall, consisting of a mass of brick-work, stones, and rubbles, with dilapidated arches turned entirely of tiles, bound together by a large quantity of mortar. About a quarter of a mile south of the Infirmary are some artificial banks, known by the name of raddle, or rauwlyke; these were formerly about four yards in height, and consisted of two parallel mounds of earth, extending 67 yards in length, at the distance of fifteen yards from each other. If these remains are not peculiarly worthy notice as works of art, they are curious as vellages of remote times, and of a particular people.

The history of Leicesters, during the Saxon heptarchy, is very vague and uncertain, though, from the concurrent testimony of all writers, it was certainly a place of considerable note from the departure of the Romans to the time of the Norman conquest. According to Godwin, a bishop's fee was transferred from Sidneyece to Leicesters in the year...
At this period the Saxon kingdom of Mercia had, according to some authors, three episcopal sees: Lichfield, Dorchester, and Leicester. From the Saxon annals, it appears that Ethelfrid, king of Northumberland, being an avowed enemy to Christianity, marched an army to Leicester, where he made a great slaughter of the inhabitants. Jocelin relates that Ethelred, king of Mercia, and his queen Elfreda, who was daughter of Alfred the Great, repaired the town about the year 907, and rebuilt and enlarged the walls, which were now made to inclose the castle; previous to that period the castle appears to have been on the outside of the town. On the conquest of England by William the Norman, Leicester soon became part of the royal demesne, and a castle was either newly erected, or enlarged and strengthened to ensure the submision of the inhabitants, and those of the surrounding county. On the death of the conqueror, Leicester citadel, being held by the adherents of Duke Robert, was nearly demolished by the successful partizans of William Rufus. In the reign of Henry I. Robert, earl of Leicester, repaired, enlarged, and fortified the castle, which he made his principal residence. He was very liberal to the town, and also to his son Robert Bobby, but the arrogant behaviour of the latter to the king involved this place in broils and war; it being the practice in those times for sovereigns to revenge themselves, for the offences of the nobles, on the people and places immediately under the patronage of the offenders. This was fatally experienced in the reign of Henry II. when earl Robert Blanch mains, leaving with the king's son in his mutinous rebellion, Leicester, the chief resort of the disaffected, was, after a long siege, almost destroyed, and the castle reduced to a heap of ruins. Scarcely any thing now remains of the latter building, but an artificial mound, or the earth work of the keep, near which is a part of the town with some ancient buildings, called the "Newark," or Newwork. This name appears to have been given to distinguish it from the calls with its original buildings, which was considered as the old works. The Newark is said to have been founded by Henry, third earl of Lancaster, and his son Henry, the first duke of that name. By these two noblemen some large buildings were erected here; and John of Gaunt, who was earl of Leicester, added considerably to the pile. When completed, the whole mult have formed a grand display; but nearly all of these have fallen beneath the devastating hand of man, and the slowly devouring tooth of time. From the remains of the surrounding walls, it is presumed that the Newark was an inclosed area, bounded on the north by the castle, on the south by fields, to the west by a branch of the river Soar, and to the east by a street of the suburbs. At this side is still remaining a large caleulated gateway, called the "magazine," which name it obtained in 1682, when it was purchased by the county, and applied to the use of the train bands. Thoby says it "was built with the New-works, by the founder of the hospital and collegiate church." This gateway has a large pointed arched entrance with a small pointed door way, and communicates with an area nearly surrounded with buildings.

Among the ancient religious houses and foundations of this town, the abbey was formerly of great local importance; but its buildings are nearly levelled with the earth which covers the ashes of its inhabitants. It is said to have been founded in the year 1143 by Robert Boffin, earl of Leicester, who became one of the regular canons on his own foundation. The abbey soon acquired celebrity, and obtained numerous privileges. It was possesed of lands in thirty-six parishes in and about Leicester, and in most of the manors in this and many other counties. Several kings of England, and other distinguished personages, were entertained and lodged at this house in a grand and sumptuous style. The once great and magnificent cardinal Wolsey died at this abbey, November 29th, 1530.

In this town was formerly a mintage; and the series of coins that have been collected, prove that at the Leicestershire mint, a regular succession of coinage has been produced from the reign of the Saxon king Athelstan down to Henry II. This series has been engraved in Mr. Nichols's valuable history of this town.

The first charter granted to Leicester was by king John in the first year of his reign; and at the same time Robert Fitz-Pernel, earl of Leicester, invited the burgesses with the power of buying and selling lands, &c. A charter, granted in the following reign by earl Simon de Montfort, shows the peculiar intolerance of the times; it specifies that "no Jews, or Jews' in my time, or in the time of any of my heirs, to the end of the world, shall inhabit, or remain in" the town of Leicester. Henry VII. by charter dated 1504, confirmed all the previous privileges, and empowered the justices to remand the control of the hundred, and regulate the liberties and immunities specified and extended. The corporation are thereby empowered, among other privileges, to refuse the building of malt-kilns within the distance of thirty yards from any other building. This charter also grants a market for wool-yarn and woad, and for other commodities. All fines and assessments were ordained to be applied to the use of the poor. The corporation consists of a mayor, recorder, steward, bailiff, twenty-four aldermen, forty-eight common-counsellors, and a town clerk; the freemen are toll-free of all the markets and fairs in England. As a parliamentary borough, Leicester has returned two members to the national councils from the time of Edward I. One of the representatives was formerly elected by the "mayor and his brethren," and the other by the commonalty. This mode having excited much popular disaffection, Henry VII. ordained that "the mayor and his brethren should choose forty-eight of the most discreet inhabitants of the town," who should elect all officers for the borough, and members of parliament. Thus it continued till the reign of Charles II.; from which time the right of election has been vested in "the freemen, not receiving alms, and in the inhabitants paying foot and lot." The number of voters is about 2000.

At the time of the Norman conquest, there appear to have been six churches in this town; and it would be highly interesting to the architectural antiquary to ascertain if either of the present structures contains any part of the building then standing. Of the religious edifices now remaining, St. Nicholas's church is esteemed the most ancient. It stands contiguous to the Jewry wall, and appears to have been partly contructed with the bricks, tiles, &c. taken from the fallen parts of that building; whence some antiquaries have thought that they are both parts of the same structure, or built about the same period. The church of St. Mary, distinguished by the addition of infra or justa calixum, is a large pile of irregular building, composed of various specimens, or styles of architecture, from a very early period to a late one, when all styles were disfigured. These varieties tend to mark "the disaffection of violence, accident, and time," and prove that the neighbourhood of the church, within the outer ballium, or precinct of which it stood, was often most dangerous. That there was a church on this spot in the Saxon times seems almost certain, from some bricks, apparently

Leicester.
apparently the workmanship of that people, found in the chanseil; and the chevron work round the windows of the chancel proves that the first Norman earl of Leicester, Robert de Bellomont, constructed a church on a plan nearly like the other. It was subsequently adorned with the architecture of his time. The interior of this church is spacious; and on the south side of the nave is a singularly large semicircular arch, having a span of thirty-nine feet. The south aisle is said by Mr. Carter to have been built by John of Gaunt. At the east end of this aisle was a chapel, or choir, held by guild, or fraternity, called the 'Trinity guild.' This was founded in Henry VII's reign, by Sir Richard Sacheverelle, and the good lady Hungerford. Respecting this guild, the following list of articles, bought in for the year 1508, will serve to show the value of money, and prices of provisions at that period.

A dozen of ale, 20d.; a fat wether, 2s. 4d.; seven lambs, 7s.; fourteen goslings, 4s. 8d.; fifteen capons, 5s.; half a quarter of malt, 2s.; four gallons of milk, 4d.; a pig, 5d.

At the west end of the church is a handsome tower, surmounted by a lofty and elegant spire. The latter has twice suffered from storms. Near the north door of this church is a passage leading under an old building which forms a gateway to an area called the caille yard. Opposite this gateway is a building, partly ancient, partly modern, within which is a large hall seventy-eight feet in length, fifty-one in width, and twenty-four feet high. This hall, during the reign of Lancastrian princes, was the scene of frequent parliaments; at present it is used only for holding the alizes and other county meetings. The church of All Saints is a small, modern structure, consisting of a nave and two aisles, all nearly of the same length. The church of St. Martin, formerly called St. Croft, is a large old building, consisting of a nave, three aisles, and a tower, with a lofty crocketted spire. This church, being the largest in the town, and even in the whole county, is used at all the public meetings of the district for the bishop, judges, &c. The churchwardens' accounts respecting this church and parish are copious and well preferred. They begin in 1544, and contain many curious notices, descriptive of the peculiar manners and customs of the different times. In this church was held St. George's guild, a fraternity which was invested with p.cular privileges, and annually ordained a fort of jubilee in the town, called "the Riding of St. George." It contained also another guild called Corpus Christi, which Mr. Throfty says, "was the most ancient and principal in Leicester."

The register of this parish records the calamitous effects of a plague which raged here in the years 1610 and 1611, during which period 166 persons were buried. In the marriage register is an entry of the names of Thomas Tilley and Ursula Russel, the father of whom being "deo et alto domo, it was agreed by the bishop, mayor, and gentlemen of the town, that certain signs and actions of the bridegroom should be admitted instead of the necessary words." St. Margaret's church, according to Leland's account, is "the fairest church in that place, which once was a cathedral church, and near which the bishop of Lincoln bath a palace, whereof little yet standeth." This edifice consists of a nave, side aisles, chancel, and a handsome tower, and was annexed as a prebend to the college of Lincoln by the bishop of that diocese, at the time when the other churches were given to the abbey. Besides these churches, here are chapels or meeting-houses for different sects of dissenters, presbyterians, independents, and baptists. The county gaol, erected in the year 1791, at the expense of five thousand pounds, occupies the site of an old prison, and is built after the plan recommended by Mr. Howard, with solitary cells, &c. The town gaol is a commodious stone building, de-

signed by Mr. Johnson, a native of this town, and executed by Mr. Firmadge in 1792. The other public buildings are a grammar school of great antiquity; several charity schools; various hospitals; an asylum for indigent lunatics; an exchange for public business; the hotel, now used as assembly rooms; and a commodious theatre. Among the curiosities of the town, is the old wooden bedstead said to have belonged to King Richard, and on which he slept, or rather reclined, the night preceding the battle of Bosworth.

The principal, and almost only article of manufacture in Leicester, is that of stockings, which has been an established and staple commodity here for above two centuries. It finds employment for a great number of persons, as hosiers, stocking-makers, wool-combers, dyers, frame-smiths, comb-makers, winders, fivers, framers, spinners, hobbinsers. sockmakers, stocking-needle-makers, &c. &c. Mr. Throfty states that in Leicester there were "upwards of twenty manufacturers, called hosiers, who, it is computed, employ 5000 persons; including the wrought goods they individually purchase; about 6000 persons being directly or indirectly employed in this great business." This town and its vicinity, with Nottingham and its neighbourhood, are the principal places in England for the manufacture of stockings; the latter is the most noted for silk, and the finer sort of goods, while the former is chiefly devoted to the coarser articles, of which a very large quantity is annually made. The trade at present is very flourishing, and in the "Walk through Leicester" it is stated "that 15,000 dozen per week" of stockings are made on an average. (See Stockings.) Leicester is 97 miles distant from London: the market is held on Saturdays; and seven fairs annually; all on a very large scale. This town was returned to parliament in the year 1801 as containing 3290 houres, and 16953 inhabitants.

Among the natives of this town, of literary eminence, is Dr. Richard Farmer, who was born in 1735, and died in 1797. Nicholls's History and Antiquities of Leicester, seven vols. fo. A Walk through Leicester, 12mo. is an interesting and well written topographical work.

LEICESTER, a township of America, in Addison county, Vermont, situated on the east side of Otter creek, containing 522 inhabitants.

LEICESTER, called by the Indian natives Towand, a considerable post-town in Worcester county, Massachusetts, containing 1192 inhabitants; situated upon the post-road from Boston to Hartford, New York, and Philadelphia; 6 miles W. of Worcester, and 54 W. by S. of Boston; settled in 1720, and incorporated in 1750 or 1751. It has three meeting-houses for Congregationalists, Anabaptists, and Quakers; and an academy incorporated in 1784, and well endowed. Wool-cards are manufactured in this town.

LEICESTERSHIRE, called in the Domesday Survey Leicesters Arist, is an inland county, situated nearly in the middle of England, and environed by the counties of Rutland and Lincoln to the east, Nottingham and Derby on the north, Staffordshire and Warwickshire to the west, while part of the latter county and northamptonshire attach to the southern border. A part of the great Roman road, called Watling-street, appears to have formed a regular division between Leicestershire and Warwickshire. The district included within these boundaries was, at an early period, a part of the territory belonging to the Coritani. After the Romans had subjugated the Britons, and had established colonies in different parts of the island, this county was included within the province of Flavia Caesariensis, and had military stations established at Rathe (Leicester); Verno-
LEICESTERSHIRE.

metum, on the northern border of the county; Biexion, near High-Croft; and Mandueldham, at Manceter. These stations were connected by regular artificial roads, or military ways, known by the names of Waling-Street, Fofe-Way, and Via Devana. The first enters this county at Dowbridge or Dovebridge, on the Northamptonshire border, where the station called Trampton was fixed, hence to Mandueldham it passed nearly in a straight line, having the small station of Biexion on its course. Near this place the Fofe-Way intersects it at right angles, and paffes on to Retce; whence it continues in a northerly direction to Vernevetum, and thence on to Margidunum, a station near Earl Britford, in Northamptonshire. After the Romans had evacuated the island, this district became part of the kingdom of Mercia; and when the sub-division of the Anglo-Saxon provinces into counties was established, and bishops' fees erected, the town of Leicester was constituted the seat of the diocesan. The Mercian kingdom was divided into southern and northern; and the inhabitants of Leicestershire were denominated Mediterraneans, or Middle Angles. They were frequently harassed by the invading Danes, who entering the district from the eastern coast, laid the whole country under contribution between the German ocean and Leicester; and having conquered this place, established themselves here for some length of time: indeed, Leicester was considered as one of their five chief cities in the island. After the Norman invasion in 1066, Leicestershire experienced a complete revolution in its civil and manorial privileges; as the conqueror divided it among his relations and adherents. Two hundred and twenty-eight lordships, the chief parts of the county, were allotted and parcelled out to different Norman chiefs; who again regranted various allotments to their followers and dependants, to be held of them by knight's service. The king, the archbishop of York, and the bishops of Lincoln and Conftance, were also poffeffed of landed property in the county; and some was annexed to the abbeys of Peterborough, Coventry, and Cropland. The Norman chiefs, in order to secure their newly-acquired possessions, soon built, on their respective estates, strong and magnificent castles, which might at once secure themselves, and keep the conquered English in awe. The several townships, in which such castles are known to have been erected, with the names of the founders, are Leicelle, Mount Sorel, Whetstone, and Shilton, founded by the earls of Leicelle; Goby and Hinckley, by Hugo de Grenewe; Donnington, by Eulace baron of Halton; Melton, by Roger lord Mowbray; Ravenston, by Goeffred Hanfelin; Sauney, by lord Baflet of Weldon; and Thorpe, by Ernald de Bois. Most of these castles, during the unquiet reigns of Henry II., John, and Henry III., being held by the rebellious barons, and rendered receptacles of thieves and freebooters, were, by command of the latter king, utterly demolished; and though some of them were afterwards rebuilt, yet at this day there is not one of them remaining entire, and even the ruins of most of them are entirely defaced. The Norman chiefs, after settling their possessions, and fortifying themselves within their respective domains, next directed their attention to the religious habits and prejudices of the times; to secure the favour and influence of the monks, in an age when they were almost omnipotent, or at least could command and intimidate the whole community, was a necessary branch of military policy, which the provincial barons neither overlooked nor neglected. Accordingly, part of their estates were appropriated to the foundation of abbeys, priories, nunneries, and other monastic establishments. In this county were founded four abbeys, at Croxton, Garendon, Leicester, and Olvedon; twelve priories, at Belvoir, Bradley, Bredon, Charley, Hinckley, Kirkby Beker, Laund; at Leicester were four, for Eremites, Black Friars, Grey Friars, and Audin Friars; and Ulvedon; two nunneries at Gracecill and Langley; two collegiate churches in Leicester; and various free chapels, hospitals, preceptories, and chantries, in different parts of the county.

At the time of compiling that great national work, the Domesday Survey, Leicestershire was divided into four wapentakes or hundreds; Framland, Gutchlaxton, Garte, and Gofcoat; and thus it continued till the 20th of Edward III., when an additional hundred, Sparkenhoe, was taken out of Gutchlaxton; and afterwards Gofcoat was divided into two, denominated, from their situations, Earl and Welf Gofcoat. In these five hundreds are 196 parishes, and 12 market-towns, viz., Leicester, Abbot de la Zouch, Bosworth, Halton, Harborough, Lutterworth, Melton Mowbray, Mount Sorel, Billesdon, Hinckley, Loughborough, and Waltham on the Wold. The whole county is within the ecclesiastical jurisdiction of the see of Lincoln, and in the province of Canterbury; under one archdeacon, and fix deaneries. Mr. Nichols states, from the Domesday Survey, that the whole county, at the time that record was compiled, contained 34,000 inhabitants. The number returned to parliament, under the population act of the year 1800, was 130,081; of whom 23,823 are rated to be employed in agriculture, and 42,036 in trade and manufactures; the number of houses being 26,734. The representatives in parliament are but four: two for the county, and two for the borough of Leicester. The circumference and extent of the county have not been satisfactorily defined. Mr. Nichols states the former to be about 150 miles; whilst Mr. Monk sets the same down at about 96 miles. The superficial contents are estimated at about 540,000 acres.

This county has not any rivers of importance; but those which pass through it are convenient and ornamental. The chief are the Soar, the Swift, the Welland, the Avon, the Wreke, and the Anchor. The Soar, anciently called Leire, which is the largest of these, rises from two heads or fountains in the south-western part of the county, and, after receiving a small tributary stream near Whetstone, paffes by the west and north sides of the town of Leicester. Leicestershire being more an agricultural than a commercial district, and deprived of any particular mines, has not equally participated with many other English counties in canal navigation. Some plans for this purpose have been projected at different periods, and a few have been executed. In 1782, a bill was brought into parliament for making a navigable canal from Chilver's Coton in Warwickshire, to pas through a great part of Leicestershire; but being opposed by a variety of interests, it failed of success. In 1782, another bill was introduced for opening a canal communication between Loughborough and Leicester; but it was thrown out on the second reading. In 1791, another application was made with better success; and an act was obtained for making the said communication: the proprietors are by this act, "the company and proprietors of the Leiceter Navigation." In the same year, another bill was obtained for making navigable the rivers Wreke and Eye; and in 1793, a bill was passed for making the "Oakham Canal," from a town of that name in Rutlandshire, to Melton Mowbray.

The whole of Leicestershire presents nearly a flat surface, and is chiefly appropriated to the grazing lyth. It has obtained peculiar celebrity, among agriculturists, for a breed of sheep, distinguished by the name of the hire; and the late Robert Bakewell of Difiely, acquired for himself and the county much popularity, by the experiments and
and improvements he made in the breed of cattle and sheep. Among the different breeds of sheep in the county, the Old Leicester, the Forell, and the New Leicester, or Dihley, constitute the principal sorts, and of them the latter is in the highest repute. The extraordinary profit for which many of the New-Leicester-sheep have been fold at public auctions, and the large sums for which some of the rams and bulls have been let for the season, serve at once to shew their estimation in public opinion, and the laudable zeal that prevails for improving the breeds of cattle, &c.

At an auction of ewes, belonging to Thomas Pagett, esq., in the year 1793, the following sums were given:—Five ewes, at 62 guineas each; five, at 52 guineas each; five, at 45 guineas each; ten, at 30 guineas each; and severally at 25, 20, and 16 guineas each. One of these sheep, which was killed at Walsgrave in Northamptonshire, was of the following weight: the carcass 144 lbs., blood 51 lbs., fat 161 lbs., head and entrails 12 lbs., skin 18 lbs.; making in the whole 195 lbs. It is no uncommon thing to fall down the mutton as a subliterate for bacon. In the year 1793, Mr. Pagett sold several bulls, heifers, cows, and calves, by public auction, when some were brought at the following very extravagant prices: a bull, called "Shakspere," described in the catalogue as "(bred by the late Mr. Fowler) by Shakspere, off young Nell. Whoever buys this lot, the seller makes it a condition, that he shall have the privilege of having two cows bullied by him yearly."—*Four hundred guineas: a bull calf 31 guineas; three years old heifer 70 guineas; others at 35 and 32 guineas each; a two years old heifer at 84, and another at 60 guineas.

It will be difficult to define the soils of the whole county. Very little of the land can with propriety be called a mere sand or gravelly soil; nor is there any great quantity that may properly be called clay. The best soil is upon the hills; and the worst, or nearest approaching to the clay or cold lands, in the vallies; though there are many exceptions to this rule. The soil, or what the farmers generally call mould, is generally deep, which makes it very proper for grass; such deep soils not being very soon affected by dry weather. About Lutterworth, some part is a light rich loam, excellent for turnips and barley; a part light loam, inclining to marle, or rich clay; the remainder, chiefly a fort of medium between both, with a subsoil inclining to marle, bearing excellent crops of oats and wheat, and good turnips also, though not so well adapted for being eat off the land by sheep. Most of the land round Hinckley is a good mixed soil, bearing good crops of grass. Abhystead-la-Zouch, and the northern parts of the county, exhibit various soils, sand, gravel, loam, and clay. In Melton Mowbray the soil is in general a heavy loam; and immediately underneath a very stiff impervious clay, mixed with small pieces of lime-stone. These lands are very wet in winter, and the turf so tender, as scarcely to be able to bear the treading of sheep, without injury. At Market Harborough the soil is in general a very strong clay, chiefly in gramps. Since the commencement of the last century, cheese has become an article of some importance to the Leicestershire farmers; and a large cheese-fair is annually held in the county-town. Among the different sorts manufactured in the county, that called Stilton chese is deemed the finest; and consequently obtains the highest price. It acquired the title of Stilton from a place of that name, on the great North road in Huntingdonshire, where it is well known to have been first publicly sold by retail. This cheese is sometimes called the Parmesan of England, and is usually formed in square vats. The cheese feldom weigh more than twelve

pounds each, and from that to fix pounds is the general average weight. They are sometimes moulded in nets, but this mode is not deemed so eligible as that of the vat. A considerable quantity of this cheese is made on the farms about Melton Mowbray.

Leicestshire is described by Mr. Marshall, in his "Rural Economy," as a very fertile district; and the only parts which are not absolutely in good cultivation, are Charnwood-Forell, also a tract of land in the northern part of the county, called the Wolds or Woules, and another similar tract on the southern side. Nichols's History and Antiquities of Leicestshire, 7 vols. folio.

LEIDENSDORT, a town of Bohemia, in the circle of Leitmeritz; 20 miles W. of Leitmeritz.

LEJEUNE, in Biography. See CLAUDE.

LEIGE. See LIEGE.

LEIGH, Sir Edward, in Biography, was born at Shadwell, in Leicestershire, in the year 1602. He received the rudiments of learning at Walsall, in Staffordshire, and in 1616 was entered a commoner of Magdalen-hall, in the university of Oxford. From the university, he went to study the common law in the Middle Temple. When the plague broke out in 1625, he went into France for a short time, and returning thence, he applied himself most sedulously to his studies, which comprised not only the law, but divinity, history, and the learned languages. During the civil wars he was chosen member of parliament for the town of Stafford, and was one of the perfons appointed to fit in the assembly of divines. He was greatly distinguished for the talents and learning which he displayed in the debates of that assembly. In the year 1648, when the Presbyterian party was excluded from the house by the army, he was in the number of proscribed members, and was for some time kept in confinement. From the period of his liberation till the reformation, he chiefly employed himself in prosecuting his literary studies, and in publishing various works, which discover profound erudition and general knowledge. He died in 1671, at the age of 69. He was author of "Selected and choice Observations concerning the twelve Cæsars;" "Analefia Cæfarum Romanorum;" "A Treatife of divine Promifes;" "Critica Sacra," in 2 vols. 4to; "Annotations on all the Books of the New Teftament;" "A Philological Commentary, or an Illuftration of the moft obvious and useful Words in the Law;" "A System of Divinity;" "Annotations on five poetical Books of the Old Teftament, viz. Job, Psalms, Proverbs, Eccle- fiafies, and Cafticles;" "Choice Observations on all the Kings of England, from the Saxons to the Death of King Charles I." Gen. Biog.

LEIGH, Wyl, in Geography, a market town in the hundred of Wilt Derby, Lancashire, England, is situated six miles from Wigan, and 198 from London. The church
is a handsome structure, with a square tower; the body being supported by two rows of pillars. Leigh has a considerable manufacture of suti and other cotton stuffs; and by its canal navigation, which communicates with the rivers Mersey, Dee, Ribble, Ouse, Severn, Humber, Thames, Avon, &c. it carries on an extensive traffic. Coals are abundant; and the dairies round the town produce excellent cheese.

The town, according to the official report in 1801, contained 277 houses, and 1429 inhabitants. A weekly market is held on Saturdays; and a fair on the 26th of April. The parish is of great extent, and contains the townships of Attley, Bedford, Pennington, and Tyldefley, the hamlet of Shackefelley, and the chapelry of Chobwent, inhabited altogether by nearly 13,000 persons.

The chapelry of Chobwent has greatly increased in houses and population within the last 20 years. Its chapel, though regularly consecrated by the bishop of Sodor and Man, is exempt from episcopal jurisdiction, and the patronage is vested in the proprietor of Atherton Hall, which formerly was the seat of a family of that name, but is now the property of the Hon. T. Powis. The house, which was built by Gibbs, is large, and has a spacious cubical entrance hall. A plan of this mansion is given in the "Vitruvius Britannicus.""

The township of Tyldefley has grown up with the manufactures of the county. A family of that name was seated here so early as the reign of Henry III. Of this family was Sir Thomas Tyldefley, who signalized himself during the troubles of Charles I.'s reign, and fell in the battle of Wigan lane, Aug. 25, 1550. He was buried in Leigh church; and on a pillar near Wigan is fixed a brass plate, with an inscription to perpetuate his memory.

Leigh's Island. See Cocoa-nut Island.

Leighlin, a bishopric of Ireland, in the province of Dublin, founded in 632, and united with Ferns in 1603. The united bishopric comprises the whole counties of Carlow and Wexford, with part of the Queen's county, Wicklow, and Kilkenny. There are 232 parishes in the union, forming 79 benefices, in which are 71 churches and 26 glebe houses. The cathedrals are small, and serve for parish churches. The residence of the bishop is at Ferns.

Leighlin, Old, a village of Ireland, near the river Barrow, and in the county of Carlow, 2½ miles W. by N. from Leighlin bridge. It was incorporated in the year 1216, and continued to send members to parliament till the Union; and is still the seat of the cathedral church of the diocese.

Leighlin Bridge, a post-town of Ireland, in the county of Carlow, on the river Barrow, over which it has a bridge, first built in the year 1520. It originated in a monastery, which, on the suppression of religious houses, was converted into a fort to protect the bridge; and lately, on account of the navigation of the Barrow, it has considerably increased, being now a thriving town. It is 45 miles S.S.W. from Dublin, on the Great Southern road, and 6 miles from Carlow.

Leighton, Alexander, in Biography, a Scotch presbyterian divine, was born at Edinburgh in 1587. He became noted for the sufferings which he endured in the reign of Charles I., on account of a work which he published, entitled "An Appeal to the Parliament; or Zion's Plea against Pre-acy." For this he was tried in the high-commission court, and being convicted, which, in those days, and in that court, was but another term for being accused, he was condemned to be imprisoned for life, and pay a fine of 10,000l: he was to be set in the pillory twice, and to be whipt, have one of his ears cut off, one of his fingers cut off, and be branded in the face with a double S.S. as a tower of sedition. When this savage sentence was passed on him, the cruel Laud exhibited signs of the most indelent joy, and publicly gave God thanks for it. Excepting the imprisonment for life, and the fine, the sentence was put into execution to the full extent. He was released by the Long Parliament after an imprisonment of ten years. His confinement and cruel usage had ho impaired his health, that when he was released he had scarcely the power of walking, or seeing, or hearing. As a sort of remuneration for his troubles the parliament appointed him keeper of Lambeth palace, at that time converted into a prison. He died in 1644, infane. Tolman's Neale's Hist. vol. ii.

Leighton, Robert, a Scotch prelate in the seventeenth century, was son of the preceding. He was educated in Scotland, where he distinguished himself above his contemporaries, in all the branches of useful learning, particularly in the study of the scriptures. Having finished his course of academical studies he went to the continent for improvement, and spent some years in France. On his return he obtained Presbyterian ordination, and was chosen to a congregation at Newbottle, near Edinburgh. Very soon after his settlement at this place he conceived a dislike to the Presbyterian form and manner of church discipline, and chose rather a life of retirement than to attend at the presbytery. His main object was to instruct his flock in the principles and duties of religion and morality, urging them not to trouble themselves with religious and political disputes. In the year 1648, he declared himself for the engagement for the king, on account of which he would have exposed himself to much trouble, had not the earl of Lothian, who lived in his parish, proved his friend, and prevailed with the men in power not to molest him. At length, finding that he could no longer submit to the ecclesiastical impositions of the Presbyterians, and being unwilling to live in strife and contention, he resigned his parish in silence, and withdrew into retirement. Shortly after, he was chosen principal of the college of Edinburgh, the duties of which office he performed with great reputation during ten years. Upon the restoration, when it was determined to establish episcopacy in Scotland, Leighton was fixed on as a proper person for the mitre. He was consecrated, with other bishops, at Wemminster; he would now gladly have promoted some plan for uniting the Presbyterians and Episcopatians, but was thwarted in all views on this subject. When he found that the government was determined to enforce conformity on the Presbyterians by the most rigorous measures, he laboured with all zeal to shew the impolicy of such proceedings: but he struggled ineffectually against the current, and all that he could do was to practise in his own diocese, the moderation which he had recommended generally, and to set an edifying example to the rest of his dignified brethren. Thence, however, profited but little either from his advice or from the exemplary conduct which he manifested. He remonstrated with the king respecting the arbitrary proceedings of the ecclesiastical high-commission court, and more lenient measures were promised to be pursued with respect to Scotland. He begged permission to resign his see; but the king, so far from listening to the prayer of his petition, urged him to accept of the diocese of Glasgow, which was a more important bishopric, and one in which he might be more useful. To induce him to accept of this preterest, he was promised the affiance of the court in bringing about his favourite scheme of a comprehension of the Presbyterians. He accepted the fee, but after a short time found himself
himself wholly unable to carry on his great designs of healing the divisions, and reforming the abuses in the church, and begged permission to retire into private life, which was at length granted him. He went to live in Suffolk, where he occupied himself in doing all the good in his power. He died in 1684, at about the age of eighty. He was author of "Prelaciones Theologicae:" "A Commentary on the first and second Chapters of the first Epistle of St. Peter;" and of "Sermons," including other pieces: to the volume of sermons, published in 1758, is prefixed a life of the author, to which the reader is referred for ample particulars of this excellent divine.

LEIGHTON, Sir William, knight, one of the honourable penitentiaries, who seems to have been a dilettante of considerable erudition in music; he published, in 1614, "The Tears or Lamentations of a Forrowful Soul," composed with musical airs and fongs, both for voices and divers instruments. The bell composers of the time contributed to this publication. See LAMENTATIONS.

LEIGHTON-Buzzard, or Beaudesert, in Geography, a market town and parish in the hundred of Manheath and county of Bedford, England, is situated on the banks of the river Oue. 41 miles from London, and contained, according to the return made in 1800 to parliament, 357 houses and 1963 inhabitants, of whom 1014 were rated to be employed in trades and manufactures. The market, which is held on Tuesdays, is one of the most ancient in the county; the tolls were valued at 7l. per annum at the time of the Norman survey. Here are six annual fairs, of which two were granted in the year 1447. The principal antiquity in the town is a beautiful pentangular cross, built of stone, and situated in an open area near the market-house: it is supposed to have been erected about the beginning of the fourteenth century. It consists of two stories; and the whole height is thirty-eight feet. (For a particular description, with an engraving, see Britton's Architectural Antiquities of Great Britain, vol. i.) The church is a large antique building, which, from the various grotesque carvings, appears to have been built about the same time as the cross; and is consecrated with the same font of stone. It has a square tower, surmounted by a spire, the whole being 192 feet in height. A priory of foreign monks was established in the reign of Henry II at a place called Grovebury, within this parish: and here was also a house of Cisterian monks, which was a cell to Woburn abbey. About half a mile from the town are the remains of a Roman encampment; from which, and other corroborating circumstances, Leighton-Buzzard is supposed to be the Lygneburg of the Saxon Chronicle, which, with several more towns, was taken by the Britons from the Northumbrians and inhabited by them, A.D. 571. Lyofon's Magna Britannia, vol. i. p. 400.

LEIN, or LEINE, a river of Germany, which runs into the Neiße, 4 miles N. of Gotha. LEINEIN Zen, a town of Prussia, in the principality of Culin; 9 miles E. of Thorn.

LEININGEN, or LINANGE, lately a county of Germany, bordering on the bishoprics of Worms and Strie, and almost surrounded by the palatinate. The soil is fertile in corn, fruit, and wine; the forest abounds with game, and it has also mines of copper and iron, and quarries of stone. By the peace of Lunyville it was annexed to France.

LEININGEN, a town of France, in the department of Mont Perrier, the castle of which was demolished by the French; 11 miles S.W. of Worms. N. lat. 49° 30'. E. long. 8° 4'.

LEINLETTER, a town of Bavaria; 10 miles S.E. of Bamberg.

LEINSTER, the eastern province of Ireland, comprising twelve counties, viz. Louth, Dublin, Wicklow, and Wexford on the sea-coast; Meath, Westmeath, Longford, King's county, Queen's county, Kildare, Carlow, and Kilkenny. This was originally one of the kingdoms into which Ireland was divided at the time of the English invasion, and it was the sovereign of it which facilitated the conquest by soliciting aid from Henry II and giving his daughter in marriage to earl Strongbow. The English pale was entirely within this province, and it is, on the whole, that which is most populous and best cultivated.

LEIOBATUS, in Ichthyology, a name given by Aristotle and Athenaeus to a species of the ray-fish, called by many of the old authors "bass marinus," and by the later authors "laurarae," or "raia oxygynus;" which see.

LEIOPODES, formed of λίος, light, and πεδα, foot; an epithet used by the old medical writers to express such persons who had feet perfectly smooth and even at the bottom, without the usual hollow between the heel and the fore part of the foot.

LEIPHEIM, in Geography, a town of Bavaria, in the territory of Ulm, on the S. side of the Danube; 11 miles N.E. of Ulm.

LEIPNIK, a town of Moravia, in the circle of Preuza; 6 miles N.E. of Preuza. N. lat. 49° 28'. E. long. 17° 37'.

LEIPPODERMOS, from λεπτα, to be deficient, and δέρμα, the skin, one who has lost the prepuce.

LEIPSICK, or LEIPZIG, in Geography, a city of Saxony, and capital of a circle of the same name. This is one of the most celebrated towns in Germany, pleasantly situated in a fertile plain, on the river Pleisse. Its circuit is estimated at 8654 paces; and its suburbs are extensive, and consist of good buildings and gardens, being separated from the town by a fine walk of lime trees, which runs round the town, and in the town ditches are planted mulberry trees. Its university, which is famous, was founded in 1409, and contains six colleges, two good Latin schools, and two celebrated societies, viz. a German society, and another for the encouragement of the liberal arts. Leipzick is one of the principal trading towns in Germany, and it is in a peculiar degree the mart of German literature. Besides its foreign commerce, it has three celebrated fairs, at Easter, Michaelmas, and the beginning of the year, at which foreign and domestic wares afford an extensive trade. It has also a differing privilege, confiding in the right of having all staple commodities, imported within the circuit of 60 miles, laden here, and at lawful for three days offered for sale to the burghers of the place, and then carried away without being unladen any where else. In the citadel, called Pleißenburg, situated on the Pleisse, are a mint, founded in 1752.
LEI 1752; and a chapel for the Roman Catholic worship. The market place, which is spacious, and the council-house, stand in the centre of the town. The exchange is a good building, and the roof of its hall is well painted. The city contains eight parish churches for Lutherans, and also a place of worship for Calvinists. The manufactures are various; consisting of gilt, silver, flax, wool, and linen yarn, which are wrought here; and also of stuffs, velvets, stockings, cloths, and linen. Here are also honies for the dyeing of flax, the printing of cotton, and the making of tapestry. Leather, Prussian blue, &c. are prepared here, and the Orphan-house is appropriated to the culture of flax.

In Leipsic are suppos'd to be 20 book-fellers, 50 French and Italian merchants and tradesmen, 50,000 wholesale dealers, 250 retailers, and many dealers in cloth. According to Dithmar, in his Chronicle, this place subsisted, as a town, as long ago as the year 1015. The circle of Leipsic contains 33 towns, and more than 1000 villages. The city is 56 miles W.N.W. of Dresden. N. lat. 51° 13'. E. long. 12° 19'.

Leipsic, as well as Dresden and the whole of Saxony, keep accounts in six-dollars of 24 good groschen; each groschen being divided into 12 pennings current. A special rix-dollar is reckoned at 15 rix-dollar current, or 32 good groschen. For the coins, see SAXONY. Bills of exchange are paid at Leipsic, since 1786, in Saxon currency, or in August d'ors, Carl d'ors, Fredericks, &c. reckoned at rix-dollars. The time of payment of bills of exchange, presented for acceptance during the four first days of the fair, is during the five first days after the close of the fair is proclaimed; in default of which the bills must be presented before 10 o'clock at night, or the drawer is not liable.

During the fair, when Dresden was in its glory, serious operas were frequently performed at Leipsic by the best musicians, vocal and instrumental; and to the greatest personages in Germany. In 1774, the comic operas of M. Hiller, in the language of the country and without recitative, were the favourite amusements of that flourishing city. Every part of Europe, except Italy, seems unanimous in bannishing recitative from their comic operas, indeed every nation has melodies of its own; but there is no recitative, except the Italian, which is fit for dramatic purposes.

LEISZNIG, a town of Saxony, in the circle of Leipsic, on the Mulda, containing two churches, and having manufactures of cloth, lace, stockings, &c. It has a citadel, called Mildenstein; 24 miles E.S.E. of Leipsic. N. lat. 51° 7'. E. long. 12° 50'.

LEITÂ, or LEVTHA, a river that rifes in the S.W. part of Austria, and joins the Raab at Raab in Hungary; and afterwards, the united stream runs into a branch of the Danube; nine miles W. of Comorn.

LEITH, a sea-port town and burgh of barony, situated on the Frith of Forth, in the county of Midlothian, Scotland. It is about two miles distant from Edinburgh, and may not improperly be called the harbour of that northern metropolis. This town was originally denominated Inverleith; the word inner, prefixed to the name of a river, being a frequent appellation in Scotland, and implies a town near the mouth of that river, or its confluence with another. The etymology of this term is very uncertain, some alleging it to be of French, and others of Gaelic derivation.

The period at which Leith was first founded is unknown, but it is undoubtedly a place of great antiquity. It is mentioned by the name of Inverleith in the charter for erecting the abbey of Holyrood, which was built by David I. in the year 1128. About a century afterwards the harbour of Leith and its mills were granted to the magistrates of Edinburgh by Robert I., and in 1568 they acquired all the other rights and privileges of it, with the exception of the superiority from Logan of Reifalrig. Mary of Guise, queen regent of Scotland, constituted this town a burgh of barony in the year 1549. At this time the inhabitants of Leith were divided into four classes, or corporations; the mariners, maltmen, tradesmen, and traffickers, each of which will retain its original charters. In the same reign, the citizens purchased the superiority of their town from the descendants of Logan, but after the death of the queen, Francis and Mary, in violation of the private rights of the people, sold the superiority of the burgh to the magistrates of Edinburgh, to whom it has since been confirmed by several successive charters. Leith suffered considerably when the earl of Hartford invaded Scotland in the year 1541, being on that occasion pillaged and burnt by the English soldiers. After this, however, Leith was rebuilt and fortified anew, but soon after the expulsion of the French in 1560, the council of the kingdom, to prevent the danger arising to the liberties of the country, from the introduction of foreign troops, ordered the fortifications to be demolished. Oliver Cromwell once more raised fortifications for its defence. The citadel, which still remains, was built by that usurper. It then consisted of five bastions, but two of them were entirely demolished at the restoration of the English monarchy, and the site of the whole given to the duke of Lauderdale, then prime minister for Scotland, from whom the magistrates of Edinburgh were compelled to purchase it, at the enormous sum of 6000l. sterling. Since the alarm, excited by the appearance of Paul Jones in the Frith of Forth, a battery of nine guns has been erected a little to the westward of the citadel, for the defence of the port and shipping. A party of artillery constantly reside at this battery, which is kept in excellent order; and of late a considerable park of artillery has likewise been stationed here.

Leith is divided into two parishes by the river from which it derives its name. These are distinguished by the appellations of North and South Leith, and communicate with each other by means of two drawbridges, one of which has been very lately erected. The greater part of the town is situated in the parish of South Leith, which also extends over a considerable country district, and includes the ancient parish of Reifalrig. North Leith is a much smaller parish, and consists of only about 170 acres. Both on the south and north side of the river, the streets of this town are extremely irregular, and of mean appearance. In the suburbs of South Leith, however, a number of respectable houses have been erected by the more opulent merchants, and may be said to vie, in internal accommodation and exterior appearance, with those of Edinburgh.

Prior to the year 1721, Leith was ill supplied with water, and the streets were neither properly cleaned nor lighted; in that year, however, an act of parliament was obtained to remedy these defects; and the great change which has taken place since that period shews the good effect of the act, and that it had been judiciously prepared and was carefully executed. At Reifalrig are still extant some ruins of the old or mother church. This place is about a mile eastward of Edinburgh. The church was founded by king James III., and endowed by the three succeeding monarchs. It was highly ornamented with statuary and sculpture, representing many objects of religious worship. In 1650, the general assembly, in their zeal against Popery, ordered this church, as a monument of idolatry, to be pulled down and entirely demolished. In consequence of this mandate, the inhabitants of South Leith...
Leith reforted for divine worship to the chapel of St. Mary, which was afterwards declared by authority of parliament to be the parish church of the district. It is a handsome spacious building; but being found insufficient to contain the inhabitants, a chapel of ease was erected in 1772. Here is also an episcopal chapel; and, as in all towns of any consequence in Scotland, some meetings of Presbyterian dissenters.

The civil government of Leith is vested in a magistrature sent from Edinburgh, having the power and title of admiral of Leith, and in two saluting bailiffs, who are elected from the inhabitants of Leith by the town-council of Edinburgh.

The harbour of Leith, which is the chief source of wealth to the place, is formed by the conflux of the water of Leith with the sea. The depth of the water at the mouth of the harbour is at neap tides about nine feet, but in high spring tides about fifteen. It is entirely a tide harbour; the water in the river being too trifling to give any important aid towards the navigation. About the beginning of the last century, the magistrates of Edinburgh improved the harbour at a great expense, by extending a stone pier to a considerable distance into the sea. In the year 1777, they further improved it by erecting an additional stone quay towards its west side. It is accommodated with wet and dry docks, and other conveniences for ship-building; which is carried on to a considerable extent; and vessels come hither to be repaired from various parts of the eastern coast of Scotland. It has been thought advantageous to extend the harbour further into North Leith; and very considerable works are now carrying on for that purpose; which, when completed, will render it a very commodious, as well as a safe and convenient station for trading vessels of almost any burthen. Ships, indeed, can only enter at full tide; but the roads of Leith, which are about a mile from the mouth of the harbour, afford most excellent anchorage at all times.

Leith carries on a very considerable trade; the imports from the southern parts of Europe are wines, brandy, and fruits; from the West Indies and America, rice, sugars, rum, and dye-stuffs; but the principal traffic is with the Baltic, for which it is peculiarly well situated. The shipping of Leith causes a great demand for ropes and sail-cloth; of which articles here are several manufacturing companies. Two glas manufactories are established here, which, in the year 1790, wrought above nine million pounds weight of that article. The manufactures of soap and candles are also carried on to a very great extent; here are also a considerable carpet manufactory, and several iron forges. In 1784, the trade of Leith was estimated at half a million sterling, exclusive of glas-works and ship-building; and there is every reason to believe that, since that period, the amount has been doubled. In the year 1791 the population of North Leith was 2409, and of South Leith 11,422; total 13,841, which was an increase of 4436 since the year 1755. Beauties of Scotland, vol. i. Picture of Edinburgh.

Leith Water, a river of Scotland, which runs into the Firth at Leith.

Leithen, a river of Scotland, which runs into the Tweed at Inverleithen.

Leitmeritz, a city of Bohemia, in a circle of the same name, seated on the Elbe, well built, and populous; the see of a bishop, suffragan of Prague.

The circle, distinguished by its beauty and fertility, is called the "Bohemian Paradise;" and, independently of its own resources, it has ample supplies, by means of the Elbe, from other countries. It is famous for the wines, produced near Aufl, and called "Podhalsky," and for the fulubrious mineral waters of Topolitz. In this circle, which comprehends 89 liegnories, castles, and fees, are tin and precious stones; 28 miles N.N.W. of Prague. N. lat. 50° 31'. E. long. 14° 15'.

Leitrim, a county of Ireland, in the province of Connought, which is bounded on the north by Donegal and Fermanagh; on the east by Cavan; on the south by Cavan, Longford, and Roscommon, and on the west by Sligo. In form somewhat like an hour-glass, it varies greatly in breadth, being in the widest parts 16, and in the narrowest only six miles across. Its length is 41 Irish, or 52 English miles. It contains 155,950 acres, or about 400 square miles (407,260 acres, or 652 square miles in English measure.) The parishes are 17 in number, partly in the diocese of Kilmore, and partly in that of Ardagh. There are very few unions, and a church in almost every parish. When Dr. Beaufort wrote, the number of houses was rated at 10,026, from which he estimated the population at upwards of 59,000; but Mr. Robertson in 1806, on what authority he has not stated, rates it at 76,070. Of the five baronies into which Leitrim is divided, the two northern are not as populous as the other three. Towards the sea there is an alliance of wild and lofty mountains, which are divided from one another by deep valleys. These are the mountains of Sliebahaneew or Dartry, the latter of which towers to an immense height above the level of the sea. Near the interior, the immense Sliebh an-Erin divides the mountainous from the level parts of the country. These great hills are far from unprofitable, for producing abundance of coarse grasses, they annually pour forth immense droves of young cattle. The southern baronies are level. Few counties are so plentifully watered as this. The Shannon rises in a plain at the base of Quilac ac, forming Lough Clean, a small lake, which is considered as the fountain of that noble river; from this it flows to Lough Allen, nearly in the centre of the county, which is 7 miles long and about 30 in circumference; and then, curling in a variety of forms, it glides by Carrick on Shannon, where it leaves the county, taking a southern direction. There are several other lakes and small streams, which are stocked with trout, pike, eel, perch, and bream. The natural wants of this county seem abundantly outweighed by its numerous minerals. Iron ore is contained in great quantities in the high grounds. Deep and rich beds of it are also found on the lower grounds; and a vigorous search would undoubtedly discover it in almost every situation. Copper and lead are also met with, but not in such quantities. Coal in deep and rich strata is visible in many places. A variety of clays and plenty of limelight gravel are likewise found. The soil is exceedingly diversified. A rich dark soil on a limestone bottom, a ferruginous loam on the mountains, and an argillaceous stratum, are its chief characteristics. Great quantities of bog and moor tend to interrupt the general fertility of the county. The mode of agriculture adopted by the farmers is injudicious in many particulars. Potatoes, barley, rye, and wheat, are reared in small quantities; oats in abundance for home consumption. A considerable portion of the land is paiturate. The farms are small, and generally occupied in common by a number of tenantry. Draining is greatly neglected. Manufactures are rapidly improving, particularly that of linen. There are several bleach-greens. Pottery is numerous about Leitrim and Drumahare. The traveller who is anxious for variety, will no where find it in greater perfection than in Leitrim. Extensive tracts of waste may be contrasted with rich lands. The uniform and regular improvements of art are lost in the wild grandeur of picturesque natural disorder. The dale is frequently terminated by the stupendous moun-
tain, and the beauties of the rich luxuriant woods on the
demesnes, are enriched by the vicinity of beautiful fleets of
water. Near a century ago, the county was a continued
forested. Immense heaps of charred timber are seen at Drom-
shambó. A considerable time ago, great exertions were
made to plant woods, and it now abounds with almost every
variety which the nursery can afford. No town of any size
ornaments the county. Carrick on Shannon is the faire
town, but does not contain above 100 houses.

"The obstructions," says Mr. Robertson, "which have so
long retarded the improvement of Leitrim, have been occa-
sioned by the inhabitants, not by nature; she has made
ample store for the exertions of their industry, by bestowing
on them valuable minerals. Thence, however, have not been
wrought with sufficient activity, and the public have as yet
received little benefit from them. The want of water-
carriage has likewise had a great effect; but this promises
to be speedily obviated. Palturage being pursued to a
considerable extent, has in a great degree impeded the general
improvement. The consequent want of population has re-
tarded the cultivation of the bog and other waste land.
But when the true interest of the people shall be sufficiently
understood, the minerals will be wrought, palturage will be
supplanted by tillage, the bogs and moors will be covered
with luxuriant crops, and in the end Leitrim will become
one of the most wealthy counties in Ireland." Beaufort's
Memoir; Robertson's Traveller's Guide.

LEITRIM, a small town of Ireland, which gives name to
the county, but is not considerable enough to be a poft-
town. It is three miles N. by E. from Carrick on Shannon,
and situated on the river Shannon.

LEITSHACH, a town of the duchy of Stiria; 13 miles
N.W. of Marburg.

LEITURGI, Anologion, among the Athenians, persons of
considerable estates; who, by their own tribe, or the whole
people, were ordered to perform some public duty, or supply
the commonwealth with necessaries at their own ex-
penes.

LEITZKO, in Geography, a town of the Middle Mark
of Brandenburg, infaluted in the duchy of Magdeborg; 14
miles E.S.E. of Magdeborg.

LEIXLIP, a poft-town of the county of Kildare, Ire-
land. It is beautifully situated on the banks of the river
Liffey, and near it is a fine waterfall, called the Salmon
Leap. It is eight miles W. from Dublin.

LEKÉO, one of the Japan islands, about 120 miles in
circumference; 20 miles S. of Ximo. N. lat. 31° 20'. E.
long. 152° 40'.

LEKINPOUR, a town of Hindooftan, in the circar of
Cattack; 12 miles N.E. of Cattack.

LEKNO, a town of the duchy of Warsaw; 28 miles
N.N.W. of Gnefina.

LEKSEND, a town of Sweden, in Dalarlilia; 20 miles
N.W. of Falun.

LELAND, John, in Biography, was born in London
about the end of Henry VIIIth's reign, and was educated at
St. Paul's school, under William Lily, from whom he was
sent to Chirih's college, Cambridge. He removed from this
university to All-soul's, Oxford; and for further improve-
ment, especially in the Greek language, he went to Paris,
cultivated an acquaintance with the principal scholars of the
age, and acquired a knowledge of several modern languages.
Upon his return he took orders, and was appointed one of
Henry VIIIth's chaplains. The King conferred upon him
the office of keeper of his library, and gave him the title of
royal antiquary, which no other person in this kingdom be-
fore or after possessed. To the title was annexed a commis-
fion, empowering him to search after all objects of antiquity
in the libraries of all cathedrals, abbeys, priories, colleges,
&c. He spent much time in travelling through England;
and in visiting all the remains of ancient buildings and mo-
ments of every kind, with the view of collecting every
thing that could illustrate the history and antiquities of this
nation. At the dissolution of the monasteries he made ap-
lication to secretary Cromwell to get the MSS. which they
contained conveyed to the king's library. He obtained
considerable preferment in the church, the duties of which
he did not require much active service; he accordingly retired
with his collections to his house in London, for the purpo-
se of digesting them and preparing the publications he had pro-
mised the world; but not being able to plan such great
undertaking, he sent some parts of his MSS. to the king's
library, and was allowed to make a careful survey of
many other MSS. which he never recovered. He died in
1572. During his life, he published several Latin poems,
and some tracts on antiquarian subjects. His MS. collec-
tions, after passing through many hands, came into the Bod-
leian library, furnishing very valuable materials to Camden,
Dugdale, Burton, and others. After his decease in 1580,
a volume of his small Latin poems was published by Mr.
Thomas Newton of Chefield, under the title of "Princi-
pum et illitterum aliquot et eruditorum in Anglia vironum
Encymice." From his collections, Anthony Hall published,
in 1709, "Commentarii de Scriptoribus Britannice." "The
Itinerary of John Leland, the Antiquary," was pub-
blished by Hearne at Oxford, in nine vols. 8vo. The same
editor published "Joannis Lelandi Antiquarii de rebus

LELAND, John, a dissenting minister, was born at Wigan,
in Lancashire, in the year 1691. While he was very young
his father removed with his family to Dublin, where the son
was feized with the small-pox of so malignant a nature, that
it entirely deprived him of his understanding and memory.
In this melancholy condition he remained twelve months,
but after his recovery, he recommended himself to much
notice by the quickness of his parts, and by the proficiency
which he made in his learning. He was therefore educated
for the Christian ministry among the Dissenters; and was,
in due time, invited to become joint-pastor with the Rev.
Mr. Weld, to which office he was ordained in 1716. He
first appeared as an author in 1733, by publishing "An
Answer to a late Book, entitled 'Christianity as old as the
Creation &c.' in two volumes." In 1737, he embarked in
a controversy with Dr. Morgan, by publishing "The Di-
vine Authority of the Old and New Testament affording
against the unjust Aperitions and false Reasonings of a Book,
titled The Moral Philosopher." The learning and abili-
ties displayed by Mr. Leland in these publications, and the
service which he rendered by them to the Christian cause,
procured him many marks of respect and esteem from per-
sons of the highest rank in the established church, as well as
from the most eminent of his dissenting brethren; and from
the university of Aberdeen he received, in the most honour-
able manner, the degree of doctor of divinity. In the year
1742, Dr. Leland published an answer to a pamphlet, en-
titled "Christianity not founded on Argument!" and in
1753, he distinguished himself still further as an advocate in
behalf of Christianity, by publishing "Reflections on the
late Lord Bolingbroke's Letters on the Study and Use of
Hilory; especially far as they relate to Christianity and the
Holy Scriptures." Dr. Leland was now fully con-
firmed in a matter in this branch of controversy, and at the
request of some valuable friends he sent to the press, in 1754.
"A View of the principal deistical Writers that have ap-
peared in England, in the last and present Century, with Ob-
fervations,
LEL, the design of this work was to give some idea of the productions of the delitful writers, and of the several schemes which they have advanced, as far as the canse of revealed religion is concerned. In this work, the author ably maintained the reputation which he had acquired by his former productions, and met with a very favourable reception. He afterwards published a supplement relating to the works of Mr. Hume and lord Bolingbroke, and this was followed by a third volume, comprehending the author's additions and illustrations, with a new edition of his "Reflections upon Lord Bolingbroke's Letters, &c." The whole of this work is now comprized in three volumes; it secured the author general public approbation, and encouraged him to continue his exertions to a very advanced age. Accordingly, when he was upwards of seventy years old he published, in two volumes 4to, "The Advantage and Necessity of the Christian Revelation, shewn from the State of Religion in the ancient heathen World, especially with respect to the Knowledge and Worship of the one true God; a Rule of moral Duty, and a State of future Rewards and Punishments, &c." This work was afterwards reprinted in two volumes, 8vo. Dr. Leland died in his seventy-fifth year, on the 16th of January 1766; he was distinguished by considerable abilities, and very extensive learning; he had a memory so tenacious, that he was often called the "walking library." After his death a collection of his sermons was published in four volumes octavo, with a preface containing some account of the life, character, and writings of the author, to which our readers are referred for farther information respecting him.

LELAND, Dr. Thomas, a divine of the church of England, was born at Dublin about the year 1702. Having received the elements of a good education, he was admitted a student, and afterwards became fellow of Trinity College, Dublin. He was author of "A History of Ireland," 4to.; "The Life of Philip of Macedon;" and "The Principles of human Eloquence." He also translated the orations of Demosthenes, in two volumes, 8vo., which came out separately, and were well received by the public. Dr. Leland died in 1755, at the age of eighty-three.

LELCA, in Geography, a town of Ruffian Poland, in the palatinate of Volhynia; 60 miles N. of Zytomiers.

LELEES, in Ancient Geography, a collection of people from different nations, as the supposed etymology of their name, derived from λήγε, I assemble, importus. They anciently occupied the territory adjoining to that of the people called by Homer Cilices or Ciliaces; and when Achilles ravaged their country, which lay north-west of the gulf of Adrarmando, they passed over into Caria, and took possession of the environs of Halcarminus. Their town was the metropolis of Caria, near Myra. They were a kind of robbers and vagabonds, who resembled the Cilicians in their disposition and manners. The first king of Laocoon, according to Paufanias, was Leles; and the country took the name of Lelegia from these people.

LELIAN, in Geography, a town on the north coast of the island of Bouro.

LELIAT PATTAN. See Pattan.

LELOW, a town of Autfrian Poland, in the palatinate of Cracow; 32 miles N.W. of Cracow.

LELUND, a river of Africa, which joins the Zaire, about 60 miles from its mouth.—Also, a town of Africa, in the kingdom of Congo, on the fore-mentioned river; 35 miles E. of St. Salvador.

LEY, Sir Peter, in Biography, the most excellent portrait-painter this country possessed, after the death of Vandyke. Many of his works continue to be held in most deferred estimation, and to be ranked amongst the clusses of the arts. He was born at Swall, in Welphalia, in 1617. His family name was Vander Van; but from the circumstance of his father, who was a captain of foot, being born in a performer's shop, whose sign was a lily, and receiving the appellation of captain Du Lys, or Lely, our artist obtained it as a proper name.

He was first instructed in the art by Peter Grebber at Haerlem; and having acquired a knowledge of its principles, and a very considerable degree of skill in execution, he came to England in 1644, and commenced portrait-painter. After the kingdom had sustained the irreparable loss of Vandyke, and the restoration was completed, he was appointed state-painter to Charles II., and continued to hold that office with great reputation till his death, which happened in 1680. He was seized by an apoplexy, while painting a portrait of the duchess of Somerset, and died instantly, at the age of sixty-three.

Though Lely's talents, as an artist, do not entitle him to hold a rank equal to that filled by his great predecessor; yet they justly claim very great respect and admiration. He fell short of Vandyke in two very essential parts of portraiture, viz. taste and expression. Of the former it must be acknowledged that he sometimes caught a glimpse; and, in the dispositions of a piece of loose drapery, exhibited it with an enchanting style: but that high clafs of taste, which evidently sways the artist's mind who arranges, without apparent study, all the parts of a composition in an agreeable and effective manner, he does not appear ever to have felt or understood. It is in parts only that he was greater; in the ringlets of the hair, for instance; seldom in the actions of his figures, and scarcely ever in the tout-ensemble of his pictures. As to the expression of his portraits, it is almost entirely described, at least in those of his females, by what the poet has said, that he

"- on animated canvas heeole
The sleepy eye that spoke the melting soul."

The consequence is, that individual expression, the very essence of portrait-painting, is lost sight of; and a certain air of general resemblance is seen in them all. Yet in spite of these great deficiencies, Lely's pictures, by the matter of his execution, and his skill of imitation, where he pleased to employ it, will ever command admiration. He poifessed the art of flattery more than most artists; and no doubt by that secured the approbation of his contemporaries, and consequently great practice. He painted drapery in a flyle peculiarly his own, with great richness and fulness of effect; and he understood fully the union of folds, though he did not always dispose them in just or agreeable shapes. His pencil is broad and full, and the markings of forms and features are free and decided in his pictures, which are to be found in almost every noble mansion in the kingdom; so great were the encouragement and employment he enjoyed.

By it he acquired a very considerable fortune, of which he employed a large portion to furnish himself with a collection of pictures and drawings. These, at his death, were sold by auction, and were so numerous, that forty days were consumed in the sale; and the product amounted to 26,000l.; besides which, he left an estate he had purchased, of 900l. per annum.

LEMA, in Geography, a small island in the Chinesfe sea. N. lat. 22°. E. long. 114° 17'.

LEMA Islands, a cluster of small islands in the East Indian sea,
sea, near the west coast of the island of Borneo. S. lat. 1° 10'. E. long. 108° 45'.

LEMAIRE, in Biography, is now generally supposed to have added, about the middle of the seventeenth century, the syllable / to the hexachord, in order to furnish a name, in foliation, to the sharp 7th of the key, and ease the students in singling of the embarrassments of the mutations. Many volumes have been written for and against the mutations. We believe that in the conservatories at Naples and Venice they are still preferred; and by the organists of our cathedrals who teach the choristers; but in many other parts of Europe, besides France, the / has been adopted. Though much has already been said on both sides the question, much still remains to be paid by the champions of both methods. See Mutation, Solmisation, Hexachord, and the syllable Si in their several places.

LEMAN LAKE, in Geography. See Geneva and Lake.

LEMAN, Department of, one of the eleven departments of the eastern region of France, composed of Gen' and Geneva, and the north part of Savoy, in N. lat. 45° 10', on the frontier of Switzerland, and so called from lake Leman. It is bounded on the north by the lake, Switzerland, and the department of Jura; on the east by the Valais, and the departments of the Doria and Mont Blanc; on the south by the department of Mont Blanc; and on the west by the departments of the Ain and Mont Blanc. Its chief towns are Geneva, Thonon, and Bonneville. It contains 197 square leagues, and 215,884 inhabitants; and is divided into three circles or districts, including 23 cantons, and 276 communes; viz. Geneva, comprehending 103,550 inhabitants; Thonon, the inhabitants of which are 39,465; and Bonneville, including 72,869 inhabitants. Its contributions amount to 969,622 francs, and its expenses to 200,473 francs, 66 cents. This department consists of hills, valleys, and plains; producing grain, wine, fruits, and pastures. It has forests and iron-mines.

LEMAVI, in Ancient Geography, a people of Spain, in the Tarraconensis. Their capital was Daedonium, according to Ptolemy.

LEBA, a town of Asia, which Josephus classifies in the number of those which the Jews possessed in the country of the Moabites.

LEBA, in Geography, a town of Africa, in the kingdom of Congo.—Allo, a town on the west coast of the island of Celebes. S. lat. 3° 15'. E. long. 119° 52'.

LEBACH, a town of Austria; 9 miles S. of Aigen.

LEMBOECK, a town of France, in the department of Schelde; 8 miles S. of Ghent.

LEMBIGE, or LEMBAK, a city of Austrian Poland, and capital of Galicia, large and opulent, and well fortified with timber. It lies low on the banks of the river Peltew, which soon after joins the Berq; being surrounded with hills and mountains which command the town. It is the seat of a Polish archbishop, and also of a Ruffian and Armenian bishop. It has two castles, one within and another without its walls; the latter standing on a high hill, and having the Carmelite monastery, which is fortified, for a citadel: and it carries on a considerable trade. Lemberg has a magnificent cathedral, several other churches, a gymnasium or seminary, an arsenal, a public granary, two Jewish schools, &c. A provincial diet and court of judicature are held in this town. It is inhabited by a mixed people of different nations; but no Protestants are tolerated; 72 miles S.S.E. of Chemnitz. N. lat. 49° 51'. E. long. 23° 59'.

LEMBBO, a town of Africa, in Congo, on the Zaire; 40 miles S.W. of Erona.

LEMERY, Nicholas, in Biography, an eminent French chemist, was born at Rouen, in November 1645. His father, Julian Lemery, was a procureur in the parliament of Normandy, and of the Calvinitz persuasion. Nicholas was brought up to the business of pharmacy, under an apothecary of Rouen; and he went to Paris in 1666, with the view of obtaining farther improvement, especially in the art of chemistry, which he perceived to be the basis of correctness in the processes of pharmacy. Here he studied under Glafer, demonstrator of chemistry in the royal garden; and afterwards spent five years in travelling, for the purpose of adding to his knowledge. He refixed a considerable time at Montpellier, then famous for its apothecaries; and brought with him to Paris, where he settled in that capacity in 1672, all the knowledge in his department of the art which the kingdom at that time afforded. In order to give public proofs of his information and skill, he announced a course of lectures on chemistry, which his friend, M. Martin, apothecary to the prince of Condé, allowed him to deliver in his laboratory, at the hotel of that prince. He afterwards procured a laboratory of his own, which, though little better than a dark cella, soon became the centre of attraction, not only to the first scientific characters in Paris, but to ladies, who reforted thither partly from a love of knowledge, and partly from fashion. Chemistry was then indeed coming into great vogue in that metropolis; and Lemery contributed greatly to its advancement, by treating it in a simple and peripatetic manner, divesting it of the jargon of mysticism in which it had been hitherto obscured, and, by the dexterity of his experiments, exhibiting the facts which it discloses to the comprehension of every understanding. By these means, Lemery established such a character for superior chemical skill, as enabled him to make a fortune by the sale of his preparations, which were in great request both in Paris and the provinces. One article in particular was the souce of great profit, namely, the oxyd, or, as it was then called, the magistery of bismuth, and known as a cosmetic by the name of Spanish rubic, which no other person in Paris knew how to prepare. In 1675 he published his “Cours de Chymie,” which was received with general approbation and applause, and passed through numerous editions; indeed seldom has a work on a subject of science been so popular. It sold, says Fontenelle, like a novel or a satire: new editions followed year after year; and it was translated into Latin, and into various modern languages. Its chief value consisted in the clearness and accuracy with which the processes and operations were detailed; the science was not yet sufficiently advanced for a rational theory of them. Indeed he seems to have worked rather with the view of directing apothecaries how to multiply their preparations, than as a philosophical chemist; and his materials are not arranged in the most favourable manner for the instruction of beginners in the science. Nor did he divulge the whole of his pharmaceutical knowledge in this treatise: he kept the preparation of several of his chemical remedies secret, in order to obtain the greater profit by their sale.

Hitherto our chemists, though openly professing Calvinistic principles, had not been interrupted by the spirit of persecution, which disgraced the latter part of the reign of Louis XV.; but in 1681, he received an order to discontinue
time his public lectures within a limited time. While under this interdiction, he was invited to Berlin by the elector of Brandenburg; but he preferred removing to England, where he was favourably received by Charles II., who had an attachment to chemical pursuits. Circumstances, however, did not accord with his expectations; and he returned to his own country, and took the degree of doctor of physic at Cæn, with the hope of thus protecting himself from further persecution. He actually acquired considerable employment in his new character at Paris; but the revocation of the edict of Nantes, in 1685, by which the practice of physic was interdicted to Protestants, deprived him of his means of subsistence, and reduced him to such difficulties, that his confinny at length gave way, and, in the following year, he with his family was reconciled to the Catholic church. He then readily obtained letters patent, allowing him to resume his practice, and his office of public teacher; and he again derived considerable emolument from the sale of his medicines. In 1697 and 1698 he published two works of considerable value, but not without many imperfections. These were, 1. "Pharmacopoea universelles," containing a collection of the formulas given in all the reputable dispensatories in Europe, with corrections and improvements. Like the pharmacetical works of that time, it was overloaded with articles, but was superior to its contemporaries. 2. His "Dictionnaire universel des Droges Simples," which was a still more useful work than the former.

On the reestablishment of the Academy of Sciences in 1669, Lemery was appointed associate-chemist, and succeeded to the office of pensionary, on the death of Bourdon. He then read before that body the papers on the subject of antimony, which were printed in 1707, under the title of "Traité de l'Antimoine." Upon this subject he had a controversy with an anonymous critic, in which he was considered as not very successful. He was now advancing in years, and found the infirmities of age increasing upon him, when his life was suddenly terminated by a fit of apoplexy, on the 15th of June 1715. Lemery was one of the ablest chemists of his time, and indefatigable in his researches, having spent his life in his laboratory, or study, at the bed-side of the sick, or in the Academy. He was a man of great simplicity of manners, sincere in his friendships, and of the strictest integrity in the commerce of life. Eloy Dict. Hist. de la Méd. Gen. Biog.

LEMERY, Louis, son of the preceding, was born at Paris in January 1677, and obtained a reputation for knowledge in chemistry and medicine worthy of his name. He was intended for the profession of the law; but he had imbibed from the puritus of his father so great a taste for those sciences, that he entered the faculty of medicine of his native city, and received the degree of doctor in 1698. Two years afterwards he was admitted into the Academy of Sciences, and in 1708 he delivered lectures on chemistry in the royal garden. In 1710 he was appointed physician to the Hotel-Dieu, a post which he occupied during the remainder of his life. In 1712 he obtained the rank of associate in the Academy, and succeeded his father in that of pensionary in 1715. He purchased the office of king's physician in 1722; and in that capacity he accompanied the infant of Spain on her return from France, whither she had gone with the view of being married to Louis XV. After his return to Paris, he was honoured by the queen of Spain with the title of her consulting physician. In 1731 he was appointed professor of chemistry in the royal garden, in the place of Geoffroy. At a subsequent period, he became particularly attached to the establishment of the duchesses of Brunswick, with whom he frequently visited in the palace of Luxembourg; and he likewise obtained the patronage of the princes of Conti, in whose hotel he regularly paused a part of every day, and there composed several of the chemical papers which he read before the Academy of Sciences. Thee papers treat of the subjects of iron, of nitre, and of some other salts, of vegetable and animal analyses, of the origin and formation of minerals, &c. Louis Lemery died on the 9th of June 1743, and the loss of him was much regretted; for to the mild and polished manners of the gentleman, he united great sincerity and confidence in his attachments, and sentiments of liberality and generosity in all his proceedings.

In addition to the papers published in the Memoirs of the Academy, he left the following works: 1. "Traité des Alimens," Paris, 1702, which was frequently reprinted, and greatly augmented by Bruhier in the edition of 1755; 2 vols. 12mo. 2. "Dissertation fur le Nourriture des Os," Paris, 1704, 12mo. In this work he maintains that the bones are nourished by a peculiar gelatinous fluid, deposited in their subsistence by the small arteries, and not by the marrow, as had been supposed by some. He likewise published three letters, on the generation of worms in the human body, in opposition to the treatise of Andry, with whom a sharp controversy was carried on upon this topic. Eloy Dict. Hist. Gen. Biog.

LEMEYBAMBA, in Geography, a town of Peru, in the diocese of Truxillo; 22 miles S.W. of Chucapoya.

LEMGO, or Lemgow, a town of Welfpaha, in the county of Lippe, on a small river, near the Werra, divided into the Old and New Town, each of which has its own magistrates; formerly one of the Hanse towns; 17 miles S.S.W. of Minden. N. lat. 52° 2'. E. long. 8° 44'.

LEMIA, a small island in the Pacific ocean, near the coast of Chili. S. lat. 44° 6'.

LEMINGTON, a pott-town of America, in York county, Maine; 610 miles N.E. from Washington.—Also, a township in Essex county, Vermont, on the W. bank of Connecticut river, and near the N.E. corner of the state. It contains 52 inhabitants.

LEMLANT, a small island in the Baltic, near the S.E. of Aland; about 20 miles in circumference. N. lat. 65° 4'. E. long. 10° 58'.

LEMLEM, a country of Africa, in the interior part of Negroland; 500 miles E.S.E. from Tombucto.

LEMLUM, a town of the Arabian Itrak; 33 miles S.E. of Hellah. N. lat. 31° 43'.

LEMLIA, in Botany, a name borrowed from the ancient Greek writers, whose λυμυς is supposed to have been so called from λυμος, a shell, bark, or membrane, and to have been either one of their Dicksweeds, see Lemia; or some other aquatic production, whether of the vegetable or the coralline kind, that adhered to shells. July 16. — This name was given by Bernard de Jussieu to the proper Macilia of Linneus, for which it seems difficult to give a good reason. We may indeed allude to the separation of Micheli's Salsinium from that genus (see Jussieu); but this does not oblige us to abrogate a name long destined to commemorate a meritorious naturalist. See Marbilea.

LEMLIA, λυμυς, of λυμος, or a shell, in Mathematics, denotes a previous proposition, laid down in order to clear the way for some following demonstration; and prefixed either to theorems, in order to render the demonstration of them less perplexed and intricate; or to problems, to make the resolutions of them more easy and short. Thus, to prove a pyramid one-third of a prism, or parallelopiped, of the same base and height with it, the demonstration of which, in the ordinary way, is difficult and troublesome, this lemma may be
LEM

be premised, which is proved by the rules of progression, that the sum of the series of the squares, in numbers in arithmetical progression, beginning from 0, and going on, is always subtriple of the sum of as many terms, each equal to the greatest; or is always one-third of the greatest term multiplied by the number of terms. Thus, to find the inflection of a curve line, this lemma is first premised, that a tangent may be drawn to the given curve, in a given point.

So, in physics, to the demonstration of most propositions, such lemma as these are necessary first to be allowed: that there is no penetration of dimensions; that all matter is divisible; and the like. As also in the theory of medicine, that where the blood circulates, there is life, &c.

**Lemma**, in the *Ancient Myth*, a reed or pane of a *short* fyllable in the catalectic rhythm. See *Rhythm*.

**Lemma**, *λεμμα* in *Pharmacy*, a term used to express the hulk or shell of certain fruits, as the almond and the like; and, in general, whatever is taken off in decortication: thus, the hulks of oats, barley, &c. are the lemmata of those seeds.

**LEMME**, *Tie*, in *Geography*, a sea-port of Friesland, near the Zuyder sea; 20 miles S. of Lewarden. *N.* lat. 52° 52'; E. long. 5° 30'.

**LEMME**, or **Le Mmm**, in *Zoology*. See *Sable Mouse*.

Gen. Ch. cal. Perianth inferior, of one leaf, roundish, obtuse, obscurely two-lobed, soon disapparising. Cor. none. Stam. Filaments two, awl-shaped, spreading, more or less unequal, longer than the calyx; anthers terminal, of two round lobes. Pf. Germin superior, ovate; style columnar, shorter than the flamin; stigma siple, or slightly notched. Peric. Capsule roundish, of one cell, not burling. Seeds few, oblong, striated, pointed at each end, vertical, ranged in a simppl circular row.

Obf. The first person who ever observed the fructification of a *Lemmna* appears to have been Val申し込み, whose effay on the subject, describing the flowers of *L. minor*, is published in the *Ephemerides Natura Curiosorum*, and in the Italian folio edition of his works, v. 2. S. 1. 14. 15. His figure of the flower is borrowed by Dillenius, in the appendix to his *Planta Giftenes*, cited above. Michelli, several years after, published excellent representations of the flowers and fruit, observed in two or three species, to which he applied the generic name *Lenticula*; calling by that of *Lenticularia* such as he could not meet with in a flowing state. This is a distinction without a difference, and of the latter *L. trifula* has since been found in perfection by Mr. Dawson Turner of Yarmouth, in June, 1801. Wildenow says it has been found by Wolf. Ehrhart, in his German *Beiträge*, f. t. 43, has given an entertaining account of his examination of *L. gibba* in flower at Hanover, July 15, 1779. This was found near Lewes in Sussex, by Mr. W. Borrer in June 1804. It was minor by the fame gentleman in 1802, so that three species being now distinctly figured in fructification, in Engl. Bot. t. 926, 1095 and 1233, we are no longer in the dark on the subject, and we venture to remove the genus from *Monoeia* to *Dianira*, as suggested in Fl. Brit. 1958. and Prodr. Fl. Grce. v. 1. 11. One British species still remains, the *polyrhiza*, whose flowers appear to have been seen by one person only, Grauer, a young friend of Wiggers, at Kiel, about 1780.

The calyx seems to be variable in this genus, and is proballoy foon evanent. Some flowers also occasionally want the complete germin, but this is accidental, and they appear to be in no ipeces, truly monocious, nor regularly polynymous.

1. *L. trifula*. Ivy-leaved Duckweed. Linn. Sp. Pl. 1376. Engl. Bot. t. 926. (Hederia aquatica; Lob. C. v. 2. 26. Ger. em. 830.)—Leaves falked, lanceolate, proliferous.—Found throughout Europe, floating in clear still pools and ditches. Mr. R. Brown has observed it in New Holland. It is a pale-green, smooth, pullicid, annual herb, floating in fresh water, near or upon the surface, and consisting of several lanceolate, ribbed, entire, sometimes waved, toothed, leaves, each, with its stalk, about an inch long. Each leaf throws out from its centre underneath a foliary simple root, descending, to more than the length of an inch, into the water, and tipped with a membraneous leaflet. From the same point whence the root originates, spring a pair of young divericated flat leaves, looking like lobes of the old one. The flowers proceed solitarily from a marginal chink, at one or both sides of a leaf, and are scarcely perceptible but by their prominent yellowish anthers. Wolf, the author of a differentiation on *Lemmna*, published at Altorf in 1821, and quoted by Willdenow, appears to have been the first who ever found the flowers of this species.

2. *L. minor*. Lesser Duckweed. Linn. Sp. Pl. 1376. Engl. Bot. t. 1095. Michaux Boreali-Amer. v. 2. 163. (Lens palafris; Camer. Epit. 852. Ger. em. 829.)—Leaves sessile, nearly flat on both sides. Roots solitarily.—Common and abundant in summer time, on the surface of stagnant pools throughout Europe. Michaux has also observed it in Carolina, and Brown in New Holland. This being the common species in Greece, Dr. Sibthorp justly premised it to be the *flicus*, or *εις τον τελειον* of Dioscorides; not that we would fuppore this ancient fage accurate or attentive enough to have distinguished it from the two or three following, which may possibly grow likewise in the country he investigated. The leaves are ebovate or elliptical, entire, slightly convex beneath, in consequence of the formation of the air within, by which they become buoyant, and float in dense masses over the whole surface of the water, being much smaller and more crowded than in the former. They are, like that, in some measure proliferous. The roots are solitarily from the centre of each, and are temporary, not perennial, nor forming offsets. Flowers from marginal chinks, always, as far as we have seen, furnished with both stamens and pistil, and their calyx is more ample, as well as more evidently two-lobed, than in the above. The seeds when ripe doubleds descend, and take root in the mud, as Val申し込み observed the young plants acord in the form of a green soft pulp, full of air-bubbles, from the bottom to the surface, early in the spring, and soon after the waters were mantled with an entirely green covering of the perfect leaves, lying over each other.

Michelli’s *Lenticularia media*, t. 11. f. 2, and *minor*, f. 5, both perhaps belong to this species.

3. *L. gibba*. Gibbons Duckweed. Linn. Sp. Pl. 1377. Engl. Bot. t. 1233. (Lenticula paludaria major &c.; Mich. Gen. 15. t. 11. f. 1, not 2.)—Leaves sessile; slightly convex above; hemispherical beneath; Roots solitarly.—Leaves frequent by far than the half, in full pools of various parts of Europe. Hudson considered this as a variety only, but it
differs in being larger than minor, remarkably timid, succulent, and fucular. Its upper surface is convex, ufually of a fine green; but often purplifh; the lower almost hemispherical, and paler. Roots generally folitary, sometimes in pairs. Micheli fays the calyx soon disappears; and Mr. Borrer's fpecies were too far advanced to shew it, though the flumes and style were in perfection.

LEMNIAN EARTH, Lemnia terra, comprehends several varieties of clay, moftly red and ferruginous, formerly preerved under this name, and employed in medicine. They were diftinguifhed into the white, the yellow, and the red. They were brought from the Levant, moftly in the shape of small cakes, bearing the imprefion of a feal, whence the name of Terra Sigillata. Several of them are to be referred to Bole; which fee. The whitifh kind, which appears to be the true Lemnian earth, and fo highly valued by the anients, on account of the alexipharmic virtues which they ascribed to it, is defcribed under the article Fuller's Earth.

The red earth is dug in a hill in the island of Lemnos, and in no other place, fo far as is yet known; and the fine and true earth only in one pit, which ufed to be opened once every year, and no ofiner, with great folemnity; and the earth, fuficient for the year's demand, was taken out and fold to the merchants; some falted with various figures, other quantities unufed; but what was there bought unufed, was generally formed into fmall maffes, and falted before it was offered to sale in Europe; the druggifts always expeeting to find Lemnian earth falted.

This earth, to which imaginary virtues were attributed, was too often adulterated, frequently by the Turks upon the fpot, either by mixing it with other earths, or another earth alone being fold in its place; but more frequently in Europe, where every wholefale dealer knew how to make a composition of our own clays, and properly tinge them with ochre, and afterwards give an imprefion relluming that of the genuine.

This earth, was celebrated by the anients as a fovereign remedy againft poifons and the bites of reptiles: the Turks and Greeks still retain that notion, for the cups out of which the grand fegrinn drinks are made of this red earth, fo that it is revered chiefly for the fultan's ufe. But the alexipharmic and aflringent property of this and the other boles is now in little or no ufe. (See Bole.) It is alfo dug in the island of Lemnos, and was ufed in the German shops as an aflringer and feudoric, and faid to be of great efficacy in dysenteries, hemorrhages, and malignant fevers. The anients knew this kind, but never ufed it in medicine, efteeming the other fuperior, but they employed it as the cinamia in cleaning linen and woollen cloths.

The yellow Lemnian earth is counterfeited two ways: the one by a yellow ochre, which may be difcovered by its flaining the hands, and the other by a yellow clay; but this is easily known by its want of the true florid colour, and having all the characters of a clay, not a bole. The genuine is found only in the island of Lemnos, and is the ftratum next above the red. It was formerly efteemed a fuorinice, aflringent, and vulnerary. Da Cotta's Hill of Fofills, p. 1, 14; and 22.

LEMNIS, in Ancient Geography, an island of Africa, in Mauritania Caftarifienis, E.N.E. of the mouth of the river Melias.

LEMISCATE, in the Higher Geometry, is the name of a curve which has the form of the figure of 8. If we call A P, x, (Plate XI. Analysis, fig. 1), and P N, y, and the conflant line B C, a, the equation of the curve will be

\[ a^2 = x \cdot (a - x) + y^2 \]

which is an equation of the fourth degree; it is also evident that a right line which paffes through the double point A will cut this curve in four points, the double point being reckoned equal to two. See CURVE.

LEMISCIA, in Botany, so called by Schreber, from lemnica, a bandage, or fillet, in allusion to the shape of its petals. Schreb. 358. Wild. Sp. Pl. v. 2. 1172. Mart. Mill.
LEM

Mill. Diff. v. 3. (Vantanae; Aubl. Guian. v. t. 572. t. 229. Jul. 434. Lamarek. Illurst. t. 471.)—Clafs and or-

th. Acer. Petals five, linear, long, acute, re-
curved, adhering to the cup-shaped, flabelly, short nectary which accompanies the geranns. Stain. Filaments numerous, from seventy to eighty, capillary, longer than the cor-
olla, inserted into the nectary; stamens roundih, small, Priif. Cermen superior, roundih, immersed in the nectary; style thread-shaped, the length of the flaminns; stigma obtu-

Eff. Ch. Calyx five-toothed. Corolla of five petals. Nectary cup-shaped, bearing the flaminns. Capsule five-
celled, with a seed in each cell.

1. L. floridius. Willd. (Vantanea guianensis; Aubl. Guian. t. 229) — Found at Guiana, where it is called Juantanan, whence Aublet derived its barbarous appellation Vantanea. It flowers in August. The trunk of this tree rises to the height of about fifteen or twenty feet, and is much branched. Bark brown and smooth. Wood whitish and compact. Leaves alternate, on short footstalks, smooth, oval, pointed, the larger ones about five inches long. Flowers forming large, handsome bunches at the extremity of the branches, of a red, coral colour. Stamas incrustated upon a yellow, flabelly disk, in the form of a cup, which almost covers the geranns.

Ob. The long narrow petals of this plant greatly remind us of those in the neighbouring genus Alangium.

LEMNIUS, or LEMMENS, Lévin, in Biography, was born at Zirickée, in Zealand, in May, 1508. He studied at Louvain, and by the advice of his friends applied both to medicine and theology. He principally distinguished himself, however, in the former of these sciences, and practised the profession for upwards of forty years, chiefly in his native place, where he settled in 1557. He obtained the full confidence of his patients by his knowledge and eloquence, and especially by a mild and humane expressio of comtance and manner, which never failed to interest the sick. After the death of his wife, Lemmuns became a priest, and was made a canon of the church of St. Lieven, at Zirickée, where he died in July 1568. He was the author of several works, the style of which has tone force and even elegance. These are: "De Alstrologia Liber unus, &c.; De termino vitae Liber. De honello animi et corporis obselemento, &c. &c." Antwerp, 1554.—"De occultis natura miraculis Libri duo," ibid. 1559. — "De occultis natura miraculis Libri quattuor," ibid. 1564. These works contain many observations relative to natural philosophy, botany, physiology, and medicine, and especially concerning vegetation and monstcrs; but they also contain many fables. "De Habitu et Constitutione corporis, quam trivales complacentem vacant, Libri duo," ibid. 156 , and several sub-

LEMNOs, in Ancient Geography, an island situated in the Ægean sea. This island was consecrated to Vulcan in the time of Homer, probably on account of two volcanoes, which were here continually calling forth flames, and which were considered as the forges of the husband of Venus. No vestiges of these volcanoes now remain; but Somnini thinks it probable that interior fires are still burning here; for he met with a spring of hot water, which has been brought to

supply baths, and another of aluminous water. Lemnos was celebrated amongst the ancients, on account of the foczouc which it afforded to the Argonauts; of which Apollonius Rhodius has given a particular account. As it was near Asia, it was almost always dependent on that province. The priests of Lemnos were reckoned famous for the cure of wounds. For this reason the Greeks, who went to the siege of Troy, left here Philoctetus, after he had been wounded in the foot by one of the arrows of Hercules. The efficacy of their skill depended, as it has been said, upon the quality of that bode under the denomination of LEMNIAN earth; which fee. It is also said, that Galen made a voyage to Lemnos on purpose for ascertaining the virtues of this earth; and that he found a person who had availed himself of it as an antidote to the bites of reptiles, and to poison. The first inhabitants of this island were the Pelagi, who expelled, the descendants of the Argonauts, by whom it was previously occupied, and took possession of it about 1160 years before the vulgar era. This island retained the name of Lemnus, by which it is even now known; but navigators have given it the name of Stilbem. The island is hilly, but extremely fertile; it yields corn, cotton, oil, and silk, with which a few light stuffs are manufactured. To be flourishing, fays Somnini, Lemnos wants only to be delivered from its oppressors. Nature has done every thing for it, and we lament the state of languor and wretchedness to which its destiny has reduced it. Its inhabitants were formerly much given to navigation, or at least to the carrying-trade; they are sill trading mariners, because this kind of industry escapes more easily the cupidity of tyrants than alfluence produced only by agriculture, or by a sedentary traffic. Some of its women are extremely beautiful. The whole east coast is inaccessible, on account of a ficial, which extends four leagues into the offing; the west coast affords to ships a few places of shelter against northerly winds. To the north is a large road; but there are no real harbours except on the south part, where are to be found two, at no great distance from each other, viz. Port Cadi and Port Sain Antonio. Somnini's Travels in Greece and Turkey.

LEMO, in Geography, a town of Sweden, in the govern-
ment of Abo; 12 miles N.W. of Abo.

LEMON, or LIMON, in Botany, Gardening, &c. See CItrus and CITRIC Acid.

LEXON-tree. See CITRUS Medicus. The name is some-
times given by the Welsh to Pyrus Aria of Fl. Brit., the White Beam-tree, whence certain travellers have reported the lemon to be a native of the bleak cliffs of Penmaen-
more!

LEMON, in the Materia Medica.

Lemons are cooling and grateful to the stomach, quenching thirst and increasing appetite; useful in fevers, as well common as malignant and phlegmatic; they also provoke urine. The juice, which is more acid than that of the orange, possesses similar medical virtues. (See ORANGE.) This juice, however, is always preferred, where a strong vegetable acid is required. Saturated with the fixed vegetable alkali, it is in frequent extemporaneous use in febrile diseases; and by promoting the secretions, especially that of the surface, proves of considerable service in abating the violence of pyrexia. Mixed with falt of wormwood, it is an excellent medicine to stop vomiting, and to strengthen the stomach. As an antifebriculent, lemon juice is very generally taken on board ships, defined for long voyages. See CITRUS, and CITRIC Acid.

Whytt found the juice of lemons to alloy hysterical pal-
pitations of the heart, when various other medicines had
LEMOS

proven ineffectual; and this juice, or that of orange, taken to the quantity of four or six ounces a day, has sometimes been found a remedy in the jaundice. (See Saunders's Elem. of the Practice of Physic, p. 170.) The yellow rind is a grateful aromatic, and commonly used in fo-

4
27
mache sic tinctures and infusions, and for rendering other me-

dines acceptable to the palate and stomach. The lemon peal, though less warm than that of the orange, possesses similar qualities, and is used with the same intentions. It is sometimes ordered to be candied. In distillation it yields an essential oil, extremely light, almost colourless, frequently employed as a perfume, and brought to us from the southern parts of Europe, under the name of "essence of lemons." This oil is an ingredient in the spiritus amon-

omine compositae, or aromatic spirit of ammonia, and in other formulæ. A mixture made by saturating six drams of the juice of lemons with about half a dram of fixed alkaline salt, with the addition of a small quantity of some grateful aromatic water or tincture, as simple cin-

amon water, is given in cases of nausea and reachings, and generally abates, in a little time, the severe vomitings that happen in fevers, when most other liquors and medicines are thrown up as soon as taken. It is also used as a saline ap-

rient in icterial, hydropepial, inflammatory, and other dis-

orders. A fyrnup made by dissolving fifty ounces of fine

fugar in a quart or two pounds and a half of the depurated

juice, is mixed occasionally with draughts and juleps, as

a mild antiphlogistic, and sometimes used in garganisms

of inflammations of the mouth and tonsils. Lewis Mat. Med.

LEMONADE, a drink prepared of water, fugar, and
citron, or lemon-juice. This factitious liquor has been so popular in Paris, that it has given its name to a new established company called

lemonaders.

LE MONNIER, Peter Charles, in Biography, a
French astronomer, member of the Academy of Sciences,
and of the National Institute, was born at Paris in 1715, and accompanied Maupertuis in his tour to the north pole, for
measuring a degree of the meridian. His principal works
are: "Astronomical Institutions;" "Lunar Nautical Astron-
yomy;" "Tables of the Sun, and Corrections of the Moon." He died in 1796. He had a brother, Lewis William, a very able experimental philosopher, who died in 1799. But neither of these is to be confounded with an abbe of that name, who translated Terence and Perius into French, and was author of fables, tales, and

epistles. He died in 1796.

LEMOS, in Geography, a distric of Spain, in Galicia,
E. of Minho; the chief place is Montforte de Lemos.

LEMOSANO, a town of Naples, in the county of
Molise; 8 miles N.E. of Molise.

LEMOV, Niznei, a town of Ruffia, in the govern-
ment of Penza; 72 miles W. of Penza. N. lat. 53° 25'.
E. long. 43° 34'.

LEMOV, Vershebei, a town of Ruffia, in the govern-
ment of Penza; 38 miles S.W. of Penza. N. lat. 53° 16'.
E. long. 43° 14'.

LEMPA, a river of Mexico, which runs into the Pa-
cific ocean, N. lat. 13° 36'.

LEMPACH, a town of Austria; 14 miles W.S.W. of
Vienna.

LEMPALA, a town of Sweden, in Tavalland; 27
miles N.W. of Tavallus.

LEMPYS, Grand, a town of France, in the department of the Ille, and chief place of a canton, in the district of
La-Tour-du-Pin; 18 miles N.W. of Grenoble. The place
contains 1680, and the canton 14,883 inhabitants, on a territ-
ory of 200 kilometres, in 15 communes.

LEMPSTER, an inconsiderable township of America,
in Cheshire county, New Hampshire; incorporated in 1761,
and containing, in 1800, 729 inhabitants.

LEMPTA, a sea-port town of Africa, on the E. coast
of the kingdom of Tunis. It was the "Leptis parva" of the
ancients; the other being in the kingdom of Tripoli.
Lemphta appears to have been a mile or more in circuit; but
nothing now is left but the ruins of a castle; with a low
shelf of rocks, that probably made the northern mouth of
the ancient Cuthon; 60 miles S. of Tunis. N. lat. 35° 30'.
E. long. 10° 54'.

LEMPITA, a desert country of Africa, inhabited by a bar-
barous and fierce people, who plunder the caravans that pas-

t from Conflantia and other towns towards Nubia, situated
about N. lat. 26° 30'. E. long. 9°.

LEMU, a small island in the Pacific ocean, between
the island of Chiloe and the continent. S. lat. 44° 10'.

LEMVIG, a town of Denmark, in North Jutland, situ-
ated on the Lise-Fjord, or Lympurt; 84 miles N. of
Ripen. N. lat. 56° 44'. E. long. 8° 18'.

LEMUR, in Zoology, a genus of Primates. The
fore-
tooth in the upper jaw amount to four in number, the inter-

diater ones remote; those in the lower jaw to fix, their

form more elongated, extended, compressed, parallel, and

approximate; grinders many, somewhat lobate, the foremost
longer, and sharper.

The animals of the lemur genus approach the monkey

tribe in the form of their feet, which in several of the species
are furnished with flat and broad nails, resembling those of
the human hand, excepting generally that of the birt finger
next the thumb, which is long and incurved; they have either
two or four toes, and some of the species have the tail of
considerable length, while others have none. Notwithstanding
the resemblance these animals bear to the monkey race,
they have nothing of the mischievous and petulant disposition
of those creatures; they are mild and peaceable in their
manners, at least when domesticated, and there are few spe-
cies of the tribe that cannot readily be reduced to that flate
of docility by proper treatment. Some of the species eat

on fruits, eggs, and small birds, others subsist entirely on
the former. They inhabit chiefly the Indian islands, and the
continent of South America.

Species.

TARDIGRADUS. Tail none; body somewhat tawny a. Gmel.
Lemur tardigrauus, Erxleben. Le loris gréle,
Audebert. Sigo loris, or loris.

Under the Linnean specific name of tardigradus, the best
authors appear to have confounded two, if not a greater

number of distinct species. The little animal described by
Erxleben under that title, is remarkable for the peculiar
elegance of its figure, and the singularity of its conformation.
The head is roundish; the muzzle projecting; the eyes extremely large and contiguous to each other; the ears large and round; instead of a tail a tubercle is situated in that part; and the whole body is covered with fine hair of a reddish-grey colour. The sexual organs of the female, according to the observations of Daubenton, present some curious particulars of interest to the comparative anatomist.
This species inhabits Ceylon, is remarkable for its agility,
is quick of hearing, and corresponds with the squirrel.

ECAUDATUS. Tail none; a dark-rufy line along the
middle of the back from the rump to the forehead; orbits

surrounded
LEMUR.

The distinction between this and the preceding species has not been regarded with sufficient attention by all writers, and hence we sometimes find the description and history of one applied to and blended with the other. The latter is about thirteen inches in length, the head almost round, the muzzle very little pointed. The ears are small, oval, and straight, and almost entirely concealed under the woolly hair. The eyes are placed in front immediately above the nose, and are very close to each other; their form perfectly orbicular, their size remarkably large in proportion to the body, and of a brown colour. The nose is small, flat, and open at the sides; the teeth of the same form and number as in the former animal. The hair of the fur is long, fine, and woolly, but rough to the touch; the colour in general grey, or yellowish-ash, inclining rather more to reddish upon the flanks and limbs.

INDRI. Tail-fe., black; beneath greyish; rump whiteish. Lemur indri, Gmel. Indri, Somnerat. Indri macacus, Penn.

This is a very large species; the colour entirely black, except on the face and beneath, which is greyish; and the space of white on the rump, or sometimes the face, is white. The muzzle is lengthened as in the dog tribe, the ears shortish and slightly tufted; the hair silky, thick, and in some parts curly. According to Somnerat, its first describer, the height of this animal is three feet and a half; the tusks in each jaw are eight, the fore-teeth above two, beneath four; the feet five-toed; nails flat and acute, those of the great toe large; the rudiment of a tail is inconstant to the touch. It is said to be a gentle, docile animal, capable, like the dog, of being trained when young to the chase, and is commonly employed in hunting by the natives of Madagascar; the country it inhabits: its voice resembles the crying of an infant. At Madagascar it is known by the name of indri, which signifies the man of the wood. Geoffroy observes, that the cutting teeth in the upper jaw are four in number, instead of two, as mentioned by Somnerat.

RUFUS. Yellowish-red; head at the summit, temples, checks, and tail beneath whitish. Lemur rufus, Aud. Maki-rus, Defn.

This resembles the mongoz in size, and various other respects; it nevertheless differs in having the ears shorter, the tail longer, the hair in general shorter, and the colour of the fur yellowish-red instead of brown-grey; upon the summit of the head is a black line, and the tail at the extremity is brown. Whether allied to the following species or not seems difficult to determine.

A native of Madagascar; the length twenty-one inches; hair soft, curled, about the loins reddish tawny; face black; ears small; eyes large and greenish-grey; in the upper-jaw two fore-teeth, in the lower four; tail nine inches long; feet five-toed; nails long, great toe-nail rounded. There are two or three fuppoled varieties of this species.

PORTO. Sub-ferruginous; tail fame colour. Gmel. Pato, Bofman.

Inhabits Guinea. An obscurely described species, conceived to differ from the indri only in the length of the tail. Bofman, who relates the fuppoled history of this animal, on the authority of the negroes (in his account of Guinea), attributes to it nearly the same manners as those of the European sloth.

The mongoz is a larger species than the ring-tailed lemur, the size about that of the common or domestic cat; the upper part of an uniform fulvous-brown colour, with the breast and belly whitish. The fur consists of silky curling hair. The nose is larger than in the ring-tailed lemur, and much resembling that of lemur macaco, the colour black; the eyes are yellow, or orange, remarkably vivid, and are nearly surrounded by a circle of black placed at a small distance above and beneath each eye, then uniting between them, and passing down the middle of the snout to the nose; the hands and feet are naked and fulvous; the nails flat, except on the interior toe of the hind feet next the thumb, which is furnished with a sharp claw; and the tail, which is very long, covered with a thick fur.

No less than seven fuppoled varieties of this species are described by writers; in one kind the body is grey or brown, with a white face and hands black; in another grey or black, with a black spot near the eyes; and in a third the body is brown, with the nose and hands white; the face is also sometimes black, the hands yellow, or varying from that to deep tawny, and the body grey; and again, others occur that are uniformly brown.

This animal is a native of Madagascar and some other Island islands; it is an active animal, filthy in its dispositions, and feeding on fruits and leaves of trees; it constantly refuges in woods: like some other animals, which nature has furnished with a tail of great length, it is observed occasionally to amuse itself by nibbling and biting the end of the tail, and is on this account sometimes found with that part deftite of the four or five extreme vertebrae.

The individual described by Buffon was neither of a gentle nor sportive disposition, and was necessarily confined by means of a chain to prevent its doing mischief; fruits, sugar, and comfits it devoured with apparent eagerness and satisfaction, besides which it was fed on bread; it almost incessantly uttered a low grunting noise, or when tired of being alone, croaked in the manner of the frog, and so loud as to be heard at a great distance. The tongue was rough like that of the cat; and Buffon observes, that when permitted it would lick a person's hand till the skin became inflamed; its careless, usually concluding with a bite of its teeth upon withdrawing the hand from him. This individual was a male, and from its partiality to cats it was suspected its attachment might have been productive of an hybrid offspring; but these expectations were never realized.

An inhabitant of Madagascar, and the adjacent islands; its size exceeds that of the mongoz, and in the ferocity of its manners it very far surpasses that species. Travellers describe it as being fearlessly less furious than the tiger; it is dangerous even to be met in the woods by two together, or even one, and yet they sometimes assemble to the amount of a hundred in company, when nothing can resist their attacks. Edwards is the only writer who speaks of it as an insensible creature, and the individual he mentions was in a state of captivity; he mentions it as "a very sociable, gentle, harmless-natured animal, not having the cunning, mischievousness, or malice of the monkey kind." The colours of this animal vary much in different individuals, yet
LEMUR.

are in general diversified with patches of black and white, though sometimes it appears they are totally white or brown. The voice of this animal is loud and terrible, and is by some compared with the roaring of the lion, or rather its cries resemble those of the howling-monkey of Brazil and Guiana; it delights in sun-shine, and sleeps in dark places. The fur of this animal is long, the muzzle large and rather long, the ears short and fringed with long hairs; and the eyes of such a deep orange as to appear of a fiery redness. The ruff, or cravet-like ring of long fur that surrounds the neck, is peculiarly striking in its appearance, and serves principally to characterize this species; besides which it may be observed, that the great hind-toes are almost fustulate. It refues eggs, fish, and fift.

The mococo, says Buffon, is a beautiful animal, with a fine countenance. Its fize is rather smaller than that of the full-grown cat, the shape more flender; its colour above and on the outside of the limbs somewhat furrinous, the under parts whitith, and the fur throughout remarkable for its luster. The eyes are large, of a bright orange, inclining to hazel, and are surrounded by a dilhent circle of black; the muzzle is black, and the hands and feet of the fame colour; the fingers and toes furnished with round nails, the nails of the great toes not being longer or fustulate as in most other species. The tail, which it always carries erect in a graceful position, is very long; the hair upon it longer than the rest of the fur, and marked with about thirty equiffant or regular dilhent circles of black and white. The manners of this species are gentle and lively, in various respects resembling those of the monkey-tribe, without its petulance and malice; when pleased it purrs like a cat. In a state of liberty these animals live in focieties of thirty or forty together in the woods; in ascending trees they climb with all their feet like the ape; their food consists of fruits, herbs, and roots, and it is also affeited they will eat animal food; like the squirrel they sometimes feed fitting upright, and often extending their hands forwards, and in the fame manner, when in a state of captivity, take their flation before a fire to warm themselves. This species inhabits Madagascar.

Supposed to inhabit South America; the head is obtufe; nails fubulate; toes white.

This species inhabits Madagascar; its length is five inches and a half from the tip of the nose to the base of the tail; the muzzle shorter than in most other species. An individual of this kind brought from its native country was preserved alive in France for some years. It evinced a remarkable degree of acuity in its motions; its cry was feeble like that of the squirrel; and its food consisted of fruits and almonds. The history of this curious little species, as related by Buffon (under the title of rat de Madagascar), is erroneously placed by Mr. Pennant, in his work on quadrupeds, under the description of his Murius macaco, by which means the two species are confounded together. Dr. Shaw, from his adherence to this writer, has also fallen into the same opinion in his General Zoology.

This beautiful little animal is a native of Madagascar. The whole body, except the face, feet, and hands, are covered with greyish wolly hair; the tail is very long, and covered with short woolly hairs, like the rest of the body. It much resembles the lemur catta in its general appearance; the posterior limbs are much higher than those before.

One of the smaller species of the tribe, measuring six or seven inches from the nose to the tail, the latter eight inches. The ears are very large, thin, upright, and rounded at the tip; the hind legs much longer than the anterior ones; the nails of the hands rounded, except that of the fore-finger of each, which consists of a sharp claw. These animals, according to Adanson, are of a peaceable disposition; they feed on insects, and live in trees. The negroes of Galam hunt them for the sake of their flesh, the flavour of which is, however, very indifferent.

This is a species allied so nearly to the squirrel tribe, to which it is referred by Gmelin, that it admits of doubt whether Schreber is entirely correct in confining it to the lemur tribe; and it also approaches very closely the family of monkeys. Its length is eighteen inches, the colour pale-furrinous grey, with a blackish cast on the back and limbs; the tail entirely black, fides of the head, neck, lower jaw, and belly greyish. The head is shaped like that of the squirrel; the ears large, round, and naked; their colour black; and in front of each jaw are two cutting teeth; the feet long; the interior toes of the hind feet short, and furnished with flat round nails. All the claws on the fore-feet sharp and crooked, the two middle ones in particular very long, extremely thin and naked, except at their base. It is a timid animal, uncommonly slow in its movements, and of a mild disposition. M. Sonnerat observes, that its eyes were of an ochre-colour, and resembled those of the owl, and like that bird the animal can scarce fee distinctly by day. The individuals kept by Sonnerat lived only about two months; they slept almost continually, and were scarcely to be awakened but by shaking two or three times. Their nourishment consisted of boiled rice which they took up with their long fore-toes, in the manner that the Chinefe use their eating fisks. It is a native of Mada- gascar, where it is rare. Fruits and insects appear to be its usual food.

Some indication prevails among naturalists respecting the lemur genus, and its immediate affinities; the Linnean and Gmelinian character is not altogether sufficiently precise, and thus embraces more than one distinct natural genus, of which the galeopithecus (lemur-volans, Linn.) is a prominent example. The number of genera into which Geoffroy divides the lemures is considerable, amounting (independently of the galeopithecini) to no less than five, namely, lemur, indri, loris, galago, and tarbux. This distribution, with some slight occasional deviations, is adopted by the latest French writers. The genus Lemur (maki) is characterized as having the muzzle very long; four inclive teeth in the upper jaw, beneath six, inclining forwards; grinders tuberculated; ears short, or thortill; tail very long. Under this are retained the Linnean lemur cats, mongos, and macaco; lemur rufus of Audubert; lemur bicolor.
bicolor (Abbifrons, Geoff.) and the two little species, called by Geoffrey girens and pusillus. Isori, the second new genus, consists at present but of two species, the Limacean lemur indri and laniger; the former of which is indigenous of Geoffrey; and the latter indri longicolus of the same author. These have the muzzle very long; in each jaw four incisive teeth; the upper ones standing distant in pairs; and grinders tuberculated; in other respects they resemble the lemur. In the genus Loris the head is rounded, the muzzle short; incisive teeth in each jaw four, the lower ones directed forwards; eyes very open; ears moderate; nostrils situated on the sides of the nose; no tail, but in its place a tubercle; postorbital tarsus; this consists of two species, lemur tardigradus, Linn.; and lemur gracilis, Geoff. Galago, the fourth genus, is distinguished by the rounded form of the head, short muzzle, two incisive teeth in the upper jaw, very remote; in the lower one six; grinders with pointed tubercles; nostrils placed at the sides of the nose; ears naked, sometimes very large; anterior legs short, posterior ones elongated; second finger of the hind foot shorter than the rest; tail longer than the body, and hairy; fur very thick. This comprehends galago fagenalis of Geoffrey, and le petit galago, (lemur minutus, Geoffiers) Taribus is the half of these: new genera; its characters consist in having the head rounded; muzzle a little prolonged; in the upper jaw four incisive teeth, in the lower only two; canine teeth several, and shorter than the incisive ones; the grinders with pointed tubercles; posterior hands uncommonly long; tail long and tufted; ears large and naked. This genus, which can scarcely, perhaps with propriety, be referred to the Genelinian lemur, although partially affined to some authors, comprises tarbue dabanitoni of Geoffrey (lemur tarbins, Pallas); and delphinae dornubini, Geoff.; and with two others, one lemur of Pallas, the other tarbue fithechery, Nob.; a species very recently described, and named Fivelheri after professor Fisher, by whom it was first introduced to general observation.

LEMURES, in Antiquity, spirits or hobgoblins; retfiefs ghosts of departed persons, who return to terrify and torment the living.

There are the same with larves, which the ancients imagined to wander round the world to frighten good people, and plague the bad. For which reason, at Rome they had Lemuria, or feasts instituted to appease the powers of the defunct. See LARES.

Apuleius explains the ancient notion of manes thus; the souls of men, released from the bands of the body, and freed from performing their bodily functions, became a kind of demons or genii, formerly called lemures. Of these lemures, those that were kind to their families, were called lures famillares; but those who, for their crimes, were condemned to wander continually, without meeting with any place of rest, and terrified good men, and hurt the bad, are vulgarly called larves.

An ancient commentator on Horace mentions, that the Romans wrote lemures for remures; which last word was formed from Remus, who was killed by his brother Romulus, and who returned to earth to torment him.

Put Apuleius observes, that in the ancient Latin tongue lemures signifies the soul of a man separated from the body by death.

LEMURIA, or LEMURALIA, a feast solemnized at Rome on the ninth of May, to pacify the manes of the dead, or in honour of the lemures.

The institution of this feast is ascribed to Romulus, who, to rid himself of the phantom of his brother Remus (whom he had ordered to be murdered) appearing always before him, ordained a feast, called after his name Remuria, or Lemuria.

In the Lemuria, they offered sacrifices for three nights together, during all which time all the temples of the gods were shut up, nor were any marriages permitted. There were many ceremonies in this feast, chiefly intended to exorcise the lemures, and prevent their appearing, or giving any disturbance to the living.

LENA, in Geography, the greatest river of Eastern Siberia. It takes its origin on the north-western side of the Baikal, in a morass; runs at first westwards, then to the district of Yakutsk cafiers, and finally towards the north, where, after having divided itself into five great branches at its mouth, and thereby formed four considerable islands, it flows into the Frozen ocean. Its course is computed to be 5000 miles. Its source is in N. lat. 52° 30'; its mouth in 73° lat., and the western arm in 153°, and the eastern in 143° of longitude. This river has in general a very gentle current; its bottom is mostly sandy, and the shore only in the upper regions befted with hills and cliffs. Of the numerous rivers which it takes up in its course, the largest are the Vitim, the Olenek, the Vilyuy, and the Aldan. Out of the Lena travels passes into the Aldan, from that into the Men, from the Men into the Yenisey, and from this they have but a short route to make by land to Omsk. Tooke's Rej. Emb. vol. i.

LENA, a harbour on the W. coast of Mandana. N. lat. 64° 42'; E. long. 122° 12'.

LENAE, ALEN, in Antiquity, a festival of Bacchus, named Lenae, from Lena, i.e. a wine-press. Besides the usual ceremonies at feasts, sacrificed to this god, it was remarkable for poetical containing, and tragedies acted at this time. Potter's Archzol. lib. ii. cap. 20. tom. i. p. 412.

LENATO, in Geography, a town of Italy, in the department of the Olona; 5 miles S. of Milan.

LENBERAN, a town of Perian Armenia; 168 miles E. of Erivan.

LENCLOISTRE, a town of France, in the department of the Vienne, and chief place of a canton, in the district of Chatellerault; 14 miles N. of Poitiers. The place contains 2114, and the canton 7350 inhabitants, on a territory of 182 square kilometres, in nine communes.

LENCLOS, ANNE, or NINON DE, in Biography, an illustrious woman, born at Paris in 1616, was daughter of the sieur De l'Enclos, a gentleman of Touraine, who had served with reputation in the army; her mother was a devotee. She left both her parents at the age of fifteen, and being left mistresses of a large fortune without any one to control her, determined to adopt a mode of life suited to her inclinations. She had already derived her philosophy from the works of Charren and Montagne; she was beautiful, and by much attention became very accomplished, and qualified for the company of the most cultivated persons of her time. Amorous in her constitution, and licentious by principle, she resolved to give free indulgence to the tender passion, without the shackles of a serious engagement. She never sold her favours; and her attachments seem partly to have been prompted by personal attractions, and partly by vanity, as they included persons of high rank and reputation, as well as men of gallantry and fashion. She was complimented and confounded by the most eminent writers of that time, and her friendship was sought by some of the most respectable of her own sex. She was intimate with madame de Maintenon, when the wife and widow of Scarron, who wished to engage Ninon to...
to live with her, when a partner in the throne, to dispel the dreadful ennui which was the price of her elevation. Nisnpreferred her liberty to the prison of a palace, and as she retained her personal charms to a late period, and her mental attractions to the close of life, she was very long the object of admiration, and had the honour of forming more than one generation of young men of fashion. Mothers, so licentious was the age, were pleased to see their sons in her train, as she always promoted decorum, and the air of good company; and it was universally admitted that she was capable of disinterested friendship to those who confided in her. If she were an object of envy to by-flanders, she was, at the same time, conscious of having taken the way to true happiness; for in one of her letters to St. Evremond, she says, "Every one tells me that I have left to complain of time, than any other person. However that may be, if such a lilt, as I have spent, had been proposed to me as my lot, I would have辈子 myself rather than have passed through it." She died at the age of eighty. She is reputed to have been the author of a set of letters to the marquis de Saviger. Some of her real ones are contained in the works of St. Evremond. Moreri.

LENCZICZ, or LEXTSCHITZ, in Geography, a town of the duchy of Warsaw, formerly capital of a palatinate of the same name in Poland; surrounded with a wall and moat, and defended by a castle placed on a rock. A provincial diet, a court of judicature, and provincial synods of the clergy, are held in this town; 60 miles W.S.W. of Warsaw. N. lat. 51° 52'. E. long. 19° 17'.

LENCZNA, a town of Poland, in the palatinate of Lublin; 16 miles N.E. of Lublin.

LENDAR, a town of Iliria; 19 miles E. of Cape d'I'llria.

LENDENARA, a town of Italy, in the Polese di Rovigo; containing two churches and four convents; 8 miles W. of Rovigo.

LENDORA, a town of Ruffia, in the government of Olonez; 100 miles W.N.W. of Povenetz.

LENE Lough, a lake of Ireland, in the county of Wefmuth, near the small town of Fore.

LENEs, a small isle in the North sea, near the coast of Norway. N. lat. 67° 40'.

L'ENFANT, DAVID, in Biography, a French Dominican friar, was born at Paris in the year 1633. He embraced the ecclesiastical life at the age of seventeen, and manifested a most ardent thirst for knowledge, together with very uncommon literary industry. He died in the year 1688, at the age of eighty-five. His principal work is "A General History of all Ages," in three vols.; which was afterwards extended to six volumes. He also published "Sancti Bernardi Abbatis Biblia," containing a collection of all the illustrations of texts of scripture dispersed throughout the works of that author; and similar works respecting biblical illustrations of St. Augustine, and St. Thomas Aquinas. Moreri.

L'ENFANT, James, an eloquent as well as very learned French Protestant divine, was born at Bazoche in the year 1651. He pursued his theological studies at Saumur, under Lewis Cappel, profeffor of Hebrew, and afterwards at Geneva. In 1683 he left Geneva, and was admitted in the following year to the exercise of the ministry at Heidelberg, and ordained pastor of the French church in that place. Owing to his superior pulpit talents he was appointed chaplain to the envoy of France at Constantinople. In 1688, on the invasion of the palatinate, he removed to Berlin, and was appointed pastor of one of the churches. He was in a short time nominated preacher to the queen of Prussia. In 1707 we find him in England, and nominated one of the chaplains to queen Anne, an honour which he declined on account of his great attachment to Berlin. He died in 1728, at the age of sixty-seven. His publications were numerous in divinity, ecclesiastical history, criticism, and polite literature. Those which are held in the highest estimation are his "Histories of the Councils of Pisa, Constance, and Basil." These histories are written with great ability and impartiality, and they abound with interesting facts and curious researches. L'Enfant, in conjunction with M. Beaufoubre, published "The New Testament translated from the original Greek into French," in two volumes 4to. with notes, and a general preface, or introduction to the reading of the holy scriptures, useful for students in divinity. He is known also by his "De Inquirendis Veritatis," which is a translation of Malebranche's "Search after Truth," "The History of Pope Joan," "Poggias, or the Life, Character, Opinions, &c. of Poggio, the Florentine, with the History of the Republic of Florence," and other works. Moreri.

LENGA DE BAZARA, in Biography, a province on the coast of Caramania. N. lat. 56° 33'. E. long. 34° 11'.

LENGEFELD, a town of Saxony, in the circle of Erzgeburg; 12 miles S.E. of Chemnitz. N. lat. 50° 40'. E. long. 13° 7'.

LENGEFIELD, or Lengenhof, a town of Saxony, in the Vogtland; 10 miles S.S.W. of Zwickau. N. lat. 50° 27'. E. long. 12° 22'.

LENGER, a town of Persia, in Khorasan; 162 miles N.W. of Herat.

LENGER KURAN, a town of Persia, in Chilan; 120 miles N.W. of Reihd.

LENGFURT, a town of Germany, in the county of Wertheim; 12 miles S.S.W. of Wertheim.

LENGHIER, a town of Persia, in Khorasan; 70 miles E. of Herat.

LENGIUM, a town of Sweden, in West Gothland; 42 miles E. of Gothenburg.

LENGLET, du Fresnoy, Nicholas, in Biography, was born at Beauvais in 1674. He applied himself particularly to the study of theology, and composed several works in a strain of freedom, which attracted the cenfure of the Sorbonne, and other established bodies. Disgusted with the opposition which he met with, he quitted divinity for politics, and in 1705 was sent by Torcy, minister for foreign affairs, to refide at the court of the elector of Cologne, as secretary for the Greek and Latin languages. He was entrusted with the management of the foreign correspondence with Bruxelles and Holland, by means of which he became acquainted with various plots against the French interest. Lenglet returned to France at the conclusion of the war, and employed himself in many literary works. In 1721 he went to Vienna, and was appointed librarian to prince Eugene, a post which he did not long retain, on account of some misconduct. Owing to this circumstance, he always remained in indigence, though he had friends that would have raised him to a better condition. Some of his writings were composed in fo free a style as to cause the author to be imprisoned several times in the Bastille. He was accidentally burnt to death in the year 1755, in his eighty-second year. Of his various works we may notice those which are most esteemed, viz. "Methode pour étudier l'Histoire, avec un Catalogue des principaux Historiens," 12 vols.; "Methode pour étudier la Géographie," with maps; "Histoire de la Philosophie Hermetique," and "Tablettes Chronologiques de l'Histoire Universelle," two vols. 1744. An enlarged
LEN

LENGO SENGANDO, in Geography, a town of Africa, in Congo; 45 miles S.W. of Bomba.

LENGU, in the Amazon. To passage a horse upon his own length, is to make it go round in two tracks, at a walk or trot, upon a path or course to narrow, that the horse’s hooves being in the centre of the vol, his own length is much about the foundation of the volt; the horse still walking between the two wheels, without putting out his crupis, or going at half faster or slower than at first.

LENGTHENING, in Naval Architecture, is the operation of separating a ship athwart the midships, and adding a certain portion to her length. It is performed by clearing all the fardings near the butts of these planks as may be required, and the others are cut adunder. The after end is then drawn or launched apart to the required distance. The keel is then made good, and a sufficient number of floors are led, and timbers railed to fill up the vacancy produced by the separation. The keelson is then replaced to give good sort to the seams of the keel. The planks on the outside are then replaced with a proper flit, also the clamps and fastenings inside. As many beams as are necessary are next placed athwart and kneed, the decks made good, and the ship completed in all respects as before. Sometimes ships are shortened in a similar manner.

LENGUR, in Geography, a town of Persia, in the province of Mazanderan; 15 miles N.W. of Amol.

LENHOFDA, a town of Sweden, in the province of Smaland; 30 miles N.W. of Stockholm.

LENIOR, a county of America, in Newbern district, North Carolina, surrounded by Glasgow, Craven, Jones, and Dauphin; containing 3898 free inhabitants, and 1457 slaves. The chief town is Kingston.

LENS SPIRITUS, in Profundi. See SPIRIT.

LENTIVE, in Physics, sometimes denotes a softening, reluting remedy, that moistens the parts diseased, and dilutes any sharp humour collected there.

LENTIVE is more frequently used for laxative.

LENTIVE ELLIPSE is more peculiarly used for a gentle purging effect. See ELLIPSE OF AGRAM.

LENKERAN, in Geography, a town of Persia, in the province of Ghilan, near the Caspian sea. N. lat. 28° 40'.

LENAN, a town of Persia, in the diocese of La Paz; 27 miles N. of Patefi.

LENNEP, a town of the Duchy of Berg, inhabited for the most part by Lutherans; 20 miles E.S.E. of Dusseldorf. N. lat. 51° 5'. E. long. 7° 18'.

LENNO, a harbour on the W. coast of the island of Mandaoe.

LENNICK-SAIN'T-MARTIN, a town of France, in the department of the Dyie, and chief place of a canton, in the district of Brussels. The place contains 1559, and the canton 10,066 inhabitants, on a territory of 120 kilometres, in 13 communes.

LENOS, in Hippocrates, denotes an old machine for reducing fractures and dislocations.

LENOX, in Biography. See RICHMOND, Duke of.

LENNOX, in Geography, an island in the Mergui Archipelago, about five miles in circuit. N. lat. 9° 21'.

LENNOX, the shire town of Berkshire county, Massachusetts; it is a pleasant and thriving town, and has a court house and a gaol. The river Kennettrick terraces the town; 145 miles N. of Boston. The number of inhabitants is 1041.

LENOS, in Hippocrates, denotes an old machine for reducing fractures and dislocations.

LENOW, a post-town of Buckingham county, North Carolina; 290 miles from Washington.

LENS, in Dioptrics, properly signifies a small, roundish glafs, of the figure of a lentil; but is extended to any detached portion of a transparent substance, of which the opposite sides are regular polished surfaces of such forms as may be described by lines revolving round a common axis; or to any optic glafs, not very thick, which either collects the rays of light into a point, in their passage through it, or diverges them farther apart, according to the laws of refraction. A lens is generally supported, in simple calculations, to be infinitely thin, and to be denfer than the surrounding medium.

Lenses have various figures; that is, are terminated by various surfaces, from which they acquire various names. The lines that form them may be portions of circles, of ellipses, of hyperbolae, or of any other curves, or they may be right lines. But, in general, one of the fides is a portion of a spherical surface, and the other either a portion of a spherical surface or a plane. Hence some are plane on one side, and convex on the other; others convex on both sides; both which are ordinarily called convex lenses; though, when we speak accurately, the former are called plano-convex, and the latter, double convex. Again, some are plane on one side, and concave on the other; and others are concave on both sides, which are both usuallly ranked among the concave lenses; though, when distinguished, the former is called a plano-concave, and the latter, a double concave. Others, again, are concave on one side, and convex on the other; which are called convexo-concave, or concavo-convex lenses. The figures of all these are sufficiently described by their names (see also Plate VI. Optics, fig. 5.); except that the term monofocal, which properly implies a little moon or crescent, is applied in general to all lenses which are convex on the one side, and concave on the other, although they may be thicker at the edges than in the middle. Sometimes, however, a lens of this kind is distinguised by the term concavo-convex. See MENDOCS.

When the particular figure is not considered, a lens that is thickest in the middle is called a convex lens; and that which is thinnest in the middle is called a concave lens, without further dilinction.

It is to be here observed, that in every lens terminated in any of the foregoing manners, a right line perpendicular to the two surfaces is called the axis of the lens; which axis, when both surfaces are spherical, passes through both their centres; but it is manifest, that no lens, except the sphere, can have but one axis; and therefore all pencils of rays are oblique, excepting those whose focus are in the axis of the lens; but if one of them be plane, it falls perpendicularly upon that, and goes through the centre of the other. The points where the axis cuts the surface are called the vertices of the lens, and the middle point between them is called the centre. This is the case, when the lenses are thin, as they are usually supposed to be; but when the lens is pretty thick, and its surfaces of unequal curvatures, then the centre of the lens is nearer to one vertex than to the other; by as much as the radius of curvature of the former surface is less than that of the other.

For the explanation of other terms that pertain to lenses, and of their general effect, it is obvious, that if a ray of light falls perpendicularly upon the vertex of a lens, or coincides with its axis, it must pass straight through the lens without suffering any refraction; but when it falls obliquely upon it, it must emerge out of the lens in a direction inclined to its former direction. Thus, when the rays of light, which,
ILLUMINATING FROM THE LUMINOUS POINT A, (Plate VI. Optics, fig. 6.) fall upon the lens B E, the ray AC, which proceeds in the direction of the axis of the lens, must pass straight through it; but the ray AB, falling obliquely upon the surface of the lens, must be refracted, or bent, and if the lens be a plano-convex, or double convex, that ray must be bent inwardly, that is, towards the axis; consequently it must intersect the axis in some point, as F. This point F is called the refracted focus of that ray, or rather of the rays A B, A E, &c., which fall upon the lens at equal distances from the axis AC, and which all meet and cross at the same point F; but the point A from which they issue, is called the radiant point, or the focus of incident rays; and both these points, in reference to each other, are called the conjugate foci. If a lens be concave, as in fig. 7, then the oblique rays A B, A E, &c., will be bent outwardly, or from the axis; in which case the refracted rays are supposed to be continued backwards until they meet the axis as at F, then the point F is called the virtual focus of the refracted rays, being in fact the centre of divergence of the rays. In this case the conjugate foci are both on the same side of the lens; viz., the real focus of incident rays, and the virtual focus F of the refracted rays B G, D O, E S. It is to be observed, that all the rays which fall upon the surface of a lens, whether it be convex or concave, will not meet at one and the same point when the lens is convex, nor have a common virtual focus when it is concave; but those rays which are more distant from the axis, after the refraction, meet sooner than those which are nearer to the axis: and this effect is greater in proportion as the surfaces of the lens are farther from each other, and consist of larger spherical segments. Hence a glass globe renders the above-mentioned effect very conspicuous; and hence the lenses are made as thin as possible; but in all cases, a lens which consists of spherical surfaces, does never refract the rays which fall from a luminous point, precisely to the same focus. The rays which fall upon the edge of the lens have their refracted focus not only nearer to the lens, but also further from the axis, viz., on one side of it. Lines drawn through the refracted focus of the rays, which belong to one luminous or radiant point, form two curves, which make an angle with each other at the axis, or principal focus, and are called "caustics by refraction" (see Caustic); which are real in convex lenses, but imaginary in those that are concave. When the lenses are thin, and their sphericality not very great, these caustics are so trifling that the eye does not perceive them; but lenses that are thick and of great convexity produce a considerable aberration of the rays, and an evident distortion of the object to an eye that looks through them. This aberration may be exhibited experimentally by covering one side of a glass globe or thick lens with a circular piece of brown paper, having a row of equidistant pin-holes in its diameter. Let the light which passes through these holes, and through the lens, fall upon a piece of white paper held perpendicular to the rays of light, and you will find that when the paper is held near to the globe or lens, the spots of light upon it are at equal distances from one another successively; but if the paper be gradually withdrawn from the lens, the intervals between the exterior spots grow less than the intervals between the interior, and soon unite. If the same operation be performed with a thick concave lens, the intervals between the exterior spots will be found to grow larger than the interior, &c. There is another aberration, resulting from the different refrangibility of the rays of light; and which causes a much greater imperfection in lenses. For an account of both, see aberration. Notwithstanding these aberrations, glass lenses, that are not very thick, are reckoned to have a determinate focus of refracted rays, originally issuing from a single radiant point; and the distance of that focus from the surface of the lens is called the focal distance of those rays. In order to prepare the way for determining their focal distances, it may be considered, that about the middle of the surface of every lens there is a point, upon which, if a ray falls and passes through the lens, the emergent part will be parallel to the incident; for the point of incidence and the point of emergence may be so situated, that if two planes touch the surfaces at these points, they may be parallel to each other. That ray or part of a pencil of light, which thus passes through the lens, without being bent, is called the axis of that pencil, and this axis passes through the centre of the lens. When rays of light fall upon the same lens with different inclinations, it is evident that after the refraction, they must have their foci at different distances from the lens. When rays of light come parallel to each other, such as those which come from a point of the sun's surface, or from any other distant point, and fall perpendicularly, or nearly so, upon the surface of a lens; then the focus of these rays, after refraction, is called the geometrical focus, or the principal focus of that lens, and its distance from the lens the principal focal distance of that lens. The principal focus of a lens may be found either experimentally or by computation. In a plano-convex, double-convex, or menisic, the principal focus is real; in the other lenses the focus is virtual. See the Theory of Lenses demonstrated under Refraction and Dioptrics, and the application thereof under Microscope, Telescope, Burning-Class, and Focus.

Some confine lenses within the diameter of five or six lines, and will have such as exceed that diameter called lenticular glasses.

Lenses are distinguished, with regard to the manner of their preparation, into ground and blown.

LENS. Blown', are little globules of glass, melted in the flame of a lamp, or taper. See Microscope.

Lenses, Manner of grinding. A little piece of copper is cemented to the end of the arbor of a lathe, and turned till it form a 5th, or bafon, of the diameter of the lens required. Then a piece of clear glass is cemented, on one of its flat sides, to the end of a little maundrel, with black Spanish wax; and thus ground, on the side not cemented, on a grindstone, with water, till it hath nearly acquired a convex figure. It is finished in the lathe, by turning it in the bafon, with fine wet sand, grit-floane, or emery. The grit must be often repeated fresh till the lens appear very round; when it is come to that point, they cease to take any fresh stone, but continue to turn it in the bafon, till the remains of the sand are become so fine as to have polished it. This they perceive, when, upon wiping it, the image of the window of the place is seen painted on its surface; if it does not, it is wetted in water without any sand, and turned till it hath got a polish. The bafon is then covered, within-side, with two or three folds of linen, and the polish finished with putty, or trioply of Venice steeped in water. It is known to be perfectly polished, when, viewing it with a magnifier, there appear no scratches of the sand. The cement is then broken off, and the side polished cemented, to work and grind the other, as before, till the edges of the lens be become sharp, and it be perfectly polished on either side. When finished, it is washed in spirit of wine, to take off all remains of the wax.

According to the mode now generally practised, optical glasses are fixed on blocks by means of a cement, and ground with emery by a tool of proper convexity or concavity;
cavity; if they are small, a large number is fixed on the blocks at the same time. The tool is sometimes first turned round its axis by machinery, and when the lenses are to be finished, a compound motion is given to it by means of a crank; and in order to make it more smooth, the wheels turn each other by brushes instead of cogs. The point of the lens where its two surfaces are parallel, is determined by looking through it at a minute object, while it is fixed on a wheel with a tubular axis, and shifting it, until the object appears no longer to move; a circle is then described, as it revolves, in order to mark its outline. The differences in which lenses are sometimes ground are of bell metal; and the emery is prepared by eutrition.

In the Philosophical Transactions, we have the figure of a machine for grinding lenses spherically. It is a contrivance to turn a sphere at one and the same time on two axes, intersecting each other at right angles, with an equal velocity and pressure on each. See the Transactions, N. 459, feet. 1. See Grinding of Optic Glasses.

Lenses, for convex, the laws of their refraction, and their effects depending thereon, are as follow. — 1. A ray of light, $E G$, near the axis (Plate VI. Optics, fig. 8.), and parallel to it, striking on the plane surface of a plano-convex lens, directly opposite to the luminous body, after refraction concurs with the axis in the point $F$; and if $C$ be the centre of the convexity, $C F$ will be to $F L$, that is, the distance of the centre from the point of concurrence, or focus, will be to the distance of the centre, from the convex surface, in the ratio of the refraction.

For the plane surface being directly opposite to the luminous body, the ray $E G$ is perpendicular to $A B$, and therefore will pass unrefracted to $H$: thus it strikes on $A H B$, still parallel to the axis; and therefore coming out of a denser medium into a rarer, it will meet with the axis of the lens in $F$; and so as that $C F$ will be to $F L$ in the ratio of the refraction of the plane to the angle of incidence: as will be demonstrated under the head of Refraction.

And, therefore, $C F = F L$, or $C L$ is to $F L$ as the difference of these lines is to the tangent of the angle of incidence; and $C F = F L$, or $C L$ is to $F L$ as the same difference is to the tangent of the refracted angle.

If then the refraction be out of a glass lens into air, $C F : F L :: 3 : 2$, or $C L : F L :: 1 : 2$, and $C L : F L :: 3$; and therefore $F L = C L + L F$, that is, parallel rays, near the axis, will concur with it at the distance of the diameter. Moreover, if parallel rays pass out of air into glass, it will be $C F : F L :: 2 : 3$, and $C L : F L :: 1 : 3$, and $C L : F C :: 1 : 2$. It is evident from hence, that if $C L$ be diminished, without any variation in the refracting power, $F L$ would also be diminished. Again, if the refraction were out of water, i.e., out of a plano-convex lens filled with water, $C F : F L :: 4 : 3$, or $C L : F L :: 1 : 3$; and therefore $F L = 3 C L + L F$, that is, parallel rays, near the axis, will concur with it at the distance of a diameter and a half. It is easy to deduce the effect of refraction out of air into water.

So that if a lighted candle be placed in the focus of a plano-convex lens, that is, in the point $F$, distant from the surface of the lens $A L B$, by the length of the diameter; and from the surface of the water lens by a diameter and a half, its rays, after refraction, will become parallel.

2. If the ray $K I$, (Plate VI. Optics, fig. 9.) near the axis of a plano-convex lens, and parallel to it, strike on its convex surface $A H B$, after a double refraction, it will meet the axis in $F$; so as that $H G$ will be to $C G$, and $G D$ to $F D$, in the ratio of the refraction.

For the ray $K I$, parallel to the axis $E G$, by virtue of the first refraction in $I_i$ will tend to the point $G$, so that $G H$ will be to $G C$ in the ratio of the sine of the angle of incidence to the sine of the refracted angle: therefore, by virtue of the second refraction in $I_i$, it will concur with the axis in $F$; so that $G D$ will be to $F D$ in the ratio of the sine of the refracted angle, to the sine of the angle of incidence. See Refraction.

So that the semi-diameter, and thickness of the plano-convex lens, with the ratio of refraction, being given, we shall have a method of determining the focus of parallel rays striking on the convex surface. For, if the ratio of refraction be expressed by $m : n$, $G H = \frac{n}{m}$ and $G D = \frac{n}{m} \times HC$; from which subtracting the thickness of the lens, $D H$, and $G D = \frac{n}{m} \times HC - HD$. Then the ratio of the thickness of the lens to $F D$ is the given ratio of refraction, $F D = \frac{m}{n} \times CH - \frac{m}{n} \times HD = \text{rejecting the quantity of } n \times HD 	ext{ as very small} \frac{m}{n} \times CH$.

Hence, if the lens be glass, $F D = 2 CH - \frac{4}{3} HD$, and therefore, if $\frac{4}{3} HD$ be inconsiderable, $F D = 3 CH$, or if $\frac{4}{3} HD$ be inconsiderable, $F H = 3 CH$. Parallel, and near rays, therefore, are united at the distance of a diameter and a half, if the refraction be in water, even when the convex surface is opposed to the luminous body.

3. Hence, also, arises a method of determining the focus of parallel rays striking on a lens convex on both sides, the two semi-diameters, and the thickness of the lens, being given.

For the ray $H J$, (Plate VI. Optics, fig. 10.) near the axis $D G$ and parallel to it, fall on a lens convex on both sides, after a double refraction, it will meet the axis in $F$, provided that $G E : GC$ and $D K : DO$ have the ratio of refraction. And $G D$ will be to $G K$ as $G O$ to $G F$. Since $E G : GC$ in the ratio of refraction, the ray $H J$ will tend to the point $G$; and if $D K$ be to $DO$ in the ratio of refraction, after the second refraction at its edge, it will meet the axis in $F$, and $G D : G K :: G O : G F$. See Refraction.

And therefore, $G D : D K :: G O : F O$. Let the ratio of refraction be that of $n : m$, then $G E : GC :: n : m$, and $G D : D K :: n : m$; and, therefore, $n - m : n :: CE : G F$, and $n - m : n :: KO : D K$; wherefore if the ratio of refraction and the semi-diameters $CE$ and $KO$ are given, $GE$ and $DK$ may be found: and since $GD = DK + EG - EK$, and $GK = GE - EK$, and $G O = GE + KO - E K$, and $GD : G K :: G O : G F$; $G F$ may be found: moreover $G E = G F = E F$. If $E K$ be rejected as very small, $GD = DK + EG$, $G K = GE$, and $G O = GE + KO$; and therefore, $DK + EG : GE :: GE + KO : G F$.

Hence,
Hence, if the lens be glass, since \( GE = 3 CE \), and \( DG = K \), and \( K = 3 KO \), \( 3 KO + 3 CE \); \( 3 CE \); \( 3 CE + KO \); \( GF \); consequently \( KO + CE \); \( CE \); \( CE + KO \); \( GF \).

And substituting for \( KO \), \( a \), \( CE \), \( b \), and \( GF \), \( x \),

\[
-x = \frac{3b + b}{a + b} + \frac{a}{a + b},
\]

and \( FE \) or \( FK \), (rejecting \( EK \)) \( = \frac{3b}{a} \), \( \frac{3b + b}{a} \), \( \frac{3b + b}{a + b} = 2a \).

Also, for the sum of the focal lengths of the two sides, \( GF = 2 CE \); and \( FK = \frac{2a^2}{a} = a = CE \); i.e.,

the distance of the focus from the lens is equal to the radius of convexity.

If the lens were full of water, since \( GE = 4 CE \), and \( DG = K \), \( 4 KO + 4 CE \); \( 4 CE \); \( 4 CE + KO \); \( GF \); consequently \( KO + CE \); \( CE \); \( CE + KO \); \( GF \).

Therefore substituting as before \( x = \frac{4bb + ab}{a + b} \), and \( FE \) or \( FK \) \( = \frac{4bb + ab}{a + b} = \frac{3ab}{a + b} \); consequently the sum of the focal lengths of the two sides, \( GF \); \( CE \); and \( FK = \frac{3aa}{a} + \frac{3a}{2} \), i.e. the distance of the focus from the lens is \( \frac{3}{2} \) of the radius.

In order to find the principal focus of a plano-convex or double convex lens experimentally, various methods have been devised and recommended. One is as follows: Measure exactly the thickness of the lens in the middle and at the edge, and also its breadth; then it will be as the difference of the above thickness is to half the breadth, so is half the breadth to the focal length required. The following method will serve, according as the centres of the sides are on different sides or on the same side of the lens; as the sum or difference of the radii of the sides is to one of them, so is double the other to the focal distance from the lens. If the curvature of each side is the same, the radius of that curvature may be denoted the focal length; and if one side of the lens is plane, the focal length may be reckoned equal to twice the radius of the spherical side. The focal length of a convex lens may be also found by the following methods: Darken a room, so that no light shall enter it except through a tube in one of the window-flutters; then, placing the lens against and close to this hole, move a white paper behind it, till the picture of a particular object, directly facing the lens, appears most distinct, and then fix the paper; then measuring the distances betwixt the paper and the object from the lens respectively, there will be sufficient data for finding the focal length required. Let \( OP \) (fig. 11.) be the object without doors, \( A \), the lens in the window-flutter, \( q \) the place of the paper where the image of \( OP \) is most distinct, and \( QA \) \( = \) the axis of the lens. Having measured the distances \( QA \), \( qA \), it will be, \( OQ = QA = QA \); \( GF \); and \( QA - QO = AF \) the focal length required.

The focal length of any lens, it is observed, is in strictness the distance from its principal focus to the respective focal centre; and in the example above given, the distance betwixt the focal centres of the lens should have been subtracted from \( OQ \); and for \( QA \) we should have taken the distance from \( Q \) to the nearest focal centre. But in experiments of this kind, these niceties would be superfluous. Moreover, in the above experiment, there will be a certain part of the axis, extending on each side of the geometrical focus \( q \), within which, wherever the paper is placed, the picture as to sense will be equally distinct. Having found nearly the place of \( q \), move the paper from thence both ways along the axis, till an indistinctness begins to be perceptible in a particular small part of the picture; and having noted these two places, the middle point between them may be taken for the focus \( q \). Again, if the focal length of the lens does not exceed two or three feet, it may be found without darkening the room, by holding the lens at such a distance off, that the image of the window-facing may be distinct upon the opposite window; then computing as above, the window-facing being now the object. And for common purposes, when the focal length of a lens is but short, this length may be reckoned the distance from the lens to the place where the image of a remote object appears most distinct. For if the object be distant from the lens 100 or 1000 times the focal length, the image will be beyond the principal focus only the 100th or 1000th part of that focal length. The focal length of a lens may be found, without computation, by making the flame of a candle the object, thus: Move the lens or the candle, and the paper for receiving its image, so that, when the image is most distinct, the lens be exactly in the middle betwixt the other two; then half the distance betwixt the object or its image and the lens is the focal length required. Or if either the lens, or the candle, or the paper for receiving its image, be moved, while the other two are fixed; having measured the respective distances, the focal length may be found in the manner already stated. Or, if a small hole, of about one-fourth or one-eighth of an inch broad, be made in the window-flutter of a darkened room, and a lens and a paper be held behind this hole at proper distances; the place where the image of the hole is most distinct may be determined very accurately, and so the focal length of the lens may be found as above. Again, place the lens so that its axis may point as nearly as possible towards the sun; then holding a paper behind it, the burning point, or that in which the sun's image is smallest, and when its limb appears most distinct, is the focus of the lens. See these various methods illustrated more at large in Harris's Optics, book ii, § 4.

On the principles above illustrated is founded the structure of refracting burning-glasses, the sun's light and heat being exceedingly augmented in the focus of the lens, whether convex or plano-convex; since the rays, falling parallel to the axis of the lens, are reduced into a much narrower compass; so that it is no wonder they burn some bodies, melt others, and produce other extraordinary phenomena. See Burning Glasses.

4. If a luminous body be placed in a focus behind a lens, whether plano-convex, or convex on both sides; or whether equally or unequally; the rays, after refraction, become parallel. In this case the refracted rays become the incident rays, and vice versa; and consequently the refracted are parallel. Hence, by means of a convex lens, or a little glass's bubble full of water, a very intense light may be projected to a vast distance.

And this furnishes us with the structure of a lamp, or lantern, to project an intense light to an immense distance;
for a lens, convex on both sides, being placed opposite to a concave mirror, if in the common focus of both be placed a lighted candle, or vick, the rays reflected back from the mirror to the lens will be parallel to each other; and after refraction will converge, till they concur at the distance of the semi-diameter, after which they will again diverge. As the candle being likewise in the focus of the lens, the rays it throws on the lens will be parallel; and therefore a very intense light meeting with another equally intense, at the distance of the diameter from the lens, the light will be surprising; and though it afterwards decreases, yet the parallel and diverging rays going a long way together, it will be very great at a very great distance. Linterns of this kind are of considerable service in the night-time to discover remote objects, and are used with success, by fowlers and fisher men, to gather their prey together, in order to take them.

If it be required to have the light, at the same time, transmitted to several places, as through several streets, &c. the number of lenses and mirrors is to be increased.

If the luminous body placed in the focus be of a larger extent, the rays, flowing from points ineflibly distant from each other, cannot be parallel; but they will confitute several trains, or parcels of rays, parallel to each other.

5. The images of objects, opposed in any manner to a convex lens, are exhibited, iner tively, in its focus.

Hence, if a paper be applied to a convex lens (especially in a dark room) at the distance of its focus, the images of objects shining upon it will be represented distinctly, and in their natural colours, upon it: nor is the focus of the sun's rays any thing else, in effect, but the image of the sun. Hence in solar eclipses, the sun's image, eclipsed as it is, may be burnt by a large lens on a board, &c. and exhibit a very entertaining phenomenon.

Hence, also, if a convex lens, of any kind, be expofed both to nearer and remote objects, and a paper at the fame time be applied, so as to receive the images of objects distinctly, the distance of the focus from the lens, and thence the diameter of the convexity, may be determined. See the above.

6. If a concave mirror be fo placed, as that an iner t image, formed by refraction through a lens, be found between the centre of the focus, or even beyond the centre, it will again be iner ted by refection, and fo appear ered in the firft place beyond the centre; and in the latter, between the centre and the focus. On these principles is conducted the correa obfcura, which fees.

7. The diameter of the image of an object delineated beyond a convex lens, is to the object itself in the ratio of the distance of the image to that of the object. Since then the image of a remote object is less distant from the lens than that of the nearer, the image of the more remote will be less than that of the nearer. And because the distance of the image from the lens is greater, if the lens be a segment of a greater sphere than of a lens; hence the image will be greater in the former case than in the latter. The image therefore will be of such a magnitude, as it would be of, were the object to shine into a dark room through a little hole upon a wall, at the same distance from the hole at which the focus is from the lens. When an object is less distant from a lens than the focus of parallel rays, the distance of the image is greater than that of the object; other wise the distance of the image is less than that of the object; in the former case, therefore, the image is greater than the object; in the latter less.

If the images be made greater than the objects, they will not appear distinctly; because in that case there are fewer rays which meet after refraction in the fame point; whence it happens, that rays proceeding from different points of an object terminate in the fame point of an image, which is the cause of confusion. Hence it appears, that the space aperture of a lens may be admitted in every case, if we would keep off the rays which produce confusion. However, though the image is then more distinct when no rays are admitted but those near the axis, yet for want of rays the image is apt to be dim.

8. If the eye be placed in the focus of a convex lens, an object viewed through it appears erect, and enlarged in the ratio of the distance of the object from the eye, to that of the eye from the lens, if it be near; but infinitely, if remote.

The theory of real images may be thus illustrated by an experiment. Upon a long table draw the line BD (Plate VIII. Optics, fig. 1.) and over some point there as A, place the convex lens O, whose principal focuses are F, f, so that the axis Ff of the lens be parallel to BD. In the line BD, take A F, A f, each equal to OF or O f in the axis O g. On one side of A divide the line A B into the parts 1, 2, 3, 4, &c. each equal to A F; and on the other side take A f 1 equal to A f or A F, and divide it into f 1, f 2, f 3, &c. If these parts be respectively equal to 1 2, 3 4, &c. of f 1 or A f. Then if the room be darkened, and a lighted candle be placed over any one of the divisions in the line A B, as at 2; the image of the candle will be seen distinctly but inverted, upon a paper held over the corresponding fraction on the other side, as at 2. If the candle be placed at the point 3 or 4, &c. the paper for receiving the image must be held over 4 or 3, &c. So that if the candle be moved from 2 to an infinite distance, the whole motion of the image will be from 4 to f. If the candle be placed at 1, the image will be at 1, at the same distance from the lens on the other side. If the candle be brought nearer to F, the motions of the image and candle will now be reciprocal, to what they were before. But if the candle be placed any where between F and the lens, there will be no image formed.

Since an object placed at any distance, and its image, subtend equal angles at the fociocentres, s, s, of any lens; the angle under which any remote object appears being given, it will be easy to find the diameter of its image: let q (fig. 2.) be the principal focus of the convex lens O, and let the angle P s R ( = p o r) be that under which the fun (or any other very remote object) appears to the naked eye; bisect the angle p o r with the line o g; then in the right angled triangle o g r, we shall have the side o g and all the angles; whence it will be easy to find q o or q r, the diameter of the image. See Image and Refraction.

Lenses, for concave, their laws are as follow.—1. If parallel rays strike on a plano-convex lens K L, and F C be to F B in the ratio of refraction, the rays will diverge from the axis; and the point of divergence, or defpersion, called the virtual focus, will be F. See Plate VII. Optics, fig. 3. See Focus.

For the rays H I, parallel to the axis, is perpendicular to K L, and will therefore pass unrefracted to E. Wherefore F C being to F B in the ratio of refraction, F will be the virtual focus.

If then the lens be glafs, F B = 2 B C; i. e. the virtual focus F will be distant from the lens K L by the space of the diameter 2 B C.

If the refraction be in water, F B = 3 B C; i. e. the virtual focus F will be distant from the lens K L a diameter and a half 3 B C.

2. If
2. If the ray $AE$, parallel to the axis $FP$, strike on a lens concave on both sides; and both $FC$ be to $FP$, and $IP$ to $PH$ in the ratio of refraction; and $FP : PH :: FB : BG$; $G$ will be the point of diffraction, or the virtual focus. See Plate VII. Optics, fig. 4.

If, therefore, the refraction be $n : m$, $CB$ $= a$, and $II = b$; $FB = na - nb$, and $PI = nb - n$ $m$; consequently, disregarding the thickness of the lens, $FP$ $= FP + IP = na + nb$, and $PH = PI - IH = nb - nb - n - m$ $m$ $m$.

Consequently, the thickness of the lens, $IP = \frac{na + nb}{n - m}$, and $PH = \frac{nb}{n - m} - \frac{nb}{n - m} - \frac{nb}{n - m}$. Therefore, $a + b = \frac{nb}{n - m}$, or $a = \frac{nb}{n - m}$; and $BG = \frac{na}{n - m}$.

If, therefore, the refraction be in a glass lens, so that $m = 2$, $n = 3$, and $a + b = 2b = a = BG$; the sum of the semidiameters $CB$ and $HI$ will be to the diameter of the concave of either, $2IH$, as the semidiameter of the other $CB$, to the distance of the virtual focus from the lens, $BG$.

But if the semidiameters $HI$ and $CB$ are equal, or $a = b$, $BG = \frac{2a^2}{2a} = a$; or $BG$, the distance of the virtual focus from the lens, is equal to the semidiameter $CB$ or $HI$. If the refraction be made in water, $m = 3$ and $n = 4$, and, therefore, $a + b = 3b = a = BG$; i.e., the sum of the semidiameters $CB$ and $HI$ will be to a diameter and a half of either concavity, $3HI$, as the semidiameter of the other $CB$ to $BG$, the distance of the virtual focus from the lens:

In this case, if $a = b$, or $HI = CB$, $BG = \frac{3a^2}{2a} = \frac{3a}{2}$. $CB$, i.e., the distance of the virtual focus from the lens $BG$, is to the semidiameter $BC$ in a sesquilateral ratio.

Hence, the sun’s rays striking on a convex lens, their light, after refraction, will be considerably weakened; so that the effect of concave lenses is opposite to that of the convex ones.

To find the focal length of a concave lens experimentally, let the lens be covered with paper, having in it two small circular holes, and at $O$, $v$ (Plate VII. Optics, fig. 5); and on the paper for receiving the light, describe two small circles as $a$, $b$, whose centres are placed at twice the distance apart of the centres of $O$, $v$, and it will be best if their diameters are also double those of $O$, $v$. Thus, moving the paper to or fro, till the middle of the sun’s light coming through the holes $O$, $v$, falls exactly on the middle of the circles $a$, $b$; that distance of the paper from the lens will be the focal length required. For it is evident, that $a + b = Ov :: AF = OF$; or, whatever is the distance of $a$, $b$, it will be, $a - b = Ov :: Ov$, the focal length of the lens. Instead of the paper with the holes, small patches may be stuck on the lens.

The focus may also be found by candle-light; thus: let $Q$ be the place of the flame; $a$, $d$, the bright spots upon the paper, and $f$ the point where the lines $v d$, $O a$, produced, backwards, would intersect. To find the point $q$, it will be $c d - O v :: O v = O f :: O f = O q$. Then $Q q = Q O :: Q O = Q a$, and $O a$ is the focal length required.

The focal length of a concave lens may be readily found by joining it to a convex one, having a shorter focus. Let $Q$ (fig. 6) be the image of any object formed by the convex lens $A$, fixed at $A$; and let $Q$ be the image of the same object, when the convex lens $O$ is joined to $A$. Having measured the distances $Q q$, $Q O$, for finding the focal length of the concave lens, it will be (as before) $Q O :: Q O = Q F$; then $Q F - Q O = O F$.

3. An object viewed through a concave lens appears erect, and diminished in a ratio compounded of the ratios of the space in the axis between the point of incidence, and the point to which an oblique ray would pass without refraction, to the space of the axis between the eye, and middle of the object; and the space in the same axis between the eye and the point of incidence, to the space between the middle of the object, and the point the oblique ray would pass without refraction.

Though the properties of lenses have been here considered principally with regard to rays falling near the axis, and parallel to it; yet the reasoning will be easily transferred to rays remote from the axis, and falling in any direction.—Thus we may say universally, that in a convex lens, all parallel rays become converging, and converge in a focus; that diverging rays either become less diverging, or run parallel, or converge; and that converging rays converge the more; all which alterations are more sensible in oblique rays than in perpendicular ones, because the angles of incidence in that case are greater.

In concave lenses all parallel rays become diverging, and all diverging rays diverge more; converging rays either converge less, or become parallel, or go out diverging; all which things hold of oblique as well as direct rays, but more sensibly in the first.

For the further illustration of this part of the subject of the article before this, we shall now subjoin two or three propositions; first, premising, that all pencils of rays (see Pencil), refracted by a lens, excepting that whole axis is perpendicular to both the surfaces, are said to be oblique, and are called oblique pencils."

If "In every oblique pencil of rays, refracted by any lens, there is one ray wholly incident and emergent parts are parallel; and this ray is the axis of that pencil, or that ray of it which undergoes the least refraction." In Plate VII. Optics, fig. 7 to 12, let $R$, $r$, be the centres of the spherical fides $A$, $a$; and in fig. 7, 8, let $r$ be the centre of the spherical fide $a$. In the flat side of any lens whatsoever assume any point $B$, at which let a ray of light be refracted, either at its entrance into the lens, or at its emergence out of it; draw $RB$ perpendicular to that side, and parallel to it draw also $rb$ perpendicular to the other side $a$; join $Bb$, then will $Bb$ be a ray, whose parts $PB$, $p$, $b$, without the lens, will be parallel. For the ray $Bb$, drawn between the two parallels $RB$, $rb$, is equally inclined to them both, and consequently $PB$, $b$, are also equally inclined to $RB$, $rb$, (by the law of refraction,) and therefore parallel to one another. After the same manner, wherever the point $B$ is assumed, we can find a ray $Bb$, that shall be equally inclined to both the surfaces; and therefore in every oblique pencil of rays there is one ray wholly incident and emergent rays are parallel. It is evident also, that every other ray passing through $B$ will be more refracted than the ray $Bb$; for a plane touching the lens in any other point besides $b$ will be inclined to a plane touching it in $B$; and, therefore, a ray passing through $B$, and any other point besides $b$, will be bent out of its course, more or less, according as these planes are more or less inclined. Whence the proposition is evident. $Q q$ is the axis of an oblique pencil on the contrary side of
of the axis of the lens. Hence it appears, that the axis of any oblique pencil whatsoever is equally inclined to each side of the lens, and the lens oblique is the pencil, the nearer the point B will be to the vertex A; and the lens will be the distance between the parallel rays P B, P b.

2. In every oblique pencil of rays (figs. 7 to 12), the part B b of the axis within the lens, produced, if need be, will intersect the axis of the lens in the very same point O; and the point O divides the axis of the lens in such a manner, that A O : O R = R r : r s; that is, 1. The point O is in the vertex of a plano-convex and plano-concave lens (figs. 7 and 8).

3. In the double convex and double concave (figs. 9 and 10), the point O divides that part of the axis, which is within the lens, in the ratio of the radii of the sides, the shortest part being next that side which has the greatest curvature. 3. The line B b must be produced without a concavo-convex lens (fig. 11 and 12), before it will intersect the axis; and the point O in the axis, where the said line B b produced intersects it, lies next to that side which has the greatest curvature; and its distance from the sides is as the radii of the sides respectively.

Let the radius of the flattest side A be called R, and the radius of the other side, r; and because the axis B b of any oblique pencil passes through the vertex a, and therefore the point O is also in a. For no perpendicular to the spherical side can be parallel to a perpendicular to the plane side, but that only which passes through the vertex a. Again, because R in this case is infinite, and O coincides with a; it will be R = r A O : a O. Cæs. 2 and 3. Because the radii R, r are parallel (by hyp.), the triangles B R O, r b o are similar; and, therefore, R B : r b = R O : r O. Also R B + r B = R O r B or r B = R O + r O : R O or r O. But the three first terms being invariable quantities, the 4th is fo likewise; that is, in the plane lens the point O is invariable. And from the position of the parallel radii R, r, it is plain that the point O must be within the double convex and double concave lens, and without the concavo-convex. Again, because R O = R A (R O + R A) = R A + a O (R O a R a) = r a; that is, A O : a O = R : r; whence another part of the proposition is manifest.

Hence it follows; that the point O is in the middle of a double convex and double concave, whose sides are segments of the same sphere; and in every lens whatever, the greater proportion the greater radius bears to the lefier, the nearer will the point O be to the vertex a of that side which has the greatest curvature.

3. "If the axis B (fig. 7 to 12.) of a pencil of rays is not very oblique to the axis of the lens; the points, s, v, where the parts without the lens, P B, P b, produced, of the axis of the oblique pencil, and the axis of the lens, divide that axis in such a manner, that A O : a O = m : n. The angles, R B, A B, R B O, or their supplements, are the angles of incidence and refraction at the first side A; and therefore their lines are as m to n. In figs. 7 and 8, the angle A B = A O B. And in figs. 8 and 9, the difference between the angles, R B, A B, R B O, or their supplements, and the respective angles A B, A O B, is equal to the angles A R B, as will appear by drawing a B parallel to the axis R A. And therefore the sides of these respective angles are nearly in the same ratio; that is, sine < A B = sine < A O B : m : n nearly. But the sides of the angles, A s B, A O B, are as the sides B O, B s; and when the point B is not very remote from A, B O and B s will be as A O and A s nearly; and therefore when the point B is the nearest of all to A, it will be A O : A s : m : n. In figs. 9 and 8, the points a, v, and O, coincide; and in figs. 9 and 10, it might be proved as above, that when the point B is very near to a, it will be, a O = a v = m : n. Hence the further the point B is from A, and b from a, the greater will be O z and O w. Let s and v be points belonging to pencils that have the least obliquity to the axis of the lens; then will A s = a v = m : n. Let the thickness, a O, of any lens be called t; then in a plano-convex and plano-concave lens, A s = n m t. And in a double convex and double concave, whose sides are segments of the plane layer, A t = a v = n m t. Hence again, in a plano-convex and plano-concave glass, A s = n m t; and in a double convex glass of equal convexities, and in a double concave glass of equal convexities, A s = a O = 1 t. It appears, moreover, that the focal length of any 3 lens is to be reckoned from the point v, if the flattest side is exposed to parallel rays; and from the point s, if the parallel rays are incident upon the most convex or concave side; the point v, in all cases, being the most remote from the flattest side, A, of the lens. The points, s and v, may occasionally be called the "focal centres" of the lens. Hence it follows, that the focal length of a convex lens is, properly, the distance between the principal focus and the next focal centre; and the focal length of a concave lens is to be reckoned from its principal focus to the farthest focal centre. As the axes of the several pencils that are not very oblique, are refracted from the same point v or s nearly; to the refraction of these causes a tolerable confusion in the image. Moreover, because A s = n m A O, and a v = n m a O, and because R = r A O, and a v = n m A O; therefore A s = A t = a v = n m A O.

R ± r : R = R t : (A O + a O); therefore A O = R t : (A O + a O) = R t = R t + r; and a O = R t : (A O + a O) = R t + r; and a O = n m x R t + r; and multiplying one side of each equation by m x R, it will be A s = n m A t = n m R t.

4. "The focus of both direct and oblique pencils of parallel rays are nearly at the same distance from the focal centre (s or v), as the case is, of any lens." Let A R (Plate VIII. Optics, fig. 1 to 6.) be the axis of the lens, r the centre of the first surface a h, Q the principal focus of that surface, and F the focus of the lens. Let p B P be the axis of any oblique pencil; and let the emergent part, B P, produced backwards cut the axis of the lens in t. Of all the rays parallel to the axis p B P, there shall be one as D d which will fall perpendicular upon the first surface a d; and therefore if the medium was continued, this ray (produced backwards from a concave lens, but continued through
through a convex lens) would pass through the centre $r$, and the geometrical focus of rays parallel to it would be at $q$, so that $r q = r Q$. This is plain, because $d r q$ is perpendicular to the surface $a$, as well as $a r Q$. Again, of all the rays parallel to the axis $p b$, there shall be one as $E e$ (if the lens is broad enough) which shall be refracted into $e G$, perpendicular to the second surface $A B$; and therefore the focus of this ray shall be in $r F$ produced, and in $e G$ produced; that is, in the point of intersection $f$. Neglecting the aberration of the first surface $a b$, $e G$ would unite with the axis $d r q$ in $g$. Hence we are to thaw that $s f = s F$ nearly.

Cafe 1. When one side of the lens is plain. (Fig. 1, 2.) Because $s r, f g$, and $s f, r q$ are parallel; $s f = r q = r Q = s F$.

Cafe 2. When both sides of the lens are spheric. (Fig. 3—6.) Let $R$ be the centre of the second surface $A B$, and because $e G$ is perpendicular to this surface, it will pass through the centre $r$. And because $r q$ is parallel to $s f$, it will be $R r : R s :: r q : s f$. The two first terms, $R r, R s$, being invariable quantities, and $r q$ being allowed to remain invariable, $s f$ will also be invariable; that is, $s F$ will describe the focus $F$, and $s f = s F$. But because of the aberration by the first surface $d r q$, no ray, as $E e$, parallel to and remote from the axis $D r q$, can be refracted to the focus $g$; but it will cut the axis $r Q$ in some point $y$ between $q$ and $r$ (fig. 1 to 6); and therefore a ray parallel to $p b$, that shall be refracted perpendicularly to the second surface $A B$, must be some ray $b k$ between $E e$ and the axis $p b$, if the centres, $R r$, are on different sides (figs. 3 and 4); otherwise $b k$ will be farther from the axis than $E e$ (figs. 5 and 6); and consequently this ray will cut the axis $s f$ in some point $x$, between $f$ and $t$. But it has been already shown, that if the lens had no aberration, $f g$ would be the focus of all the rays parallel to the axis $p b F f$; and as the aberrations at the different surfaces are contrary, it is sufficiently evident that the focus of those rays which are nearest to the axis $p b F f$, will not be remote from $f$.

In every lens whatsoever, the true focus $g$ of an oblique pencil of parallel rays will be between $f$ and $t$; that is, $s g$ will be less than $s f$ or $s F$. Because if there was no aberration at either surface of the lens, $s g$ would be equal to $s F$ or $s f$; and therefore it must follow, that if the aberrations at each surface were equal, they would destroy each other. (Figs. 3, 4.) Let rays of light be within the lens, on each side of the axis $b B$, and let their inclination to that axis be such, that they would emerge at the side $b$, parallel to $b p$. It is plain, that a ray parallel to the oblique axis $p b F P$, and between the said axis and the perpendicular $d r$, will be more oblique to the emergent side $A$ than to the incident side $a$; and therefore, in this case, the aberration at the side $A$ is the greatest, and this excess of the aberration contracts the focus nearer to $s$ than $f$, as to $g$. In like manner, if the parallel ray be on the other side of the oblique axis, the greatest aberration will be on the incident side $a$; and in the present case likewise, this excess of aberration contracts the focus nearer to the lens, as to $g$; and it is plain, that the more oblique the pencil, the greater will be $f g$: whence the proposition is manifest.

5. "The focus of incident rays, either diverging or converging upon any lens, being given: to find the focus of the emergent rays." Let $F / F$ (Plate VIII. Optics, fig. 7 to 12.) be the axis of any lens $B b$, whose focal centres are $s, v$; and principal foci are $F, f$. Let any point $Q$ in the axis of the lens be the focus of incident rays, either diverging as $Q B$, or converging as $M B$; and let $f$ be the geometrical focus of those rays parallel to the axis of the lens, whose incidence is on the same side with the ray $Q B$, or $M B$. To find the focus of the emergent rays, lay $Q F : F s :: v f (F s) : f q$; and placing $q$ the same way from $f$ that $F$ is from $Q$, the point $q$ thus found will be the focus required. Let the point of incidence $B$ be not remote from the vertex of the lens; from the centre $v$ describe the arc $f d$, and draw $v d$ parallel to the incident ray $Q B$, or $M B$; then will $d$ be the point where the emergent ray intersects the axis $a d$; and therefore the point $q$, where the emergent ray $b d$ (or $N b$) produced, intersects the axis of the lens, is the focus required. Again, draw $D$ parallel to $q B$; then will the triangles, $Q D v, v d q$, be equilateral, and therefore $Q D : D v :: v d : d q$. But $D$ is a point where the incident ray $q b$, or $N b$, after refraction by the lens, will intersect the axis $s D$, so that $s D = s F$ nearly; and when the triangles, $Q D v, v d q$, are vanishing, the point $D$ will coincide with $F$, and $d$ with $f$, wherefore $Q F : F s :: v f : f q$. Hence it follows, 1. Because $F s = v f, F s$ or $v f$ is a mean proportional between $Q F$ and $f q$; that is, $Q F : F s :: F s : f q$. 2. If $f q$ be the focus of incident rays, $Q$ will be the focus of the emergent rays. 3. The focuses, $Q, q$, move both the same way, and always lie contrary to $F$ and $f$. And the distances, $F Q, f q$, vary reciprocally; that is, as one increases, the other decreases, but with a different velocity, according as they are differently situated. When $Q$ coincides with $F$, $q$ will be at an infinite distance; that is, the refracted rays will emerge parallel to the axis. And in figs. 7, 8, when $Q Q = 2 O F$, $Q q$ will be $O Q$; whence the difference of the focal distances of the refracted rays, when $Q O = 2 O F$, and when $Q O$ is infinite, is only equal to $O F$. 6. When the focus $Q$ of rays diverging upon a convex lens (fig. 9) lies between $F$ and the lens, the refracted rays ($b N$ instead of crossing the axis) will diverge from the focus $q$. And if incident rays upon a concave lens converge towards the point that is nearer to it than $F$ (as in fig. 10), the lens in this case will have a real focus; that is, the refracted rays will cross the axis in $q$. And universally, 7. When the focuses, $Q, q$, lie both on the same side of the lens; if the incident rays diverge from $Q$ (fig. 9—12.), the emergent rays will diverge from $q$. And if the incident rays emerge towards $Q$ (fig. 10, 11.), the emergent rays will converge towards $q$. And in all these cases, the nearer $Q$ is to $O$, the nearer also will $q$ be to $O$; and if one of these focuses be in $O$, the other also will coincide with it. And the contrary happens, when $Q$ and $q$ are on different sides of the lens; that is, rays diverging from $Q$ (fig. 7.) will converge towards $q$; and rays converging towards $Q$ (fig. 8.) will diverge from $q$.

We have hitherto taken notice of the progress of a single pencil of rays, or such as come from a single point, through a lens; but it is easy to apply the same kind of reasoning to the various points of an object. Let $D E$ (Plate VIII. Optics fig. 13.) be an object, $A B$ a double convex lens, whose centre is $C$; and let us examine the pencils of rays which come from three points only of the object, since the
situation of the intermediate pencils is evidently comprehended between tho' three. Of all the rays which proceed from each of these points, that which passes through the centre C of the lens must proceed, if the lens is not remarkably thick, in a straight line, so that D C I, F C H, and E C G, are straight lines; secondly, the focus of the rays D B A, after refraction, must be somewhere in the axis or straight line D C I; also that of the middle pencil, F B A, must be somewhere in F C H, and the focus of the third pencil must be in E C G. Thirdly, the refracted focus of each pencil must be on the contrary side of the axis of the lens, to what its incident or radiant focus is; for instance, the refracted focus I is below the axis of the lens, whilst its incident or radiant focus D is above it; and the refracted focus G is above the axis, whilst its radiant point E is below it: the consequence of which is, that if the object D E be sufficiently luminous, and a piece of white paper, or other flat and opaque body, be situated at G I, an image of the object D E will be formed upon it, but in an inverted position. If the opaque body be removed, then no image will be seen by a spectator situated on one side; for the rays of light, though they meet at their respective foci in I H G, yet they proceed divergingly beyond that place through the air or other transparent body, and none come to the lateral spectator. If the paper be situated nearer or farther from the lens than the place G I, then an imperfect image, or no image at all, will be formed upon it, because the rays of the respective pencils do not meet at any other place.

From what has been said above with respect to the conjugate foci of the same pencil, it will be clearly deduced, that if the object D E be brought nearer to the lens, the refracted foci, or the image G H I, will be formed farther from the lens, and vice versa. And from this it follows, that (since the angles D C E, G C I, formed at the centre of the lens by the axes of the two extreme pencils, are equal) when the distance of the object from the lens is equal to that of the image from the lens, the size of the image is equal to that of the object; when the former distance is less than that of the latter, then the image is larger than the object; and when the former distance is longer than the latter, then the image is smaller than the object.

With respect to the brightness of that image it must be considered, that of the innumerable rays which are incessantly emitted in every direction from each point, for instance D, of the object, a considerable number, viz. D A B, falls upon the lens, and are converged to a single point I; therefore that point must be more or less bright in proportion as the surface of the lens is larger or smaller. Hence also a very remarkable property of those lenses is easily comprehended, which is, that when an image G H I is thus formed, if you cover part of the lens, be it the middlemost or some lateral part of it, the image I G will not thereby be rendered partly invisible,—the whole image will be seen as well as before, but it will appear less bright than before; for if we consider each indefinite part of the lens, we may easily perceive that rays of light from every point of the object must pass through that part, and must meet at the respective foci in G H I.

The above explanation of the progress of various pencils through a convex lens, may, mutatis mutandis, without much difficulty be adapted to explain the action of concave lenses. Newton's Optics. Smith's Optics. Harris's Optics. Cavallio's Philosophy, vol. iii.

Lens, or Lenticula, was the name of a kind of weight among the Romans; being the hundred and eighth part of a drachm; equal to a grain and a half. LENS, in Anatomy, a transparent body, nearly spherical in figure, placed in a depression in front of the vitreous humour of the eye. It is generally mentioned with the epithet crystalline. See EYE.

Lens, in Botany, the Lentil, Erustum Lens of Linnaeus, but in reality a Species of Cicer; see Sm. Fl. Brit. 725, and our article Erustum. The Latin word lens is said to have originated from lens, mild, because those who fed on this sort of pulse were supposed to become mild and gentle in disposition.

Lens, Polyptych. See Duck's Meat.

Lens, in Geography, a town of France, in the department of Jemnappe, and chief place of a canton, in the district of Mons. The place contains 1259, and the canton 1274 inhabitants; on a territory of 327 3/4 square miles, in 19 communes.—Alfo, a town of France, in the department of the Frats of Calais, and chief place of a canton, in the district of Bethune, seven miles N.W. of Douay. The place contains 2325, and the canton 13265 inhabitants, on a territory of 1251 square miles, in 21 communes.

LENSWYCK, a town of Norway; 20 miles W.N.W. of Dronthiem.

LENT, Quadragesima, a time of mortification, during the space of forty days, wherein Christians are enjoined to fast, in commemoration of our Saviour's miraculous fast to long in the desert, and by way of preparation for the feast of Easter.

In the ancient Latin church, Lent only consisted of thirty-fix days. In the ninth century, to come somewhat nearer to the miracle, several took upon them to add four days more; which in time became a general practice; though the church of Milan is said still to take up with the ancient thirty-fix.

According to St. Jerom, St. Leo, St. Augultine, and others, Lent must have been instituted by the apostles. Their way of reasoning is thus: whatever is generally received throughout the whole church, and whose institution we do not find in any council, must be esteemed to have been established by the apostles. Now such, they say, is the fast of Lent. Its institution is not spoken of in any council; but many of the ancient councils, particularly that of Nice, that of Laodicea, &c. and some of the oldest fathers, particularly Tertullian, speak of it as a thing of some standing.

The reformed, generally, hold Lent to be a superstitious institution, let on foot by some vain enthusiasts, who durst undertake to ape the miracles of Jesus Christ; as, in effect, it appears to have been from a passage of Irenæus quoted by Eusebius.

Some will have it to have been first instituted by pope Telephorus, in the second century; others, who own that there was a kind of abstinence observed in the ancient church before Easter, yet contend that it was entirely voluntary, and never enjoined by any law till the third century. See EAST.

This religious season is said to have been first observed in England by our Saxon ancestors in the year 640. Anderson's Hist. of Commerce, vol. i. p. 25.

Political Lents have been often enjoined by statute and royal proclamation. See ABSTINENCE.

King James I. issued a proclamation against eating flesh in Lent in 1619, and another in 1625. A similar proclamation was also issued by Charles I. in 1627, and another in 1631.

There was some difference between the practice of the Greek
Greeks and Latin churches, as to the business of Lent; the Greeks beginning it a week sooner, but at the same time allowing more days of intermission than the Latins: those who held it seven weeks did not fast on Saturdays, as those who observed but six did.

The ancient Latin monks had three Lents; the grand Lent before Easter, another before Chrismas, called the Lent of St. Martin; and a third after Whitunday, called the Lent of St. John Baptist; each of which consisted of forty days.

The Greeks, besides that before Easter, observed four others; that of the Apostles, of the Assumption, of Chrismas, and of the Transfiguration; but they reduced each of them to the space of seven days. The Latins, besides a fifth, which they called the Repentance of Nineveh, and the Maronites a sixth, called the Exaltation of the Holy Cross.

By the ninth canon of the eighth council of Toledo, it is ordained, “That if any person, without evident necessity, eat flesh in Lent, they shall be deprived of the use of all the rest of the year.”

By the fifth chapter of the fourteenth session of the council of Trent, confession is enjoined as peculiarly fit and acceptable at this season. Hard. Conc. tom. x. P. 93.

The forty days in Lent, say some, are observed in remembrance of the forty days wherein the world was drowned; or, as others say, of the forty years wherein the Jews wandered in the desert; others of the forty days allowed Nineveh for repentance; others of the forty stripes by which malefactors were to be corrected; or, the forty days during which Moses fasted at the receiving of the law; or the forty days fast of Elias; or finally, the forty days fast of our Saviour.

LENTAGO, in Botany, a name adopted by Cephalinus, (de Plantis, 76.) for the Laurustinus, Viburnum Tinus of Linnaeus, and said to be of Tuscan origin. Linnaeus has applied it to an American species of Viburnum.

LENTILLA, in Geography, a town of Naples, in Abruzzo Cita; 18 miles N.E. of Civita Borella.

LENTIMENT, Fr. in Micros. This word is equivalent to large in Ital., and implies a slow movement. Its superlative, lentimentum, very slow, is the slowest of all movements.

LEN E T E N, in Geography, a town of Norway; 20 miles N. of Bergen.

LENTES LAMPEE, fojelle lentis, in Natural History, the name given by many writers to a very remarkable fojelle substance, usually found immersed in hard stones, and of a roundish but flattened shape, resembling not unaptly a pea or lentil flattened by pressure. They generally lie in great quantities in the same mass of stone; and are of very different appearance when their sides or ends are seen, from that which they exhibit when their flat surfaces come in view.

They are generally supposed to be lentils petrified and bedded in stone, and as their sides come in view in some parts of the mafes, they are not perceived to be a part of the same substance, but are called the remains of seeds of other plants, and the whole stone is usually named lapis frumentarium.

We are not to suppose, that so light a body as the lentil feed, or a common pea, could be easilie petrified and preserved in its own form in stone; since if these soet substances were readily capable of such a change, they are not very common in their recent state, that they must be expected to be found in this fojelle condition very frequently also, and in great variety. This, however, is not the case. But this improbability is not all the reason we have to conjecture, that these are not what they are vulgarly supposed to be,
LEN

little round leaves, which resembles that of the Lens, or Lens seed. See Lens.

LENTICULA. See Petechia.

LENTICULAR SCALPEL, from lentilique, doubly convex, in Surgery, denotes an instrument usually placed among those which are considered necessary in the operation of the trepan. Its particular use is to cut off the irregularities which often present themselves at the edge of the perforation made with the trephine, and which might, if unremoved, cause irritation and injury of the dura mater. The shape of the instrument can hardly be conceived without an engraving, or, at least, a reference to an engraving. (See the Plate of Trimming Instruments.) We can only state, that one side of its blade is convex, the other concave, and one of its edges sharp. On the end of the blade is fixed a little shallow cup, with its concavity towards the handle of the instrument. This small cup-like part serves the purposes of receiving the little pieces of bone when detached, keeping the end of the blade from hurting the dura mater, and when applied under the margin of the perforation in the cranium, enables the operator to guide the instrument all round with steadiness and security. Dict. of Practical Surgery.

LENTICULARRE, GANGLION, in Anatomy, a small ganglion in the orbit, from which the nerves of the iris are produced. See Nerve.

LENTICULARIS, in Botany. See Lens.

LENTIGO. See Freckles.

Lentigo is also used by Dr. Quincy for a brown, scaly, or scurvy eruption upon the skin; that, especially, as is common to women in the time of child-bearing.

LENTIL, LENS, in Botany, a species of Erum; which see.

Lentils are the best as well as cheapest food for pigeons. The seeds of lentils are frequently the common food of the poor in some of the islands of the Archipelago, and other warm countries, when they can meet with no better fare. Another sort of lentil has of late years been cultivated in England, under the name of French lentil. This is the lent major of Caliphar Bahun; and being twice the size of the common lentil, is by far the better worth cultivating. This is called till in many parts of England. Miller's Gard. Dict.

The ancients affirm, that lentils, eaten with their skins on, bind the body, and flop a looseness; and yet at the same time, that the liquor they are boiled in loosens the belly. They are but rarely used in physic, though the flour of them may be used outwardly in cataplasmis, for the same purposes as bean-flour.

LENTIL, in Agriculture, the name of a plant of the vetch or tare kind, which is cultivated in some places as fodder for cattle. Lentils grow a foot and a half in height, with flanks and leaves like those of tares, but smaller; and, like them, they bear their seeds generally three or four in little pods. These seeds are round, hard, smooth, and flat, but thicker at the sides. There are two sorts of lentils, the white and the yellow; but the latter affords the greater quantity of fodder. The seeds of this plant are commonly sown in March, where the land is dry; but in moister ground, April is a better season. The usual quantity of seed allowed to an acre of land is from one bushel and a half to two bushels. If these are sown in drills in the same manner as peas; they are paid by some to succeed better than when they are sown broad-cast. The drills should be a foot and a half asunder, to allow room for the hoe to clean the ground between; for if weeds are permitted to grow among them, they are apt to get above the lentils, and prevent them from being properly supported.

This is a crop not uncommon about Chichester, in Sussex, where they sow a bushel an acre on ploughing in the beginning or middle of March. “It is there the custom,” Mr. Young says, “to make hay of them, or feed them, for cutting into chaff for rough-meat for sheep and horsey, and they sow them on both heavy and dry fields.” It is added, that the whole country is of a calcareous nature; and likewise that attention should be paid not to water horsey soon after eating this sort of food, as they are apt to have them. They are likewise affected to be cultivated for the same purpose in Oxfordshire, and probably in other districts.

LENTILIUS. See Linzenbaart.

LENTINI, in Geography, anciently Leontini or Lentium, which was a spacious, rich, and celebrated city of Sicily, and the rival of Syracuse; is now reduced to a population of 4000 persons, who occupy a very inconsiderable portion of the ruins of ancient Leontium. It is situated in Noto, on a river of the same name, about five miles from the sea. The air of the adjacent country, which abounds in marbles, is so infulibrous, that it prevents the increase of inhabitants, notwithstanding the fertility of the soil and the variety of its productions. Three miles from Lentini is a large lake, estimated at about 20 miles in compass, called “Bivieri,” or the lake of Lentini, belonging to the prince de Butera, which produces 1000l. a year; for the leaf of the fihery, consisting of eels, tench, and cefanu, or a sort of barbel, that feeds in either fresh or salt water. The vicinity also yields great plenty and variety of game; 19 miles N.N.W. of Syracuse. N. lat. 37° 18'. E. long. 15°.

LENTISCASIA, a town of Naples, in Principato Cita; nine miles S.W. of Policastro.

LENTISCUS, in Botany, the Maily tree, supposed to have derived its name from lentus, and lentos, alluding to the pliability and tenacity of its gum or resin. See Pistacia.

LENTISK. See Pistacia and Mastic.

LENTISK, African and Persian, or Indian Mastic. See Schinus.

LENTO, Ital., a musical term for slow, or a movement between largo and grave.

LENTO, in Geography, a town of the island of Corsica; 11 miles S. of Olette.

LENTON, John, in Biography, a musician in the band of king William and queen Mary, whose instrument was the common flute. He composed and published, in conjunction with Tollet, a work entitled “A Confort of Musick, in three parts,” probably two flutes and a base-viol or archlute. At the beginning of the last century, the flute à bec, or common flute, was in much higher favour than the violin, or German flute, which was then hardly known in this country. There are catches of Lenton's composition printed in "The Pleasant Musical Companion."

LENTO, in Medicine, a term employed by Boerhaave and his followers, to denote a suppressed glutinous or glutinous condition of the fluids of the body, to which they ascribed the origin of many diseas of

It is scarcely necessary to enter at any length into the detail or refutation of an hypothesis, which was founded at the beetle upon a gratuitous and mistaken view of the operations of the animal economy, and which a better pathology has long ago exploded. Boerhaave, in his observations on diseases arising from a spontaneous gluten, (see his Aphorisms, § 69, et seq. and the commentary upon them in his "Praxis Medica,"
culica," considers the direct effect of it to be an obstruction to the free circulation of the blood, especially through the small ramifications of the vessels. "Hence all the consequences, circulations, secretions, excretions, all the vital, natural, and animal motions are disordered; whence arise suffocation and death." (4, p. 73.) Under this head, then, he readily includes not only inflammations, tumours, and concretions, but almost every species of chronic disease, especially where there is any change either in the qualities of the secretions, as the saliva, urine, &c. in the colour and complexion, as in chlorosis, leucophaegmatism, jaundice, &c.: or where any part, either external or internal, is altered in its form; as in all eruptive or cutaneous complaints, in scrofula, cancer, schirrus, meliceres, or other species of swelling. But in all these instances, the altered presence of a gluten or lentor is gratuitous; there is no evidence of any such change in the property of the circulating blood; and the morbid humour, where any such palpably exists, is found out of the course of the circulation, and is, in all probability, the result of a deranged action of the vessels in the part where it is found. Thus, in a bicephalous, following a phlegmonous inflammation, (as in a common boil,) it is clear that there is no such thing as a purulent lentor in the mafs of the blood; the pus is generated in the inflamed part, by an operation of the vessels, analogous to the secretion of bile or saliva, and is a new product, not a pre-existing matter. The argument, deduced from the appearance of the buffy crust on blood, drawn during the existence of inflammatory fever, is altogether fallacious; as this buff is but the ordinary coagulated lymph of the blood, somewhat more separated from the red globules. See Blood, and Humoral Pathology.

LENTZ, in Geography, a town of Prussia, in the territory of Ermeland; eight miles N.E. of Elbing.

LENTZBURG, an extensive bailiwick of Switzerland, in the canton of Berne, which was formerly a rich and powerful country. Its capital, of the same name, is one of the four municipal towns of the Aryan, having a considerable trade, and manufactures of flowered linens and cotton, tobacco, &c.; 16 miles W. of Zurich.

LENTZEN, a town of Brandenburg, in the mark of Pommern, near the Elbe; 74 miles N.W. of Berlin. N. lat. 53° 0'. E. long. 11° 36'.

LENZA, a small island in the Adriatic. N. lat. 44° 31'. E. long. 15° 31'.

LEO, LION, in Astrology, the fifth of the twelve signs of the zodiac.

The arts in the constellation Leo in Ptolemy's Catalogue are 27, besides the inermes, which are eight; in Tycho's 30, in the Britannic Catalogue 95. See Constellation.

LEO I., in Biography, emperor of the East, succeeded Marcian, in the year 457, through the favour and interest of the patrician Apsar, who, on account of his Arian principles, was excluded from the empire. Leo was a native of Thrace, who had gradually risen in the Roman armies to the rank of military tribune, and was principal steward of Apsar's household. He received the imperial crown from the hands of the patriarch of Constantinople, which is the first instance of an ecclesiastic being employed in that ceremonial. Under Genesic the Vandals planted themselves in Africa, and Apsar favoured their cause. Leo became jealous of the influence and power of Apsar, and in the end caused him and his son to be put to death without the form of a trial, upon the mere charge of aspiracy. The remaining parts of his family and friends attempted to revenge this treachery, and the Goths, attached to them, committed great disorders in Constantinople, which were suppressed by Zeno. The Arians, having lost their patron, were treated with great rigour by Leo. From the Goths he was obliged to purchase a peace, which he did not long survive. He died in January 474, after a reign of nearly nineteen years. His moderation and love of justice have been praised, and several of his laws remain in the code of Justinian.

LEO III., surnamed the Isaurian, from Isauria, the place of his birth, was born of low and obscure parents. He entered the army, and became a guard to Justinian II. He attained the rank of general under Anastasius II., who took him in 717 as a coadjutor in the empire. The Saracens having ravaged Thrace, laid siege to Constantinople, which was bravely defended by Leo, who compelled them to retire. His reign was marked with acts of atrocious tyranny; he drove the patriarch Germanus from his place, and gave it to Anastasius. In the fifth year of his reign, he caused his son Constance, surnamed Copronymus, to be feolemly crowned. In 726 he made his famous attack on the image worship, which has rendered his reign memorable in ecclesiastical history. The destruction of objects long so much venerated, and especially of a statue of Jesus Christ placed over one of the gates of the city, struck the people with so much horror, that a serious insurrection was the consequence. Leo had authority sufficient to enforce his reform in the eastern empire, but in the West it encountered a more formidable opposition. Pope Gregory II. declared with great warmth against the imperial edict, and the people of Italy openly revolted. Leo sent a fleet to chastise the revolters, which was wrecked in the Adriatic, a circumstance that was interpreted as a divine interposition. The emperor, irritated by his want of success, inflicted great cruelties on the opposite party; the Saracens took advantage of these diversions to make incursions into the bordering provinces. A dreadful earthquake added to the calamities of this reign. Leo died in 741, after a reign of twenty-four years.

LEO IV., the son of Constance Copronymus, succeeded his father in 775, at the age of 25. The first object of his reign was to secure the succession of his son Constance, whom he had by Irene, an Athenian lady of great accomplishments. He cau sed the youth to be feolemly crowned, and declared a partner in the empire. Leo IV. inherited his predecessor's eminence to images, and is on that account reckoned, by the Catholics, one of the impious "iconoclasts." He obtained some advantages over the Saracens, and initiated into the Christian religion a king of the Bulgarians, who, in the preceding reign, had inflicted great evils on the empire. He died in 780, and his death was imputed to an eruption on his head, which was said to have been excited by a crown that he wore, and which was bedded with jewels, that he had sacrilegiously taken from the great church of Constantinople.

LEO V., the Armenian, son of a patrician, commanded an army against the Saracens in the reign of Michael I. His successes, contrived with the disgrace incurred by the emperor himself, caused a revolt of the army, and Michael hims elf quitted the throne, to which Leo succeeded, without opposition, in the year 813. He had been educated in the camp, and was ignorant of laws and letters; his administration, therefore, partook of severity and military discipline. In religion he followed the footsteps of the iconoclasts, and drew upon himself an execration from pope Paschal I. He attempted a reform in the abuses of government, by which he made himself many enemies. At the head of these was Michael, formerly his fellow commander in the army, and a principal instrument of his elevation. Though he had been enriched and promoted by Leo, he was dissatisfied with his rewards, and formed a conspiracy.
perceiving and lie of arrested, the demonstrations and A post under the Hift. whom he had retired to the altar, and disregarding the crofs which he held, they cruelly affinilated him. This event took place in 820, after Leo had reigned with reputation seven years and a half.

Leo VI., the philofopher, was the fon and successor of Basil, the Macedonian, who had caufed him to be crowned as his partner in the empire in 870. By the treachery of a monk he had nearly loft his eyes and his inheritance, but his friends zealously exerted themselves to procure his release, and restoration to favour. On the death of Basil in 886, Leo succeeded to the imperial throne, having a nominal partner in his brother Alexander, but he himfelf pooffed the sovereign power. The Bulgarians, in this reign, renewed their usual hosilities againft the eastern empire; and the ill succefs of the generals of the emperor, obliged him to submit to fuch terms of peace as they were pleased to impose. With the Saracens likewise feveral actions were fought by sea and land with various succefs. But he was chiefly haraffed by conspiracies at home, and had more than once nearly loft his life. By his literary reputation he acquired the title of "philofopher," but his private conduct difplayed an indolent and voluptuous character. He had in his theological zeal prohibited third marriages, whereas having himfelf lost three wives, he entered into the holy flate a fourth time, which led to his excommunication. It has been urged, in excufe of his conduct, that he had no remaining fince by the firft three marriages. He was, during his whole reign, much under the dominion of favourites; he was superflitious, and made pretentions to the art of foretelling future events by divination. A defeat of his fleet by the Saracens preceded his death, which happened in 911, after he had been on the throne twenty-five years. He bequeathed the empire to his brother Alexander, as a truft for his fon. Leo had been educated an the learned Photius, from whom he derived an attachment to various kinds of erudition. He was fuppofed by fome to have been the author of a collection of sermons or homilies; of a letter to the caliph Omar on the truth of the Christian religion; of a pastoral letter to his fubjefts; of a treatife on military discipline, and a collection of laws begun by his father. For farther particulars relating to the foregoing emperors, see Gibbon's Hist. and Univer. Hist.

Leo I. pope, faminated "The Great," was a native neither of Tuscan or Rome; at the latter place he was educated. Nothing certain is known of him till he was raised to the dignity of archdeacon of the Roman church under the pontificate of pope Celefine. He occupied the fame toil under Sixtus III. and acquired a very high reputation for piety, orthodoxy, eloquence, and prudence, in the management of bufinefs. He was employed to negotiate certain differences which had a rifed in Gaul, between Aetius and Albinus, and succeeded in the object of his mission. While he was in Gaul, Sixtus III. died in 440, upon which the universal voice of the Romans proclaimed Leo his successor, and upon his return he was received with the greatest demonstrations of joy. He commenced his pontificate with the moft zealous exertions of a Christian bishop, and he was particularly anxious for the advancement and grandeur of the papal fee. In the year 442, he extended the law of celibacy to the archdeacons, who nevertheless were not to abandon the wives whom they had married, while in inferior situations, but were in future to live with them as fifters. In the year 445, he quarrelled with Hilary, bishop of Arles, for opposing the power of the papal fee, and obtained an edict from the emperor Valentinian, which put an end to the jurisdiction and liberties of the Gallican churches, and enforced the appeals to Rome which gradually subjected all the western churches to the jurisdiction of the pretended successors of St. Peter. About this time many of the Manicheans flying from Africa, after the conquest of Carthage by Generic, king of the Vandals, had repaired to Rome as a place of safety. The zeal of Leo would not fuffer them long to enjoy tranquillity, but caufed great numbers of them to be feized and imprisoned. Those who abjured their diflinguifhing tenets were admitted into communion, but thofe who steadily adhered to their principles were condemned to perpetual banifhment. The pope found that many of the Manicheans had made their escape from Rome; he accordingly fent a circular letter to all bishops, exhorting them to be upon their guard againft the faid heretics, and when difcovered, to profeff them without mercy. His holines was not contented with what he could do by the power with which he himfelf was armed, but he applied to the emperor Valentinian, for a law to exclude fuch perofns from all civil and military employments, and to declare them incapable of giving or receiving any property by will or testament, or of making any contract. Leo was equally violent against the Prifcillians, who pretended to high degrees of purity of life and manners, who prattised great mortifications, and whose opinions were a compound of Gnosticism and Unitarianism. For propagating them, their leader, Prifcillian, had been put to death, and was accordingly regarded as a faint and martyr. Leo now condemned the doctrines and practice of his followers as impious and deteftable, and declared all thofe who tolerated heretics, no lefs guilty than thofe who embraced their opinions. The document of Eutyches, which maintained that there was but one nature in Chrift, roused the zeal of Leo, and after much difcufion, concerning which our limits do not allow us to enlarge, he caufed the heretic to be condemned, fent into banifhment, and deprived of his facerdotal dignity; and a decree was paffed, that "in Chrift there were two diflinguent natures united in one perfon, and that without any change, mixture, or confusion." During the pontificate of Leo the fourth general council was held, in which the famous canon was enacted, which rendered the fee of Conftantinople equal to the fee of Rome in all respects, except precedence. This canon was evidently intended to check the growing power, and to oppofe the daily encroachments of the bishop of Rome. When Leo was made acquainted with the determination of the council, he was filled with the utmost rage, and resolved to oppofe it with all his might. He faw his rival but one ftep behind him, and apprehensive he might foon get before him; he was, therefore, determined to difpute his power in every flage. Withflying, however, that he might be thought to be acting upon Christian motives, he pretended to be influenced only by a zeal for the decrees of the council of Nice, for the practive of antiquity, and for the rights and privileges of the patriarchal fees of Alexandria and Antioch. During the year 452, Attila, king of the Huns, made an irruption into Italy, foon became master of feveral important cities, and then bent his march towards Rome, hoping to enrich himfelf with the fpoils of the metropolis. At this time the city was not in a condition to bear a fiege, and the emperor fent a folemn embaffy.
embassy to Attila, with such proposals as might be acceptable to him and his army. Leo himself went at the head of the embassy, in which he was joined by two men of the first rank, and of long experience in negotiations. On their arrival with a grand and numerous retinue, at the enemy's camp, in the neighbourhood of Mantua, they were received by the king of the Hunns in a very favourable manner, which the ecclesiastical writers ascribe to the fame of Leo's extraordinary sanctity. The terms which they proposed were readily agreed to by Attila, and a treaty of peace was soon concluded between him and Valentinian, in consequence of which he repassed the Alps, and retired beyond the Danube. In the year 455, Leo's zeal was directed towards the conversion of the monks of Palestine and Egypt, who denounced war against all the abettors of the council of Chalcedon, and sacrificed, without mercy, such of the clergy and laity, as had the courage to profess a belief in the two natures in Christ. In 455, Leo's attention was drawn off from the affairs of the East, by the calamities produced in Italy, in consequence of the death of Valentinian. That prince was murdered by Maximus, who not only usurped his throne, but obliged Eudoxia, the emperor's widow, to marry him. Determined to revenge the death of one whom she had loved with the greatest tenderness, and to deliver herself from the tyrant, she applied to Generic, king of the Vandals, in Africa, who, she well knew would be glad of any favourable opportunity of invading and plundering Italy. To him she dispatched a confidential messenger, conjuring him to come without delay and rescue her out of the hands of Maximus, alluring him that he would meet with no opposition, and promising to affit him to the utmost of her power. Generic gladly seized the opportunity, and appeared in a short time with a very powerful army in the neighbourhood of Rome. His appearance struck the Romans with dismay, and instead of preparing for defence, they threw open their gates, and surrendered at discretion. In this extremity of distress, Leo went out to meet the enemy, and endeavoured by prayers and tears to mediate for the safety of the city. The pope could not prevail, and the army of Generic plundered the city, and carried away the inhabitants into captivity. After spending fourteen days in rapine, they set fire to the houses, churches, and public buildings, and stripping them of all their wealth, and valuable monuments, the Vandals re-embarked, and returned to Africa, with an immense booty, and as many captives as they could carry on board the fleet. These troubles, and the mischiefs which they occasioned, engrossed much of Leo's care and attention to mitigate them, till, on the death of the emperor Marcian in 457, the Eutychians once more obtained the ascendency in Egypt. The chief of this revolution was Timothy, surnamed Ælurus; who assembled his council, consisting of a small number of Eutychian bishops, in which he openly anathematized the council of Chalcedon, pope Leo, and the Catholic bishops. In virtue of this sentence, he excommunicated, deposed, and drove from their sees, all the bishops of the patriarchate of Alexandria, who refused to abjure the faith of Chalcedon, and in their room took care to place such as had distinguished themselves by their zeal for the Eutychian doctrine. In the year 458, the emperor invited Leo to Constanitnople, that he might converse with him, in person, on the subjects of the decree of Chalcedon, and the intrusion of Ælurus. To this invitation his holiness replied in two letters; one containing his excuses for not undertaking such a journey, and the other intended to explain and confirm, with the testimony of the fathers, the doctrine of the two natures. The last named letter became very famous with the orthodox, and was often quoted by the writers of that and succeeding ages. After this Ælurus gave the pope a public challenge to debate the points in disputation. But Leo refused to comply with the proposal, alleging that it was dangerous and unnecessary to examine anew, or to question what had already been examined and defined by an ecumenical council. From this time Leo continued his efforts, with unabated zeal, in defence of the Catholic cause, and omitted no opportunity of endeavouring to impress the emperor's mind with a sense of the heinousness and enormity of Ælurus' crime. In 460, the bishops of the East united in the same cause with so much ardour, that an order was obtained from the emperor to expel and banish the heretic, which was carried into execution without delay. This event was followed by the election of a Catholic bishop to the see of Alexandria, and the restorition of those prelates who had been displaced for their adherence to the council of Chalcedon. The news of this important change afforded the highest satisfaction to Leo, but the pleasure was of short duration only, as he died in the year 461, having presided over the Roman church twenty-one years. Leo was a man of great learning, and of eminent abilities; but his ambition was unbounded, and with him every object, every consideration was made to yield to his predominant passion for aggrandizing his see, or, in other words, for extending his own power and authority. His works consist of 141 letters, and 66 sermons. The first edition of them was published at Paris in 1675, in two vols. 4to., which was reprinted in folio at Lyons, in the year 1700. The style of Leo's writings is energetic and elegant, though sometimes, in the pursuit of elegance, he renders his discourse too highly polished.

LEO II., pope, a Sicilian by birth, was raised to the papal dignity in the year 682. With the decree confirming his election, he received an account of the proceedings of the sixth general council, held at Constantinople, by which pope Honorius I. was anathematized as a monothelite. In reply to this letter, he says, that he had received this council as he received the five preceding general councils, and anathematized all whom the council anathematized. He also sent letters to the metropolitans of the different provinces of the West, acquainting them with the proceedings of this council, and requiring them to receive it, as well as to cause it to be received by the bishops in their respective jurisdictions. By this conduct he acquired so much interest at court, that he found the opportunity favourable for extending the power of the papal see, and procured an edict, subjecting for ever the fee of Ravenna to that of Rome. He died in 683, after a pontificate of only ten months. Five of his letters may be seen in the fifth vol. of the Collect. Concil.

LEO III., pope, born at Rome, was in due time appointed to the office of prebender in the church; and upon the death of Adrian, in 795, he was unanimously elected to the papal see. Upon his ordination, he wrote to Charlemagne, acquainting him with his promotion, and, at the same time, sending him the keys of the tomb of St. Peter, and the standard of the city of Rome, with other presents, and requesting him to send some fit person to receive the oath of allegiance from the Roman people. The answer of the king was conceived in equally civil and complimentary terms, and it was accompanied with immense treasures to be employed by Leo in repairing and adorning the churches of Rome, especially that of St. Peter. In the year 796, he restored the fee of Canterbury to that jurisdiction over all the churches of England, which had been taken away by Offa. Towards the beginning of the year 799, Leo assembled a council at Rome, in which Felix, bishop of Urgella, and Eliphand, archbishop of Toledo, were condemned. During the
the same year, a conspiracy was formed against Leo, by two nephews of pope Adrian, who had been raised by him to high employments in the church, and governed all things at Rome, during his pontificate, with an absolute sway. To them, indeed, Leo had been greatly indebted for his election, and they supposed that gratitude would have led him to surrender all power into their hands. Leo, willing to shew his own authority, checked them in their designs, and in turn they resolved to put him to death. The attempt was made on the festival of St. Mark, when the pope was proceeding from the Lateran palace to join in an annual procession. The design did not succeed, though he was exposed to the most imminent danger, and was in fact thrown into a dungeon covered with wounds. From his prison he was rescued by the duke of Spoleto, who conveyed him safely into his own territory. From Spoleto the pope wrote to Charlemagne, to acquaint him with the cruel treatment he had met with, and soon after sent out a visit to that prince, to solicit protection against his enemies. Charlemagne received him with the greatest marks of respect and friendship, and after assuring him of his protection, sent him back to Rome, attended with several bishops, and a force sufficient to protect him against any farther attempt of his enemies. He entered the city amidst the loud acclamations of the people, and took possession once more of the Lateran palace, where the nobles and bishops who had accompanied him assembled, and to which all were summoned who had any cause of complaint against Leo, these being commissioned by the king to hear them and do them justice, if in any respect they had been injured by the pope or his ministers. Some did appear, and among these the nephews of Adrian, who accused him of several crimes, but not being able to substantiate the charge, they were sent to prison, tried, and sentenced to death for the conspiracy, in which they had been the principal actors. At the earnest solicitation of Leo their lives were spared, and their sentence exchanged to banishment. About this period, the title of emperor of the Romans was revived in the person of Charlemagne, who, on the proposition of the pope, was saluted Augustus by all classes of the Roman people, and on the day of his coronation received their homage, as well as that of Leo. In 803, the pope having expressed his wish to celebrate the nativity of Christ, with the emperor Charlemagne, the latter sent his son as far as St. Maurice, in the Valais, to meet his holiness, and went himself to Rheims, where he received Leo with extraordinary marks of esteem and friendship. From Rheims they proceeded to Quiercy, where they kept their Christmas, and then repaired to Aix-la-Chapelle. Here, after entertaining him for eight days, Charlemagne dismissed the pope with rich presents, and an escort, who were ordered to attend him as far as Ravenna. In 809, the dispute was revived in France on the question concerning the procession of the Holy Ghost; by the first council of Conantinople, an addition was made to the symbol of Nice, declaring that "The Holy Ghost proceeded from the Father." In the fifth and sixth centuries, the churches of Spain added to the symbol of Nice and Conantinople the word filioque, "and from the fon;" and their example was followed by most of the Gallican churches. The question now under discussion was, whether the expression "filioque" ought to be added or omitted. Leo was for the omission, though he adhered to the doctrine attached to it; because he said if it were received by the churches, it would be a fair plea for the addition of many other articles of equal importance. To shew more decidedlly that he did not approve it, he caused two tables of silver to be set up at the tomb of St. Peter, and the symbol to be engraved in Greek on one, and on the other in Latin, without the words "and from the son," which, however, were afterwards added to the creed by his successors. Leo palled the remainder of his pontificate in tranquillity, till the death of Charlemagne, his great friend and protector, in 814: when the relations of pope Adrian and their partisans formed another conspiracy against him, with the design of depoing and murdering him. The plot was discovered in 815, some time before he was ripe for execution, and caused all who were concerned in it to be apprehended, and put to death without mercy. It has been said that he glutted his revenge by executing some of the conspirators with his own hands. His severity excited the displeasure of the new emperor Lewis, who commanded his nephew Bernard, king of Italy, to proceed immediately to Rome, and to take cognizance of the whole affair on the spot. The emperor was said to be perfectly satisfied with the pope's justification of his conduct, but the people, who felt for themselves and for their friends, who had been the victims of his cruelty, were not so easily appeased: they destroyed every thing belonging to his holiness that they could get at, and would have excited an insurrection, had they not been suppressed and dispersed by a body of troops under the duke of Spoleto. The pope died in June 816, after he had presided over the Roman church more than twenty years. He left behind him thirteen letters, which are to be found in the seventh vol. of the Collect. Concil. He has been celebrated for having enriched the churches of Rome with the most costly and valuable ornaments, for which he was chiefly indebted to the liberality of Charlemagne.

Leo IV., pope, was born at Rome, and educated in the monastery of St. Martin, ordained sub-deacon by Gregory IV., and prebendar of the Roman church by Sergius II. Upon the death of the latter, he was unanimously elected to the pontifical throne. The first object of his care was to restore to their former splendour, at an immense expense, the churches of St. Peter and St. Paul, which had been deftroyed of their ornaments by the Saracens, and like-wise to secure them against the future attempts of such plunderers. With this view he resolved to build a new city upon the Vatican, and to enclose it, as well as the church of St. Peter, by a strong wall. This resolution met with the approbation of the emperor, who not only contributed himself to the work, but engaged contributions from his brothers in support of the same cause. With this encouragement Leo set about the undertaking with the utmost diligence and ardour, performing in his own person the daily office of overseer, in all kinds of weather. In 849, he was interrupted in the work by a threatened attack upon the city by the Saracens. The attempt was made, but a storm arising, the enemy's fleet was driven on shore, and almost all the ships dashed in pieces, and those on board perished. Of the vessels that escaped the fury of the waves, some fell into the hands of the Romans, of which the greater part of the crews were hanged, and left on gibbets to strike terror into the minds of their countrymen, and the rest were put into iron, and forced to labour in the pope's new works. While the Romans were celebrating the victory obtained over their enemies, Lewis king of Italy arrived to be crowned emperor, in order that he might share the empire with his father. This was in 850, and in 852 Leo saw his new city completed, which was called, after the founder, the Leonine city. In the following year Leo assembled a council at Rome, for the purpose of restoring discipline, and banishing abuses that had crept into the church: among other things which they did, was the deposition of Anathafius, cardinal presbyter of the church, for abjuring himself from his see five years. In the same year, the illustrious Alfred was sent
by his father to Rome, to be educated under the care and
direction of the pope. The Saracens continued still to infringe
the court, notwithstanding their late defeat and consequent
disasters: he accordingly fortified the cities on the coast
to guard his people from their depredations, and he built a new
city which he called Leopolis. Scearly had he finished this
city, when he was surprised with the intelligence that the
emperor Lewis was arrived in the neighbourhood of Rome,
at the head of a large army. Leo was soon informed of the
definition of his coming, which was to bring to trial Gratian,
commander of the Roman militia, one of the pope’s coun-
sellors, who was accused of having solicited another com-
mmander to join him in driving out the French, and calling
in the Greeks in their room. On the day of trial, the in-
nocence of Gratian appeared perfectly clear, and the accuser
was delivered up to be disposed of at pleasure. His life
was, however, spared at the solicitation of the emperor.
Leo died in 855, after a pontificate of eight years and up-
wards. He was, according to Aethaenus, polleft of all
the moral and Christian virtues, without the alloy of a
single vice. He left behind him two letters, and a discurse,
designed for the instruction of the clergy in the duties of
their office, which are to be found in the eighth vol. of the
Collect. Concil.
Leo V., pope, a native of Ardea, ascended the pontifical
throne in the year 903, but scarcely had he attained to this
distinguished honour, before he was deposed by one of his
own priests, and thrown into prison, where he shortly died
of grief.
Leo VI., pope, a Roman, was elected to the papal dig-
nity on the death of pope John X., in the year 928. He
held the high office but about six months, when he was de-
posed and imprisoned.
Leo VII., pope, a Roman, was raised to the pontifical
throne by the unanimous vote of the clergy and people, on
the death of John XI., in the year 936. He is highly com-
manded for his zealous efforts to restore ecclesiastical disci-
pline, to reform the monastic orders, and to correct the
abuses which prevailed in the Roman and other churches.
He died in 939, after having sat on the pontifical throne
three years and a half. He has left three letters, inferted
in the Collect. Concil.
Leo VIII., pope, though by others styled antipope, was
born at Rome, and was chief secretary of the Roman
church, an office in which he succeeded his father. Upon
the deposition of John XII., in 903, Leo, on account of
his excellent character, was elected to the pontifical dignity,
with the approbation, if not by the influence, of the
emperor Otho. He enjoyed his situation but a short time;
the people, instigated by John, drove him from his elevated
station, and Benedict was placed there in his stead, the par-
tizans of whom bound themselves by the sanction of an
oath, never to submit to Leo, whom they called the empe-
or’s pope. Leo was, however, in a short time reëlected
to his holy office, and died after a pontificate of fifteen
months.

Leo IX., pope, was born at Toul, in Lorraine, in the
year 1002, and being educated for the church, he was or-
dained deacon in 1025, and promoted to the bishopric of
his native place in the following year. By his conduct
in that he acquired so high a reputation for learning,
prudence, and piety, that on the death of pope Damasus II.
in 1048, he was chosen as the most fit person to be his suc-
cessor. He went from Toul in the habit of a pilgrim, and
was received by the people at Rome with fongs of joy and
loud acclamations. An assembly of the clergy and people
was convened, at which he informed them of his having been
nominated to the apostolic see by the emperor, but that he
did not consider his election valid unless made by them, and
that, therefore, they were at full liberty to choose or reject
him; and that, if he were not unanimously chosen by them,
he would return to his bishopric as willingly as he had un-
willingly left it. This address was received with every de-
monstration of respect and satisfaction; and he was pro-
claimed sovereign pontiff under the title of Leo IX.
In

Vol. XX.
labria to that of Apulia. The pope now received a letter from the emperor, in which he expressed a great desire to see the ancient union restored between the sees of Constantinople and Rome, and offered to contribute whatever lay in his power towards so good a work. Before any thing could be done to effect this, the pope was seized with a severe and fatal illness, which put an end to his life in the year 1574, at the age of sixty-two, after having governed the Roman church five years and two months. He was zealous in reforming abuses, and is highly commended for his prudence, his humanity, and his pietie. For his attempts to aggrandize the holy see he has been honoured with a place among the saints in the Roman calendar. He was the first pope who made use of the Christian era in the date of his bulls, his predecessors having followed that of the Indictions. Nineteen of his letters are preserved in the ninth vol. of the Collect. Council and several of his homilies or sermons were published at Louvain in 1567.

Leo X., pope, born at Florence in December 1475, the second son of Lorenzo de Medici the Magnificent, bore the baptismal name of Giovanni, or John, was originally destined by his father for the church, and received the tonsure at the age of seven years. Being then declared capable of receiving ecclesiastical preferment, Lorenzo obtained two rich abbacies; and the list given of the preferments accumulated upon him at an early age, amounts to the number of twenty-nine, a proof of the great interest of his family, and of the scandalous corruption of the church. It was the great object of his father's ambition to decorate his house with the popedom, and upon the accession of Innocent VIII. to the pontificate, Giovanni, then thirteen years of age only, was nominated to the dignity of cardinal. Lorenzo was not wanting in exertions to make his son worthy of his premature advancement, and the disposition of the youth, which was grave and solid beyond his years, contributed to the success of his instructions. When he was nominated to the cardinalate, it was made a condition that he should spend three years at the university of Pisa in professional studies, before he was invested formally with the purple. In 1492 this solemn act took place, and he immediately went to reside at Rome as one of the sacred college. His father soon after died, and was succeeded in his honours in the Florentine republic by his eldest son Piero. The young cardinal's opposition to the election of pope Alexander VI. rendered it expedient for him to withdraw to Florence, from whence, at the invasion of Italy by Charles V., he and the whole family were expelled, and obliged to take refuge in Bologna. About the year 1500 he again fixed his residence at Rome, where he resided during the remainder of Alexander's pontificate, and likewise in the early part of that of Julius II. cultivating polite literature, and the pleasures of elegant society, and indulging his taste for the fine arts, for music, and the chase, to which latter amusement he was much addicted. The depression of his house occasioned frequent embarrassments in his finances, but his cheerful temper supported him under difficulties, and he extricated himself without loss of honour. In 1505 he began to take an active part in public affairs, and was appointed by Julius to the government of Perugia. By his firm adherence to the interests of the pope, the cardinal acquired the most unlimited confidence of his holiness, and was entrusted with the supreme direction of the papal army in the Holy League against the French in 1511, with the title of legate of Bologna. At the bloody battle of Ravenna, in 1512, he was made prisoner, and was conveyed to Milan, where the favor of his function caused him to be treated with great respect. The French in their retreat carried the cardinal with them, but on his arrival at the banks of the Po he effected his escape. About this time the family of the Medici was restored to its former condition at Florence, and the popular constitution of that republic was overthrown. The cardinal contributed to this event, and remained at Florence, till the death of Julius II. called him suddenly to Rome. At the funeral for a new pontiff in 1513, the election was declared to have fallen on the cardinal de Medici, who was then only in the thirty-eighth year of his age. He assumed the name of Leo X. and ascended the throne with greater manifestations of good-will, both from Italians and foreigners, than most of his predecessors had enjoyed. One of his first acts was to interpose in favour of some coadjutors against the hojse of Medici at Florence, and he treated with great kindness the family of Soderini, which had long been at the head of the opposite party in that republic. He exhibited his taste for literature by the appointment of two of the most elegant scholars of the age, Benofo and Sadoleti, to the office of papal secretaries. With regard to foreign politics, he pursued the system of his predecessor, in attempting to free Italy from the dominion of foreign powers; and in order to counteract the autipapal council of Pisa, which was assembled at Lyons, he renewed the meetings of the council of Lateran, which Julius II. had begun, and he had the good fortune to terminate a division which threatened a schism in the church. Lewis XII. who had incurred ecclesiastical censure, made a formal submission, and received abjuration. Having secured external tranquillity, Leo did not delay to consult the interests of literature by an ample patronage of learned studies. He restored to its former splendour the Roman gymnasium or university, which he had enriched by new grants of its revenues and privileges, and by filling its professorships with eminent men invited from all quarters. The study of the Greek language was a very particular object of his encouragement. Under the direction of La forca a college of noble Grecian youths was founded at Rome for the purpose of editing Greek authors; and a Greek press was established in that city. Public notice was circulated throughout Europe, that all persons who possessed MSS. of ancient authors would be liberally rewarded on bringing or sending them to the pope. Leo founded the first professorship in Italy of the Syriac and Chaldaic languages: this was in the university of Bologna. With regard to the politics of the times, the pope had two leading objects in view, viz. the maintenance of that balance of power which might protect Italy from the over-bearing influence of any foreign potentate; and the aggrandizement of the house of Medici. When Francis I. succeeded to the throne of France, it was soon apparent that there would necessarily be a new war in the north of Italy. Leo attempted to remain neuter, which being found to be impracticable, he joined the emperor, the Swifs, and other sovereigns against the French king and the state of Venice. The rapid successes of the French arms soon brought him to hesitate, and even to stand aloof, and after the Swifs army had been defeated, the pope thought it expedient to detach his caufe from that of his allies, and to form an union with the king of France. Thence two sovereigns, in the close of the year 1515, had an interview at Bologna, when the famous Pragmatic Sanction (which fee), was abolished, and a concordat established in its stead. The death of Leo's brother left his nephew Lorenzo the principal object of that passion for aggrandizing his family, which this pontiff felt full as strongly as any one of his predecessors. Under the influence of this passion, he found a pretext, in 1516, for influing a monitory against the duke of Urbino, and upon his non-appearance, Leo inflicted an excommunication against him, and feized
his whole territory, with which, together with the ducal title, he invested his nephew. In the same year a general pacification took place, though all the efforts of the pope were made to prevent it. In 1517, the expelled duke of Urbino collected an army, and, by rapid movements, completely regained his capital and dominions. Leo, excessively chagrined at this event, would gladly have engaged a crusade of all Christliam princes against him. By an application, which nothing could justify, of the treasures of the church, he raised a considerable army, under the command of his nephew, and compelled the duke to resign his dominion, upon what were called honourable terms. The violation of the safe conduct, granted by Lorenzo to the duke's secretary, who was feized at Rome, and put to torture, in order to oblige him to reveal his maller's secrets, imprints on the memory of Leo X. an indelible stain. In the same year his life was endangered by a conspiracy formed against him, in which the chief actors were cardinal Petrucci. The plan failed, and the cardinal, being decoyed to Rome, from whence he had escaped, was put to death; and his agents, as many as were discovered, were executed with horrorous tortures. The conduct of Leo on this occasion was little honourable to his fortitude or clemency, and it was believed that several persons suffered as guilty who were wholly innocent of the crimes laid to their charge.

To secure himself for the future, the pope, by a great stretch of his high authority, created in one day thirty-one new cardinals, many of them his relations and friends, who had not even riven in the church to the dignity of the episcopal office; but many persons also who, from their talents and virtues, were well worthy of his choice. He belloved upon them rich benenices and preferments, as well in the remote parts of Christendom, as in Italy, and thus formed a numerous and splendid court attached to his person, and adding to the pomp and grandeur of the capital. During the pontificate of Leo X. arose the daring Luther, whose life will be given farther on; nevertheless, in this place, we must notice certain facts with which Leo and the reformation are closely connected. The unabounded profusion of this pope, in every object of expense attached to a tale for luxurious magnificence, had rendered it necessary to devise means for replenishing his exhausted treasury; and one of those which occurred was the sale of those indulgences which the church claimed a right of dispensing from the lore of her spiritual wealth. The cardinals appointed for this traffic in Germany, exaggerated the efficacy of their wares in such very extravagant terms, as gave great offence to the pious and thoughtful. Luther, a public preacher at Wittenberg, warmly protested against this blufe in his discourses, and in a letter addressed to the elector of Mentz. He likewise published a set of propositions, in which he called in question the authority of the pope to remit sins, and made some very warm criticisms on this method of raising money. His remonstrances produced considerable effect, and several of his chlist undertook to refute him. Leo probably regarded theological quarrels with contempt, and from his pontifical throne looked down upon the efforts of a German doctor with scorn; even when his interference was deemed necessary, he was inclined to lenient measures. At length, at the express desire of the emperor Maximilian, he summoned Luther to appear before the court of Rome. Permission was, however, granted for the cardinal of Gaeta to hear his defence at Augsburg. Nothing satisfactory was determined, and the pope, in 1518, published a bull, affenting his authority to grant indulgences, which would avail both the living, and the dead in purgatory. Upon this, the reformer appealed to a general council, and thus open war was declared, in which the abettors of Luther appeared with an strength little calculated upon by the court of Rome. The sentiments of the Christian world were not at all favourable to that court. "The scandal," says the biographer, "incurred by the infamy of Alexander VI., and the violence of Julius II., was not much alleviated in the reign of a pontiff who was characterized by an inordinate love of pomp and pleasure, and whose classical taste even caused him to be regarded by many as more of a heathen than a Christian."

The warlike disposition of Selim, the reigning Turkish emperor, excited great alarms in Europe, and gave occasion to Leo to attempt a revival of the ancient crusades, by means of an alliance between all Christlian princes; he probably hoped, by this show of zeal for the Christian cause, that he should recover some of his lost credit as head of the church. He had, likewise, another object in view, viz. that of recruiting his finances, by the contributions which his emililies levied upon the devotees in different countries. By the death of Maximilian in 1519, a competition for the imperial crown between Charles V. and Francis I. took place. Leo was decidedly against the claims of both the rival candidates, and attempted to raise a competitor in one of the German princes, but he was unable to refit the fortune of Charles. At this period he incurred a very severe domestic misfortune in the death of his nephew Lorenzo, who left an infant daughter, afterwards the celebrated Catherine de Medicis, the queen and regent of France. The death of Lorenzo led to the immediate annexation of the duchy of Urbino, with its dependencies, to the Roman see, and to the appointment of Giulio, Leo's cousin, to the supreme direction of the state of Florence. (See Clement VII.) The rapid progress of the Reformaion forcibly recalled the attention of the papal court, and Leo, anxious for an amicable negotiation, employed a Saxo nobleman to treat in person with Luther, but the matter was, at this period, carried too far to admit of reconciliation. Luther appealed to the scriptures for his authority; and the pope infilled upon unqualified submission to the decrees of the Catholic church. The reformer was persuaded to addresse a letter to his holines; but, instead of expressing humiliation, he contained much bitter invective against the court of Rome. It was, therefore, determined to condemn him and his doctrines; and a bull to that purpose was issued, June 15th, 1520, which occasioned a total separation between the papal see and the reformers. The writings of Luther were publicly burnt, an inful which he boldly retaliated by an equally solemn and public confutation of the papal decrees and constitutions, and the bull itself. Leo was not satisfied with his own exertions, but was desirous of gaining on his side the Imperial court. Before, however, the emperor would condemn, he determined to hear, in person, what Luther had to say in his own justification, and a mandate was issued for his appearance at Worms. (See Luther.) We may observe here, that Leo conferred on Henry VIII. of England the title of "Defender of the Faith," for his appearance on the side of the church as a controversial writer. The tranquil state of Italy, at this period, allowed the pope to indulge his taste for magnificence in shows and spectacles, and in the employment of those great artists who have reflected so much lustre on his pontificate. His private hours were chiefly devoted to indolence, or to amusements, frequently of a kind little suited to the dignity of his high station. He was not, however, so much absorbed in them as to neglect the aggrandizement of his family and estate. Several cities and districts in the vicinity of the papal territories, and to which the church had claims, had been seized by powerful citizens, or military adventurers; some of these the
the pope summoned to his court to answer for their conduct; and in default of an exculpation of their crimes, he caused them to be put to death. His relations next laid a plan to get into his possession the city and territory of Ferrara. He had set his heart upon this object, and being unable to attain it by open means, he had recourse to treachery, and it has been asserted that his plan included the affixation of the duke. The commander of a body of German troops was bribed to deliver up one of the gates to the papal forces, which were to be in readiness; but he took the pope's money, and apprized the duke of the plot, which was thus happily defeated.

Another plan, which entered deeply into the views of the pope, was the expulsion of the French from Italy. In 1521, he formed a treaty with the emperor for the re-establishment of the family of Sforza, in the duchy of Milan. He engaged a large body of Swiss in his service, who, under the pretence of different measure, made much progress against the French, and drove their troops before them; but in the midst of these successes, and while public rejoicings were making in Rome on account of them, the pope was seized with an illness, which at first was considered as a slight cold only, but which put an end to his life in a few days. This event happened on the 1st of Dec. 1521, when Leo was in the 46th year of his age, and the ninth of his pontificate. The people at large expressed much concern at his death, but the honours rendered to his memory were not such as might have been expected. An exhausted treasury was the pretext for an economical funeral, and amidst all the eminent scholars of his court, an illiterate chamberlain was appointed to pronounce his funeral oration.

Leo was himself but moderately furnished with solid erudition; he afforded liberal encouragement to useful and reputable studies, but he also lavished his patronage upon productions and persons of an opposite character. The merit of a sovereign in promoting those ornamental arts by which alone he can display a magnificence superior to that of a private citizen, can rank no higher than an exertion of good taste; and this quality may be undoubtedly conceded to Leo. He was, however, rather the unfortunate inheritor, than the creator of great talents. Michael Angelo and Raphael had both risen to fame under his predecessor, Julius II., who had planned and made a commencement of the stupendous edifice of St. Peter's: the Vatican palace had likewise received some of its noblest ornaments in his and the former pontificates. But the reader who wishes to obtain an accurate view of the state of literature and the arts in Italy prior to, and during the reign of Leo, will have recourse to Mr. Rolfe's "Life and Pontificate of Leo X.," from which the foregoing facts are principally drawn. The character of this pontiff has been finely celebrated by Pope in the following lines:

But fee! each mufe, in Leo's golden days,
Starts from her trance, and tries her with'er days;
Rome's ancient Genius, o'er its ruins spread,
Shakes off the dust, and rears his rev'rend head.
Then sculpture and her finer arts revive:
Stones leap to form, and rocks begin to live;
With sweeter notes each rifing temple rung,
A Raphael painted, and a Vida sung.

Leo XI., pope, the son of Octavio de Medici, cousin of Cofmo, duke of Tuscany, was born in the year 1535. He was made archdeacon of Florence, and filled the post of ambassador from France, the great duke, at the court of Rome. He was created cardinal by Gregory XIII., and by Clement VIII., he was sent legate to Henry IV. of France, and he was successfully employed in adjusting the terms of peace between Philip II., king of Spain, and the French monarch, and for his good offices he received from the latter a noble present. On the death of pope Clement VIII., in the year 1605, he was elected pope by the unanimous suffrages of the concile when he took the name of Leo XI. The Romans and Florentines were highly delighted with his elevation on account of his distinguished talents and virtues, and because they knew that to his zeal for the interests of the church, he united a liberal spirit, a love of learning and learned men, and, as it were, an hereditary taste for the polite arts. On the day of the procession, when the pope commences his office with great pomp and form, the several orders of the city endeavoured to surpass each other in their demonstrations of joy on the occasion. Their satisfaction, however, was of very short continuance, and was speedily changed into grief and mourning, on account of his death, which happened on the 25th day after his election, in the 70th year of his age. Bower's Lives of the Popes. Bayle. Moreri. Lardner.

Leo Allatus. See Allatus.

Leo, the Grammarian, of whose personal history nothing is come down to us, was author of a continuation of the Chronicle of Theophanes, in the Greek language, comprising the lives of the seven emperors of the East, from the year 813 to 1015. It is annexed to Combee's edition of the chronicle, printed at Paris in 1655. Moreri.

Leo, John, named Africenus, a traveller and geographer, was a native of Granada of Moorish extraction. When that city was taken by Ferdinand and Isabella, in 1492, he retired into Africa, and on that account obtained his surname. He studied the Arabic at Fez, was employed by the king as ambassador, and took several journeys into Europe, Levant Asia, and Africa, of which he wrote a narrative in the Arabic language. He once fell into the hands of some pirates, and was sold as a slave to a mallet, who presented him to Leo X. The pontiff highly esteemed him on account of his learning and knowledge, and having persuaded him to renounce Mahometanism, gave him his own names of John and Leo at the time of his baptism. He now applied himself to the attainment of the Italian language, and translated into it his description of Africa. This work is reckoned one of the most curious of the early voyages and travels. The author describes what he had himself seen, chiefly on the northern and western coasts of that peninsula, and it supplies deficiencies from the relation of others; but as a geographical work it has various imperfections and defects. It has been translated into Latin and French. Leo probably died soon after he had rendered his work into the Italian language in 1526. He was a native of Lisbon, and was named after the title of "De vitis Philosphorum," printed at Zurch in 1664. Moreri.

Leo of Orvieto, born in the territory of Orvieto, in Tuscany, became a monk of the Dominican or Franciscan order, who flourished towards the commencement of the fourteenth century. He was author of two "Chronicles," one of the popes, down to the year 1314; and the other of the emperors, terminating at the year 1308. They were brought into notice by John Lamy, who published them in his "Deliciae Eruditorum, seu Veterum Anecdotum Opera- cularum Collectanea," printed at Florence. Both the chronicles were published in 1737, in two volumes 8vo., with notes and illustrations. The second volume contains a sketch of the history of France, written by John de l'Ile, supposed to have been a monk of the abbey of St. Denis, in the 15th century, entitled "de Gesta et Fatis memoria- bilibus Francorum." Moreri.

Leo de Modena, a learned rabbi, whose Jewish name was
was R. Jehudah Arie, was born at Modena, and flourished in the seventeenth century. He was for a considerable time chief of the synagogue, and esteemed a good poet both in Hebrew and Italian. He was author of a valuable work on the ceremonies and customs of the Jews, which is held in estimation by the learned of all nations. It is entitled "Italia de Riti Hebrei, vita et Obervanze de gl iHebrei di quefchi Tempè." The first edition of this work was printed at Venice in 1638. It was translated into the French language in 1674, by Richard Simon, with supplements relating to the facts of the Karaites and Samaritans. Leo meant to have given an Italian translation of the Old Testament, but he was prohibited from publishing it by the Inquisition. He compiled a Hebrew and Italian dictionary, entitled "The Mouth of the Lion." This work was published at Venice in 1612, and was afterwards reprinted in an enlarged form at Padua, in 1640. Leo died at Venice in 1674, in about the eightieth year of his age.

Leo de St John, a French monk, born at Rennes in the year 1600. Before he entered into the religious profession, his name was John Mace. He was nominated to all the honourable and confidential posts of his order, and acquired the title of pope Leo X., and Alexander VIII, and of several cardinals. He was an eloquent preacher, and had the honour of performing the duties of his office before Lewis XIII. and Lewis XIV. He was the friend of cardinal Richelieu, by whom he was patronized. He died in 1671, leaving behind him numerous works, the principal of which is entitled "Studium Sapienziae Univeritals," in three volumes folio. His "History of the Carmelites," "Lives of the famous Saints," and "Journal of what took place during the last Sickness, and at the Death of Cardinal Richelieu," are well known and frequently referred to.

Leo, in Botany, a name used by some authors for the cumbine, or aquilegia. Columella, besides others, calls it by this name. See AQUILEGIA.

Leo, the lion, in Zoology. See FELIS Leo.

Leo, Formica. See FORMICA Leo.

Leo Pulex, a name given by M. Reaumur to a species of insects which feeds on the pules arbores, or common tree-puceron, in the same manner that the creature called the formica leo does on the ants: this being also, like that, an animal, yet in an imperfect state, and finally to be changed into a different creature. This author has kept up the remembrance of this analogy between them, by giving this a similar name.

The leo pulex is usually bred among the herds of the pulices, which he devours most unmercifully. He is a worm of the hexapode, or fix-legged kind, and very soon arrives at the time of his change; after which he becomes a green fly with four wings. Another animal of this kind, and not less destructive of this small race of animals, is a fix-legged worm of a whitish colour, and smaller than the former, which finally becomes a round-bodied beetle. Another species of these devourers this author calls vermis hybris, the porcupine-worm, from the vast number of spicules, and tender prickles, with which he is armed. This also finally becomes a round and small beetle. Reaumur, Hist. Insect. tom. i. See LION puceron.

LEOBEN, or LEUBEN, in Geography, a town of the Duchy of Steiri, on the Muehr; 68 miles S.W. of Vienna. At this town the preliminaries of peace between the emperor and the French republic, were settled on the 20th of April 1797. N. lat. 47° 22'. E. long. 14° 55'.

LEOBSCHUTZ, or LUBSCHUTZ, a town of Silecia, and capital of a circle, in the principality of Ingerndorf; 10 miles N. of Raitabor. N. lat. 50° 5'. E. long. 17° 44'.
eight beadles, and eight free tenants. When the survey
was made, the manor belonged to the king; great part of
the culuminary rent was paid as composition for salt, fish,
and cells. Here was also a wood six miles in length, and three
broad; but part of it was even then begun to be "affarled,"
and cleared for tillage; "an aerie of hawks" is also men-
tioned in the same record. About the time of William
Rufus, the fortifications of Leominster were strengthened
and enlarged, the better to secure it against the incursions
of the Welsh. In the reign of King John, William de Braose,
lord of Brecknock, a turbulent and high-spirited baron,
plundered this town, and burned great part of it, together
with the priory and church. In Henry IV.'s reign, Leo-
minter was for some time in the possession of Owen Glen-
dour, after he had defeated the earl of March. In the next
century, the inhabitants of this town took a decisive part
towards the establishment of queen Mary on the throne; for
which service the granted them the first regular charter of
incorporation, with many valuable privileges. An annual
fair had been granted in 1172, by Henry II.; two addi-
tional fairs, each of six days continuance, were granted by
Edward I.

The church of Leominster, having been partly destroyed
by fire March 18, 1700, was re-edified at the expense of
nearly 17,000l., the whole of that part used for divine
service being entirely new. The church in its present state
is irregular, both in its form and architecture. The most
ancient parts are the east wall, the north side, the tower
which stands at the north-west angle, the west end, and the
wall and windows of the south side. In the interior the
chief part is modern, excepting what is called the back aisle,
which, as well as the lower part of the tower, is principally
Saxon workmanship. The exterior of the east end has
three large buttresses, a high pointed window with inter-
secting mullions, and two smaller windows. On the north
side is a very strong semi-circular arched door-way, with a
smaller one within it. The upper part of the tower is in
the pointed style and embattled; the lower part is Saxon;
its displays a singularly rich entrance door-way on the west,
having a recessed arch, with three pillars on each side, the
capitals of which are ornamented with sculptures of foliage,
a crouching man, a tyger, snakes entwined round branches,
and birds. The mouldings supported by these pillars are
slightly pointed, but are embellished with lozenge and zig-
zag work. On the north side of the church is the nave and
north side of the ancient structure, which are separated from
each other by a range of massive circular columns, with
round arches, over which are Saxon arcades; the arch of
the tower which opens into this part is pointed, and reaches
nearly to the roof. Besides the church, there are four
places of religious worship in the town, for the respective
denominations of Baptists, Presbyterians, Moravians, and
Quakers. During the time of rebuilding the church, divine
service was performed in a contiguous building, anciently
called the Chapel in the Forbury, erected by Peckham,
archbishop of Canterbury, about the end of the thirteenth
century. It was afterwards appropriated to the purpose of
tuition, and thence called the school-house; but has lately
been converted into a regular theatre; it is a plain building,
with pointed windows. The priory was situated to the
north-east of the church, on the little river Pinsey; some
of the buildings are yet standing, among which is the priory-
house, which has undergone various alterations since the
dissolution. The town-hall, or butter-clofe, as it is com-
monly termed, is a singular building, constructed of timber
and plaster about the year 1633. The architect was the
celebrated John Abel, who built the Shire-hall at Hereford,
in the year 1645. This fabric stands on twelve oak pillars,
furnished on stone pedestals; the brackets and spandrels
above the arches, and the upper parts of the building, dis-
furred with carving. A new gable was erected in the year
1750; and a market-house in 1802. Several improvements
have been recently made in the town; the trade is flour-
ishing, and many of the shops are respectable. The clothing
and hat trade provide employment for a great number of
the inhabitants. The wool grown in the vicinity is pro-
verbially excellent; the cider also, and the hops, are held
in high estimation.

The corporation consists of a bailiff, chief steward,
recorder, twenty-four capital burgesses, a chamberlain,
and two serjeants at mace. Two representatives in parliament
are chosen by the corporation and inhabitants paying scot
and lot; the number of voters being about 500; the earliest
return was in the twenty-third of Edward I.

Leominster is 137 miles distant from London; the popula-
tion, as returned under the act of 1800, amounted to 3019;
the number of houses to 736. The site of the castle or
palace mentioned by Leland as belonging to Merwald, is
supposed to be the mount to the eastward which overlooks
the Hay lane.

Berrington, about four miles to the north-east, was the
seat of the late Right Hon. Thomas Harley. About a mile
to the south-east from the town is Eaton, formerly the seat
of the Hacklutters, a family of great antiquity and re-
spectability. On the Brierley hills, about two miles south-west
from Leominster, is Ivinson camp, a strong fortifica-
tion divided into two parts by an entrenched more modern
than the outer works. This is supposes, with great prob-
bility, to be the camp occupied by Owen Glendour.
Price's History of Leominster, 8vo. Beauties of England
and Wales, vol. vi.

LEOMINSTER, a post-town of America, in Worcesters
county and state of Massachusetts; 46 miles W. of Bof-
ton. It has a printing office and several neat buildings.
This township was taken from Lancaster, incorporated in
1740, and contains 1486 inhabitants. On the streams that
passes through this town are several mills of different kinds.
About 200,000 bricks are annually made here. The manufac-
ture of combs is also carried on in great perfection and with
considerable profit.

LEON, in Ancient Geography, a promontory of Greece,
in the isle of Euboea.—Also, a promontory of the isle of
Crete.—Also, a river of Phocis. Ptolomy.

LEON, in Geography, a province of Spain, called a king-
dom, situated towards the N.W., and included between El-
trimadura, Old Catile, Galicia, and Portugal. Its form
is a kind of irregular long rectangular figure. Its mean
length from N. to S. is estimated at about 52 leagues, and its
mean breadth from E. to W. about 30 leagues. This is the
country which was formerly inhabited by the Vetones, men-
tioned by Strabo. It is bounded on the E. by Old Catile;
the S.E. and S. by Eltrimadura; on the W. by the pro-
vinces of Beira, Tra-los-Montes in Portugal, and Galicia;
and on the N. by the Aftarías. Its capital has given name
to the country, which was for a long time a separate
monarchy; but its crown was united with that of Catile in
1669; but without losing the title of kingdom. Its terri-
ory is mountainous; nevertheless it contains many beautiful
fields, good pastures, and large fertile valleys, which pro-
duce a great quantity of grain, as wheat, barley, &c., wine,
and excellent flax, both in small quantities, vegetables, and
good fruits. Its mountains are covered with different kinds
of trees, and they afford iron and copper mines, mineral
waters, &c. The mules bred in this country are of a supe-
rior...
LEON.

Leon is the capital of the above province, or kingdom, is a very ancient town, founded before the reign of Galba; it was called by the Romans "Legio Septima Germania," from the legion that bore that name being stationed there. This city is situated between the two sources of the Exla, which are called the rivers of Torio and Bermenja. It is one of the most famous and most ancient episcopal sees in Spain, and possessed, in the time of the Gothic kings, the privilege of appealing immediately to Rome. The bishopric is suffragan to the archbishop of Compostella, without being in any respect dependent on its jurisdiction; this episcopal polities revenue a revenue of 22,000 ducats. Its diocese contains 823 villages, 883 parishes, 26 convents of monks, 11 of nuns, colleges, and hospitals. When the kings reigned here, till the 13th century, its population was considerable; but it is now much reduced. According to the statement of 1788, there were within the jurisdiction of the intendant of Leon 250,134 inhabitants. A great part of its walls consists of green marble. It contains 13 parish churches, one collegiate church, four convents of monks, five of nuns, and a number of hospitals and hermitages. Here are the royal hospitals of San Isidoro and San-Marianos of the order of St. James; and a chapter of noble canons, not cloistered, but who take the vows. This town was the first of any importance which the Christians retook from the Moors. Pelagius made himself master of it in 722, fortified it, and built a good castle, to defend the approaches to it.

It had the honour of being the capital of the first Catholic kingdom of Spain, and of being, for three centuries after the invasion of the Arabs, the residence of the kings. The palace which the duke of Alphonso built here at the end of the 11th century is still to be seen. Among its most splendid edifices we may reckon the cathedral church, which in beauty surpasses the most admired in Spain, and is one of the most attractive.
attractive monuments of Gothic architecture. The hotel of the counts of Luna is also large and handsome. The town-house has a good appearance, with a tolerably regular front. The palace of the Guzman is magnificent, ornamented with a superb portal, and secured by very strong walls. Among the gates of the town one was formerly a famous prison; and at the bottom is the statue of king Don Felagius, with an inscription. The Place Mayor has a beautiful appearance. There is a number of other fountains and handsome fountains. Notwithstanding the antiquity and importance of this city it is very deficient in cleanliness. It is surrounded by trees, and the country about it is every where embellished; it has beautiful promenades, as well as broad and noble avenues of handsome trees. In the environs of the town the corn harvests are not abundant; but this deficiency is supplied by many excellent vegetables, fruits, flax, and verdant meadows, which furnish good pastures. At Leon there are several manufactories for different woollen articles; stockings, hosiery, leather, gloves, &c. are also made here. Leon is 150 miles N.W. of Madrid. N.lat 45° 36'. W.long. 5° 37'.

Leon, a town of Spain, in Catalonia; 43 miles N.W. of Urgel.

Leon, a town of France, in the department of Stura; 4 miles N. of Savigliano.

Leon, Isle of, a kind of island four leagues from Xerez, in Andalucia, formed by a canal which surrounds it, ten miles long, and 24 feet deep in high water, and capable of admitting the largest ships. This island was entirely deferted in the seventeenth century, and there was scarcely a house upon it. At present the principal street of the town is two miles long, with rows of shops on each side, and containing upwards of 2000 inhabitants.

Leon, a river which falls into the gulf of Mexico, from the N.W., at the bay of St. Bernard.

Leon, a town of Mexico, in the province of Guadalupe; 40 miles E. of Guadalajara.

Leon, a town of Mexico, and capital of the extensive province of Nicaragua, situated on a large lake of fresh water, abounding with fish. It is a bithospher, but a town of little importance. It has about 1200 houses, four churches, and several convents. Its situation near a mountain, in which is a volcano, renders it subject to earthquakes. The lake is divide into ebb and flow like the sea. Realjo is a small entrenched town, with an excellent port, and serves Leon the capital.

Leon de Caracas. See CARACAS.

Leon de Guanaco. See GUANACO.

Leon, New, one of the seven domains, called kingdoms, into which the Spanish dominions in North America are distributed. This name is restricted by the maps to a small province round the town of Monterey, which must not be confounded with another of the same name, to the N. of California. It is bounded on the N. by the Savage nations, on the E. by New Mexico Proper, on the S. by a part of Mexico, and on the W. by New Bifcar. New Leon proper, a district ridiculously called a kingdom, is divided from Guadalcazar on the S. by the desert of Jumave, and mountains of Tamalipa. It is very mountainous, produces little except lead, and is very thinly peopled. The other provinces of the domain of New Leon, besides New Leon proper, are Sootander and Coaguila, or New Eframadura.

Leonan, a small island in the East Indian sea, near the N.E. coast or Borneo. N.lat 6° 39'. E.long 117° 48'.

Leonardo of Pisa, in Biography, an Italian mathematician, who flourished at the commencement of the thirteenth century, was the first person who brought into Europe the knowledge of the Arabic cyphers and algebra. He gives an account of the fact himself, and says, that being at Bugia, a town in Africa, he was instructed in the Arabic method of keeping accounts, and that, finding it more convenient, and preferable to the European method, he had drawn up a treatise for the purpose of introducing it into Italy. From Italy the knowledge of the Arabic cyphers and algebra was afterwards communicated to the other countries of Europe. He was author of a treatise on surveying, preferved in the Magliabechi library at Florence.

Leonardo Leo, principal organist of the chapel royal at Naples, was not only admired and respected by his contemporaries, but his memory still continues to be held in reverence by every profligate that is acquainted with his works. The first opera of his composition that we were able to find, is "Sofonibia," which was performed in Naples in 1718, and the last, "Siface," in Bologna, 1733. Between these he produced three operas for Venice, and four for Rome. Leo likewise set the "Olimpide" of Metastasio, in which the duo, "Ne i giorni tuoi felice," and the air, "Non so domandarvi," are admirable, as is "Per quel paterno amplissimo," in Arturofe, the only air in that opera that we have seen. "Dirti ben mio, vioce," was in extreme high favour, as set by Leo, about the middle of the last century, in England, where it was to be heard at every musical performance, both public and private. Leo likewise set Metastasio's oratorio of "St. Elena al Calvario," of which we have seen some very fine airs. His celebrated "Miferere," in eight real parts, though imperfectly performed in London at the Pantheon, for Anfani's benefit, 1781, convinced real judges that it was of the highest class of chorale compositions.

The purity of his harmony, and elegant simplicity of his melody, are no less remarkable in such of these dramas as we have been able to examine, than the judicious arrangement of the parts. But the masses and motets, which are carefully preserved by the curious, and still performed in the churches at Naples, have all the choral learning of the sixteenth century. There are likewise extant, trios, for two violins and a base, superior in correctness of counterpoint and elegance of design to any similar productions of the same period. This complete musician is equally celebrated as an instructor and composer; and the "Solfeggio," which he composed for the use of the vocal students, in the conservatorio over which he presided at Naples, are still eagerly sought and studied, not only in Italy, but in every part of Europe, where singing is regularly taught.

This great musician died about the year 1742, at the age of fifty-three. His death was unhappily precipitated by an accident which at first was thought trivial; for having a tumour, commonly called a burr, on his right cheek, which growing, in process of time, to a considerable magnitude, he was advised to have it taken off; but whether from the unskilfulness of the operator, or a bad habit of body, a mortification ensued, which cost him his life. After expiring the reverence which we have always had from our earliest youth, for the productions of this admirable composer, we shall transcribe a character of him from "L'Essai fur la Musique," drawn up with elegance, force, and feeling, which does not seem to flow from an exclusive admirer of Rameau, under the guidance of the intolerant preacher of the triple precession.

"Leonardo
he attained the age of ninety-six years, and died in 1574, poissified of all his faculties. To one who, inquired, with astonishment, by what secret he had preserved this entire possession of his faculties, together with an erect body, and vigorous health, at so great an age, he replied, that it was the effect of innocence of manners, tranquility of mind, and frugality in diet. The duke and frateau of Ferrara erected a monument to his memory. He left several works, most of which have been several times reprinted. "De Philitii et allorum Medicinorum Medicinum in Crassinulas, &c." Ferrara, 1493. In a posthumous edition, printed at Bette, in 1532, some other opuscula were added, particularly "De Herbis, Fructibus, Animalibus, Metallis, Serpentibus, Tiro seu Viperar." "Libero de Epidemia quam Itali Morbus Gallorum vocant, Galli vero Neapolitanum," Venice, 1497. In several subsequent editions, the title "De Morbo Gallico" was adopted.—"Praefationes in Libros Galeni aen tranlatatos," ibid. 1508, folio, with other verse treatises. "Opus de tribus doctrinis ordinatis secundum Galeni fundamentium," ibid. 1508, fol. "Libri duo Galeni de curandis ratione ad Glaconem Latine verbo," Paris, 1514, 4to. "Hippocratis Aphorismorum Libri VII., Graece et Latina," ibid. 1526, 8vo. "Conversio et explicatio primi Libri Aristotelis de partibus Animalium," Eptle, 1541, 8vo. "Galenii Ars Medicina," Venice, 1606. Eloy Dict. Huit. de Med.

LEONICO, TOMEIO, NICOLAS, was born in Venice, of an Albanian family, in the year 1456. He studied Greek at Florence, and made such progress, that he became able to explain Aristotle in the original language. For this purpose he was invited to Padua in 1497. He was brought up to the church, and taught the learned languages at Venice, but in 1520 he returned to Padua, where he gave instructions to cardinal Pole. He was much attached to the Platonic philosophy, and paissed his time remote from worldly pursuits, and solely intent upon his studies. Bembo, Giosia, and others, speak of him with great esteem, and Erastus mentions him with honour, as a man equally respectable for the purity of his morals and the profundity of his erudition. He died in 1531, and was buried in the church of St. Francis, at Padua. He translated several of the works of Aristotle, Proclus's Commentary on the Timaeus of Plato, and other treatises of the ancient philosophers. He wrote ten dialogues on subjects philosophical and moral, a work, "De Varia Historia," and some Italian poems.

LEONIDAS I., king of Sparta, succeeded to the throne in the year 491, B.C. When Xerxes, king of Persia, invaded Greece, Leonidas was appointed by the Lacedaemonians to the chief command of their forces to oppose him. He marched at the head of 4,000 men, to take possession of the fraths of Thermopylae. Aware of the great danger of the enterprise, he confided himself as one devoted to the safety of the country. He polished his small army so skillfully, that the Persians, on arriving at the fraths, found that it would be difficult to force them, and Xerxes endeavoured to bribe the commander to his interest, by the offer of making him master of Greece. The proposal was rejected with indignation, and the monarch immediately sent a herald to order the Grecians to lay down their arms. "Let him come and take them," was the reply of Leonidas. Thrice the Persians were repulsed with great loss, and when a treachorous Greek had led a chosen body of 10,000 Persians by a secret passage to the rear of Leonidas, he determined to afford a memorable example of what the Greeks could do when called upon to die for their country. Xerxes marshed his whole army to the entrance of the fraths, where Leonidas advanced to meet him. The efforts of valor, heightened...
ed by despair, were terrible, and the Spartan king fell amidst a heap of slaughtered enemies. His friends defended his body, till the appearance of the foe in the rear caused the survivors to collect into one close band, facing every way. All these, overpowered by numbers, were left on the field of battle, having amply revenged their fall. The Persian tyrant, enraged at his loss, caused the body of the hero to be nailed to a cross, but the memory of his valour and patriotism could not be obliterated, and the defence of Thermopylae is consecrated among the noblest actions of antiquity. The gratitude of his country raised a splendid monument upon the spot to the fallen, and a funeral oration was for a long time annually pronounced amid the celebration of martial games, over their tombs.

LEONINE, in Poetry, is applied to a kind of verftes which rhyme at every hemilie, the middle always chiming to the end.

In this kind of verse we find several ancient hymns, epigrams, prophecies, &c. For instance; Muretus, speaking of the poetry of Lorenzo Gambara of Brefle, says,

"Drixia velrata, qux conduit carminina vates Non font noctales teregere digna nates."

The following one is from the school of Salernum:

"Ut vites panam, de potibus incepta canam."

The origin of the word is somewhat obscure: Paquier derives it from one Leoninus, or Leontius, who excelled in this way, and dedicated several pieces to pope Alexander III.; others derive it from pope Leo, and others, from the beast called lion, because it is the loftest of all verbes.

M. Fauchet makes the leonine rhyme the same with what the French call the rich, and we the double rhyme, i.e. where two syllables have the same orthography, accentuation, and pronunciation, with two others.

Gen. Ch. Cal. Perianth inferior, of one leaf, tubular, oblong, with ten flight ribs, permanent; its orifice unavailingly toothed, with from six to ten teeth. Core of one petal, ringed; tube cylindrical, longer than the calyx; upper lip elongated, slightly concave, bearded, undivided; lower much smaller, in three nearly equal segments. Stem. Filaments four, concealed by the upper lip, two of them longer than the red; anthers of two oblong divericated lobes. Pfl. German superior, four-lobed; style the length and position of the filaments; stigma clavate, acute, its upper segment short-telt. Peric. none, except the permanent calyx. Seeds four, oblong, triangular.

1. L. nepetifolia. Catmint-leaved Lion's-ear. (Pholmis nepetifolia; Linn. Sp. Pl. 830. Cardiaceae americana annua, nepeta folio, floribus brevibus phoeniceis villosis; Herm. Lugd. Bat. 115. t. 117.)—Leaves heart-shaped, pointed. Calyx with eight spinous teeth; the upper one largest. Stem herbaceous.—Native of the East Indies, from whence Sir Joseph Banks procured it for Kew garden in 1778. It is a tender annual, kept in the flowe, and flowering in September and October. Hermann received the seeds from Suri-

nam; Linnaeus from the East Indies, and it flowered in the Upal garden. The whole plant is hoary, with extremely soft muante pubescence. Stem four or five feet high, quadrangular, with opposite spreading branches. Leaves opposite, two or three inches long, and one or two broad, heart-shaped, veiny, deeply crenated or serrated, pointed, on stalks of their own length. Flowers in dense whorls, with linear spinous bracteas, and strongly spinous calyx-teeth. Corolla about an inch long, most elegantly clothed with dense scarlet hairs, paler at the edges.

2. L. Leonurus. Narrow-leaved Lion's-ear. Lion's-tail. (Pholmis Leonurus; Linn. Sp. Pl. 820. Currit. Mag. t. 478. Leonurus capitis bone spe; Breyln. Cent. t. 85.)—Leaves lanceolate. Calyx with ten regular teeth, five smaller than the rest.—Native of the Cape of Good Hope, from whence it was brought into the European gardens, for the sake of its beauty, early in the last century, and is still kept in greenhouses, being propagated by cuttings, and flowering abundantly in autumn. The stem is thurvy, seven or eight feet high. Leaves lanceolate, rather narrow, bluntly serrated; about two inches long, of a dull green, roughish, tapering down into short footstalks. Flowers large, in dense bracteated whorls. Calyx downy, its teeth regular, very small, and scarcely spinous; the five alternate ones smaller than the rest. Corolla two inches long, slender, incurved, downy, of a fine tawny orange, or somewhat scarlet colour, the lower lip small and brown.

3. L. Leonotis. Round-leaved Lion's-ear. (Pholmis Leonotis; Willib. Sp. Pl. v. 3. 128. Ph. Leonotis; Linn. Mant. 85. Leonurus minor, capitis bone spe; Mill. t. 462. t. 162.)—Leaves ovate, blunt, crenate. Calyx with eight awned teeth; the upper one largest. Stem thurvy.—Native of the Cape of Good Hope, from whence it was brought early in the last century, but is less frequent in our greenhouses than the foregoing; from which it differs in its smaller size, roundish long-talked small leaves, and rather shorter more obtuse corolla, besides the essential distinctions of the calyx.

LEONTARI, in Geography, a town of the Morea; 20 miles N.W. of Mytra.

LEONTESERES, in the Natural History of the Ancients, the name of a species of agate, famous in early times for its imaginary virtues in taming the rage of wild beasts, and not a little esteemed among us for its beauty. It is the most variegated of all the agates. Its ground colour is yellow, and its variegations are flame-coloured, white, black, and green.

Sometimes it is one irregular congeries of all these colours, but more frequently it is very beautifully variegated with them in form of clouds and veins; the black and green particularly are usually disposed in concentric circles round one or more points. It is found only in the East Indies, and is very scarce.

LEONTEVKA, in Geography, a town of Russia, in the government of Novgorod; 40 miles S.E. of Valdai.

LEONTASIS, in Medicine, a name given by the ancients to the elephantiasis, improperly called the Arabian leprosy, from a supposed resemblance of the tuberculated countenance of the patient, in some instances, to the vifage of the lion (leo). See ELEPHANTIASIS.

LEONTEC, beasts, or sacrifices celebrated among the ancients, in honour of the sun.

They were called leontes, and the priests who officiated at them leones, because they represented the sun under the figure of a lion radiant, bearing a tiara, and grasping in his two fore-paws the horns of a bull, which struggled with him, in vain, to diengage himself.
The critics are extremely divided about this seat: some will have it anniverary, and to have made its return not in a solar, but in a lunar year; but others hold its return more frequent, and give instances where the period was not above 220 days.

The ceremony was sometimes also called Mitbria; Mitbrius being the name of the fun of the ancients of Pergamum.

There was always a man sacrificed at these feasts, till the time of Hadrian, who prohibited it by a law. Commodus introduced the custom afehr, after whose time it was again exploded.

Gen. Ch. Cal. Perianth inferior, of six linear, spreading deciduous leaves, the intermediate ones smaller. Cor. Petals fix, ovate, acute, twice as long as the calyx. Nectary of fix half-ovate, spreading, equal, falked scales, inserted into the base of the petals. Starn. Filaments six, thread-shaped, very short, opposite to the petals; anthers erect, of two cells, and two valves, burting from the base upwards. Pfl. Germen superior, oblong-ovate; style short, nearly cylindrical, inserted obliquely upon the gernen; stigma simple. Peric. Berry hollow, inflated, globose, with a point, of one cell, but only fucculent. Seeds few, globose.

1. L. Chryphogonum. Pinnated Lion's-leaf. Linn. Sp. Pl. 447. (Leontopetanum affinis, foliis querniis; Moris. v. 2. 285. sect. 3. 1. 15. f. 7. Chryphogonum Dioscoridis; Rauv. Linn. t. 119. Chrifogono di Dioscoridi; Poni. Balf. 141.)—Leaves radical, pinnated, deeply cut.—Native of corn-fields in Greece. Dr. Sibthorpe gathered this species near Aby- dos. It is much to be regretted that so curious a plant, though cultivated by Miller, is now a stranger to our gardens, and that even dried specimens are so very rare. Whether it be really the Chryphogonum of Dioscorides, its short description must ever leave doubtful. The leaves are not much like an oak, nor the flower like a Mullein, though the tufuous root may be compared to a turnip. He describes it as his very red within. "Authors represent our as having a perennial, flefty, somewhat conical root, producing several upright falked leaves; these are about a span long, fmoother, rather glaucescent, fimply pinnate; the leaves not quite opposite, about nine or ten pair, f尕le, oblong or rounded, either wedge-shaped or in some degree heart-shaped at the base, entire at the fides, but more or less fquently cut towards the top. In our specimens they are by no means so deeply divided as in the figures above quoted, which have led professor Willdenow to fuppose them whorled. Flower-flaks one or two, radical, a little taller than the leaves, many-flowered, branched, fcorystate, round, fmoother, leaflets. Bractæus elliptical, coloured, fmalht at the base of each branch. Flowers yellow, somewhat like those of Celanthe. Authors ovate before they burst.

f. 6.)—Radical leaves twice or thrice ternate; lem-leaves ternate.—Abundant in corn-fields in the Levant, flowering early in the spring, and ripening fruit in May. Gerarde says, lord Zouch in his time brought a plant from Italy, but, as far as he knew, it perished. Miller, however, ap-
ticular, and that it was of great virtue in curing discharges of the \astraarteria, or wind-pipe.

This medicinal plant of the Greeks was very different from that now called cacalia. Some have described it to have flowers like the oak, others like the olive-tree, but the old manuscripts of Dioscorides all say, the flowers were like those of broony. Hence it could by no means be the cacalia of the moderns; nor is it easy to say, from such short and uncertain accounts, what it was. See the preceding article.

LEONTINI, or LEONTIUM, in Ancient Geography, a town of Sicily, called also, as Dioscorides informs us, \textit{Xuthia}, a name given probably to the small district in which it is situated. It was situated, according to Herodotus's account of it, between two rivers, which, after their junction, ran into the southern part of the gulf of Catania. One to the S. was called "Lifius," now Lillo, and the other to the N. "Tetrica," called St. Leonard's stream. The town was built, at the same time with Catania, by the Chalcidians, under the conduct of Thoeeles, the Athenian, in the 11th year of the 13th Olympiad, as we are informed by Thucydides; in whose time it was defended by two strong citadels, one called the citadel of Phoene, the other the citadel of Brinoinia. The adjacent territory was so fruitful, that it yielded, according to Piny, crops of corn an hundred fold, and Cicero calls it "the grand magazine of Sicily." Its wines were the most delicious of the whole island, but the inhabitants perverted the benefit into an occasion of intemperance, so that it became a proverbial saying, "the people of Leontini are always at their cups." Leontium had its tyrants as well as Syracuse, and between these two cities there subsisted a constant rivalhip and enmity. This was the birthplace of the celebrated rhetorician Gorgias, whose eloquence astonished even the Athenians, and who perjured them to undertake the unfortunate expedition under Nicias. Leontium at length fell under the power of Syracuse, Dio-

muus the tyrant having removed the inhabitants thither.

The situation of the castle, and the fertility of the country, rendered Leontium at all times a place of importance to the different nations which possessed Sicily. The earthquake of 1693 completed its destruction, and reduced it to its present state of wretchedness. The ancient city, built on four hills, presents to the observer nothing but a spot of ground torn by four ravines, which lay open a few wretched grots, the sole remains of its former greatness. The cattle feed on a detached rock, opposite to the city, which was originally hewn out of it, and has been successively built and rebuilt according to the style of different ages, and the prevailing modes of besieging and defending places.

The rich country of Leontium, so luxuriant in corn, is now called the plain of Catania; it is 12 miles wide by 20 in length, and was formerly the country of the Gargoriones, divided and bathed by the "Simachtos," the largest river in Sicily, which rolls along in its stream a quantity of black and yellow amber, which is sought for where it disgorges itself into the sea, and is washed up at Catania.

LEONTIUM, in Biography, an Athenian courtezean, at one time noted for the licentiousness of her life, and afterwards distinguished by her application to the study of the Epicurean philosophy. It has been asserted, that she did not de
dilf from her intrigues after she was an attendant on Epicurus, but prostituted herself to the disciplics of his school, and even to the philosopher himself. She became the wife of Metrodorus, one of the principal disciples of Epicurus, and had a son by him, whom Epicurus commended to the notice and regard of his executors. Leontium applied with great diligence to the study of philosophy, and wrote, in defence of the Epicurean doctrines, against theophrastus, one of the principal of the Peripatetic sect. The book is acknowledged by Cicero to have been written in a polite and elegant styte. Bayle. Moreri.

LEONTIUS, surnamed the Scholastic, who flourished in the sixth century, was a native of Constantinople, was educated an advocate and afterwards became a monk. He lived till about the close of the century. The principal work of Leontius is "A Treatise on the Sects of Heretics," divided into ten discourses. It was published in Greek and Latin at Basil, in 1578. He was also author of various treatises against the Eutychians, Neotinians, and Appollinarists; a discourse on the festival celebrated between Eaf
ter and Whitsunday; and there are "Orations" and "Ho
milies" ascribed to him in the Bodleian and Vienna libraries. Moreri.

LEONTODERON, in Natural History, a name given by several authors to a species of agate, of a plain yellowish colour, without varieations.

LEONTODON, in Botany, derived from \textit{Leonti}, \textit{a lion}, and \textit{don}, \textit{a tooth}, and so called from a similarity in the shape of its jagged leaves to the teeth of a lion. Lin
cenus beilow this name upon the genus in just preference to the compound one of \textit{Dens Leonis} given by Tournefort. The English name \textit{Dandelion}, which is a corruption of \textit{Dent de Lion}, is expressive of the fame idea, and might possibly have given rise to its botanical appellation. Dr. Smith has described the leaves of \textit{Leontodon Tarraxacum}, in his Intro
duction to Botany, p. 157, as runcinate or hom-toothed, cut into several transverse, acute segments, pointing backwards. A striking character of this fort, which, at first sight, fuggis a name, borrowed from some familiar or popular re
march. Ill. t. 0533.—Clafs and order, \textit{Syngemata Poly

Gen. Ch. \textit{Common calyx} imbricat, oblong; its interior scales linear, parallel, equal; their scales fewer in number, often reflexed at the base. \textit{Cor.} compound, imbricat, uniform; the florets hermaphrodite, numerous, equal, each of one petal. ligulate, linear, abrupt, with five teeth. \textit{Stam.} Filaments five, capillary, very short; anthers united into a cylindrical tube. \textit{Pfl.} Germin near ovate; style thread
shaped, as long as the florets; stigma two, revolute. \textit{Peric.} none, except the oblong, straight, at length reflexed, calyx. \textit{Sepals} solitary, oblong, rough; down capillary, shortly. \textit{Recept.} naked, dotted.

This genus is much more ample as it stands in Linnaeus. We have adopted all the species retained by Willdenow, who has removed the rest to different genera, as follows.

**Leontodon bufofrus**, and *auricus*, are referred to *Hieracium*: *L. baftis*, *tuberosus*, *autumnalis*, *alpinus*, and *bipilatus* to *Aparigia* of Schreber: *L. bufrus* to *Thrinica* of Roth, and he has followed Swartz in calling *L. tomentosus*, *Tulipago albicans*. We do not follow Willdenow in reforming the genus of *Leontodon*, especially as we have the authority of Jacquin and Smith for having done so in *Tragogeton*.

**Leontodon Taraxacum**, or Common Dandelion, in the *Materia Medica*, &c. The young leaves of this plant in a blanched state have the taste of endive, and make an excellent addition to those plants eaten early in the spring as salads. At Gottingen the roots are roasted and sublimated by virtue of the poorer inhabitants; who find that an infusion prepared in this way can hardly be distinguished from that of the coffee-berry. Dandelion is generally considered by medical writers as the most active and efficacious of the lacteal plants; the expressed juice is somewhat acrid, the root itself more bitter, and proffering more medicinal power than any other part of the plant. Taraxacum has been long in repute as a mild detergent and aperient, and its diuretic effects may be inferred from the vulgar name it bears in most of the European languages, "quasi lactantia et urina herba dietur." Bergius recommends its use in obstructions of the liver, hypochondriac, and jaundice. We have various proofs of the good effects of the Taraxacum related by different authors, in jaundice, dropsy, pulmonic tubercles, and some cutaneous disorders. The leaves, roots, flower-flanks, and juice of dandelion have all been separately employed for medical purposes, and seem to differ rather in degree of strength than in any essential property; therefore the expressed juice, or a strong decoction of the roots, has been most commonly preferred, from one ounce to four, or two or three times a day. The plant should not be always used fresh; for even extracts prepared from it appear to lose much of their power by keeping.

**Woodv. Med. Bot.**

**LEONTODONTOIDES**, in *Botany*. See HYoseris. **LEONTOPETALO AFFINIS.** See LEONTICE.

**LEONTOPETALOIDES**, the name of a genus of plants described by Dr. Amman, being a species of the *leontice* of Linnaeus; which see. See also TACCA.

**LEONTOPETALON**, from *leon*, a lion, and *petalon*, a leaf. Lion’s-leaf. *Tourn. Cor.* 49. t. 484. See LEONTICE.

**LEONTOPODIUM**, from *leont*, a lion, and *pep',* the foot, has been applied as a name to several plants, whose thick and soft hairiness, enveloping their flowers or flarks, as the claws of a lion are enveloped, seems to have given rise to the idea. Among these are *Mygidae* sertodothae; several species of *Gnaphalium*, especially the elegant *Filago Leontopodium* of Linnaeus, now restored by Willdenow, very justly, to *Gnaphalium*, where Linnaeus at first placed it; *Alchemilla vulgaris*, called *Leontopodium* by Brunfels, v. 2. 53; and *Plantago erecta*, the *Leontopodium* of Clusius. What Dioscorides, the father of the name, intended by his *Leontopodium*, is very difficult to be guessed. Dr. Stithorp thought it might be *Microtus erectus*, which is very common in Cyprus and several of the Greek islands; but it hardly answers to the description.

**LEONTOPOLIS**, or LEONTON, in *Ancient Geography*, a town of Egypt, and capital of a nome, which took the name of "Leontopolites nomos." Ptolemy.

**LEONURUS,**
LEONURUS, from leo, a lion, and app, a tail; a name given by Tournefort to some Linnaean species of Pimpinella, (see Leonotis,) but applied by Linnaeus to the Cardiaca of Tournefort, for which it is now retained. Motherwort.—
Jull. 144. Lamarck. Illutr. t. 500. (Cardiaca ; Tourn. t. 87) — Class and order, Didynamia Gymnosperma. Nat.
Ord. Ferticillata, Linn. Labiate, Jull.

Gen. Ch. Cal. Perianth inferior, of one leaf, tubular, with five angles, and five awl-shaped, spinous teeth, permanent Cor. of one petal, ringent; tube narrow; limb growing; throat long; upper lip longest, fimbriulilibr, concave, gibbous, flabby, rounded and obtuse at the top, undivided; lower reflexed, in three deep segments, not quite equal. Stam. Filaments four, concealed under the upper lip, two of them shorter than the others; anthers oblong, incumbent, their lobes parallel, and near to each other, befrinkled with minute, globular, flintered, elevated granulations. Pet. none, the permanent calyx containing the seeds in its cavity. Seeds four, oblong, convex on one side, angular at the other.

44. t. 4.—Leaves with three or five lobes, deeply toothed, rugged and wavy. Corolla longer than the calyx.—Native of Siberia. Said to have been cultivated in the Oxford garden in 1658. It has all the appearance of being a luxuriant or monstrous variety of the following.

2. L. Cardiaca. Common Motherwort. Linn. Sp. Pl 517. Engl. Bot. t. 286. Fl. Dan. t. 727. (Cardiaca; Ger em. 705. Camer. Epit. 804. Rivin. Monop. Ir. t. 20. f. 1.)—Upper leaves lanceolate; three-lobed or undivided. Corolla longer than the calyx; the middle lobe of its under lip acute.—Native of waste ground in the more northern parts of Europe, not frequent in England. It loves a gravelly or calcareous soil, and is perennial, flowering in July and August. The herb is bitter, with a pungent unpleasant smell. Stem a yard high, purplish, square, regularly beft with numerous, opposite, flatked, roughish, dark-green leaves; of which the lower are broadest, three-lobed, and more or less deeply cut; the upper gradually narrower and less divided, till they become lanceolate, acute, and quite entire. Flowers numerous, in dense whorls. Bracttas awl-shaped, pungent. Calyx-teeth spreading, rigid, nearly equal, broad at the base. Corolla purple, variegated; its upper lip elegantly villous with white hairs. The anthers are marked with shining points, but is not peculiar to the genus.

3. L. Marrubiflorum. Small-flowered Motherwort. Linn. Sp. Pl. 517. Ehrh. Pl. Exilte. n 157. Jacq. Anim. t. 405. —Leaves ovato-lanceolate, strongly ferrated. Corolla scarcely longer than the calyx; the middle lobe of its under lip rounded, obtuse.—Native of Bohemia, Germany, Tartary and Siberia. The leaves vary in breadth, and are either strongly ferrated or entire, but never cut or jagged like the preceding. The calyx-teeth also are narrower and longer; and the corolla totally different, scarcely exceeding the length of the calyx, but slightly downy, and the middle lobe of its under lip almost heart-shaped, or at least dilated and very blunt. The root moreover is said to be only annual, or biennial. The plant has little to excite notice, and is only kept in curious gardens.

4. L. jupinum. Decumbent Motherwort. Willd. n. 57, "Leaves mostly five-lobed; the lobes obtuse, toothed at the summit. Calyx fiddle. Stems ascending."—Native of Siberia, communicated to professor Willdenow by his friend Stephan. "Root perennial. Stem several, half a foot high, ascending, branched, square, downy. Leaves opposite, half an inch long, with three or five lobes, which are oblong, somewhat wedge-shaped and obtuse, furnished at the extremity with three or five obtuse teeth; downy on both sides, especially the under. Footstalks the length of the leaves. Whorls of four to five flowers, fiddle. Bracttas bristle-shaped, pointed, downy, shorter than the calyx. Calyx downy, its segments ovate, spinous. Corolla white, rather longer than the calyx, its lip three-lobed, obtuse." Such is Willdenow's description; made from the dried plant, which in almost every minute particular accords so well with our Lamium palmatum, (see Lamium,) that we should conclude them to be the same, were it not for the bracttas, of which our plant is certainly delirious.

5. L. matricaria. Tartarian Motherwort. Linn. Sp. Pl. 818. (Cardiaca folis tenuissimis et profundis incisis glabra; Mill. Jov. c. 5. 3.)—Leaves in three deep divisions; their lobes jagged. Upper lip of the corolla flattened, upright, reflexed.—Native of Tartary. It differs from the corolla softly.—Native of Siberia, China, and the East Indies, a hardy annual in our gardens. Stem two or three feet high, branched. Leaves deeply cut in a three-fold manner, into various deep divisions, mostly narrow and bluntish, more or less downy. Flowers crimson, in dense whorls, with awl-shaped bracttas. Calyx silky. Corolla twice as long as the calyx; its upper lip concave, but straight; lower in three lobes, the middle one dilated, heart-shaped. Mr. Sowerby found a double row of crimson glands in the mouth of the tube. The calyx is often spinous, but not always so.

For the L. Galeobdons of Willdenow; see Galeobdolon. LEOPARD, in Zoology, the English name of the long-tailed felis, or Felix pardus of Linnaeus; which see.

LEOPARD'S Bane, in Botany. See Doronicum.

LEOPOLD I., in Biography, emperor of Germany, son of Ferdinand III. was born in 1640. He was elected king of Bohemia in 1654, and of Hungary in 1655, and he succeeded to the imperial crown in July 1658. His reign was fruitful of important events. A war with the Turks, which broke out in 1661, was brought to a conclusion in 1664, in consequence of a victory obtained over the grand vizier, at St. Gothard, in Hungary. This was succeeded by a revolt of the Hungarians, excited by those infringements of their privileges which have been continually renewed under the princes of the house of Austria. The execution of the leaders in 1671, for a time, quelled the disorders, without removing the causes of discontent. In 1672 Leopold joined in a league with other powers to protect the Dutch against Lewis XIV. At this crisis the Hungarian malecontents took the opportunity of shaking off the Austrian yoke and affering
affecting their original independence. Headed by count
Tekei, and supported by the Turks, they again rose in
arms, and obtained various successes against the Imperialists.
In 1782 a new war broke out between the empire and
France; and about the same time the breach of a truce by
the Hungarian revolters, and the irruption of a vast Turkish
army, reduced Leopold to the greatest danger. His general,
the duke of Lorraine, was obliged to retreat under the walls
of Vienna, and the grand viceroy laid siege to that capital,
while the emperor with his court withdrew to Lintz. A
series of successes afterwards attended the imperial armies
in Hungary, and all that had been lost was gradually recov-
ered. The rebels were tried, the noblest blood was shed
without mercy or remorse, and the Hungarians were so far
humiliated, that an assembly of the states, in 1687, declared
the kingdom hereditary in the house of Austria, and elected
for their king the archduke Joseph, then only nine years of
age. Three years afterwards, Leopold procured the election
of his son Joseph to the succession of the empire, as king of
the Romans. The war with France was carried on with
various successes, till the general peace, concluded at Ryswick,
in 1697. In 1699 a long truce was agreed on between the
German and Turkish empires, on terms favourable to Leo-
pold, whose arms had obtained great glory under the illu-
rious prince Eugene. The war, on account of the Spanish
succession, plunged Europe again in blood. Leopold
 regained the elector of Brandenburg to the party of the
allies, by confenting to recognize him as king of Prussia.
The events of the war were at first unfavourable to the
emperor, but the decisive battle of Blenheim or Hochheidt, in
1704, changed the face of affairs. Leopold did not long
enjoy the brighter prospect which was opening upon him: he
died in the following May, at the age of sixty-five, after a
reign of forty-six years, leaving the power of his house much
augmented in his hands. "His original education," says
the historian, "which was that of an ecclesiastic, had con-
cided with his natural disposition, in producing a cold
formality of character, and the narrowness of his ideas
threw him into the power of favourites, whom his jealousy
of authority led him frequently to change. The great ob-
jects of his policy were, however, pursued with a recklessness
which ensured their final success." Modern Univer. Hist.
LEOPOLD II., emperor of Germany, born in 1747, son
of the emperor Francis I. and the empress-queen Maria
Theresia, was created grand duke of Tuscany about the year
1755, and during a reign of twenty-five years, displayed
a constant regard and attention to the happiness and prosperity
of his people. He carried into effect a number of improve-
ments relative to all the branches of administration, which
rendered that portion of Italy peculiarly flourishing. He
diminished the taxes, and yet augmented the revenue; intro-
duced an exact police; encouraged the arts, manufactures,
and agriculture; freed industry from the fetters of numerous
fisivals, mitigated the condition of the public hospitals and
prisons, and promulgated an entire new code of laws, cha-
acterized as well by their humanity as their simplicity. In
the preamble to this code he says, "We have considered
the examination and reform of the criminal laws as one of our
principal duties," and after much experience he says with
true patriotic exultation, "With the utmost satisfaction to
our paternal feelings we have at length perceived, that the
mitigation of punishments, joined to a most scrupulous at-
tention to prevent crimes, and also a great dispatch in the
trials, together with the leniteness of punishment to real de-
linquents, has, instead of increasing the number of crimes,
considerably diminished that of the smaller ones, and ren-
dered those of an atrocious nature very rare;" so rare, in-
deed, that during ten years not a single execution took place
in his dominions. Leopold protected the lower ranks from
the oppression of the higher, and his palace was ever accessible
to the meanest supplicant. Though the father of his people, he
was also their master, and would admit of no opposition to
his will; though sincerely desirous of doing good, he was
sold to the lowest aim of policy. In 1792 the imperial crown, and
the succession to the Austrian dominions, devolved on him on
the death of his brother Joseph. The result of that fortunate
prince's schemes had been an absolute revolt of the Low
Countries, the disaffection of Hungary, and the jealousy of
all the surrounding states. Leopold, by employing the arts
of conciliation, in conjunction with firmness and prudence,
was able in a short time to recover the Low Countries, to
quell the opposition of the Hungarian emperors, to
strengthen his house by splendid alliances, and to establish
peace with the Ottoman Porte. He restored a good under-
standing between the courts of Vienna and Berlin, and con-
cluded with England in checking the ambitious projects of
Russia. Soon after the commencement of the French revo-
lution, Leopold formed with the congress of Pilnitz, a
coalition with Prussia, for the avowed purpose of giving a
government to France, and the subsequent invasion of that
country by the united forces of the two powers is to be
regarded as a consequence of this alliance. Leopold did not
live long enough to witness the commencement of hostilities.
He died in the month of March 1792, at the age of forty-
four, leaving behind him a numerous progeny, of whom his
cidet for Francis II. succeeded to the vacant throne.
duke of Tuscany, printed by the celebrated Mr. John
Howard.
Leopold was passionately fond of Italian poetry and music,
and is paid by Quadri (Storia d'Ogni Poetia, vol. i.) not
only to have been the constant patron of bath, but to have
composed masques and motets for his own chapel, and to have
written, and set to music, himself, many beautiful canzonets
and madrigals. This prince, early in his reign, retained in
his service the Italian lyric poet Minato, and Antonio
Draghi, to write and set operas for the imperial court at
Vienna.
LEOPOLDSSTADT, in Geography, one of the suburbs
of Vienna, large and populous; situated on the N. side
of the Danube, and communicating with the city by a bridge.
—Alto, a fortified town of Hungary, on the river Vag, 59
miles E. of Vienna. N. lat. 48° 28'. E. long. 17° 54'.
LEOSTENIUS SISUS, in Ancient Geography, a gulf of
Thrace, upon the Thracian Boithorus, toward the northern
part of the Hermian promontory.
LEOTAUD, VINCENT, in Biography, a French Jesuit,
and able mathematician, was born at Laval-Louayle, in
the diocese of Embrun, and died in the year 1672. He pub-
lished a work on the quadrature of the circle; "Arithmeti-
cal Institutions, in four books; a treatise "On Cyclo-
metry;" a work "On Magnetology;" and a work "On the
Primum Mobile."”
LEOTIA, in Botany, perhaps so called from λεων, or
λαος, the people, or vulgar; yet it does not appear to be either
a common genus of fungi, nor vulgarly used as food, like
many others. Its aspect indeed is ordinary enough, being
that of a small Agaric without gills. Peron. Syn. Fungi,
511. Obs. Mycolog. v. 2. t. 5. f. 1. t. 6. f. 1. 2.
Eff. Ch. Head roundish, reflexed at the margin and
closely embracing the stalk, bearing seeds in its exposed
surface.
The species enumerated by Persoon are nine, four of
which,
which have a smooth conical or ovate head, three an orbicular one, and the other two are oftentimes doubtful.

Among the first is *L. Mirulus*, the *Ehewa eucliiata* of Batich, f. 132, and probably *Gloaaria ferruginea* of Sowerby's Fungi, t. 84; found in autumn growing copiously on decayed leaves of Scotch fir. The *flank* is near an inch high. *Head* conical or ovate, of a pale crimson colour; white and fleshy within.

In the second section is *L. lubricata*; (Helvella gelatinosa; Bulliard 296. t. 473. f. 2.); not unfrequent, after much rain, in beech woods. It is of a light greenish buff colour, and tender sufficiency. *Stalk* two or three inches high, hollow, tufted in the lower part; and the cavity is continued into the *head*, which is rounded, depressed, umbilicated, and obscurely lobed, about an inch in diameter, composed as it were of two coats, with a hollow space between.

*Helvella Kelbani*, Sowerby t. 11, is one of the doubtful species. **LEPI**

**LEIP**

**LEPVILLE**, in Geography, a town of France, in the department of the Lower Charente; eight miles N. of Montlucon.

**LEWITZ, CYRIAN**, in Biography, a celebrated astronome in the sixteenth century, was born in Bohemia, and was appointed mathematician to Otto Henry, elector palatine. He acquired a high reputation by his astronomical productions, of which the principal were "Ephemerides ab anno 1750, ad Amn. 1800"; "Expedita Ratio continuiti The- matis euclidis", "Loca fiallarum fixarum ab anno Dom. 1749, in fine in Amn. 1752," and "De Echiptibus Liber," His celebrity occasioned Tycho Brahe to pay him a visit in the year 1750, when they had several conversations on their favourite subjects. Notwithstanding the great learning of Lewitz, he was weak enough to become the dupe of judicial astrology. He died in Swabia in 1754. He had predicted that the world would come to an end in 1584, and of this prophecy many priests and preachers took advantage as the important period approached, and enriched themselves at the expense of the fears of their people. Bayle, Moret.

**LEPA**, in our Old Writers, a measure which contained the third part of two bushels. Whence we derive a *seed lap*.

**LEPANTO**, in Geography, a sea-port town of European Turkey, in the province of Livadia, situated in a bay formerly called the "gulf of Corinth," now the "gulf of Le- panto." This town is fortified and defended by a castle on an eminence. N. lat. 38° 37'; E. long. 22° 0'.

**LEPAS**, in Conchology, a genus of the multivalve order, the animal of which, according to the Linnaean Syllabus, is a triton, the shell affixed at the base, and confining of many unequal erect valves. This genus, as defined by Linnaeus and Gmelin, comprehends two very distinct genera, the union of which, under one name, is liable to much objection; though, for the sake of uniformity, we are not inclined in this article to separate them. One of these natural tribes, for example, has the shell of a conic form more or less tubular, the base firmly affixed upon rocks or other extraneous substances, without any tendinous tube; the shell is composed of fix valves; and the truncated opening above is closed by a four-valved operculum. In the other genus the shell, instead of being conic, is broad, flattish and wedge-formed, and in many species resembling, in some degree, the *fcap* or head of an arrow; it is besides composed, in general, of a much greater number of plates or valves, the aperture of which is lateral instead of being at the summit, and has no operculum; and lastly, the shell is not affixed by its telfaceous base, but is placed at the extremity of a tendinous tube, the base of which unites it to the rocks or other substances to which, for convenience and security, the animal connects itself. The very obvious dissimilarity that prevails between these two genera attracted the particular attention of early writers, even before the time of our countrymen Lifer and Petiver, the term Balanus being adopted for the former, and Concha antifera for the latter, and by these names the two tribes of shells are recognized in the writings of Gemeny, Aldrovandus, and others. Linnaeus, notwithstanding these authorities, however, confounded them together. Da Coila was the first among the English authors who again separated them; he assigned to the first the original name of Balanus, or acorn shell, at the same time that he retained the former under the name of lepas, or in English bernacle, a term preferable, no doubt, to that of Concha antifera, which applied to a single species rather than the whole genus. The observations of Da Coila, as they militate in various respects against the conchological writings of Linnaeus, have never perhaps been regarded in this country with sufficient attention, nor with ordinary liberality; he is not, we admit, on every occasion lucid, neither as a systematist does he deserve mention; yet, upon the whole, his remarks are often judicious, and almost constantly correct, and his strictures on the genus lepas, as proposed by Linnaeus, are in particular satisfactorily; he has restored both genera to their proper station. Among the collectors of shells in Britain, from the time of Da Coila to the present, the names of balanus and lepas have been almost constantly adopted, but the separation of them is ascribed to Dr. Solander, and the discrimination of earlier writers ceases to be remembered. In England, as before observed, the Linnaean term of lepas has been retained for one of the two genera; the continental writers, on the contrary, though they adopt this genus in the same form, reject the word lepas, and substitute that of anatìta in its place; the French call it anatif, and under the latter term it is distinguished by their bell writers. Having pointed out the leading character of the two genera into which the lepas of Linnaeus and Gmelin is divided, it only remains to enumerate the species described by those and succeeding writers to the present time.

**Species.**

Frequent on the British and other European shores, adhering in vast numbers to rocks, stones and stones; the colour generally whitish or greyish, and the form rather variable.

Found, like the former, in great abundance on the shores of Europe, and also those of the American and Indian seas. When affixed on an uneven surface, the base of this shell sometimes extends down into a pretty long rounded tubular stalk or root. This variety is noted by Pennant, and an extraordinary, but mutilated specimen, is shown in one of the shells of Brit. Zoöl. Another occurs in Brit. Shells. Donov. The colour is commonly greyish; the tips of the valves, as in the last-mentioned variety, greenish.

"This rare species is the lepas intertexta of the Portland museum, and was filled up at Weymouth, adhering to a valve of the ortre faberius, &c." Brit. Shells.

**COSTATA.** Somewhat conic and sulcate, the ridges equidistant.
LEPAS.

A new species found adhering to pieces of broken rocks on the coast of Pembrokeshire.

A new species described above, the specimen was found by Mr. Dryer, of Weymouth, affixed to a shell of the lepas anatifera.

Found adhering in large clusters to the bottoms of ships in most seas. A supposed variety of a dirty whitish colour is mentioned by Chemnitz as a northern kind.

Inhabits the North seas.

A new species, recorded as above fluted. "A few small clusters, with few detached specimens of this curious species of balanus, were discovered about the year 1830, attached to the bottom of the Warship's ship of war, when taken into dock to be repaired, after lying in the harbour of Portsmouth for a great length of time. Dr. J. Hay of Portsmouth soon after found two or three shells of the same kind, by dredging in Portsmouth harbour." The species appears to be very rare; we have one specimen attached to the valve of an oleara rufus brought from Newfoundland." Vide Brit. Shells.

A curious and rare species, about the size of a walnut, or sometimes larger; colour whitish. Inhabits the European and Indian seas.

BALANUS. Shell somewhat conic; lobes six elevated wrinkled and four-parted; the operculum membraneous and bidentate. Müll. Chemnitz, &c. Whale acorn shell, Donov.

Found adhering to the fins and pedoral wrinkles of the whale (Balena hoops); its size resembles the last, but its form is very much deprefed, colour the same as in B. diadema, as are also the furrows of the lobes. This is erroneously described by some authors as the B. diadema of De Cotta; we rejoice the example described by De Cotta under this name, and can in confidence affirm it to be the former species. See Brit. Shells.

PALLIPES. Shell ereft, conic; operculum acute and transversely fluted. Oaff.

Size of a pea, and smooth. Inhabits the ocean.

GALEATA. Shell helmet-form, with a lateral aperture. Schrot.

Discovered adhering to the gorgonia verrucosa, and ventilabrum; shell boat-shaped and smooth; aperture rhombic.

Native of the Indian seas.

TESTUDINARIA. Shell plano-convex; rays six excavated and fluted. Linn.

Inhabits the depths of the ocean, and is usually found ad-}

hering to other shells; the form resembles a globe cut off in the middle.

A most curious and very elegant species, resembling in some measure the following kind, but rather smaller. Gmelin describes it as a native of the Norway seas, on the authority of a specimen met with by Dr. Pontoppidan, the bishop of North Bergen, and which is described by Mr. J. Ellis in the Philosophical Transactions, A.D. 1758. He found it sticking on the Norway sea-fan, and, from the peculiarity of its structure, was induced to call it the Norway sea-fan periwinkle. "This very rare shell is introduced into the British Fauna, on the authority of an example found attached to some sea-weeds, dredged up on the coast of Weymouth, which, after passing through the collections of the late duchefs of Portland and Dr. Fordyce, is at present in our possession." Vide Brit. Shells.

Found in most seas, and is usually found affixed in clusters to the bottoms of ships, and pieces of decayed timbers floating in the water. The colour whitish, with a fine polish beneath the thin epidermis, and tinged with reddish or blueish-violet; the flens of the finest red.

The tentacula of these animals are long and pefminated like a feather, for which they were in fact mistaken in the sixteenth century; and hence arose the whimsical belief that the barnacle shell was the parent of the barnacle goose! Nor was this the vulgar opinion only; it was sanctioned by the grave details of learned naturalists of that time, and particularly by Gerard, whose observations are generally noticed by authors, in describing this singular marine production. See Barnacle Goose. See also Gerard's Herbal, p. 1587.

There are several suppoed varieties of lepas anatifera, in one of which the peduncle is black.

"A native of the American and Atlantic seas, and is chiefly distinguished from lepas anatifera by having the valves ftriated with elevated lines; the valves in the former being perfectly smooth. Lepas anserifera has been heretofore confidered as a native of the American and Atlantic seas; but that it inhabits likewise the English coast is certain, the shell with the living animal having been dredged up at Weymouth." Brit. Shells.

DILATA. Shell comprefed, five-valved, and thin; dorfal valve dilated at the base with an acute angle, and ftoned on a peduncle. Donov. Brit. Shells. Lepas fajetiformis, Ellis Zoophytes. Lepas fjjatulum, Muf. Portl. ?

The first and only account we have of this kind of lepas, except that inferted in "British Shells," is that given by the late Mr. Ellis, from whom we merely learn that it is from St. George's Channel. The specimen appears to have been fent by Mr. Ellis to the late duchefs of Portland, from whence it paffed through the hands of the late Dr. Fordyce, and at his death came into our possession, under the title of lepas fijatulum of Solander. Unlike lepas anatifera, or anferifera, (though it is larger than either,) the valves of this shell are uncommonly thin and brittle, in a certain degree corneous, with the largest lateral valve rather crumpled in the usual course of the ftriae, and marked transversely with
obfolete rays. The shell is likewise covered with a fine pale brown skin, or epidermis. The acute prominent dilatation at the base of the valve on the back is very singular. We must be excused for having expatiated with more than usual minuteness on local particular, in describing the last-mentioned species; as it is principally, and in some instances entirely, on the authority of the individual examples mentioned, that the species are recorded, and their excellence ascertained.

Angustata. Shell elongated, smooth, fix-valved; the aperture narrow; operculum very minute. Chemn. Country unknown. Porosa. Shell granulated, ferrated, conic, and tubular; the operculum obtuse. Schroet. Inhabits India. When living, the shell is green, becoming black after death. A supposed variety of a larger size, and broader in proportion, is described by Klein under the name of balanus major latus. Elongata. Shell cylindrical, snowy, pellucid, fix-valved, and cleft above; lid obtuse, grooved, and transversely ferrated. Chemn. A small and very rare species, found in the Iceland seas.

Patellaris. Shell fix-valved; externally violet variegated with white, and marked with fine longitudinal flutings; within calcated; valves denticulated at the margin. Spengler. Native of Coromandel. A rare species; teeth of the valves inflected in each other alternately.

Spinosa. Shell conic, with twelve triangular valves, fix of them more depressed, less, and white, with transverse flutings; fix purple, and longitudinally ferrated, and all armed with tubular recurved spines. Gmel. Inhabits India.

Violacea. Shell thick, glabrous, fix-valved, and white, with rays of violet. Chemn. Native of India. The shell slightly groove within.

Pollilis. Shell compressed, erect, many-valved, smooth, and seated on a short, hard, lacy, coriaceous peduncle. Gmel. Found in the Mediterranean. The longer valves turned towards each other like the beak of a bird; lesser ones more than twenty.

Cylindrica. Cylindrical, slightly curved, with a very large oblique orifice; operculum horned. Gmel. Balanus maxillaris, Gronow. Lepus fijllis cupidos, &c., Ellis. Native of Africa under the torrid zone.

Crispata. Shell oval-truncated and conic, with fix white valves shaded with white, and fix elevated reddish ones spiny and perpendicularly ferrated. Schroet. Country unknown.

Cariosa. Shell solid, white, depressed with various grooves; within unequally smooth. Pallas.

Native of the seas about the Kurile isles.

Streemia. Conic-convex, with four ferrated trivalved valves; operculum two-valved. Mull. Inhabits the Danish sea.

Leptastrum, derived from the Greek λεπτός, a scale or plate, and αστρum, a star, in Natural History, the name of a genus of shells, of the clads of the science, composed of lamintes arranged into broad plates, and these disposed in the form of a radiated star.

Of this genus there are two known species: the one a bright brownish-white kind, with thinner valves; the other a white dull-looking kind, with thick valves. They are both found on the shores of Shetpey Island in Kent, and form themselves in the cavities of the septum, called by authors Indus Helmutii, and the spatula, with that adhering to them, have been accounted a separate species of that body, and called the frayed waved vein, or Indus Helmutii flutatus.

Lepi, in Geography, a town of Spain, in the province of Seville, celebrated for its grapes, figs, and wine; 20 miles E. of Avamonte.

Lepechina, in Botany, was named by Professor Willdenow, in his Hortus Berolinensis, as a tribute of respect to the labours of John Lepechin, Fellow of the Academy of Sciences at St. Petersburg, who published various tracts upon natural history in the Transactions of that Society. Many of these were botanical monographs; such as, 1. A description of Iris Guldenschenia. 2. Novae species Menitei descripta. 3. Quatuor Ducorum species descripta. 4. Reflections on the necessity of studying the virtues of indigenous plants. He appears to have been an able chemist as well as naturalist, and to have travelled through various provinces of the Russian empire in the years 1765 and 1766. We are unable to discover either the time of his birth or of his death, though from the date of his Travels he must have lived about the middle of the last century. Willd. Hort. Bot. 21. Att. Hort. Kew. ed. 2. v. 3. 590.—Clas and order, Didynamia Gymnosperma. Nat. Ord. Veritá; Linn. Labiate, Sull.

Ell. Ch. Calyx two-lipped. Upper lip of the corolla cloven, lower one deeply divided into three nearly equal segments. Stamens spreading.

1. L. fijllata. Att. Hort. Kew. ed. 2. v. 3. 590.—“Spikes of flowers on bracteate footstalks. Leaves ovate, crenate, truncated at the base.”—The native country of this hardy, perennial plant is unknown. The species in question was introduced into the Royal Gardens at Kew in the year 1800, by Mr. John Hummell, who received it from his friend Willdenow in Germany. By the above specific character we presume there are other species.

Lepegeia, in Geography, a town of Hindostan, in the circuit of Gangpaur; 30 miles S.S.W. of Gangpaur.

Lepel, a town of Russian Lithuania; 55 miles S.E. of Polock.

Lepers. See Elephasiasis and Leptosy.

Leper, isle of, in Geography, one of the New Hebrides, situated between Espiritu Santo and Aurora island, eight leagues from the former, and three from the latter, in 8° lat. 15° 23'; and nearly under the same meridian as the south-east end of Malicollo. It is of an egg-like figure, very high, and 18 or 20 leagues in circuit. In the north-east part there is anchorage half a mile from the land. It derived its name from Bougainville, who visited it in 1768, and found the inhabitants in general deformed with the leprosy. He describes the inhabitants as being of two colours, black and mulatto. Their lips are thick, their hair frizzled, and that of some is a kind of yellow wool: they are small, ugly, and
ill made. Few women were seen, but they were no less dif-
gusting than the men. They were naked, hardly covering
their waists with a mat. They carry their children on their
backs in a kind of fcar; they wear ornaments in their no-
strils; and have no beads.

* LEPIDUM *, in Botany, is the *Actinidia * of Theophrastus
and other ancient writers, and is said by Prof. Marten
to be derived from * Lepis *, a scale, no doubt from the fealy
appearance of its pods after their seed is discharged, but
that is so usual a circumstance with plants of this tribe, that
we are rather inclined with Ambrofinus to consider the word
* Lepidum * as derived from * Lepis *, to be fat, or papritic, be-
cause other plants which have agreed with this genus in its
quality of pungency, but in no other way whatever, have
distinctly been distinguished by the name * Lepidum *, and hence

(Nasturtium; Tournef. t. 193.)—Classt and order, * Tetrady-

Gen. Ch. Col. Perianth of four, ovate, concave, deci-
duous leaves. Cor. crucifomi, of four equal obovate petals,
twice as long as the calyx, with narrow claws. Stam. Fil-
aments mostly fix, awl-shaped, the length of the calyx, the
two shorter ones opposite; anthers simple. Pjfl. Germin
superior, corolla; style simple, as long as the stamens;
flame obtuse. Peric. Pouch heart-shaped, emarginate,
compressed, acute at the margin, two-celled; valves boat-
shaped, keeled; partition contrary, lanceolate. Seeds few,
ovate, pointed, narrower at the base, pendulous
Eff. Ch. Pouch notched, elliptical, with few seeds; valves
keeled, contrary to the partition.

Obf. It is in some cases difficult to draw the line between
the pouch of this and * Tulipa *; even Gartner considers them
as of the same figure. He would retain in * Lepidum *, which
he wishes to call * Nasturtium *, those which have solitary feet,
referring the others to * Tulipa *. The regular corolla differ-
ligintus this genus from * Iberis *, which with it is otherwise
most closely allied. The number of flumes is few, in some
species is fewer than fix.

The species of * Lepidum *, in the fourteenth edition of
Linnæus’s * Systema Vegetabilum *, are twenty; Willdenow has
twenty-nine. Of these * L. didymum * belongs to the genus
* Coronopus *, Fl. Brit. Three of the remainder are natives of
England.

Engl. Bot. t. 111. Jacq. Auctr. t. 131.—Leaves pinnate,
entire. Petals not longer than the calyx, slightly notched.—
This rare English plant is found on St. Vincent's rocks near
Bristol Hot-wells, which has been its habitat ever since the
time of Ray. It is occasionally found in other places that
are open and exposed, in the south of England, flowering in
the early spring; * Root biennial, fibrous. Stems two or
three inches high, spreading, leafy, somewhat downy.
Leaves alternate, unequally pinnatifid, of many pairs of
finao opposite segments, which are elliptical or oblanceolate,
entire. Corollas of many small, white, hexadromous flowers.
Pouch elliptic-oblong, compressed, smooth. Seeds roundish,
two in each cell.

Pl. 899. Engl. Bot. t. 182.—Leaves ovato-lanceolate, un-
divided, ferrated.—This is also a rare plant, found in moat
falt marshes, and on maritime cliffs, as at Sheringham, by
Cromer, in Norfolk, flowering in July.— * Root perennial,
branched, very long. Stems three feet high, erect, leaves
round, smooth, panicked, many-flowered. Leaves alternate,
lanceolate or somewhat ovate, attenuated at the base, ferrated
more particularly in the middle. Flowers hexadromous,
small, white. Pouch elliptical, with a sessile stigma. The
whole plant is bright and disagreeable. An infusion of it is
said by Dr. Withering to be emetic.

Pl. 900. Engl. Bot. t. 135.—Flowers with two flumes,
without petal. Lower leaves pinnate, toothed; upper
ones linear, entire.—A native of muddy and calcareous soils,
which it prefers to sand, in the neighbourhood of the sea.
It keeps flowering from June to August.

* Root biennial, branched. Stem a foot high, erect, branched, leafy, wavy,
round, hoary. Leaves brackish, smooth. Flowers small,
apetalous, diandrous; the clusters when in fruit becoming
very long. Pouch elliptical or roundish, emarginate, smooth.
Seeds generally foliar, pendulous, obovate. Dr. Smith
mentions in his * Flora * that he never found any petals to this
species, nor many more than two flumes, though Withering
describes the petals as “sometimes wanting” and that the
flumes are either two or four.

As to the foreign species, we shall say a few words upon
such as are more especially interesting.

Pl. 897. Jacq. Auctr. t. 346.—Lower leaves much divided
in a pinnate manner; upper ones heart-shaped, embracing
the stem, entire.—A native of Austria and the Levant. It
flowers in July. * Root annual. Stem a foot high, smooth,
tinged with purple, dividing into various slender branches,
at the end of which are corymbs of small and compressed
flowers in long loose spikes. Calyx-leaves yellowish-green.
Pouches orbicular, smooth, having a single, bay-coloured
seed in each cell.

Pl. 898. (L. orientale; Tourn. Cor. 15. Buxh. cent. v. 1.
t. 25.)—Leaves pinnate: segments linear. Stems inflated
at their joints.—A native of Iberia and the dry plains of
Media, where, according to Buxbaum, it flowers in July
and August. Dr. Smith has perhaps the only specimen of
this species to be seen in this country, which was given him
by the celebrated M. Le Monnier from his garden at Ver-
sailles in the year 1785. Stem two or three feet high,
remarkably inflated at the joints. Leaves pinnate, with
long, narrow leaflets. Flowers small, white. Pouch very similar
to that of * L. ruderalis *.

Jacq. Pl. Auctr. t. 137.—Leaves pinnate, entire, smooth.
Flower-flask naked, ascending. Petals larger than the
calyx. Pouches lanceolate, pointed.—A native of the Ger-
man, Swiss, and Italian Alps, where it may be seen in flower
from May to August. This pretty little perennial has a
flender root. Stems very short, clothed with alternate leaves.
Flower-flasks an inch or two in length, bearing a corymbose
cluster. Leaves thick, dark green. Flowers milk-white;
their petals roundish and entire. Pouch ovate or lanceolate,
compressed, with the style at the end. The whole plant is
smooth, and has the flavour of Cress.

Pl. 898. (Nasturtium hortenfe; Dod. Pempt. 711.)—
Flowers tetradynamous. Leaves oblong, much cut and
jagged.—The habitat of this plant so commonly cultivated
was unknown, till Dr. Sibthorp discovered it in Greece.
* Root annual, white, spindle-shaped. Stem upright, smooth,
from one to two feet in height, branched at the top. Stems
and branches terminated by a spike of flowers. Lower
leaflets

4 A 2
LEP 

kafets which resembling those of Parsley; upper ones linear, or lanceolate. Flowers small, white. Calyx very small, greenish. Pouch roundish; valves winged. Seeds brown, solitary, taking like Mustard. This is undoubtedly the Lepidocarpos of Dioscorides, and is universal request for salads in the winter and spring. There are two varieties frequently to be met with, one of them having broad, the other curled leaves. It is said to act as a diuretic and antiscorbutic when taken largely.

L. oleraceum. Notch-leaved Pepper-wort. Willd. n. 16. Forre. Ecol. 69. (L. bidentatum; Montin in Nov. Act. Nat. Cur. 6. 324. t. 5. a.)—Leaves elliptic-oblong, acute, ferrated. Flowers tetraedrous.—A native of the sandy shores of New Zealand. Root perennial. Stem herbaceous, from one to three feet in height. Leaves serrated, alternate; the upper ones smaller, ferrated only at the tip. Flowers white. Pouches ovate, or heart-shaped, compressed, containing an ovate, acute, reddish-yellow seed in each cell. Forster says that this plant, together with Ajania or Smulage, and Teragona balmiformis, was of considerable service to the fishers' crews under Captain Cook, when they lay in Charlotte Sound.

L. virginicum, a native of the Caribbea Islands, is eaten by the natives in salads, like our Garden Cress.

L. psyllium, found in the South Sea Islands, is made use of by the inhabitants for catching fish by immersing it. It resembles L. oleraceum, and is elegant like that species.

LEPIDIOIDES, in Gardening, comprises a plant of the herbaceous annual kind, of which the species cultivated is the garden or common cress (L. fativum). But there are other species which may be cultivated for variety.

It has several varieties, as with broad leaves, with curled leaves, and the common form with the leaves multiform.

Method of Culture.—These herbaceous plants are raised by sowing the seed as wanted for use, at different times of the year, as one a week or fortnight, where a constant succession of small herbs in their young growth is wanted for salads, when only a few days or a week or two old; or, where a constant supply of these small herbs is required in their young feeding growth, some seed, as just noticed, should be sown in succession every week or fortnight at first in, all spring, summer, and autumn; and once a fortnight in the winter season. The order of sowing them in the different feasons is, in a warm south border, or other similar situation, or under a frame, &c. in the early spring months; and as the warm season advances, in any open compartment, all in as light earth as the garden affords; but in summer, or hot dry weather, in somewhat shady borders, or in a free situation, shaded with plants from the scorching sun, and daily watered; and in winter, in the warmest situation, or in shallow frames defended with lights, and under hand-glases; but in frothy or other very cold weather, in that season, on moderate hot-beds; and hot-bed sowings are also requisite during the colder part of the spring, or at any time in cold feasons, where a supply of these and other small salad herbs are required to be raised as quickly as possible. The method of sowing the feed, in all the cases, is very thick, as the plants are mollily used in small young growth, and generally in small, flat, shallow drills, about three inches asunder, so thick as almost to cover the earth, being lightly earthed over a quarter of an inch thick, or less; or on the plain surface, first raking it smooth, then sowing the feed thick as above, smoothing it down with the back of the spade, and either with the spade spreading some fine earth lightly over it as thinly as possible, or covering it by sifted earth over it evenly a small depth, just to cover all the feed properly. This fort of salad herb should always be cultivated to as to grow as rapidly as possible, being cut while perfectly young, and in a crisp state. See SALAD HERBS.

LEPIDOCARPUS, in Botany, from Lepidos, a scale, Lepto, leaf, and Carpos, a fruit; a name given by Boerhaave in his Hort. Lugd. Bat. ed. 2. v. 2. 185, to the Protea with hemispherical heads of flowers, conspicuous for the ample and beautiful feales of their calyx, of which Linnaeus composited his genus Leucadenodron, in Gen. Pl. 46, but which he subsequently united to Protea. See LEUCADENDRON.

LEPIDOIDES, from Lepidos, a scale, and -oid, figure, or Lepidoleides, in Anatomy, a name of the squamous or scaly future of the cranium.

LEPIDOLITE, Lepidolite, Hairy Lilacite of some other mineralogists.

The colour of this mineral is generally pale peach-bloomed, or rote red, with an admixture of grey; but it also occurs of a pale violet and light cochineal red; sometimes the greyish-red variety passes into blue and greenish; and a variety has been observed, in which the green approaches the tint green.

Occurs only massive; but its fragments are said sometimes to have a tendency to adopting a prismatic form.

Its internal fibre is glintening, passing into thinning; it appears sometimes between resinous and vitreous.

Fracture uneven, prelenting fine-grained and scaly distinct concreations; fragments generally indeterminately angular, with pretty sharp edges, which are faintly translucent.

It is moderately hard, passing into soft; brittle; though not easily frangible.

Specific gravity, 2.850, Haid; 2.816, Klaproth; 2.372, Gerhard.

Before the blowpipe the lepidolite, after a flight degree of intumescence, melts into a milk-white semi-transparent pearl. With borax it fuses more readily into a transparent colourless pearl.

Klaproth was the first who analysed this mineral. Among the results of his analysis was a deficiency of 64 per cent., which a subfequent chemical examination, (made by the fame chemist, with a view to ascertaining the presence of potash, which he had a short time before discovered in the leucite) proved to be occasioned by the loss of the fame alkali, till then unsuspected to enter the composition of mineral substances. Vaquetin afterwards found the fame alkali, but in far greater proportion.

The fluate of lime, in Vaquetin's analysis, is probably owing to particles of flour spar that were adhering to the specimen examined by that chemist.

Lepidolite is found (exclusively, as it is supposed) on mount Radice, near Rozane in Moravia, in a kind of gneifs, which is said to pass into granite on one side, and into mica slate on the other. The accompanying minerals, with
with which it is also mixed, are quartz, feldspar, fluor spar, flori-beryl, apatite, and common fiorl.

Fichtel makes mention of a masf mixed of brownish-violet grains of quartz, whithfl finging feldspar, and light and dark coloured lepidolite, which, (if the last-mentioned sub stance be confidered as a fubftitute for morion, with which it is indeed nearly allied,) confifts a particular kind of granite hilltoft unnoticed.

Beyer has defcribed a variety of lepidolite from Sudermanland, in Sweden: but fome writers have doubted this to be real lepidolite.

The lepidolite was, by its discoveries and other mineralogists, referred to zeolite: it had also been miftaken for a variety of foliated pygym. Klaproth, who determined its real nature, bifcribed it for the talletteis name of "Scleria," that of lepidolite, derived from its fealy structure.

What has been defcribed as crystallized lepidolite, is the red varift of flori-beryl, or picrite, which is likewise found at Rozena in Moravia, in a quartz matrix.

LEPIDOPTERA, from *labris*, a leafe, and *papio*, wings, in the Linnean Syfem, an order of insects, with four wings, imbricated with fcales: in the mouth is contained a spiral tongue, and the body is hairy. This order comprehends three genera, viz. the paphio or butterfly, the fiphnx, and the phaenale or moth; and each genus includes a number of fpecies.

LEPIDOSARCOMA, from *labris*, a leafe, and *sph^i*; *florh*. Severinus, a furgical author, implies by this term a farcomatous and flaly tumour in the mouth.

LEPIDOSPERMA, in Botany, fo called by Labillar-diere, from *labris*, *labris*, a leafe, and *sph^i*; fo called, becaufe of the fix permanent feales which infekt the bafe of that part. Labillard. Nov. Holl. v. t. 14. t. 11—17.

Gen. Ch. Cat. Spikelet imbricated every way, of one or two flowers, and one leef; fcales feveral, ovate, concave, acute, for the moft part empty. Cor. none, except we fo call the fix flat, membranous, thickfih fcales, united at their bafe, which infekt the bottom of the germen. Sten. Filaments three, capillary, projecting; antlers terminal, oblong, acute, pendulous. Fl. Gemen superior, very small; fyle cylinferical, erect, as long as the flamen, deciduous; fligments three, equal, recurved, flender, downy, acute. Peric. none. Nut roundish, obtufe, not burfting, accompanied by the above-mentioned fix fcales, of one cell, with a fingle roundifh kernel.

Eiff. Ch. Spikelet of one or two flowers, and one leef. Glumes charta, imbricated every way, molt of them barren. Six* flat combined permanent feales at the bafe of the germen. Style deciduous. Nut fotary, bald, obtufe.

This genus is allied to the Cladium of Browne's Jamaica, (confounded with Schoenus by Linnaeus,) but is diftinguifhed by the fix fcales that accompany the germen. From the Scheria of Bergius it differs in the number of its glumes, and in having always androgynous spikelets, of which the upper flower is only male. Labillardiere defcribes and figures seven fpecies; Mr. Brown defines 19, all from the colder parts of New Holland, or from Van Diemen's land. They are hard rigid ruify plants, one or two feet high, with strong perennifal roots, fimple leaflesfs ftem, encompassed at the bottom with severall long, narrow, mollfy equitant, leaves, which are more or lefs comprefled and acute, their edges either smooth or minutely serrated. The paniyle or spike is terminal, mollfy branched or divided.

Examples of this genus are

L. gladiata. Labill. Nov. Holl. v. t. 15. t. 12.—Panicule dense, repeatedly compound. Stem comprefled with an elevated rib at each fide; its edges smooth, like thofe of the leaves. Glumes rather sharp.—Gathered by Mr. Brown at Port Jackson, as well as in Van Diemen's land, and the south part of New Holland. The stem is fott and rigid, from eighteen to twenty-four inches high. Leaves half an inch broad, smooth. Panicle upright, large, of numerous acute, oblong, fcaly spikelets.

L. tetragona. Labill. Nov. Holl. v. t. 17. t. 17.—Panicule dense, somewhat compound. Leaves quadrangular. Stem bluntly angular.—Gathered by the author cited, in Van Diemen's land. The fquare leaves are very remarkable. It is a much smaller plant than the foregoing. The fcales of each spikelet are from four to fix only. The bun is elevated on a more confpicous fpongy bafe: than in molt of the other fpecies.

Nothing can give a more unfavourable idea of the fertility, comfort, or beauty of a country, than the prevalence of fuch plants as these; flight examples of which may be seen in our Schoenus nigricans, Nardus firiata, and fome others, found on the molt dreary and barren inland lands.

Such of them as inhabit the sea-fhore, anfwer the molt valuafble purpofe poifible, in forming a natural bafe against the encroachments of the ocean. See Elymes.

LEPIDOTES, in Natural Hiffory, the name of a flone bearing a reffemblance to the fcales of fishes. The word has been used by fome, as the name of fuch ftones which are compofed of small fkaes, or fcales of tale, and by others to exprefs the ftones containing fih, or the impressions of fih, found in many parts of Germany.

LEPIDUS, M. Aemil. in Biography, a Roman triumvir, was defended from one of the moft illustrious families in Rome, and rofe to the highest emploiments of the state. On the death of Caesar, Lepidus, who was zealoufly attached to his interefts, thought it prudent to conceal himfelf. He afterwards joined Antony in driving away the confpirators, and obtained the dignity of chief pontiff, through the influence of that leader. Afterwards, when Antony was treated as a public enemy, Lepidus commanded an army of seven legions in Transalpine Gaul. Here Antony arrived in a very diftractcd fition, and conjured his friend to join his forces to thoef of which he commanded. Lepidus refufed, but affured him he would not act with hoftility againft him. Antony knowing in what efimation he was held by the army, rushed into the camp of Lepidus, where he was faluted with the loudeft aclamations. Lepidus was now, in his turn, glad to fupparate the aid of his competitor. Antony treated him with apparent refpect, left him the nominal command, while he himfelf exercised all the real authority. By this conduct, Lepidus loft the confidence of the fenate; and in a fhort time he was declared a public enemy, and Octavianus and Decimus Brutus were fent out againft him and Antony. In dividing the Roman world between three matters, Lepidus was allowed a place, principally by way of a connecting medium between the other two. He possessed a confiderable family-interest, and was not deftitute of military abilities; but he had neither capacity nor temper to take a leading part in political concerns.

In the formation of the triumvirate, it was agreed, that while Antony and Octavianus fhoild carry on war againft Brutus and Cassius, Lepidus fhoild remain at Rome with four legions, and maintain their authority in the capital. At the bloody profcription, and while the butcherly was still raging, Lepidus had the unfeeling vanity to influt the public diftrefs by a triumph, on account of fome inconfiderable victories formerly obtained by him over the revolted Spaniards.
Spaniards. He was consul a second time, B.C. 42, with
Manutius Plancus. The part of the empire which was al-
lotted to Lepida, after the Triumvirate (which see) 
was fully established, was Africa. In the war with Sex- 
tus Pompey, Lepidus brought a large force to Sicily, 
with which he joined Octavianus; and he shared in the 
victory obtained against that great general. The con-
fidence he felt at being at the head of a large army, 
induced him to treat his colleague with haughtiness and 
neglect; but he had soon 
the mortification to see himself deserted by all his 
troops, who joined Octavianus. He now supplicated his 
life of his rival, which being granted him, he retired into a kind 
of exile at Circeii, a small town in Latium, where he puffed 
the remainder of his days in obliquity. Plutarch. Univer-
Hill.

LEPIN, Francesca Margarita. See Mar-

LEPIDOTA, in Botany, from \textit{lepis}, a thin membranous 
layer, or cuticle, the first section of the great genus \textit{Agara-

or} in Peron's \textit{Synopsis Medicinalis Fungorum}; the character of 
which is to have the gills dry and membranous, as the name 
expresses, not clouded nor footy, and the flâk encompassed 
with a ring. It includes twenty-nine species, of which 
\textit{Agaraucus procerus} is the first and most remarkable.

LEPISTMA, in Entomology, a genus of apetera. Gmelin, 
after the Linnaean manner, defines it as having four feelers, 
two of which are fetteaceous, and two capitated; the lip 
membranaceous, roundish, and en-marginated; antennae fa-
teous; body inbricated with scales; flail ending in fette-
aceous bristles; legs fix, and formed for running. The 
character of lepifma, as thus expressed, combines the more 
effential character of Fabricius with that of Linnaeus. La-
marck and others propose some further alteration; and, 
laftly, Latreille, in whole arrangement they form the first 
family (lepifmenae) of the order thymannoura, divides them 
to two distinct genera: lepifma and maculili. The true 
lepifma, according to the new definition, has the antennae 
affected between the eyes, the body flat, and the tail ending 
in three equal bristles. This genus walks and runs. In the 
genus maculili, (which moves by skipping,) the antennae are 
feated under the eyes, the body convex, and the middle 
bristle of the tail longer than those at the fides. The three 
first species are described by Linnaeus; the other by Fa-
bricius, and by Müller the author of Zoöl. Dan. All the species, 
except the fift, are natives of Europe. In their 
invarfé flates of growth they prey on decayed wood, and 
mold or rotten substances; and are most commonly found in 
damp cellars, neglected water-course, leaf gutters, and 
similar situations. The larvae, like the pupa and perfect 
flate, are furnished with fix feet, and are remarkable for 
their activity and swiftneas.

Species.

\textit{Saccharinum.} Scaly, silverly; tail triple. Fabr. Le-

Lepisna vulgaris, Scop. Forbiculus, Aldrov. Forbiculus plana, 

Originally a native of America, from whence it has been 
introduced and naturalized in Europe. The body is oblong 
and tapering; antennae as long as the body; tail terminating 
in three bristles, and two pair of smaller ones beneath. It 
secretes itself among old furniture, and runs, when disturbed, 
with great agility: is often found among sugars.

\textit{Polyoda.} Skipping; tail triple; segments of the ab-
domen villous each side beneath. Fabr. Lepisna incuru-

It inhabits among rones and rubbish on sandy sea-shores, 
and possesses the faculty of leaping to a prodigious height,

by means of the springs under the tail; antennae as long as the 
body.

\textit{Terestris.} Naked; tail triple. Linn. En. Suec.

Gmelin mentions the close affinity this indiflinct species 
bears to the podura tribe, to which it may perhaps belong. 
It is entirely white and cylindrical, with obtuse antennae half 
the length of the antennae.

\textit{Lineata.} Tail triple; body brown, with two white 
fillets. Fabr.

Inhabits old walls in Helvetia. Antennae as long as the 
body, which latter is brown above, with cincereous specks; 
legs short; thighs compressed.

\textit{Villosa.} Brown, with a triple villous tail. Fabr.

Native of China. The head villous-whitish; body be-
neth whitish; middle fpine of the tail longer; legs short 
and white.

\textit{Collaris.} Black, with a snowy band on the neck 
and end of the abdomen; tail triple and villous. Fabr.

An inhabitant of the South American islands. Antennae 
as long as the body, and brown, with the base pallid; head 
whitish; beneath the tail two short bristles; legs pale.

\textit{Polypus.} Scutate; tail triple. Müll.

Native of Denmark.

\textit{Minutus.} Yellow; tail of three bristles. Mull.

Inhabits same country as the latter. Appendages of the 
tail sometimes wanting.

\textit{Lepita, in Hindoo Mythology, a name of Sarawati, 

fponofe of Brahma, and goddes of literature, harmony, 
rhetoric, and the fine arts. See Sarawati.

\textit{Lepium, one of Hill's names for a variety of ymp-

Lepois, Nicholas, in Biography, a physician of cel-

lebrity in the sixteenth century, was born at Nancy, in 1527. 
He studied medicine at Paris under Sylvius, together with 
his elder brother, Anthony Lepois, who was afterwards fift 
physician to Charles III. duke of Lorraine. In this office 
Nicholas succeeded his brother in 1578. He spent his 
whole time in sick-chambers, or in his clofet, perusing the 
ancient authors from Hippocrates downwards. He drew 
up the result of his readings, corrected and corroborated 
by his personal observation, in an aphoriftic form, chiefly 
with the view of being serviceable to his sons, Christian and 
Charles, whom he defined for the medical profession; but 
his friend the celebrated Feuillus, and several other persons, 
having seen his MS. prevailed upon him to publish it. It was 
first printed at Franckfort, in 1580, in folio, under the 
title of "De cognoscendis et curandis pecptus internis hu-

manti corporis morbis, Libri tres, ex clarissimorum medici-
corum, tum veterum, tum recentiorum, monumentis non 
ita pridem collecti."--Boerhaave had so high an opinion of 
this author, that he edited this work, adding a preface to it, 
at Leyden, 1736, in two volumes 4to. Eloy Dicé.

Lepois, Charles, more generally known by his Latin 
name, Carolus Pifo, was son of the preceding, and born 
at Nancy in 1561. He was sent at the age of thirteen to 
the college of Navarre, at Paris, where he remained five 
years, and disdained himself by his rapid advancement in 
the knowledge of the languages, belles lettres, and phi-
losophy. He received the degree of Master of Arts in the 
university of Paris in 1581, and immediately commenced his 
career in the schools of medicine. After four years, spent 
in the faculty at Paris, he went to Padua in 1585, and 
visited the other schools and the learned men of Italy before 
he quitted that country. He returned to Paris in the be-

ginning of 1588, and took his bachelor's degree in medicine, 
and two years afterwards became a licentiate; but he left 
Paris without having taken the degree of doctor, from in-

ability
bility to defray the expenses of that ceremony, in consequence of the small income left him by his father. He therefore returned to his native city, where duke Charles III. of Lorraine appointed him his consulting physician, and retained him near his person both at home and in his travels. Duke Henry II. likewise held him in the same estimation; and, among many other marks of his esteem for Lepois, he instituted a faculty of medicine at Pont-a-Mousson, and nominated him dean and first professor. In order to undertake these offices, he repaired to Paris, where he received the degree of M.D., which gave him the power of conferring the same degree upon others, and commenced the duties of his professorship in November 1508. He had now an opportunity of displaying the stores of knowledge, which his acquaintance with the Greek and Latin, Arabic, Hebrew, Italian, and Spanish languages had enabled him to obtain; he was indefatigable in his observation of diseases, and omitted no opportunity of examining by dissection the bodies of those who died; from which he judiciously anticipated the most important improvements would accrue to medicine. His reputation was elevated to the highest degree, so that he was the physician of all the honourable persons in Lorraine. His zeal in the practice of his profession continued unabated, and ultimately occasioned his death at the age of seventy; for he died of the plague at Nancy, whither he had gone to administer relief to those afflicted by the pestilence, in the year 1543. He left the following works, which have transmitted his reputation to posterity; particularly the first, entitled "Selectionm Observationum et Conflitorum de praeteritis hactenus morbis, effectibusque praeter naturam ab aquis, feu cerou colonie et deluvie ortis, Liber fingulare," Pont-a-Mousson, 1618, in 4to. This work passed through several subsequent editions, one of which, (that of Leyden 1754,) was published with a preface, by the celebrated Boerhaave. A selection from, or an abridgment of it, was also printed in 1639, with the title of "Pifta caelestis," in 12mo. His other works were, "Phylicum Comete Speculum," Ponte de Moitionem, 1619, in 8vo. and "Difcours de la Nature, Caufes, et Remedes, tant curatif que prefervatif, des Maladies populaires, accompagnées de Dyferent et autres Flux de Vente," ibid. 1623, in 12mo. He translated from the Spanish into Latin, "Ludovici Mercati Institutiones ad umum et examen eorum qui artem luxatoriam exercent," Franckfort, 1623, in folio. He likewise published the following eulogy of his first patron, "Caruli III., Sereniffimi, Potentiffinum Ducis Lotharingius, &c., Macarumus, feu felicitatis et virtutum egregio Principe dignarum coronas," 1650.

Lepotl, in Geography, a town of Georgia, in the province of Kaket; 22 miles S.E. of Kaket.

Leppowirta, a town of Sweden, in the government of Kuopio; 24 miles S. of Kuopio.

Lepra, a disease, that is, a state, a state, a state; whence our English term leprosy; which see.

Leptra Lankeng, in Geography, a town of Tibet; 68 miles S.E. of Toudlong.

Leptras, in Ichthyology, the name of a sea-fish of the turdus, or wraffe kind, remarkable for the great variety and beauty of its colouring. It is seldom caught of more than five or six inches in length, and is considerably broad and flat. It sometimes grows to a foot long, but that only in the ocean, never in the Mediterranean sea, where it is usually caught; and even there very rarely. It is spotted all over like the body of a leopar. It is one of the most beautiful fish of the Mediterranean, but is not much esteemed at table, being of an inimical and watery taste.

Lepreum, Leprosus, or Leptra, in Ancient Geography, a town of Triphylia, near the confluence of the rivers Jardanus and Alcidon, N.W. of Chaa. It is said to have been founded by a person of the name of Lepros, a famous writer, who contended with Hercules, by whom he was vanquished and killed. In the time of Paulistas, the inhabitants of Lepreum assumed the appellation of Arcadiens. In this town was a temple of Ceres, constructed of bricks, and near it was the fountain called Arene.

Lepria, an island on the coast of Ionii, mentioned by Pline.

Leprosus Amovendo, in Laws, an ancient writ that lay to remove a leper, or lowar, who thrust himself into the company of his neighbours in any parish, either in the church or at other public meetings, to their annoyance. The writ lies against those lepers that appear outwardly to be such, by foles on their bodies, smell, &c. and not against others: and if a man be a leper, and keep within his house, so not to converse with his neighbours, he shall not be removed.

Leprosy, in Medicine, a denomination which has been given to a variety of chronic diseases, chiefly affecting the skin; but which has not been exclusively appropriated to those that are characterized by the formation of scales, as the origin of the term imports. Even the Greek writers themselves, and more especially the later ones, have not adhered uniformly to the proper import of the appellation; but the confusion which has prevailed in subsequent periods of medical history, in regard to the application of this term, almost bids defiance to the industry and discrimination of the inquirer. This is partly to be ascribed to the difficulty of conveying accurate notions of cutaneous appearances by verbal descriptions, partly to the extreme variety in which those appearances present themselves, and partly to the neglect of minute observation, where distinctions can only be detected by a careful and practiced eye. Thus the latter Greek physicians applied the term lepra in a more extended sense than their predecessors, and rendered future discrimination more difficult. But this difficulty was exceedingly multiplied by the translators of the works of the Arabian physicians into Latin, after the revival of learning. The Arabs appear to have distinguished the lepra and elephantiasis of the Greeks, by appropriate terms in their own language; but the translators rendered the word which denoted the latter (sce. fucum, and barus or albarus) by the Greek term lepra; and the Arabic words (albaui and alkoaua) which seem to have signified the name with the lepra, apos, and plora of the Greeks, they translated by the terms impetigo and morphae.
LEPROSY.  

The term, *leprous*, has, moreover, been applied by the translators of the sacred writings, to a variety of cutaneous diseases, respecting the nature of which there has been some difference of opinion; some referring it to the scaly leprosy of the Greeks, and others considering it as a variety of the elephantiasis of the same people; we mean the lence, vitiligo, or albaras alba.

In order to arrive at a tolerably clear notion of the several varieties of signification, which have been given to the term, we must, therefore, consider it under four different heads; namely, the leprosy of the Arabsians, of the Greeks, and of the Jews, and the leprosy of the middle ages.

*Leprous* of the Arabsians, or *Lepra Arabum*, is the same with the *Elephantiasis* of the Greeks. See *Elephantiasis*.

Under that head, we have described at length the symptoms of this formidable disease, as detailed by Arztius and the other Greek physicians; as well as the appearances which it has been said to assume in the West Indies, in Arabia, and in other southern climates, in modern times. We must here, however, observe, that the appellation of *Arabian leprosy* has originated in error; and that the imputation of having misapplied the Greek term (*lepra*), which has been generally cast upon the Arab physicians, appears to be altogether incorrect. This imputation arose from the misinterpretation of their translators, as above stated: and as the works of the Arabsians were known only to European physicians, through the medium of these translations, into Latin, it was naturally inferred that the original writers had committed the error. Avicenna describes the elephantiasis under the title of *juzam*, or *aljuzam*, (the appellation which is still given to the disease in Arabic, according to Niebuhr), and likewise distinctly treats of the *albers* or *albaras*, and the *albohek* or *albopek* (*morphia* of the translators). He carefully distinguishes, however, the albaras from the albohek, the former of which has several symptoms in common with the confirmed elephantiasis (*aljuzam*), and is said often to terminate in it. These symptoms are, a loss of sensibility in the parts affected; a change of colour in the hairs, which become white; and ultimately a loss of the hair; and a change in the colour and texture of the skin, and of the subcutaneous flesh under it, which becomes white and bloodless, like that of oysters, and finally periures and falls off. These symptoms have, in consequence of the mistakes of the translators of the Arabsians, been transferred to the proper scaly lepra, and are conjoined, in the ordinary descriptions of the latter, with the symptoms properly belonging to it alone. But it seems obvious that the Arabian terms albohek and albaras are of nearly the same import as the Greek terms *alphos* and *lence*, which both Hippocrates and Celsus have carefully distinguished; considering the former as a mere blemish of the skin, but the latter as a formidable and almost incurable disease. See LECCE. See also Hipppocr. lib. Ψ. 1. 119. Celsus, lib. v. cap. 28, and Willan on Cutaneous Diseases, ord. ii. genus 1.

*Leprous* of the Greeks, or *Lepra Graecorum*, is principally characterized, as the term imports, by the formation of *scale* on the surface of the skin, which consist of morbid laminae of the cuticle, hard, thickened, opaque, and of a whitish colour, and appear in patches of different sizes, having always nearly a circular figure.

Such is the description of the disease which has been left us by the Greek writers, and which is given as the character of the *lepra* by the best writer on the subject in our own time; we mean Dr. Willan. Hippocrates has not left any circumstantial detail of the symptoms of lepra, but speaks of it, together with the *alphes*, *psora*, * lymphus*, &c. as an external blemish, rather than a disease. The later Greek writers, however, although brief in their description of lepra, have pointed out the distinctions between it and other similar affections, with which it was conjoined by their predecessors. Aëtius states, that it differs from the *leucus* (vitiligo, or white elephantiasis) in not penetrating deeper than the skin, and leaving the subjacent flesh found; from the *alphes*, which, though scaly, is more superficial; and from the *psora*, in having large scales, like those of fish; whereas, in the latter, only scurf, or branny exfoliations, appear. (Aët. Tetrabib. iv. fermo i. cap. 134.) It must be here observed that the *psora*, simply, signifies a flight, scaly disease; and not the *scabies*, or itch, which is designated, together with the moth-tetter, by the epithet *ulcerating psora*, *Lepra leuces;*. (Aët. loc. cit. cap. 126, 127, and 150. Galen, Introd. Paul. lib. iv. cap. 2.) Paulus Epigone, in a chapter on *Lepra and Pthora,* observes, that "both these diseases are characterized by roughness and itchiness, and a separation of a melancholic humour; but *lepra* affects the skin deeply, in circular patches, at the same time throwing off scales like those of large fish; whereas *psora* is more superficial, variously figured, and throws off little bran-like substances."

(Lib. iii. cap. 2.) Aëtius has given the same account of these diseases. (De Meth. Med. lib. ii. cap. 11.) This scaly *psora* will be afterwards considered, under the appellation of *Psoriasis*, which Dr. Willan has appropriated to it, in order to avoid the confusion which would ensue in retaining the term *psora*, which has been applied by many of the moderns exclusively to *scabies*, or itch.

Three varieties of the scaly *lepra* are observed in this country, according to Dr. Willan, which he has denominated *Lepra vulgaris*, *L. alboheides*, and *L. nigricans*.

1. The *lepra vulgaris* first shews itself in small, reddish, and shining elevations of the cuticle, on the tops of which thin white scales are seen within twenty-four hours from their appearance. After three or four days, the small elevations are flattened, and at the same time diluted, by an extension of their bastes, to the size of a silver penny. These patches continue to enlarge gradually, until they become nearly of the size of a crown piece; they always retain a circular or oval form, are covered with dry scales, and surrounded by a red border. The scales often accumulate on them, so as to form a thick prominent crust, which is quickly reproduced, whether it fall off spontaneously, or have been forcibly detached. On its removal, the surface appears, through a magnifier, to be porous and irregular, or wrinkled; but the furrows do not coincide with the lines of the contiguous found cuticle. The eruption is not attended with any pain or uneasiness, excepting a slight degree of itching, felt when the patient becomes warm in bed, and a sensation of tingling upon
LEPROY.

upon any sudden change in the temperature of the atmosphere. This species of lepra often appears first at the elbow, or on the fore-arm, but more generally about the knee; in the latter case, the primary patch forms immediately below the patella. Within a few weeks, several other scaly patches appear along the fore parts of the leg and thigh, increasing by degrees until they come nearly into contact. The disease is then often stationary for a considerable length of time; if it does advance farther, its progress is towards the hips and loins, afterwards to the sides, back, and shoulders, and about the same time to the arms and hands. In a great number of cases, the hairy scalp is the part last affected; although the circles formed on it remain for some time distinct, yet they finally unite, and cover the whole surface on which the hair grows with a scaly incrustation, producing, especially in hot weather, a troublesome itching. In some instances, the nails, both of the fingers and toes, are thickened, and deeply indented longitudinally; either the whole, or some part of each nail is harder, and more prominent than usual.

When the lepra extends to all the parts above-mentioned, it becomes highly disgusting in its appearance, and not only inconvenient, from the stiffness and torpor which it occasions in the limbs, but painful when the skin is red and tender, as it sometimes becomes, in the flexures of the joints. The disease, however, is seldom disposed to terminate spontaneously: it continues nearly in the same state for many weeks, or months, sometimes for several years, or even during the remainder of life, yet without being apparently connected with any disorder of the constitution. An appropriate course of medicine, with a regular diet, acts very slowly on the lepra, but will at length accomplish its cure; and it then proceeds to a termination in the following manner. First, the inflammation separates from about the centres of the patches, and is no longer reproduced. The scales being farther and farther removed, a circle of red shining cuticle, deeply indented, appears within the original patch, which still retains a broad hard scaly ring, or border; this border continues till the cuticle within it attains the usual colour and texture. It then gradually softens, and the cuticular lines being extended over its entire velvety surface of the disease is cured.

It may be observed, with respect to the scaly lepra, that the patches are generally situated where the bone is nearest to the surface, as along the skin, about the elbow, and upon the ulna in the fore-arm; along the spine, as ilium, and shoulder-blade; and on the scalp. They rarely appear on the calf of the leg, or the shinny part of the arm and thigh, or within the flexures of the joints. The disease almost constantly affects both sides, appearing at each elbow, or at each knee about the same time, and extending from thence along the limbs in a similar manner. But although fresh patches arise, from time to time, in different situations, there is no cessation of the complaint in the parts first affected, as happens in some cutaneous diseases; but when it is about to terminate, all the patches assume a favourable appearance at the same time, those nearest the extremities going off somewhat later than the rest. When the extremities, back, loins, and head, are all at the same time covered with dry crusts, it might be expected that the obstruction of the perspiration on so large a surface would produce disagreeable consequences; which, however, is not found to be the case.

The cause of the common lepra are not satisfactorily ascertained. Some writers maintain that the disease is both contagious and hereditary; but its contagious nature has probably been ascribed from the erroneous notion of the affinity between the lepra vulgaris, and the elephantiasis. Dr. Willan, in his accurate observation, we are indebted for the description of lepra, affirms, justly, that it is not a contagious disease. He admits, however, that an hereditary predisposition to it is occasionally transmitted from the parent to the offspring. A flow of purulent, or a languid circulation of the blood, and, what must generally be connected with it, a harsh, dry, impermeable state of the skin and cuticle, appear to constitute a fundamental part of the predisposition. The morbid effects of such a state of the integuments are most likely to be felt in the decline of life; accordingly, the disease is of more frequent occurrence, and proves more invariable after the age of forty, than at any earlier period; an observation made long ago by Hippocrates and Galen. Willan, loc. cit.

Among the exciting causes of this form of the lepra, particular kinds of diet, as dried meats, fish, oatmeal, and some incongruous mixtures of food, are usually mentioned, but not on sufficient authority: at least the disorder is very frequent in this metropolis and its environs, where the articles of diet just mentioned are little used. Nor does it appear that the general opinion, that lepra is more prevalent in sifting-towns on the sea-coast, than in other situations, rests upon any better foundation. Exposure to cold and moisture, and the accumulation of fords on the skin, are the only exciting causes of this variety of lepra which Dr. Willan has been able to point out. From the last-mentioned cause, he says, it frequently arises in bakers, bricklayers, labourers, coal-heavers, duff-men, laboratory-men, and others who work among dry powder substances; for these persons are not able to attend very carefully to personal cleanliness, from the want of public baths, and an imperfect supply of water in their own houses. For our own parts, however, we have seen the disease most frequently in females, where the last-mentioned circumstances had not operated.

2. LEpra aboloides. In this form of lepra, the scaly patches are smaller than in the lepra vulgaris, and have their central parts a little depressed. The eruption usually begins about the elbow, with an inflamed, hard, protuberance, not much larger than a pimple, and of a dull red colour. These, in a short time, dilate to nearly the size of a silver penny: two or three days afterwards the central part of them undergoes a suppuration, within which minute white scales may be observed. The surrounding border, however, still continues to be raised, but it retains the same size, and the same red colour as at first. All the fore-arm, and in many cases the back of the hand, is spotted with similar patches, which seldom become confluent; but there is sometimes a white incrustation round the point of the elbow. This eruption appears in the same manner upon the joint of the knee, but without spreading far along the thigh or leg. It rarely, if ever, appears on the trunk of the body, or on the face.

This is a disease of long duration, and not less difficult to cure than the foregoing species of lepra; even when the scaly patches have been removed by a perseverance in the use of suitable applications, the cuticle remains for a long time red, tender, and brittle; but the small hairs of the skin are not destroyed, nor altered in their colour and texture, as some authors have stated, and as occurs in the leucæ. This form of the disease seems to have been ranked by the ancients under the head of albulae aploths, which Galen affirms to be a lighter affection, and less rough than the common lepra. Cellius, indeed, has classed it (under the generic term vitiligo) with the leucæ; but he points out with care the distinction between the slight albus and the incura leucæ.

The exciting causes of this form of the disease are probably
Leprosy.

bally the same as those of the preceding species. It chiefly affects women and children; and is not infrequently seen, according to Dr. Willan, in those who are employed to dress flax, hair, or feathers.

3. The lepra *nigricans* does not differ much from the lepra *vulgaris*, with respect to its form or distribution; but chiefly in the colour of the patches, which are dark and livid. They appear first on the legs and fore-arms, extending afterwards to the thighs, loins, neck, back, and hands; their central part is not depressed, as in the *albida*. They are somewhat smaller than the patches of the *L. vulgaris*, and have a livid or purplish border. The skin, likewise, appears of a livid colour through the feely incrustations, which are seldom very thick. It is further to be observed, that the scales are more easily detached than in the other forms of lepra, and that the surface remains longer excoriated, discharging lymph, often with an intermixture of blood, till a new incrustation forms, which is hard, brittle, and irregular. This complaint is particularly troublesome when it covers the scalp.

The *lepra nigricans* affects soldiers, sailors, seadmen, flage-coachmen, butchers, brewers'-labourers, and others, whose occupations are attended with much fatigue, and expose them to cold and damp, and to a precarious or improper mode of diet. Women, habituated to poor living, and constant hard labour, are also liable to this disease. It was probably comprised under the denominations of *black elfus* (*Mocca*), by the Greeks, and of *black aloobak* by the Arabsians (or *black morpha* of their translators.) On comparing their accounts, however, it will be found that some of them represent the black *elfus* as smooth and shining, like the leucæ; while others assert that it is rough and scaly. By this inaccuracy respecting the black as well as the white *elfus*, they have led succeeding writers to confuse the lepra and elephantiasis, diseases generically different.

Treatmeat of Lepra Gracorum.—In the treatment of lepra, the Greek physicians always premised bleeding and strong purgative medicines; but they seem to have depended chiefly on external applications, such as alun, sulphur, nitre, lupines, cabbage-leaves, elm-bark, the dung of goats, mice, and foxes, human urine, and the gall of bears. They likewise used several vegetable and mineral substances, which had a corrosive or vesicating quality; as hellbore, colophon, the roots of white lily, onion, bayruth, arsenic, rancanulus, and anemone, the seeds of maifard, and barberry, quicklime, nitric, &c. Remedies of this kind, or even blisters, are, however, found to have only a temporary effect, their operation being soon succeeded by a re-production of the feely crusts. Liniments, composed of tar, or of some mercurial preparations, have been much employed, both in ancient and modern practice, with somewhat more beneficial effect.

Of all the external remedies, however, which can be employed in the two first species of lepra, frequent bathing or washing is the most advantageous. Dr. Willan was averse to warm-bathing, or the external use of any mineral water, from some theoretical notions, and censures especially the Bath waters, as having converted many cafes of flicht eruption into a confirmed leprosy. (Dr. Medicam. Operat. sect. iii. c. 7.) It is pretty well ascertained, however, from experience, that not only the waters of Bath, but also the sulphurous waters of Harrowgate, Croif, Moffat, &c. used both externally and internally, prove very beneficial in many cafes of the lepra. Where the skin is not very irritable, much advantage may be also derived from baths prepared with a solution of alkaliized sulphur, and muriate of soda; and when the surface is very tender, simple ablation with warm water, or bran and water, has the effect of abating the tingling or itching of the skin, of encouraging the removal of the scales, and of rendering the skin fester and more pliable. Similar effects are produced by the use of the Bath waters, according to Dr. Falconer. (See Memoirs of the Med. Society of London, vol. iv.) "The method in general pursued," this respectable physician states, "is to order the patients to bathe twice or thrice a week, according to their age, strength, and other circumstances. This course is accompanied with a direction to drink the waters, which, at a medium, are taken in the quantity of about a pint daily, and are thought thus to second the good effects of the bath, by promoting an easy and gentle perspiration. If the amendment appears to proceed according to expectation, no other medicines are given, but occasionally such as are opening, if the body be costive." Dr. Falconer also states, that the whole number of persons admitted into the Bath hospital for this disease in the space of four years, from June 12th, 1775, was 83; of whom were discharged 52 "cleaned", and 24 "much better.

Bathing in sea-water, Dr. Willan observes, is a certain auxiliary in the cure of lepra. "It is useful, and seems proper, first to use a bath of warm sea-water, till the skin be softened, and the feely incrustations removed; after which a cure is soon obtained, especially in young persons, by bathing in the open sea. As the disease is apt to recur in winter, or in spring, the same plan may be requisite for several successive summers; but I have known it, by perseverance, finally eradicate the complaint. A simple warm-bath, the same physician observes, "with moderate friction, likewise contributes to remove the scales, and to produce a soft red skin, which, in time, regains the usual colour and texture. This plan is sufficient in the slighter cafes of lepra, without the use of internal remedies. If the disease afflicts the extremities only, bathing the whole body is not necessary; it may be enough to apply steam, or warm-water, frequently to the disordered parts." Loc. cit.

Of the mercurial preparations employed externally, we learn from the fame author, the muriate, (or sublimatum,) and the unguentum hydrargyri nitratii, seem most efficacious in restoring the cuticle, after the leprous crusts are removed. He does not, however, think the latter preferable to the tar-ointment, which Dr. Willis and others have recommended. This ointment should be well rubbed upon the parts affected every night, and carefully washed off, the following morning, with warm-water, or with a slight alkaline lotion. We may add, that in sight or insipient cafes, where there is much dryness and an inritable state of skin, the scales may be often removed by a spirituous lotion; and that the thick crusts which sometimes form upon the patches, may be softened and removed by strong alkaline applications. The use of the decoctions of *fritum dulcamara*, or herb bitter-sweet, or of elm-bark, by way of lotion, has also been found of considerable service in several infirmities.

Many internal remedies have been employed and recommended for the cure of lepra, the efficacy of which has not been strongly established by frequent experience. Respecting thieves, Dr. Willan remarks, that antimonials, sulphur, and nitre, have not alone any considerable efficacy; that decoctions of emollient herbs, of guaiacum-wood, farfapariila, mezereon, or of elm-bark, which have been recommended as specifics, by no means deserve that character; that calomel, *hydargyrum calceatus*, *plumbum hydargyrum*, or mercurial frictions, applied so as to produce salivation, do not remove the difæce; and that the nitrous and muriatic acids, lately recommended in obstinate cutaneous eruptions, though
LEPROSY.

though successful in some cases of leprosy, have been given in other cases, for three or four successive months, without any manifest advantage. The tincture of cinchonæ has often been prescribed for the lepra Greceorum, as on the authority of Dr. Mead; but that physician recommended it only in cases of elephantiasis, or lepra Arabum; and it has been found totally useless in the scaly lepra. See Falcone, loc. cit.

The following substances may be mentioned, however, as having evinced considerable efficacy, when taken internally, in many cases of lepra. The corrosive sublimate of mercury, dissolved inspirit, and taken in small doses for a length of time, has sometimes proved useful; especially when its operation was assisted by some antimonial, given at the same time, with any of the decoctions above-mentioned. The caustic potash in solution, or aqua bali puri of the late dispensatories, given in the dose of twenty or thirty drops, thrice a day, in a cupful of any mild fluid, has also manifested some influence over the disease. But the preparations of arsenic have been employed with more considerable success, in obstinate cases of lepra, both in form recommended by the late Dr. Fowler, and in that of Dr. De Valangin. The doses of the solution prescribed by Dr. Fowler are larger than are necessary. Five or six drops taken three times a day will be generally sufficient for an adult. We have seen several cases in which the disease yielded readily to this remedy. See Dr. Willan’s Treatise, 2d edit. p. 137, where is also an interesting communication on the subject, from Dr. Girdlestone, of Yarmouth.

Among the vegetable remedies, the tincture of black hellebore has been occasionally prescribed by Dr. Willan, its dose being regulated so as not to disorder the bowels, and he is of opinion that it has some efficacy; but not more than the mineral remedies already mentioned. The decoction of the twigs and leaves of the solanum dulcamara (Linn.), has also been found beneficial in the scaly lepra, when taken internally, as well as when applied externally as a waft. Out of twenty-three cases, in which it was employed by Dr. Crichton, two only relapsed its action; all the others were cured. The decoction is now ordered in the pharmacopoeia of the College, an ounce of the plant to be boiled in a pint and a half of water down to a pint. Of this decoction Dr. Crichton prescribed two ounces, at first, to be taken every morning, noon, and evening, but the quantity was afterwards increased, until the pint was consumed every day; at the same time, the patient was ordered to wash the skin with a stronger decoction of the same plant, which considerably accelerated the cure. The remedy seldom begins to exhibit any evident good effects for the first eight days.

The remedies above-mentioned are applicable only to the two chief species of lepra; none of them being particularly serviceable in the lepra nigricans. This form of the disease requires, in the first place, a regular and nutritive plan of diet, with moderate exercise; it may be afterwards wholly removed by the use of cinchona, and the mineral acids, fever-bathing, &c. Willan, loc. cit.

It will be observed, before we conclude, that, in the venereal disease, circular patches sometimes appear, which resemble those of the lepra nigricans in size and colour, but which are not incurable. The dryness and hardness of the skin, so remarkable in the lepra vulgaris and algæ, do not occur in the venereal lepra; its patches, when somewhat advanced, being as soft and pliable as other parts of the skin. These patches are generally distinct, and at a distance from each other; they seldom exceed the size of a pilling; yet it is probable, Dr. Willan remarks, that they might acquire a greater magnitude, if the progress of the disease were not early arrested by the use of mercury. As the disease yields to the influence of this remedy, a circular red spot appears for some time in the place of each declining patch, and a minute shallow depression, like a cicatrix, is left at the centre; but no permanent discolouration of the skin remains, as in some other cases. If no medicines were employed, these, like other syphilitic eruptions, would at length terminate in ulcerated blotches.

LEPROSY of the Jews. The nature of this disease, which appears from the writings of the Hebrew legislators to have prevailed extensively among that people, after they quitted Egypt under his guidance, has been the subject of much dilussion, and of considerable difference of opinion. Some writers have referred it to one of the species of leprosy above-mentioned, and some to the other; and some again have considered it as a disease peculiar to the Hebrew people, differing from every malady with which other nations have been afflicted, and not by Providence upon them, as a supernatural punishment. Many of the ancient historians assert, that the Hebrews were expelled the Egyptian territories, in consequence of the general or even universal prevalence of the leprosy among them. Manethon, an Egyptian, who wrote a history of the religion of his ancillors, makes this assertion; and a similar account is given by Lycurgus, Plutarch, Josephus, Tacitus, and others. The learned Jewish writer, Josephus, however, denies these accounts as altogether fabulous; and states some substantial arguments in proof of their absurdity and falsehood. (See Joseph. Antiq. Judic. lib. iii. contra Apion, lib. i.) The concurrent testimony of the historians, physicians, and poets of antiquity, indeed, goes to prove, that the inhabitants of Egypt, for many ages, were subject to elephantiasis, and that, in fact, the disease originated on the borders of the Nile; and modern observation has ascertained its more recent prevalence in the same countries. This circumstance seems to have led some writers to conclude, that the Hebrew leprosy was the elephantiasis, or lepra Arabum, as it has been called. But a consideration of the symptoms, enumerated by the divine lawgiver, indicates the conclusion, that the majority of writers have drawn upon the subject, that it was neither the elephantiasis, in its ordinary tubercular form, on the one hand, nor the scaly lepra of the Greeks (which, however, it more nearly resembled in its external appearance) on the other; but that it was the leprosc of the Greek writers, the eunomos of Celsum, and the white albaras of Avicenna, and the other Arabic physicians. (See Lyrec.) See also Leon. Euchili, Parad., lib. ii. cap. 16. Greg. Hort. Obf. Med. lib. vii. p. 332, &c. Campanella, Ord. Medic. lib. vi. cap. 23. art. 3. Foredl, Obf. Chirurg. lib. iv. Obf. 7. Raymond. Hist. de l’Elephantiasis, p. 64. Hender, vom Abendlandischen Aufstaz, p. 341.

It will be sufficient to compare the observations of Avicenna, when pointing out the distinction between the albaras and the algæ (morpha of the translators), with the marks of differentiation detailed in the book of Levitica, respecting the ulean leprosy, and those forms of it which were not deemed unclean, in order to be convinced that the same disease is, in both cases, under the view of the writer. Avicenna states that "both species of algæ (viz. albus and melas of the Greeks) are confined to the skin, and merely superficial; but the albaras affects both the skin and the flesh, even to the bones." And again: "there is this difference between the white algæ and the white albaras, that hairs grow upon the skin affected with the former, and they are of a black or brown colour; but those, which grow in the albaras are always white." and at the same time the skin is more defpelled than, without the melas face.
Leprosy.

face of the body. Some depression may, perhaps, occur in the skin, but it is very slight. Moreover, a puncture of the skin with a needle draws blood in the guada; but no blood follows it in the furas, only a watery humidity; and this is incurable.” (Avicenna, Canon. Med. lib. iv. Fen. letr. iii. cap. 9.) In the five or six species of leprosy described by Moses, namely, as beginning with a scab or bright spot, a swelling, a rawness of the heel, a boil or ulcer, and a burning or inflammation, as well as the leprosy in the head, and that connected with baldness, it will be observed, that the two characteristic symptoms are the subi- nes of the hair, and the depuration of the skin conjoined, as in the quotation from Avicenna. The whiteness of the surface alone, without change of color in the hair, or any depuration (as it occurs in the alphai, morphai, or lepra Grzorum), is expressly noted not to constitute an uncleane leprosy. When a man shall have in the skin of his flesh a rising, a scab, or bright spot, and it be in the skin of his flesh like the plaque of leprosy, then shall he be brought unto Aaron the priest, or unto one of his sons the priests; and the priest shall look upon the plaque in the skin of the flesh. And if the hair of the plaque be turned white, and the plaque in sight be darker than the skin of his flesh, it is a plaque of leprosy, and the priest shall look upon him and pronounce him uncleane. But “if the bright spot be white in the skin of his flesh, and in sight be not darker than the skin, and the hair thereof be not turned white; then the priest shall him up that the plaque seven days,” in order to ascertain the nature of the disease by future inspection. “And the priest shall look on him the seventh day; and behold, if the plaque in his sight be at a flary, and the plaque spread not in the skin, then the priest shall him up seven days more; and the priest shall look on him again on the seventh day; and behold, if the plague be somewhat dark, and the plaque spread not in the skin, the priest shall pronounce him clean; it is but a fest; and he shall wash his clothes, and be clean.” Leviticus, chap. xiii.

Nay it appears that the whiteness of the skin, even when extending over the whole body, was not considered as constituting of itself the true leprosy, unless some excoration, or appearance of “raw flesh,” was conjoined with it, or the hair was changed to white, or the depuration of surface was observed; and even after excoration had occurred, if it were scaled over, or became white, nevertheless the person was declared clean. “And if a leprosy break out abroad in the skin, and the leprosy cover all the skin of him that hath the plague from his head even to his foot, wherewith the priest looketh; then the priest shall consider; and, behold, if the leprosy have covered all his flesh, he shall pronounce him clean that hath the plague: it is all turned white; he is clean. But when raw flesh appeareth in him, he shall be unclean. And the priest shall see the raw flesh, and pronounce him to be uncleane: for the raw flesh is unclean; it is a leprosy. Or, if the raw flesh turn again, and be changed into white, he shall come unto the priest, and the priest shall see him: and, behold, if the plague be turned white, then the priest shall pronounce him clean that hath the plague; he is clean.” (Lev. xiii.) And, in like manner, when the cutaneous disease originates from a “boil,” or from a “hot burning,” (i.e. if there be a boil or a bright spot on the body, or if there be a white point on the skin, or if there be a white point on the back, or if there be a white point on the head, or if there be a white point on the legs), when the priest toucheth it, he shall declare it to be a leprosy. And if the priest touch the plaque, and the plaque be therein and, if it be not lower than the skin, but be brown and thicke; then the priest shall him up seven days, and if, in the mean time, it remains stationery, “it is a burning boil, and the priest shall pronounce him clean.”

And, further, when the hairy scalp, or the beard, is affected with leprosy, “if it be in sight deeper than the skin, and there be in it a yellow skin hair,” the person is pronounced uncleane; “it is a dry scalp, even a leprosy upon the head or beard.” But even if there should be no depuration of the surface, yet if there be likewise no black and thick hair (i.e. hair of the natural appearance), it is still to be considered as “the plaque of the scalp,” and the person is to be blotted up for seven days, and to be suffered, for the purpose of more accurate investigation.

Lastly, when after these successive extinctions and examinations, at intervals of seven days, in any of the cases, the uncleane leprosy is confirmed; then “the leper in whom the plague is, his clothes shall be rent, and his head bare, and he shall put a covering upon his upper lip, and shall cry ‘uncleane, uncleane.’ All the days wherein the plague shall be in him, he shall be defiled; he is uncleane: he shall dwell alone; without the camp shall his habitation be.”

It is to be inferred, from the preceding quotations, that the Hebrews, during their migration from Egypt to the land of Canaan, were subject to a variety of diseases of the skin and muscular solids, to which the appellation of leprosy was applied, as a general term; but that the most incurable and loathsome species, which was called the lpropy, by way of eminence, was that malady, which has been subsequently known in the countries which they traversed and inhabited, and on all the eastern shores of the Mediterranean, under the various denominations above mentioned, of leucis, vitiligo, albaras alba, and elephantia alba (Pln. Hift. Nat. lib. xxv. cap. 5). That it was not the elephantiasis of Aretæus, in which the face was deformed with tubercles, the lips thickened, the note dilated, the ears enlarged and tuberous, and the countenance disfigured, with a reddish brown complexion tending to black; and ultimately with an ulceration of the rugous and tuberculated parts, (see Elephantia- sis), is obvious from a perusal of the foregoing description. The extreme subternis, indeed, is mentioned in various parts of scripture, as characteristic of the leprosy, and is several times compared to that of fow. This color is the only circumstance that is stated, in respect to the miraculous lep- rosy of the hand in Moses himself, as well as in that of Mi- niam and Gehazi: (see Exodus, chap. iv. ver. 6, also 2 Kings, chap. vi. ver. 27. Numbers, chap. xii. ver. 16); and the bright and smooth surface and depuration of the spots also afford a contrall to the prominent and rough tubercles of elephantiasis. Nevertheless the leuce has some affinity to the elephantiasis in the lost of sensibility in the integuments and muscles which are affected by it. It would seem, however, to be a legitimate inference from the simile of Moses, that the tubercular elephantiasis was either extremely rare, if not altogether unknown to the Hebrews, or that it was not deemed unclean or contagious.

It is scarcely necessary to remark to the English reader, that the word plaque, in the preceding passages, obviously signifies only the spot or disease; and implies nothing pesti- lential or infectious. The word, in the Septuagint, is δερματικον, ὑποσκολυτον (a stroke); the latter of which is used in the Vulgate.

It is by no means clear, indeed, that this form of leprosy was actually contagious, or was even deemed contagious; although so much care was enjoined by the law in the examination of the symptoms, and the expulsion of the diseased from the camp was strictly commanded, in case the existence of
of the true leprosy were ascertained. For in the first place, so prehension of the communication of the disease by infection is any where explicated: the leprous person is said to be unclean. But other circumstances, where no contagion or communication of disease could be suspected, were said, in like manner, to render a person unclean; and the law enjoined, in these cases also, a temporary separation of the person from society, and similar rites, offerings, and ablations, at the time of being declared clean before the priest. (Levit. chap. xv.) Thus any issue or discharge from the body, the occurrence of the catamenia in women, child-bearing, &c. all rendered a person unclean, and equally subject to separation and the subsequent ceremonies. It would seem, therefore, that the loathsome and foul nature of the disease, which inspired this people with a similar horror and disgust to that which is felt towards a corpse ("tanquam nihil a cadavere differentes"); Josephus Antiqu. Judaic. lib. iii. chap. x. see also Numbers, chap. xii. ver. 12.) was the principal reason for the severity of the law of exclusion, which was ordained against lepers. For we are informed by Josephus himself, that, so far from being supposed to be capable of infecting those about them with their disease, "lepers, in many countries, not only mix in society, but are even held in high estimation; so far from being banished, or looked upon with contempt, they are honoured, in warlike expeditions, with military dignities, and with offices of trust in the administration of public affairs; neither are they excluded from the places of public devotion." (Loc. cit.) The scriptures, indeed, furnish us with an example of the high station of a leper, in the person of the Syrian general, Naaman, who was in great favour with his king. And even among the Israelites themselves, it would seem that the exclusion of the leprous was not very rigidly enforced. For we find Gehazi, the servant of Elisha, filled in the employment of the prophet, and conversing even with the king, after the leprosy had been inflicted on him "and his feed for ever:" (2 Kings, chap. v. and vi. and again chap. vii. v. 4.) to say nothing of the four lepers sitting at the gate of Samaria, who afterwards returned to communicate the news of the departure of the Syrian camp. (Ibid. chap. vii.) And in after times the lepers had free access to Christ, and joined in the crowds that followed him. (St. Matthew, chap. viii.) They were also inhabitants of the towns and villages; for Jesus was "in the house of Simon the leper, in Bethany." (Ibid. chap. xxvi. v. 6.)

The facts, then, afford more than presumptive evidence, that the Hebrew leprosy, the leuce, or vatisgo alba, was not a contagious disease, any more than the white scale leprosy, or elephantiasis, was equally void of contagious qualities, as we shall presently state, notwithstanding the strong allusions to the contrary, among the ancients. We have already observed, however, that the latter was considered as a consequence of the white leprosy in many instances, or as the same disease, in a more severe degree; for the leprous was said to change into elephantiasis (Galen. de Tremor. præfcr Nat. cap. 13.); and this author also mentions two cases, in which, on the contrary, elephantiasis was changed into lepra by a particular mode of treatment. Galen. de Simplic. Med. Fac. lib. xi.

Little can be said, that shall possibly any interest, respecting the treatment of the leuce, or Jewish leprosy. It was generally deemed an incurable disease in ancient times, and is almost unknown, we believe, at present in Europe. It still, perhaps, appears occasionally in Iceland, and other northern regions, as a precursor, or as a modification of the elephantiasis, according to the observation of a late intelligent traveller in the island just mentioned. He states, that he saw a woman affected with a horrible disease, which is there called Lichdrum, by which her face was so corroded as to present a most disgusting spectacle. Her legs and hands, he adds, "were swollen to an enormous size, these latter being also covered with a thick and almighty white skin lying in great swelles." (Hooker's Journal of a Tour in Iceland, p. 135.) The thickened and rugged skin, with the ulcerations of the face, belong to elephantiasis; while the morbid subtilum is characteristic of leuce. Mr. Hooker also expresses his opinion, that this disease was not contagious. No light has been thrown upon this disease by a still later traveller in the same island, who has recounted the symptoms of elephantiasis, as commonly given in books, and apparently added nothing from personal observation. (See Mr. Holland's Paper on the Diseases of Iceland, in the Sir G. Mackenzie's "Tour" in that island, just published. Dec. 1810.) Professor Henler mentions a case, which he once saw for a few minutes, and which appears to have resembled that mentioned by Mr. Hooker. "The whole countenance was puffed up; the cuticle was of a dirty white, or whitish-grey colour, dry and shrivelled; but soft to the touch, as if diürread with a watery fluid; with fissures here and there, from which some exudation took place." The cuticle also exhibited some furrowed and powdery exfoliations. Henler remarks, that the comparison (applied by Aaron to his sister Miriam, in Numbers, chap. xii. v. 12.) of such a person to a dead and macerated fetus, is a most happy illustration of the appearance. ("Let her not be as one dead, of whom the flesh is half consumed, when he cometh out of his mother's womb.") The physician who attended the patient, seen but once by Henler, compared the appearance of the skin to that of thick, stiff, dried leather; it was so thick, that an experienced surgeon made several attempts to open a vein, without success, in various parts of the body. There was great swelling, thickening, and tension of the eyelids, with a frequent ophthalmia, and great tenderness to light. A thick and festid crust covered the scalp. She was twice so nearly cleared of the leprous, as to go out of doors again; the first time by large doses of conium with sublimate of mercury; the second, by tincture of cantharides, after antimonials and mercurials had increased the symptoms. A third time she was improving much, under the use of small doses of arsenic, which, however, was necessarily omitted; and she ultimately died. (Henler vom Abendlandischen Auflatz 3' Abschluss, § 11. p. 351.) It is worthy of remark, that the leprous, in this case, subverted a pulmonary consumption, the symptoms of which never afterwards returned.

Of the causes of this form of leprosy, we shall say nothing, until we come to treat of the leprosy of the middle ages.

With respect to the leprosy of the archives and of clothes, mentioned in the Mosaic code, it is probable that the expression was merely analogical, the spots and diseafcbations which appeared upon the vails and articles of apparel being looked upon as resembling the leprous spots: while, at the same time, as they were most probably the consequence of humidity, the appearance of them might either actually accompany, or precede and prognosticate, diseases in the inhabitants of the houses and wearers of the garments. (Levit. chap. xiii. and xiv.) It is no where said that the disease, called leprosy, is capable of being communicated to the inhabitants or wearers, in these cases; but that it is unclean. The garments were ordered to be burnt, and the houses to be taken away, and replaced by others, or the house ultimately
to be destroyed, when, after certain inspections by the priest, the greenish or reddish spots in them continued.

Leprosy of the middle ages. The history of Europe, from the sixth to the fifteenth century, is scarcely less full of the descriptions of the physical difficulties of the people, occasioned by famine, pestilence, and diseases of the most loathsome and fatal kind, than of the political and moral evils which befall them. Among the maladies of those times, leprosy, under all the forms to which the term has been applied, appears to have existed so generally and unceasingly, as to have claimed a more universal attention than even the plague itself. It was one of the first subjects, on which the active benevolence of the early Christians exerted itself, and ultimately it absorbed a very large proportion of the wealth of Christendom, which was appropriated by the donations of the pious to the maintenance and relief of those who were afflicted with it. These immense charities, however, were at length administered under great abuses, and afford no accurate grounds upon which to calculate the extent of the prevalence of the malady.

In investigating the history of the disease in the middle ages, we shall probably find it sufficiently clear that the leprophobias, or tuberculous diseases, (the Lepros of the translators of the Arabians,) was the principal form against which the precautionary laws were framed; but that almost all cutaneous diseases were popularly considered as of a leprous nature; that, in fact, many mistakes were committed, and many wilful deceptions practiced, by which other diseases were confounded with elephantiasis; and that its disappearance from Europe is probably the result of the amelioration of the moral and physical condition of society, which the progress of civilization and science has brought about.

The general opinion, which was prevalent among the Greeks and Romans, that leprous diseases originated in Egypt, is in some measure confirmed by the particular consideration given to them in the first history of man; and the more copious and distinct description of these diseases, subsequently given by the Arabian physicians, as well as the accounts published by travellers in more recent times, (see those of Prosper, Alpinus, Tournefort, Neuber, Bruce, &c.) who witnessed their frequent occurrence in that and the neighbouring countries, have led to a common belief, that the infection was brought into Europe, in the eleventh century, by the armies that returned from the crusades. But independently of the doubts, which may be entertained, in respect to the contagious nature of elephantiasis and lepra, there is sufficient evidence recorded, especially among the transcriptions of the faults, in proof of the prevalence of leprosy in the well, at a much earlier period. Lepers are mentioned in many public acts, according to Muratori (Antiqu. Ital. Med. Ét. t. ii. diff. 26.), in the sixth century; and Gregory of Tours speaks of a place, where these unfortunate persons were accustomed to walk themselves, as well as of a hospital appropriated for them. Gregory the Great, in the same century, likewise alludes to the subject, and particularly mentions one leper, "quem deinde vulneribus morbus leptherias deferoxat." In the following century, Rhotaris, king of the Lombards, published an edict against lepers, by which they were considered as dead in the law, and enjoined not to come near to found persons, but to appraise them of their approach, by making a noise with a wooden clapper. There was a river near Atri, in Lombardy, famous in those times for the cure of leprosy; whence, in the eighth century, the Lombards were considered as a filthy leprous people; and the wife pope Sylvester, upon the plea of leprosy, dissuaded the king of France from marrying a Lombard princess. So early as the eighth century, St. Othmar, in Germany, and St. Nicholas de Corbie, in France, instituted leprosies houses, which had been already numerously established in Italy. King Pepin, in 757, and Charles the Great, in 789, issued ordinances, by which the marriages of lepers were dissolved, and their association with the healthy prohibited. In the life of St. Athanasius, in the ninth century, lepers are also mentioned; and indeed, in general, the acts of the saints, compiled by the Jollandists, are replete with examples of the malady, throughout Europe, in the middle ages; even in the life of St. Antoninus, so early as the fourth century, a case of leprosy, "torrediumfima elephantica lepra," is mentioned. Muratori, loc. cit.: also Raymond, Histoire de l'Elephantiasis, p. 157: Henri?l, Uber den Aussatz, p. 211.

These facts imply the general prevalence of leprosy in Europe, long antecedent to the Crusades. It is clear, however, that many severe diseases afflicted Europe to a much greater extent, and with augmented virulence, about the period when those fanatical expeditions were executed, or rather from the tenth to the sixteenth centuries, than before; and, among the rest, the leprosy appears to have been everywhere prevalent. Every country abounded with its hospitals, established for the exclusive relief of lepers, although the number of these institutions has been probably exaggerated. Several authors have, by an error in translation, quoted Matthew Paris (Hist. Angl. ad annum 1244) for an affirmation, that nineteen thousand lazarettos existed in Christendom; but that author only states, that the hospitals were, at that period, possessed of 19,000 "manorios Habent hostitarii novem decem millia manoriorum in Christianitate." It is affirmed, however, that Lewis VIII., king of France, made bequests, in the year 1257, to two thousand leproseries within his own kingdom. (Raymond, loc. cit. 166. Collect. des Hift. de France. Du Cange, Glos. voc Lazari.) In this country, there were a great number of these establishments. It is affirmed, that the city of Norwich alone contained five. (Sprengel, Geschichte ii. Theil, p. 491; who quotes Hinchinloun, in the Poit. Mag. for Feb. 1789, p. 93.) The most extensive institution of this kind was in Leicestershire, at a place thence called Burton-Lazars; it was founded in the reign of king Stephen, and dedicated to the Virgin and St. Lazarus, and became possessed of immeasurable riches; so that all the inferior lazaret-houses in England were in some measure subject to the master of it, as he himself was to the master of the lazars at Jerusalem. (See Nichols's Hist, of Leicestershire.) In London there were six, according to Becket, the largest of which was that of St. Giles, without Temple Bar.

Moreover, the general existence of leprous diseases is further evidenced by the creation of an order of knighthood, which sprang from the singular combination of military ardour with a zeal for the religion of peace, so prevalent in those times. In the parable of the rich man and the poor man covered with ulcers, recorded in the New Testament, the latter was mentioned by the name of Lazarus; whereas the devout disposition of the times invented a St. Lazarus, whose name was given to the order of knighthood, and who was deemed the tutelary saint of the leper-houses, and of each individual leper. So far, indeed, did the milky piety of the age extend, that not only was every man, who returned from Palestine afflicted with foul sores, deemed a saint, Lazarus; but was particularly recommended to the devout, as one under the special punishment of God, for the benefit of his soul. Wherefore pious persons of the highest rank believed that they could bring themselves no greater favour...
favour in the eyes of the Deity, than by their attention to
telecly suffering, by wailing, killing, and even licking
their wounds. Not only priests and archbishops, but even
kings are recorded to have performed this nauseous piety at
certain leaffons. King Robert of France, and Louis IX.,
have been particularly mentioned as practising these cer-
emonies. (Du Cange, voc. Lazar. Joinville Hist. de St.
Louis. Sprengel, Geschichte, ii. 459, &c.) The kings of
St. Lazarus had the double duty assigned them of holy
warriors and attendants upon lepers; and the lazaretos were
placed generally under their control. Lepers, indeed, were
admitted into the order, and the multiplication of it was also
required to be a leprous knight. (Medicin de Medicis
equilibr. dignitate ordinis, p. 72, quoted by Henler.) The
immense wealth, which they accumulated, became at length,
however, a temptation to the rapacity of some sovereigns;
and Philip V., especially, accused all the hospitallers in
France of high treachery, by conspiring with the Turks and
Jews, seized their property, and ordered them to be burnt.
We may observe, by the way, that the application of the
name of Lazarus to every thing relating to leprosy, affords
another proof of the very vague manner in which the sub-
ject has been generally confidered. For not only was the
disease of Lazarus not termed leprous by the divine speaker
of the parable; but the statement that his body was
"covered with leprosy," neither represents the picture of the
Jewish leprosy, nor of the elephantiasis, nor yet of the lepa
of the Greeks. (See a learned diff. by Fred. Hoffman,
"De Morbo Lazari," in his works, Supplem. tom. iii.
P. 553.
In all the towns, where lazaretos were establfihed, med-
ical officers were appointed by the police, to examine all
persons, who were supposed to be affected with leprosy,
previous to their feclusion in those receptacles; indeed,
where no fue establishments existed, huts were erected a little
way out of the towns (where also the hospitalls were gen-
erally placed) for each individual leper. The rules and
edicts, with regard to the conduct of the lepers, were, as
far as the circumstances admitted of it, nearly copied from
the Mosiac laws. It is obvious, however, from the writings
of those physicians, who held the office of examiners after
the revival of learning, and indeed it was avowed by them,
that the tubercular leprous, or elephantiasis, was the disease,
to the detection of which their inquiries were particularly
directed. The earliest writers, who appeared in the dawn
of modern learning, (and several of whom added original ob-
ervation to what they borrowed from Avicenna, and the
other Arabians,) described the elephantiasis under the ap-
pellation of lepra. (See the works of Guid. de Caulco;
Guil. de Saliceto, and the Compendium Medicinae of our
learned and able countryman, Gilbertus, who lived about
the reign of Edward I., and has left a descrip-
tion of leprosy, so full and minutely, as to evince a
considerable share of personal observation, notwithstanding
the charge of plagiarifm from the monk, Theodorick, which
Dr. Friend enforces against him.) Greg. Horfl, who was
one of the appointed examiners at Ulm, in Bavaria, at the
end of the sixteenth century, has left us the particulars of
the examination, ufially practiced by himself and his col-
lleagues, when summoned by the magistrates for that purpofe.
After the preliminary questions relative to the age and fam-
ily of the patient brought before them, they examined him
respecting the existence of the disease in his parents and pro-
genitors; his habits of life and his associates, with a view
to the probability of contagious; his peculiar temperament,
and previous state of health, and particularly as to the sup-
prehension of customary evacuations; and then as to the cli-
mate, soil, habitation, and diet, to which he had previously
been accustomed. They then questioned him, "seriatim," as to
the state of all the functions, mental and corporeal; and
lately, denudatis partibus omnibus, they examined the whole
body, with a view to ascertain the presence or abfence of the
following external symptoms. First they inspected the head,
to see whether the hair was beginning to fall off; whether
that of the beard was becoming softer and thinner; and
that of the eye-brows and eye-lashes was disappearing; and
whether, when the hairs were pulled up by the roots, a part
of the skin was brought away with them; whether the eyes
were round and grim, the ears acuminated, the lips thick,
the nose pinched externally, the nostrils internally, and ulcerated,
the face unequally swelled with tubercles, and of a livid red hue? Whether the veins under the tongue
were enlarged with tubercles, as if varicose? Whether the
skin was unctuous, so that water ran off it, or there were
under it tubercles nearly without fenfibility, especially be-
hind the ears, and on the extremities? Whether the skin
was rough, like that of an unfeathered goose, or affected
with horrid fissures, and rages, resembling the hide of an
elephant, or covered withwarts, like the grandulines of swine,
or affected with morphea, impetigo, or a dry and incurable
flebias? Whether there were any nodes about the joints?
Whether the muscles of the extremities, especially about
the thumbs, were emaciated? Whether the nails were in-
curved? Whether the skin was fenfible to the puncture of
the surgeon's needle? Whether there were offensive ulcers
with a bad habit of body, especially ulcerations and fissures
in the fingers and toes? and whether the voice was hoarse
and obtuse? They then drew some blood, for the purpose
of examining it. "These symptoms being present," says
the author, "we deem the difeafed elephantiasis, and decree
that the patient, insomuch as he is affected with an incurable
and contagious leprosy, is to be separeted from all commu-
It is obvious, however, from the acknowledgment of
Horfl himself, as well as from the concurrent obervations
of several physicians before his time, that the elephantiasis
was by no means the only difeafe of the kind admitted into
the lazaretos. He goes on to observe, that where the tu-
bercles of the face, the thick lips, acuminated ears, flat-
tened nose, round eyes, (the essential symptoms of elephant-
iasis,) are absent; yet where the patients are affected only
with a dry and foul lebias, with putular eruptions, fissures,
and branny exfoliations, which constitute the \textit{psora}
of the Greeks; or even with great itching, emaciation, ulceration,
and exfoliations of thicker scales, affecting also the head
and face, which are the \textit{lepra} of the Greeks; nevertheless they
are wont to the lazaretos, if they are poor, for the means
of subsistence. "Hence it happens," he adds, "that here,
and elsewhere, \textit{very few} instances of real elephantiasis are
found in the lazaretos, whilst \textit{many} are there, affected only
with an obiolute \textit{psora} or \textit{lepra Gracorum}." We have also
the direct testimony of an able observer, Van Forcell, (better
known by his Latin appellation, Forellus,) who practifed
at Allemaer and Delft, in the middle of the sixteenth cen-
tury, and who has also left an account of the mode of exa-
mination of lepers, adopted by himself, that a very small
proportion of the patients, who wandered about the Low
Countries, as lepers and beggars, were true lepers; but were
merely affected with lebiasies, or some external deftruction
of the skin. "Nay," he says, "not \textit{one in ten} of them is truly
a leper, or afflicted with the legitimate elephantiasis." And
he adds the authority of a physician at the Hague, who had,
with him, lamented the carelessness or ignorance of the public examiner at Harlem, by whom a great number, (quem phriri, mihi) who were the subjects of some ordinary cutaneous eruption, were declared leprous. (See Forciti, Obscr. Chirurg. lib. iv. Obs. vii. Schol.) But, above all, Riedlin, who was physician to the leper-hospital at Augsburg, affirms that, out of fifty-nine cases, he saw but one which was elephantia-
sic, and that in a flight degree; all the rest were instances of the 
flea and lepra of the Greeks. (See Shrocck, Morb. Anf. 1669, p. 61, and Henfler, loc. cit.) It is probable, moreover, that in addition to all the ordinary cutaneous diseases, which were thus denominated leprous, the 
twenty itself (we mean the true scorbntus, which was formerly so well known in our fleets, and which appears to have been not unfrequent in the middle ages, during periods of scarcity and famine) was confounded with the same disease. This idea was thrown out by Hoffmann. "Quando magno perpendo hodierni vel primitus symptomata, vix mihi temperare possit, quin, nisi cum additionibus elephantiocorum collatis, scorbuntum leviorem elephantiasos esse spectum affirm; at in mirum morborum pro diversa regionum ac saevis constitutionum mutatione confiderem. Sed tradant hie coniectura, digna igni penitenti invigarat." (De Morbo Lazari, § v.) Prof. Sprengel also suspects that those forms of leprosy, which have been called mal de la roya in Afturia, and pellagra in Lombardy, were scorbnti (Geschichte der Arzneyklinik, ii. 486) ; and many analogies between the two diseases are pointed out by Raymond. Hist. de l' Elephant. p. 113, et leq.

The leprous complaints began to decline in number and violence, in Italy, about the end of the fifteenth century, and in France and Europe, in general, in the sixteenth. In the middle of the fifteenth century, indeed, the tubercular dis-
ease, elephantiasis, was almost unknown in Italy. For Ant. Benveni, who died very old at the beginning of the sixteenth, observes, that he once saw at Florence a stranger, affected with elephantiasis; a disease, he says, almost never seen (in his time) in Italy, and almost unknown to physi-
cians. At the beginning of the sixteenth century, Alex. Benedetti and Joh. de Vigo omit the tubercular leprosy from the list of diseases, mentioning it only cursorily, and not from experience; but the latter speaks fully of morphus, impetigo, bars, alopecia, mal morbo, and other diseases that have been classed with leprosy. (Henfler, loc. cit.) About the middle of the sixteenth century, Francis I. ordered the number of lepers in each lazaretto, or maladie, to be reported, and after appropriating a sufficient fund for their support, ordered the remainder of their revenues to be given to the grand almoner, for general use. In the seven-
teenth century, leper-houses were still continued, (though similar measures had been generally adopted since the de-
cline of the disease throughout Europe,) and were greatly abused by the admission of beggars, and idle vagrants of all descriptions, who employed every species of trick to imi-
tate leprosy, or to produce appearances of cutaneous disease. The elephantiasis itself, however, still occasionally appeared, of which several recorded cases are referred to by Henfler. Some writers, indeed, have supponed, that the changes, which took place from the close of the fifteenth century downwards, were rather changes of names than an actual disappear-
cance or diminution of leprosy; and that the vener-
real disease, which was first noticed at that period, was in fact the leprosy with a new appellation. Indeed, some au-
thors actually denominated the morbus Gallicus, or syphilis, a leprosy; as Campanelli, who treats of it among other leprous diseases, under the title of lepra Gallica. (See his Med. Predict. lib. vi. cap. 25.) But although the secondary symptoms of syphilis might be mistaken for leprosy, or called leprous, in common with other ulcerations and cutaneous affections, in a considerable number of instances, and for some time; yet, as the learned and able Altnar, after Leonicenus and others, has shown, there were many points of obvious and decided difference, in the symptoms and pro-
greos of the two diseases, as rendered such a confusion to any great extent improbable. (See Altnar, de Morb. Vener.
vol. i. lib. i.) Nevertheless, when we reflect upon the un-
varing adherence to ancient authority, which characterized the profession for centuries after the revival of learning; and when we consider, that the measles and small-pox, for in-
stance, were deemed the same disease, including also scarlet fever, so late as the time of Dioscorides (see his Trad.
de Variois et Morbills, cap. 13): we shall readily con-
ceive, how slow the early physicians would be in acknowledg-
ing a new disease, which had not been mentioned by the Ar

At all events, we are entitled to infer, from the pre-
ceding view of the subject, that, during the middle ages,
most erroneous notions prevailed respecting the leprosy,
and that the terrors of the ancients, respecting the con-
tagions and unclean nature of leues and elephantiasis, were transferred almost indiscriminately to every chronic cutaneous disease, whether scaly, fesable, purulent, or unclean, con-
tagious or non-contagious, which then occurred. And as we are now well acquainted with the latter classes of disea-
(although, from causes to be mentioned immediately, they may be much less frequent than formerly), as we know that all the forms of scaly disease, such as the modifications of lepra, pellagra, ichthysiasis, and ptyriasis, to use Dr. Wil-
plan's nomenclature, as well as the running latters, or impe-
tigines, the vescular eruptions, herpes, miliaria, and pom-
pholyx, and the lichenes, prurigo, &c. among the pub-
lous affections, are all void of any infectious quality; we must be satisfied, on the one hand, how mistaken was the charity, which erected thousands of hospitals, and appro-
priated immense treasuries, for the maintenance of those who were affected by these disorders, and for the fancied security of the healthy; while, on the other, we see the cruelty and ab
duracy of the regulations and ceremonies, which were in-
fitted in regard to such patients, somewhat after the man-
er of those enjoined in the thirteenth chapter of Leviticus,
for the Jewish lepers. In fact, a person infected with the real or fupposed leprosy, was treated like a dead body: fun-
ereal obloquies were performed, and masses said for the be-
 nefit of his soul. The whole is thus described by a French

"A priest, clothed in a furphice and robe, repaired with the crofs to the leper, who was prepared for the ceremony. The holy miniter began by exhoriing him to bear patiently, in a spirit of regiftration and penitence, the incurable affifection with which God had thriken him; he then beprinkled the sufferer with holy water, and conduced him to the church. Here the leper put off his ordinary clothes; and, having put on a black habit prepared for the purpoze, fell on his knees before the altar, between two treffles, and heard mass; after which he was again beprinkled with holy water. This ceremony, it will be remarked, differed very little from that which is usually performed at funerals. While the leper was conduced to the church, the fame verses were sung as at burial, and after the mass, which was also the fame as that which was performed for the dead, the Liber was sung, and the leper was then conduced to the houfe defined for him. When he had arrived, the priest again exhorted and consoled
confined him, and threw a shovel-full of earth on his feet. The hut (where there was no lazaretto) was small, and was furnished with a bed and bedding, a vessel for water, a cheff, a table, a chair, a lamp, a towel, and other necessaries. He was presented with a cowl, two shirts, a tunic, and a robe called bouffe, a little cask, a funnel, a rattle (des etiquettes), a knife, a flick, and a girdle of copper.

"Before the priest Quited him, he interdicted him from appearing in public without his leper's habit and naked feet; from going into churches, mills, or where bread was cooking; from washing his hands and clothes, &c. in the wells and brooks; from touching any commodities that he defined to purchase at market, except with a flick, in order to point out the article wanted; and from entering houses, or taverns, for the purpose of purchasing wine, as he had only the privilege of remaining at the door, of asking for what he required, and receiving it in his little cask. He was further enjoined not to draw water, but with a proper vessel; never to reply to the questions of any one who met him on the road, unless he was to leeward, in order that the inquirer might not be infected by his breath, and the contagious odour exhaling from his body; never to place himself in narrow roads; never to touch children, nor to give them any thing which he had touched; never to appear in public meetings; and never to eat or drink with any but lepers. In short, these wretched people were regarded as dead among the living: their children were not baptized at the fonts; and the water employed at their baptism was thrown into lonely places. When a leper was sick, the priest administered the sacrament to him, and extreme unction; and when he died he was buried in his hovel, or in the place of interment appropriated for the lepers." See Ogée, Abrecé de l'Hiilt. de Bretagne, prefixed to the Diction. de Bre- tagne.

In most places these miserable outcasts were allowed to enter the towns, near which their hovels or lazarettoes flourished, at certain times of the year, especially about Easter and Christmas. The following law existed at Martheilles. "Fermiti, constitutioe firmas de leprosos obstinandum, quod nulli Leprofi seu Mezelli, dixitos vel paisores, pollint vel debeat flare infra Maflliam, nec conversari demineps, nisi tantum per xx dies ante fachia, et per viii dies ante Natale Domini, &c."

(Stat. Maffil. lib. v. cap. 15.) When they walked, or came into a town, they made a noise with their rattles, to warn passengers of their presence. In short, their situation was truly melancholy. The ties of marriage were dissolved, where one of the parties only was affected; but they were allowed to marry when they could find a lepros companion. They were, indeed, allowed the usufruct of property; but they could neither transfer nor inherit it; they were deemed to have suffered a civil death, and to be "hors de la loi mondaine." See Henle. loc. cit. § 4. Sprengel. loc. cit. p. 491-2. Raymond. p. 112.

Yet not only were these laws executed against multitudes who were affected with cutaneous diseasés, neither properly lepros nor contagious; but it is even very questionable whether the true tubercular leprosy itself, any more than the lesser formidable baras alba, or leuce, were actually contagious. We have already stated the reasons which tend to disprove the infectious nature of the latter. (See Leprosy of the Jews.) The evidence against the probability of contagion, in the case of elephantiasis, rests partly upon the facts, which are casually mentioned, in more ancient times; and partly upon those which have been more carefully and correctly ascertained nearer to our own. The obervations of Aretæus, which have been echoed by almost all succeeding writers, are given with an appearance of terror, excited rather by an acquaintance in the popular belief, than from any actual knowledge of the fact. When we descend to the early ages of Christianity, we find these terrors perpetuated by the laws respecting lepers, which were at once the effect and the cause of a contamination of the popular opinions; but at the same time, we find kings and bishops mixing familiarly and frequently with these very objects of legal proscription, and confederating to offices which require the cloistered contact with their persons, not only without any expressions of approbation, but without any one recorded instance of the difcase being so communicated: we find, too, that for a term of several days, during certain feasts and festivals, these infected people are actually allowed to mix in the towns; facts which stand in direct contradiction to the traditional prejudices and laws upon the subject.

Defending, still farther, to the period when learning and observation had again enlightened the minds of men, we find these very prejudices and laws extending equally to a numerous tribe of cutaneous disorders which we know are not contagious, as to the elephantiasis; an error which must render the accuracy of the opinion, as to the contagious quality of the latter, exceedingly questionable. At the same time we discover the contention between observation and pre-conceived opinion in the minds of the learned, which almost breaks forth in the admission of the truth. Thus Fernel, who adopted the common notion of its contagious quality, admits, nevertheless, that from all the observations he has been able to make, he has never discovered a case which proved its excellence (De Morb. Occult. lib. i. cap. xii.) and Forestus, Fabricius, Plater, &c. who still held the popular opinion, expressing their astonishment at seeing the daily commerce between the leprosy and healthy, even in married persons, without any communication of the disease; so that they are compelled to ascribe its origin to certain qualities of the air and the diet.

When we come to the evidence of our own times, we have still more convincing testimony of the non-contagious nature of the tubercular leprosy. Dr. Thomas Heberden, still retaining somewhat of the prejudices of education, when speaking of the cases of the difcase which he saw at Madaira, says: "Notwithstanding the just abhorrence which every one entertains of this loathsome disease, it certainly is not so contagious as is commonly imagined;" and then he relates his observations, which prove that it is not at all contagious. "For I have never heard of any one," he adds, "who has contracted the distemper by contact of a leper; and, on the contrary, I not only am a daily witness of communication between lepers and other people, without the least ill consequence, but know several instances where a leprosy husband, married to a found wife, has cohabited with her for a long series of years, and had several children by her, without her having contracted the leaff symptom of the disorder, although the children have inherited it; and vice versa between a leprosy wife and found husband." (See Med. Transf. of the Coll. of Phys. vol. i. p. 32.) Still more recently, Dr. Adams has investigated the nature of elephantiasis, in the same island, where there is still a lazaretto, near Funchal; and his observations not only confirm those of Dr. Heberden, as to the non-contagious nature of the disease; but they also shew that other mistakes, which originated probably in the terrors of the imagination, when the difcase had acquired the appellation of Satyrinia (from the accumulated ears, flattened nose, and rugous front); namely, that so far from being poiffessed with a libido inexcipibilis, the pro-creative appetite and power are gradually destroyed, if the disease arise in the age of manhood, and
LEPROSY.

never developed if it commence before that of puberty. See Adams on Morbid Poisons, 2d edit. chap. 18.

It is true, that about the middle of the 18th century, Dr. Hillary had described the elephantiasis as occurring in the West Indies, with all the characteristics attributed to it by the ancients. But the description of that learned physi-

ian is but too obviously a transcript of the account given by Aretæus, uncorrected by his personal observation. (See his Obf. on the Diff. of Barbadoes.) In this the learned writer affords but one example, among a long series of medical scholars, in whom authority but too often dimmed the eye of observation, or distorted its views.

If the leprosy of the middle ages, then, were not conta-
gious, whence did it originate and spread so widely? Pro-

bably the hint thrown out by Forellius, Plater, and others, and more fully developed in the excellent treatise of Ray-

mond, already often quoted, may afford an adequate expla-
nation of the fact; to wit, that the uncultivated and mar-

thy condition of the soil; the consequent humid and miasmatic condition of the atmosphere; the fat, putrid, indigestible al-

mint, and the frequent scarcity even of that which the phy-

sical and political disorders of the times produced; the infa-

lubrious condition of the towns and habitations, both in

respect to bad situation, want of cleanliness, and other per-

nicious circumstances; in short, these combined evils, which

appears to have existed in those times and countries where

the lepers, among other frequent and distressing maladies, pre-

vailed, were, in all probability, the causes from which these
cachectic diseases sprang.

It has been satisfactorily shewn, from a review of the
domestic history of the times, in which frequent and fatal

epidemics have raged, how much these were connected with
the circumstances just enumerated (see Epidemic, and
Health); and it is interesting to trace the diminution,
and ultimately the total disappearances of these pestilences,
in proportion to the amelioration of those physical and

moral evils; and to discover, that while the happiness and

comforts of man are extended by the advancement of civil-

ization, the word diseases that haras and shorten life are at

the same time nearly extinguished. (See the excellent Obf.
on the Increafe and Decreafe of different Difeases, by Dr.
Heberden; also, Ann. Med. Regilier and Review.) If

we turn from the febrile plagues to the more chronic mal-
dies which are the subject of the present article, we find that
they have generally gone hand in hand. See SCURVY, LION
SACER, ENVOY, &c.) The history of the fcurvy, in particular,
affords an anological illustration of the influence of the cir-
cumstances alluded to, in producing many of the loathsome
symptoms enumerated among those of leprosy; especi-
ally the defecations of the skin, the swellings of the limbs, the
ulcerations, fungous excrescences, fatful discharges, gan-
grenes, and lofs of joints and limbs.—appearances as hide-

ous as any of those ascribed to leprosy. Now, this dis-

case has been banished from our fleets within the last half century, fol-

ly by the substitution of wholesome and digestible alim-

ent, and by the adoption of ventilation and internal clea-

ning; it has, in like manner, been subdued in Germany, and those
parts of the north of Europe, in which it prevailed greatly in the

time of the Romans, in proportion as agriculture and the

arts have changed the face of that once marthy and uncult-

ivated region, and obtained a regular supply of nutritious

and wholesome food.

If our space would admit of a review of the physical
and political circumstances of the times, in which leprosy

diseases have been so extensively prevalent, it would be easy
to adduce ample proof that, from the beginning of history,
these maladies have occurred under such states of society;

and that they have commonly visited, almost exclusively,
those claffes of society who were most exposed to the in-
fuence of those circumstances; namely the poor. Lower

Egypt has, from the earliest antiquity, been subject to these
diseases, and from the extensive inundations occasioned by
the overflowing of the Nile, can never be rendered a dry or

salubrious country. The ancient historians concur in their
descriptions of its heavy and miffy atmosphere, furcensed
with vapours. (Strabo, lib. xvi.) The inhabitants ate a
glutinous fort of bread made of the roots of the lotus, &c.;
and used much fish in every flate; and having few trees,
they had no wholesome fruits to conjoin with their diet.
But how much more imperfectly the Hebrews were nouris-
hed in their long march through the wildnesses of Arabia
is obvious, and indeed recorded; to which all the insalub-
rous circumstances of a camp were added. Perhaps no
combination of circumstances could be conceived more
 favourable, as well to the production of frequent pestilences,
as to the excitement of those cachectic states of the body,
in which feverbatic and leprous affections originate, than the
foil and marshes of an uncultivated land, the fordes and

mihilata of an immense encampment, frequent scarcity of
provisions, fatigue, and universal public anxiety and diffi-
satisfaction, for the quelling of which the great leader had

referece to supernatura1 means.

It appears from the account of Prosper Alpinus, a pro-

feffor of Pavia, who visited Egypt late in the sixteenth

century, that both the lepra and elephantiasis of the Greeks
were common among the poor at that period; and he

attributes them to the causes above-mentioned. "They are

compelled through poverty," he says, "to drink muddy

and semiutrid water; they eat the flesh of camels and beef,

and fish salted and half putrid, caught in the marshes and

lakes; but they principally live upon a sort of chefe, im-

moderately salted and semiutrid, which is sold at a very

low price:" (De Medicina Egyptian, lib. 1, cap. xiv.) a
diet very much resembling that formerly used on shipboard

in long voyages; when, as we have been informed, the falted
provision, which had been sometimes two years in eafe,

emitted an almost intolerable fench during its maceration,

before being cooked.

Without attempting to trace the progress of leprosy dis-

eases, in connection with the physical and political arrange-

ments in various countries, (a satisfactory sketch of which
the reader will find in Raymond's treatife,) we shall merely

exemplify this view of the subject by a bight notice of the

state of Europe in the middle ages, when leprosy and pel-

ilence of every species prevailed. From the fifth century,

when the empire at length fell under the repeated assaults
of the northern invaders to the tenth, the finest parts of Eu-

rope lay in a state of devastation, little cultivation was prac-
ticed, all the arts were neglected or loft, and clothing, habi-
tations, and food were alike insufficient and wholesome;

and for three centuries more this dilution was increased,

if possible, by the incessant wars that were waged. There

were fourteen plagues in the fourteenth century, with inter-

vals of but six years between each; and frequent famines.
The food confifled, even in England at a later period, of

much salted provision, especifally in the winter, and of a

hard and black bread, chiefly of rye, to the scarcity of

which corn, rather than to its ergoted or diseased condition,
the ignis facer, maladies ardens, and other fimilar maladies,
should doubtfes be attributed. So little were vegetables

cultivated, indeed, or gardening underflood, even in the six-

teenth century in this country, that, in the year 1509,
queen Catharine could not procure a fallad, till Henry fent

to the Netherlands, and engaged a gardener to come over to

raie
raise the proper articles here. (NORTHOUCK'S HILL. OF LOND.
BOOK 1. CHAP. 7.) HOW TOTAL DEFITUTE OF SUCH DIET MUST
THE PEOPLE IN GENERAL HAVE BEEN AT A MUCH LATER PERIOD!
SEE HEALTH OF LONDON.

In short, in whatever country an un cultivated soil, a
marshy surface, and a humid atmosphere have been found,
together with a diet generally consisting of a salted, emi-
nilurid, insufficient, or indigestible aliment, and composed
clearly of animal flesh or fih, with a small proportion of
 nutritious vegetable matter; there, from the earliest times,
human life has been shortened by the multiplication of pel-
tential fevers and cachexies of a leprous and febrile nature.
Therefore, as Raymond observes, even if the ecle-
chialical writers of the middle ages had left us no records
of the history of such maladies; the history of the soil, of
the circumstances of the times, and of the food generally used,
would afford an incontestible monument of the existence of
leprosy.

1. Leptat. Or, of the attempts to remedy a disease which
was generally admitted to be incurable, it would be futile
to enter into any detail. The treatment of those forms of
cutaneous diseases, which were clasped with the elephants,
will of course be described under their respective heads.

LEPSIA, in Ancient Geography, an island in the sea of
Rhodes, near the coast of Caria. Pliny.

LEPSINA, in Geography, a town of European Turkey,
in Livadia, anciently called "ELEPHUS" of which considerable
ruins remain; 12 miles N.W. of Athens. See ELEPSINIA.

LEPSIS, in the Greek Muse, is a name given to one of
the rules of the ancient melopeia, called alto sometimes,
ceutha; by which the composer discerns in which of the three
systems of sounds he should place his melody:—in the grave
part of the scale, called hypateida; the acute, called netaideis,
or the mean, called meloidis. See MELOPSIA and USUS.

LEPSTI, in Geography, a town of European Turkey,
in the province of Macedonia, in the gulf of Saloniki; 12
miles S. of Jenitza.

LEPTA, in Botany, so called from ληθος, slender, or
minute, from the remarkable diminutiveness of its flowers.
Louire. Cochinch. v. 1. 82.—Clafs and order, TETRAMERYNI
NAT. ORD. HEDEERACEE, Linn. Fites, J.ull.

Gen. Ch. Cal. Perianth inferior, spreading, small, divided
into four ovate segments. Cor. Petals four, somewhat triangular, furrowed, inflexed, twice as long as the calyx.
Stam. Filaments four, awl-shaped, inflexed, inserted into the receptacle at the angle of the base of the petals; anthers ovate, two-celled. Fil. Germ. superior, round-
ish, four-furrowed; style feebly antr.; stigma obtuse. Peric. Berry four-lobed, lobes ovate, slightly confluent to-
wards the centre, single-fed. Seeds roundish.
Eff. Cal. Calyx four-leaf, inferior. Corolla of four
triangular petals. Berry four-lobed, four-celled, each cell containing a feaf.
in Cochinechina, and called by the natives Cay Mat.—This
tree is about ten feet high, and exceedingly branched.
Leaves terecate, lanceolate, entire, waved, smooth. Flowers
white, very small, in compound, small, axillary clusters.

We are acquainted with this plant from Louiroue's ac-
count only, which approaches so nearly to many different
things, that we dare not offer any conjecture respecting it.
The habit of this genus very much resembles that of Ciffis,
but the character of its fruit appears to be essentially
different.

LEPTADENIA, from ληθος, slender or sharp, and αινει,
ατησις, a gland, expressive of the continued acute termina-
tion of the mafles of pollen, which makes a very peculiar
part of the generic character. Brown Asclep. 23. Mem. of
the Wernercian Soc. v. 1. 34.—Clafs and order, Pentandria
Dasyne. Nat. Ord. Contortae, Linn. Apocynae, Jull. As-
le pie sti, Brown.

Eff. Ch. Corolla somewhat wheel-shaped; tube short,
orifice crowned with five scales, standing between the seg-
ments; limb bearded. Crown of the flaman wanting.
Anthers unconnected, simple at the top. Male of pollen
erect, attached by their base, contracted and pellucid at the
summit. Stigma pointifles. Follicles . . .

Mr. Brown has examined three species, reducible to this
genus, in the Bahnian herbarium, none of which are yet
described, nor has he named or defined them specifically.
One was gathered by Forkall. They are all natives either
of the East Indies, or of Africa. They appear to be per-
nennial, herbaceous, climbing plants, clothed with a grey-
ish, impalpable, powdery down. Leaves flat, opolite. Umbil.
ch between the footstalks, sometimes eynolve. Stigma
minute.

LEPTANTHUS. See Heteranthera.

LEPTASPIS, from ληθος, slender or sharp, and ωιοω, a flake,
a genus of graffes, separated from Phorus by Mr. Brown
in his Prodr. Nov. Holl. v. 1. 211, on account of the pecu-
lar ovate concave outer valve of the corolla; but its habit
and influence are so like Pharus latifolius, that the author
himself candidly expresses his doubts of the propriety of
this measure. One species was found for Sir Joseph Banks
in the tropical part of New Holland; another comes from
the Molucca isles.

LEPTAUREA. See ZEUGIA.

LEPTIS MAGNA, in Ancient Geography, a town of
Africa, on the sea-coast, in the Syrtic region, at the S.E.
extremity of that which was particularly denominated Tri-
polis; not far to the E. of the river Cinyphis. It was also
called Neapolis. Leptis was a Roman colony, and in pro-
cess of time became episcopal. See LEMPITA.

LEPTIS PARUS, Lempita, a town of Africa, on the
sea-coast, S.E. of Adriumetum, about a mile in compass.
Some ruins of the ancient town remain. See LEMPITA.

LEPTOCARPUS, in Botany, from ληθος, slender or
sharp, and ωιοω, fruit, the minute seed or nut being pointed
with the permanent base of the filey. Brown Prodr. Nov.
Holl. v. 1. 250.—Clafs and order, Dioecia Triandria.
Brown.

Gen. Ch. Male, Cal. of several coriaceous, keeled feales,
either falciculated or imbricated, each one or two-flowered.
Cor. Petals six, membraneous; the three inner ones thinner
and narrower. Stam. Filaments three, flatflah; anthers
simple, peltate.

Female, on a separate plant, Cal. and Cor. as in the
male. Fil. Germ. superior, roundish; style solitary,
thread-shaped; stalks two or three, oblong, downy, acute. Peric. Nut small, roundish, not burling, tipped with the
base of the style, with one cell and one kernel.
Eff. Ch. Male, Calyx-foae clustered or imbricated.
Petals six. Anthers simple, peltate.

Female, Cal. and Cor. as in the male. Style one. Stig-
mas two or three. Nut crumaceous, single-fed, crowned
with the base of the style.

A genus of hard rushy plants, of nearly the fame de-
scription as Lepidopermea; see the conclusion of that article;
but more akin to the Linnaean Lepis, from which it differs
in having a simple single-fed nut, instead of a capsule
with two or three cells and as many valves. The stems
are generally quite simple, leafed, but clothed with sheaths
split at one side. Flowers either in tufts, or in spike-like
clusters. Mr. Brown thinkns those which come under the
first
LEP

first description may hereafter be separated from the latter. Examples of Lepicarpus, are Raffia dichrobas of Rottboll's Icones 8, t. 3, f. 5; and Schizanthus flexus of Linnell, Nov. Holl. v. 2, t. 259, the female plant. Seven species are defined as natives of New Holland, and there are supposed to be several at the Cape of Good Hope, besides the above, Raffia and R. umbertus of Thunberg.

LEPTOCEPHALUS, in Ichthyology. See Morris.

LEPTODECARHOMIS, a name given by Dr. Hill to some prismatic varieties of selenite. See Gypsum.

Gen. Ch. Cal. Perianth superior, of one leaf, in four or five deep, widely spreading, permanent segments, internally coloured. Car. Petals none. Nectary glandular, crowning the germen, in four or five lobes. Stam. Filaments four or five, awl-shaped, shorter than the calyx, inserted into the base of each segment; anthers roundish. Fig. Germen inferior, ovate; style very short; stigmas depressed, of from two to five rays. Peric. Drupa ovate, more or less juicy, crowned with the calyx. Seed solitary.

Eff. Ch. Calyx of one leaf, wheel-shaped, superior, bearing the flaminas. Nectary glandular, crowning the germen, four or five-lobed. Stigma divided. Drupa of one seed.

Eight species are defined by Mr. Brown, as natives of New Holland. They are slender branched shrubs, with scattered minute leaves, or none at all. Flowers minute, white, reddish or green; generally spikcd, with a small deciduous bractea to each; sometimes axillary, without bracteas. The genus is akin to the species of Thesium which grow at the Cape of Good Hope, but differs in its glandular nectary, which is either of one piece, lobed, crowning the germen, or composed of glands, each of which fiddles at the base of one of the segments of the calyx. Three of the species have a flabby five-rayed acute stigma, and five-cleft, spikcd, bracteated flowers; among which is L. Bilardiri, (Thesium drupaceum; Labill. Nov. Holl. v. 1. 68. t. 93.) from Van Diemen's land, a slender much-branched shrub, fix feet high. One, L. acerba, found at Port Jackson, has a two-lobed obstate stigma, four-cleft flowers, and no leaves. The remaining four have a drier drupa, a notched blunt stigma, and five-cleft flowers, and all grow on the south coast of New Holland.

LEPTOS LIBANOTIS, in the Materia Medica of the Ancients, a name given by fome of the Greek writers to the small frankincense, that is, such as came to their hands in small flakes, broken from the larher masses in the gathering or packing up. This was also called manna liburnia, the manna of frankincense. The word manna being of old used to express any thing formed of granules, or small pieces. The ancients esteemed this leptos libanotis, or manna liburnia, when pure, beyond any other kind, for they always valued that frankincense most, which was dried and mottl brittle; and such only as was so, could break off in the small flakes. The medicine, however, soon became subject to adulteration, and lost its credit; for the dust of the frankincense being allowed to be put up among this manna liburnia, Dioscorides tells us, that in his time people, greedy of gain, had found the way to adulterate it, by adding, instead of this genuine dust, the sifted powder of the resin of the pine tree. See FRANKINCENSE.

Gen. Ch. Cal. Perianth half-superior, in five deep, ovate-oblong, or roundish, often coloured segments. Cor. Petals five, with claws, roundish, equal, twice the size of the calyx, and much longer than the stamens. Stam. Filaments numerous, inserted into the calyx, awl-shaped, curved, shorter than the corolla; anthers small, roundish, two-lobed. Fig. Germen half-inferior, turbinbate; style simple, columnar, erect, about the length of the stamens; stigma capitulate, umbilicated, undivided. Peric. Capsule roundish, coated in the lower part, of three, four, or five cells, and as many valves, bursting at the upper part, the partitions from the middle of each valve, opposite to each calyx-tooth. Seeds numerous, linear, somewhat angular, tapering at each end, very small, inserted into the central column.

Obf. L. ambiguum only has the stamens longer than the corolla.

This genus of New Holland shrubs was confounded by Dr. Solander with Philadelphus, and by Gartner, Forster, and others with Metrodorus and Melaleuca. The former is distinguished from it by having the style deeply four-cleft, with simple stigmas, the petals broad at the base and feathery, leaves opposite and deciduous, and the habit indeed altogether unlike; Metrodorus differs in its simple stigma, extremely long thread-shaped flaminas, and more dilated habit, in which characters Melaleuca accords with the latter, with a few exceptions as to habit in the foliage of some species, but differs from it and from Leptopterum in the polyadephous flaminas.—The species of the genus before us are rigid, branched shrubs, of rather humble, sometimes prostrate, growth, aromatic when bruised; their leaves alternate, small, entire, evergreen; flowers numerous, usually solitary, white, often with a purple tinge about their organs of impregnation. The following are all at present known to us.

1. L. ficariurn. New Zealand Tea, or common Southsea Myrtle. Andr. Rep. t. 625. (L. squarrosum; Gartn. v. 1. 174. t. 35. Melaleuca ficaria; Linn. Suppl. 343. Forli. Prodr. 37. Pl. Ero. 78. Schrad. Sert. Hanss. 25. t. 15. Philadelphia ficaria; Soland. in Ait. Hort. Kew, ed. 1. v. 2. 156. Tea plant; Cook's Second Voyage, v. 1. 100. t. 22.)—Leaves ovate, sharply pointed, obliquely three-ribbed. Calyx smooth; its teeth membranous and coloured.—Native of the coast of New Zealand, where it was discovered by Sir Joseph Banks and Dr. Solander, and was thought by captain Cook to have been very serviceable to the health of his crew. Its infusion or tea is pleasantly aromatic and fragrant; if not suffered to stand too long, in which case it becomes bitter. Mixed with an equal quantity of the New Zealand Spruce, (see Dacrydium,) it was found to make excellent and highly palatable beer, of the most salutary qualities, the Dacrydium being too astringent alone. This plant, raised at Kew from seed in 1772, is easily kept in our green-houses, and is covered in summer with elegant white blossoms, whose calyx-teeth, flaminas and style are purplish. In New Zealand it becomes a small tree. The leaves are numerous, feathery, evergreen, small, nearly seflile, entire, sharp-pointed, rigid, smooth,
smooth, dotted, paler beneath, more or less ovate, but varying extremely in length and breadth, so that the two varieties indicated by authors are by no means distinctly marked, and the gardeners make many more, which are equally evanescent. The capitate is hard and woody, permanent on the old branches long after the seeds are dispersed, as in most New Holland plants of this family.

2. L. flavescens. Yellowish South-sea Myrtle. Sm. Tr. of Linn. Soc. v. 3. 262. Willd. n. 3. Brown in Ait. Hort. Kew. ed. 2. n. 2. (L. Tha; Willd. n. 2. Melaleuca Tha; Schraed. Sert. Hannov. 24. t. 14.)—Leaves linear-lanceolate, obtuse, without lateral ribs. Calyx smooth; its teeth membranous, coloured, naked. Native of New South Wales. It was procured from thence for Kew garden, by Sir Jos. Banks, about 1787. The branches are longer, and more flexible, than in the former; leaves narrower, longer, almost linear, inclining to elliptic, and pointless. Petals white, often with a purple tinge, turning yellowish in drying. The calyx-teeth are coloured, that is, whitish, not green; which Williamson, in copying the character, has omitted, and this caused the fame omission in Hort. Kew.

3. L. attenuatum. Fine-branched South-sea Myrtle. Sm. n. 3. Willd. n. 4.—Leaves linear, slightly lanceolate, acute, three-ribbed. Calyx clothed with silky hairs; its teeth membranous, coloured, nearly naked.—Native of New South Wales, sent to Kew by Sir Jos. Banks in 1795. Its slender habit, and narrow acute leaves distinguish this from both the former. The flowers more are smaller, often together, their filaments, germs, and base of the calyx clothed with silky, silvery, rather spreading hairs. Petals and calyx-teeth white. It blooms from May to July.

4. L. grandifolium. Large-leaved South-sea Myrtle. Sm. Tr. of Linn. Soc. v. 6. 290.—Leaves lanceolate, sharp-pointed, obscurely five-ribbed, downy beneath. Calyx hairy; its teeth membranous and coloured.—Sent from Port Jackson, New South Wales, in 1795, by Dr. White to Mr. Lambert. It is larger than any of the foregoing in all its parts; the leaves above an inch long, and near a quarter of an inch broad, lanceolate inclining to obovate, with a small prominent sharp point; shining and smooth above, except when young; paler, opaque, dotted, downy, and marked with two long lateral ribs, on each side the principal one, beneath. Flowers large, white and handsome, all parallel, numerous, and solitary at the ends of the short lateral leaf branches. The base of their calyx-teeth, as well as the germ, is covered with wool, white, shaggy hairs.

5. L. trinerve. Silky South-sea Myrtle. (L. lanigerum; Willd. Sp. Pl. n. 5. Melaleuca? trinervia; White’s Voyage, 229. t. 24.)—Leaves lanceolate inclining to obovate, three-ribbed. Calyx silky; its teeth leafy, permanent.—Native of New South Wales; Dr. White. This has much the habit of the last, but is in all its parts only about half the size. The leaves vary in breadth, and are more or less oblong. The germ, with the calyx and its teeth, are entirely clothed externally with beautiful, clofe-pretted, silky or silvery hairs. Petals white.

6. L. lanigerum. Hoary South-sea Myrtle. Brown in Ait. Hort. Kew. ed. 2. n. 4. Sm. Tr. of Linn. Soc. v. 3. 263. (Philadelphus laniger; Ait. Hort. Kew. ed. 1. v. 2. 150.)—Leaves oblong or obovate, obscurely three-ribbed, somewhat hairy. Calyx clothed with long shaggy hairs. —Native of Van Diemen’s land, and of New South Wales. In the Trans. of the Linn. Soc. this was confounded with the last, but Mr. Brown has corrected that mistake. The present species has the germ and whole calyx remarkably hoary with long spreading hairs, not silky with close or erec
d one. The leaves when young are more or less hairy, and the young branches downy. The scales of the flowering buds appear also to be larger and more permanent, imbricated, elliptical, and externally hairy.

7. L. parasolium. Small-leaved South-sea Myrtle. Sm. Tr. of Linn. Soc. v. 3. 263. Ait. Hort. Kew. ed. 2. n. 5.—Leaves obovate, imbricated, ribbed. Young branches and calyx clothed with spreading hairs; teeth membranous, coloured, naked. —Sent to us from New South Wales by Dr. White in 1795. It is said to have been communicated to Kew garden by Sir Jos. Banks in 1789. The leaves are not a quarter of an inch long, numerous, imbricated, either obovate or exactly elliptical, blunt, flat, thickish, without any rib, dotted, smooth, on short pale smooth stalks. Flowers terminal, solitary, small, white. Germin and base of the calyx clothed with spreading hairs, but the teeth are naked, roundish and coloured. The younger branches are rough with coarse, long, spreading hairs.

8. L. imbricatum. Imbricated South-sea Myrtle. Sm. Tr. of Linn. Soc. v. 6. 30.—Leaves obovate, imbricated, ribbed. Branches and calyx smooth; its teeth membranous, coloured, naked, keeled.—Gathered at Port Jackson, New South Wales, by Mr. David Burton, and communicated to us by Sir Jos. Banks in 1797. It greatly resembles the last, but the copious little leaves are still more distinctly imbricated, especially on the long lateral branches, which more are smooth, as well as every other part. The flowers are extremely small, flattened two or three together about the end of each branch; their germ and calyx perfectly naked; the teeth of the latter sharply keeled, which in L. parasolium are only a little convex.

9. L. arachnoideum. Cobweb-flowered South-sea Myrtle. Sm. Tr. of Linn. Soc. v. 3. 263. Gartn. v. 1. 174. t. 35. f. 3.—Leaves awl-shaped, sharp-pointed. Branches hairy. Gernen and calyx entirely clothed with long spreading hairs. —Native of New South Wales. The stem is stout, apparently of humble growth, with numerous, short, zigzag, leafy, hairy, lateral, compound branches. Leaves crowded, awl-shaped, sharp-pointed, smooth, dark-green, about half an inch long, channelled above, convex beneath, resembling some slender kind of juniper. Flowers small, solitary, terminating the short side-branches of the branches, and remarkable for the very long and fine white spreading hairs, like a spider’s web, which clothe the germ and whole calyx. It is a stranger to our gardens.

10. L. juniperinum. Juniper-leaved South-sea Myrtle. Sm. Tr. of Linn. Soc. v. 3. 263. Venten. Malmaif. t. 89.—Leaves linear-lanceolate, sharp-pointed. Young branches silky, Calyx smooth; its teeth membranous, coloured, naked.—Native of New South Wales. Mr. Fairbairn raised it in Chelsea garden about the year 1790. This is an upright bushy shrub, whose young branches are clothed with silky hairs. The leaves are larger, and still more like juniper, than those of the preceding; silky when young. Flowers numerous, white, solitary at the ends of the very short, lateral, axillary, leafy shoots. Germs depressed, smooth as well as the calyx and its teeth, which are broad and coloured.

11. L. tribulare. Three-celled South-sea Myrtle. Venten. Malmaif. t. 88. —Leaves linear-lanceolate, sharp-pointed. Calyx silky; its teeth coloured, minutely fringed. Stamens fifteen. Capsule of three cells.—Native of New Holland. We know it only by the plate and description in M. Ventenat’s superb Jardin de la Malmaison. The habit and foliage are much like the last. Branches downy and reddish. Germs rather more elongated, clothed with short silky down, as are also the calyx-teeth, which are fringed, and 9 coloured.
couloured of a purplish red. Petals white. Stamens but fifteen, and cells of the fruit only three.

12. L. bacatum. Pulpy-fruiting South-sea Myrtle. Sm. Tr. of Linn. Soc. v. 3. 264. (L. juniperifolium; Cavani. Jc. v. 12. 183. 331. f. 2) — Leaves linear-lanceolate, sharp-pointed. Bracteae smooth. Germen and calyx-teeth downy. Capsule with a pulpy coat. — Native of New South Wales, sent to Kew garden by Sir Jof. Banks in 1790. A low depressed rigid shrub, with the habit and foliage of our English dwarf variety of the juniper. Flowers much like some of those last described, but their germen and whole calyx with its teeth are clothed with white cottony, rather than silky, hairs. The germen is closely enveloped in smooth, somewhat fringed, concave bracteae, which, being taken for the germen itself, caused an error in the original description of this species; but indeed that part becomes smooth as it ripens into fruit, as well as very thick and pulpy. The petals are yellowish in the dried plant, but probably white when recent, like L. flowefenis. Cavanilles's synonym seems rightly applied in Hort. Kew, though he describes the calyx as smooth. The fruit in our plant, as well as his, has five cells.

13. L. ambiguus. Hook-leaved South-sea Myrtle. Sm. Tr. of Linn. Soc. v. 3. 264. Exot. Bot. v. 1. 115. t. 59. (Metrodoreus coronifolium; Venten. Malmaif. t. 46.) — Leaves linear-lanceolate, recurved at the point. Calyx nearly smooth; its teeth leafy, lanceolate, naked. Stamens longer than the corolla. — Native of New South Wales, sent to Kew garden by Sir Jof. Banks in 1791. It forms a handsome bushy evergreen shrub, blossoming plentifully in the green-house in summer. The branche are downy. Leaves numerous, crowded, dark-green, channelled, dotted, bluntish, recurved at the tip, often roughish. Flowers white, with very numerous spreading flamen's, that are peculiar in this genus as being longer than the corolla, yet not so long as in Maeruchus, and the capitate flage itamps our plant a Leptospermum, which the habit altogether confirms. Ventenat describes the germen as of three cells only; we find four or five, so that this character appears variable.

14. L. virgatum. Wand-like South-sea Myrtle. Forf. Gen. 36. Wildn. n. 12. (Malacea virgata; Linn. Suppl. 343. Forf. Prodr. 37.) — Leaves opposite, linear-oblong, bluntish. Stalks axillary, three-flowered. — Gathered by Forfier in New Caledonia. As Willdenow has admitted this into Leptospermum, we would not leave it out, notwithstanding the reasons given in Tr. of Linn. Soc. v. 3. 205, which strongly induce us to think it a decannate Brachia. The flamen's are ten. Leaves opposite, whereas in every certain Leptospermum they are alternate. The umbellate flower-flake's too are not natural in this genus.

15. L. pulchrites. Downy Twisted South-sea Myrtle. Wildn. n. 6. See Tr. of Linn. Soc. v. 3. 263. — Leaves elliptic-obovate, downy, twirled, with a small recurved point. Germen and calyx-teeth downy. — Native of New Holland, common in gardens. We subjoin this as a species taken up by Willdenow from the Linn. Trans. but whose limits we have not yet fully determined. It does however seem distinct enough from langor and trinervus, as well as from all the rest. Much more light is to be expected relative to all the species of this genus from the sequel of Mr. Brown's Prodromus, and we therefore leave these two last species for future determination, especially as the pulchrites is not inserted in the second edition of Hort. Kew. — For similar reasons we leave unnoticed the three species figured in Cavanilles, t. 330 and 331, which most probably are referable to some of the above; but his plates and descriptions are insufficient to determine which, and would therefore still be useless, if by any means determined.

LEPTOSTACHYA, from L. erect, flender, and stachys, a spike of flowers; elegantly applied by Mitchell to the Phryma of Linnæus, and retained by the latter as the specific name. See Phryma.

LEPTOSTOMUM, from L. erect, flender or narrow, and stoma, the mouth, expressive of the narrow orifice of the capsule. Brown. Tr. of Linn. Soc. v. 10. 320. — Class and order, Cryptogama Myrtacei. Nat. Ord. Myrtac.

Eff. Ch. Capsule oblong, without furrows, terminal. Lid hemispherical, without a beak. Fringe a simple, flat, annular, undivided membrane, from the inner coat.

All the four known species of this genus are natives of the southern hemisphere. They are moles of a densely tufted mode of growth, with upright, branched, perennial stems. Leaves moderately spreading in every direction, broadish, entire, revolute, with a strong midrib, and a terminal hair, which is suspected by Mr. Brown to be sometimes branched. Fruit-flake terminal. Capsule either erect or drooping; tapering at the base into an inerfibly conical apophysis; much contracted at the mouth. Veil smooth and naked, deciduous.

1. L. incanus. Tr. of Linn. Soc. v. 10. 320. t. 23. f. 2. — Leaves oblate, obtuse. Capsule drooping, obovate-oblong. — Found by Mr. Brown in Van Diemen's land, upon rocks and flones at the east side of Table Mountain, near the summit, in 43° south latitude, and from 3000 to 3500 feet perpendicular above the sea. This mofs is two or three inches high. Stems but little branched, leafy in the upper part, densely clothed with ruliy down below. Leaves slender, very minutely dotted or reticulated, tipped with a twisted hair from the length of each leaf. Fruit-flake brown, smooth. Sheath at the base accompanied below by numerous abortive petals and capillary, jointed, fuculent threads.

2. L. ericinum. Leaves oblong-parabolic, obtuse. Capsule oblong, erect. Found by Mr. Brown on the east coast of New Holland, in a mountainous part of the country, growing on rocks near the banks of the rivers Hawkebury and Grofe. Stems about as tall as the former, simple or branched, clothed with rufty down in their lower part, leafy above. Leaves crowded, a little incurved and close-pressed by drying, each tipped with a simple hair. Fruit-flake elongated, brown, smooth. Capsule straight. The lid had fallen off.

3. L. gracile. Leaves ovate-oblong, rather pointed; terminal hair half their length. Capsule oblong, straight, drooping. — Gathered by Mr. Archibald Menzies, at Dufky bay in New Zealand. The flamen's are densely tufted, somewhat branched, about an inch high, thickly clothed with rufty down in their lower part. Leaves yellowish-green, dotted, close-pressed when dry, pullycrid, strongly revolute, with a very thick rib, and a smooth terminal hair. Fruit-flake near two inches high, flender, tawny, with a sheath at the bottom, the flume very flender and drooping. Capsule nearly pendulous, a quarter of an inch long, flender, straight, slightly swelling in the middle, of a dark opaque brown. Lid very small, obtuse, of a still deeper brown.

4. L. Menziesii. Leaves oblong-lanceolate, acute; terminal hair a quarter their length. Capsule cylindrical, drooping, recurved. — Discovered by Mr. Menzies at Staten-land in 1797. We, as well as Mr. Brown, are indebted to him for fine specimens of this and the last. The flamen's of L. Menziesii are half an inch or more in height, mostly simple, with dense rufty fibres and roots. Leaves bright yellowish-green, crowded, finely dotted, wavy and close-
pressed when dry, with a shortish terminal hair. Fruit-stalk about an inch high, foliary, erect. Capside light brown, smooth, one-third of an inch long, drooping, cylindrical, singularly recurved, with somewhat of a turgid appearance. Lid very small; after it is fallen the white, membranous, very delicate fringe becomes distinctly visible.

Mr. Brown with good reason suspects Bryum macrorcepm of Hedwig, Crypt. v. 3. t. 10, may belong to this genus. If so, there is an error in the delineation of its fringe; and it will prove the only known species whose leaves are tipped with a branched hair.

LEPTUM, in Antiquity, a small piece of money, which, according to some, was only the eighth part of an obolus; but others will have it to be a silver or brass drachm.

LEPTURA, in Entomology, a genus of Coleoptera: the antennae are fuscaceous; palpi four, and filiform; wing-cases tapering towards the tip; thorax flender and rounded. Those of the Limnean leptra which have the lip entire, constitute the genus Donacia of Fabricius; and such as have the lip bifid form a part of the leptra of that author; for the latter do not exclusively confine of those insects which, according to the Limnean character, belong to leptra; leptra abbrevia of Fabricius, for example, is neocyphalis major of Limneus, and leptra variegata, the Hemicnian neocyphalis variegata. Most of the leptra tribe are furnished with legs of pretty considerable length; run with much speed and activity; and are found on flowers.

Species.

The colour of this species varies from reddish, or brassy, to green; the antenna blackish, with pale tesselace at the joints; head with a line down the middle; thorax grooved; body beneath downy; legs obscure, tesselace. Common in Britain, and other parts of Europe, on aquatic plants, particularly the nymphaea.

SIMPLEX. Golden; thighs simple. Fabr. An European species, perhaps leptra aquatica mutica of Degeer.

MICANS. Posterior legs bidentated; flanks simple; wing-cases glossy-violet. Hoppe.

Allied to L. aquatica, and inhabits the same places.

HOLOSERICA. Shining-green; antennae and legs fuscous, black; posterior thighs dentated. Herbr. An European species, found in damp fields, &c.

PALUSTRIS. Blackish-violet; antennae and legs chestnut; posterior thighs dentated. Herbr. A native of Pomerania; found in marshes.

CINEREA. Cinerous, speckled with coppery. Herbr. Inhabits with the former.

MARGINATUS. Posterior thighs one-toothed; wing-cases golden; margin and spot at the base rufous; abdomen and legs silvery. Hoppe.

On aquatic plants in Germany.

Nymphalis. Posterior thighs dentated; thorax and wing-cases coppery; body cinereous, downy. Fabr.

Native of Europe, on the leaves of the nymphaea alba. The head is coppery; antennae and mouth black; body beneath silvery-brown.

SAGITTALIS. Posterior thighs one-toothed; wing-cases green-golden, minutely punctured and truncated; abdomen and legs golden. Hoppe.

Antennae blackish; thorax wrinkled and furrowed. VIOLACEA. Deep black, and somewhat brassy; wing-cases obscure, violet; abdomen fuscaceous. Pallas.

Size of leptra aquatica, and inhabits Siberia.

ANNA. Posterior thigh armed with one tooth; wing-cases brassy, equal, rounded; abdomen and legs brassy. Hoppe. Leptura anica, Linn.

Native of Europe.

BICOLOR. Golden; thorax above, with the wing-cases green, the latter with three of impressed dots; posterior thighs dentated. Linn. Muf. Linn.

An European species.

FUSCA. Posterior thighs with a single tooth; body brown; wing-cases frigate and punctated; mouth, antennae, and legs rufous. Linn.

Inhabits with the former.

CRASSIPES. Posterior thighs unarmed; body green-bronzed, beneath cinereous, brassy; wing-cases frigate with punctures, and marked with transverse small lines; mouth, antennae, and legs rufous. Linn.

Native of Europe.

REPOI. Posterior thighs dentated; body reddish-bronze; beneath cinereous-bronze; wing-cases frigate, punctated with crenated wrinkles. Linn.

Inhabits Germany and Sweden.

INHABITA. Posterior thighs toothed; body shining-green gold; wing-cases frigate and punctated, with crenated wrinkles, and a broad, common, purple-green fillet; abdomen, antennae, and legs gold. Linn.

Native of Europe.

CREOLEA. Posterior thighs dentated; body blue; wing-cases frigate, punctated with crenated wrinkles; an- tenne brassy. Linn.

Inhabits Europe.

CLAVIFES. Posterior thighs unarmed; body brassy; abdomen covered with silvery down. Fabr.

Native of Germany, on aquatic plants.

PASCICULA. Body black; posterior legs long; thighs unarmed; the flanks with a tuft of long feathers. Fabr.

Inhabits Cayenne; the body very slender, with a silvery gloss beneath.

LINEARIS. Posterior thighs unarmed; wing-cases linear, truncated, shining-brassy; legs somewhat tesselaceous. Hoppe.

A species found in Europe; antennae blackish; abdomen cinereous.

HYDROCHARIS. Posterior thighs unarmed; wing-cases cinereous, glossy, rounded at the end; body and legs cine- reous. Hoppe.

Native of Germany; the antennae cinereous.

MICRONA. Posterior thighs unarmed; body above livid; beneath, head, and antennae black; thorax with two divergent lines; wing-cases spinous at the end. Hoppe.

VULGARIS. Posterior thighs unarmed; body fuscous; wing-cases frigate and punctated, with crenate wrinkles, and a broad, common, purple-green fillet; head, abdomen, and legs silvery-she.

** Lip bifid.

UNIPUNCTATA. Black; wing-cases rufous, with a black dot in the middle. Fabr.

Inhabits about Dresden.

HASTATA. Deep black; wing-cases red; tip and future in the middle black. Fabr. Stenocerus nigre, &c. Geoffr.

Native of the southern parts of Europe. Segments of the abdomen with silvery down at the edge.

BIPUNC-
LEPTURA.

BIPUNCTATA. Black, villous; wing-cases livid, with a black dot in the middle. Fabr.

Inhabits Siberia.

TOMENTOSA. Thorax villous and golden; wing-teifaceos, with the tip black. Geoff.

Head and antennae black; wing-cases smooth, slightly notched at the tip; abdomen covered with silvery down; tail emarginate; legs black.

Native of France.

MELANURA. Black, wing-cases reddish or livid, the future and tip black. Schaff.

Inhabits Europe on flowers.

LEVIS. Black; wing-cases and legs livid, future, and tip of the wing-cases blaclk. Fabr. Leptura futuratis.

Antennae black; body clothed with silvery down. Native of Europe.

LIVIDA. Black; wing-cases teifaceos and without spots; legs black. Herbst.

Wing-cases rounded at the tip, and scarcely emarginate. Native of Germany.

VILLICA. Ferruginous; antennae, wing-cases, and breast brown. Schaff., &c. Fabr.

Inhabits Europe; first joint of the antennae rufous.

MERIDIANA. Thorax somewhat pinious; wing-cases fagitate; breast shining. Schaff.

Male black, female teifaceous; legs of the larva long.

Native of Europe.

STRIGILATA. Black; wing-cases teifaceous, with a blackish fillet. Fabr.

Native of Sweden.

EMARGINATA. Black; wing-cases purple, tip black, and emarginate. Fabr.

Inhabits Cayenne, the abdomen bidentated at the end; segments shining silvery at the base.

SANGUINOLENTA. Black; wing-cases fanguineous. Linn.

Ph. Su. Leptura dubia, Scop.

Native of Northern Europe.

RUBRA. Black; thorax, wing-cases, and shanks purple-red. Linn.

Inhabits Sweden.

TESTACEA. Black; wing-cases teifaceous; shanks rufous; thorax rounded behind. Fabr.

Found in the north of Europe, and is supposed to be the male of the former.

REVESTITA. Teifaceous; wing-cases, breast, and antenne deep black. Schreber.

Native of Germany.

PUBESCENS. Black, with cixereous down, rib of the wing teifaceous at the base. Fabr.

Inhabits Sweden.

VIRENS. Silky greenish; antennae varied with brown and green. Oliv.

SMARAGDULA. Silky greenish; antennae and legs black. Fabr.

Inhabits Sweden.

ATRA. Body entirely deep black. Oliv. Fabr. Leptura ethiops, Pod.

Legs sometimes teifaceous; abdomen with white silky down.

HUMERALIS. Black; shoulders and abdomen ferruginous. Fabr.

Native of Germany.

SCUTELLATA. Black; scutel white. Fabr.

Inhabits Italy.

SUTURATA. Cinereous; wing-cases teifaceous, with a black future. Fabr.

Found in Germany; the antennae teifaceous, with black tip; legs rufous, the joints black.

EXCLAMATIONIS. Black; wing-cases with a yellow line down the middle, and a dot at the base. Fabr., &c.

A small species found in Sweden.

LUBIDA. Ferruginous; wing-cases teifaceous. Fabr., &c.

Inhabits districts of Hircania.

FEMORATA. Black; thighs rufous at the base. Fabr.

Found in Saxony.

RUFICORNIS. Black; antennae and legs rufous. Fabr.

Native of Italy. Body covered with yellowish down.

MARGINATA. Black; margin of the wing-cases and hind shanks rufous. Fabr.

Inhabits Norway.

NIGRA. Wing-cases tapering; body black, polished; abdomen red. Schaff.

An European species.

PRAEUSTA. Body covered with golden down; head and tip of the wing-cases black. Fabr.

First joint of the antennae ferruginous; legs red.

Native of Europe.

QUADRIMACULATA. Black; wing-cases teifaceous, with a black ring. Oliv.

Native of Germany.

4-GUJTATA. Brown; wing-cases black, with two ferruginous dots at the base. Fabr.

Inhabits Saxony.

ROSTRATA. Dull braffy; legs yellow. Fabr.

SUBSPINOSA. Black; wing-cases teifaceous, with four black bands, the first punctuated; antennae and legs yellow. Fabr. &c.

Perhaps the female of the last. Head black, with a fulous frontal band; wing-cases emarginate; three segments of the abdomen yellow. Native of Germany.

AURULENTA. Black; fore and hind margin of the thorax golden; wing-cases teifaceous, with four simple black bands. Fabr.

Inhabit Germany; segments of the abdomen edged with white.

DUBIA. Black and somewhat villous; wing-cases teifaceous, dotted with black; legs black. Fabr.

Native of Siberia. Allied to Leptura attenuata.

SEXGUTTATA. Black; wing-cases with three yellow spots. Fabr.

Inhabit Germany. Herbst.

QUADRIFASCIATA. Black; wing-cases teifaceous, with four indented black bands. Linn. Leptura oitomaculata, Degeer. Cerambyx fajciatus, Scop.

Native of Europe.

3-FASCIATA. Black; wing-cases with three yellow bands, the first interrupted. Fabr.

Antennae pale ahi, with the base black; first band on the wing-cases composed of two dots, the second with a small tooth, the third lunated. Inhabit Sweden and Germany.

RETICULATA. Black; wing-cases teifaceous at the base, reticulated with yellow, and tipped with black. Fabr.

Native of Italy. The antennae black; joints at the base yellow; legs rufous, with black joints.

SERICEA. Green-blue; wing-cases somewhat fagitate. Fabr.

This and the seven following inhabit Europe.

COLLARIS. Thorax globular, and with the abdomen red; wing-cases black. Fabr.

VIRGINEA. Thorax globular and black; wing-cases violet; abdomen rufous. Oliv.
LEPTURA.

CARBONARIA. Black; wing-cases telfacreous, tiipped with brown. Linn.
Native of Africa. Antennae yellowish at the base; thorax and wing-cases smooth.

LUTHERA. Yellow; thorax with two black lines; wing-cases with four black bands. Fabr.
Inhabits Carolina. Head and antennae yellow; legs yellow; posterior thighs with a black ring.

4. POSTULATA. Black; wing-cases with two remote ferruginous spots. Fabr.
Native of Sweden.

5. MACULATA. Black; wing-cases livid, with four black spots. Schaff.
An European species.

INTERPOLATIONS. Black; wing-cases yellow, with a longitudinal curved black line, and four marginal spots. Linn. Donov. Br. Inf.
Native of the northern parts of Europe.

MARIA. Blackish; future of the wing-cases, two marginal spots, and tip yellow. Fabr.
An inhabitant of Italy.

6. MACULATA. Black; wing-cases telfacreous, with three indented black bands, the anterior one a little interrupted. Schaff. &c.
Native of Europe.

7. PUNCTATA. Black; thorax telfacreous, with a black dot; wing-cases telfacreous, with seven black dots. Fabr.
Small, linear; head with a large frontal telfacreous spot; abdomen telfacreous; legs black. Native of Hungary.

8. MACULATA. Black; wing-cases yellow, with six large black spots on each. Fabr.
Native of Siberia.

ATTENUATA. Wing-cases tapering, yellow, with four black bands; legs telfacreous. Schaff.
Inhabits Europe; abdomen entirely black, or rufous, with the tip black.

CALCARATA. Black; wing-cases tapering, yellow, with a black band, the first punctured, second interrupted; posterior shanks bidentated. Herbit.

NIGELLA. Black; wing-cases telfacreous; anterior shanks rufous. Linn.

ERYTHROPS. Black; legs red; base of the thighs, tips of the shanks, and ends of the legs black. Linn.

5. MACULATA. Black; antennae annulated with black; legs and wing-cases telfacreous, the latter with five black spots and three bands. Linn.

FUSCA. Brown, with golden down; base of the anterior telfacreous; fore thighs and shanks telfacreous, the former with four telfacreous bands, the latter telfacreous at the base. Linn.

MORIO. Thorax orbicular; body entirely black and polished. Fabr.
Native of Sweden.

CERAMBEICORNIS. Black, with whitish down; wing-cases yellowish, with five black spots and a line in the middle. Herbit.
Found in Hungary and Austria.

RUSICA. Black, with whitish down; wing-cases yello\-wz?h, with five black spots and a line in the middle. Herbit.
Inhabits Russia.

LAVIN. Black, beneath silky; antenna yellowish-brown; anterior legs ferruginous. Herbit.
Native of Pomerania.

SOLITARIUS. Black; antennae ferruginous at the base; legs and wing-cases yellow, the latter edged with black. Herbit.

Inhabits Prussia.

4. NOTATA. Black, with yellowish down, beneath with whitish; antennae brown at the base; thighs ferruginous at the base; wing-cases punctured with two orange spots. Herbit.

Same country as the preceding.

SPLENDIDA. Black, with yellow down; wing-cases glabrous at the tip; legs fulvous; antennae brown, with ferruginous base. Herbit.

Inhabits Germany.

PLUMIPER. Brown, punctured; thighs subfuscous; hind-legs very long, the shanks; rufous at the tip. Pallas.
Country unknown.

RUPER. Black; legs rufous; thighs black at the base. Schaller.
Native of Germany.

OCTO-MACULATA. Black; wing-cases telfacreous, with six black spots and tip. Schaller.

Inhabits Saxony.

SCHALLEN. Brown; base of the shells with four rufous spots. Schaller.

Inhabits Germany.

POMARIA. Brown; anterior legs telfacreous, the thighs black above. Schaller.

Native of Saxony. A rare species, found on rhamnus cathericicus.

USULATA. Black; thorax and wing-cases telfacreous, tipped with black; legs telfacreous.

Inhabits Germany on flowers.

PAREMIX. Black; base of the antennae and thighs redish. Thunb.

Oblong, narrow. Inhabits Germany.

BIPUSTULATA. Wing-cases black, frilliated with dots, and marked with two telfacreous spots. Thunberg.

Inhabits Upsal.

SCOPOLI. Abdomen and thorax at the posterior margin red; wing-cases telfacreous, pellucid, and attenuated; tip and margin below the middle black. Scop.

NIGRIPIER. Black; wing-cases dull yellow-tef\-fzreous; legs black. GMEL. DEGEER. &c.

Country unknown.

TOLIS. Black; anterior shanks fulvous. Müll.

Native of Denmark.

MACULOSA. Black; wing-cases livid-tef\-fzreous; antennae spotted with black. Degeer.

Country unknown.

LUNULATA. Black; thorax with a narrow yellow band behind; wing-cases with two ferruginous lunules. Sweden.

Inhabits the Cape of Good Hope.

BICOLORATA. Pale ferruginous; eyes, wing-cases, wings, and tail above black. Leptura bicolor. Sweden.

Native of America.

VITTATA. Pale telfacreous; antennae annulated with fulvous; wing-cases dotted with black, with four yellow stripes. Sweden.

Inhabits America.

10. PUNCTATA. Black; thorax subglobular; wing-cases with ten dots. Lepech.

Inhabits Ural.

VII. Villous, hoary; thorax subglo\-bular; wing-cases black with white dots, and four interrupted bands. Lepech.

Same country as the former.

4 D

VIRIDIS,
1. L. Viscitca, Viscacha, Viscachos, the Peruvian hare, with a longish tail, befted with bristles. Molin. Hil. Nat. Chile. Hares of this species inhabit the plains and bafes of mountains in the colder parts of Peru and Chili. The fur is of a moufe colour, and fo fine and soft, that, in the time of the Incas, it was woven into cloth for the Peruvian nobles, and is that employed for bonnets by the Chilenes. In habit and manner this species resembles the rabbit, and digs holes under ground, in which are two contiguous chambers, one in which it sleeps, and the other, which is lower, is employed for eating its provisions, that are collected in the night; the tail is bushy, and much longer than that of any other species, and in general it turns up and is ufed as a weapon of defence.

2. L. Timidus, common hare, has a very short tail, the ears longer than the head, and black at the ends. Of this there are two varieties, viz. the horned common hare, L. timidus cornutus, having lightly branched horns, an animal probably fabulous; and the yellow common hare, L. timidus melinus, of a flar yellow, of the fame fize with the hare, and running like it. Cook's Voy. iii. Temant's Quad.

This species inhabits the whole of Europe, and more plentifully in Bulgaria; in the northern parts of Peru, Japan, Ceylon, and almost the whole of Africa in Egypt and Barbary; in North America, and even in Chili. The hare is very timid, very quick in its flight and bearing, and very swift, particularly in running up hill; when hunted it runs circularly, gradually leaving the circuit, and often doubling back parallel to its path, and leaping through a great interval at the turn, in order to throw off the dogs. (See Hare Hunting.) The hare feeds only by night, and chiefly on the twigs and bark of shrubs and young trees. It is hunted for sport with dogs or hawks, and, in India, with some species of the cat genus. It is said to be fond of the sound of a drum; it is much infelt with fleas; it does not burrow, but makes a kind of nest, called by sportmen a "form," among bushes or long grass; its urine is fatty, which it takes care not to discharge in its nest. It does not pair, but breeds often in the summer and spring, the male pursuing the female, when in feafon, by the scent; after going 30 or 31 days, the female brings three or four at a litter; and as hares are very liceitious, superfetation is not uncommon. It is about two feet in length, when full grown between eight and nine pounds in weight, sometimes, though rarely, twelve; the head is oblong or oval; the ears long and tipt with black, the eyes large, prominent, and black, placed much outwards, and provided with a nictitating membrane, which remains open when the animal is asleep; the upper

LEP

Viridis. Greenish; thorax somewhat ovate, with two darker lines; the back black. Lepech.

Native of Siberia.

Nigres. Thorax globular, and with the abdomen black, with yellowish shining down; wing-cases black, with four broad yellow bands; legs ferruginous. Forster.

Inhabits North America.

Blainea. Blackish-brown; thorax with two yellowish lines; wing-cases with feathered dots. Scop.

Found in Carolina.

Cemelia. Blue; anterior shanks rufous. Scop.

Native of Italy.

Squalida. Black; wing-cases telescopic at the base and inner margin. Scop.

Same country as the former.

Bipartita. Black; thorax ferruginous with a black line; wing-cases with a common ferruginous spot. Schrank.

This and the two following are natives of Germany.

Ferruginea. Black; wing-cases ferruginous, with a broad patch of black. Schrank.

Lambda. Black; wing-cases with three white bands. Schrank.

Maculata. Black, with yellow downy spots; thorax globular; antenna half as long as the body. Geoffr.

This and the five following are inhabitants of France.

Nevia. Black, with yellow down; wing-cases with two black glabrous spots. Geoffr.

Punctulata. Blackish; head and thorax red, dotted with black. Geoffr.

Strigosa. Yellow downy; wing-cases with three narrow black bands. Geoffr.

Gallica. Blue; shanks rufous; thorax subglobular. Geoffr.

Bimaculata. Rufous; thorax cylindrical; wing-cases dotted, with a spot and waved line of white. Müll.

Inhabits Europe.

Volosa. Black, villous; thorax cylindrical, with pale longitudinal line. Müll.

Native of Denmark.

Lepturus, in Botany, from λ θ ρ υ ς, slender, and υς, the tail of an animal, a genus of grasses, established by Mr. Brown. Prodr. Nov. Holl. v. 1, 207, and so called from its long slender cylindrical spike. It is founded on Rettsbilia repens, Forst. Prodr. 9 u. 50, with a question whether K. incarnata of Linnaeus and Fl. Brit. as well as R. filiformis of Roth, may not belong to the fame. The chief difference between Lepturus and Rettsbilia fecans to lie in the joints of the spike being single-flowered in the former, two-flowered in the latter; for in the detail of the florets, respecting the presence or imperfection of the parts of impregnation, this tribe of grasses, and indeed all grasses, are to be trusted with great caution.

Lepturus, in Ichthyology. The name is of Greek origin, and is formed of λ θ ρ υ ς, slender, and υς, a tail, expressing that the fish bearing this name has a very long and slender tail. See Trichurus lepturus.

Lepturus, in Ornithology. See Phaeton aetherus.

Lepus, the Hare, in Astrology, a constellation of the southern hemisphere; whose stars in Pтолемy's catalogue are twelve; in that of Tycho thirteen; in the Britannic catalogue nineteen. See Constellation.

Lepus Aquatus, the water-hare, in Ornithology, a name given to the crested diver, or columbus of America, which is the same species with the large European kind, though described by many authors as a different bird. It has the name of the sea-hare or water-hare, from its great nimble-ness in the water. It is caught with much difficulty; and the Mexicans have a thousand fabulous stories about it. See Columbus erithenus.

Lepus, in Zoology, a genus of the order of Glirides, in the clafs of Mammalia, the characters of which are that the animals of this genus have two fore-teeth in each jaw; in the upper jaw is a second inner row of fore-teeth, which are considerably smaller than the outer or primaries; the fore-teeth have each five, and the hind-teeth four toes. These animals are very timid; they live on vegetable food; and they use the hind-teeth in walking as far as the heel, running by a kind of leaps, or repeated bounds. They have either exceedingly short tails, named fuits, or none at all.

* With tails.*
LEPUS.

Lip is divided; the snout furnished with long white whiskers, the chin white; the fur on the face, back, and sides white at the roots, black in the middle, and tawny red at the ends; the breast and throat are reddish; the belly is white; the tail is black above and white beneath; the hind thighs are strong, thick, and fleshy, with a cavity on each side of the pubes; the feet are thickly covered with hair on the soles. This animal is fond of birch, parsley, and pinks. Its flesh was forbidden by the Druids, but much esteemed by the Romans. For other particulars, see Hare.

3. L. Parvula, varying hare, Alpine hare, has a very short tail, the ears shorter than the head; the whole fur becomes white in winter, except the tips of the ears, which remain black. Of this species there is a variety, called the L. variabilis hybridus, or spurious varying hare, the sides of which only turn white in winter. This species inhabits the coldell and most hilly parts of Europe and Asia, as Scotland, Norway, Lapland, Ruflia, Siberia, Kamtschatka, Greenland, and in America, about Hudson’s bay, and Labrador. The spurious variety is a mixed breed, between the varying and common species, furnishing a partial change of colour, and found only in the southern and western parts of Siberia. In autumn the varying hares sometimes collect in flocks of 50 or 60; driven from the mountains of Ruflia and Siberia, they migrate in quest of sustenance into the lower country, and return in spring. The flesh of this species is harder, drier, and less flavoured than that of the common kind. It never mixes with the common species, but keeps on the tops of the highest hills; it does not run swiftly, but when pursued, takes shelter in the clfts of rocks; is easily tamed and very frolicsome; fond of honey and sweetmeats; it eats its own dung before a storm; changes to white in September, and recovers its grey colour in April; and it is subject to these changes when kept in a warm room; in Greenland, it is always white. Penn. Quad. Arctic Zool. Forster. Phil. Trans. lxi.

4. L. Niger, the black hare, has a very short tail, fur entirely black, or very dark tawny, the whole year, and inhabits Siberia, and the government of Cassian. It is much larger than the common kind, and very glossy.

5. L. Americana, American hare, Hudson’s bay hare, Hudson’s bay quadruped, Phil. Trans. lxi. with the tips of the ears and tail grey, has a very short tail. The hind legs are a half longer than the body; the tips of the ears and tail grey. This species inhabits North America. In New England, Canada, and farther north, this species acquires a long, filly, silver-white coat of fur during winter, the edges of the ears only remaining grey; to the south it retains the whole year a short fur of an ah colour, mixed with rufy and black, on the neck and body, the legs pale-ah colour, and the belly white. It is smaller than the common hare, shelters in hollow trees and under fallen timber, and breeds once or twice a year, producing from five to seven at a litter; the fore legs are proportionally shorter, and the hind legs considerably longer than those of the common kind.

6. L. Talai of Buffon, Baikal hare of Pennant, the Daurian hare of Erxleb, the conilus leporinus of J. G. Gmelin, has a short tail, and the edges of the ears black. This species inhabits the country beyond the lake Baikal, in the desert of Gobi or Cobi, and as far as Thibet. This is larger than the former species; in summer of much the same colour with the varying hare, and in winter a little paler; the legs are smaller and the hind legs longer; the tail longer than that of a rabbit, but shorter than that of the common hare, and like that black, especially at the root. It does not burrow, runs straight forward when pursued, and shelters in the holes of rocks. Its flesh is white, like that of the rabbit.

7. L. Minimus, Chiloe hare, has a very short tail, and the ears of an uniform colour. Molin. H. N. Chil. This species inhabits the kingdom of Chili. It is small, not exceeding the size of a small rat; its body is of a conical form, its ears are small and sharp-pointed, its snout is lengthened, the fur is tawny and very short; the flesh is white and good for food. It resembles the domestic rabbit in varnables of colour, in its prolific quality, producing almost every month six or seven young ones at a time; and in Chil it is domesticated.

8. L. Canescens, Cape hare, has a bushy tail, as long as the head, and red feet. It inhabits the country three days’ journey from the Cape of Good Hope; dwells in the cavities of rocks, and does not burrow; about the size of a rabbit, and probably the same animal that is mentioned by Aelian as found in Ethiopia, which, he says, is smaller than the common kind, with a colour between that of a rabbit, and has white flesh.

9. L. Cuniculus, common rabbit, has a very short tail, almost of the same colour with the body, ears black at the points, and hind legs shorter than the body. Of this species there are the following varieties, viz. cuniculus fuscus, or wild rabbit, of a brownish-grey colour; cuniculus domificus niger, of an uniform black colour; cuniculus albus, of white colour, with fiery red eyes; cuniculus variegatus, pied tame rabbit, of a pied or mottled black and white colour; cuniculus argentatus, silvery tame rabbit, of a silvery grey or ash-colour, with tawny feet. This species inhabits naturally the warmer parts of Europe, Asia, and Africa; it is not a native of Britain, but has inhabited in a wild and tame state in this country for several ages. It occupies principally dry sandy soils, in which it forms long winding burrows; confining itself to these holes in the middle of the day, and wandering in the evening, night, and morning, in search of food. It feeds on all kinds of green vegetables and grain. Its flesh is white and much esteemed. The female breeds six or seven times in a year, going 30 or 31 days with young, and bringing from four to eight at a litter: it acquires its full size in five months, and lives about eight or nine years; the male is very falcous, and apt to destroy the young; rabbits are preyed upon by hawks, badgers, and polecats, and are caught by means of terriers, nets, and ferrets. Numbers of them are bred in a wild state in places fitting apart for the purpose, called “warrens,” and many are bred in houfes in a domestick state. The wild variety is of a brown ash-colour, having the upper part of the tail black, and the under part white. The fur of the silvery variety is valuable.

10. L. Siccatus, hooded rabbit, Russian rabbit, has a double fold of the skin behind the head, and another under the throat. This animal’s habitat is unknown. It is described by Mr. Pennant, from a drawing by the British Museum by Mr. Edwards, and called by him a Russian rabbit, but it is unknown in that empire.

11. L. Sericeus, Angora rabbit, is covered with long, waved, fily hair. The Russian rabbit is reckoned by Gmelin a variety of this. It inhabits Angora in Asia Minor, and is exceedingly beautiful on account of its fine, white, fily fur, which is a valuable article in commerce.

* * Having no Tail.

12. L. Brasiliensis, Brazilian hare, named “Tapeti” by the natives, has very large ears, no tail, and, for the most part, a white ring or collar round the neck. (Pallas Ghr.). This species inhabits South America and Mexico; it is of
the same colour and magnitude with the common hare, but
darker, with similar large ears; in its general appearance it
resembles the rabbit. It lives in the woods, does not bur-
row, and its flesh is good food.

13. L. Pufillus, calling-hare of Pennant, has no tail, tri-
angular ears, white at the edges; the upper parts of the
body are dark-brown, mixed with blackish-grey, and the
under parts nearly white. (Schreber.) This species inhabits
the more elevated and the colder parts of the Altai chain.
It feeds chiefly on the flowers and bark of the Cyrticus fulvisus,
Robina fruticosa, Ceratophyllum pinnata, and Malus fytversis; digs
holes in dry places, amid bushes, and leads a very retired
life, near its burrows, which are long and intricate, with a
very small entrance. These animals are discovered by their
voice, which is very loud and noisy, like the piping of a
quail, and may be heard at a great distance; it is repeated
at short intervals, three, four, or six times, molly at
night and morning, and never in winter or bad weather.
This species is gentle, and easily tamed; it sleeps little,
drinks frequently, and it is not safe to leave in the night seas;
its pace is not quick, but slow.

14. L. Alpinus, Mountain hare, Alpine hare of Pallasi,
&c. Mufela Daurica, or Daurian weasel, has short rounded
ears, and no tail, of a bright bay colour, with brown
ears and hind feet. (Schreber.) This animal inhabits the
Altai chain of mountains, to the extremity of Asia, and
beyond the Lena and Yenisei, occupying the most rugged
and inaccessible parts of the mountains, burrowing in the
crags of the rocks, or living in the hollow trunks of decayed
trees. Its voice or cry resembles a loud whistle.
The mountain hare is preyed on by fables and Siberian weasels,
and is much infested by the Oedrus leporinus, a species of
gad-fly, which lodges in their skins, and often destroys them. This species varies in size from seven to
nine inches in length, and weighs from 1 1/2 pound to four
ounces.

15. L. Ogotosa, the Ogotoa hare, or Mongolian weas-
el, has oblong, oval, or somewhat pointed ears, of the same
colour with the body, which is pale grey; but it has no tail.
(Schreber.) It inhabits the mountains beyond the lake Baik-
al, and all Mongolia, especially the great desert of Cobi;
dwelling sometimes in rocky places, among stones, or
forming in the field with two or three entrances. Its voice
is sharp and claraous; it feeds chiefly on the bark of the
Pyrus baccata, and on the fackers of the dwarf elder, and
in spring on various herbs which grow on the sandy soil.
It is nimble, and fiercely capable of being tamed; it is preyed
upon by various speeies of the weasel tribe, by the Manul
cat, hawks, wood-peckers, and owls; it differs from the
calling and mountain hares, chiefly in size, being about 6 1/2
inches long. It procreates in spring, and the young ones
are fully grown by the end of June.

LEPYRODIA, in Botany, in much, fibular, scaly, so called on
account of the inner scales of the base of each flower.
Brown Prod. Nov. Holl. v. 1. 247.—Clasf and order,
Dioecia Triandria. Nat. Ord. Triphaloides, Linn. June,

Ell. Ch. Flowers either dioecious or hermaphrodite.
Petals fix, nearly equal, prominent, with one or two scales
at their base, within the proper scale of the spike, or
catkin.—Male, Stamens three. Anthers simple, peltate.
A rudiment of a pistil. Female, Styles three. Capsule of
three cells, three-lobed, burbling at the prominent angles.
Seeds solitary.

This genus is very near Elegras, Linn. Mant. 2. 162,
(which was afterwards funk in Relfe), but differs in the
presence of inner scales to the flowers, and in the male
flowers being like the female, with nearly equal petals, as
well as in having the sheaths of the stem permanent, not
separating just above their base, and in the firaller size
of the stamens. The Calorophus of Labillarii are exactly
answered to the above character, but is a totally different
plant.

Spike compound; its lower branches rather distant. Three
outer petals short.—Gathered by Mr. Brown at Port
Jackson, New South Wales.

Spike compound; its branches rather crowded. Petals all
nearly equal.—Native of the fourth coast of New Holland.

Spike compound; its branches imbricated, divided. Three
inner petals immeaile.—Found at Port Jackson.

4. L. hermaphrodita. Stems perfectly simple. Sheaths
lax. Spike compound; its branches imbricated, divided.
Seeds inner petals immeaile.—Found on the fourth coast of New Holland.

Of an account of this genus is entirely taken from Mr.
Brown’s work, with the same difference in terms, accord-
ing to what we have used in the articles LEPTOCCARUS and
LEPIDOFERMA.

LERANG POINT, in Geography, a cape on the N. coast
of the island of Java. S. lat. 6° 37’. E. long. 111° 27’.

LERAY, a town of France, in the department of the
Cher, and chief place of a canton, in the district of
Sancerre; 8 miles N. of Sancerre. The place contains 1109,
and the canton 6544 inhabitants, on a territory of
1700 kilometres, in 7 communes.

LERCHEA, in Botany, was so named by Linnizarus, as
a tribute of respect to the botanical acquirements and pub-
ications of John James Lercbe, principal physician to the
Russian armies, who was born at Potdamin the year 1703,
and who died at St. Petersburg in 1780. He published a
description of certain plants growing at Astrakan, and in
the provinces of Persia, which border on the Caspian sea. This
tract is printed in the 4th vol. of the New Translations of
the Academy Natura Curiosorum, Appendix 161. 266.
He also furnished an account of the Nymphaeus Nelumbo
of the Caspian sea. Haller mentions that Lercbe made many
curious observations on the agriculture and botany of the
countries through which he travelled.—Linn. Mant. 155.
v. 3. Jaff. 421.—Clasf and order, Monadelphus Pentandria.

Nat. Ord. unknown.

Gen. Ch. Cal. Perianth of one leaf, tubular, five-toothed,
permanent. Cor. of one petal, funnel-shaped; tube longer
than the calyx; limb five-toothed, nearly erect. Stiam. Fil-
ament scarcely distinct from the tube of the gerum; an-
thers five, oblong, placed upon the tube of the gerum.
Pfl. Gernm superior, somewhat ovate, terminated (within
the corolla) by an obtuse tube; style within the tube of
the gerum, thread-shaped, the length of the stamens; stig-
mas two or three, rather obtuse. Peric. Capsule some-
what globoso, turbolose, of three cells, sometimes only two.
Seeds numerous.

Ell. Ch. Calyx five-toothed. Corolla funnel-shaped, five-
toothed. Anthers five placed on the tube of the gerum.
Style simple. Capsule of three cells and many seeds.

256. There is no figure of this solitary species of Lerehca,
which is a native of the East Indies, and a plant of irregular
growth, furnished with flanking jointed branches. Leaves
opposite, on foot-stalks, lanceolate, smooth, entire, a foot
in length. Stipula sword-shaped, shorter than the foot-
stalks.
flaxes. Spike terminal, flender, a foot high; flowers remote, scattered, small.

The above description is entirely taken from the works of Linnaeus, the only person who ever saw the plant. No trace of it is to be found in his herbarium, yet it is to be presumed the specimen exists somewhere in his collection, probably without a name.

LERENZA, in Geography, a town of New Granada; 25 miles N. of Tunja.

LERE, a town of Sweden, in West Gothland; 4 miles N. of Gothenburg.

LERI, John de, in Biography, a French Protestant minister, was born at La Margelle, a village in Burgundy, and professed his academic studies at Geneva. In 1556 he was selected to accompany two ministers, on a mission to join an intended colony of the reformed religion in Brazil, under the protection of admiral de Coligny. On their arrival, they found their project so involved with difficulties, that Leri returned to France in the following year, having endured astonishing hardships during his voyage. He afterwards was admitted to the office of the ministry, and exercised it at La Charitée, at the time of the massacre of St. Bartholomew, when he was obliged to make a very hasty escape to the town of Sancerre. It was during the memorable siege of this place that he was granted a pension from marshal de la Chaîre, permitting him to retire wherever he pleased; he went to Bern in Switzerland, where he was received in the most kind and hospitable manner by M. de Coligny, son of the admiral. In 1574 he published an interesting "History of the Siege of Sancerre," giving an account of the transactions of that siege, and of the horrors of famine to which the Protestants submitted in defence of their religion, and all that was dear to them, which was widely dispersed, and went through many editions. In 1577 he published an account of his voyage to Brazil. He died at Bern in 1611, greatly regretted by all who knew him. Bayle. Moreri.

LERIA, in Ancient Geography, an island of the Ægean sea; one of the Sporades, according to Strabo. Also, a town of Spain, in the Tarragonensis, and in the interior of the country of the Edetani. Ptolomy.

LERIDA, in Geography, anciently called Ilerda, a town of Spain, in Catalonia, distinguished in ancient and modern history for the great events which have rendered it memorable. It was the capital of the country of the Ilergetes long before the first invasion of Spain by the Romans, and had its own particular princes. In the plains of Lerida Scipio gained a signal victory over Hannibal, the Carthaginian general, A.U.C. 537. It was, likewise, under the walls of this town that Julius Caesar conquered the lieutenants of Pompey, A.U.C. 705. The beauty of its situation and the fertility of the country attracted the attention of the Romans; and so soon as they had made a conquest of it they planted colonies there, and gave it the title of "Municipium Ilerdense." This town, having fallen under the dominion of the Goths, embraced the Christian religion, and was the seat of a celebrated council held here A.D. 528, or 524. A council held here in 546 is remarkable for two of its canons: one prohibiting ecclesiastics from shedding human blood, and another permitting the communion to be administered to magicians when they are dying. After the conquest of the Moors, it became at first subject to the caliph of Damascus, and afterwards to the Moorish kings of Cordova; but its own governor erecting the standard of rebellion and usurping the supreme power, it had a separate king. In 1149, Raymond Berenger, the last count of Barcelona, who had just ascended the throne of Aragon, took Lerida from the Moors, and from that time it formed a part of Catalonia.

This town is situated on the declivity of a hill, at the top, of which the castle stands, on the right and west bank of the river Segra, which bathes the walls of it. It is long, narrow, almost triangular, close, and ill built. It has one tolerable street, a quarter of a league in length, but, like the others, narrow and ill paved. A quay, lately built, extends through the whole length of the town, which forms a kind of promenade for the inhabitants. Their number is about 18,000. It is an episcopal see, suffragan to Tarra- gona. Its diocese includes 150 parishes; Lerida itself has one cathedral chapter, four parishes, eight convents of monks, three of nuns, one hospital, and one college. The town has a civil and military governor, a small garrison, and an alcaide-major for the administration of justice. Its university, established in 1200, by James II., king of Aragon, was suppressed by Philip V. at the commencement of the eighteenth century. The cathedral is the only edifice in Lerida that claims attention. Lerida formerly carried on a trade in salt-fish, which has wholly failed. Its present commerce is confined to the exportation of some productions of the land, chiefly fruits and pot-herbs; great quantities of which are sent to Urgel and Aragon. The adjacent country is very fertile, and valuable on account of the variety and abundance of its produce; consisting of wheat, oats, flax, hemp, oil, wine, beans, and all kinds of excellent fruits and pot-herbs. The country is intersected with canals supplied by neighbouring rivers, and is skilfully and carefully watered. Some fljg-worms are also bred here, but in no great number; 62 miles E. of Saragossa. N. lat. 41° 29'. E. long. 0° 25'.

LERIKA, a town of Swedish Lapland; 100 miles W.N.W. of Tornea.

LERILLON, a small island in the Grecian Archipe- lago, near the N. coast of the island of Lero.

LERIN, a town of Spain, in Navarre; 15 miles E. of Estello.

LERINA, in Ancient Geography, Lurins, an island of the Mediterranean, upon the coast of Gallia Carbonennis, S.W. of Nicea. Strabo, who calls it "Planafia," from its form and situation, says that it had a garrison.

LERINS, in Geography, a name given to two small islands in the Mediterranean, near the coast of France, about six miles S. of Antibes; called "St. Marguerite" and "St. Honorat," near these are some other islets.

LERNA, a dismantled town of Spain, in Old Caffile, on the Arlanza; 23 miles S. of Burgos. Also, a town of Mexico, in the province of Yucatan; 12 miles S. of Campeachy.

LERNA, in Ancient Geography, a lake or marsh, now called "Molinii," in the Argolid, a little N. of Gennem. It is rendered famous by the fact of the defeat of the hydra with many heads, which retired hither and was killed by Hercules. The people of the country pretend that near this lake Neptune ran away with Proserpine; in memory of which event were annually celebrated the mysteries consecrated to Ceres: and hence these mysteries were denominated the "Lernian mysteries." Near the lake was a wood consecrated to this goddess, which commenced at mount Pontinus. Pauly. Corinth. i. ii. c. 36.

LERNEA, in Zoology, a genus of the class Vermes, and order Mollusca, which is characterized by Linnaeus as having an oblong, somewhat cylindrical and naked body; tentacles or arms two, or sometimes three on each side and round, by which it affixes itself to any substance; two ovaries projecting like tails from the lower extremity. They are without eyes,
eyes, and are very troublesome to fish, adhering very firmly to them, chiefly to the gills and fins. There are fifteen species, which we shall briefly enumerate.

Species.

**Branchialis** is one of the largest, being about two inches in length. The body is round and flexuous, the mouth is lateral, and the thickened between three slightly branched horns. It inhabits the northern seas, and is found adhering to the gills of cod-fish. It is used as food by the Greenlanders. Müll. Zool.

The body of this species is hollow, membraneous, thicker before and behind; dull white, dirty red. The neck is long, tubular, and filiform; tail ending in a perpendicular groove; ovaries two, composed of long twirled cirri.

**Cyprinacea.** Body cylindrical, clavate behind; thorax forked; tentacula lunate at the tip. It has four tentacula, two of them lunate at the tips; it is only about half an inch long, and of the thickness of a small straw; the body is rounded, of a pale greyish-white, glossy on the surface, and somewhat pellucid; it is thrall out of a kind of sheath at the base, which is of a white colour, and a thick skin; towards the other extremity of the body there are three obtuse tubercles, one of which is much larger than the rest. It is found on the sides of the bream, carp, and roach of our ponds and rivers, in abundance.

**Salmoena, or Salmon hose.** Body obovate; thorax inversely heart-shaped; tentacula two linear and approaching each other. It is rather more than half an inch long, and is found, as its name imports, adhering to the salmon about its gills. Barbut.

The body is pale and soft, head small, oblong, rather convex, with two horizontal lips; the upper one is armed with two rigid moveable hooks, the lower short, bifid; abdomen inversely ovate; ovaries round, granulate within, and as large as the whole body.

**Anellina** has a lunate body, and corseled thorax, and is found in the gills of cod-fish and herring. Barbut.

**Hudsonis.** Body knotty; two tentacula; ovary double and united behind; is found in the gills of the salmo huch, in northern lakes and rivers. The body is clear white and somewhat cartilaginous.

**Clavata.** Body cylindrical, sublunate and tripled beneath the tip and snout. Müll. It is found in the fins, gills, mouth, and eyes of the Perca Norvegica.

**Unciata.** Body rather heart-shaped; snout simple, curved, and the mouth terminal. Müll. It is found on the gills and fins of cod-fish in the Greenland seas. The body is soft, pale, with a longitudinal groove down the middle of the back; the ovaries are round and thickened towards the tip.

**Gorina.** Body rhomboid; it has two arms before and two behind, all of which are nodose; the head is armed with two curved horns. Shaw. Müll. It inhabits the gills of the Cottus gobio, or Miller's thumb, and is nearly three quarters of an inch in length.

Body blueish-white; head roundish, with two incurved horns; the mouth is placed between the horns, and is furnished with three lips; the tentacula are angular, curved, knotty; intestines translucent above; tail bifid; ovaries spiral, round, subulate.

**Radiata** has a square depressed body, with three pair of arms and four horns. Müll. It is found in and about the mouth of the Coryphena rupestris, in the Greenland seas. It is rather more than an inch in length; whitish or cinereous, and rough with hardish tubercles; the fins a little crenate; head depressed, rounded, and covered with numerous papillae; ovaries large, oboval.

**Nodosa.** Body square tuberculated; with two very short arms beneath each side, Müll. Shaw. It inhabits about the mouth of the Perca Norvegica.

Body soft, pale cinereous, convex above, and concave beneath, with four hard white tubercles in the middle of the back, and five white teeth on each side; head rounded, and divided by a streak in the middle.

**Cornuta.** Body oblong, with four straightly emarginate arms; head tufted, Shaw. Müll. It is found on some species of the Pleuronectes.

Body covered with a pellucid skin; front with two horns and a single tooth; the month has two feeders; ovaries brown, and its eggs are of a tawny colour.

**Pectoralis.** Head orbicular; hemispherical; abdomen obcordate, with a terminal truncate papilla. Müll. Shaw. It is found on the gill and pectoral fins of the flounder, or Pleuronectes flabellus, and other species of the same genus.

Body white, diaphanous, covered with small blackish dots; the crown has two subcylindrical projections; snout conical, truncate, with four minute horns, two short spines, and two feeders near the third conic spine. Two tentacula, not curved; ovaries two, rather narrow, sub-annulate, and of equal diameters.

**Lotse, found on the gills of the Gadus lata, has four unequal ovaries; the mouth has two hooks; four cruciate appendages.**

**Cyclopterus.** Body round, flexuous, with a double office in the middle of the snout; snout terminated by three horns, divided into three parts. It inhabits a species of the Cyclopterus, or Lump-fish.

Body resembles the branchiatus above described, but the horn is slender, turned up and entire at the tip; tail is narrower, with two convex lobes on each side; ovaries simple, spiral, and nearly five inches long when extended. There is another variety which is rather less and has greenish ovaries.

**Pinnareum** is of a reddish colour; head cylindrical and rostrate on the fore-part; it has two tentacula, which are lunate, and bifid at the tip. It is found on the dorsal fins of the Gadus barbaetus.

Body depressed, fleshy, grooved on the back, with a cylindrical arm placed on the fore-part of the back, concealed in a groove; the ovaries long and cylindrical.

**Lerneb, in Geography, a town of Algiers; 20 miles S. of Tipsa.**

**Lero, anciently Leros, or Leras, an island of the Grecian Archipelago, N.N.W. of that of Calemi (which see). Strabo says that it was formerly inhabited by a colony of Milicians. It is about eight miles long, and two broad. It has a good harbour and a few coves, and also high mountains, in whose forests mines and quarries of marble might be worked; its soil is ungrateful, and its inhabitants are under the necessity of seeking lucerns abroad by navigation and traffic. N. lat. 37° 15'. E. long. 26° 35'.**

**Leronia, a town of Italy, in the Orvietan; 7 miles N.W. of Orvieto.**

**Lerot, or Garden Squirrel of Buffon, in Zoology.** See **Myoxus Nitera.**

**Le Roy le vent, a form of words, by which the royal assent is signified by the clerk of the parliament to public bills; to private bills this assent is expressed by fait fait comme il est dit.**

**Le Roy s'avoira.** By these words to a bill, presented to the king by his parliament, is understood his absolute denial.
denial of that bill in a more civil way; and the bill thereby becomes wholly null and void. See Royal and Parliament.

LERIVATILLA, in Geography, a town of Spain, in the province of Leon; 15 miles S. E. of Ciudad Rodrigo.

LERWIA, or LEWWE, in Zoology. See Antelope Jerwia.

LERWICK, in Geography, a sea-port town, situated in a parish of the same name, on the east side of the Mainland of the Shetland isles. It is distinguished as the seat of the court held by the sheriff-depute of this stewartry, and as the general rendezvous of all the vessels employed in the whale-fishery. The harbour is one of the safest and largest in Great Britain. It is formed by the island of Bressay, and is particularly commodious from the circumstance of having two entries, one from the south, and another from the north. On the outside of the north entrance is a rock, which is called the Unicorn. It derived its name from the Unicorn man-of-war, which was sent in pursuit of the earl of Bothwell, when that nobleman fled to Shetland. As this vessel appeared at the mouth of the forth entry, before her approach was discovered by the earl, he with difficulty escaped by the north passage. The Unicorn eagerly pursued, but having no pilot on board, she struck upon this rock and was wrecked. The town of Lerwick is about half a mile in length, and is irregularly built, but contains several excellent houses. Near the north end is a small fortification, called Fort Charlotte. It is usually garrisoned by a party of invalids, and serves to protect the north entry of the harbour. About a mile and a half from the town are the remains of two ancient Danish castles. The parish extends about six miles along the coast, but at no point is more than one in breadth. The surface of the ground is for the most part rocky and mountainous. Immediately upon the shores, however, there are many very fine arable fields, the soil of which, though light and sandy, possesse Considerable fertility. The population of the whole parish, according to the parliamentary returns in 1850, amounted to 1500 persons; about 600 of whom are resident in the town. Sinclair's Statistical Account of Scotland, vol. iii. communicated by the Rev. James Senda.

LESAIA, a small island in the Baltic, E. of Aland. N. lat. 60° 18'. E. long. 20° 10'.

LESBIAN CYMATIUM. See Cymatium.

LESBUIM MARMON, a name given by the ancients to a species of marble of a blueish-white, sometimes used for the vases and other ornamental works, but principally in the walls of public buildings.

LESEONAX, in Biography, a native of Mitylene, who flourished in the first century of the Christian era, was a disciple of Timocrates, afterwards became a teacher of philosophy in his native city, and obtained a great number of scholars. He was author of many books of philosophy, and Photius says he had read sixteen orations written by him. Two of these, it is supposed, have reached modern times, and were first published by Aldus, in his edition of the ancient orators, in 1513. They were afterwards published by Henry Stephens, with the orations of Aeschinis, Lyias, and others. They were also published, in 1619, by Gruter. Lebonax is said to have been the author of a treatise "De Figuris Grammaticis." He left a son named Potamon, an eminent rhetorician at Rome, in the reign of the emperor Tiberius. So sensible were the magistrates of Mitylene of his merits, and of the utility of his labours, that they caused a medal to be struck in his honour: one of which was discovered in the south of France about four

fcoee years ago, and an engraving of it published in 1744, by M. Cary, of the Academy of Marckes. Moreri.

LESBOS, in Ancient Geography, now called Melinda, an island of the Grecian Archipæleg, situated N. E. and S. W. and occupying in its length the port of the gulf of Adamyttion, on the coast of Asia Minor. It extended in latitude from 39° 5' to 39° 30', S. E. of the island of Lemnos. It is said, that the Pelagis first settled themselves in this island under the conduct of Xanthis, son of Triopus, king of the Pelagis, driven from Argos, who passed from Lycia to this island, called Iba, and named by him Pelagis. Seven generations after this time, the inhabitants perished in the deluge of Deucalion, or rather in an inundation that overwhelmed this island. It was then left desert. In times of peace Maccareus, an inhabitant of Ionia, afterwards denominated Achaia, formed an embellishment in this island. This prince was accompanied with Ionians; and some other people of different nations. Lesbos, is said, came hither some time after Maccareus, his progenitor.

Eutathius, in his Commentary on the third book of the Odyssey, says, that this island contained five towns, viz. Lesbos, whence it derived its name, Antilla, or Iba, Pyrrha, Methymna, and Mitylene, whence this island has been since called Mitylene and Metelin. This last town was the capital. Lesbos, originally governed by rulers chosen among its own inhabitants, became afterwards subject to the dominion of foreign tyrants. It succcessively passed under the domination of the Persians, and under that of the Greeks, till its liberty was restored to it by Alexander the Great. This liberty it preferred till the time of Pompey, who reduced it into the state of a Roman province; continuing, however, for some time to Mitylene its ancient privileges. The Crusaders next embellished themselves for a certain period, and the Genoese were masters of it when the empire of the East fell into the hands of the Turks. It was on this occasion that Mahomet II, ten years after the capture of Constantinople, equipped a considerable fleet in order to subdue it. Mitylene, Methymna, and most of the places of this island had been well fortified; the knights of Rhodes furnished them well; and the inhabitants, who knew the cruelties committed by the Turks at the capture of Constantinople, were all disposed to defend their lives. The Ottoman forces, although very considerable, would undoubtedly have miscarried against thousands of heroes, if these heroes had not been betrayed by the treachery of Lewis Gattilubo, who thought of obtaining the sovereignty of the island by delivering it up to Mahomet. Accordingly, he persuaded his cousin Gattilubo to sign a shameful capitulation. However, as a recompence for the treachery of the one, and for the weakness of the other, Mahomet caused them to be cruelly put to death a short time after. Lesbos gave birth to several persons of distinction; among whom may reckon Alceus, a lyric poet, who long declined against tyranny; Sappho, the celebrated poetess, whom antiquity has placed among the Muses, and who, by an unfortunate passion, was impelled to precipitate herself from the promontory Leucates; Theophrastus, a disciple of Plato and Aristotle; Pittaccus, whom Greece reckons among her sages, and who, more ardent in the pursuits of the happy citizens than of his own, conceived and executed the project of subduing power in order to restore liberty to his country; and lastly, Potamon, born at Mitylene, a distinguished rhetorician, who lived at Rome under Tiberius. This latter, wishing to return to his country, and there establish a chair of eloquence, obtained from Tiberius letters, in which it was expressly mentioned, that whoever should dare to insult Potamon, would insult in his person the emperor...
pier himself. We might also mention, in more modern times, the two brothers, Barbaroff, sons of a pirate, who from simple sailors, became famous pirates, and were afterwards, in succession, sovereigns of Algiers. The younger, appointed high admiral by Soliman I., is more known than his brother in the history of the Ottoman empire. For an account of the present state of Lesbos, see Metelin.

LESCAILLE, James, in Biography, a Dutch printer and poet, born in 1610, was descended from a family of distinction and much consideration at Geneva, which took refuge in Holland on account of some persecution. By profession he was a printer and bookbinder, and gained great reputation by the beauty and accuracy of various editions of books which he published. He was in high estimation as a poet, and was noticed by the emperor Leopold. He died in 1677, leaving behind him a daughter, Catherine, born in 1649, and so distinguished by her poetical talents, that she was called the Dutch Sappho. Her brother-in-law, Ranck, published, in 1728, a volume of her works, which contains seven tragedies, besides other pieces. She died in 1717.

Moreri.

LESCANO, in Geography, a town of Spain, in the province of Guipuscoa; 9 miles S.S.W. of Tolosa.

LESCAR, a town of France, in the department of the Lower Pyrenees, and chief place of a canton, in the district of Pau; 3 miles N.W. of Pau. Before the revolution, it was the seat of a bishop, suffragan of Auch. The place contains 1885, and the canton 7523 inhabitants, on a territory of 1775 square, in 15 communes.

LESCHERES, a town of France, in the department of the Upper Marne; 9 miles S. of Joinville.

LESCHIVER, a town of Perla, in the province of Irak; 101 miles W. of Hamadan.

LESCZY, a town of Poland, in Volhynia; 24 miles N. of Berdicyow.

LESDIGUERES, François de Bonne, Duke of, in Biography, was born of an ancient family, in the Upper Dauphine, in 1543. He was brought up to the military profession, and acquired, while he was yet a young man, so much reputation for skill and true courage, that he was chosen by the Calvinists of his native province their leader, after the death of Montbrun. Soon after the command devolved upon him, he took a number of provinces, and at length the capital of Grenoble. This was in the year 1590. When the duke of Savoy, taking advantage of the disbursements in France, projected an invasion of Provence and Dauphine, Lediguieres, who acted as an independent commander, covered the latter province with his arms. He now went to court to demand the government of Grenoble, which Henry IV. could not grant him, as he had, by the advice of his council, referred it for a Catholic; the envoy being refused his request, he applied to the council assembled, "Gentlemen, if you do not think it proper that my master should have this government, you should think of the means of taking it from him." This energetic answer was not displeasing to the king, who was glad to be under the necessity of promoting a general of the Protestant persuasion. Lediguieres was, from this time, appointed lieutenant-general of the king's armies in Piedmont, Savoy, and Dauphine, and by his vigilance and activity disapproved all attempts of the duke of Savoy, who was accustomed to call him the fox of Dauphine. When that prince was constructing a strong fort on the French territory, Lediguieres was reproached by the king for allowing it, to which he replied, "Your majesty has occasion for a good fortress to bridle that of Montmelian. Since the duke of Savoy is willing to build one at his expense, let him do it: I engage, as soon as it is completed, and furnished with cannon and ammunition, to take it from him." He performed his promise, and his services were rewarded, in 1608, with the staff of a marshal of France, and his estate of Lefdigueres erected into a dukedom and peerage. In the succeeding reign he favored his antagonist, the duke of Savoy, when attacked by the armies of Spain. In 1620, when the civil war was renewed, he received great offers from his party, the Calvinists, to accept the post of commander-in-chief, but he preferred his fidelity to the king, and accompanied him into the field. Upon the death of the confable of France, nothing but his religious zeal in the way of his succeeding to the high office, and this obstacle he removed by abjuring the Calvinistic creed. The patent which conferred upon him the office, gave as a reason for his appointment, that it was on account of "his having been always victorious, and never vanquished." Having apostatized from his creed, probably for the sake of honours and wealth, of which he was exceedingly avaricious, he did not hesitate to take the command and his party, and was uniformly successful in the service, till his death, in 1626, when he had attained to the age of eighty-four. Notwithstanding his defects, Lediguieres had a great mind: while leader of the Calvinists, his principal domestic was bribed to assassinate him: the plot was discovered, and taking the masque, he ordered him to arms, at the same time he armed himself: "Since you have promised," said he, "to kill me, try to do it now, and do not forfeit your character for valor by an act of cowardice." The man threw himself at his feet, confessed his crime, and the general not only pardoned, but continued to employ him.

LESGNA, in Geography, a town of France, in the department of the Aude; 11 miles W. of Narbonne.

LESDINA, Phares, an island in the Adriatic, between Brazza and Corzola Nigra, about 44 miles long, and 5—8 broad, lying from W. to E. in N. lat. 43° 30'. In the highest part it is rocky and barren, but nevertheless contains some good land, yielding abundance of corn. Its principal productions are also wine, oil, figs, almonds, fyrn, honey, aloes, oranges, wool, cheese, and salt. Marble, in great quantities, is found on the island. Salt-fish is the chief article of commerce. Its capital is Lesina; which is a small, fortified town, at the bottom of a bay near Cape Pellegrino, the site of a bishop, and residence of a governor, with a capacious and safe harbour. The number of inhabitants is reckoned about 1200; 20 miles S. of Spalatro. N. lat. 43° 5'. E. long. 16° 50'.—Allo, a town of Naples, in Capitanata, the site of a bishop, suffragan of Benevento, on a lake of the same name communicating with the Adriatic; almost totally destroyed in 1627 by an earthquake; 26 miles N.W. of Manfredonia. N. lat. 41° 59'. E. long. 14° 30'.

LESKAU, a town of Bohemia, in the circle of Pillen; 7 miles E. of Plau.

LESKEA, or Leskia, in Botany, an Hedwigian genus of mosses, named by its author in his Hist. Nat. Museorum Prondoformorum, v. 2, 93, in memory of his friend Leke, prosector of Economy at Leipsic, and afterwards of Nat. Hist. at Marburg, who died in 1786, aged 35. This genus is by British botanists united to Hymen, as agreeing with entirely in habit, and differing only in a very minute and uncertain character of the inner fringe, which is furnished with 16 simple teeth, instead of double or compound ones. See Fringe of Mosses, and Hymen.

LESKEN, in Geography, a town of Prussia, in Pomeraelia; 6 miles N.W. of Marienburg.

LESKIRCH,
LESKIRCH, a town of Transylvania; 14 miles W. of Fogaras.

LESKNITZ, or Leseitz, a town of Silesia, in the principality of Oppeln; 18 miles S.E. of Oppeln. N. lat. 50° 25'. E. long. 13° 6'.

LESKO, a town of Austrian Poland, in Galicia; 48 miles S. of Lemberg.

LESKOVETZ, a town of European Turkey, in Bulgaria; 84 miles W.N.W. of Sophia.

LESLEY, JOHN, in Biography, bishop of Rofs, of an eminent family in the northern part of Scotland, was born in 1527. He was educated at Aberdeen, and was prefered, in 1547, with a canonic in the cathedral of that city. Having obtained this preferment, he spent some years at the French universities, and took his degree of doctor of laws at Paris. In 1554, he returned to Scotland, and, taking orders, was appointed official and vicar-general of the diocese of Aberdeen. He took a most active part against the reformation, which was now taking root in Scotland; and appeared as a principal champion of the Roman Catholic party, in a disputition held between them and the reformers at Edinburgh, in 1560. When the young queen Mary was invited to return and assume the reins of government, he was sent over by the Catholics to persuade her to throw herself into the arms of the Popish party. He embarked with her at Calais in 1561; and soon after her arrival was one of the senators of the college of justice, and privy-councillor. Shortly after this, he was nominated to the see of Rofs. He did not confine his labours to the duties of the church, but was appointed by the queen to collect and revise the subtiling laws of the realm; and the collection printed at Edinburgh in 1566, called the black acts of parliament, from being in the black letter, was the refult of its labours. When the unfortunate queen had taken refuge in England from the fury of the covenanters, and commissiiters were appointed by queen Elizabeth to examine the dispute between her and her subjects, the bishop of Rofs was one of those whom Mary chose for the defence of her cause. When reasoning and argument were found to be ineffectual, he joined in conspiracies, for her deliverance, which were dangerous to the person and government of Elizabeth. He urged the duke of Norfolk to those designs which proved his ruin, and was himself involved in considerable danger: he was taken into custody, his papers searched, himself committed to the Tower, treated with the utmost rigour, threatened with capital punishment, and, after a long confinement, set at liberty, on condition that he should leave the kingdom. He accordingly went into the Netherlands, and employed himself in the most perfuing solicitations to the kings of France and Spain, the German princes, and at length to the pope, in order to obtain Mary's liberation. He published several books in her defence, and in vindication of her right and title to the crown of England. In 1579, he was appointed suffragan and vicar-general of the archbishopric of Rouen; but on making his visitation of the diocese he was fixed, imprisoned, and forced to purchase his liberty by a high ransom. In 1593, he was nominated to the bishopric of Conflance. When there was no hope left him of returning to his own country, he retired to a monastery near Bruffels, where he died in 1596. He was a man of learning, an able statesman, and a faithful servant and subject of his sovereign: his principal works, as an author, are, 1, his history, entitled "De origine, moribus, et rebus gestis Scotorum," in ten books: of the last three books are dedicated to the queen, to whom they were presented in English, before their publication in Latin; and, 2, a geographical work, entitled "Regimia et Inflarum Vol. XX. Scotise Descriptio." Gen. Biog. Robertson's Hist. of Scotland.

LESLEY, JOHN, an Irish prelate in the 17th century, was born in the north of Scotland, and received the early part of his education at Aberdeen. From this place he was sent to Oxford to complete his studies. He afterwards visited Spain, Italy, Germany, and France for farther improvement, and made a proficiency in polite literature, as well as in the abstruse branches of learning. He was so great a master of the Latin, that it was said of him when in Spain "Solus Leffius Latine loquitur." He continued abroad twenty-two years, became conversant in Courts, and procured the favour and friendship of many foreign princes: and on his return he was honoured with the patronage of Charles I., who admitted him into his privy-council, in which he was continued by Charles II. after the restoration. In the church of Scotland he was preferred to the bishopric of Orkney, and was translated, in 1632, to Raphoe, in Ireland. Here he built a stately palace in the form of a castle, which was found of great utility in the civil wars, as it sustained a siege, with the bishop as a kind of commander, who was, in fact, the last person who maintained the struggle in defence of the royal cause in those parts. After the restoration, he was preferred to the bishopric of Clogher. He died in 1674, being upwards of an hundred years old, and having worn the mitre more than fifty years. He wrote many curious and very learned works, which he designed for publication, but which were destroyed, together with his valuable library and MSS., the fruits of many years collection, in the civil wars. Biog. Brit.

LESLE, CHARLES, second son of the preceding, was educated in grammar-learning at Innskilling; and, in 1604, was admitted a fellow commoner of Trinity-college, Dublin, where he took his degrees. Upon the death of his father he came over to England, and entered himself of the Temple, at London. He soon abandoned the study of the law for that of theology, and was, in 1686, admitted into holy orders. In 1685, he was made chancellor of the cathedral church of the diocese of Connor. About this time he made himself extremely obnoxious to the Popish party in Ireland, by a zealous opposition to their doctrines, and by an earnest attachment to the Protestant religion, which he endeavoured to propagate by every means in his power. The Papists, encouraged by the reigning prince, James II., aimed at engrossing civil as well as spiritual offices; and a high-sirif of their party was appointed for the county of Monaghan. Mr. Leslie, as a magistrate, and as conversant with the law of the land, was applied to with regard to the legality of the appointment: he infantly decided that it would be as illegal for the people to permit the sheriff to act, as it would be in him to attempt it. The magistrates, at the next quarter-jennings, inquired if the sheriffs were legally qualified, to which he replied, that "he was appointed by the king, and was of the king's religion." The answer to this was, that they boldly agreed to commit him for intrusion and a contempt of the court. Mr. Leslie, notwithstanding his attachment to the law of the land, had imbibed the doctrines of passive obedience and non-refrissance, which so warped his understanding, that, at the revolution, he refused to take the oaths to William and Mary. He was, in consequence of this conduct, deprived of his preferments; and in 1689 withdrew with his family into England. Here he employed his pen in support of the cause and the party which he embraced, and was esteemed one of the ablest champions which the non-jurors had. He published an answer to the "State of the Protestants in Ireland, under the late King James's Government," by bishop, afterwards
archbishop, King. He published a weekly paper, entitled
"The Rehearsal," consisting of dialogues on the affairs of
the times: this was continued fix or seven years, when the
papers were collected and published together; and it was
paid by bishop Burnet, that the fame thread of the argument
was purfued through them all, against the lawfulness of reafon-
date in any case whatever, deriving the fource of government
wholly from God. Mr. LeFèvre wrote againft Drifts, Jews,
Papifts, Socinians, and Quakers: all his writings he after-
wards collected, excepting an illebil piece againft the
learned Tillotfon, and published in two volumes folo. The
frequent visits which he made to the continent, rendered him
obnoxious to the British government; and the hatred of
him was much increased by a piece, entitled "The heredi-
tary Right of the Crown of England aferted," of which he was
the reputed author. He went to Bar-le-Duc to at-
tempt the conversion of the fon of James II. to the Protestant
religion, in the hope that he might one day be fettled on
the throne. Towards the clofe of queen Anne's reign, he
took much pains in recommending him as her fucceffor.
The attempt was made in vain; and after the rebellion of
1715, he retired with the young Pretender to Italy. In
1721, he made up his mind to return and die in his native
country; and his friends implored the protection of govern-
ment, which was granted. He died at his own house in Glaf-
lough, in the county of Monaghan. He was unquestionably
a man of extenfive learning and great merit, and diftinguifhed
by his piety, humility, and integrity. Biog. Brit.
LESSNEVEN, in Geography, a town of France, in the
department of Finiflerre, and chief place of a canton, in the
district of Bruffel; 13 miles N.E. of Bruffel. The place
contains 2030, and the canton 16,024 inhabitants, on a
territory of 1674 kilometres, in 10 communes. N. lat.
48° 34'. W. long. 4° 14'.
LESNICA, a town of Lithuania, in the palatinate of
Minifk; 48 miles N.E. of Minifk.
LESNIOW, a town of Poland, in Volhynia; 18 miles
S. of Lucyko.
LESONDELOK, a town in the duchy of Warfaw; 35 miles
S. of Pofen.
LESOANDELOR, a town of Afiaic Turkey, in Car-
umania; 40 miles S.S.W. of Cogni.
LESPEARRE, a town of France, and principal place of
a district, in the department of the Gironde; 11 miles
N.N.W. of Bourdeaux. The place contains 800, and the
canton 15,247 inhabitants, on a territory of 4424 kilomet-
res, in 18 communes. N. lat. 45° 19'. W. long. 0° 50'.
LESPEDAIZA, in Botany, fo named by Michaux, in
compliment to his friend and patron Lefpedetz, governor of
Florida, who was very favourabie to his botanical expedition
through that country, though it does not appear that the
governor himself was a botanift. Michaux Boreali-Amer.
v. 2. 70.—This genus differs from Hedyfara, fee that ar-
ticle, in its legume, which is elliptical and turgid, smooth,
of one cell, with a foltary feed. The fligma moreover is
faid to be capitate and somewhat conical.—The leaves are
moftly ternate, rarely fimple.—It appears to be a good
genus, and merits further examination, for its species will
probably be found rather numerous. Examples are L. fijfa-
flora, (Hedyfara junceum; Walter Carolin. 184. Mich-
dicago virginica; Linn. Sp. Pl. 1056.) a native of Virgi-
nia and Carolina: and L. polyphylvds, Michaux, 140, (Hedy-
farum hirtum; Linn. Sp. Pl. 1055.), found in Carolina and
Georgia. The habit is fender and thurby. Flowers
small, purplift, in longiflalked spikes.
LESSANITZ, in Geography, a town of Bohemia, in the
circle of Kaurzim; eight miles S.E. of Prague.

LESSAY, a town of France, in the department of the
Channel, and chief place of a canton, in the district of
Coutances; 11 miles N. of Coutances. The place contains
1503, and the canton 13,644 inhabitants, on a territory of
260 kilometres, in 13 communes.
LESSNE, a law term employed in leaffing land, to
signify the tenant. See LEASE.
LESSINES, in Geography, a town of France, in the
department of the Jemappe, and chief place of a canton,
in the district of Tourney, situated on the river Dender,
and celebrated for its linen manufacture; 23 miles W.S.W.
of Bruffels. The place contains 3037, and the canton
14,708 inhabitants, on a territory of 175 kilometres, in 11
communes.
LESSING, Gottfried, Ephiain, in Biography, was
born at Kamenz, in Pomerania, in 1720. Having received
the early part of his education partly at home, and partly
at a boarding school, he was admitted, at the age of twelve,
to the free-school of Meifen, where he remained five years,
and laid in a flock of Greek and Latin. Some odes of
Anacreon, which he translated at this school, were afterwards
published in his works. His removal to the university of
Leipsic opened a new feene to him; he paid little attention
in the lectures of the professors, but studiously fought out
the company of the students most distinguished for talents,
and bold and singular opinions. He became a frequenter
of debating clubs, and was not furpafled by any perfon in the
focieties in the originality of his sentiments, and the acuta-
ness with which he defended them. After he had spent
three years at the university, his father, who could ill bear
the expence, urged him to take orders, or to pursue fome
profefion by which he might support himfelf. He declined
this reasonable propofal, and fet about tranflating, and or-
iginal compositions for the stage. After many changes, and
much roaming about, he went to Gottingen, where he took
his degree of Master of Arts, with a view to a pro-
fefforhip at Gottingen, but he still continued to find fupport
by literary employment, which conftituted in tranflations,
compilations, and fome original pieces. He was a great
proficient in the game of chiefs, a circumstance that intro-
duced him to the acquaintance of Moles Mendelfohn; and
the printer Nicolai made the third of a literary trio, who
mutually sharpened each other's intellectual faculties, and
influenced each other's opinions. Ramler the lyric poet,
Suflzer the critic, and Suflmich the Viaifte writer, were
occasionally of their parties, and Germany perhaps could not
then boast of conversations more literary and enlightened.
In conjunction with Nicolai and Mendelfohn, he undertook a
periodical work, entitled "The Library of Belles Lettres,"
which was a kind of review of works in polite literature,
with original correspondence. In 1760, he was elected
member of the Academy of Berlin, and soon after was ap-
pointed fecretary to general Tafenziar; his income at this
period was considerable, which he spent liberally upon his
relations and friends. His military afciatics gave him a
tale for high play, which he found arguments to justify.
In 1763, he accompanied his general to the fiege of Schweid-
zig; but after the peace, he was introduced to the king of
Prufia, and then refumed his literary occupations at Berlin.
Though he produced many works, yet they were not the
source of much profif, and, in 1769, his circumftances were
so narrow, that he was obliged to fell his library for fupport.
At this critical juncture he met with a generous
patron in Leopold, heir-apparent to the duke of Brunfick,
through whole means he was appointed librarian at Wolfen-
butte.
LES

battle. One of the fruits of this very desirable situation was a periodical publication, entitled "Contributions to Literary History," containing notices and extracts of the most remarkable MSS. The "Contributions" were made the vehicle of "Fragments of an anonymous Writer discovered in the Library at Wolfenbuttel," which consisted of direct attacks upon the Christian revelation. They occasioned a great commotion among the German theologians, and would not have been printed but for the interference of Prince Leopold with the licencers of the press. In 1778

LESSE, in Geography, an island of Denmark, in the Scagerac, nine miles long, and from one to four wide; within are some small villages, and about it some islands; about 12 miles from the coast of Jutland. N. lat. 57° 17′. E. long. 11°.

LESSE, a town of Norway, in the province of Agderhus 135 miles N. W. of Christiania.

LESSON, in the Manager, is used for any piece of instruction in that art, whether given to the scholar or the horse.

LESSONS, among Ecclisial Writers, portions of the holy scripture, read in Christian churches, at the time of divine service.

In the ancient church, reading the scriptures was one part of the service of the catechumens, at which all persons were allowed to be present, in order to obtain instruction.

The church of England, in the choice of lessons, proceeds as follows; for the first lesson on ordinary days, the direct, to begin at the beginning of the year with Genesis, and to continue on till the books of the Old Testament are read over, only omitting the Chronicles, which are for the most part the name with the books of Samuel and Kings, and other particular chapters in other books, either because they contain names of persons, places, or other matters less profitable to ordinary readers.

The course of the first lessons for Sundays is regulated after a different manner. From Advent to Septuagesima Sunday, some particular chapters of Isaiah are appointed to be read, because that book contains the clearest prophecies concerning Christ. Upon Septuagesima Sunday Genesis is begun, because that book, which treats of the fall of man, and the severe judgment of God inflicted on the world for sin, befit suits with a time of repentance and mortification. After Genesis, follow chapters out of the books of the Old Testament, as they lie in order; only on festival Sundays, such as Easter, Whit Sunday, &c. the particular history relating to that day is appointed to be read; and on the Saints days, the church appoints lessons out of the moral books, such as Proverbs, Ecclesiastes, Ecclesiasticus, &c. as containing excellent instructions for the conduct of life.

As to the second lessons, the church observes the same course both on Sundays and week-days; reading the gospels and Acts of the Apostles in the morning, and the epistles in the evening, in the order they stand in the New Testament; excepting on saints days and holy days, when such lessons are appointed, as either explain the mystery, relate the history, or apply the example to us.

LESSONS for the Virginal, Spinet, and Harpsichord, have undergone great changes in the denomination and arrangement of their movements, from the time of queen Elizabeth to the present. In that princess's virginal book, now in the possession of Vicecount Fitzwilliam, we find pavanas in general to be the slow movement, and galliarda the quick. Now and then a fantasia, a coranto, and a gigue; but as single movements, not parts of a suite of lessons. Preludium, or prelude, frequently occurs without leading to any other movement; as does paffamexzo, alman, toccata, once; but the rest are chiefly old tunes with variations. These pieces are all written on a staff of fix lines.

Lady Nevil's Virginal Book.—This lady was a pupil of our admirable countryman Bird; and all the lessons in her book, a thick quarto, are of his composition. They are admirably transcribed by John Baldwin, a singing-man of Windlor, and a celebrated copyist of that time, 1591.

Its contents are: "My lady Nevil's grounds", with eight variations. Qui poffe, four variations. March before the battle, 12 military movements. Old tunes varied. Grounds and fancies, with 18 pavans, and two leffons of voluntaries, all neatly written on four-lined paper of fix lines.

Thus far all our music for keyed-instruments was in MS. But in the reign of James I the following book appeared in print, fill on fox-lined paper. "Partperia, or the Maydenhead of the first Musick that ever was printed for the Virginall" composed by three famous Masters; William Byrde, Dr. John Bull, and Orlando Gibbons, Gentlemen of his Majesty's most illustrious Chapel. Dedicated to all the Masters and Lovers of Musick. "The pieces in this collection seem to follow in fuits, of which the first is of Bird's composition; as prelude, pavanas, galliarda, all in G minor; then a prelude, and a galliard in C; and a pavan, and two galliardos in G, by the same.

The next author in the collection is master doctor Bull, whose pieces are arranged in the following order, "A pavan and two galliards in A minor; prelude, pavan, and galliard, in G major; two galliards in D minor." Orlando Gibbons' pieces have little connexion, being a galliard in C natural; a fantasia in four parts, in A minor; a pavan in D; the queen's command in C, and a prelude in G. This book was again engraved on copper in 1651, fol.

The title of Handel's two sets of leffons is in French, and the movements of each suit have the same denominations as many French composers of leffons had long used in Louis XIVth's time; as prelude, allemande, courante, gigue, with sometimes adagio, farandole, allegro, and air with doubles, or variations, which include all the technique of the first book.

In the second book, he has prelude, aria con variationi, minuet, chaconne, and gavotte. The movements of the second book are of a lighter kind than those of the first, as the first and third set of Corelli's sonatas are called "Suonate da Chiesa," and the second and fourth sets, "Suonate da Cembalo." Scarlatti's leffons are almost all single pieces, and we believe Alberti's were the first harpsichord leffons published in England, that were called sonatas. "Suonate da Cembalo," which, without accompaniments, is still the general title of what used to be called leffons.

LESSOR, a legal term, applied to the landlord, proprietor, or person who lets the land. See Lease.

LESTANO, in Geography, a town of Italy, in the Friuli; 15 miles W. of Udine.
LESTI, a town of Sweden, in the government of Vasa; 54 miles E. of Jacobstad.

This genus is separated from Cellox only on account of its fligmas, which are three or four, slender and recurved, instead of being capitate or two-lobed. It includes Celloxa paniculata and trigyna of Linneus, with some others, but Mr. Brown hints that it is probably a natural genus, not established on sufficient grounds. His L. harborensis, the only species mentioned as found in New Holland, was gathered by Sir Joseph Banks in the Tropical part of that country. It has a shrubby twining stem; elliptic-oblong, somewhat pointed, smooth leaves; terminal as well as axillary panicles; and three fligmas, which, according to Dr. Solander’s remarks, are deeply emarginate. The manner in which the fruit burrs has not been observed.

LESTIGUANO, in Geography, a town of Etruria; 27 miles W. of Volterra.

LESTOFF. See LAVESTOFF.

LESTORNE, Sir Roger, in Biography, was a great lover of music, and a performer. His family, one of the most ancient in Norfolk, were always great patrons of music, and musicians. Jenkinson was frequently an inmate at Hinton, where, during the seventeenth century, when times were tranquil, professors and dilettanti frequently assembled to sing madrigals, and make use of several sheets of viol in the performance of fantasies in fixed parts, by the best composers of the times.

LESTRIGONS, in Ancient Geography and Fabulous History, inhabitants of Sicily towards the S.E., who are represented to have been a ferocious people. It is reported that they took Elpe, the daughter of Polyphemus the Cyclop, by force from Ulysses, who had seized her and was running away with her, and returned her to her father. If we may credit the poets, both the Lestrigons and the Cyclops were real cannibals, who devoured six of Ulysses’s companions. The learned Bochart will have the rise of this fable to be, that the Lestrigons were anciently called Leontini, a name derived from their barbarous and cruel manners; “a Leontinis moribus.”

LESTWITHIAL, in Geography. See LESTWITHIAL.

LESTWASIO, a town of Austrian Poland, in Galicia; 28 miles N.W. of Przemyl.

LET-Fall, in Sea Language, the word of command for putting out a fall, when the yards are aloft, and the fall is to come down from the yard; but when the yards are flirken down, then the fall is loosed below, before they hoist the yard.

Let-fall is not properly said of top-falls, because they lie on the top; and therefore the word for them is, Have out your top-falls. Nor can it be applied to the main-fall; for the word is, Strike the main and set it. So that in strictness the term let-fall belongs only to the main-fall, fore-fall, and sprit-fall, when their yards are hoisted aloft.

Let-in, in Ship Building, is the letting of one thing into another for support or security, as the beams into the clamps, carlings into the beams, &c. by scores being cut to receive them.

LETA, in Geography, a cape on the W. coast of the island of Jersey; 6 miles N.W. of St. Aubin.

LETA, a town of Sweden, in the government of Abo; 30 miles N.W. of Abo.

LETHAIS, a town of Mingrelia, on the Black sea; 10 miles N. of Anarghia.

LETHAM, a town of Scotland, with a market, in the county of Fergus; five miles E. of Forfar.

LETHARGY, in Medicine, Λεθαγία, Λεσταγία, signifying literally an indolent forgetfulness, (δεισία ὀρθομορίας), from δεισία and μορία, is commonly used to denote an inefcient and irrefitable sleepinez, accompanied by an impaired state of the memory, but without delirium.

The lethargy is, in fact, a minor degree of apoplexy, and originates from the same causes, and implies a similar state of pressure on the brain, the common centre of the nervous system, and occasions that diffuse. Various denominations have been given to lethargic complaints, according to the difference of the degree of severity, and some nosologists have treated of these varieties as distinct species of disease.

Sauvages, for instance, has three genera of sleepy affections, Letharius, Cataphora, and Carus. The cataphora he defines, a state of somnolence, from which the patient may be easily roused, without fever, delirium, or loss of memory; the lethargy, a soporofate state, from which the patient may be easily roused, accompanied with the greatest torpor of the memory and imagination, and with fever; and carus, a profound sleep without scoring; for when the scoring is present, he denominates it apoplexy. (See his Nofol. Method. Clas. iv. Ord. 5.) But it is obvious, as Dr. Cullen long ago observed, that these various appellations and definitions delinate the same disease, in different degrees of severity; we may, therefore, refer to the article APoplexy for a general view of the nature of the malady. We may obseve, at present, that it originates from some compression upon the substance of the brain, by which its functions are impeded, and its influence on the system at large, through the medium of the nerves, obstructed; that such compression may be occasioned by fractures of the skull, when the fractured portion of the bone is depressed inward; from tumours within the head; from over-dilatation of the blood-vessels of the brain; or from fluids effused in or upon the brain; but that the most frequent of all these causes of compression is a plethoric state, or an accumulation and congestion of blood in the venous vessels of the head, operating, according to its degree, in producing over-dilatation or effusion.

Lethargic complaints may, therefore, both precede and succeed actual apoplexy, and are not unfrequently the forerunners of a fit. From this consideration, the importance of avoiding their progress in the outlet, before a rupture of the vessels of the brain, or actual effusion, takes place, must be obvious; for, however impracticable it may be to remove the fluids so effused, or to occasion their absorption, so as to preserve the life of the patient, or to save him from an incurable palsy, if he survive; yet, in the previous state of mere plethoric of the vessels of the brain, the proper remedies may be employed with every prospect of removing the lethargic symptoms, and warding off the impending danger. The plethors may be corrected by general evacuations by blood-letting; if there is an imminent threatening of apoplexy; or by local evacuations by means of leeches, scariation, and cupping, blisters, or injures, where the danger is less imminent. At the same time, the urine excretions should be promoted by proper laxative medicines, the diet should be light, and rather spare, and unstimulating, consisting of a large proportion of vegetable matter; and fermented liquors of all kinds should be very sparingly taken, or altogether disencarded. Exercise in the open air should be regularly perfi dined in, and the hours appropriated to sleep shortened. In a word, a lethargy is to be considered as an impending apoplexy, or an apoplexy already begun, and to be treated accordingly. See APoplexy.

LETHE, Ληθή, in the Ancient Mythology, one of the

rivers
The LET

rivers of hell, signifying oblivion or forgetfulness; its waters, according to poetic fiction, having the peculiar quality of making those who drank them entirely forget every thing that was past; or, according to Virgil, "longa potat oblivia vitæ."

Leth, Lethb, or Lathe, a meaure or portion of land, making one of the ancient divisions in England.

King Alfred divided England into counties, as it stands at present; and those counties he subdivided into hundred or tithings. The hundred was a division, wherein were a hundred officers to secure the peace; the lath or lathe comprehended three or four of these hundred.

Lethis was also the jurisdiction of a viscount; or a kind of afoze, held once a year in each village, about Michaelmas. Whether this was instilled by Alfred, or not, is a question.

LETHERS, in Geography, a town of Hindoostan, in the circuit of Sambul-poor; 15 miles W.N.W. of Sambulpour.

LETHRAEBOR, or Landeborg, a town of Denmark, in the island of Zealand; four miles S.W. of Roselchild.

LETHUM, in Ancient Mythology, was distinguished by the Roman poets from mors, or death. See Petronius Arb. ver. 263.

Mr. Spence conjectures, that by Lethum they meant that general principle, or source of mortality, which they supposed to have its proper residence in hell; and by mors, or morsus, the immediate cause of each particular instance of mortality on our earth. The poets give him a robe, but mention his arms being exerted out of it, as reaching at his prey. They hint at his catching people in a net, and his hunting them as they did beasts, within his toils. They represent Lethum as nearly related to Sleep; and Valarius Placcus, in particular, acquaints us that they were brothers.

LETHI, GREGORY, in Biography, was born at Milan in 1630. He received his education at the Jesuits' college at Cofenza, and afterwards passed some years in an unstilled state, manifesting a strong repugnance to the ecclesiastical profession, which was proposed to him by his uncle the bishop of Aquaspenae. Falling in company, at Genoa, with an officer of the Calvinistic persuasion, he became a convert to the reformed religion, and openly avowed it at Laufanne. He went to Geneva in 1660, married there, and settled as a man of letters. His talents were held in such estimation, that the right of citizenship was prefixed to him gratuitously; but his temper was so farcasse, as to involve him in great troubles, and in 1680 he retired to England. Here he was favourably received; a pension was granted him, and he was promised the office of hibigrapher; but before he obtained it, he was ordered to quit the kingdom on account of some freedom which he had exercised in a work entitled "Reatro Britannico." He went to Amsterdam, became acquainted with the celebrated Le Clerc, who married his daughter, and obtained the title of historiographer of that city. Leti was a most industrious writer; his works are paid to amount to a hundred volumes. Most of them are historical, but they are frequently detestate of truth, and cannot be relied on unless supported by other authority, than the dictum of the writer. All his works are written in Italian, in a lively style, but diffuse and void of taste. His best productions are the lives of Sixtus V.; Charles V.; queen Elizabeth; Philip II.; and Cromwell. He died suddenly in the year 1701.

LETI, in Geography, a small inland in the East Indian sea, near the island of Timor. N. lat. 8° 28'. E. long. 127° 14'.

LELING, a town of Brandenburg, in the New Mark; five miles E. of Cuitrin.

LENA, a river of Russia, which runs into the Vitiaea, at Podrelkoi.

LETSCHKOM, or Dbsolute, a town of Asiatic Turkey, and capital of Mingrelia; the residence of the chief and see of a Greek archbishop; 60 miles N. of Cottais.

LETTER, or Letterbach, a town of Bavaria; 11 miles N. of Bamberg.

LETT, LITERA, a character either in print or writing, by which any people have agreed to express one of the sounds, used in conveying their thoughts to each other in speech. Letter is by some defined a simple uncompounded sound of the voice, that cannot be subdivided into any more simple, and generally marked with a particular character.

But it must be owned that, literally speaking, a letter is not found itself, but rather the sign of a sound; for γερμανος, litera, is derived from γερμανον, to write, and litera is formed from liter, the participle of liter, to write; to make, or mark; whence letter litters signifies to blot out.

Where a sign or character does not express a sound entirely simple, but one resolvable into several, it is not so properly a letter as an abbreviation, containing in itself as many letters as its power does simple sounds. This is evident in the Latin &, x, and the Greek η, τ, to, &c. which are composed of e, t, k, s, x, φ, φ, &c.

On the contrary, a simple sound, though expressed by several characters, is yet to be esteemed one letter; for 速度快, gb, are single letters; as much as φ, φ, and f.

The letters, f, g, b, h, q, x, y, w, were unknown to the ancient Romans, as is proved by Dauquis in his Orthography, where he traces the origin of the several letters. See F, G, H, &c.

Grammarians distinguish letters into vowels and consonants; into mutes, diphthongs, liquids, and characteristics. See each of these terms respectively.

The Hebrews divide their letters into guttural, as d, n, a, ch, gn, aleph, he, cheth, hain, expressed by ל, Gates; denial, as y, t, r, rh, zain, famech, thafe, rech, chen, expressed by מ, ס, פ, lhalial, as h, m, u, p, beth, mem, vau, phe, expressed by the word מ, lingual, or those chiefly formed by the tongue, as d, t, n, th, dalet, teb, lamed, nun, thau, expressed by מ, ק, ק, ק, and palatal, as g, i, e, k, q, h, giemel, jod, kaph, koph, expressed by פ, פ.

Printers distinguish their letters into capital, majuscule, initial, or upper-case letters, which serve for the titles of books, proper names, &c.; and minuscule, small, or under-case letters, which are again divided, according to their size, into pearl, nonpareil, pica, greatprimer, cannon, &c.

They have also their flourished letters, engraved on wood or metal, which take place of the illuminated letters of the ancient manuscripts.

There are letters of various sizes, or bodies; each of which, again, are sometimes call with the Roman, sometimes an Italic, and sometimes an English, or Black letter face. There are also bodies with Greek, Hebrew, Arabic, the muite face, &c.

Letters make the first parts or elements of grammar, constituting the subject of orthography; an assemblage of these compotes syllables, of those words, and of these sentences. See each under their titles.
The alphabet of every language consists of a certain number of these letters, which ought to have a different sound, figure, and signification. See Alphabet.

As the difference of articulate sounds was intended to express the different ideas of the mind, so one letter was originally intended to signify only one sound, and not, as at present, to express sometimes one sound, and sometimes another; which practice has brought a great deal of confusion into the languages, and rendered the learning of the modern tongues infinitely more difficult than it would otherwise have been. This consideration, together with the poverty of all the known alphabets, and their want of some letters to express certain sounds by, has occasioned several attempts towards an universal alphabet, to contain one enumeration of all such single sounds or letters as are used in any language. A thing of very considerable use; a specimen of which is given by Mr. Lodwick, in the Philosophical Transactions. See Universal Character.

According to Cæcilius, Moses invented the Hebrew letters; Abraham the Syriac and Chaldee; the Phœnicians those of Attica, brought into Greece by Cadmus, and thence by the Pelasgians into Italy; Nicolltrata the Latin; Ias the Egyptian; and Ulphilas, about three hundred and seventy years after our Saviour, those of the Goths. Yet as to the first letters, what they were, who first invented them, and among what people they were first in use, there is still room to doubt; however, setting aside conjectures and prejudice, the busses of antiquity seems to lie between the Egyptians and Chineses. Philo attributes the first invention of letters to Abraham; Josephus, St. Ireneeus, and others, to Noah; Bibhander, to Adam; Euebius, Clement Alexander, Corn, Agrrippa, &c. to Moses; Pomponius Meta, Hero-dian, Ratus Filitus, Pliny, Lucan, &c. to the Phœnicians; St. Cyprian, to Saturn; Tacitus to the Egyptians; and some to the Ethiopians.

The Egyptian mummies and obelisks prove a great antiquity on the side of the hieroglyphics; but if the Chineses chronology may be credited, their characters are much more ancient than those of the Egyptians. The Chineses made Foii, the first of their kings, supposed by many learned and judicious writers to have been no other than the patriarch Noah, the inventor of their letters, and compute him to have lived two thousand nine hundred and fifty years before Christ, during all which time they pretend to have certain and written accounts in their books. If this holds true, their character must be older than Moses by fourteen hundred years, and even prior to Menes, the first king of Egypt, by five hundred years; so that the Chineses letters appear to be the most ancient of that kind; and the book Yekim, said to be written by Foii, the most ancient book.

But as China is so remote, and had so little communication with the rest of the world, we may reasonably make another enquiry into the original of letters in the hither parts of Asia, Egypt, and Europe. Here, indeed, the Egyptians seem to have the best title. It is more than probable, from the obelisks, &c. that their hieroglyphics were the first manner of writing, and the original characters in these parts, as being prior to Moses; and were made, at least in great measure, while the Israelites were slaves among them, and consequently not well qualified for inventions so very curious and judicious.

To this source the learned bishop Warburton ascribes the origin of alphabetical writing among the Egyptians: for as philosophy advanced, and their learned men wrote much, the exact delineation of hieroglyphic figures became too tedious and too voluminous; and they, therefore, by degrees perfected another character, which he calls the running hand of hieroglyphs, resembling the Chineses characters, which being at first formed only by the outlines of each figure, became at length a kind of marks. See Hieroglyphics.

This running character was denominated by the ancients hieroglyphical, and led to the compendious use of letters by an alphabet, which method of writing, as the ancients inform us, was invented by the secretary of an Egyptian king, and first used for secrecy in the conveyance of letters of state, whence it was called epistolary writing: but afterwards letters became common, and, as he observes, hieroglyphics secret and mysterious. This political alphabet, he adds, soon occasioned the invention of a facred one, used by the priests, and called hierogrammatical. But the precise time of the invention of Egyptian letters cannot be so much as guessed at, because hieroglyphics continued in use long after letters had been found out: it is certain that they were very early, because the invention of them was ascribed to their gods. Bishop Warburton farther conjectures, that Moses brought letters with the rest of his learning from Egypt, and that he both enlarged the alphabet, because the Hebrew alphabet which he employed in the composition of the Pentateuch is considerably fuller than that which Cadmus brought into Greece; and altered the shapes of the letters, reducing them into something like those simple forms in which we now find them, in order to prevent the abuse to which they would be liable as hieroglyphic marks and symbolic images. He argues, that, considering the importance of letters among the Hebrews, with regard to the integrity of their religion, if God had been the immediate author of them, Moses would have recorded the history of their invention, as the best foundation of their use and beneficial influence from the danger of hieroglyphic writing, to which this people, so fond of Egyptian manners, were very powerfully inclined. Divine Legation, vol. ii. p. 122, 124, &c. See also on this subject Sharpe's Origin of Languages, p. 56, &c.

Many of the fathers, and some learned men among the moderns, have imagined that the knowledge of alphabetical writing was either supernaturally imparted to our first parents, or discovered very soon after the Creation by the effort of their own powers. Others have supposed that alphabetical letters were introduced very early after the deluge, about the time of the dispersion of mankind, to which period the records of the Chaldean astronomers very nearly extend. Mr. Shuckford, who supposes that they were invented both in Assyria and Egypt, conjectures that the great project of Babel, next to the building of the tower, was the improvement of language, by disjoining the monosyllables, of which the first language of mankind consisted, into words of various lengths, in order to obtain new sets of names for new things; and that a project of this kind might gradually lead to the invention of alphabetical letters. Con. of Sacred and Prof. Hist. vol. i. p. 248.

But to these conjectures it may be replied, that we have no authentic relation of any alphabetical character before the flood; the account of the inscription upon pillars by the first Mercury from Manetho, or of Seth mentioned by Josephus, being too fabulous to deserve credit. Besides, if they had been in use among the patriarchs after the deluge, many occasions occur, in which they would not have been omitted; and as we have no account of the use of alphabetical characters in epistles or contracts, or for other purposes to which they would naturally be applied, we may infer that they were not known. To which we may add, that none of the revelations of God to the patriarchs, were enjoined to be recorded till the giving of the law. Others have ascribed the invention of letters to the Arabs,
Arabs, before the time of Moses; but when we consider the
rudeness of their lives and manners, this opinion is by no
means probable; and, therefore, the greater number of
writers among Jews and Christians, both ancient and modern,
have contended themselves with tracing their origin to Moses,
supposing to be the fame with the Egyptian Thoth or
Hermes, mentioned in the history of that nation; alleging
that God taught him the use of alphabetic letters, in the
exemplar of the two tables, written, as the text affirms us,
with the finger of God; which words can be understood to
mean only that they were written by a divine order and direc-
tion, as is evident by comparing Exod. xxxiv. 27, 28, and
ch. x. 4. It has been said by some of the advocates of this
opinion, that the elements of language were thus superna-
turally revealed to Moses upon the first arrival of the
Israelites before Horeb, but that their characters, with the
arrangement of them, might be left to his discretion. But
it seems more probable, that letters were at this time well
known to the Israelites, as God thought fit to deliver the
first elements of their religion in that kind of writing: more
especially as the history of so momentous a circumstance
is not recorded; a circumstance, the memory of which
would have been one of the greatest barriers against idolatry.
From the Israelites, it is supposed this art of alphabetical
writing passed to the Syrians, and from them it was communi-
cated to the Phenicians and Egyptians: though it seems probable that it was of a more an-
cient date among the latter than the time of the decalogue,
or the delivery of the law on mount Sinai.

Sir Isaac Newton, in his Chronology, allows the Midian-
tes, sprung from Abraham by his concubine Keturah, to
have instructed Moses in the knowledge of writing.

Nevertheless, whether Cadmus and the Phenicians learnt
letters from the Egyptians, or from their nearer neighbours
of Judea and Samaria, is a question; since some of the
books of the Old Testament, written in letters, is more
likely to have given them the hint, than the hieroglyphics
of Egypt. But when or wherever the Phenicians learnt
this art, it is generally agreed, that Cadmus, the son of
Agenor, first brought letters to Greece; whence, in the
following ages, they spread over the rest of Europe.

Herodotus, in his fifth book intitled Terpsichore, informs
us, that those Phenicians who accompanied Cadmus into
Greece, and settled there, among many other arts and sci-
ences, introduced into that country the knowledge of letters,
which the Greeks, in his opinion, were ignorant of till that
time; their first letters were such as were in use among the
Phenicians; but some time after they altered them a little,
both with regard to their make and sound; which alteration
may be supposed to have been the change of the Hebrew
characters into those that were afterwards called the Samar-
ritan; and as at that time many of the neighbouring parts
were inhabited by such as were originally Ionians, who also
had received their letters from the Phenicians, they mixed
the one with the other; and hence those characters were
termed Phenician, because they were brought out of Phæ-
nicia into Greece. Herodotus also adds, that he saw at
Thebes, in Bcctia, in the temple of Ifmenian Apollo, three
tripods, that had inscriptions upon them in Cadmean
letters, which very much resembled the Ionic. The time of
this expedition of Cadmus into Greece, is fixed by Sir Ifaac
Newton to about the 1245th year before Chrift. The num-
ber of letters which Cadmus brought into Greece, accord-
ing to Aristotle, as cited by Pliny, was eighteen; but ac-
cepted by Plutarch and Pliny himself, sixteen; to which
Palamedes, in the time of the Trojan war, added four, and
Sionides four; so that the Greek alphabet was gradually
perfected. The alterations and improvements introduced
into Greece have led some writers to ascribe the invention of
the alphabet to the Greeks; thus, Voflius de Arte
Gram. lib. i. cap. 10. affirms, that Cecrops, who was much
older than Cadmus, was the frift author of the Greek
letters; and others ascribe them to Linus, or to Palamedes.

(Diod. Sic. lib. iii. Tacitus, lib. xi. cap. 14.) But the
more general opinion of the ancient writers is that they
were derived from the Phenicians and Egyptians. Dio-
dorus (lib. vi.) says expressly, that they were invented by
the Syrians, and communicated by them to the Phenicians,
who changed the form of the characters brought into Europe
by Cadmus. Pliny, (Nat. Hist. lib. vii. cap. 56.) says, that
he is of opinion, that they were Assyrian, though he acknow-
ledges that others thought they were invented by the Egyp-
tians, and that Mercury was their frift author. Diodorus,
(lib. ii.) ascribes the invention of them to the fame perfon;
and likewise Plutarch Sympof. lib. xx. cap. 3. and Cicero de Natura
Deorum, lib. iii. And the era of this invention is com-
pounded by chronologers to be as early as the year of the world
2054, and before the incarnation 1650 years. The Greeks
retained the names and orders of several of the oriental
or Cadmean letters, though they altered the form of them;
and there are seven letters, viz. ț, Δ, Η, Κ, Λ, Ρ, Τ, whose
original figures were retained by the Greeks with very
little variation. As to the Latins, all writers agree, that they
received their letters from the Greeks, being flrst taught
the use of them by some of the followers of Pefagus, who
came into Italy about 150 years after Cadmus came into
Greece; or by the Arcadians, whom Evander led into those
parts about 60 years after Pefagus. Pliny (lib. vii. cap. 56.)
and Solinus imagined the Pefagi to have been the frift
authors of the Latin letters; but Tacitus (lib. xi. p. 131.)
was of opinion, that the frift Italians were taught letters by
the Arcadians; and Dionyfius Halicarnaffeus (lib. iii.) ex-
prefsly affirms the fame thing. That the Latin letters were
derived from the Greek feems very probable from the simi-
laritie which the ancient letters of each nation bore to one
another. Tacitus (Annal. lib. xi.) observes, that the shape
of the Latin letters reembled that of the most ancient
Greek ones; and the fame obfervation was made by Pliny,
lib. vii. cap. 58, and confirmed from an ancient table of brails
1617, and Voflius, lib. i. cap. 24, 25, have adopted and
supported the fame opinions. See thofe citations in Shuckford's
Conn. vol. i. p. 223, &c.

Thus we find, that Greece was the centre from which
the rays of science fliot into the weftern world; and the
barbarous nations which penetrated into Italy towards the
clofe of the Roman empire, carried arts and learning back
into the North; or the knowledge of letters might be in-
troduced among the northern nations from the borders of
Asia, in an earlier age. (Sharpe's original Powers of Let-
ters. Observations on Alphabetical Writing, 1772.) Rnd-
beeks, who, in his Atlantica, claims the glory of all inven-
tions, from all other nations, for the Swedes, maintains,
that the Ionians had letters before Cadmus; that at the
time of the siege of Troy, the Greeks had but sixteen
letters, whereas the Phenicians had twenty-two; whence, he
 concludes, that it was not either Cadmus, or the Phenici-
ans, who taught this art to the Greeks. But, because the
ancient northern nations had but sixteen letters, like the
Greeks, he concludes the Greeks must either have taught
them to the people of the North, or have learnt of them.
But because the form and make of the Roman let-
ters is more artife and coarfe than that of the Greek letters,
he concludes, that these laft must be derived from the former;
taking it as a principle, that those who derive any thing from another, polish and improve it. He even affirms, that by the golden apples, which Hercules was obliged to steal, must be understood the letters in use among the Hyperboreans.

There are few things on which there has been so much written as on the original Hebrew letters. Origen, Eusebius Caesariensis, St. Jerom, &c. have made it the subject of their enquiry. See Hebrew and Samaritan.

The art of joining letters to form words, and of combining the one and the other an infinite number of different ways, is a secret unknown to the Chineese. Instead of the alphabetical letters, they at first, like the Egyptians, used hieroglyphics; they painted, rather than wrote; deriving, by the natural images of things drawn on paper, to express and communicate their ideas to one another.

To remedy the inconveniences of this method, they changed, by little and little, their manner of writing, making it more simple, though less natural. They even invented several characters, to express things that did not come within the reach of painting to represent; as voice, smell, thoughts, passions, and a thousand other objects that have no body or figure. From several simple strokes they afterwards framed others more compound; and in this manner multiplied the letters and characters to infinity, contriving one, or more, for every word.

This multitude of letters seems the source of that ignorance which we find among the Chineese; their whole lives being spent in learning their letters, they have no time to apply themselves to the study of things, but think themselves very learned when they are able to read. There are scarcely any of them that know all their letters; they think it is a great progress they have made, when, after forty or fifty years hard study, they are able to understand fifteen or twenty thousand. But the generality of their learned men come short of this. Father Le Compte is of opinion, that the greatest doctor among them never understands half of their letters well; for the whole number he reckons eighty thousand. This is a prodigious inconvenience to foreigners, of which the missionaries in that country make loud complaints.

Among the Chineese letters, there are some now almost worn out of use, and only preferred out of respect to antiquity. There is a second clafs, much less ancient than the former, only used in public inscriptions. A third, much more regular and beautiful, used in printing, and even in ordinary writing. However, as the strokes are to be distinctly formed, they cannot be written with any expedition. For this reason, they have invented a fourth kind, where the strokes, being closer, and less distant from each other, allow them to be written with more ease and readiness; and this they call the running letter. See Chinese Tongue.

The Americans had no letters before the discovery of that country by the Spaniards. The Acanibas engrave their memorable events and epochs on flones and metals; their fongs supply the reel. In Peru and Chili, to keep an account of their goods and chattels, and to preserve the memory of their particular affairs, the Indians have recourse to certain knots of wool; which, by the variety of their colours and ties, serve instead of characters, and writings. The knowledge of these knots, which they call, quipes, is one of their great sciences; but which is always kept as a secret, and never revealed to the children, till the fathers think themselves at the end of their days. See on the subject of this article Language, Grammar, and Writing.

Letters, or Literal Notation, in Music. The Greeks used all the twenty-four letters of their alphabet as musical characters; and the not sufficing for all their modes and genera in their natural state, were sometimes used as capitals, sometimes small; some entire, some mutilated; some doubled, and some inverted; to the amount of 1620 notes. See Alysius, and Notation.

Letter, Dominical. See Dominical.
Letter, Double. See Double.
Letter, Final. See Final.
Letter, Guttural. See Guttural.
Letter Foundery. See Foundery.
Letter Founders' Furnace. See Furnace.
Letter Founders' Mould. See Mould.
Letter, Labial. See Labial.
Letters, Numeral, are those used, instead of ciphers, to express numbers.

The Roman numerals are, C, D, I, L, M, V, X; which are all formed by describing a circle, and drawing two lines through it, crossing each other at right angles in the centre. See Character.

Letter, Nundinal. See Nundinal.
Letter is also a writing addressed and sent to one. See Epistle.

By 9 Geo. I. cap. 22. amended by 27 Geo. II. cap. 15. knowingly to send any letter without name, or with a fictitious name, demanding money, &c. or threatening, without any demand, to kill or fire the house of any person, is made felony without benefit of clergy. And by 30 Geo. II. cap. 24. perfoners sending letters with or without a name, or with a fictitious name, threatening to accuse any one of a crime punishable by law with death, transportation, pillory, or any other infamous punishment, in order to extort money or goods, shall be punished at the discretion of the court by fine and imprisonment, pillory, whipping, or transportation for seven years.

Letters of abjuration were formerly granted by an abbot, to release any of his brethren from the obligation of subscribing and obedience, and to make them capable of entering into any other religious order.

Letter of attorney, in Law, a writing authorizing an attorney to do some legal act in our stead; as, to give seisin of lands, to receive debts, to sue a third person, &c. And letters of attorney are either general or special. Weit. Symb. par. 1. flat. 7 R. II. cap. 13.

The nature of this instrument is to give the attorney the full power and authority of the maker, to accomplish the act intended to be performed. Sometimes these writings are revocable, and sometimes not; but when they are revocable, it is usually a bare authority only; and they are irrevocable, when debts, &c. are assigned to another; in which case the word irrevocable is inserted.

Letters, or claus, or clafs, are opposed to letters patenti. See Close Rolls.

Letter of credit, among Merchants. See Credit.
Letters communicatory. See Letter communicae.
Letter of exchange. See Bill and Exchange.
Letter of licence in Trade, an instrument or writing granted to a man who has failed, or broke, signed and sealed by his creditors; which letter usually gives a longer time for payment; so that the debtor, having such an assurance, may go about his business, without fearing an arrest.

Letters of mart, or marque, are letters under the privilege granted to the king's subjects; empowering them to take, by force of arms, what was formerly taken from them by the subjects of some other state, contrary to the law of mart. Letters of marque, in the British dominions, are to be
be granted by the admiralty; and they empower the com-
mander of a merchant ship or privateer to cruise against
and make prizes of the enemies ships and vessels, either at
sea, or in their harbours. See MARQUE.
Letter missive, in the Election of a Bishop. See Bishop.
Letter missive, in Chancery. If a peer is defendant in
this court the lord chancellor sends a letter missive to him,
to request his appearance, together with the copy of the
bill; if he neglects to appear, then he may be served with
a subpoena; if he continues still in contempt, a sequestration
issues out immediately against his lands and goods, without
any of the mene process of attachments, &c. which are di-
rected only against the person, and therefore cannot affect
a lord of parliament. The same process issues against a mem-
ber of the house of commons, except that the lord chan-
celloir does not send him any letter missive.

Letters patent, or covert, are writings sealed with the
great-fool of England, whereby a man is authorized to do
or enjoy any thing, which of himself he could not do. They
are so called, on account of their form; as being open with
the seal affixed, ready to be flown for the confirmation of
the authority given by them; and usually directed or ad-
dressed by the king to all his subjects at large, thus, and in
some other respects, differing from close letters. See Close
Rolls.

Common persons may grant letters patent; but they are
rather called patents, than letters patent; yet for distinction,
tho' granted by the king, are sometimes called letters
patent royal.

Letters patent conclude with tale mezzo: charters with
his syllibus. See Patent.

Letters of refit, letters signed by a prince, in favour of
home or unfortunate debtors, against too rigorous cred-
itors, whereby payment is delayed for a certain term.
The use of these letters is very ancient. Caffinorous ob-
serves, they were in use in the time of Theoderic, king of
the Goths; others will have them introduced towards the
end of the eleventh century, by pope Urban II. in favour
of those who went on the croisades.

They are still in use in France and some other countries,
and take their name, a respiranda, because they give the
debtor a breathing time.

St. Louis granted three years refitpe to all who made the
voyage of the Holy Land with him.

Letters circular, dimifioy, frank, monitory, pacific, paf-
chol. See the several adjectives.

LETTERE, in Geography, a town of Naples, in Prin-
cipato Citra, the see of a bishop, suffragan of Amalii; 12
miles W.N.W. of Salerno. N. lat. 40° 43'. E. long. 14°
20'.

LETTERED, LITERADO. See Literati.

LETTERKENNY, in Geography, a township of Ame-
rica, in Franklin county, Pennsylvania; containing 1497
inhabitants.

Letterkenny, a part-town of the county of Donegal,
Ireland, situated on the river Swilly, over which it has a
bridge. It is 115 miles N.W. from Dublin.

LETTERN, from Letrinum, the reading desk in an-
cient churches, &c., from which the epistles and gospels of
the liturgy were read. The desks for the former frequently
represented the prophet Moses with his horned countenance,
tho' for the latter an eagle, the well-known emblem of St.
John the Evangelist.

LETTES, a people of Russia, derived from the Slavi
and evincing a near affinity with the Vendi. Originally they
were one people with the Lithuanians; as is evident from
the identity of their language and even of their names. In
the middle ages the following denominations are used with
dilution; viz. Letthia, Letthovia, Lithavia, Lithia-
nia, Lottavi, Litthvini, Letthovini, Lettvanni, Lettones, &c.
Probably, says Tooke, the Lettes obtained their particular
name from their first homestead. In the circle of Valas,
not far from the town of Venda, a river named Letca
takes its rise; this river is called in Letthia "ta Latte,
and a Latte is in their language Latvis, a man living by the
river Latte. Till towards the end of the twelfth century,
Lithuania or Letland was entirely unknown to the German
historians; it is mentioned only by Danes, Swedes, and
Russians. By the two former on occasion of their piracies,
and by the Russians for denoting their dominion over that
country. Although Neltor, the oldest and most authen-
tic Russian annaul, does not expressly mention the Lettes;
this may possibly be owing to their not being at that time
a particular nation distinct from the Lithuanians. It ap-
pears unquestionable from many testimonies, that the dis-
trict inhabited by the Lettes on the Baltic already belonged
to Russia in the earliest periods of its monarchy; it never-
theless appears that Lithuania had then no settled confi-
mation, nor was bound to the parent state by any firm
political tie. (See LIVIA.) The homestead of the
Lettes is not the whole of Lithuania, but only a part of
it which is callea Letland, confining of four of the nine
districts or circles into which Lithuania, or the present
co-royalty of Riga, is divided; the remaining five circles being
inhabited by Lithuanians. Besides, the Kures in Courland,
Semigalia, and the bishopric of Pilen are true Lettes; by
whom, in part, the Lithuan language is spoken in the
greatest purity; and these people are mostly degenerated
in Polish Lithuania, where they are mixed with Poles and
Russians. The number of them at present cannot be properly
declared; but in the vice-royalty of Riga alone, there
were upwards of 226,000 Lettes, according to the last cen-
sus. At present they are no longer known as a separate
people; they were mingled by imperceptible degrees, and at
last blended with the Lettes, the Eithes, and the Courtes,
as they are usually called, the Lithuanians, the Eithonians,
and Courlanders. The Lettes, or Lithuanians, are repre-
sented as a people always peaceable, industrious, hospitable,
frugal, and of a somewhat better disposition than the Ei-
thonians; and they inhabited the greater part of the Ven-
den district, and extended themselves even into Dorpat,
and hence it is that the chronicles mention the Lettes in Unga-
nia. Their origin has been at one time sought for among
the Grecians, and at other times among the Sarmatian tribes.
By their language, however, it is perceived, that they bear
an affinity with the Courlanders, or Courtes, and that they
are properly of Lithuanian, or in general of Slavonian ori-
gin. At present they occupy two districts, which both to-
gether are after them called Letland. By the augmenta-
tion which they received from the Liefs, now reckoned with
the Lettes, the Vends, the Lettgallians, and the Eithonians,
they are more numerous than they were in the twelfth
century. The Lettes call themselves Latvewits.

Both Lithuanians and Lettonians, admitting many excep-
tions, are addicted to intemperance. Without beer and
brandy they have no conception of pleasure. The aged in
particular are hard drinkers, and continually smoke tobacco.
They derive also a great part of their pleasure from sing-
ging and music. At their work in the field, as well as at their
play, the girls are always singing. The most usual instru-
ment with both nations is the bag-pipe, made by themselves,
and founded in proper time, in two keys, with great dext-
ernity. The miserable horizontal harp, and the fiddle,
which the Lettes are very fond of at all their festivals, were first introduced among them by the Germans. They are also very fond of dancing. Among their favourite summer pastimes is the buying; and this diversion, for which there is accommodation in every village at every house of entertainment, is in high vogue in Easter. In hot weather swimming is also practised by persons of all ages and sexes, and the boors without exception are passionately fond of scalding hot-baths. Infidelity towards their maids, difficult, a disposition to cheat and steal, and such like, are the vices to which they are addicted, and they certainly take their rise from the slavery in which they are held. They rarely rob one another; but they are very ingenious in devising means to impose upon their maids. Against them they have frequently risen in rebellion. Lying, cursing, and swearing are very current among them. Of their religion we shall only say, that when they were heathens, they were much given to superstitition. Their paganism, it is said, was very similar to that of the Celts and ancient Germans. They had no temples, and acknowledged only one God, whom they adored under various names. They performed their religious rites in the open fields, on the top of a mountain, near a spring, or under the shade of a tree; and reckoned these places sacred. They believed in inferior deities, to whose care and government certain regions were allotted, and whom they much feared to offend. They had a god Thos, to whose influence they ascribed all aerial phenomena. Of the places and groves, where the ancient Lieflanders, as well Githians as Lettonians, were accustomed to perform the holy rites of paganism, many, notwithstanding the strict orders that have been issued for their demolition, still remain, and they testify towards them an awful reverence. Offerings of wood, wax, yarn, bread, &c. are still in use among them, by laying them on the holy places, or crumbling them in the hollows of aged trees. Springs and rivers likewise have their fashes of these unbloody sacrifices. At their secret idolatrous assemblies, the keeping up of the fire, into which they throw all sorts of offerings, is still a principal observance. In Liefland they had idols, but no proper idol temples. The religious rites of the Celts and Lieflanders seem very much to resemble one another. Among both the Lettes and the Eithes many remains of heathenism is still observable; although in the twelfth century the Liefs, and afterwards the Lettes, were brought to the profession of Christianity by the Germans; and a part of the Eithes by the Dames. Tooke’s View, &c. vol. i.

LETZKAW, in Geography, a town of Prussia, on the Viarta; 13 miles S.E. of Danzicz.

LETZNIG, a town of the duchy of Holstein; six miles S.S.W. of Segeberg.

LEVANDIS, Millium Expensis. See Expensis.

LEVANGHE, in Geography, a small island near the coast of Lithuania. N. lat. 55° 10’; E. long. 15° 52’.

LEVENT signifies any country situated to the east of us, or the eastern side of any continent or country, or that on which the sun rises.

LEVANT, or Titans, one of the Hivres islands, on the Mediterranean, near the coast of France. N. lat. 43° 44’; E. long. 6° 54’.

LEVANT, in Matters of Commerce, &c. is generally restrained to the Mediterranean seas; or, rather, to the countries on the eastern part of it; or the coasts of Asia, and especially Asiatic Turkey, from Alexandria in Egypt to the Black sea, including the islands of Cyprus, Rhodes, and the Archipelago.

Hence, our trade thither is called the Levant trade; and a wind that blows from thence, out of the Straits mouth, is called a Levant wind.

France was the first nation that made treaties of commerce with the Porte. The fieur de la Foret signed them in 1535; in the name of Francis I. and thereby obtained many privileges in favour of that kingdom; which they alone enjoyed, until the Venetians, the English, the Hollanders, and at length the Genoese, likewise obtained particular privileges for themselves.

LEVANT Measires. See Measure.

LEVANT, Bole of the. See Bole.
LEVANT and Couchant, in Lawi, is, when cattle have been so long in another man’s ground, that they have lain down, and risen again to feed, which, in general, is held to be one night at least. See Distress.

LEVANTINE VALLEY, or Valle Leventina, in Geography, a valley of Helvetia, subject to the canton of Uri, and situated S. of St. Gotthard, watered by the Tefino, and inhabited chiefly by Italians. It is supposed to retain by its name, traces of the “Leponits,” the ancient inhabitants of the surrounding regions. Its length, from the summit of the passaghe on the St. Gotthard, is about eight leagues; the breadth is very inconvenient. The lower part is extremely populous, rich in pasturage, and produces much hemp and flax. In the vicinity of the lofty mountains adjacent to it, the climate is various, and the country subject to much rain. To prevent the rain, from damaging the crops, the inhabitants suspend and dry the corn and graps, on bars supported by two high poles about 15 feet asunder. The houses are entirely of wood, and externally appear like Swiss cottages; but a neglect of cleanliness proves the vicinity and greater familiarity to the Italians. The Tefino is here joined by the Brumio, a torrent which takes its rise in mount Ucello, or the Vogelberg, near Splagen; a bridge over it is the boundary of the two bailiages of the valleys Levantine and Polefe, and leads into that of Riviere. The valley now becomes perfectly flat, and of course subject to violent inundations; the few villages are scattered on the sides of the steep mountains; all below is defoliate. Offgone, the residence of the bailiff, consists only of a few hovels.

LEVANTO, a town of the Ligurian republic, on the coast of the Mediterranean; eight miles W. of Spezza.

LEVANZO, a small island in the Mediterranean, near the W. coast of Sicily; about nine miles W. of Trapani.

LEVARE, Antiphonum, in the Music of the Roman Church, is to begin or open the first note of an anthem.

LEVARI FACIAS, in Lawi, a writ directed to the sheriff for levying a sum of money on a man’s lands and tenements, which has forfeited his recognition; in virtue of which the sheriff may seize all his goods, and receive the rents and profits of the lands, till satisfaction be made to the plaintiff: but this writ has now given way to the remedy by ejects. There is also a levare facias damnarum difficiliorum, for the recovery of debts, wherein the sheriff must have been formerly condemned to the difficulty; and also a levare facias residuum debitor, to levy the remainder of a debt upon lands and tenements, or chattels of the debtor, where part has been satisfied before. And farther, a levare facias quando viocences returnavit quod non habuit emptores, commanding the sheriff to sell the goods of the debtor which he has taken, and returned that he could not sell.

LEVARLOW, in Geography, a town of Poland, in the plateanite of Lublin; 40 miles S.S.W. of Lublin.

LEVASCHEVA, a town of Russia, in the government of Olonetz, on the W. coast of the lake Latcha; 16 miles S.S.W. of Kargapol.

LEVATIO ARIETUM. See Arietum.

LEVATOR, in Anatomy, a name given to various muscles, which have the effect of drawing parts upwards, or elongating them.

LEVATOR ANIS, is a muscle connected with the inferior extremity of the intestinal canal. See Intestine.

LEVATOR ANXI, is a muscle of the lips, described under Deglutition.

LEVATOR COMMUNIS LABORIORUM, is the same with the levator anguli oris.

LEVATORIS STERORUM, are the commencements of the external frata of intercostal muscles. See Intercostal.

LEVATOR LABII SUPERIORIS ET ALI NASIS, a muscle common to the upper lip and the wing of the nose. See Deglutition.

LEVATOR LABII SUPERIORIS PROPERIUS, is a portion of the former, sometimes described as a distinct muscle.

LEVATOR LABII INFERIORIS, is the same with the levator menti.

LEVATOR MENTI, is a small muscle situated in the chin, and described with the muscles of the lips in the article Deglutition.

LEVATOR OCLI, a name sometimes given to the superior orit straight muscle of the eye. See Eye.

LEVATOR PALATI NODIS, a muscle of the soft palate described in the article Deglutition.

LEVATOR PALPEBRAE SUPERIORIS, a muscle of the orbit belonging to the upper eye-lid. See Eye.

LEVATOR SCAPULÆ, a muscle of the scapula, called also angularis, and, by Dumas, tracheo-scapulien. It is situated in the upper part of the back, and on the lateral and posterior part of the neck; it extends from the superior angle of the scapula to the transverse processes of the four first cervical vertebrae. It is elongated, flattened, and broader below than above. Its external surface is covered below by the trapezius, above by the sternocleido-mastoideus, and in the middle by the skin. The internal surface covers the serratus anteriorius scalenus, the facio-lumbalis, the transversalis coli, and the splenius. The edges present nothing remarkable; the posterior is longer than the anterior, and covers a part of the upper edge of the rhomboideus.

The inferior extremity is attached to the superior angle of the scapula, to the upper part of its bals, and to the internal portion of its upper edge. From this point the muscle passes upwards and forwards; it grows narrower, and is soon divided into four portions, which are at first united together by cellular tissue, but afterwards separate to be attached to the points of the transverse processes of the four first cervical vertebrae. These portions are often connected to the splenius and scalenus posterior. Sometimes the levator scapulae has only three portions fixed to the three first vertebrae of the neck; that which is attached to the atlas is larger and longer than the others, which diminish successively in size and length downwards.

It is tenacious at its attachments, and fleishy in other parts. The posterior fibres are longer than the anterior; a falciculus of fibres is sometimes added to its front edge from the first rib.

The name of this muscle has led to a notion that it elevates the shoulder; and it has been called musculus patientiae, from the supposition, that it acted in shrugging the shoulders. In fact it rather depresses than elevates this part; it draws the superior angle of the scapula upwards and forwards, but then the bone is rotated in such a way that its anterior angle, forming the shoulder joint, is depressed. It is allied by the pectoralis major. If the trapezius act in conjunction with it, the shoulder will be elevated. Supposing the shoulder to be fixed, it will incline the head and neck backwards, and towards its own side.

LEVATUM. See Terris & Catalis tenis ultra debitem.

LEUBITZ, in Geography, a town of Hungary; eight miles S. of Podolitz.

LEUBUS, a town of Silesia, in the principality of Wohlen, on the Oder, near which is a celebrated Cistercian abbey,
abbey, founded at the commencement of the 11th century; nine miles S.W. of Wohlen.

LEUCA, in Ancient Geography, a small town in Italy, in the country of the Saluvini, and in the vicinity of the Japyian promontory. Strabo.—Also, a town of Afa Maer, on the confines of Ionia and Eolia. Pompionus Mele places it near Phocasa, in the gulf of Smyrza; and Pliny places it near Phocaza, on a promontory which was formerly an island. Diodes and Stelus says, that Leuca was situated between Cumae and Chamosa.

LEUCACANTHA, in Botany, a name used by Dioscorides, and the other Greek writers, for the σαία tree, which produces the gum arabic, but it was also used for a kind of prickly plant, called also amega by some of the Arabian; as being a plant whose roots were knotted and jointed. These joints were separated and dried, and then used in medicine as cardinals and carminatives, under the names of bank or banken.

They were of a very agreeable aromatic smell, and very little taste; and the ancients always preferred such of them as were yellow and light, rejecting those which were heavy and white, and which wanted smell. It is not well known at this time what these roots were; but it is necessary, in order to the right understanding the works of the ancients, to know that there were such roots; and that though called by the same name with the gum arabic tree, they were of a very different nature.

LEUCACHES, in the Natural History of the Ancients, the name of an agate, not a peculiar species, but only a particular appearance of the lead-coloured agate, called phauchasites.

LEUCADENDRON, in Botany, from luce, white, and δέντρον, a tree, expressive of the hoary or silvery white-ness for which the first and finest of the species is remarkable. The name seems to have originated with Hermann, who communicated to Plukkenet the Silver-tree of the Cape, under the appellation of Leucadendros africana, for which Linnaeus, in his Classis Plantarum, adopted it; but he afterwards, in his Genera, applied this name to another tribe of the same order, and subsequently sunk both in Protea. Mr. Brown has restored the original Leucadendron. Silver-tree. Brown Tr. of Linn. Soc. v. 19. 50. (Conocarpodendron; Buch. Lugd.-Bat. ed. 2. t. 195, 197, 200, 202—4.)—Clas and order, Dicotyledon. Nat. Ord. Agregate, Linn. Protes, Juss. Proteaceae, Brown.

Female, Cal. like the male; its scales permanent, dilated and hardened. Cor. like the male; bearing abortive stamens. Pist. Germen superior, fiddle; style simple, straight, rigid, terminal; stigma oblique, club-shaped, emarginate, rather hispid. Peric. none, except the permanent woody calyx, whose scales are sometimes confluent. Nut solitary, concealed by the scales of one seed.

Female, Calyx imbricated, permanent. Petals four. Stigma oblique, club-shaped, emarginate, rather hispid. Nut of one seed, concealed by the hardened scales of the calyx.

Thirty-eight species of this noble genus are defined by Mr. Brown, all natives of southern Africa, near the Cape of Good Hope, where they usually grow in moist stony or sandy places, about rivers, and, as far as we know, in no other part of the world. A few of them have long been cultivated in the greenhouses of Europe, but the greater part are only known in the herbariums of the curious. One of the finest collections of this whole natural order was procured from the Cape by Mr. Niven, for his patron G. Hibbert, esq., to whose liberality we are indebted for specimens of the whole.

The habit of Leucadendron is arborescent or shrubby, but sometimes tortuous and defracted. Leaves flat, linear, lanceolate, or obovate. Heads of flowers often yellow, not large, but frequently accompanied by very large, spreading, defracted, pahis bracteas, which are highly ornamental.

Examples are

Corolla of the male filky.—This splendid tree, growing about the bays and shores of mountains at the Cape, soon attracted the notice of the first European visitors, and was brought into the Dutch gardens, from whence probably it came to England early in king William's reign. The flowers are not ornamental, nor are they fearfully ever seen here, but the silvery splendour of the leaves is unrivalled; they are three or four inches long, sefikle lanceolate, acute, entire, spreading in every direction, clothing the branches in great abundance. Flowers solitary, terminal.—The whole style is permanent in this and four other species only.

L. corimbosum. Berg. Cap. 21, male plant. (Protea corimbosum; Thumb. Diff. de Protea, n. 28. t. 2, male plant. Andr. Repof. t. 409, female.)—Leaves linear-awl-shaped, imbricated, smooth. Scales when in fruit acute, recurved at the points. Seeds somewhat compressed, ir-}verly heart-shaped, hairy at the edge. Found at several places near the Cape. Much akin to the last in its flowers, but the leaves are totally different, resembling the narrow foliage of an Erica or Diophna. The young branches are purplish, whence it used to be called by gardeners, before it blossomed. Protea purpurea. Mr. Brown observes that each sex has four glands, or nectaries, at the base of the germen, which our last-described wants.

L. concolor. Brown n. 15. (Protea globoflex; Andr. Repof. t. 307. Sims in Curt. Mag. t. 878, both male plants. P. flabellina; Schrad. Sert. Hanno, t. 1, female.)—Leaves spathulate-oblong, with a callous point; smooth when full grown; the floral ones of the same colour. Branches downy. Scales of the fruit obtuse, fring-d.; woolly at the base.—Found near the Cape. Said to have been first raised in England by Meffra. Lee and Kennedy. This belongs to a handsome tribe of species, whose large heads of yellow flowers are encompassed by large spreading floral leaves or bracteas, which in most are coloured, but in this agree in hue with the foliage, and like that are about
two inches long, and nearly one broad, with red callous tips.

L. grandi follicum. Brown n. 16. (Euryaspernum grandi
folium; Salt. Parad. t. 105.)—Leaves oblong-oblong,
with a caulis point; smooth when full grown; the final
ones colored. Branches very minutely downy. Scales
of both faces ovate, bluntish, smooth, colored.—Gathered
on mount Wynberg at the Cape, by Mr. Niven, who sent
it to Mr. A. Mill. It is larger and handier than the
L. sambre, having splendid whiffit bracteas, resembling the petals
of some fine polyanthus flowers.

L. flavidum. Brown n. 21. (Euryaspernum falcifolium;
Leaves smooth, linear, with an awl-shaped point. Bracteas
ovate, acute, colored, longer than the flowers. Scales
of the fruit dilated, rounded, smooth. Seeds without wings,
dotted.—Native of moily Rocky places, about rivers, at the
Cape, according to Dr. Roxburgh. Mr. Zive seems to
have introduced this pretty species to our gardens, which is
distinguished by its narrow leaves, copious and ornamental,
though small, flowers, whose bracteas are white and pointed.
—This species is nearly allied to Protea palaea and confera
of Linnaeus and other authors, the former of which appears
to be the male, and the latter the female, of Mr. Brown's
L. adspersa.

L. abscissum. Brown n. 31. (Protea teretifolia; Andr.
Repert. p. 461)—Leaves all thread-shaped, channelled,
bluntish, smooth, spreading, curved slightly upwards. Scales
of the fruit united by their lower part; distinct and two
lobed above.—Frequent about the Cape. A humble frut, with
numerous spreading fir-like green leaves, the uppermost
of which, unchanged, encloses the few yellow heads of female
flowers, instead of bracteas. The heads of male
flowers are smaller, and more elevated.

LEUCADIA, St. Maure, in Ancient Geography, an
island, or rather a peninsula which was attached to Epirus
by a straight isthmus, about 150 paces long and 600 broad.
Upon it was situated the town of Leucas, on the summit
of a mountain towards the N.E. Homer places here three
towns, viz. Neriton, Croceya, and Agyripa. On the face
of the first of these towns the Corinthians built which already
mentioned; Leucas is now an island, the isthmus having been
separated from the continent. Thus Ovid describes it:

"Leucada continuam veteres habuere coloni
Nunc fretam circumvenirem." 

It was a tradition that unfortunate lovers made choice of
this promontory for precipitating themselves into the sea.
On this promontory Apollo had a temple. See St. Maure.

LEUCANTHEMUM, in Botany, from leucos, white,
and anthos, a flower, has been the appellation of several
plants of the compound radiated kind, whose rays are
white; and now remains as the specific name of the common
English Chrysanthemum Leucanthemum, Great Ox-eye, or
Moon Daisy.

LEUCARUM, in Ancient Geography, a place of Great
Britain, on the route from Calerva to Uricomum, according
to the Itinerary of Antonine. It is supposed to be the same
with the Leucanum of the anonymous of Rovenna. It lies be.
tween Scaudson Nunniorium and Bomium, and is supposed to
be near Galtenbury. Camden, Gale, and Baxter, imagine
that Leucanum was situated where the village of Locharnum
or Locherlinds, on the bank of the river Locher in Glasmorganshire.
But this seems to be at much too great a dis
tance from the other stations of Cliffeborough and Axbridge.

LEUCAS, in Botany, so named by Burmann and Brown,
in allusion to the downy whiteness of its flowers, from
being an ancient Greek name of some herb, now unknown
Nov. Hoth. v. 1. 504. All. Hort. Kew. ed. 2. v. 3. 409.—Cliffs and order, Didymia Gym

Gen. Ch. Cal. Periander inferior, of one leaf, tubular,
oblung, with ten ribs, permanent, its office unequally
toothed, with from six to ten teeth. Cor, of one petal,
ringet; tube cylindrical; upper lip valved, bearded,
undivided; lower longer, in three segments, the middle
one largest, often notched. Stam. Filaments four, orange
by the upper lip, two of them longer than the red, anthers
of two oblong dilated lobes. Tib. - Cermen superior,
four-clft; syle the length and position of the stamens;
 stigma twelve, acute, its upper segment shortell. Petiole
none, except the permanent calyx. Scales four, oblong,
triangular.

Eff. Ch. Calyx with ten ribs; unequally toothed.
Upper lip of the corolla bearded, undivided; lower longer,
three-clft; the middle segment largest. Lobes of the anthers
divariated. Upper segment of the stigma divided.

1. L. zeylanica. Ceylon Leucas. (Phlomis zeylanica;
Ponoria; Rumph. Ambon. v. 6. 39. t. 16. f. 1)—Leaves
lanceolate, slightly ferrated. Whorls nearly terminal.
Bracteas fringed. Calyx oblong, with ten nearly equal
toothed. Native of the island of Mauritius; as well as of
Java, and other parts of the East Indies. The root is
annual. Stem square, downy, leafy, about a foot high,
branching from the bottom in a corymbiform bushy manner.
Leaves opposite, about an inch and half long, scarcely half
an inch broad, lanceolate, bluntish, finely downy, veiny,
wavy, or bluntly ferrated, tapering at the base into a short
footstalk. Whorls dense, axillary, one or two at the top
of each stem or branch. Surmounted by leaves, and accom-
panied by several linear-lanceolate, acute, downy, strongly
fringed bracteas. Calyx downy, frowning upward, its
orifice oblique, fringed with ten, nearly equal, small lip
petals. Corolla twice as long as the calyx, white, hairy
externally, especially the upper lip.

2. L. braundulifolia. Lavender-leaved Leucas. (Leon-
urus indicus; Linn. Sp. Pl. 817. Phlomis zeylanica; Syn.
linear-lanceolate, nearly entire, Bracteas linear, downy.
Calyx oblong, with seven teeth; the uppermost largest.
Native of the East Indies. Linnaeus had it from Burman.
He first described it as a Leonurus, but afterwards con-
cluded it with his Phlomis zeylanica, of which he bad
but a very imperfect specimen. The present is distinguished
by its much longer, and nearly, if not quite, entire leaves;
the whorls are more numerous; bracteas more linear,
downy, but not fringed; and the calyx is essentially different,
having but seven, and those very unequal, teeth. Corolla
much like the last. It is hard to say whether Jacquins's and
Ramphius's synonyms belong to this or the zeylanica, for
they neither of them teach any thing ellenial, but Jacquins's
leaves certainly most resemble the present. The three
figures of Plaknet, cited doubtfully by Linnaeus, do not
well accord with either.

3. L. martinicennis. Well Indian Leucas. (Phlomis mar-
Ph. carabae; Jacq. Ic. Rar. t. 110. Swartz. Ind. Occ. v. 2.
1009.)—Leaves oblong-oblong, fringed, downy. Bracteas
brittle-shaped, fringed. Whorls globos. Calyx incurved,
with ten teeth; the uppermost elongated.—Native of Bri.
and
and the West Indies, from whence Mr. Maffon sent seeds to Kew in 1781. **Root annual. Stem branched, two or three feet high. Leaves talc-alked, an inch and half long, oblong, more or less ovate, hairy above, more downy and paler beneath, bluntish, strongly ferrated; entire and tapering at their base. Whors numerous, axillary, dense, many-flowered, and nearly globose, with narrow, throngly fringed or brilliantly *bracteas*. Caflx curved forward, downy, with strong green ribs and white reticulated spaces between; its orifice bordered with ten spinous, all rather unequal, teeth, of which the upper one is twice or thrice as long as the rest. **Corolla small, white, brown in decay.**

4. _L. urticifolia_. Nettle-leaved Leucas. (Phlomis urticifolia; Vahl. Symb. v. 3. 76. Willden.)—Leaves ovate, ferrated, hoary. *Bracteas* awl-shaped. _Caflx_ obliquely truncate, membranous, with nine teeth. **—Native of Arabia Felix, and the East Indies.**—**Root annual. The plant resembles _Phl. indica_ of Linnaeus (our _Leucas indica_), but the stem, as well as _leaves_, are not downy, but hoary and extremely minute hairs. The _leaves_ are of the same colour on both sides, deeply ferrated, flat not ruged, downy underneath. **_Caflx_ rather small.**—We know this merely from the above authority.

5. _L. indica_. East Indian Leucas. (Phlomis indica; Linn. Sp. Pl. 526.)—Leaves ovate, ferrated, very downy beneath. *Bracteas* linear, hairy. _Whors_ globose. _Caflx_ oblique, with one three-toothed lip.—Native of the East Indies. The seeds were sent to England by M. Thouin in 1789. **Root annual. Leaves ferrated, ovate, two inches long and one broad, ferrated, downy above, but whiter and softer beneath. **_Corolla_ very hairy. **_Caflx_ much enlarged and elongated after flowering, its foartpart extended into an upright, oblong, ribbed and reticulated lip, with three spinous teeth at the extremity, the opposite or upper side of the orifice being short, with three or four very minute teeth.**

7. _L. biflora_. Two-flowered Leucas. (L. folis rotundis ferratis, flore albo; Brem. Zeyl. 140. t. 63. f. 1. Phlomis biflora; Vahl. Symb. v. 3. 77. Willd. Sp. Pl. v. 3. 124.)—Leaves ovate, ferrated. Flowers axillary, foliarty, opposite. Caflx with ten regular teeth. Native of the East Indies. A slender downy or rather hairy plant, with the habit of a _Stachys_ or _Sideritis_. Leaves about half an inch long, ferrated, ovate, bluntish, with five or six ferratres at each side. Flowers nearly sessile, without *bracteas_. Caflx funnel-shaped, hairy, throngly ribbed, with ten sharp taper teeth, of which the five intermediate ones are rather shorter than the others. **Corolla twice the length of the _caflx_, white, downy.**

"The _caflx_ is shrubby, with figure hipped branches. Leaves opposite, ovate and somewhat heart-shaped, ferrated, clothed with silky down. Whors axillary, of five or six flowers, on stalks. _Caflx_ funnel-shaped, with ten furrows and ten awn-teeth. **Corolla_ white, its upper lip compressed, hairy externally, especially the margin; lower three-lobe, nearly naked."—Retzio.—It is to be presumed the _caflx_-teeth are regular, probably five rather the shortet as in the laf. We have never seen this species, and it stands here on Mr. Brown's authority. Retzius's account of the compressed upper lip should, however, make it _2 Phlomis_.

9. _L. moluccoides_. Wing-flowered Leucas. (Phlomis moluccoides; Vahl. Symb. v. 1. 42. t. 14. Willd. Sp. Pl. v. 3. 125. Cinopodium fruticosum; Fork. Egypt. -Arab. 107.)—Leaves ovate, ferrated, finely downy. Flowers whitish, ferrated. *Bracteas* linear-lanceolate. Lower segment of the _caflx_ dilated, rounded, membranous, ribbed, obtucely toothed.—Gathered by Forkali in Arabia, on the hills of Hadie. One of his specimens in ripe seed, and Vahl's figure in flower, fully authorizes us in referring this plant also to _Leucas_, though Mr. Brown has not mentioned it. The _caflx_ is shrubby, five or six feet high, with roundish downy branches. Leaves ferrated, shorter; round and punctate above; paler and very downy beneath; an inch or more in length. Whors many-flowered, ferrated, with downy _bracteas_, cut into many deep, linear, or somewhat lanceolate, segments. Flowers white, the size of _Lamium album_, hairy, their lower lip, according to Forkali, convex, three-lobed, the middle lobe broad, long, and heart-shaped, which agrees with the generic character, but is not properly represented in Vahl's plate, though indicated in his description. The _caflx_ is very peculiar, and really two-lobbed; the upper lip small, ovate and acute, the lower very large, especially when in seed, spreading, rounded, five-lobed, with seven or eight hairy ribs, and numerous reticulated veins; the margin wavy, or slightly toothed, not awned nor spinous; the tube is hairy, and has ten strong ribs. We can see nothing of the lateral lobes mentioned by Vahl, and indeed he seems, in his description and figure, to have been bewildered between the lower lip of the _caflx_ and that of the corolla.

10. _L. glabrata_. Smooth Leucas. (Phlomis glabrata; Vahl. Symb. v. 1. 42. Willd. Sp. Pl. v. 3. 126.)—Leaves ovate, ferrated, slightly hairy. Flowers whitish. *Bracteas* minute, bristle-shaped, smooth. Lower segment of the _caflx_ elongated, three-toothed. Hairs of the _caflx_ deflexed,—Gathered in Arabia by Forkali, amongst whole plants it was found without a name. Vahl describes it as "herbaceous, the _caflx_ acutely angular, its angles and joints rough with reverted hairs. Leaves ferrated, spreading, ovate, bluntly ferrated, entire at the base, acute, slightly hairy, about an inch long. Whors remote, of five or eight flowers. *Bracteas* minute, in four deep, bristle-shaped, rather pungent, smooth segments, yellowish at the extremity, but one-fourth so long as the _caflx_; which is bell-shaped, smooth, with ten furrows, its orifice oblique, the lower lip being elongated, with three equal bristle-shaped teeth, the upper with seven teeth. **Corolla like the last.**"

It will readily be perceived that the great diversity and irregularity of shape in the _caflx_ of the different species, directly militate against the Linnaean division of _Didyma_ _argiofermis_, into genera whole _caflx_ is more or less exactly five-cleft, and others in which it is two-cleft; but
Leucos is not on that account the less a natural genus, and this very irregularity is its striking character. How far it might be possible or eligible to separate from it the species with a stiffly regular calyx, may be worthy of future consideration. Mean while it had best stand in the first of the above sections, as not being regularly or properly twolipped, as well as on account of its affinities.—Phloemis alta, Vahl. Symb. v. 1. 43, should seem also to belong to Leucos, though the calyx has but five teeth, but we have never had an opportunity of examining it.

Leucos Delphinus. See Delphinus.

Leucasia, in Ancient Geography, an island of the Tyrrhenian sea, upon the western coast of Italy, in the gulf of Pusium, according to Strabo and Mela.

Leucaspis, a port of Africa, in the gulf of Libya.

Leucata, a promontory of Gaul, in the Mediterranean: now called "Cap de la F ranqu¡." 

Leucate, or Leucatis, a promontory of Asia, in Bithynia, and one of those which formed the gulf called "Affacens Sinus," according to Piny.

Leucate, in Geography, a town of France, in the department of the Aude; situated on the N. side of a large lake of the same name; 17 miles S. of Narbonne. N. lat. 42° 54'. E. long. 37° 7'.

Leucé, or Achilles Insula, in Ancient Geography, an island in the Euxine sea, at the mouth of the Bosphorus. Strabo says, that it was consecrated to Achilles. Sailitt, in his Fragments, says that it was of small extent and desert; and that it was famous for a temple, and for the statue and burying-place of Achilles.

Leuces, a small island on the N. coast of the isle of Crete, according to Diodorus Siculus.

Leucé, Leuca, in Medicine, a term nearly synonymous with the vitis of the Latinis, signifies a leprous affection of the skin, of a white colour, with a loss of sensibility in the parts affected, the hair at the same time becoming white, and falling off.

The latest Greek physicians consider the alphas and leucé as the same disease essentially, differing only in degree, and not in kind. The alphas they describe as a superficial disease, in which the surface of the skin becomes white, but no farther change takes place: whereas the leucé penetrates below the surface, affecting the flesh, and being much more difficult to heal. They ascribe to it an error in the alimentary powers, in consequence of which a phlegmy or putridous and viscous blood is generated, which is incapable of being converted into a proper red flesh, but produces a sort of flesh like that of loculi, and other crustaceous animals: the hairs, at the same time, turn white, and fall off, and the skin becomes smooth and bright, and the parts lose their sensibility; so that they may be pricked with needles, without suffering any uneasiness. In a word, the disease, thus described, is a species of elephantiasis, and appears to have been the same thing with the leprosy of the Jews. The Arabians properly call it the substantive albaras; nevertheless, with the later Greeks, they consider it as differing only in degree from the white albohak, (or morphka, as it has been called by the Latin translators,) which is the alphas of the Greeks. Hippocrates, however, seems to distinguish the leucé from the alphas: for he observes that the latter should be considered as an external blemish, rather than as a disease; but he speaks of the leucé as a diitterer of the most fatal kind. (De Affection. lect. 5.) It would appear, therefore, that the word alphas denotes a modification of the scaly disease, the lepro Creorum, and perhaps also an incipient leucé; and that leucé is a variety, a precursor, or a stage of the elephantiasis. In this light Dr. Willan, in his able treatise on cutaneous diseases, considers them. (See that work, p. 124—126.) Cellus has clasped the alphas and leucé, together with the melas, (which differs from the alphas only in the blackish colour of the scaly spots,) under one generic term, vitis : at the same time, he points out the affinity of the alphas and melas, and the peculiar and distinct features of the leucé. The two former, he says, are commonly a little rough, and not continuous, but differed in drops, as it were, here and there: sometimes, indeed, it spreads more extensively, but leaves interfaces of the skin unaffected. They are the same in all respects, with the exception of colour. "The leucé," he adds, "has some resemblance to the alphas; but it is whiter, penetrates deeper, and the hairs are white and downy. They all three spread, but with different degrees of rapidity in different individuals. The alphas and the melas appear and disappear in some persons at irregular periods; but the leucé does not readily quit a person whom it has once attacked. The two first are not very difficult of cure: but the latter is scarcely ever removed, and if it is at any time alleviated, yet the natural colour of the skin is never entirely restored." (Cellus, de Re Med. lib. v. cap. xxivii.) He then states the observations in regard to the prognosis, which are repeated by the Greek physicians; namely, that if we would ascertain whether the disease be curable or not, we should prick or scratch the skin with a needle. "If blood issues, which generally happens in the two former, the case is remediable; but if a white humour appears, it will not admit of a cure, and therefore we must make no such attempts." (Loc. cit. Compare also Aetius, Tetrabib. iv. ferm. i. cap. xxxiii. Aelius Aristides, Meth. Med. lib. ii. cap. xii. Paul. Ægineta, de Re Med. lib. iv. cap. v.) The impaired sense in the parts is mentioned as an additional symptom of the irremediable state of leucé, by the last named authors. See also Forel, Ol. Chirurg. lib. v. obf. iii.

The appellation of leucé is derived either from λευκός, leucos, white, or from λευκός, leucos, the white poplar tree, the whiteness of the bark and leaves of which has perhaps been supposed to resemble the condition of the skin in the disease above described. See Gorter, Definit. Med. See also Leprosy.

Leucécrulum, a name given by some authors to the sort of amber which is white and opaque, and usually of a fatty look.

Leuchars, in Geography, a town of Scotland, in Fifeshire, near the German ocean. In 1801 the number of inhabitants was 1687; 6 miles N. of St. Andrews.

Leuchtberg, a town of Bavaria, and capital of a landgrave, to which it gives name; 36 miles E. of Nuremberg. N. lat. 49° 35'. E. long. 12° 11'.

Leuchtenshausen, a town of Germany, in the margravate of Anspach, on the Altmuhl; 7 miles W. of Anspach.

Leuci, in Ancient Geography, a long chain of mountains in the isle of Crete, so called from their whitened, being covered for a great part of the year with snow. They are now known by the names of Madara and Specia.

Leuciscus, in Ichthyology. See Dace.

Its colour is commonly greyish or yellowish-white, seldom ash-grey, milk-white, or greenish and reddish-white, passing into flesh and tile-red.

It occurs in grains, but most frequently in round crystals.
of twenty-four trapezoidal planes, (Amphigene trapezoidal, Haüy, p. 147, f. 62.) or, as the form is defined by Werner, low double eight-sided pyramids, in which the lateral planes of the one are set on the lateral planes of the other, while the sumits are flatly acuminated each by four planes placed on the alternate edges. They are more or less regular; sometimes perfectly so, at other times rather rounded on the edges. They are crystallized all around, and imbedded. Their size varies from very small to middle-sized: crystals of more than one inch in diameter are, however, seldom seen. No other modification than the trapezoidal has been hitherto observed.

The surface of the grains is rough, and dull or weakly glimmering; that of the crystals glittering and smooth, not frosted, as in the garnets of the same form: there are, however, sometimes minute rents seen to run parallel to the short diagonal of the trapezoidal planes. Externally they are glimmering, internally shining, with vitreous lustre rather inclining to refrinous.

Fracture imperfectly and flat conchoidal, sometimes inclining to foliated; fragments indeterminately angular, more or less sharp-edged.

It occurs commonly slightly translucent, but also nearly transparent, and rarely with perfect transparency.

The leucite is hard in a low degree, scratching glass with difficulty: it is brittle, and easily frangible. Specific gravity, 2.461, Karsten; 2.406, Kirwan; 2.468, Brilhon; 2.440 (from Vefuvius), and 2.490 (from Albano near Rome,) Klaproth.

It is insublect before the blowpipe without addition; with borax it melts into a light brown, transparent glass.

The leucite was first analyzed by Klaproth, who discovered it in a considerable portion of volcanic alkali; a substance till then unsuspected to form a constituent of mineral substances. Vaucqelin’s subsequent analysis completely agrees with that given by Klaproth.

Mean of different Analyses. Klaproth. Vaucqelin.
Silica - 100 100
Alumine - 54 50
Potash - 44 20
Lime - 21 20
Leps - - 1 3

Leucite occurs particularly in lava, and also in rocks belonging to the flint transformation of Werner. It should, however, be observed, that what has been described by several authors as leucite in basalt, trap, &c. is nothing but cubic zoilite (analcite of Haüy). Faujas, Esnars, and others have fallen into this error.

Many places have been mentioned where leucite is found; but the best authenticated locality is that of the neighbourhood of Naples, and of Rome. They are found in immense quantities in the mountains of Alba, Tivoli, Caprarola, Viterbo, Aquavendente, Civita Castellana, and Borgenitto, where they are seen enclosed in lava, often accompanied by mica, felspatic, and hornblende.

Von Buch, Salmon, Patrin, and others, are of opinion, that the leucite crystals were formed in the lava when fluid in a fluid state; Dolomieu and Werner, on the other hand, consider them as having pre-existed in the rocks that were afterwards converted into lava. The idea of other mineralogical writers, who look upon these crystals as being garnets altered by volcanic fire, is now decidedly exploded.

Haüy’s name of Amphigene is derived from the double origin of the leucite, with regard to its primitive form, which may be either the cube or the rhombohedral doceahedron.

LEUCOCRAGA, in Natural History, the name given by many authors to a bird, supposed to be the swiftlet of all creatures in the world: others have called it leucocraga, but the true name is leuconegra.

LEUCOCRAGA, a name by which some authors have called the substance, more usually known by the name of morochthus, and called in English, French chalk, or Briton chalk.

LEUCOGRAPHS, the name used by some of the ancient writers, for the substance commonly called morochthus, or French chalk.

Gen. Ch. Cal. Spatia oblong, obtuse, compadred, opening at the flat side, withering. Cor. bell-shaped, spreading; petals five, equal, ovate, flat, coalescing at the base; their tips thickish and straight. Stam. Filaments five, brilhshaped, very short; anthers oblong, obtuse, quadrangular, erect, dilatant, bursting in the upper part. Pyl. Germi inferior, roundish; style mostly club-shaped, obtuse; stigma falcate, erect, acute, longer than the filaments. Peric. Capsule terbinated, of three cells and three valves. Seed numerous, roundish.

Obs. Leucium autumnale and trioplyllum have a thread-shaped style.

1. L. vernum. Spring Snow-flake. Linn. Sp. Pl. 414. Curt. Mag. t. 46. Jacq. Pl. Aulfr. t. 312.—Spaitha single-flowered. Style club-shaped. - A native of moist woods and shady places in various parts of Italy, Switzerland, Germany, and the south of France. It flowers in the early spring; its specific name indeed is indicative of this circumstance. Bulb oblong, smaller than that of the Daffodil. Leaves flat, darkish-green, about four or five in number, broader and longer than those of the Snow-drop. Stalk radical, angular, hollow and channelled, furnished towards the top with a whitish spathe, opening at the side, from whence the flower proceeds. Corolla rather large, its petals white, tipped with green. The plant has an agreeable fragrancy, something like Hawthorn.

2. L. effl. Summer Snow-flake. Linn. Sp. Pl. 414. Engl. Bot. t. 621. Curt. Lond. f. sce. 5. t. 23. Jacq. Aulfr. t. 203.—Spaitha many-flowered. Style club-shaped. - First deter mined to be a native of this island by Mr. Curtis, who found it growing between Greenwich and Woolwich, as well as in the Isle of Dogs. It has since been gathered in many other parts of England, particularly Wellmoreland, Suffolk, and Berkshire, flowering in May. Root a roundish bulb. Leaves numerous, erect, a foot and a half in length, obtuse, keeled, bright-green. Stalk radical, as long as the leaves, compressed. Spatlia lanceolate, erect. Partial flalk solitary and single-flowered. Flowers pendulous, white; petals
LEU

petals tipped with green. **Anthers** oblong, burbling by two pores at the summit. **Capsule** elliptical, three-celled. **Seeds** globular, large.

The plant is entirely without smell, but is exceedingly ornamental, and may be often seen in rudy gardens.

3. L. **autumnale**. Annual Snow-flake. Linn. Sp. Pl. 414. Curt. Mag. t. 960. Redouté Liliac. t. 150. f. 2. — Spatha many-flowered. Style thread-shaped. — A native of Spain and Portugal, flowering, as its name imports, in the autumn. **Bulb** thickish, of many glutinous coats, covered with a white membrane. **Stalk** radical, about six inches in height, reddish-brown, mostly bearing two or three white, pendulous, inodorous flowers, red at their base. **Leaves** capillary, springing up after the plant has flowered. Curtiss however says that in specimens which were sent from Gibraltar, the leaves appeared at the same time with the flowers, though considerably shorter than they afterwards grew.

4. L. **trichophyllum**. Brushe-like Snow-flake. Brod. Luft. p. 1. 553. Redouté Liliac. t. 150. f. 1. — Spatha two-flowered, many-flowered. Style thread-shaped. — Gathered on the sandy plains of Barbary, flowering in the midst of winter. **Leaves** thread-shaped, membranaceous. **Stalk** radical, by the leaf at its base, thread-shaped, five or six inches high. **Flowers** from two to four, pendulous, white, occasionally tinted with red on the outside.

Redouté regrets that he could not call this by **name**, as the name of **trichophyllum** had previously been applied by Reinaeumius to the last species, to which indeed this is closely allied. The specific name of **byname** would have been particularly desirable on account of carrying on the analogy of nomenclature with the three other species. It is greatly to be wished that botanists who give new names to plants would well consider such analogies.

For L. **fruticosum**, Hort. Kew. ed. 1. 407. f. 5, see

STRUAMARIA.

**LEUCOMIUM**, in Gardening, comprehends plants of the bulbous-rooted flowery or perennial kind, of which the species cultivated are the great spring flowery (L. vernum); the summer flowery (L. verum); the autumnal flowery (L. autumnale); and the many-flowered Cape leucomi (L. fruticosum). The frill has an oblong bulb, shaped like that of the daffodil, but smaller; the leaves are flat, deep green, four or five in number, broader and longer than the frill of the common flowery; the frill angular, near a foot high, hollow, and channelled; towards the top comes out a whitish sheath, opening on the side, out of which come out two or three flowers, hanging on slender peduncles; the corolla is much larger than that of the common flowery; and the ends of the petals are green. They appear in March, and have an agreeable scent, not much unlike those of the hawthorn.

The flowers, which at first slight resemble those of the common flowery, are easily distinguished by the absence of the three-leaved nectary. They do not come out so soon by a month. The frill is called by Mr. Curtis the spring flowery.

In order to distinguish the second from the galanthus, Mr. Curtis names it the summer flowery; and in gardens it is commonly known by the name of the great summer flowery, and the late or tall flowery.

**Method of Culture.**—These plants are readily increased by off-sents from the roots, which should be separated from the old roots about every third year, in the summer season, as soon as their leaves begin to decay, in the same manner as other bulbous roots. See **BULBOS ROOTS**.

They are also capable of being increased by seeds, which

should be sown in the latter end of August, in a border of light bog-earth. The plants should remain in this situation till the second summer, and be then taken up at the proper period, and planted in beds, till they begin to flower, when they should be removed into the borders. In this way they are three or four years before they flower. But by much the best method is to procure the roots from the nurseries, and plant them in the beginning of the autumn, in an eastern or northern border, where the soil is of a boggy quality, in patches of three or four together, in the fronts, putting them in to the depth of about three or four inches.

The off-shoots should be planted out in beds a year or two after being taken off, till fit to be set out for flowering.

A soft loamy soil, or a mixture of loam and bog-earth, are the most suitable to their healthy growth. The last year requires protection in the house, with other Cape bulbs.

By planting them in the different aspects mentioned, a longer succession of flowers may be produced.

They are very ornamental in the fronts of the borders, or the sides of the lawns, and other parts near the house, or other public situations.

**LEUCOMIUM Indicum et lacteum.** See Stock **Gilly Flower**.

**LEUCOMIUM Bulbosum.** See **LEUCOMIUM, lapra.**

**LEUCOLIBANON**, in the Materia Medica of the Ancients, a name given to the white oblanum, or frankincense, which they carefully distinguished from the reddish or yellowish oblanum. This was also called argyrolibanum, or the silver-coloured oblanum; and the yellow or calcholibanum. This latter word is used in the Apocalypse of St. John, and is misapplied to the bosom, or to be translated balsam, and supposed to be a kind of balsam from Mount Lebanon. See **CHALCOLIBANON** and **FRANKINCENSE**.

**LEUCOLITHOS**, in Natural History, a name given by some of the Greek writers to the pyrites argentae, or livery pyrites. The ancients had a great opinion of these foils in diaphane of the eyes; they used all the kinds of pyrites, or marcasite, after calcination, for this purpose; but as they distinguished four kinds of them, they attributed these virtues, in different degrees, to the different kinds; therefore they had recourse to fo many peculiar names for distinguishing them; and the white kind was called **LEUCOLITHOS**, to distinguish it from the last called iron pyrites, and the deeper and paler yellow kinds, called the gold and brunt marcasites.

**LEUCOMA, diaphaneus**, among the Athenians, signified a public register of the whole city, in which were written the names of all the citizens, as soon as they came to be of age to enter upon their paternal inheritance.

**LEUCOMA (derived from LEUCOS, white),** signifies, in Surgery, a whitish opacity of the cornea. Professor Scarpa, of Pavia, has made some interesting remarks on this case in his "Osservazioni sulle Principalità Malattia degli Occhi." He informs us, that the albigo and leucoma are very different from what has gone under the name of the nebula of the cornea, since they are not the consequence of a slow chronic inflammation of the eyes, accompanied by a variecolate flake of the veins, and an extravasation of a thin milky serum into the texture of the delicate layer of the conjunctiva spread over the cornea; but are either produced by a violent act of the crystalline, wherein a dense coagulable lymph is effused superficильно or deeply into the substance of the cornea itself, or else are occasioned by wounds, or ulcers attended with loss of substance. Albigo strictly denotes the first of these cases; leucoma the last, particularly when the scar, or opaque spot, occupies the whole or a considerable portion of the cornea.

A recent albigo, remaining after the subsidence of a violent...
LEU

violent acute ophthalmal is of a clear milky colour; but when inveterate, it puts on a chalky or pearl colour, and in this frequently appears to have no vascular connection with the rest of the cornea. Occasionally no uneasiness, and being incapable of being absorbed.

Provided the texture of the cornea be not disorganized by the coagulable lymph extravasated in a case of recent albigo, the opacity may often be dispersed by employing, in the first stage, general and local bleeding, internal anti-phlogistic medicines, and emollient applications; and in the second stage, mild astringents and corrosorians. These last, as soon as the inflammation is subdued, excite the action of the aborbmets, by which velfels the opaque extravasated lymph, forming the albigo, is to be removed.

But although a recent albigo may often be dispersed, this object cannot be so easily effected when the disease has existed a long while, in which case the aborbmets have frequendy lost their activity, and the structure of the cornea become fo disorganized, that this membrane must for ever remain opaque at the part affected. According to Scarpa, the circumstances favourable to the cure are a recent flat of the disease without disorganization of the cornea, or of the delicate layer of the conjunctiva spread over it, and the patient being young, as at this period of life the aborbmets are most capable of action. Scarpa affirms us, that he has seen many examples in children, where the specks, left on the eye after a violent ophthalmal, have spontaneously disappeared in the course of a few months.

The following local remedies Scarpa has found most serviceable, both to recent and inveterate cases of albigo. A collyrium, composed of two scruples of sal ammoni, four grains of aruge, and eight ounces of aqua calcis. There are to stand for twenty-four hours, and the liquor then be filtered for use. An ointment, confining of the following ingredients. R. Tuttis p. s. Aloe f. p. Calom. á a gr. Butyr. recent. 3°. M. Janin's ophthalmia ointment, and the gall of ox, sheep, pike, and barbel, applied to the cornea with a hair-pencil, are also favourably spoken of.

When the eye was too irritable to bear the preceding application, Scarpa sometimes used with advantage the oil of walnuts, somewhat rancid. Two or three drops were introduced into the eye every two hours, and the plan followed up for several months. He has likewise found the juice of the lesser centuary, mixed with honey, a good application.

How unpromising forever things may seem, the surgeon is to perseve in the trial of remedies, at least three or four months, before the case is to be fet down as absolutely incurable.

Scraping and perforating the cornea, and forming an artificial ulcer upon it, are all unavailing expedients in cases where the albigo or leucoma is in a state that Scarpa terms inveterate and corioeacous, such measures being the invention of persons quite ignorant of the structure of the cornea, and the principles upon which its transparency is to be restored.

LEUCOMENAS, in Ichbyology, a name by which some have called the slim, a small fish caught in great plenty in the Mediterranean.

LEUCOPETALOS, in Natural History, the name of a beautiful stone deprived by Phiny, as being of a fine gold yellow, variegated with white.

LEUCOPETRIANS, in Ecclesiastical History, the name of a fantastical fish which sprang up in the Greek and Eastern churches towards the close of the twelfth century; the fanatics of this denomination professed to believe in a double Trinity, rejected wedlock, abstained from flesh, treated with the utmost contempt the sacraments of baptism and the Lord's supper, and all the various branches of external worship, placed the essence of religion in internal prayer alone, and maintained, as it is said, that an evil being, or genius, dwelt in the breast of every mortal, and could be expelled from thence by no other method than by perpetual supplication to the Supreme Being. The founder of this enthusiastic sect is said to have been a person called Leucopetra, and his chief disciple Tychicus, who corrupted, by fanatical interpretations, several books of scripture, and particularly St. Matthew's gospel. Mofheim.

LEUCOPHÆA ANTeloPE, in Zoology. See Antelope Leucophæa.

LEUCOPHAGHUM, a name given by some physicians to a sort of medicinal aliment good in consumptions, and other general decays. It is composed of sweet almonds macerated in rose-water with the tender flesh of a capon, all being finally boiled together to a pulp, capable of being pashed through a sieve.

LEUCOPHLEGMATIA, in Medicine, from λυκς, albius, and φλεγμα, phlegm, a term applied to the droply of the skin, or anginacea, in confession of the very palid hue of the skin and complexion under such circumstances.

Dr. Cullen remarks, that the terms anginacea and leucophlegmatia have been commonly considered as synonymous; but some authors have proposeth to consider them as denoting distinct diseases. The authors who are of this last opinion, employ the name of anginacea for that disease which begins in the lower extremities, and thence gradually extends upwards; while they term that leucophlegmatia, in which the same kind of swelling appears, even from the beginning, very generally over the whole body, and in which there appears to be a greater deficiency of the blood; such as occurs after proflate hemorrhages, or other great evacuations. The distinction, however, is principally verbal. See ANASARCA, and DROPSY.

LEUCOPHRA, in Zoology, a genus of the clafs Vermes, and order Insectodya; this worm is invisible to the naked eye, and every where ciliate. There are eight species, of which four are found in the waters or marshes of our own country.

Species.

CONFICTOR. Spherical, sub-opaque, with movable intestines; it is found in clear water; is of a yellowish colour, with dark edges, and filled with very minute molecules in perpetually violent agitation. This animalce is decribed and figured in Adams' Essays on the Microscope. It is said to be rather a heap of animalcules than a single individual, is larger than most species of the vorticella, perfectly spherical, and semi-transparent. It rolls at intervals from right to left, but seldom removes from the spot where it is first found. In proportion to the number of molecules above-mentioned, which are accumulated on one side or the other, the whole mass rolls either to the right or left; it is then tranquil for a short time, but the conflict becomes more violent, and the sphere moves the contrary way in a spiral line. It is a fine object for the microscope, but requires to be observed with much attention. When the water begins to fail, the little creature asume an oblong, oval, and even cylindrical figure; the hind part of some being compressed into a triangular shape, and the transparent part escaping as it were from the intestines, which continue to move with the same violence till the water wholly fails, when the molecules are spread into a shapeless mass, which soon vanishes, and
and the whole float into a form, having the appearance of crystals of sal-ammoniac. See Adams, p. 500.

Vesiculifera is ovate with vesicular interstices. This animalule is a fort of mean between the orbiculiform and oval, very pellucid, with a defined dark edge, and inside containing some very bright vesicles or bladders. The middle frequently appears blue, and the vesicles seem as if set in a ground of that colour. The accounts given of this animalule by Spallanzani and Muller differ in some respects; but, however, admits that he once saw an individual like those described by Spallanzani.

Acuta. The oval leucophora, which is round, with a black point at the edge.

Fluxa. Situate, kidney-shaped; body oblong, yellowish, obtuse on one part, the other produced into a cone, and generally filled with molecules.

Armilla. Round, annular; body thickened above and bent like a ring.

Cnunica. Inferredly conic, green, opaque. This animalule has a resemblance to certain species of the vorticelles, and requires to be observed some time before its peculiar characters can be ascertained: the body is composed of molecular vesicles, of a dark green colour, for the most part it is like an inverted cone, the fore-part being wide and truncated, with a little prominent horn, or hook, on both sides; the hind-part is conical, elided, the hairs exceedingly minute; those in the fore-part are three times longer than the others, and move in a circular direction. The hinder part is pellucid, and sometimes terminates in two or three obtuse pellucid projections. The animalule will at one moment appear oval, at another reniform, and elided at the fore-part; but at another time the hairs are concealed. When the water which contains it evaporates, it breaks and dissolves into molecular vehicles. It is found late in the year in marshy grounds. See Adams, Pl. 25.

Heteroclitus. Cylindrical, obtuse on the fore-part, the hind-part furnished with a double hooked organ, which it can thrust out and draw in at pleasure. To the naked eye it appears like a white point; interstices visible by a microscope, when it seems a cylindrical body; the fore-part obtusely round, the middle rather drawn in, the lower part round, but much smaller than the upper part. With a lens of pretty high power the whole body is found to be elided.

Noducla. Ovate-oblong; depressed, with a double row of tubercles. This species is found in the interstices of the Lumbricus terestris, and Nais littoralis; it is very pellucid, shining like silver, and is propagated by a transverse division; it is of an oval shape when young, and growing more oblong with age; it is truncate at the tip.

Leucopiper, in the Materia Medica, a name by which some authors have distinguished the white pepper.

Leucopogon, in Botany, so named by Mr. Brown, from Leucos, white, and pogon, a beard, on account of the white erect hairs on the upper side of the segments of the corolla, very conspicuous even in dried specimens. Brown, Prodr. Nov. Holl. v. 541. At. Hort. Kew. ed. 2. v. 1. 523.

(Perophis; Cavay. 1.c. v. 4. 29)—Chief and order, Pentandria Monogynia. Nat. Ord. Experipedia, Brown.

Gen. Ch. Col. Perianth interior, of seven leaves, erect, permanent; the five innermost equal, lanceolate, concave, two outer ones ovate, opposite, much shorter. Cor. of one petal, funnel-shaped, limb in five spreading equal segments, longitudinally bearded on the upper side, with dense, erect hairs. Nectary glandular, surrounding the base of the ger- mien. Stam. Filaments five, thread-shaped, equal, inserted into the tube; anthers incumbent, oblong, bursting lengthwise, rising just above the tube. Piffl. German superior, roundish; style short, columnar; stigma obtuse. Peric. Drupa more or less succulent, or sometimes dry when ripe, sometimes crustaceous. Nut of from two to five cells, with one or two pendulous seeds in each.

Ebr. Ch. Outer calyx of two leaves. Corolla funnel-shaped; its limb spreading, longitudinally bearded. Filaments included in the tube. Drupa of from two to five cells.

In the Prodromus of Mr. Brown, so rich in botanical novelties, we find the definitions of forty-eight species of this new genus, which he has separated from the Stryphula of preceding writers; retaining in the latter such plants only as have four or more leaves to their external calyx; a more elongated and cylindrical corolla, with five internal tufts of hair near the bottom, the limb revolute as well as bearded; filaments prominent; and a rather dry drupa, always of five cells.

Leucopogon is divided into five sections, of each of which we shall give some examples.

L. lanceolatus. Brown n. 1. (Stryphula lanceolata; Smith Bot. of New Holland, 49; excluding the synonymy from both authors.)—Spikes drooping, aggregate. Fruit oval, of two cells. Leaves lanceolate, flat; many-ribbed beneath; with three furrows above. Branches smooth.—Sent dried from Port Jackson, New South Wales, by Dr. White, in 1793. The living plant we believe has never been brought to this country: L. lanceolatus of the new edition of Hort. Kew. being certainly Stryphula pasqueflora of Andr. Repof. t. 287; S. Cniidiun, Vutten. Malmaif. t. 23, which appears to us a very different species, rather agreeing with the characters of L. opiculatus, Brown n. 7.—The true lanceolatus is a larger shrub, with copious, slender, leafy, round branches, usually quite smooth, sometimes very minutely downy; the young ones reddish, becoming angular and flattened when dried. Leaves scaterred, slightly spreading, sessile, lanceolate, flat, sharp-pointed, entire, smooth, above an inch, but rarely approaching to two, in length, a quarter of an inch broad; of a full rather glaucous green above, and marked with three fine, often oblique, furrows, from the bafe to the middle; the under side paler, with numerous, branching, parallel ribs. Staples tooth. Spikes clustered about the ends of the branches, spreading or drooping, nearly the length of the leaf, slender, leafy, many-flowered, the common falk slightly downy. Flowers small, white, sessile. Bracteas solitary under each flower, ovate, concave, ribbed, downy-edged, of the size and exact appearance of the two outer calyx-leaves, placed contrary to them, permanent. Inner calyx-leaves twice as long as the outer, and smoother, rather shorter than the tube of the corolla, whole limb is reflexed, with a tolerably dense, but not very white beard, at least in the dried specimen. Drupas of two cells, oval, twice as long as the inner calyx-leaves, crowned by the Hyde, which is about a third of its length.

L. verticillatus. Brown n. 6.—Spikes mostly terminal, aggregate; drooping when in fruit. Drupa of five cells, five-ribbed. Leaves interruptedly clustered, somewhat whorled, oblong-lanceolate, taper-pointed. Gathered by Mr. Brown on the southern coast of New Holland. We have what answers to his description from King George's Sound, on the west coast, communicated by Mr. Menzies. It is much larger than the preceding. Leaves from two to three or four inches long, and three quarters or more broad, somewhat roughish to the touch, marked on both sides with five ribs, besides innumerable oblique lateral ones beneath;
four or five growing together in a form of whorls. The lateral branches are also often whorled. Spikes much as in the last, but longer. Braeæs ribbed, smooth, twice as large as the outer calyx-leaves.

L. apiculatus. Brown n. 7. (Styphelia parviflora; Andr. Repol. t. 287? S. Gnidium; Venten. Malmaif. t. 23?)—Spikes terminal, somewhat aggregate, of five to seven flowers. Braeæs lanceolate, rather larger than the outer calyx-leaves. Leaves lanceolate-oblong, erect, slightly concave, callous-tipped, smooth at the edges. Drupa crustaceous, tubunate, depressed, shorter than the calyx.—Gathered by Mr. Brown on the south coast of New Holland. He observed a smooth variety and a downy one, which he suspected may be distinct species. The above characters must minutely answer to the above plant of Andrews, raised from New Holland seeds, and to be seen in several greenhouses, flowering in May. It is a small shrub, with apparently deciduous, rather glaucous leaves, hardly an inch long, smooth, with little, dense, upright, usually solitary, terminal spikes, of pretty fine-white flowers.

L. revolutus. Brown n. 13.—Spikes mostly terminal, aggregate, of four or five flowers. Calyx and braeæs minutely downy, the latter half the size of the outer calyx-leaves. Leaves rather spreading, linear-oblong, obtuse, with a blunt callous point; convex and rough above; smooth and furrowed beneath; the edges reflexed and naked. Branches finely downy. Drupa dry, obovate, with five cells.

—Found by Mr. Brown on the south coast of New Holland, and by Mr. Menzies at King George's sound. It is not very unlike the latter, but the leaves are smaller, more spreading, and rough on the upper side with minute points. The flowers are larger, and very conspicuous for the long white hairines of their segments.

L. ericoides. Brown n. 17. (Styphelia ericoides; Smith Bot. of New Holl. 48. Epaclus purpureus; Cavan. t. 4. 27. t. 347. f. 1.)—Spikes copious, axillary, solitary, of three or four flowers. Leaves oblong-linear, spreading, sharp-pointed; recurved at the edges; roughish above. Braeæs pointless. Inner calyx-leaves membranous. Drupa dry, angular.—Native of New South Wales, and of Van Diemen's land. A bushy shrub, with leaves scarcely half an inch long, almost every one of which is accompanied by a much shorter axillary spike of three or four flowers. The segments of the corolla are straight and sharp, looking redish (as Cavanilles describes them) when dry, elegantly bearded with white hairs, which, as the flowers open, seem to form a dense web in the mouth of each.

To this section also belong, among others, the Styrherea, tab. 64, 65, 66, 67, of Labillardiere.

3. Spikes axillary or terminal. Leaves heart-shaped. Calyx and braeæs membranous or leafy. Five species.

L. amplexicaulis. Brown n. 21. (Styphelia amplexicaulis; Rudge Tr. of Linn. Soc. v. 8. 292. t. 8.)—Spikes axillary and terminal, spreading, stalked, longer than the leaves, which are heart-shaped, pointless, clasping the stem; minutely downy beneath; recurved and fringed at the edge. Branches hairy. Drupa lenticular, of two cells.—Found near Port Jackson. The spikes are several from one root, mostly simple, round, redish, clothed with fine horizontal hairs. Leaves spreading, near an inch long, half an inch wide, with many ribs. Calyx and braeæs linnen, acute. Segments of the corolla recurved, very hairy. Drupa compressed, oblique.

L. dyflans. Brown n. 23.—Spikes terminal, aggregate, zigzag. Flowers diurnal. Leaves ovate, somewhat heart-shaped, deflexed, pointless, minute; convex above; downy beneath. Drupa crustaceous, obovate, flat-topped, of five cells.—Gathered at King George's sound by Mr. Menzies, to whom Mr. Brown, like ourselves, was indebted for specimens. The branches are long, clothed with numerous little reflexed convex leaves. Spikes very peculiar, being long, slender, with remarkably zigzag, downy flanks. Braeæs heart-shaped, concave, ribbed, permanent. Calyx-leaves very broad. Segments of the corolla recurved, very densely bearded.

L. microphyllus. Brown n. 26. (Perojoa microphylla; Cavan. t. 4. 299. t. 299.)—Spikes clustered, of few flowers. Leaves of the calyx pointed, half membranous. Braeæs leafy, ribbed. Leaves oval, flat, obtuse, pointless; of the same colour on both sides. Drupa crustaceous, of one or two cells.—Native of the neighbourhood of Port Jackson. A pretty little shrub, with minute, rather imbricated, smooth, thickish leaves. The little flowers, clustered at the ends of each branch, form round heads. The inner leaves of the calyx are narrow, acute, smooth, and thin. Segments of the corolla thick, recurved, very densely covered with white hairs, as in L. dyflans, and indeed the generality of the species.

5. Stalks axillary, two-flowered; here and there only single-flowered; in which case there are several braeæs. Drupa dry. Fifteen species.

L. acuminatus. Brown n. 37.—Stalks very short, erect, mostly two-flowered. Leaves nearly upright, linear-lanceolate, very sharp, flat, with a brilly point; their margins rough, finely toothed.—Found by Mr. Brown in the tropical part of New Holland, as are fix others of this section, one of them, L. rufofolius, having been discovered there by sir Joseph Banks. Most of the rest are natives of Port Jackson, but none of them have come under our inspection.

This is, on the whole, a very elegant as well as natural genus, and it is to be regretted that only one of the species has hitherto been made known to our cultivators of curious plants. The plumy whitefences of the flowers give a striking and peculiar aspect to the whole.

LEUCOPSIS, in Zoology, a genus of the Hymenoptera order, of the class Insects. The mouth is hurny with short jaws; the mandible thick and three-toothed at the tip; the lip, which is longer than the jaw, is membranous, and emarginate at the tip; it has four feelers, short, equal, and filiform; antennae shorter and clavate; thorax with a long lanecleate scale beneath; wings folded; wing reflexed and concealed in a groove of the abdomen. There are four species, all foreign insects; three found in the south of Europe, and one in Tranquebar.

Species.

GIKAS. Black; thorax with two dorsal yellow dots; abdomen fuscous, with four yellow bands. It inhabits France; the wings are dusky; hind-thighs with numerous teeth.

DORSIGERA. A abdomen fuscous, black, with two yellow bands, and a dot between them. It is found in Italy, Switzerland, France, and some parts of Germany. Head is black; thorax gibbous, black with a double transverse yellow line; abdomen compressed and grooved on the back; sting double, as long as the abdomen, and reflexed back into the abdominal groove; legs yellow, spotted with black; hind legs toothed, with a black spot. This beautiful insect is figured in Adams' work on the microscope; the drawing was taken from a specimen in her present majesty's cabinet of insects.
L E U

There is one also in the cabinet of Linneus, now in the possession of our very able coadjutor, Dr. Smith, P. L. S. It appears at first sight like a wasp, to which genus the folded wings would have referred it, had not the remarkable fling or tube on the back have prevented it. It is thought to be a species between, and uniting the sphex and wasp, in some degree partaking of the characters of both. The antennae are black and cylindrical, increasing in thicknes towards the extremity; the joint nearest the head is yellow; the head is black; so also is the thorax, accompanied with a round yellow line, and furnished with a cross one of the same colour near the head. The femtulum is yellow; the abdomen black, with two yellow bands, and a spot of the same colour on each side of the bands. The anus and the whole body, when viewed with a low magnifier, appear punctuated, and the points, when examined carefully, seem to be hexagonal, and in the centre of each hexagon a small hair is seen.

Petiolata. Black; abdomen petiolate farruginos; the petiole with a yellow dot each side. It is found in Tranquebar. The thorax is elevated, with two yellow streaks before; under the feetot is a yellow dot; the second segment of the abdomen is edged with yellow, and the tail is black; legs black edged with yellow; wings black.

Ccelogaster. Abdomen fiddle; talle of the thorax half as long as the abdomen. It is found in some parts of Germany. The thorax has a yellow band behind, and the eyes are black.

Leucorrhæa, in Medicine, λευκόρροο, literally signifying flour albus, or white flux, is a disorder of the uterus or its paflages, from which a whitish or pale coloured fluid is discharged, accompanied by pain in the loins, considerable loss of strength, and a wan fickly aspect. It is commonly expressed by the appellation of "the whiter" by the patients, or is simply called "a weaknès." Every ferior or puriform discharge from the vagina has been comprehended under this apellation; it is obvious, however, that such discharges may be various, and may proceed from various sources. They may proceed more especially from the vesfels of the uterus itself, or from those of the vagina only. In the latter case, which is probably not a very common occurrence, the cause of the excretion must be purely local; it sometimes happens during the period of pregnancy. In these instances, there must be either a local weaknès and relaxation of the parts, or some irritation may exist or have been applied, so as to excite the mucous glands, the secretion from which serves to lubricate the parts, to pour out their fluids in an unusual quantity. The existence of little aphthous ulcers within the labia sometimes gives rife to such a discharge, in which case there is also a considerable degree of foreenefs and tendernefs in the parts; and the use of those instruments, called peffaries, has been laid to produce a flour albus, from the pain and irritation which they occasion.

In general, however, the discharge of leucorrhæa proceeds from the same vesfels of the uterus itself which pour out the catamenia. This inference may be deduced from the following circumstances. In the firt place, the leucorrhæa is most common in those women who are subject to an immoderate flow of the menfes. Secondly, it appears principally, and often exclusively, a little time preceding, and again posterior to the menstrual discharge; the latter diminishing in proportion as the leucorrhæa is increafed, or femeing to be converted into the leucorrhæa. Thirdly, the leucorrhæa often continues after the period when the catamenia have altogether ceased, and frequently fews a considerable tendency to a periodical recurrence. And lafly, it is commonly accompanied with the fame local and constitutional symptoms as an excessive flow of the menfes; such as palefes of the countenance, a feeble pulse, an unftable debility on taking exercise, a hurry of the breathing from even moderate exertion; and at the fame time the back becomes pained by any continuance in the erect posture, the extremities are frequently cold, and some ñeema affects the feet in the evening. The debility also manifests itself by affections of the humfach; such as fobs of appetite, flatulence, and other symptoms of indigefion; by palpitations of the heart, with frequent fentations of finking and fluttering about the epigastric region, and even actual fyncope; and by a defcription of spirits, and a weaknès of mind liable to frong emotions from flight caufes, especially when operating suddenly; in a word, by all the train of diftrefing symptoms which have been denominated nervous. The inference, that the discharge is uterine, is farther confirmed, when it is observed, that it had neither been preceded nor accompanied by any symptoms of a local affection of the vagina; and that it had not appeared foon after commuication with a person who might be suspected of giving infecfion; nor had, from the firt appearance, been accompanied with any inflammatory affection of the pudenda. The laft observation applies particularly to the diagnosis between the discharge of leucorrhæa and that arising from venereal infecfion; a point which is worthy of more particular confeffion. It is very easy to diftinguifh a fimple leucorrhæa from a recent gonorrhæa; for besides the general debility, and the nervous symptoms above-mentioned, which frequently accompany the former, the colourfes nature of the discharge, which only fliffens, without staining the linen, and the abfence of all heat and fcaling on pafling the urine, together with the cesation of the discharge at the time of menstruation, sufficiently characterize the leucorrhæa; whilst in the gonorrhæa there is itching, infammation, and heat of urine, the orifice of the urinary paflage is prominent and painful, there is frequent irritation to make water, and the discharge stains the linen of a yellow or greenifh colour. But it must be remembered, that the discharges from the vagina, which have been denominated leucorrhæas, are sometimes opaque and of a yellowifh colour, and sometimes accompanied with a degree of ardor urine and infammation of the external labia. This may happen in women of bad habit of body, or where there is ulceration in the vagina or uterus; but in both thefes caufes the discharge is of a fainefs nature, and very offensive; and in the latter is commonly accompanied with severe pains in the region of the uterus, and extending from the loins round the pelvis to the groins, and even down the thighs. The discharge is sometimes fo acrimonious, in these instances, as to inflame and excoriate the paflages. In the herpetic or aphthous affection of the orifice of the pudendum, there is heat of urine with the discharge; but the discharge is very feainty, and the labia extremely tender and fent, fo as fearly to admit of fitting, except upon a soft fect; which does not take place either in proper leucorrhæa, or in gonorrhæa in general. In many caufes, the circumftances of the patient, which render it either imprOfible or in the highest degree improbable that any infecfional connection can have taken place, will of course admit of no hefitation in the decifion; and it is often upon these circumftances alone that the practitioner is obliged to depend in forming his opinion.

The caufes of leucorrhæa are chiefly to be fought for among thofe agents and circumftances, which tend to produce a debility of the fytlem in general, or of the uterus in particular. Of the former kind, are imperfect diet, fatigue, anxiety, and much watching; the practice of fucking
ling children too long; damp, close, and uncleanly habitations; causes which chiefly operate among women of the lower classes. To these may be added, the almost total want of proper exercise, living too much in warm chambers, and drinking much of warm enervating liquors, such as tea and coffee, which influence principally women of better stations. The sources of local debility to the uterine system itself are many; such as chills, bruises, and falls; frequent abortions, or frequent child-bearing without nursing, difficult and tedious labours, profuse discharge of the catamenia, or of the lochia after delivery; venus immodica; &c.

On the other hand, the effect of leneorhagia, especially when it has continued long, is, in many cases, to prevent conception and occasion barrenness; or, if conception take place, to produce a succession of miscarriages: not to mention the constitutional and nervous derangement already described. However, if the leneorhagia be moderate, and be not accompanied with any considerable overflow of the catamenia, it may often continue long without inducing any great degree of debility; and it is only when the discharge has been very copious, as well as constant, that its effects in that way are very remarkable.

The means of cure will consist of those expedients which contribute to strengthen the general habit, and the uterine system locally. The system generally is to be supported by all those means which regimen, diet, and medicine contribute; namely, by light and nutritious diet; by moderate exercise, by some means of geltation, as in a carriage, on horsecback, or failing (the exercise of walking, both from the constant erect posture, and the action of the muscles, being liable to produce irritation, and to augment the uterine discharge); by the use of the tepid or cold bath, according to the strength of the patient, and the season of the year; by drinking the chalybeate mineral waters; or by taking some of the preparations of iron in the way of medicine, especially the muriated tincture, or the sulphate, together with the cinchona, or other vegetable tonics. The mineral acids are sometimes beneficial under the same circumstances.

The uterus itself and its connections may be strengthened either by direct local applications, or by internal medicines, which are commonly determined to the urinary passages, and from the vicinities of these are often communicated to the uterus. These last mentioned medicines are cartharias, turpentine, and balsams of a similar nature; by which the discharge has often been relieved or even cured. The former claus includes a variety of astringent lotions and injections, by which the discharge may also be often diminished, and in young women, when the complaint is recent, entirely cured. Thus the parts may be washed twice or three times a day with a weak solution of the acetate of lead, or of alum, in rose water; or an infusion of roe leaves, or of green tea, or the chalybeate mineral waters, make very proper lotions; or these liquors may be thrown into the vagina twice a day, through an ivory pipe, by means of the elastic gum. But in general injections are unwillingly used, unless when the disfage is inveterate. When the matter discharged is acrimonious, and infames and excoriat the parts, or excites very troublesome and painful itching, the greatest relief is obtained by keeping the parts clean and cool, removing the acrimonious matter frequently by bathing with cold water, or with any of the above-mentioned astringent liquors.

Dr. Hamilton remarks, that women have, in many instances, been cured of the most obstinate habitual fluor albus by giving suck. See his Treatise on Midwifery, pt. i. chap. i. p. 68. See also Cullen, First Lines, § 985. Leake on the Chron. Dif. of Women.

LEUCORODIUS, in Ornithology, a name by which some have called the platea, or spoonbill, a very remarkable kind of fowl or heron.

LEUCORYX, Antelope or Antelope leucoryx, in Zoology, the Gazella Indica, having singular horns, of Nov. Com. Petrop. xiii. 470. 10. f. 5. Oryx of Oppian, Cyneg. I. v. 445; leucoryx of Pennant, is a species of Antelope, which has very long, slender, upright, taper, sharp-pointed horns, very slightly bent backwards and annulated at the base; the body being of a milk-white colour. It inhabits the island of Goa Bahrea, in the bottom of the Persian gulf, near Baffora. It is about the size of a Weller runt or small cow; the head is large and broad, with a thick broad nose, like that of a cow, and somewhat slouching ears; the body is thick and clumsy, and the whole is of a pure white except the middle of the face, the fides of the cheeks, and the limbs, which are tinged with red: the tail is longish, and is tufted at the end with a brash of hairs; the horns are of a black colour. Dr. Pallas mentions a horn, apparently belonging to this animal, or some species nearly resembling it, which was found in a fossile state, in Siberia. The female comes into seafon in autumn, and brings forth in spring.

LEUCOSCEPTRUM, in Botany, a new genus named by Dr. Smith, is derived from λυκος, white, and κεφτερ, a sceptre, on account of its elegant sceptre-shaped spike of white flowers. The author of this genus remarks that "it has the habit of a Buddelia, but belongs to the second section of Fities in Jullien, near Verbena; and should, along with Verbena, stand near Mentha in the Linnean system." —Sm. Exot. Bot. v. 2. 113.—Clais and order, Didyma Gymnospermia. Nat. Ord. See above.

1. L. canum. Hoary Leucosceptrum. Sm. Exot. Bot. t. 116.—This is the only species known, and was gathered by Dr. Buchanan in the woods of Upper Nepal, where it flowers in December, and is called Muffola by the Naws. The branches are obtusely quadrangular, compressed, clothed with fine, dense, whitish pubescence. Leaves on shortish, downy footstalks, opposite, elliptical, pointed and tapering at both ends, bluntly ferrated, veiny; green and naked above; white and downy beneath. Spike terminal, solitary, fevile, erect, cylindrical, dense, many-flowered. Bracteas small, in four rows, opposite, each common to many flowers. Calyx tubular, downy; its margin obtuse, unequally five-cleft. Corolla longer than the calyx, with a short tube; the limb in four, very unequal, obtuse segments, of which the uppermost is deeply divided; the lowermost, or lip, large, concave, and entire. Stamens declining, parallel, thread-shaped, smooth; the two longest double the length of the lip. Anthers roundish, two-lobed, yellowish. German inferior, four-lobed. Style declining, as long as the longer stamens, with a cloven, acute stigma. Seeds four, truncated, naked, in the bottom of the calyx.

This is one of the numerous splendid plants sent by Dr. Buchanan, from the mountains of Nepal, to Dr. Smith, which so greatly enrich the work whence the above description is chiefly taken.

traces, Brown.

Gen. Ch. Cal. Common Perianth of numerous single-
flowered scales, collected into a head, either permanent and 
hardened, or membranous and deciduous. Cor Petsals four, 
irregular, linear; three of them cohering by their lower 
part; the fourth separate and narrower. Stam. Filaments 
four, short, inserted into the petals; anthers linear, con-
celled by the petals, of two cells, buffing lengthwise. 37. 
Germin superior, feffil, rounded; stigma cylin-
drical, rigid, deciduous; stigma swelling, smooth, some-
Eff. Ch. Petsals four, unequal, three of them cohering 
by their lower part. Anthers fun in the holes of the 
upper part of the petals. Style deciduous. Stigma swelling, 
smooth. Nut superior, feffil, tumid, smooth.

Eighteen species are defined by Mr. Brown, all natives 
of southern Africa, about the Cape of Good Hope, growing 
for the most part in dry, sandy, rather elevated situations. 
Eight of them are cultivated in the Royal Garden at Kew.
The whole are divided into two sections: the first having a 
round head of flowers, whose calyx-scales are permanent, 
becoming somewhat hardened, of which description are 
fourteen species; the remaining four have a flatter common 
receptacle, with narrow deciduous scales, of which the 
inferior are very thin and chaffy. All are fibres of 
rather humble growth, rarely arboreous; many of them 
downy or hairy. Leaves either entire, or furrowed with 
callous teeth at the extremity. Flowers yellow, in terminal 
heads.

An interesting specimen of this genus is
(Protea tomentosa; Willd. Sp. Pl. v. 1. 514. Linn. Suppl 
118. P. candidae; Andr. Repof. t. 294.)—Style nearly 
the length of the corolla. Stem erect. Leaves linear or wedge-
shaped, downy, three-toothed. Calyx-scales lanceolate, 
nearly equal to the tube of the corolla. This is said to be 
very rare in England. Mr. Maffon sent it from the Cape to 
Kew in 1789, and Messrs. Lee and Kennedy raised it from 
seed the year following. The whole frut is clothed with 
fine short down of a glaucous hue, the stem rather hairy. 
Leaves two inches long, various in breadth, spreading, 
caricate, dilated outwards, blunt and unequally three-
toothed at the end. Heads of flowers produced in August 
and September, terminal, solitary, feffil, about the base 
of a wattle, variegated with orange and yellow, their scales 
tipped with dark brown. Few of the Proteaceous tribe 
are more difficult to increase by cuttings.

LEUCOSTAPHYLOUS, a name given by some authors 
to the water-eelder, or opulus.

LEVE, Fr. in Mug, the up, an unaccompanied part 
of a bar in bearing time. See ARMS, and ACCENT, in 
Mug.

LEVEL, a mathematical instrument used for drawing a 
line parallel to the horizon, and continuing it out at pleasure; 
and, by this means, for finding the true level, or the 
difference of ascent or descent between several places, for 
conveying water, draining fefts, placing the surfaces of floors, 
&c. level, and for various other purposes in agriculture, ar-
chitecture, hydraulics, surveying, &c.

The word comes from the Latin libella, the cross beam 
that forms the brachia of a balance, which, to be just, must 
stand horizontally.

There is a great variety of instruments of this kind, dif-
fently constructed, and constituted of different materials, 
according to the particular purposes to which they are ap-
plied, as the carpenters’ level, masons’ level, balance level, 
mercurial levels, surveying and spiral levels. But, however 
their construction may vary, they may be all referred to the 
following three classes: viz. 1. Those in which a vertical 
line is determined by a suspended plumb-line, or a balance 
weight, and the horizontal position is shown by a line per-
pendicular to it. 2. Those which determine a level line by 
the surface of a fluid. 3. Spirit-levels, which point out the 
horizontal direction by a bubble of air floating in a fluid 
contained in a glass tube. For the purposes of agriculture, 
those of the improved water, air, spirit, and foot kinds are 
most commonly used.

Those of the first kind, depending upon the plumb-line, 
are very common, but not very accurate; the simplest form 
is that of two rulers, united together in the form of the letter 
L; they must be exactly perpendicular to each other; then 
if a plumb-line is suspended from the top of the vertical
