ruler, and the edge thereof be made to coincide with the 
plumb-line, the other ruler must be horizontal. This, when 
replied to the top of a wall, a beam, or floor, will shew 
they are horizontal. This is the kind of level used by ar-
chitects; sometimes it is found like the letter A, of three rulers, 
the plumb-line being suspended from the vertex, and the two 
legs set on the surface to be levelled. The line hangs oppo-
site to a mark, made on the middle of the crofs ruler, when 
the feet are on the same level. Besides these there are many 
other forms. For an instrument of this kind, see Plate IV. 
Surveying, fig. 5.

LEVEL, Plumb, or Pendulum, that which shews the hori-
izontal line by means of another line perpendicular to that 
described by its plummet, or pendulum.

It consists of two legs, or branches, joined together at 
right angles, whereof that which carries the thread or 
plummet is about a foot and a half long. This thread is 
hung towards the top of the branch, at the point 2. The 
middle of the branch where the thread passes is hollow, that 
it may hang free every where but towards the bottom, 
where there is a little blade of silver, whereon is drawn a 
line perpendicular to the telescope. The said cavity is co-
vered by two pieces of brass, making, as it were, a kind of 
cafe, left the wind should agitate the thread; for which rea-
on the silver blade is covered with a glass G, to the end 
that it may be seen when the thread and plummet play upon 
the perpendicular. The telescope r is fastened to the other 
branch, or leg, of the instrument, and is about two feet 
long, having a hair placed horizontally across the focus of 
the object-glass, which determines the point of level, when 
the hanging and plummet hang against the line on the silver 
blade.

All the accuracy of this instrument depends on the te-
lescope’s being fitted at right angles to the perpendicular. 
It has a ball and socket, by which it is fastened to 
its foot; and is said to have been the invention of M. 
Picard.

Here we may introduce an account of other levels con-
structed on the same general principle. For the foot-level; 
see FOOT LEVEL.

LEVEL, Artillery-foot, is in form of a square, having its 
two legs, or branches, of an equal length; at a juncture 
of which is a little hole, whence hangs a thread and plummet, 
playing on a perpendicular line in the middle of a quadrant; 
it is frequently divided into 90 degrees, or rather into twice 
45 degrees from the middle. See fig. 6.

This instrument may be used on other occasions, by plac-
ing the end of its two branches on a plane; for when the 
thread,
thread plays perpendicularly over the middle division of the quadrant, that plane is assuredly level.

To use it in gunnery, place the two ends on the piece of artillery, which you may raise to any proposed height by means of the plummet, whole thread will give the degree above the level.

**Level, Carpenters' and Paviors',** consists of a long ruler, in the middle whereof is fitted, at right angles, another somewhat bigger, at the top of which is fastened a line with a plummet; which, when it hangs over a fiducial line at right angles with the base, shows that the said base is horizontal.

This and the masons' level, though very common, are esteemed the best for the practice of building, though the operations by them can only be short.

**Level, Gunner's,** for levelling cannons and mortars, is an instrument represented in *Plate IV. Surveying,* fig. 7, consisting of a triangular brass plate, about four inches high: at the bottom of which is a portion of a circle, divided into 45°, which number is sufficient for the highest elevation of cannons and mortars, and for giving the greatest range. On the centre of this segment of a circle is screwed a piece of brass, by means of which it may be fixed, or moved, at pleasure. The end of this piece of brass is made fo as to serve for a plummet and index, in order to shew the different degrees of elevation of pieces of artillery. This instrument has also a brass foot to set upon cannon or mortars, fo as when those pieces are horizontal, the whole instrument will be perpendicular.

The use of this level is obvious, and consists in placing the foot thereof on the piece to be elevated; in such manner as that the point of the plummet may fall on the proper degree: this is what they call levelling the piece.

The most curious instrument for the use of the artillerist, was lately invented by the very ingenious colonel Congreve, of the royal artillery; having the following qualifications viz. 1. It will find the inclination of any plane, whether above or below the horizon. 2. By applying it either to the cylinder, or outside of any piece of ordnance, angles of elevation or depression may be given to the 60th part of a degree, with less trouble than the common gunner's quadrant, which only gives to the 4th part of a degree. 3. It will give the line of direction for laying either guns or mortars to an object above or below the horizon. 4. It will find the centre of metals of any piece of ordnance. 5. With it, a point may be found in the rear of a mortar-bed, in the vertical plane of the mortar's axis; consequently a longer line of sight is given for directing them to the object than the usual way. 6. It answers all the purposes of a pair of callipers, with the advantage of knowing (to the 100th part of an inch) diameters, whether concave or convex, without the trouble of laying the claws upon a diagonal scale.

7. On the sides of the instrument are the following lines, viz. equal parts, solids, planes, and polygons, logarithms, tangents, verges of sides, and numbers, plotting scales, and diagonal scale of inches for cutting lines by. 8. In the lid of the instrument-case is a pendulum to vibrate half seconds. It is likewise of singular use in forging; as, 1. It takes horizontal angles to the 60th part of a degree. 2. Vertical angles. 3. Levels. 4. Solves right-angled plane triangles. 5. Oblique-angled plane triangles. 6. Answers all the purposes of a protractor, with the advantage of laying down angles exactly as taken in the field. N. B. Captain Jordane's ingenious instrument answers nearly the same purposes.

**Level, Mason's,** is composed of three rules, so joined as to form an isosceles triangle, somewhat like a Roman A; at the vertex whereof is fastened a thread, from which hangs a plummet, which passes over a fiducial line marked in the middle of the base, when the thing to which the level is applied is horizontal; but descends from the mark when the thing is lower on one side than the other.

**Level, Balance for Surveying,** consists of a telescope or ruler with sights, and another ruler fixed perpendicularly to the middle of it, in the form of T, with a weight at the lower end. The whole is suspended by a thread, or upon centres, similar to a scale beam, and the weight of the vertical leg makes the sights or telescope assume the horizontal position. Its advantage is, that it adjusts itself to the level line, which can be transferred to any distant object, by observing it through the sights or telescope. It is necessary to enclose it in a box or case to avoid oscillation from the wind. This instrument is convenient, but not very accurate.

Another balance level, called the "reflecting level," is of French invention, ascribed to Mr. Caffini. A telescope or ruler, with plain sights, is suspended vertically; a mirror is fixed just before the object glasses, being inclined at an angle of 45° with the axis of the telescope. Now as the telescope hangs vertical, and the mirror bends the rays at a right angle, they will of course be horizontal. The telescope must be provided with a diagonal eye-piece, to bend the rays again horizontal, for the convenience of observation. Other modifications of this principle by Mellis, Grandjean and Genufens may be found, in the volumes of the Machines approvis par l'Academie. They are to be considered as more ingenious in theory, than applicable to practice.

A balance level, invented by Mr. Richard Drew, is described in the 25th volume of the Transactions of the Society of Arts. It consists of a tube, provided with sights at both ends, and suspended from a point considerably above its centre of gravity. It has a floating weight, adjustable by a screw, to place the tube truly horizontal. This is, perhaps, the best kind of balance level which has appeared.

To the second class of levels belongs the *water level.* This shows the horizontal line by means of a surface of water, or other liquid: founded on this principle, that water always naturally places itself level.

The most simple is made of a long wooden trough, or canal, whose sides are parallel to its base; so that being equally filled with water, the surface thereof shews the line of level. This is the *horisote* of the ancients, described by Vitruvius, lib. viii. cap. 6.

The masons frequently employ this, where they would make the top or courses of a wall truly level; they form the trough by a ridge of mortar or clay stuck round on all sides on the top surface of the wall; and filling the trough, thus formed, with water, they can measure if it is equally deep in all parts.

This sort of level is also made with two cups fitted to the two ends of a pipe three or four feet long, about an inch in diameter; by means of which the water communicates from the one to the other cup; and this pipe being moveable on its stand, by means of a ball and socket, when the two cups become equally full of water, their two surfaces mark the line of level.

This instrument, instead of cups, may also be made with two short cylinders of glasses, three or four inches long, fastened to each extreme of the pipe with wax or mastic. Into the pipe is filled some common or coloured water, which shews itself through the cylinders, by means of which the line of level is determined; the height of the water, with respect to the centre of the earth, being always the same in both cylinders.
LEVEL.

linders. This level, though very simple, is yet very commodious for levelling small distances.

Another water level is a glass tube, bent into the form of U, having a cup at the top of each leg. This being mounted on a pedestal, and filled with water, or other fluid, it will, from the principles of hydrostatics, stand at the same level in both cups; and by looking through the glass, any distant objects which appear to coincide with the surface of the water, in both cups, will be on the same level with them.

A reflecting level is, that made by means of a pretty long surface of water, representing the same object inverted, which we see erect by the eye; so that the point where these two objects appear to meet, is in a level with the place where the surface of water is found. This is the invention of M. Mariotte.

Of a similar nature are the mercurial levels, but they are furnished with two small fids, provided with cross-hairs; thefes float upon the surfaces of the fluid in the cups, the cross-hairs of each being equally distant from the surface. A line seen through the fights will be parallel thereto, and confequently horizontal. One of these by Alexander Keith, eq. is described and illustrated by drawings in the 2d volume of the Edinburgh Transactions, p. 14, &c. from which we shall here subjoin the following extract. Fig. 8. (Plate IV. Surveying,) is a section of the instrument formed of mahogany or boxwood. A, A, are two oblong square cavities connected together by a narrow close channel, running from the bottom of the one to the other. B, B, are two grooves hollowed out of the wood, in order to contain the fights, &c. They are shut up by a lid, which turns upon a screw-nail at the centre C, as may be seen more distinctly from fig. 11.

Fig. 9. D, D, are the two fights, the one with a small hole, the other with a cross-hair. These fights are erected upon pieces of ivory or hard wood, which are shaped nearly of the dimensions of the cavities A, A, but so much smaller as to enter without touching or rubbing on the sides. Mercury is poured into the two holes A, A, till they are about half full; the two pieces of ivory which support the fights are put into the cavities, and float on the surface of the mercury.

Fig. 10. is a perspective view of the instrument when the fights are floating upon the mercury; and fig. 11. is another view of it, when the fights are taken out and the lid is open.

As the two cavities communicate with each other, the surface of the mercury in both is always upon the same level; and consequently, if the two fights are once accurately adjusted, they will ever after point out the true level, without requiring any after adjustment.

When this instrument is to be used, it may be laid on any horizontal surface, and the fights will immediately become an exact level. It may also be fixed on a tripod as the spirit-level; or it will answer equally well, if it is affixed to the top of a single fide, which is sharpened at the point so as to be pushed into the ground. If it is to be used as a pocket-instrument, it may be made of seven inches length, being about double the dimensions of the annexed draught. A common walking cane forms a very convenient support. It is affixed to the cane by means of a brass pin E, which passes through the hole G, and through the eye or hole of the walking fide; and a brass nut F, screwing to the male-screw of the brass pin, keeps them firm together. The two grooves B, B, contain the two fights and brass pin, when not in use. Two corks, covered with thin leather, fitted into the holes A, A, confine the mercury, when the instrument is to be transported; or, in case the mercury is found to escape, it may be poured into a small cafe, made of lignum vitis, like a tooth-pick cafe; and this may be stopped with a cork, and made to fit into one of the grooves.

The advantages of this instrument over the spirit-level are: 1st. It requires no adjustment, consequently two observers, though otherwise not equally accurate, must make the same observation. 2dly. With this, the level of twenty different places may be taken during the time required to adjust the spirit-level for one observation. 3dly. The nicety of the spirit-level depends upon the small curve of the glass-tube, in the choice of which no rule can be laid down; neither is there any thing gained, in point of exactness, by lengthening the spirit-tube above three or four inches. But every instrument of this kind is of one standard; and the further the two fights are removed from one another, the more any error is diminished. 4thly. This instrument can be made perfectly just, without taking any observation, or comparing it with another level. In order to do this, let the floats on which the spirit rests, be of the same dimension and weight, and let the cross-hair and eye-hole be of one height, and without further adjustment, they will point out the true level.

To the third class of levels belongs the spirit level, called also the "air level," which is more accurate than any other kind, and is most extensively used. The invention of this instrument has been ascribed to M. Thevenot. Others have attributed this application of a bubble of air to Dr. Hooke. The instrument consists of a cylindrical glass tube filled with spirits of wine, except leaving in it a small bubble of air: its ends are hermetically sealed in the fluid. This bubble, being the lightest of the contents of the tube, will, by the laws of hydrostatics, always run towards that end of the tube which is most elevated; but when the tube is perfectly horizontal, the bubble will have no tendency towards either end.

The tube is not firstiy cylindrical within, though it bears that appearance; it is slightly curved, the convex side being upwards, and by this means the bubble will rest in the middle of the tube when it is horizontal, but approaches either end which is elevated above the other. The transparent form of a spirit level for fixing any plane truly horizontal, consists of a glass tube of the above description, called a bubble tube, fixed into a block of wood, as at A B, fig. 1. of Plate V. Surveying. The lower surface D E of the block is made flat; and when the bubble C stands between the two fatches marked on the glass at a b, the line D E is horizontal. The method of making it correct is this: the tube is first fitted into the block, the lower edge, D E, of which is placed on a bench or table as nearly horizontal as can be determined, so that the bubble stands between the fatches a, b. The level is now reversed, that is, the end D is put where E was at first. In this position, if the bubble stands in the middle, it proves the level to be correct, and the table horizontal; but if it runs to either end of the tube, it shows that end to be too much elevated; suppose it B, for instance; this end of the tube must therefore be let deeper into the wood, or the surface D E rectified to produce the same effect: one-half the error must be compensated by this means, and the other half by rectifying the table or support; for D E, the level, must now be reversed again to verify these corrections; and when they are so made that the bubble stands at a b, either way, the level is correct.

To illustrate this more plainly, see fig. 2. which represents a section of a bubble tube; but, for elucidation, is shown as
if curved much more than they are ever made. Suppose the convex or upper surface of the tube to be a segment of a large circle BCD, from the laws of hydrostatics it is plain, that the bubble of air, being the lightest body in the tube, will certainly occupy the highest point of the circle at C; and the two points B, D, being equally distant therefrom, will be in the same horizontal line B D. The larger the radius of the circle B D, so will the level be the more sensible of any deviation from the horizontal, because the bubble will have to traverse a greater distance along the tube, in proportion to any partial elevation of either end. The numerous spirit levels applied to the delicate astronomical instruments made by Mr. Troughton, and described in our articles Circles, Equatorial, Transit, &c. are, in general, formed by grinding the inside of the tube to a circle of near 400 feet radius. In a level of this kind, the elevation of one minute of a degree, of the line B D, will produce a motion of three inches of the bubble; therefore a second will be 1-16th of an inch, and may be determined to the greatest precision. For common purposes, the bubble tubes have a much more rapid curvature, and are proportionably less sensible, which is very proper, because the bubbles of such delicate levels can never, in common use, be brought to stand at all ready, from the bending of the floors, and tremors of the supports they are applied to. The application of the bubble tube has been shewn in numerous instances in the articles above-mentioned; but the instrument designated the spirit-level, for surveying, remains to be described here. The most simple form is a ruler of brass, having a bubble tube fixed down upon the middle of it; at each end of the ruler a float is erected, through which the observer views any distant object, whose level is to be ascertained. This instrument is fitted upon a support with three legs, and has a ball and socket, by which the ruler and float can be turned about in all directions, until the bubble shows it to be horizontal. The spirit-level in this form, which is the original, is so extremely inconvenient for use, that it is totally unfit for the delicate observations necessary for setting out canals, and other works, where the conveyance of water is concerned, and is therefore but very little used, except in levelling for roads, where an error is of slight importance. After having described some progressive improvements in this instrument, we shall proceed to the description of the level with telescopic sights, which is universally employed for the above purposes.

The air-level, with sights, is an improvement of the simple spirit-level already described; which, by the addition of more apparatus, becomes more commodious and exact. It consists of an air-level (Plate VI. Surveying, fig. 1.) about eight inches long, and seven or eight inches in diameter, set in a brass tube, with an aperture in the middle. The tubes are carried in a strong, straight ruler, a foot long, at whole ends are fixed two goods, exactly perpendicular to the tubes, and of an equal height, having a square hole, formed by two fillets of brass, croffing each other at right angles; in the middle whereof is drilled a very little hole, through which a point on a level with the instrument is described. The brass tube is fastened on the ruler by means of two screws; one whereof, marked 4, serves to raise or depress the tube at pleasure, for bringing it towards the level. The top of the ball and socket is rivetted to a little ruler that springs; one end whereof is fastened with screws to the great ruler, and the other end has a screw 5, serving to raise and deprefs the instrument, when nearly level.

This instrument is yet less commodious than the following one, because, though the holes be ever so small, yet they will still take in too great a space to determine the point of level precisely.

**Level, Air, with telescopic sights.** This level, represented in Plate VI. Surveying, fig. 2, is like the last; with this difference, that, instead of plain sights, it carries a telescope, to determine exactly a point of level at a good distance.

The telescope is in a little brass tube, about fifteen inches long, fastened on the same rule as the level. At the end of the tube of the telescope marked 1, enters the little tube 2, carrying the eye-glass and a hair horizontally placed in the focus of the object-glass 3; which little tube may be drawn out, or pushed into the great one, for adjusting the telescope to different sights. At the other end of the telescope is placed the object-glass; the screw 3 is for raising or lowering the little fork carrying the hair, and making it agree with the bubble of air when the instrument is level; and the screw 4 is for making the bubble of air agree with the telescope. The whole is fitted to a ball and socket.

Mr. Huygens is said to have been the inventor of this level; which has this advantage, that it may be inverted, by turning the ruler and telescope half round; and if then, the hair cut the same point that it did before the turn, it is a proof the operation is just.

It may be observed, that one may add a telescope to any kind of level, by applying it upon, or parallel to, the base, or ruler, when there is occasion to take the level of remote objects.

For the method of adapting a level to the meridian telescope, see Telescope.

Mr. Hadley has contrived a spirit-level to be fixed to a quadrant for taking a meridional altitude at sea, when the horizon is not visible. See the description and figure of it in the Phil. Trans. No. 430, p. 167, &c. or Martyn's Abbridg. vol. viii. p. 358, &c. See also the method of preparing and using a water level, and a mercurial level, annexed to Davis's quadrant, for the same purpose, by Mr. Leigh, in Phil. Trans. N. 451. p. 413. or Abr. vol. viii. p. 360, &c.

**Level of M. Huygens's Invention consists of a telescope, a.** (Plate VI. Surveying, fig. 3.) in form of a cylinder; going through a ferril, in which it is fallowed by the middle. This ferril has two flat branches, b b, one above and the other below; at the ends of which are fallered little moving pieces, which carry two rings, by one of which the telescope is fixed at a hook at the end of the ferril 3; and by the other, a pretty heavy weight is fixed in order to keep the telescope in equibrio. This weight hangs in the box 5, which is almost filled with lined oil, oil of walnuts, or other matter that will not easily coagulate, for more appertly setting the balance of the weight and telescope. The instrument carries two telescopes, close and very parallel to each other, the eye-glasses of the one being against the object-glasses of the other, that may see each way without turning the level. In the focus of the object-glasses of each telescope, mount a little hair be fixed horizontally, to be raised or lowered as occasion requires, by a little screw. If the tube of the telescope be not found level when fixed, a ferril or ring, 4, is put in it, and is to be fitted along till it fixes to a level. The hook on which the instrument is hung, is fixed to a flat wooden cross; at the ends of each arm of which there is a hook, serving to keep the telescope from too much agitation in using, or in carriage. To the said flat cross is applied another hollow cross, that serves as a case for the instrument; but the two ends are left open, that the telescope may be secured from the weather.
LEVEL.

The foot of this instrument is a round brass plate, to which are fastened three brass ferrules, moveable by means of joints, wherein are put flaves; and on this foot is placed the box.

In the portable spirit-level, the tube is properly set in brass, and fixed by means of screws in a small brass trough, the bottom of which is ground very straight. The screws are useful to place the bubble in such a position that the lower surface of the trough may be parallel to a tangent suppofted to be applied to the middle point of the curve of the level. The adjustment is effected without much difficulty, by placing the level on an adjustable plane, and then revering it. If the bubble stand accurately in the same position between two marks made on the tubes in both situations of the level, it follows, that neither end of the plane nor of the lower surface of the frame of the level is elevated; or, in other words, that every surface to which the level may be applied, and on which the bubble stands in the position here mentioned, is horizontal.

This easy praxis may be effected in various ways, according to the nature and figure of the instrument of which the position is to be determined; but the accuracy of the result will depend upon the sensibility of the level; that is to say, the space passed over by the bubble for every minute or second of the quadrant, and the certainty with which, under circumstances precisely similar, it shall arrive at the fame position. In the best levels the curve must be circular; for in such the bubble will move with more activity, settle itself with more certainty, and describe equal spaces by equal changes of inclination. An ordinary good spirit-level will exhibit a movement of upwards of half an inch for every minute of inclination, and alter the position of its bubble by a change of five seconds, or lefs. In such a tube the radius of the curve will be about 150 feet. But extraordinary levels are much more delicate. De Lalande speaks of a level filled with ether, the bubble of which passed over fourteen inches by equal spaces of one-tenth of an inch for every second. The radius of this curve was conveniently 1719 feet; or near one-third of a mile.

The tubes of spirit-levels are selected by trial. If a long piece of tube be nearly filled with ardent spirit, and corked at the ends, the run of the bubble may be tried with a suitable instrument called the level-trier, throughout the whole length on all sides. By this means it may be known whether, and in which parts, it may be desirable to divide the tube for the purposes of filling and closing. It is remarkable that these tubes in general prove either good throughout, or good for nothing; for it seldom happens, where one good level can be taken, that the remainder is unserviceable. A respectable mathematical instrument-maker affirms us, that he finds it a good practice to go to the glazier's house and cause the tubes to be drawn without suffering them to be turned round.

But the most regular and accurate levels are obtained by grinding the inside of the tube. For this purpose, a cylindrical piece of wood is turned so as to go easily through the portion of tube intended to be ground. It is then worked in the tube with water and fine emery in the usual way. As soon as the polishing has by this means disappeared on one side, the tube is cleaned, filled, and tried; and accordingly as its figure proves to be more or less straight or curved, the grinding is either repeated or discontinued. Some operators polish the inside again after grinding; but this has not been found to increase their sensibility.

From the great delicacy of the spirit-level, compared with the few observables here presented on the plumb-line, the former instrument may appear greatly to deserve the preference. Astronomers are not however agreed on this point. When a spirit-level is adjusted by revering, at a certain temperature, and both ends of the bubble marked, it may be allowed that the instrument may be successfully applied to use. But if the temperature be raised, the spirit will expand, and of course the bubble will become shorter. Whence it appears necessary that a division and adjusting piece should be applied, from experiment, to ascertain the true station of the bubble at different temperatures; and even this application seems scarcely adequate to supply the place of repeated adjustments. The variation of the bubble will differ according to the quantity of spirit contained in the tube. In two good levels, of nearly the same magnitude and figure, we found it amount to one-fifth of an inch for every ten degrees of Fahrenheit. The bubble therefore may be one inch longer in winter than in summer, which in these individual levels amounts to near one-third of the summer length. The curvature of a spirit-level will also vary from unequal temperature; such, for example, as may arise from one end of the tube being touched or breathed upon, while the other end is left at the original temperature. The error from each of these causes may amount to several minutes, as is easily shown by trial; but we do not find that the presence or abence of fumes causes any perceptible difference. It is probable that the rays may not speedily alter the temperature, on account of the transparency. And with regard to these three last sources of error, it must be allowed that they are easy to be avoided, and indeed not likely to be present in the operations of accurate observers.

We have, in Plate V. Surveying, given figures of two levels by the most celebrated makers, the late Mr. Jeffes Ramden, and another by Mr. Troughton: of the former, A B, fig. 3, is the telescope, having the spirit-level C D fitted in a brass tube, fixed beneath it. The telescope is supported at its ends by resting on angular notches in two pieces of brass, Y 1, Y 2, called the ayves, from their resemblance to that letter. It is held in the angles of the eyes by a clip r r, shutting down over each and pinned fast. The eyes are supported on a brass bar E E, the middle of which has a large circular aperture in it, to receive a compass needle. A bottom plate a a, being screwed under this aperture in the bar, and a glafs cover fitted over it, forms the compass-box F, in which the magnetic needle turns round. The bottom a a of the compass-box has a long axis lighted to it, which is fitted into the dome of the circular plate G, and also passes through a spherical ball, shown by the dotted lines to be screwed fast to the underside of the dome of the plate. Upon this axis, the telescope-level and compass-box turn round horizontally; the ball, just mentioned, is received in a corresponding cavity in the socket R, which is part of the plate H. By this ball and socket the two plates G and H are united, but not confined to be parallel, though they are the parallel plates. Four screws (two of which are seen at I K) pass through the plate H, and their heads support the plate G, which can, by means of them, be placed horizontal, (and consequently the axis fixed in it vertical,) though the lower plate is not horizontal, which will depend upon accident, as it is supported on three legs set on the ground, and may therefore partake of its inclination. The legs are not shewn in fig. 1, but are the fame as those seen in fig. 3, at L M N: they are all jointed into the same piece of brass O, which has a large screw on the top of it, entering a female screw in the interior of the projecting part R, fig. 3, of the plate H. When

2dly. To make the cross-wires in the telescope intersect each other in the axis or line of collimation thereof.—The eye-piece L being drawn out to see the wires distinctly, direct the telescope to any distant object, and by the nut d adjust the focal distance to see it clearly: select some straight line in the distant object, as the side of a window, &c. Then by the screws N or O, one elevating the telescope, the other moving it sideways, and by turning the telescope in its yews, bring one of the cross-wires to coincide with the straight line of the distant object, without regarding the level. Now turn the telescope half round on its own axis, as it lies in the yews; and if the cross-wire is truly in the axis it will not appear to have changed its position; but if it has, the wire must be moved, by turning an opposite hair of the four screws at f, by these move the wire across the field of view one-half of the error, and by the screws N or O turn the telescope back the other half. The other wire is now done in the same manner, by observing its coincidence with a distant object, and then turning the telescope half round on its own axis; and both wires may be proved by observing a small object, as a circular chalk mark, &c., to be in the intersection of both wires; and turning the tube round on its axis, it will, if right, appear in the intersection in all positions. The instrument is now prepared for taking levels in the manner explained under Levellng; and, if carefully used, need not be re-adjusted for many days.

The level above described, is that which is in the most general use, great numbers having been made by Mr. Ramsden, and since his decease by his numerous pupils. It is certainly an excellent instrument in the hands of those who are ready and expert in the manipulation of the adjustments just described, and who are careful to repeat them when necessary.

The instrument delineated in fig. 4. has lately been brought forwards by Mr. Edward Troughton. Its construction is so compact, that the parts are little liable to derangement, and therefore do not need so many provisions for adjusting, by which the instrument is simplified and rendered more portable. A B is the telescope, and D E the level; its tube consists of brass tubes, the brass tube being partly received into the telescope, and folded flat thereto, so as to be in no danger of altering its position: the telescope is screwed to a strong brass bar EF, which screws to the top of a conical socket G, that turns upon a vertical axis fastened to the plate H; this is united to the lower plate I by a ball and socket, and the four screws traversing the upper plate, and resting on the lower, give the means of always setting the axis vertical: the joints O for the three legs L, M, N, are fixed to the lower side of the plate H; the compass-box P is supported over the level by four small pillars; by this means it is more readily observed than when beneath, and gives the means of laying the telescope so close to the brass bar F, that it is much more firm than the former instrument. The bubble of the level is so long, that its ends appear on both sides of the compass-box, and is shown to be in the middle by the other side. The screws which hold the telescope to the plate F are covered by caps of brass, which defend them from accidental alteration, but admit their adjustment when necessary. To make the telescope exactly perpendicular to the vertical axis, the only adjustment the instrument requires besides this is the eye-piece. It has, in lieu of cross-wires, a small micrometer or divided scale, of mother-of-pearl, fixed perpendicularly across the field of view, the divided edge intersecting the line of collimation; the central division of the
Level.

Scale has a small hole through it for distinction. It is this by which the levels of objects are observed, and it therefore crosses the focus of the telescope. It can be adjusted exactly to this by a一经 d at top, and another e beneath the tube. The manner of adjusting this instrument is as follows: the legs being set on firm ground, the vertical axis is adjusted, in the same manner as every other level is preparatory to making observations, viz., by setting the telescope over any opposite two of the four screws in the parallel plates, and turning these screws, one in and the other out, till the bubble comes right; then turn it half round, by applying the finger and thumb to the large milled nut on the top of the socket G. If it is level when thus reversed, all is right; if not, it shews the level is not perpendicular to the axis, and one-half the error must be corrected by the screws under the ends of G, and the other half by the screws of the parallel plates, the telescope being turned over the other pair of screws; and they are adjusted in the same manner. Now the axis is vertical, as is shewn by the bubble standing still while the telescope is turned all round. The plate F, being once adjusted in this manner, will not from be deranged, and when it is will immediately discover itself, and be as easily restored.

The line of sight, or line of collimation of the telescope, is made parallel to the level, by an actual trial in the field, which indeed is the most accurate method, and is referred to for very delicate purposes. In the instrument before described, to verify the adjustments after making them, the method of trial is applicable to a level of any kind, and is described under Levelling. The micrometer scale in the eye-piece is very useful in levelling; it gives the means of rigidly estimating equal distances from the instrument in any direction. A man who attends the observer holds up a staff of six feet, or any other length, perpendicular, and the observer, looking at it through the telescope, notices how many divisions of the micrometer scale the staff appears to subtend; then, if the man recedes from the instrument until the same staff reaches the same number of divisions, he will be at the same distance from the instrument. This property is extremely convenient in many instances which occur in the use of a level.

Level, American, is an instrument which is formed of two pieces of thin wood of equal length, joined together at top, and connected below by a cross bar; from the angle at top a lead plummet is suspended by a small cord, which, when the instrumentstands level on both legs, strikes upon a mark in the centre of the connecting bar, as represented by a, fig. 4. in Plate VI. Surveying. The manner of using it is simply this: At the place from which the level is to be taken, drive a wooden peg in the ground, close in to the top, upon which one of the legs of the frame may rest; then bringing round the other leg till it touches the ground, there drive a second peg, turning round the other leg as before; and where it touches the ground again, drive in another peg, and fo on along the whole line to be levelled. Thus, with very little trouble, and with as much accuracy as with the finest spirit-level, will the course of the drain be easily ascertained. But as it is necessary the drain should have as much declivity as to allow the water to run freely, it will be requisite, in taking the level, to regulate the direction of the line accordingly. Half an inch fall in the length of the frame will be sufficient, and sometimes even less. For this purpose, it will be expedient to have, besides a number of wooden pegs, one iron pin, with inches and halves marked regularly upon the sides of it from the top downwards. After having drove in the first wooden peg at the point from whence you mean to conduct the drain, and having retied the one leg of the frame upon it, turn round the other till it be level with the first peg; there put in the iron pin, so that this leg of the frame may rest on the top of it when level; then drive in a wooden peg so far, as that the top of it may be half an inch lower than that of the iron pin. Place the leg of the frame again upon this second peg, turn it round to a level, putting in the iron pin till the top of it be equal with the foot of the frame; then drive in another wooden peg close by the side of it, till the top of the wooden one be half an inch lower than that of the iron pin. Proceed in this manner so far as you mean to carry the drain, which will have the same degree of declivity all the way along. A line thus let off is marked from e to d in the figure. When made on a smaller scale, it is useful in ascertaining the proper descent along the bottom of a drain, while the workmen are laying it; but when made for this purpose, the cross bar must be fixed to the bottom of the legs, as marked with dotted lines in the plate.

There is a watering level which is much used in some places, which is formed of different pieces of wood, &c.; the usual length given it being five feet and a half, and the height from four feet to four and a half feet, according to the height of the person who is to make use of it. The object staff, fig. 5. Plate VI. Surveying, should be made exactly of the same height with the level. The cross piece, fig. 6, should be sufficiently large to be seen distinctly at a distance, and must be painted white for the purpose.

This level, in the experience of Mr. Marshall, has been found "preferable to any other level now in use, as being equally accurate in ascertaining the relative heights of distant objects, as in minutely tracing the level by the required line of communication, so as to give every part of it an equal and uniform descent." In its use in setting out a level, fo as to fix the fall accurately at one inch, foot, or yard, in a hundred of any of them, on the face of the level, which is found in general to be the most proper; it is directed to measure out one hundred feet on level ground, placing the level at one end, the object staff at the other, and then adjusting their tops to a dead level, by a dead level line exactly drawn on the face of the implement (viz., a line drawn at right angles with the upper edge of the top rail,) as shewn at a, in the figure, then measuring one foot downward on the staff, and there holding a rule or other straight edge line across the staff; bringing the top of the level, by raising its hinder foot, to range accurately with the upper side of the rule, and while they remain at rest in this position, a mark must be made where the plummet-line rests against the face of the level. After this measure out a hundred yards, and proceed in the same manner, in order to prove or rectify the first mark, on which a permanent line must be sunk on the face of the level b, in the figure, which in water-work is better than the plummet-line. Where the ground to which the water is to be conducted can be seen from the place whence it is to be taken, the staff should be set upon the highest part to which it is desirable to raise the water, and the level at the source, and after having correctly adjusted the top of the latter to that of the former mark, where the plummet rests on the face of the level, where it rests between a and b, it is necessary to consider the cafe, as, where the extent of land is small, and that of the water unlimited, little fall may be sufficient; but in the contrary circumstances, it would be improper to let it waste by the way more than is necessary; of course where the plummet rests much within the water-line, the staff must be moved and set lower down on the slope till the requisite fall is gained. But where the plummet is found to rest on the right-
right-hand side of the water-line, mark the plan and draw a pencil line, (which will be sufficiently durable for a single work, and may afterwards be easily rubbed out on the face of the level,) corresponding to the line of the plummet, as the dotted line \( c \), and thus fix the fall in this case, always making due allowance, in tracing and marking out the line with the level thus set, for the crookedness of the course; as from this lengthening the line, the declination of the channel is proportionally lessened.

It is supposed further, that "many ingenious additions" might be made to this level; but that "they would be injurious to its present simplicity." Any country carpenter may be easily instructed to contrive it in its present form, and "any common labourer be easily taught to use it, either in forming roads or water-courses." It is, however, better adapted to the latter use.

Dr. Defaguilier contrived an instrument, by which the difference of level of two places, which could not be taken in less than four or five days with the belt telescope levels, may be taken in a few hours. The instrument is as follows:

To the ball \( C \) (Plate VI. Surveying, \( f g. 7 \)) is joined a recurved tube \( B A \), of a very fine bore, with a small bubble at the top \( A \), whose upper part is open. From the construction of this instrument, it is evident, that if it be inclined in carrying, no prejudice will be done to the liquor, which will always be right both in the ball and the tube, when the instrument is set upright. If the air at \( C \) be so expanded by heat, as to drive the liquor to the top of the tube, the cavity \( A \) will receive the liquor, which will come down again, and settle at \( D \), or near it, according to the level of the place where the instrument is, as soon as the air at \( C \) returns to the same temperature as to heat and cold. For preferring the same degree of heat, when these observations are made, the machine is fixed in a tin-velvet, \( E F \), filled with water up to \( g h \), above the ball, and a very sensitive thermometer has also its ball under water, that one may observe the liquor at \( D \), in each experiment, when the liquor in the thermometer stands at the same height as before. The water is poured out when the instrument is carried, which may be done conveniently by means of the wooden frame (\( f g. 8 \)), which is let upright by three screws, \( S, S, S \), and a line and plummet \( P P \) (\( f g. 9 \)). At the back part of the wooden frame (\( f g. 10 \)) from the piece at top, \( K \), hangs the plummet \( P \), over the braze point at \( N \). \( M, m \), are brackets for keeping the upright board, \( K, K \), at right angles with the horizontal one at \( N \). The machine seen in front is represented \( f g. 11 \), supposing the fore-part of the tin velvet transparent; and here the brass socket of the recurved tube, into which the ball is screwed, has two wings at \( 11 \), fixed to the bottom, that the ball may not break the tube by its endeavour to emerge, when the water is poured in as high as \( g h \).

After Dr. Defaguilier had contrived this machine, he considered, that as the tube is of a very small bore, if the liquor should rise into the ball at \( A \) (\( f g. 7 \)) in carrying the instrument from one place to another, some of it would adhere to the sides of the ball \( A \), and upon its descent in making the experiment, so much might be left behind, that the liquor would not be high enough at \( D \) to shew the difference of the level; therefore, to prevent that inconvenience, he contrived a blank screw, to shut up the hole at \( A \), as soon as one experiment is made, that in carrying the machine, the air in \( A \) may balance that in \( C \), so that the liquor shall not run up and down the tube, whatever degree of heat and cold may act upon the instrument, in going from one place to another. Now because one experiment may be made in the morning, and the water may be so cold, that when a second experiment is made at noon, the water cannot be brought to the same degree of cold it had in the morning; therefore, in making the first experiment, warm water must be mixed with the cold, and when the water has stood some time before it comes to be as cold as it is likely to be at the warmest part of that day, observe and let down the degree of the thermometer at which the spirit stands, and likewise the degree of the water in the barometer at \( D \); then screw on the cap at \( A \), pour out the water, and carry the instrument to the place whose level you would know; then pour in your water, and when the thermometor is come to the same degree as before, open the screw at top, and observe the liquor in the barometer.

The doctor's scale for the barometer is ten inches long, and divided into tenths; so that such an instrument will serve for any heights not exceeding ten feet, each tenth of an inch answering to a foot in height.

The doctor made no allowance for the decrease of density in the air, because he did not propose this machine for measuring mountains (though with a proper allowance for the decreasing density of the air, it will do very well, but for heights to be known in gardens, plantations, and the conveyance of water; where an experiment that answers to two or three feet in a distance of twenty miles, will render this a very useful instrument. Defaguiliers's Exp. Phil. vol. ii. p. 172, &c.

**LEVEL** is a term used to denote a length or pound of a canal, and also the adit or fough to a mine or engine-pit.

**LEVEL-PEGS,** are small stakes used in levelling out an intended canal; and they are usually placed at the level of the top bank, as at \( d \), Plate I. Canals, \( f g. 7 \) and 8.

**LEVELLING,** the act or act of finding a line parallel to the horizon, at one or more stations, in order to determine the height of one place with respect to another; for the laying grounds, even, regulating defents, draining morasses, conducting waters, for the irrigation of land, &c.

The first proceeds, preparatory to taking any levels, is to prove the correctness of the instrument you employ for that purpose. Some instruments are contrived to prove themselves, as described in **LEVEL;** but others require an actual trial in the field, which is a general method, and applicable to a level of any kind. If the level is made with plain rights, the proof is very simple: first set it level, and observe some distant object; then turn the level, end for end, and observe the same object through the other right. If it is the same both ways, all is right; if not, the level must be altered one-half of the error thus discovered, which is doubled by this method of trial. For instance, if the line of right pointed down the first time, it will point as much upwards when used at the other end. A level with a telescope cannot be used at either end, and there fore this method is inadmissible, and the following may be adopted.

Choose a spot of ground where it is tolerably level for about twenty chains; set up the instrument at the point \( B \), \( f g. 1 \), Plate VII. Surveying, and, levelling the telescope by the parallel plates, that the tube will stand while it is turned all round, direct the telescope to a target held up by an assistant, upon a stake driven into the ground at \( D \), to twenty chains distant. Your assistant must, according to your signals, elevate or depress the vane of the target, till it appears in the interjection of the cross wires; now measure and write down the height \( B b \) of the centre of the telescope above a stake driven into the ground at \( B \), suppose it four feet; and also write down the height \( D d \) at which the vane of the target
LEVELLING.

get lands, which suppose fix feet; the difference between them, two feet, shows that B is two feet higher than D; but the line b d, being a tangent to the earth's surface at the point B, will be the apparent level; and the true level will be found, by deducting the allowance for 20 chains, shown by the table of the earth's curvature to be .041 of a foot. Making, therefore, the true difference of level between B and D to be 1.979 feet, to prove this, level it the other way, removing the instrument to D, and the target to the stake at B. Observe in the same manner as before, and if it gives the same difference of level as before, after deducting the allowance, the instrument is correct; if, on the other hand, the results by the two methods do not prove the same, take half the difference between the two, and elevate or depress the target that quantity, according as the last observation was greater or less than the first, and adjust the instrument, either by the screw under the wire, or the screws of the cross wires, until they appear to cut the vane of the target so corrected, when the bubble is in the middle. The instrument is now corrected, but the trial should be repeated to make it certain.

The following method of adjusting a spirit-level is rather preferable, as it does not require the instrument to be removed; but it is only applicable to those instruments where the telescope lies in wyes, and can be removed. Set up the level, as at A in fig. 1, so that you can see both ways for about 100 yards; fix up a staff in each direction at B and C, 100 yards distant, so that the two-flaves and the telescope are in a line. Now give your assistant two circular pieces of card, about twice the diameter of the telescope where it lies in the wyes, with a hole through the centre of each, large enough to receive the tube of the eye-piece of the telescope; now level the telescope, and your assistant applies one of the cards against one of the wyes, B for instance, and moves it up and down, till its centre appears to the observer to intersect the wires. The assistant now falls it into the staff at a, by two pins, but so that the centre hole can be seen clear through by the side of the staff. The telescope is now turned half round, and directed to the other staff C, which is fitted with a card at c, the same as the former. This being done without disturbing the instrument, take the telescope out of its wyes, and put down the clips again; carry the telescope to one of the wyes b, and applying its eye-piece to the hole in the centre of the card at b, direct the telescope to the wyes of the level, and, looking through them, if the card d on the distant staff c appears to fit in the wyes, the level is proved correct; if it does not, mark the place where the card d is fixed to the staff c, unpin it, and slide it up or down, till the distant card appears to fit in the wyes. Mark this position of the card, viz. at d, and pin it on its first position; repeat this operation at the staff c, and the card b will be removed to E. The figure explains the principle of this process; in the first operation the telescope set out the inclined line A a, instead of a horizontal line; the next operation was observing the inclined line A b; the third operation at the staff B formed a continuation of the inclined line b A to d; and the fourth operation continued a A as far as e. In this state it is evident, if the spaces a d, b e, each of which are double the error of the instrument, are divided into two equal parts at the points f, g, that the line f A g will be truly horizontal, and the instrument may be adjusted by the screws under the level, so as to point to f or g when the bubble is in the middle.

One place is said to be higher than another, or out of level with it, when it is more remote from the centre of the earth; and a line equally distant from the centre of it in all its points, is called the line of true level: whence, because the earth is round, that line must be a curve, and make a part of the earth's circumference, or an arc concentrical with it, as the line B C F G, Plate VII. Surveying, fig. 3, all the points whereof are equally distant from the centre of the earth A.

But the line of sight, which the operations of levels give, is a tangent, or a right line perpendicular to the semi-diameter of the earth; one extreme of which tangent being the point of contact, the other will be that of a secant drawn from the centre of the earth: and the point which determines it, will be above the surface of the earth, and of the true level, as much as that secant exceeds the radius, or semi-diameter of the earth.

This extremity of the tangent is said to be in the apparent level, as being that given by the light; but is easily reduced to the true level, because we know by trigonometry, how much each secant exceeds the radius; and because by measuring, we have discovered the precise length of that radius. Or, since the apparent level between the places B and C is B D, and the true level is the arc B C; it is plain that the former rises above the latter by the line B D. But by a well known property of the circle 2 A C + CD x B D = 2 B D, and the diameter of the earth being so great with respect to the line B D at all distances to which the operation of levelling commonly extends, that 2 A C can be safely taken for 2 A C + CD without any sensible error, we shall have 2 A C x B D = B D = C A; i.e., the difference between the true and apparent level is equal to the square of the distance between the places divided by the diameter of the earth, or the rise of the apparent above the true level is proportional to the square of the distance. It was for want of the knowledge of this, that the ancients were not able to reduce the apparent level to the true one; and accordingly, to prevent falling into an error, never levelled above twenty feet at once, whose reduction was not necessary.

By the table since made, it appears, that at the distance of 100 yards the apparent level is raised above the true one about one-third of a line; so that the ancients, in this respect, were more ferupulous than needful. By means of this reduction, we are now able to level distances of one or two miles at a single operation, which the ancients could not do in less than three hundred.

The following table, for shewing the height of the apparent level above the true, was calculated by Mr. Ferguson, to the extent of a whole degree of a great circle on the earth's surface, and it agrees so nearly with one of the same fort in Dr. Long's Almanack, as not to differ quite two inches from it at the end of the whole degree, which contains 60 geographical miles, equal to 63.41 English miles. The use of this table is as follows: If the quantity of an arc of a great circle on the earth's surface is given in minutes or seconds of a degree, its measure may be found in feet and inches. Thus, suppose the arc contains ten seconds, which is the sixth part of a geographical mile, its measure is 16.5 feet 8 inches. So an arc of one minute of a degree, which is one geographical mile, contains 6094 feet, or 2033 yards 2 feet, which is 271 yards 3 feet longer than an English mile.

To find how far one can see in a true horizon (as at sea) when the eye is raised to any given height above the horizon: suppose the eye of an observer upon a ship at sea to be 23 feet two inches above the surface of the water, he will then see 30,470 feet all around him, or to the distance of 5' geographical miles.
**LEVELLING.**

Suppose the top of a mountain to be seen at the distance of 60 geographical miles, or one degree, by an observer, whose eye is close at the surface of the sea; the height of that mountain is 3197 feet 1 inch, nearly, above the surface of the sea. An English mile is 5280 feet, a geographical mile 6094.

Suppose a spring to be on one side of a hill, and a house on the opposite hill, with a valley between them; and that the spring seen from the house appears, by a levelling instrument, to be on a level with the foundation of the house, and is a mile from it; the apparent level of the spring is 10 1/2 inches above the true level of the house; and this difference would be sufficient for the water to be brought in pipes from the spring to the house; the pipes being laid all the way in the ground.

If the distance of the object be greater than 60 minutes, or geographical miles, its height above the true level may be found thus. Suppose an eye at the surface of the sea sees the top of a mountain, which he knows to be 90 geographical miles, or a degree and a half distant from him; take half that number of miles, and multiply the height of the apparent level above the true, answering to that half distance, by 4; and the product will give the perpendicular height of that mountain. Thus, the half of 90 is 45, against which (in the table) stands 1794 feet 11 7/63 inches; which being multiplied by 4, gives 7179 feet 11 inches for the perpendicular height of the mountain above the level of the sea.

According to these measures, the earth's circumference is 311,693,510 feet, or 49,930 English miles.

At the distance of 1 second of a degree (or the 1629th of a geographical mile) the height of the apparent level above the true is .0039547 parts of an inch; at two seconds distance it is four times as much; at three seconds, nine times; at four seconds, 16 times as much; and so on, always increasing in proportion to the square of the distance.

**A Table, showing the Height of the apparent Level above the true, at any Distance within a Degree of a great Circle on the Earth's Surface; calculated to the 1000th Part of an Inch.**

**Ferguson’s Tables and Tracts, p. 243, &c. See Depression of the Horizon.**

The operation of levelling is as follows: Suppose the height of the point A (Plate VII. Surveying, fig. 4.), on the top of a mountain, above that of the point B, and at the foot thereof required; place the level about the middle distance, between the two points, as in D, and staffs in A and B; and let there be persons instructed with signals for raising and lowering, on the said staffs, little marks of pasteboard, or other matter. The level being placed horizontally by the bubble, &c. look towards the staff A F, and cause the mark to be raised or lowered, till the middle, upper edge, or other most conspicuous part, appear in the visual ray.

Then measuring exactly the perpendicular height of the point E, above the point A, which supposes 6 feet 4 inches, set that down in your book; then turn the level horizontally about, that the eye-glass of the telescope may be still next the eye when you look the other way (if you have only plain sights, the instrument need not be turned); and cause the person at the staff B to raise or lower his mark, till some conspicuous part of it fall in the visual ray, as at C; then measure the perpendicular height of C above B, which supposes 16 feet 8 inches; set this also down in the book above the number of the first observation; subtract the one from the other, the remainder will be 10 feet 4 inches, which is the difference of level between A and B, or the height of the point A above the point B.

Note. If the point D, where the instrument is fixed, be in the middle between the two points A and B, there will be no necessity for reducing the apparent level to the true level; the visual ray, in that case, being raised equally above the true level.

If it be farther required to know whether there be a sufficient descent for conveying water from the spring A to the point B, Plate VII. Surveying, fig. 5.—Here, in regard the distance from A to B is considerable, it is required that several operations be made. Having then chosen a proper place for the first station, as at I, set up a staff in the point A, near the spring, with a proper mark to slide up and down the staff, as L; and measure the distance from A to I, which supposes 2000 yards. Then the level being adjusted in the point I, let the mark L be raised and lowered till such time as you see some conspicuous part of it through the telescope, or sights of the level, and measure the height A L, which supposes 13 feet 5 inches. But in regard the distance A I is 2000 yards, you must have recourse to your table for a reduction, subtracting 10 inches 3 lines, which will leave the height A L, 12 feet 6 inches 9 lines; and this note down in your book. Now turn the level horizontally about, so as the eye-glass of the telescope may be towards the staff at A; and fixing up another staff at H, cause the mark G to be moved up and down, till you see some conspicuous part through the telescope, or sights. Measure the height H G, which supposes 6 yards, 4 feet, 2 inches. Measure likewise the distance of the points I, H, which supposes 1300 yards; for which distance, according to the table, 4 inches 3 lines must be subtracted from the height H G, which, consequently, will but leave 6 yards, 3 feet, 9 inches, 9 lines, to be taken down in your book.

This done, remove the level forwards to some other emi-

---

Vol. XX.
Levering.

ence, as E, whence the staff H may be viewed; as also another staff at D, near the place whither the water is to be conveyed. The level being again adjusted in the point E, look back to the staff H; and managing the mark as before, the visual ray will give the point F. Measure the height H F, which suppose 11 feet 6 inches. Measure, likewise, the distance H E, which suppose 1000 yards; for which distance the table gives 2 inches, 5 lines of abatement; which being taken from the height H F, there will remain 11 feet, 3 inches, 7 lines, which enter in your book. Lastly, turning the level to look at the next staff D, the visual ray will give the point D. Measure the height of D from the ground, which suppose 8 feet 3 inches. Measure also the distance from the station E to B, which suppose 900 yards; for which distance the table gives 2 inches, 1 line of abatement; which being taken from the height B D, there will remain 8 feet 11 lines, which enter as before.

For the manner of entering down observations in your book, observe, that when a proper place or station for the level, between the two points, has been pitched upon, you must write down the two heights observed at that station in two different columns, viz. under the first column, those observed in looking through the telescope when the eye was from the spring, or towards the point, which we may call back-fights; and under the second column those observed when the eye was next the spring, which we call fore-fights, in the manner following:

<table>
<thead>
<tr>
<th>Back-fights</th>
<th>Fore-fights</th>
</tr>
</thead>
<tbody>
<tr>
<td>Feet, inch.</td>
<td>Feet, inch.</td>
</tr>
<tr>
<td>Third height</td>
<td>11 : 3 : 7</td>
</tr>
<tr>
<td>23 : 10 : 4</td>
<td>29 : 10 : 8</td>
</tr>
</tbody>
</table>

Having summed up the heights of each column separately, subtract the lesser from the greater, the remainder will be the difference of level between the points A and B; as in this example:

| feet, inch. | 29 : 10 : 08 |
| 23 : 10 : 04 |

6 : 00 : 04—The difference of height, or level, between the points A and B.

If the distance of the two points be required, add all the distances measured together; and dividing the difference of height by the yards of the distances; for each 200 yards you will have a defect of about 2 inches 9 lines. This problem may be otherwise solved in the following manner: let the line F g, Plate VII. Surveying, fig. 6, represent the line of sight of the telescope drawn from f, the intersection of the cross-hairs, through g the centre of the object-glass; and the points b, b, be the marks on the glass tube, or spirit-level, a b c. While these parts of the instrument are immutably fixed, with respect to each other, it is manifest, that as often as the air-bubble is exactly reduced to the same position, with respect to the horizon, or to a plumb-line. Nor is it at all necessary, in the business of levelling, that the line of sight and plumb-line should be exactly at right angles; but only that the angles they make shall be always the same. Let p and q, q', q", be two given points in two remote places, and let it be required to find which is the lower, and how much. Let p a and q b represent two straight staffs, or poles, fixed upright by means of a plumb-line. Having placed the telescope by the side of the pole p a, and directed the line of sight to the pole q b, alter its elevation by the foresaw adapted to this purpose, till the air-bubble rests exactly at the marks upon the tube. Then let an affilient mark the point b, which appears to be covered by the cross-hairs; and also the point a exactly upon a level with the cross-hairs; which is easily done by a common square applied to the side of the pole p a. Then remove the telescope to the pole q, and here let the same things be repeated; that is, let d be the place upon a level with the cross-hairs, and e the point upon the other pole p a, that is, if we suppose p q b to represent a long canal full of flagging water, the points g, b, will both be in its surface; and, consequently, taking the lesser depth p g from the greater q b, their difference q r shews how much the point g is below the point p r.

If the places p', q', cannot be seen from each other, or if the difference of their heights be greater than the length of any common poles, then one or more intermediate stations must be chosen; and by repeating the fame practice between every two successive stations, we shall find the level of the extremes.

When the points g, b, are once found upon two poles, not far aunder, it will be convenient, by moving the cross-hairs, to rectify the line of sight, so as to be nearly coincident with the line q b, or with a line parallel to it, for then in future levellings, at greater distances, the marks b, e, will be less subject to fall above or below the poles.

This reciprocal way of levelling seems to be the most exact of any, especially if it be performed by two instruments made to agree together before-hand; which may be done by placing them together, and by altering the cross-hairs in either of them, till the same mark upon a remote object is covered by both the cross-hairs, while both the bubbles rest at their marks upon the tubes. Then may two observers find the marks upon the opposite poles at the same time, and, consequently, the refractions of the rays in the air, whatever be their quantities, will be equal as near as possible; and then the result of the practice will be as accurate as if there had been no refractions at all. For let the curve b i a, f b, g, b, represent the course of the visual ray from b to a; and let the lines a, b, touch it at a and b. Then, because the points a, b, are very nearly upon a level, the density and constitution of the air and vapours at the same instant will be nearly the same in each place; and by consequence the curve a i b and its tangents at a and b, will be equally inclined to the chord a b. For the same reasons the curve e m d will be similar and equal to the curve a i b, being situated so very near to it. Therefore, the angle e d n, under the chord e d and tangent d m, will be equal to the angle a b i, or b a k; and, consequently, since the angles q d n, p a k, are made equal in the two observations, by taking away the equal angles e d m, b a k, caused by the equal refractions, the remaining angles q d e, p a b, will be equal to each other, as if there were no refractions at all.

If the reciprocal observations be made about the middle of the same day, when the air is the purest, there will scarcely be an occasion for two instruments; but if they be made near the morning or evening, even on the same day, an equality of refractions cannot be depended upon, unless they
are made at the fame infant. The members of the Royal Academy of Sciences at Paris tell us, in their Account of the Measure of the Earth, they often found that an object, which at break of day appeared in the level, and sometimes a little above it, did afterwards, when the sun was up, appear below it. And, on the contrary, after the setting of the sun, objects far distant appeared to be raised to feebly, that in lefs than half an hour their apparent height was augmented more than three minutes. As to the cause of these appearances, they add, that the coolness of the night conduces the vapours, which descend to a lower place, leaving the air in the higher flattons more pure than in the day time. And on the contrary, when the heat of the sun has made a part of the vapours to mount to more elevated flattons, there must be lefs difference of the mediums, and consequently a lefs refraction.

Setting aside the curvity of a ray, which Mr. Picard tells us is greatly sensible about noon, when the distance of the object does not exceed 1000 toifes, the line of sight through the telescope may be set perpendicular to a plumb-line, or parallel to the horizon, in this manner. Having found two points, g, h, fig., upon a level as before, let gi be perpendicular to ge, and cut cb in i, and having computed the line bi (as follows), and made a mark at i, place the level at g, and alter the place of the crofs-hairs in the focus, till they appear to cover the point i, when the air-bubble is at its marks, and the bisects is done. Now the line bi is equal to the square of gbi applied to 2 ge, and, consequently, may be found by measuring the distance gb, and dividing its square by the diameter of the earth, which may be supposed equal to 2 ge, though it is not exactly so, the earth being not exactly spherical. For bisecting gb in, draw ec cutting gi in i; and since the triangles kgb, kge are similar, we have k: k gi: k eg: k ei, and by doubling them all, we have k: gi: ge: i. Mr. Picard computes that, when the distance gb is 300 toifes, or 1800 Paris feet, the line bi is one inch: and hence any other hi may be found for any other known distance; it being as the square of the distance gb.

Hence, when the instrument is thus rectified, the point b upon the level with g, may be found by one observation; that is, by marking the point i covered by the crofs-hairs, and by computing hi by the rule above. As the intervals between the flattons must be small in this method, because of refractions, as was said above, the readiest way is to make them all equal; which may be known exact enough for this purpose, by observing whether the pole be removed to such a distance, that its image (or the image of any given part of it) in the focus of the telescope shall be always of the same length, being measured by the distance between two parallel hairs in the focus; and then the fame allowance must always be made for the depth of the point b below i.

Lastly, by means of these parallel hairs, it is easy to find when the telescope is placed in the middle between two flattons; and then the points upon a level at each pole are presently found, by directing the telescope first to one pole and then to the other, and by marking the points covered by the crofs-hairs. And these points will be upon a level, notwithstanding any refractions of the visual rays, because the refraction of each ray will be equal. Smith's Optics, book iii. chap. 14.

Dr. Halley suggests a new method of levelling, which has been put in practice by some of the French academy: this is performed wholly by means of the barometer, in which the mercury is found to be suspended to fo much the lefs height as the place is farther remote from the centre of the earth. Hence it follows, that the different heights of the mercury, in two places, give the difference of level.

Mr. Derham, from some observations he made at the top and bottom of the Monument, found that the mercury fell one-tenth of an inch at every 82 feet of perpendicular ascent, when the mercury was at 30 inches. Dr. Halley allows of one-tenth of an inch for every 30 yards; which, considering how accurately the barometers are now made, an inch, in some of them, being divided into an hundred, or more parts, all very sensible, he thinks this method sufficiently exact to take the levels for the conveyance of water, and less liable to errors than the common levels.

The same author found a difference of three inches eight-tenths, between the height of the mercury at the top and bottom of Snowdon-hill, in Wales.

Mr. Ferguson has calculated the following table, for shewing how much the mercury would sink in a barometer at given heights above the earth's plane surface; and consequently, how the perpendicular height of any hill may be found thereby.
The following method may serve: set a pole upright in a spring, pond, river, or other place, whence water is to be brought, and mark how many feet and inches are above water. Then set up another pole, of equal length with the other, in the place to which the water is to come. Place the centre of a quadrant on the top of this last pole, the plummet hanging freely; by this through the sights the top of the pole that is in the water, and if the thread cuts any degree of the quadrant, the water may be conveyed by a pipe laid in the earth. If you cannot see from one extreme to the other, the operation may be repeated in the manner already directed.

**Leveling Staves.** are instruments used in levelling; serving to carry the marks to be observed, and at the same time to measure the heights of those marks from the ground. They usually consist of each of two long square wooden rulers, made to slide over one another, and divided into feet, inches, &c.

The levelling staff is represented in Plate VII. Surveying, fig. 10. It is composed of two pieces which slide on each other, as $aa$ and $bb$: they are each of about five feet in length, so as to form, when fully extended, a rod of ten feet. They have a graduated line of feet into hundredths of feet. The index, $c$, slides firmly on them; and is moved up or down (by signal) by the attendant who carries the staff, till the observer finds it coincide with the interfacing wires of his telescope. Its height on the staff, of course, marks the difference of the level; and it has two horizontal and parallel black strips, which, at considerable distances, are of use to direct the eye more readily to the fiducial edge at $a$.

With regard to the manner of directing its application in the business of draining, it has been observed, that after it has been properly adjusted, and the staff about ten feet in length, with the moveable vane or sight, has been affixed to it, the instrument should be set up in a situation between the object from whence the level is to be taken, and that to which it is to be directed, provided the distance from the instrument to each of them is not too great. The situation of it should also be no higher than the length of the staff will answer, and so as it may be seen from it both ways; the man with the staff should be directed to hold it at the main spring, or place from whence you mean to carry the drain; and after directing the telescope to the staff, and adjusting it to a level, make a sign to him to move the sight up or down, till it be exactly opposite the cross-hair in the telescope. This done, without shifting the instrument from its first position, and cautioning the man to fix the sight to the staff at the point directed, he may proceed forty or fifty yards farther; and after having again adjusted the level, make a sign to him to move to a higher or lower ground, till the sight on the staff coincide exactly with the cross-hair or wire on the telescope. He may then leave a peg at the place where he held the staff, and proceed in like manner to other stations, till the whole line is finished; leaving pegs, or marking pits, at the places where the staff is held during the operation.

But if the length of the line to be levelled requires the instrument to be shifted from its first position, the level must again be taken from the last station where the staff was held, and the sight on it fixed in the proper place, as before directed; proceeding in the same manner at every forty or fifty yards in length, till the whole is accomplished. After the line is thus levelled, and ascertained by marks left at every station where the staff was fixed, it may again be examined, and other pegs put in between the first, the better to direct the workmen in cutting the drain; giving the line such

</table>

By this table, and a common barometer tube, the perpendicular height of any hill may be found in the following manner.

The lower end of the tube being immersed in quicksilver in the common way, and the tube fixed to a board, let a scale, eighteen inches in length, be divided into inches, and each inch into a hundred equal parts, by diagonal lines, the divisions to be numbered downward from the top. This scale must be made to slide in a groove on the board, and have a cross index to slide upon it to any division.

Then, at the bottom or foot of the hill, place the scale so as the beginning of the divisions at its top may be just even with the top or surface of the mercury in the tube. This done, carry the machine up to the top of the hill; then set the index to the surface of the mercury, and it will show how much the mercury has sunk in the tube, at the top of the hill, from the point where it stood when at the bottom; and the number of feet expressed in the table, against the like sinking of the mercury, will be the perpendicular height of the hill.

Thus, supposing the mercury had sunk eight inches and three hundredths parts of an inch, the height of the hill must be 8400 feet, or a mile, and something more than a quarter. Proportionable allowance is easily made for intermediate heights in the table, which are only to whole hundredths of feet.

As Mr. Derham found the difference of height of the mercury at the bottom and top of Snowdon-hill, in Wales, to be three inches eight-tenths (the same as three inches eighty hundredths) it shews, that the height of that hill is 3700 feet, or almost three quarters of a mile.

N. B. 660 feet make an eighth part of a mile, 1320 feet a quarter of a mile, 2640 feet half a mile, 3960 feet three quarters of a mile, and 5280 feet make a whole mile. See Barometer and Atmosphere.

For the common occasion of levelling to be performed, without much apparatus of instruments, time, or trouble, such
such turnings, and even small deviations from the course of the level, as may shorten or straighten it, and humour the situation of the ground. And for the fake of accuracy, where the work requires it, especially if the water is to be conveyed to any considerable distance, or wanted to supply a hollow, or for the purpose of irrigation, the levels may be proved by reverting the former line of direction. The spirit level is also necessary for ascertaining how such fall can be obtained from the drain to the natural outlet where the water can be discharged; the shorter that distance the better, provided fall enough can be gotten. It is often necessary to level a much longer distance than the length of the drain may require to be cut, in order to come at the true level.

Leveelling of Land, in Agriculture, the method of filling up the holes, hollows, or other depressions and inequalities that are met with in lands, whether they are in the flat of sward, or in that of village. It should always be performed in such a manner, as the parts thus filled up may at first be somewhat higher than the common surface round them, in order to allow for the settling, which necessarily takes place; and should be done with such materials as can be most conveniently procured, and which are proper for the purpose, being filled in an even and regular manner, and well trodden down at the time. The ridges of such lands as have been long under the plough also sometimes require to be levelled down, the proper methods of doing which, under different circumstances, will be taken notice of under that head. Care is, however, constantly to be taken in the execution of this sort of business. See Ridge.

Leveelling Poles, long wooden rulers, divided into feet and inches, made to slide over each other, serving to carry the marks to be observed in levelling, as well as to measure the heights from the surface of the ground. They are likewise termed levels occasionally. See Leveling Staves, supra.

Leven, in Natural History, a term used by Boccone for the milky juice contained in the globules placed at the tops of the flaks of red coral. These round buttons are the only part of the coral which are soft while under water, and from these the milky juice is easily expressed by a gentle squeezing between the fingers. The globules are each made up of five or six little cells, not communicating with one another, and each containing a portion of the whole quantity of this white and thick juice. When the juice is newly taken up from the flake this juice is of a sharp, acrimonious, and astrangent taste; but when it has been some time exposed to the air, it loses the acrimony, and the astrangency of the taste only remains. This change in the taste is made in fix or eight hours, in hot weather, and the juice, in the same time, loses its colour and confidence, growing hard and brown. Philos. Trans. N. 100.

Leuenforde, in Geography, a town of Welfphalia, in the principality of Calenfien, on the Weser; 25 miles W.N.W. of Goettingen.

Eff. Ch. Calyx superior, two-lobed, in five deep segments. Corolla tubular; limb irregular, in five deep segments; the fifth (or lip) unlike the rest, vauleted, longer than the column, articulated with the tube, and movable. Column erect, attached below, like the lip, to the side of the tube. Lobes of the anthers one above the other, diverged. Stigmas two, capillary. Capsule of one cell.

Leven, Leva, or Levenes, a town of Hungary, near the river Gran, where the Turks were defeated, after a desperate engagement, in the year 1664, with the loss of 12,000 men killed, and 1500 taken prisoners, with their artillery, &c.; 24 miles N.N.E. of Gran.

Levanian, a lake of Prussia; 56 miles S.E. of Konigberg.

Leventi. See Lawend.

Lever, Sir Ashton, in Biography, was the son of Sir D'Arcy Lever of Alkington, near Manchester. He finished his education at Corpus Christi college, Oxford; and on leaving the university he went to reside with his mother, and afterwards settled at his family-seat, which he rendered famous by the belt aviary in the kingdom. He next extended his views to all branches of natural history, and became at length possessed of one of the finest museums in the world, sparing no expense in procuring specimens from the most distant regions. This museum was disposed of by lottery in 1785, but to the great loss of the proprietor. It was, for some years after this, exhibited to the public at a small charge, but is now dispersed, the articles having been sold separately by auction. Sir Ashton died in 1785. Europ. Mag.

Lever, or Leaver, in Mechanics, an inextensible straight bar, supported, in a single point, on a fulcrum, or prop, and used for the raising of weights.

The word is formed of the French lever, which signifies the same; formed of the verb lever, or Latin levare, to raise.

The lever is the first of those called mechanical powers, or simple machines, as being, of all such, the most simple; and is chiefly applied for raising weights to small heights. In a lever there are three things considered: the weight to be raised, or fulminated, as O; Plate XXX. Mechanis, fig. 4.; the power by which it is to be raised, or fulminated, as B; and the fulcrum, or prop, D, on which the lever is fulminated, or rather on which it moves round, the fulcrum remaining fixed.

Levers are of three kinds: sometimes the fulcrum, or centre of motion, is placed between the weight and the power, as in fig. 4. This we call a lever of the first kind, or rectus heterodromus; to which may be reduced leiffars, pinblers, snuffers, &c. Sometimes the weight is between the fulcrum and the power, which is called a lever of the second kind, as in fig. 5. Of this kind are the oars and rudder of a boat, the masts of ships, cutting knives fixed at one end, and doors whose hinges are as the fixed point. And sometimes the power acts between the weight and the fulcrum, which is the lever of the third kind. Such is a ladder lifted by the middle to rear it up against a wall; these two are called recti bonadromi.

In this last, the power must exceed the weight in proportion as its distance from the centre of motion is less than the distance of the centre from the weight. And as the first two kinds of lever serve for producing a slow motion by a swift one, so the last serves for producing a swift motion of the
the weight by a slow motion of the power. It is by this kind of levers that the muscular motions of animals are performed, the muscles being exerted much nearer to the centre of motion than the point where the centre of gravity of the weight to be raised is applied; so that the power of the muscle is many times greater than the weight which it is able to sustain. Though this may appear at first a disadvantage to animals, because it makes their strengths less: it is, however, the effect of excellent contrivance; for if the power was, in this case, applied at a greater distance than the weight, the figure of animals would be not only awkward and ugly, but altogether unfit for motion; as Borelli has shewn in his treatise De Motu Animalium. The power of the lever is founded on the following theorem; viz.: That the space, or are, described by each point of a lever, and consequently the velocity of each point of a lever, is as its distance from the fulcrum, or prop.

From hence it follows, that the action of a power, and the resistence of the weight, increase in proportion to their distance from the fulcrum.

And hence also it follows, that a power will be able to sustain a weight, if the distance of the point in the lever, to which it is applied, be to the distance of the weight, as the weight to the intensity of the power; which, if it be ever so little increas’d, must raise the weight. See this doctrine demonstrated under the word Mechanic Powers; and farther illustrated under the word Balance; between which and the lever there is a great analogy: a lever of the first kind being a sort of lever by weight to raise weights.

The power and action of the lever will be fully illustrated by the following propositions:

1. If the power applied to a lever of any kind sustain a weight, the power is to the weight in a reciprocal ratio of their distances from the fulcrum.

2. The weight of a lever of the first or second kind, A B, fig. 4, is the distance of the centre of gravity from the fulcrum C V, and the distances of the weight, and the power A C and C B, being all given, to find the power that will sustain it. Suppose the lever void of gravity, but in lieu thereof a weight hung at V: if then A C be made to C V, as the gravity of the lever to a fourth number, we shall have the weight which the lever is able to sustain; and this subtracted from the given weight, the remainder will be the weight to be sustained by the power. Let C B then be to C A, as the remaining weight to a fourth weight, and we shall have the power to be applied in B, in order to sustain the given weight with the given lever.

3. The gravity of a lever of the first or second kind, A B, the distance of the centre of gravity from the fulcrum C V, the distances of the power, and the weight B C and C A, being all given, to find the weight to be sustained. Find the part of the weight sustained by the lever alone, as in the former problem: in the same manner find the other part of the weight, which the power applied in B is able to sustain; add the two numbers together, and the sum is the weight required.

4. The gravity, and centre of gravity P, of a lever of the second kind C B, fig. 5, with the weight G; its distance from the fulcrum C A, and from the power C B, being given, to find the power capable of sustaining the weight. Suppose the lever void of gravity, but in lieu thereof a weight equal thereto hung in F, the power required to sustain the lever alone; then find the power requisite to sustain the given weight G; add the powers together, and the sum will be the power required.

5. If a power applied to a lever of any kind lift a weight, the space of the first is to that of the last, as is this last to a power able to sustain the same weight; whence it follows, that the gain of force is always attended with the loss of time, and vice versa.

When the two arms of a lever are not in a right line, but contain any invariable angle at C, fig. 6, the lever is called a bended lever; and is evidently of the first kind, and the law of the equilibrium is the same; i.e. if the power P be applied at B to the arm C B, and the weight W acts by means of a pulley M, in the direction A M, perpendicular to the arm A, the power and weight will sustain each other, if P be to W, as C A to C B, or $P \times C B = W \times C A$. If several powers act upon the arm C A, find their centre of gravity A, on the arm C A, and supposing all the powers to be united there; and if the power P be to their sum as C A to C B, it will sustain them. The sum of the powers being given, it is manifest that the farther their centre of gravity A is removed from the centre of motion C, the greater resistence they will oppose against the power P, and it will require the greater force in the power to overcome them. Hence Galileo justly concludes, that the bones of animals are the stronger for their being hollow, their weight being given; or if the arm C B F represents their length, the circle C H D a section perpendicular to the length P, any power applied along their length, tending to break them; then the strength or force of all their longitudinal fibres, by which the adhesion of the parts is preserved, may be conceived to be united in A, the centre of the circle C H D, which is the common centre of gravity of those forces, whether the fection be a circle or annulus. But it is plain that when the area of the section, or the number of such fibres is given, the distance C A is greater when the section is an annulus than when it is a circle without any cavity; consequently the power with which the parts adhere, and which resists against P, that endeavours to separate them, is greater in the same proportion. For the same reason, the flanks of corn, the feathers of fowls, and hollow spears, are less liable to accidents that tend to break them, than if they were of the same weight and length, but solid, without any cavity. In this inﬁance, says Mr. Maclaurin, (View of Sir. I. Newton’s Phil. Dirc. book ii. chap. 3. § 15.) art only imitates the wisdom of nature. See Mechanical Powers.

LEVER, or VEΛΙΟΝ, in Midwifery, an instrument used to facilitate the birth of the head of the child, when it remains long fixed in the brim of the pelvis of the mother. It is usually called the lever of Roonhuyzen, the name of a surgeon of Amsterdam, who has the credit of having invented, or first made use of it. Roonhuyzen is said to have been instructed by Dr. Hugh Chamberlen in the method of using the foreeps, (see that article,) for which he paid him a considerable sum of money: but finding, in many cases, great difficulty in introducing the second blade of the forceps, he confined himself to the use of a single blade; and procuring an instrument to be made upon that principle, he called it his lever. Ruylech was also said to participate with him in the use of this new contrivance. It was for a long time applied with great caution, and only shown to fuch of their pupils as paid them a fpecifie sum for the purpose. At length De Viecher and Van de Poll, two physicians of Amsterdam, purchased the secret of a descendant of Roonhuyzen, and published a description of the instrument, and of the manner of using it, in the Dutch language. This account was, many years after, translated into French by M. Previle, and affixed to his translation of Smellie’s Treatise of Midwifery, to which he added an engraving of the instrument.

The lever is a flat piece of iron, twelve inches in length,
LEV

one inch in breadth, and a quarter of an inch in thickness. It is straight in the middle for four inches, and moderately curved at each end. (See Plate Surgery.) In using it, one or two fingers of the right hand (the woman lying on her left side, as in a natural labour) must be introduced under the pubes, and so far, if practicable, as to reach an ear of the child, when the lever is to be slowly and gradually inrinated between the fingers and the head of the child. The fingers are now to be withdrawn, and the handle of the lever to be raised towards the belly of the woman, and gently moved about, until the head of the child is lodged in its curve. The more completely the curve touches and embraces the head of the child, the more speedily and easily the delivery will be effected. During every pain, the handle of the lever must be raised with the right hand, and its middle pressed down with the left hand. This will prevent the soft parts of the woman covering the os pubis from being injured. When by this means the head of the child has been made to descend into the vagina, the left hand must be removed from the middle of the instrument, and applied over the anus and the perineum, to guard those parts, (which will be found to be much distended,) and to prevent their being lacerated; for which purpose, also, the whole of the operation (which will usually be completed without between ten and twenty minutes) must be performed slowly and cautiously, imitating as much as possible a natural labour.

For further information on this subject, see Dr. Bland's Account of the Invention and Use of the Lever, published in the second volume of Medical Communications, 1790.

LEVERANO, in Geography, a town of Naples, in the province of Oranto; 7 miles N. of Nardo.

LEVETER, amongst Sportmen, a young hare, in the first year of its age.

LEVETT, in Geography, a township of America, in Hampshire county, Massachusetts, near Connecticut river; 14 miles W. from Boston; incorporated in 1774, and containing 711 inhabitants. A copper-mine has been lately discovered in this township.

LEVIDGE, Richard, in Biography, was a finger of Purcell's fongs, in the time of Charles II. and in that of William and Mary. During the reign of queen Anne, he performed in 1706 the part of Sir Truily, in Addison's Rotamont; and in the flirt attempts on opera on the Italian model, he sang his part in English, in Camilla and Thomyris, while Nicolini, Valenti, and the Margarita, performed their parts in Italian.

He had a deep and powerful bass voice; was a useful performer on the English stage on many occasions, particularly at Covent Garden, where he attached himself to Rich, and his pantomime entertainments, to the end of his life. He was not, however, without genius for poetry and composition, as far as a ballad went. We remember his singing one written and set by himself, "Gods of every Occupation," and several of Purcell's bass songs occasionally, which, fifty years ago, seemed antediluvian; but as he generally was the representative of Pluto, Neptune, or some ancient divinity, it corresponded perfectly with his figure and character. As he was not only a celebrated singer of convivial songs, but the writer of many that were in great favour with fingers and hands of a certain class, who more piously performed the rites of Comus and Bacchus than those of Minerva and Apollo, he had always a crowded house at his benefit; nor did he leave this fabulinary world, or the stage, till 1755, at 88 years of age.

LEVET, in Geography, a town of France, in the department of the Cher, and chief place of a canton, in the district of Bourges; 6 miles S. of Bourges. The place contains 645, and the canton 5293 inhabitants, on a territory of 2324 kilometres, in 16 communes.

LEVI, Ben-Gershon, in Biography, a learned rabbi, who flourished in the fourteenth century, was born in Provence about the year 1290. His celebrity is founded chiefly on his philosophical and theological writings. He was a disciple of Aristote, and philosophizes in the spirit of his master, when discussing subjects of sacred literature. He died in 1370, when he was 80 years of age. He was author of "Commentaries" on all the books of the Old Testament, of which some are inserted in the great bibles of Venice and Bafil; and others were separately printed at Pefaro, Venice, and Paris. He was author of a philosophical work, entitled "Millemet Hafehem," or "The Battles of the Lord," divided into treatises on the immortality of the soul, the knowledge of future events, prophecy, the interpretation of dreams, the omniscience of God, &c.; and of various other treatises, which were formerly preferred in MS. in the Vatican library, and in that belonging to the congregation of the fathers of the oratory at Paris.

Levi, ille du Fort, in Geography, an island in the river St. Lawrence, Upper Canada, in front of the township of Edwardsburg. On this island are the ruins of a French fortification.

LEVIERON, a town of Peru, in the province of Irak; 36 miles W.S.W. of Iphalan.

LEVIER, a town of France, in the department of the Doubs, and chief place of a canton, in the district of Pontarlier; 10 miles W. of Pontarlier. The place contains 1067, and the canton 7727 inhabitants, on a territory of 310 kilometres, in 15 communes.

LEVIGATION, the reduction of hard and ponderous bodies, as coral, tufiy, precious stones, &c. into a fine pulvull powder, by grinding them with water upon porphyry, or the like, as painters do their colours.

Levigation is much used in pharmacy and chemistry; but unless the grinding instruments be extremely hard, they will wear away, so as sometimes to double the weight of the medicine thus managed.

LEVIRATE, in the Jewish Customs, a term used by authors who have written on the law and customs of the Jews, to denote particularly that law of Moses, which obliges one brother to marry the widow of another, who died without children, to raise up seed to him.

The word is derived from levir, which signifies, in Latin, the husband's brother, or the brother-in-law; and the word levirate has been hence formed, to express the law whereof we have been speaking.

This law, which is an exception to that which condemns marriages between brothers and sisters, is one which has been in use among the Hebrews and Canaanites before the time of Moses; since Judah gave his first-born son, and Onan his second son, successively to Tamar, and obliges him to give her like-wise to Selah his third son. Calm. Dict. Bibl.

LEVISANUS, in Botany, a name given by Petiver, who wrote it Leviasanum, in honour of the Rev. Dr. Lewis, who sent him several plants as well as shells from Madagascar. The Cape shrub to which this appellation was given, having been referred by Linneas at one time to Brinia, at another to Protas, is now Leviasanum Leviasanum, Brown Tr. of Linn. Soc. v. 10. 55. (See LUCADENDRON) Schreber in his Gen. Pl. 149, established another Leviasanum out of Brinia;
LEV.

**Bruria;** but this is now Stuavia of Wiludenow, Sp. Pl. v. 1. 1144, a name which we presume will remain. LEVITA, in Geography, an island in the Grecian Archipelago, about eight miles in circumference. N. lat. 37°. E. long. 26° 14'.

LEVITE, an inferior kind of minister in the Jewish tabernacle and temple, who had the care and management of the sacred utensils.

The word comes from the Greek **ραβαν,** the root of which is the name Levi; which was given to that patriarch by his mother Leah, from the Hebrew **יְהֹוָּה,** **לָוָה,** *to be tied,* or **united;** Leah hoping, by the birth of this son, to be more closely linked to her husband Jacob; and, therefore, in a large sense, the Levites were the potteries of this patriarch, and constituted one of the twelve tribes of Israel. In a more restrained and peculiar sense, they were a lower order of ecclesiastical persons, inferior to the priests, and their attendants in the sacred service. The sons of Levi were appointed to this office, in consequence of the extraordinary zeal they discovered against idolatry, in the cave of the golden calf. Exod. xxxii. 26. 28.

When God miraculously destroyed all the first born of the Egyptians (Exod. xii. 29.), he spared the first born of the Israelites; and in order to preserve the remembrance of the miracle, and of that great deliverance from their bondage in Egypt, which that miracle occasioned, he was pleased to appoint that for the future all the first-born males "should be set apart unto himself." (Exod. xiii. 12. 16. Num. viii. 17.) But afterwards, on the occasion above mentioned, the whole tribe of Levi had the honour affixed to them, instead of the first-born of Israel. And that it appear there was a just sublimation of the Levites for the first-born, number for number, he ordered an embleme to be made of both; and when, on calling up the pools, the first-born were found to exceed the Levites by 273, the surplus was redeemed at the price of five shekels a head, which was paid to the priests for the use of the sanctuary. (Numb. iii. 14, ad fin.) We may here observe, as a circumstance worthy of notice, that the potteries of Moses were no more than common Levites, while the descendants of his brother Aaron were advanced, by the appointment of his law, to the dignity of the priesthood. (1 Chron. xxiii. 13. 14.) This is a plain evidence that Moses was not influenced by any worldly or ambitious views, or rather that he was not the contriver and author of the law which he gave to Israel, but received it from God: for if he had framed it, it is natural to suppose that he would have made some better provision than he did for his sons, and for the grandeur of his house, and not have advanced his brother's above his own.

The Levites were originally divided into three classes, or families, from the three sons of Levi, Kohath, Gershon, and Merari; but afterwards by David into twenty-four courses. 1 Chron. xxiii. 6. ch. xxviii. 11—13.

The Levites, in the Jewish church, were an order inferior to the priests; and answered, in some measure, to deacons, in the Christian church. On their first institution, a great part of the service that was assigned them was peculiar to the state of the Israelites at that time; and it was fervile and laborious. But when they were settled in the land of Canaan, and the tabernacle was no longer carried about as before, the service of the Levites was, of course, changed, and became much more easy. On which account, in the time of David, they were thought fit to enter on their office at the age of 20 years; whereas, by the original appointment of Moses, they were not admitted till they were 25 or 30 years of age, and were discharged at 50. (Numb. iv. 3. 13. 43. ch. viii. 24. 25.) It is an opinion among the Jews, that the Levites passed through four different degrees. From one month old to their twentieth year they were instructed in the law of God; from twenty to twenty-five, in the functions of their ministry; from that period to thirty, they served a kind of apprenticeship, beginning to exercise themselves in some of the lower branches of the sacred service; and lastly, when they attained their thirtieth year, they were fully inducted in their office. A similar gradation, probably borrowed from that of the Jewish Levites, has been observed among the veiled virgins; and some have supposed that this gradation is referred to by the apostle, when he tells Timothy, that they who perform the office of a deacon well purchase to themselves a good degree, *καλὸν* βήματα. 1 Tim. iii. 13.

We have already observed, that the Levites were originally distributed into three families; and in David's time, they were distinguished into three classes, to each of which a different service was assigned; and probably each was divided into twenty-four courses. The first class was appointed to assist the priests in the exercise of their ministry; the second class formed the temple choir; the third class had the charge of the several gates of the courts of the sanctuary assigned them by lot. (1 Chron. xxiii. 1. 13. 19. 2 Chron. xxxiv. 15. viii. 14.) The Levites exercised the office of magistrates, which office belonged to them, not as Levites, but as persons who generally addicted themselves more to the study of the law, and had more leisure to attend on the duties of the magistracy, than others who were employed in secular business. The magistrates of different ranks, both the "phureim," and "hoterim," were very generally, though not always, chosen out of the tribe of Levi. That the prophetic curfe, denounced by Jacob against Levi, (Gen. xlxi. 7.) was remarkably accomplished, (though in effect converted into a blessing,) not only in respect to the appointment of their habitation, but likewise of their offices and employments; more of them, than perhaps of all the tribes taken collectively, being officers and judges throughout the whole country; and probably, as the rabbies tell us, some of them were generally directors of their seminaries of learning. Of the consecration of the Levites, and of the ceremonies attending it, we have an account in Num. viii. 10. 11.

As to the residence and subsistence of the Levites, we may observe that they had no settled lands allotted them for their maintenance, as the other tribes had, but lived chiefly on the offerings made to God. (Deut. xxiii. 1. 2.) They were distributed through all the tribes, each of which gave some of its cities to the Levites, amounting in all to the number of thirty-five, with grounds in their neighbourhood for the subsistence of their flocks. (Num. xxxiv. 4. 5.) In the weeks of their attendance at the sanctuary, they were maintained by the dues arising from the sacrifices; besides these dues, the first fruits, which were brought to the temple, and the money paid for the redemption of the first-born, contributed to their subsistence. But, when they were out of waiting, their maintenance partly arose from the glebes belonging to their cities, and chiefly from the tithes of the produce of the whole country, which the law allotted to the tribe of Levi. (Num. xviii. 21.) A tenth of which they paid to the priests. See Tithe.

According to the numeration made by Solomon, from the age of twenty there were thirty-eight thousand Levites capable of serving; twenty-four thousand of these he appointed for the daily ministry under the priests; six thousand to be inferior judges in the cities, and to decide matters re-
LEVI7ANO, in Geography, a town of Italy, in the department of the Pararo; six miles S.S.E. of Modena.

LEUK, a small town of Switzerland, built upon an eminence about a mile from the Rhine, and the principal place of one of the dixains of the Vallais; containing two churches and a large palace of the bishops of Sion. At the distance of six miles N. are celebrated baths, said to be beneficial in rheumatisms, diseases of the skin, &c. and to resemble those of Bath. Here are several springs of different warmth and of different qualities. According to accurate experiments, the mercury in Fahrenheit's thermometer, when plunged into the principal source, falls at 115, and at 129 in the spring which flows near the bridge over the Dola. Leuk is distant 20 miles E. from St. O.

LEVKOPOL, a town of Rouflia, in the province of Tauris; 80 miles S. of Perekop. N. lat. 45° 6'. E. long. 34° 24'.

LEUNClAVIUS, JOHN, in Biography, an eminent man of letters in the seventeenth century, son of a gentleman of Welphilla, was brought up to the profession of the law; with which he was intimated acquainted, as well as with literature in general. He was a great traveller, and resided a considerable time in Turkey. He died at Vienna in 1693, about the 65th year of his age. From his knowledge of the Turkish language he was enabled to collect some valuable materials for the history of that nation, which he published under the title of "Historia Mathematica Tescarum," and his "Annales Turcii Sumptum et Pandra’tis Hist. Turcice." His intimate knowledge of the Greek language was displayed in several Latin translations of Greek authors, viz. Xenophon, Zizinus, the annals of Conitantine Manasses, and of Michael Glycas; the Greek abridgment of the sixty books of Roman law; various works of St. Gregory of Nazianzen, &c. Bayle.

LEVONOV, is Geography, a town of Ruflia, in the government of Irkutski, on the Lena; 52 miles S.S.W. of Kirenfs.

LEUPOILD, JAMES, in Biography, a very celebrated mechanician, and noted for his construction of mathematical instruments, and other machines for the elucidation of facts in philosophy, was commissary of mines to the king of Poland, and a member of the Royal Society of Berlin, and other scientific bodies. He died at Leipsic in 1727, after having acquired celebrity by the publication of a work, which is still highly esteemed, entitled "Theatrum Machinarum," in three vols. folio.

LEVRET, ANDREW, an eminent French surgeon and accoucheur, was admitted a member of the Royal Academy of Surgery at Paris in February, 1742. He obtained a high and extensive reputation in his department of the art, by the improvements which he made in some of the instruments necessary to be employed in certain difficult cases, (especially the forceps,) and by the prodigious number of pupils whom he instructed. He was employed and honoured with official appointments by all the female branches of the royal family. He published several works, which underwent various editions and translations. "Observations sur les cautes et les accidens de plusieurs accouchements laborieux," Paris, 1747.

LEVROUX, in Geography, a town of France, in the department of the Indre, and chief place of a canton, in the district of Chateauroux ; 15 miles N. of Chateauroux. The place contains 2,500, and the 8,000 inhabitants, on a territory of 522.5 square kilometres, in 15 communes. N. lat. 46° 59'. E. long. 1° 41'.

LEUSDEN, JOHN, in Biography, an eminent philologist, was born at Utrecht in 1624. He laid the foundation of a learned education in his native city, and then went to Amsterdam to improve himself in the Hebrew language, and in the knowledge of the Jewish ritual and conversation with the learned rabbis. He obtained, in the year 1649, the professorship of Hebrew and Jewish antiquities at Utrecht, which he held, with great reputation, until his death in 1669. He was a capital critic, and was highly celebrated as a teacher. He gave correct editions of the works of Buech and Lightfoot, and of Poole's Synopsis. His own writings are numerous and very valuable, of which the principal are "Clavis Hebraicae et Philologiae Vet. Test." 4to. "Clavis Graecae Novi Test. cum Annot." "Compendium Graecum Novi Test." "Philologica Notes upon Jonas, Joel, and Hosea," two vols. 8vo. Moreci.

LEUTENBERG, in Geography, a town of Germany, in the county of Schachtz-Rudolstadt, on the Sorbitz; near which are mines of silver and copper; eight miles S.E. of Salfeld. N. lat. 50° 28'. E. long. 11° 35'.

LEUTHEN, a town of Silesia, in the principality of Breslau; 16 miles W. of Breslau.

LEUTKIRCH, a town of Bavaria, near the Esbach, on a heath to which it gives name. This town was free and imperial till the year 1802, when it was conveyed, among other indemnities, to the Elector of Bavaria. It has a Lutheran and a Roman Catholic church, together with a nunery of Franciscans. The magistrates are mostly Lutheran; 28 miles S. of Ulm. N. lat. 47° 53'. E. long. 10'.

LEUTMISCHL, or LITOMYSL, a town of Bohemia, in the circle of Chrudin; 22 miles E. of Chrudin. N. lat. 49° 47'. E. long. 16° 5'.

LEUTO, Rick in Mecklenburg. See LUTT, and ThIBORO.

LEUTSCH, in Geography, a town of the duchy of Carniola; eight miles S.S.E. of Hydrin.—Allo, a town of Hungary, which has frequently suffered from fire; 14 miles W. of Steben.

LEUTZBURG, a town of Switzerland, in the canton of Berne; six miles S. of Brugg.

LEVY, LEVARE, in Law, signifies to gather or collect; as, to levy money, to levy troops, etc.

LEVY sometimes also denoes to rce, or set up; as, to levy a mill. Levy also signifies to raise or cast up; as, to levy a ditch. To levy a fine of lands, is to pass a fine.

LEVING Many without Council of Parliament. No subject of England can be constrained to pay any aids or taxes, even for the defence of the realm or the support of government, but such as are imposed by his own consent, or that of his representatives in parliament. See flats. 25 Edw. I. c. 5 & 5. 34 Edw. I. flat. 4. c. 1. 14 Edw. II. flat. 1. cap. 1. the petition of right, 3 Car. I. c. 1. flat. 1. W. & M. flat. 2. c. 2.

LEVING War against the King. See Treason.

LEUZE, in Geography, a town of France, in the department of the Jemappe, and chief place of a canton, in the district of Tournay, seated on a brook near the Dender; eight miles E. of Tournay. The place contains 3,528, and the canton 14,448 inhabitants, on a territory of 122.5 square kilometres, in 15 communes.

LEWALDE, a town of Prussia, in the province of Oberland; 12 miles N.N.W. of Soldau.

LEWARDEN, a city of Holland, and capital of Friesland, situated in a quarter called "Oosterou." From being a small town in 1190, when it was surrounded with a wall, it has become large, rich, and populous, fortified with ramparts, and defended by a large ditch, bastions, and other works; the streets are regular and spacious, and separated by canals which intersect each other, facilitate communication with the sea and with the internal parts of the province, and contribute to an extensive trade with Holland, Bremen, Hamburg, and other places. The town house, erected in 1715, is a handsome building. The magistracy consists of three burgo-masters and nine echevins; 28 miles W. of Groningen. N. lat. 53° 2'. E. long. 5° 43'.

LEWCKOCE, a town of Poland, in Podola; 44 miles N.W. of Kamieniec.

LEWDNESS is punishable by our law by fine, imprisonment, and, such corporal infamous punishment, as the court may think meet, according to the heinousness of the crime. (1 Hawk. 7.) And Mich. 15 Car. II. a person was indicted for open lewdness, in dwelling his naked body in a balcony, and other misdemeanors, and was fined two thousand marks, imprisoned for a week, and bound to his good behaviour for three years. (1 St. 16.) In times past, when any man granted a lease of his house, it was usual to insert an express covenant, that the tenant should not entertain any lewd women, etc. See ADULTERY, BASTARD, BAWDHOUSE, INCEST, etc.

LEWEGHAIN, in Geography, a town of Prussia, in the circle of Natzangen; eight miles E.S.E. of Konigberg.

LEWEN, a town of Bohemia in the circle of Leitmeritz; eight miles N.E. of Leitmeritz.

LEWES, a confederable borough and market town in the hundred of Barcombe, rape of Lewes, and county of Sussex, England, is situated on the eastern extremity of one of those bold and fertile eminences called the South downs, and joyfully celebrated in the topography of that county. Lewes, being ancolately a demesne of the crown, appears to have appertained to the South-Saxon kings, then to the Wejt-Saxon, and afterwards to the Saxon and Danish monarchs of all England; and, though each of those revolutions by which it changed its royal lord, removed the court full farther from this town, its natural advantages secured it a respectable and not inferior to that of the first boroughs in the kingdom. During the Danish ravages from the close of the eighth century to the beginning of the eleventh, Lewes was rendered, both by art and nature, the most eligible place of refuge for the inhabitants of the adjacent country, and a firm barrier against the invaders. In the reign of Athelstan, Lewes was a very confederable place; and it was then the chief town and mart of more than half the thire. And in that king's ordinance for prohibiting the coinage of money, except in towns of especial note, Lewes was allowed two mints, and Chichester but one; a proof of the early respectability of the former. On the death of Edward the Conqueror, this town, with the other appanages of the crown, devolved to Harold, and on his defeat was given by the Conqueror to his son-in-law William, lord of Warren, who made it his chief residence, and built here a grand mansion and fortifications; the gate and two towers of his castle still remain. In the time of Edward the Confessor here were 127 burgoges. Lewes con inued in the possession of the lords Warren for nearly three centuries, when the male line being extinct, it descended to Richard Fitz-Allen, earl of Arundel, son of Alice, sister of the late earl of War-
In his heirs the barony of Lewes has continued to the present time. A memorable battle was fought in the vicinity of this town in the year 1264, between Henry III. and the confederate barons under Simon de Montfort. A particular account of this is printed in Lees's History, &c. of Lewes, 8vo. 1795.

Lewes is a well built town, and one of the largest and most populous in the county. It had formerly twelve parish churches, which are now reduced to six, including St. Thomas at Cliffe, so called from its standing on the high chalky cliffs at the out-skirts of the town. The other churches are All-Saints, St. John's under the Cliff, St. Michael's, St. Peter's and St. Mary's Westout, now called St. Anns, and St. John's Southover. The diffusers, who have been respectable and numerous in this town, have also their places of worship.

Lewes is a borough by prescription, but not incorporated; the civil government is vested in two countables, who are annually chosen by the burgesses. Two members have been returned to parliament ever since the 26th year of Edw. I. The right of election is in the inhabitants paying fees and lot, in number about 310. In the year 1504 an act of parliament was obtained for holding the three or county-court alternately at Lewes and Chichester. From the town-book, since that time, a few items may be extracted, calculated to display the local and general customs of the ages in which they occurred. In 1543 the duke of Norfolk's officers were treated with "two couple of rabbits," price 6d. ; a bottle of sack, 6d. ; a quart of sack and a quart of red-wine, 6d. In 1544, the "year's wages" of John Payne, one of the burgesses for parliament in this borough, was 63 shillings. The two burgesses were paid 6l. 10s. in the year 1555. The following year was distinguished by the burning of four men, in this town, for "heresy." Here are a free grammar-school, a charity-school, and several private charities. On the banks of the river Ouse, which is navigable for barges, are several iron-works, where cannon of small sizes, and several other articles, are cast.

Lewes is 40 miles distant from Chichester, and 49 from London. Four fairs are held annually; and a weekly market on Saturdays. The population, in the year 1801, was flated in the parliamentary return to be 35,959, occupying 3,124 houses. The farmer aissises are alternately held here and at Horsham.

A priory of Cumiack monks, the first and chief house of that order in England, was founded at Lewes, in 1078, by William lord Warren and Gundreda his wife. Here was also a priory of Grey Friars, and two hospitals dedicated to St. James and St. Nicholas.

Lewes. See Louistown.

LEWESTEIN, a town of Prussia; 16 miles N.W. of Ratisburg.

LEWIN, a town of Silezia, in the principality of Glatz; 15 miles W. of Glatz. Lat. 50° 14'. Long. 16° 4'.

LEWING, in Metallurgy, the fritting of the ores of metals in water. This is done in fine sieves moved backward and forward under water; and is the method of separating the finer part of the ores which had been fusified among the larger lumps, under that part of it separated for use in the various walkings. The coarser matter, left in the sieve, is powdered again with the larger mailels, and all thus fifted together for the blowing-house.

LEWIS 1., in Biography, emperor and king of France, surnamed J. D'bonnaire, the son of Charlemagne, by a second wife, was born in 778, and while a child he was crowned king of Aquitaine, to which state he was sent to reside. Here he was carefully educated in the dead languages, and in the other branches of learning that were cultivated at that period. During his administration in Aquitaine, on account of the virtuousness of his manners, he obtained the surname already mentioned; and at his father's death in 814, he succeeded to the imperial throne, without opposition. At this period he had three sons, Lothaire, Pepin, and Lewis, among whom he divided his dominions; the first he raised to the dignity of emperor by associating him with himself; the second he created king of Aquitaine; and to the other he gave the title and power of king of Bavaria. A worse system could not have been adopted, which Lewis found to his cost, as each of his sons, feeling themselves independent of the father, violated every tie of filial and fraternal duty. Bernard, king of Italy, natural son of Pepin, the eldest son of Charlemagne, took up arms with the hope of deposing Lewis, but his army, in the critical moment, deserted him, and he was obliged to throw himself at the emperor's feet, to implore that lenency, which his misdeeds were ill calculated to inspire. The emperor referred him to the assembly of the states of Aix-la-Chapelle; by whom his conduct was investigated, and himself and associates were condemned to death. This sentence was commuted for that of depriving the guilty of their eyes; the extreme torture of the operation was the caufe of Bernard's death, which happened almost immediately after the cruel deed had been performed. The re-election of the sufferers of his nephew so afflicted the mind of Lewis, that he performed a public penance on account of it, a circumstance that rendered him contemptible in the eyes of his subjects. The fierce nations of the north, scarcely to be controlled by the genius of Charlemagne, disdained the weak arm of his successor, and it was with the utmost difficulty that their rude assaults were repelled, and themselves confined within their proper circle. The most disfavourable events of this period were the death of the emperors, and the subsequent marriage of Lewis with Judith, daughter of Guelf of Bavaria, whose splendid accomplishments concealed an ambitious mind, the source of equal calamities to her comfort and the empire. For a time Lewis was obliged to reign his power, but the jealousy of his three sons against each other caused a change in his favour, and he was again restored to power. The three brothers, in 823, joined in a new league against their father; they were supported by the pope, Gregory IV., and the emperor, defiered by his troops, surrendered himself a prisoner to his undutiful children. He was now solemnly deposed, the imperial dignity was conferred upon Lothaire, and Judith was sent into a nunnery. The misfortunes and difficulties of the great ever affect the minds of the multitude, and the compassion of his people soon began to operate in favour of the fallen sovereign. Pepin and Lewis took up arms against their elder brother, who was obliged to throw himself at the feet of his father, and ask his pardon. Lewis was again reconciled to the church, and replaced on the throne by the bishops. He now recalled his empress Judith, whose mind, unbroken by adversity, engaged in new plots against the government, with the hope of advancing her son Charles, to the prejudice of the other branches of the family. She had the address to cause him to be declared king of Neustria, and afterwards, on the death of Pepin, king of Aquitaine, in opposition to the claims of the sons of Pepin. This circumstance induced Lewis of Bavaria to assemble an army, with the intention of feizing for himself as much of the territory bordering on his dominions as he could occupy. He accordingly made himself master of the best part of Germany; the unwelcome news was received by the emperor at a moment when his mind was broken down with age, and with terror occasioned by a total eclipse of the sun; he withdrew from the seat of govern-
ment, to an island in the Rhine, where he refused almost all
fellowship, excepting the elements administered at the sacra-
ment, and died at the age of sixty-two, in the year 840.
He appointed Lothaire his successor in the empire, but his
last moments were embittered with the most lively resentment
against the king of Bavaria: he was reminded by the bishop
of Mentz that it was his duty to forgive; he replied, "I
pardon him, but tell him from me, that he must seek pardon
of God, for having brought my grey hairs with sorrow to the
game." The placid virtues and the urbanity of temper,
which distinguished the character of this emperor, very ill
compensated for the miseries which were engendered by his
feeble administration; and a prince, whose name has been
taken. His eldest son was added the epithet of gentle, lived without the regard, and
expired without the regret of his subjects.
Lewis II, emperor and king of Italy, the eldest son of
the emperor Lothaire I., was created by his father king of
Italy in 844, and was sent to Rome, where he was crowned
by pope Sergius II. In about two years he returned to
Italy, and was associated with his father in the empire.
An insurrection of the Saracens gave him employment; he
hastily went into Italy, and defeated them in several encoun-
ters. He afterwards called a council, to be held at
Toflino, for the reformation of ecclesiastical abuses. In
855, by the death of Lothaire, he succeeded to the title
of emperor, in addition to his kingdom of Italy. The
repeated incursions of the Saracens called forth his military
talents and ardour, and the actions of his own nobility
were a source of much uneasiness and great disorders.
He lived, in general, on good terms with the holy see, and
in 871, was crowned king of Lorraine by pope Adrian II.
He died in 875, greatly respected by his subjects, to whom
he administered justice with impartiality.
Lewis IIII., emperor, called also Lewis IV., was son of
the emperor Arnulf, whom he succeeded when he was only
seven years old, in the year 890. During the course of
his reign, Germany was deposed by the Hungarians, and torn
asunder by civil discord. He died in 912, and his death is
regarded as an era in the Germanic history, as he was the
last king of emperor of the race of Charlemagne.
Lewis IV. or V., emperor, son of Lewis, duke of Ba-
varia, and Matilda, daughter of Rudolph I., was born in
1284. By the death of his father, when he was only 12
years of age, his education devolved chiefly on his mother,
and he distinguished himself beyond all the princes of his
age. In 1314, he was chosen emperor at Frankfurt by a
part of the electors, while another part of them adhered to
Frederic, son of Albert, emperor and duke of Austria.
Lewis was crowned at Aix-la-Chapelle by the archbishop
of Mentz, while Frederic received a similar honour from
the elector of Cologne. A civil war ensued, and in 1316
an indecisive battle was fought between them, at Efslingen
on the Neckar. In Italy, the Ghibelline faction censured
the cause of Lewis, while the Guelfs supported that of
Frederic, and the flames of war spread over Lombardy, till
at length he gave his rival a signal defeat and took him
prisoner. From this period those contests commenced between
Lewis and the holy see, which disquieted all the latter part
of his reign. The pope, John XXII., issued a bull, assum-
ing the right of deciding between the competitors of the
empire, and commanding Lewis to desist from exercising
the imperial functions, till he should obtain his express per-
mission. The emperor protested against the bull, and was
excommunicated. To conciliate the minds of the German
princes, he made a peace with the Austrian family, and set
at liberty duke Frederic, whom he had hitherto kept in pri-
son. In 1327, he marched into Italy, and was crowned
king of that country; and in the following year he pro-
ceeded to Rome, and was crowned at St. Peter's by the
bishops attached to his party. The pope renewing his claim
of excommunication and deposition against him, he retaliated
by publicly pronouncing his indulgence a heretic, and a de-
father of his flock; and he even pronounced upon him fera-
tence of death. By a change of circumstances he was
obliged to quit Rome in haste, and from this moment his
care declined in Italy, and he found it necessary to return
into Germany. He now sought a reconciliation with the
pope, and was treated with contempt. The death of John,
in 1336, was of no advantage to the emperor, as the suc-
ceeding pope, Benedict XII., interfered in the holiness
manifested by his predecessor. About the year 1336, the
princes of the empire, as well ecclesiastical as secular,
affirming at Spire, declared the empire independent of the
see of Rome, and pronounced Lewis the lawful emperor:
after this a diet was convoked at Frankfort, in which a con-
stitution was passed into a law, for ever establishing the
independence of the empire. These decrees did not put an
end to the disputes between Lewis and the holy see: the
breach was widened by the secret intrigations of Philip of
Valois; nevertheless, the emperor retained the allegiance of
the greatest part of the empire. He died, as he was in the
act of hunting, in October 1347, at the age of sixty-three.
This prince is said to have surpassed all his contemporaries,
both in personal and mental qualities, and accomplishments.
His manners were gay and highly polished for the times in
which he flourished; and although he was capable of con-
ceiving his measures without affection, he willingly sought
the aid of good counsel. He appears to have been famed
for piety; for, notwithstanding the papal anathema, he re-
ceived the appellation of "Most Christian," and the monks of Germany, as servile,
as superfluous, preferred his knives, napkins, &c. with religious veneration. Modern
Univer. Hist.
Lewis I., king of France, has already been noticed under
the title emperor of that name, having reigned as chief of
the Germanic empire, and monarch of France. We there-
fore proceed to
Lewis II., king of France, surnamed the Stammerer, son
of Charles the Bald, who was born in 843, created king of
Aquitaine in 867, and succeeded his father in the throne of
France in 877. This prince expiated his kingdom to the
fatal consequences of a weak and divided administration.
To obtain the support of the principal people, he profusely
lavished the honours and estates of the crown upon those
who made the earliest application, so that having exhausted
his bounties, those who were the laft to present their claims
were disappointed in their hopes and expectations. Neg-
lected themselves, they murmured, and denied the right
which he had assumed of disposing of these possessions,
without the consent of the general assemblies. His party
prevailed by the force of numbers; and at his coronation he
took a solemn oath to maintain the privileges of the princi-
dees, and to respect the donations which he had conferred
on them. The vassals of Lewis soon became his equals, and
contended for the superiority. A rebellion caused him to
take the field in his own defence, but on his arrival at Autun
he was attacked with a dangerous disease, suspected to
have been occasioned by poison, which carried him off, after
a reign of about eighteen months. At the time of his death
the queen was pregnant, and was afterwards delivered of a
son, who in due time succeeded to the kingdom, under the
title of Charles the Simple. Previously to his death, and
feilible of his approaching end, he desired that his sword
and crown might be delivered to his son,

Lewis
LEWIS III, king of France, who was at that time about seventeen years of age. The great lords were furious, in opposition to the wishes of the late sovereign, to establish his other son Carolman on the throne. To prevent, however, the evils of a civil war, they agreed that the crown should be worn by both. The division of territory was made in 886, when Lewis had for his share France Proper, and Neustria; and to Carolman were assigned Burgundy and Aquitaine. The two brothers lived and reigned together in the most perfect harmony, and they displayed some of the qualities of their ancestor Pepin. They, in some measure, put a stop to the ravages of the northern brigands, fifty thousand of whom had entered by the river Somme, and had taken several strong places, among which was Amiens. Lewis defeated them in an engagement near Courtray, but having neglected to follow up his victory, they rallied, and made incursions into Picardy; here he again encountered them, and gave them a most signal defeat, leaving on the field of battle 9000 of the enemy, with their leader Guaramond. This victory had displayed much wisdom and valour; and the demise of Lewis of Germany proclaimed the moderation of the young king of France, who rejected with firmness the crown offered him by the inhabitants of Lorraine, and yielded to the superior pretensions of the emperor, Charles the Fat. The French were, however, permitted to contemplate the rising virtues of their prince only a short time. While he was indulging the hope of creating fresh trophies over the Normans, a mortal disease compelled him to renounce the enterprise. He returned to St. Denis, where he expired in the twenty-second year of his age. His premature death was marked with the suffusion of poison, a fulmination countenanced by the turbulent temper of the nobles, jealous of his active and glorious reign.

LEWIS IV, king of France, surnamed D'Outre-mer, beyond the seas, on account of his having been educated in England, was the only son of Charles the Simple, by Egira, daughter of Edward the Elder. He was born in 917, and upon the deposition of his father, was taken by his mother to the court of Athelstan, in England. Here he remained till the year 936, when he was invited to return and ascend the throne of his ancestors. He landed at Boulogne, proceeded to Laon, and was crowned in that city by Artaud, archbishop of Rheims. His return was chiefly owing to the influence of the powerful Hugh the Great, duke of France. The first measures of Lewis promised to maintain the internal tranquillity of his kingdom. To disburden his obligation to Hugh, and to secure the fidelity of that nobleman, he appointed him minister, and committed the reins of government into his hands. The fervent son raised himself above the matter; and the attempts which Lewis made to free himself from this state of dependence, gave rise to a civil war, which for several years threw the kingdom into confusion. By the mediation of Otho, his brother-in-law, emperor of Germany, and that of William, duke of Normandy, a peace was concluded in 942, between Lewis and his rebellious subjects. On the death of the duke of Normandy, Lewis attempted to add that duchy to the kingdom: for this purpose he united with Hugh the Great, in an open invasion of the country. Lewis was entirely defeated and carried prisoner to Rouen, whence he was not released till he had entered into a treaty to secure the independence of Normandy: even after this he was detained in captivity till he had procured for himself a grant of the city and territory of Laon. Lewis seized upon the first opportunity to avenge his resentment against his powerful vassal, and the provinces of France were alternately afflicted by the arms of Lewis, of Otho, and of Hugh. During five years the flames of civil war raged without intermission, and the precarious peace which was concluded in a personal interview, may be considered as a suspension of hostilities rather than a restoration of tranquillity. The latent embers of discord were still kept alive: they broke out with renewed violence, and were finally extinguished by the two filters, comforts of the king and Hugh. A permanent peace was established, and Lewis prepared to assert his authority over the revolted lords of Aquitaine, when his plans were broken by a sudden and accidental death. As he was pursuing a wolf, routed by chance, with inconsiderate ardour, his horse stumbled and threw him: the injury proved fatal, and in a few days he closed his life at Rheims, after a stormy reign, having been eighteen years on the throne.

LEWIS V. was associated with his father Lothaire in the government, whom he succeeded in the year 986, being in the nineteenth year of his age. He manifested a violent and turbulent character: he quarrelled with the queen-dowager; expelled the bishop of Laon from the kingdom; and upon a dispute with the archbishop of Rheims, forcibly entered that city with a considerable slaughter. At the time that he was preparing to march against the Saracens, he was taken off by poison, administered, it was imagined, by his own wife Constance. With him ended the race of kings of the house of Charlemagne, which had swayed the sceptre nearly 240 years.

LEWIS VI., surnamed Le Gros, son of Philip I., was born in 1031. He was associated with his father in the government in the year 1100, having already acquired a high reputation for valor, prudence, moderation, and a freedom from those vices incident to his age and rank. By the vigour of his conduct he held in awe the discontented nobles, repressed the rebellious, demolished their castles, and compelled them to restore the estates which they had usurped from the clergy. His mother-in-law, Bertrade, jealous of the reputation of the young prince, and considering him as the only obstacle to the elevation of her own sons, attempted, by every means in her power, to distray him. He happily escaped her machinations, and Philip, discovering her real character, forced her to make such submissions as disarmed the resentment of his son. In 1108, Lewis, by the death of his father, succeeded to the throne, and in a short time he became engaged in a quarrel with Henry I., which may be regarded as the commencement of the long contests between the kings of France and England. Lewis, in the first instance, wishing to avoid the effusion of blood, sent a challenge to Henry to decide the point at issue in single combat, which Henry declined. A battle ensued, Lewis was victorious, and in a treaty concluded not long after, it was agreed that William, the son of Henry, should do homage to the sovereign of France for the duchy of Normandy, which Henry himself had refused to do. War was again renewed, and in an action at Brenneville, an English warrior seized his horse's bridle, crying, "the king is taken!" to which Lewis replied, "at cheval, the king is never taken," and instantly laid his antagonist dead with his sword. Lewis endeavoured to deprive Henry of the dukedom of Normandy, but was unsuccessful. In 1119, at a council at Rheims, in which the emperor Henry V. was excommunicated by pope Calixtus II. Lewis lodged his complaints against the king of England, but was unable to draw down the censures of the church upon him. After this the emperor, exalted by Henry I., who was his father-in-law, invaded France, but the common danger induced the French to rally round the standard of their king, and he shortly found himself at the head of 200,000 men. It was at this crisis
cries that the famous oriflame, or banner of the abbey of St. Denis, was displayed as the king's standard. Lewis next had a dispute with some of his prelates, which brought upon him a sentence of excommunication from the bishops of Paris and Sens, but it was taken off by the pope. He now attempted to put an end to the schism in the popedom between Innocent II. and Anaclet, the former of whom he supported as lawful pontiff. The great habit of his body, from which he derived his surname, forewarned him of his approaching end, for which he prepared by settling the affairs of his kingdom. He caused his son Lewis to be solemnly crowned, and when he found himself almost in the last stage of existence, he drew the signet from his finger, and fixed it upon that of his son, charging him at the same time to remember, that the sovereign authority, of which this was the symbol, was a public trust, for which a strict account would be required in a future world. He died in 1157, greatly lamented by his people, whom he had never burredthened with taxes, and whom, in many respects, he had freed from the oppressions of the great. Lewis VI. was unquestionably one of the most irreproachable monarchs of France. His reign is reckoned the era of the commencement in France of that balance to the power of the feudal lords which arose from the order of citizens. He conferred new privileges on the towns within his domains, by what were entitled charters of community, and formed them into corporations or bodies politic, with the right of administering justice, levying taxes, and embodying a militia within their own districts.

Lewis VII., son of the preceding, was born in 1120, and succeeded to the throne in 1157, having by his marriage with Eleanora, the heiress of the duke of Guinecke and count of Poitou, united to the crown of France an extensive country from the Loire to the Pyrenees. He began his reign by repelling some outrages of his nobles, and a revolt of the commons. The election of an archbishop of Bourges, without his consent, involved him in a quarrel with the clergy, and with pope Innocent II. who supported them. In the course of this dispute, Lewis made an inroad into Champagne, sacked the town of Vitri, and set fire to a church, in which more than 1000 people miserably perished. Struck with remorse for this savage action, he resolved to expiate the foul crime by an expedient to the Holy Land. In 1146, Lewis took the crois, and his example was followed by the queen, and all the principal nobility. In the following year he set out at the head of 80,000 men, on his march by land to Constantinople: from this city the French army marched through Asia Minor, to Antioch, and at length undertook the siege of Damascas. The enterprise entirely failed, and Lewis returned dispirited and disgraced. To public calamity succeeded the pang of domestic misery, and it could not be concealed from the eye of a husband that the fidelity of his queen, who had accompanied him in this expedition, had been sacrificed to her own uncle, Raymond. On his return he determined to divorce himself from the queen, which he carried into effect in 1152. By this event the provinces of Aquitaine were detached from the crown of France, and in six weeks they were transferred to that of England by Eleanora's marriage to Henry Plantagenet, then duke of Normandy, and soon after king of England, under the name of Henry II. The facility with which he parted from these wealthy provinces has for ever annexed to him, by way of reproach, the surname of Young. Lewis married for a second wife Constanția, daughter of Alphonso, king of Cathile, and soon after displayed his piety in a pilgrimage to the shrine of St. James, at Compostella. This queen dying without any male issue, he married Adelais, daughter of his old enemy, Thibaud, count of Champagne, by whom he had a son, named Philip. While a mere child, the royal youth, engaged in the pleasures of the chase, was lost in the thickwoods of a gloomy forest, and the heir of France was condemned to pass a tedious night, oppressed by solitude and despair. His feeble mind was incapable of sustaining the horror of his situation, and when found in the morning, a dangerous fit of illness was the effect of the fright. The suppliant monarch visited the tomb of Becket, to solicit the intercession of a saint, who had experienced his earthly protection. Having been kindly received at Canterbury by Henry, and having professed his offerings at the shrine of Thomas, he embarked again for France, and on his arrival his heart was gladdened with the intelligence of his son's complete recovery. The mind of the king had, however, received a blow, from the effects of which he never recovered, and in 1180, he experienced a paralytic seizure. Sensible of the great danger which hung over him, he determined to hasten the coronation of his son, and having languished about a year under his malady, he expired, after a reign of forty-three years. "If," says the historian, "the prudence and judgment of the king, in restoring the dowry of Eleanor have been arranged, his humanity has been seldom, and his piety has never been impeached. A tender husband and an affectionate father, the errors of the monarch, were lost in the virtues of the man."

Lewis VIII., grandson of the preceding, was born in 1187, and displayed, at a very early age, a martial disposition under his father at the war in Flanders, and against King John of England in Poitou. In 1216, he was invited by the barons of England to ascend the throne, of which their own sovereign had proved himself unworthy. He landed in Kent, and marched to London, where he was at first received with respect and gratitude; in a very short time the tide of public favour completely turned, and he was glad to obtain permission to return unmolested. He succeeded to the crown of France in 1223, and fearfully had ascended the throne of his ancestor, when he was urged by Henry III. of England, to make restitution of the provinces taken by his father from King John; he refused, and war was declared. Lewis was everywhere victorious, and the power of the English in France was greatly curtailed, so that nothing was left in their possession but the town of Bourdeaux, and the country beyond the Garonne. To preserve these, Henry conferred on his brother Richard the title of count of Poitou, and furnished him with ample means to support his new dignity. The inhabitants of Poitou crowded to his standard, and the spirit of opposition being revived, the career of Lewis was checked, and he was glad to make a truce for three years. The court of Rome strongly solicited the king of France to resume the crois, and to march against the Albigensians. From Lyons he directed his march along the banks of the Rhone, and invested Avignon with 50,000 men. The inhabitants, animated by despair, defended themselves with the most obstinate valor; and the king, after the lofs of the braves of his troops, was forced to grant that capitulation at last, which he had refused at first. On his return home, he was feized with an illness which put an end to his life, in November, 1226, after a reign of about three years.

Lewis IX., king of France, named Saint, fon of the preceding, was born in 1215, and succeeded to the crown in 1226: being only in the twelfth year of his age he was placed under the guardianship of his mother, Blanche of Chatine, who was nominated regent of the kingdom. Her first efforts with regard to the young king was to inspire him with a love of religion, and an attachment to the principles
priests of pure morality. When he attained the age fit for taking upon himself the rule of the kingdom, such was the respect which he bore for his mother, that her authority remained unimpaired, and for several years they may be said to have reigned jointly. Though the piety of this prince obtained for him the title of saint, yet he knew the limits between secular and ecclesiastical jurisdictions, and was jealous of usurpations in the latter. He refused to join in the crusade recommended by pope Gregory IX., though encouraged to the undertaking by the most flattering propozals. Lewis shewed himself a good warrior by his exertions in suppressing a revolt supported by Henry III. of England: he gained two victories in person, and constrained his rival to submit to humiliating conditions of peace. Two regulations proclaim the prudence and policy of this prince. The first, under pretence of preventing strangers from inheriting lands in France to the prejudice of the natives, precluded the nobles from marrying their daughters to foreigners, and restrained them from increasing their influence by connections and alliances with the neighboring powers. The second compelled the vaials of the crown of France and England to make a public avowal, as to which sovereign they would do homage, and, finally, abolished the dangerous custom of adhering to either, as their caprice or interest suggested. Yet, in the midst of this activity, the humanity of Lewis was conspicuous, and his justice indemnified those who adhered to him for the land they forfeited, by forcing them from the kingdom of England. A dangerous indisposition, which menaced the life of Lewis, was productive of a fatal vow to march in person against the infidels, whose successful victories had overwhelmed the Christians of the East: no remonstrances from his counsellors, his nobles, and even his prelates, could divert him from the resolution of fulfilling his vow. The blind zeal, however, which induced him to defend from his throne to seek the adventures of a spiritual knight-crusant, did not prevent him from concerting his measures with the utmost prudence and foresight, as well with respect to the empire itself, as the government of the realm during the king's absence. Having entrusted the kingdom to his mother, Blanche, he prepared for his departure. "To furnish," says the historian, "an armament equal to the arduous enterprise, France was exhausted of troops and treasuries; the sea was whitened with eighteen hundred ships; and nine thousand five hundred horse, and one hundred and thirty thousand foot, have been computed as the number of the martial pilgrims. The fleet, with favourable winds, reached the coast of Cyprus; the troops were disembarked on the friendly shore, and during the severity of winter, their strength was recruited and their health restored by the plenty of that island." Here it was determined to make war first upon the sultan of Egypt, for the purpose of facilitating the recovery of Palestine. In 1249, he arrived at the mouth of the Nile, and leaping into the sea, fورد in hand, gained the beach, and drove away the Saracens drawn up to defend it. Damietta instantly yielded to the aggressor, but it was now found the expedition was ill-advised; the rigour of the Nile prevented his further advance, and the delay introduced disgrace into his army, and all the disorders naturally attendant upon idleness and the want of subordination. From this period he was no longer successful: every new attempt at conquest ended in disfamer, till at length himself, his brothers who had accompanied him in the expedition, and his whole army, were under the necessity of surrendering themselves prisoners. The enemy scarcely knew any bounds to their revenge: they massacred the captives without mercy, and even treated the fallen monarch with a great degree of insolence and ri-
Lewis; the latent flame of enthusiasm which had been
damped by his defeat in Egypt was not extinguished; and
an opportunity was only wanting to revive the dormant
embers. The wisdom of his regulations had restored the
tranquillity of his dominions; his coffers were recruited, his
finances augmented, and his hopes of success were expanded,
and very fanguirine. His flent preparations had been infec-
tantly directed towards the single object of his devout am-
bit; the loss of Antioeh provoked the more immediate
execution of his designs. His example was followed by his
three sons, by his nephew the count d'Artois, and by a
multitude of the most gallant spirits of the court of France.
His intrusion into the councils of government, during his ab-
se, to the vigilance and superintendence of Matthew, abbot of
St. Denis, who derived his noble lineages from the counts
of Vendome; and to Simon de Clermont, count of Nelle.
A fea-port of Languedoc, near the mouth of the Rhone,
was rendered a second time remarkable by the embarkation
of Lewis, and the fleet of France steered immediately for
the coast of Africa. An obscure king of Tunis had pre-
ceded an inclination to abjure the tenets of Mahomet for
those of Christ; and the vain report of an immense treasure
reconciled the more interested pilgrims to the wild and
visionary enterprise. But caprice or policy had already
united the fickle or crafty barbarian to the precepts of the
Koran; and instead of a zealous profyte, Lewis encountered
an active and formidable enemy. The walls of Carthage were,
indeed, flormed by the impetuous valour of the French; but
their strength was extinguished before the gates of Tunis; and
the warriors of the well panted beneath the sultry heats, and
expired on the burning sands of Africa. The king himself
was infected by the pestilential blaff, and he breathed
his last on the inhospitable shore, in the 44th year of his
reign. In his singular character were united the virtues
of the faint and the hero: his piety and equity in peace
were not more conspicuous than his fortitude and valor in
war. The father of his people, his heart sympathized with
their miseries, and his hand was ever stretched out to relieve
their distress. His excellent understanding was clouded by
the fumes of enthusiasm; and the laughter of his subjects,
his own captivity, and at length his death, were the fatal
consequences of a blind superstition. Pope Boniface VIII.
canonized him in 1297; and his descendant, Lewis XIII.,
procured the day, dedicated to his honour, to be declared
a general feast of the church.

Lewis IX., surnamed the Bifserus, from the rude pro-
mise of his infant years, son of Philip, was born in 1201, and
succeeded his father in 1244. In a short time after his
coronation, caused his first wife to be triangled in the prison
of Chateau Gailhard, where she was confined, and endeav-
oured to forget the vices of a licentious woman in his nup-
tials with Clemente, the daughter of the king of Hungary.
An empty treasury delayed, for some time, the ceremonies
of the coronation, and the king diligently applied himself to
conciliate the jealousies and appease the discontents of his
new subjects. Lewis, notwithstanding the surname which
he had acquired, was of a quiet disposition, and surrendered
the chief authority in the state to his uncle, Charles of
Valois. The finances of the kingdom having fallen into dis-
order, the superintendent, Enguerrand de Marigny, was made
decree to the revengeful passions of the new minister.
Marigni vindicated his character with vehemence; but his
eclatuation was of no avail, he was consignate to an ignomi-
nious death on the gibbet, and his fortunes were confiscated
to the use of the sovereign, and were applied to defray the
expenses of the coronation, which was celebrated at Rheims;
and as much as they fell short of public expectation, so much
did the deficiency contribute to establish the innocence of the
unfortunate superintendent. Far different supplies were
necessary for the support of a war with Flanders, which
Lewis was desirous of engaging in, and he accordingly pro-
posed to raise the necessary supplies by a general enfran-
chisement throughout the kingdom. The inhabitants of the
towns were already free, but those of the country were
not so, and few were found willing to pay for that freedom
which was forced upon them. The decree was, however,
gone forth, and they were compelled to accept of their
liberties upon the terms proposed by the sovereign, who
preached the edict with these words: "Since, according to
natural right, every person ought to be free, &c." a maxim
not very consistent with the compulsory purchase of liberty.
The money being provided, Lewis made a campaign against
de Bethune, count of Flanders, who, feeling himself unable
to withstand the army brought against him, determined to
hend against the firm. By the furious language of sub-
nifion, he involved the king in a series of frivoulous negotia-
tions, till the feason of action was past, and the French
army was obliged to retreat, without obtaining any advan-
tage. While the king, ingoumiant at the arts of his adver-
sary, was meditating new projects for revenging himself
upon his adversary, his designs were interrupted by death.
A sudden disorder, imputed by some to poison, by others
to drinking a glass of cold water when he was heated, proved
fateful to him in June, 1216, after a reign of about a year
and a half.

Lewis XI. son of Charles VII. was born in 1423, and
at an early age displayed considerable talents, united to
a turbulent disposition. At the age of seventeen he headed
a party of discontented nobles, who engaged in a petty
war, which was soon suppressed, and the prince was glad to
submit. After this he reinstated himself in the royal favour
by his skill and valor in relieving Harfleur, invaded by
the English. He was soon bent with a body of troops to
affright the duke of Austria against the Swifs, and obtained
some advantages over them, which were succeeded by a nego-
ciation with the Cantons, in which he concluded the first
treaty between them and the crown of France. In 1446,
disguised with the ascendancy of Agnes Sorel, his father's
mistress, he left the court, and retired into Dauphine, in
which province he exercised the sovereign authority. He
established the parliament of Grenoble, made laws, and
even coined money. At length his conduct created so much
unanimity in the breast of his father, that he was determined
to get possession of his perfon; but the prince, being made
acquainted with his intention, eluded, and took refuge in
the court of Philip the Good, duke of Burgundy. Here
he was treated in a manner consistent with his rank; but
Philip would not encourage any of his sedulous projects.
In the mean time the king brought back the government
of Dauphine to its ancient form, and kept a watchful eye
over his son's motions; so jealous was he of his intentions,
that the dread of being poisoned by his contrivance was the
caufe of his death. In the year 1461, Lewis received the
news of his accession to the crown of France; he did not
afford it; he concealed the joy which the intelligence excited
in his breast. The competition of his younger brother,
the duke of Burri, vanished at his appearance; and his own
coronation was celebrated with all the magnificence at Rheims,
and honoured with the presence of Philip, his noble descendant,
and that of his son, the count of Charoleis. The first
emotions of the king's gratitude for the protection he had
met with, was displayed in his declaring the count his lie-
tenant-general in Normandy, with a very munificent salary;
but these marks of esteem and confidence soon vanished, and
were
were succeeded by an enmity between these rival princes, which only expired with life. The new king immediately dismissed the ministers of his father with disgrace, and at the same moment released from imprisonment the duke of Alençon, who had been confined for treasonable practices. With regard to foreign potentates, his conduct seemed to be defturate of every principle of justice, and dictated merely by what appeared to be the interest of the moment. In pope Pius II. he met with a politician more refined than himself, for in the hope that this pontiff would affer in replacing the house of Anjou on the throne of Naples, Lewis cancelled the pragmatic sanction of his father, which establihured the liberties of the Gallican church: afterwards, finding himself deceived in his expectations, he permitted its execution in certain points. Being constituted mediator in a dispute between the kings of Castile and Aragon, he had an interview with the former, in which he displayed the singularity of his disposition; for while the Spanish monarch with his attendants dispayed the greatest magnificence in their apparel, he appeared in a drefs of coarse cloth, with an old hat upon his head, upon which was stuck a leader image of the Virgin. This contrast between the two princes, after a fruitless conference, returned with a thorough contempt of the fordsnef of the one and the incapacity of the other. It was a great object of his policy to reduce the formidable power of the house of Burgundy; and, in the execution of his plans, he was suspected of a plot for the seizure of the perons of the duke and his son. In return, the count of Charolais joined the duke of Brittany in caballing with his discontented nobles, and formed a confedecacy, called "the league for the public good," into which the king's brother, the duke of Berri, entered. The revoters took up arms, and the count attempting to surprize Paris, an engagement took place at Montlhery, in which the victory remained undecided. Paris was, however, besieged, and the king, to avert the danger, followed the advice of Sforza, duke of Milan, which was to break the league by liberal promises, and truft to events for eluding the execution of them. He accordingly agreed to a disgraceful treaty in 1465, by which he ceded the duchy of Normandy to his brother, and granted lands out of the royal domains to others of the leaders. Some disputes between the dukes of Brittany and Normandy gave him an opportunity of recovering his power, and of dethroning his brother of the dukedom of Normandy, and of that which he before possifed. The acession of the count of Charolais to the dukedom of Burgundy on the death of his father Philip, gave Lewis much uneafiness. The fiery temper of that prince, and his declared enmity to the king, involved them in perpetual hostilites. In the course of these, the king's brother, whom he had been obliged to make duke of Guinée, died, not without suspicion of poison, and the duke of Burgundy, openly accusing Lewis of fratricide, refumed his arms. An invasion of France by the duke's ally, Edward IV. of England, threatened great danger; but Lewis, adhering to his favourite principle of diverting rather than confronting a thron, lavished his treasures upon English ministers and generals, and allured Edward himself by a promised penion of 50,000 crowns for life, by which means a treaty between them was concluded in 1475. The duke of Burgundy made a separate peace afterwards. Having thus extricated himself from foreign foes, Lewis indulged his severe disposition in taking vengeance on domestic traitors. The confiable St. Pol, who had served under and betrayed both him and the duke of Burgundy, was brought to the scaffold, as was likewise the duke of Nemours. The cruelty of making

Vol. XX.
LEWIS.

In the The integrity, France, crown restoration, Orleans. "He was resumed to nation, to the kingdom (should shortly French, meaning. The queen, he had probably to the duke of Orleans, was anxious to secure the independence of her native duchy, and flipulated, that if their union should be productive of two sons, the younger should inherit Brittany, with all the prerogatives of its former princes. This agreement proved ineffectual, by her having no son, and by the marriage of her eldest daughter Claude to Francis, count D'Angoulême, who afterwards ascended the throne. The claims of Lewis to an if the crown of Naples, now began to excite in his breast the ambition of conquest; he accordingly made an alliance with the Venetians, and, in conjunction with them, invaded the dominions of Ludovico Sforza, duke of Milan. The French generals, in the short space of three weeks, made themselves masters of Milan, Genoa, and all the strong places in the country: Lewis entered Milan in triumph, while Sforza retired with his family and treasures to Innsbruck. A sudden revolution caused the expulsion of the French, and the return of the duke, but the troops of Lewis shortly entered the Milanese, and got possession of the person of the duke, who was sent into France, where he died. Lewis now made a treaty with Ferdinand of Arragon, for the partition of the kingdom of Naples between them. In 1501 this plan was successfully executed, and Frederic, king of Naples, expelled from his dominions, put himself into the hands of Lewis, as the most generous of his two enemies. Ferdinand was not content with a part of the conquest, but took every method to secure to himself the whole spoils; and by means of his famous captain, Gonzalvo de Cordova, obtained possession, in 1503, of the whole kingdom of Naples, after defeating the French at Seminara and Cerignola. It was on this occasion that Gonzalvo got possession of the young prince, whom he conveyed to the crown of Arragon, and though treated with lenity, he was for fifty years the captive of the court of Spain, till Death, that last friend to captives, extinguished in him the Arragonec line of Neapolitan kings. In the year 1507, a revolt of Genoa called Lewis, in peril, into Italy with a powerful army; he entered it as a conqueror, seemingly bent on vengeance, but his natural clemency was displayed in a moderate chastisement which he inflicted upon it. In the following year he joined the famous league of Cambrai against the Venetians, formed by the temporary union of powers mutually jealous of each other, and opposite in interests. Lewis became a party in the league through the influence of cardinal d'Amboise. He even marched at the head of his army, and, in May 1509, gained a complete victory at Aignadel, which reduced the republic of Venice almost to ruin. Its safety arose from that diffusion which might be expected in a league formed of such discordant materials. Pope Julius II. who had chiefly contributed to its formation, resolved, after the purpose of his own ambition were answered, to employ all his efforts to expel the foreign powers from Italy. With this view he made peace with the Venetians, and openly declared war against the French. A new league was now formed, of which Julius was the chief mover: he attacked in person the duke of Ferrara, its ally, and communicated the council of Pisa, which had been assembled under the auspices of Lewis and the emperor. The military reputation of the French was ably supported by the duke of Nevers, who, in 1512, gained the battle of Ravenna, but fell in a brief pursuit of the enemy. The king, his uncle, was deeply affected by the loss of him, and of many other brave men; and deprecated a victory purchased so dearly. In a short time after this, the Swafs overran the Milanese, and the French were expelled. It was again recovered, and once more. At this period Henry VIII. of England joined the papal league, invaded Picardy, and routed the French in an action, since denominated the battle of the Spurs. Henry pursued his career of success, which was interrupted by the retreat of the Swafs and the desertion of his allies; he determined, therefore, to repel the seas with the greater part of his army, ill compensated for the expenses with which it had been attended. In 1514 the queen died, and he proposed marriage to Mary, sister of Henry VIII.; his offers were accepted, and a league offensive and defensive was formed between the two kings. Lewis, however, was obliged to purchase this alliance with a great sum of money, instead of receiving a portion with his wife. It was agreed that Henry should receive the payment of a million of crowns, being the arrears due by treaty to his father and himself; and that the princes Mary should bring four hundred thousand crowns as her portion, and enjoy as large a jointure as any queen of France. Lewis also agreed that Tournay should remain in the hands of the Englists; and that Richard de la Pole, an exile in France, who affected to revive the pretensions of the house of York, should be banished.

The new queen, being young and beautiful, was welcomed with universal acclamations by the people; who rejoiced in an alliance that converted a formidable enemy into an important friend. In the midst of festivities given on account of the marriage, formidable preparations were made for renewing the war in Italy; but his designs were broken. He had often repeated the adage, that "love is the king of youth, but the tyrant of old age," and he was now convinced to experience its truth. His constitution, already shaken, was exhausted by his affection for Mary, with whose beauty, grace, and numerous accomplishments he was enchanted. He died within three months of his marriage by a disorder of debility, in the seventeenth year of his reign, and the fifty-fourth of his age. The character of this prince was distinguished by a superior integrity, seldom to be discerned in princes; and though sometimes the duple of his goodnecess of heart, and often of the treachery of his neighbours, yet he well deserved the appellation of "the father of his people." In him expired the elder branch of the house of Orleans, and the sceptre of France was transferred to that of Angoulême.
LEWIS.

"History," says the biographer, "has taken pleasure in recording, that when, according to the usual custom, the embers announced his death, it was done in these words, "the good king Lewis, the father of his people, is dead." He was naturally inclined to economy: this was once made a topic of ridicule in his presence, to which he replied, "I had rather see my courtiers laugh at myavarice, than my people weep at my extravagance." In his manners and conversation, Lewis was affable, mild, and cheerful, prone to fallacies of innocent pleasantry, and fond of literature. He assembled men of learning at his court, and employed them in public affairs. Greek was first taught at the French universities in his reign.

Lewis XIII., son of Henry IV., by Mary de Medicis, succeeded to the throne in 1610, under the regency of his mother, being only in the thirteenth year of his age. He was declared in his majority in the year 1614, and soon after the flates-general were convoked. At the meetings of this assembly many abusés were discussed, and some few were remedied. During the minority of the king, France had been, on account of the mal-administration of the queen, a scene of faction and civil commotions: these troubles continued, and were greatly aggravated by a religious war. Lewis's character, as it opened, displayed that propensity to be governed, which indicates weakness of mind, together with much coldness and indifference. The great duke of Sully, inflexible in his plans, confiding in the integrity of his own heart, and disdaining the arts of courts, found that sincerity, which had been esteemed by Henry, no longer acceptable; he indignantly retired to the estates where he had purchased through the bounty of the late king, and resigned his offices. Every day now revealed the ascendancy of Concini, who endeavoured to remove from the eyes of the people the unpopular circumstances of foreign birth, by assuming the title of marquis d'Ancre. During the administration of this favourite, the annals of France, as they respect the internal affairs of the country, present a dreary prospect of unutterable anarchy and barren discord. The princes of the blood, inflamed with avarice, and the nobles turbulent and discontented, repeatedly erected the standard of revolt against the regal authority; as frequently, with contemptible levity, they courted the returning friendship of the crown, whose timid counsellors were content to froth, without preluding to repref, their capricious arrogance. Amidst these follies at home the king concluded his marriage, and received at Bourdeaux the hand of Anne, the infanta of Spain. Immediately after the celebration of that ceremony, Lewis marched at the head of his army with the view of reducing the prince of Conde, in order that he might impress his subjects with favourable sentiments of his courage and activity. The approach of winter suspended the operations of the contending parties, who, while they rejected all terms of accommodation, seemed inflammatory, in every enterprise, to avoid the effusion of blood. With the return of spring the royal forces were again assembled, and were again led on by the preference of their sovereign; but much was thesurprize of his subjects to learn the intelligence that the king had subscribed a peace, and submitted to the demands of those princes whom he had lately declared traitors to his throne. In 1617, Concini was murdered in the Louvre, at the instigation of Luynes, whom he had introduced to the king, and who now superceded him in the royal favour. The principal events which occurred in this reign during the administration of Luynes, were quarrels with the queen-mother, and a renewed war with the Calvinists, who were headed by the duke de Rohan. During this war Luynes died, and the Calvinists obtained an advantageous peace.

In 1624, cardinal Richelieu, who, while bishop of Luçon, had been gradually rising to political reputation, acquired the chief management of affairs, which he held with unrestrained sway so long as he lived. This great minister found a very difficult task before him, owing to the weaknesses of the king, the selfish ambition of the nobles, and the prevalence of different factions. War broke out again with the Calvinists, who complained that the conditions of a former treaty had not been observed. The sovereign appeared in arms, but the chief honour was due to Richelieu, who, after a long siege, took Rochelle, by means of a vast dyke thrown across the harbour to cut off supplies by sea. This important conquest was the means of reducing the party to civil obedience, and, to the honour of the victor, they were still allowed a good share of religious liberty. In addition to the civil contentions, a war with Spain broke out in 1635, which was at first unsuccessful on the part of France; but at length the Spaniards were reduced to the same peace. In the mean time the spirit of Richelieu's domestic administration was highly arbitrary, and the king displayed great hardnefs in his address to the parliament. The last of his favourites was Cinqmars, who was recommended to the monarch by his minister, but who was led by his ambition to cabal against his friend and patron. His ruin was the consequence, and Lewis gave him up to execution with the most perfect indifference. (See CINQMARS.) On the morning of the execution of this man, intelligence was brought of the surrender of Perpignan, and the total discomfiture of the enemy, of which facts the minister apprized the king in a single and very short sentence, "Your troops are in Perpignan, and your enemies in their graves." Immediately after these events, Mary de Medicis cloathed a wretched life, reduced to the utmost indulgence, at Cologne. The filial affection which Lewis denied to her while living, was revived on the news of her death; but the attention of France was now completely engrossed by the approaching diffusion of him, whose daring counsellors had driven her into banishment. The glories and life of Richelieu drew near their end; after the reduction of Perpignan, exhausted in body, but still vigorous in mind, he had approached the capital by land and triumphant journeys; his last moments attested his ascendancy over the sovereign. On his deathbed he prevailed on Lewis, that his counsellors had ever been directed to the honour of the crown and the welfare of the kingdom. (See RICHELIEU.) From the death of this minister, Lewis aspired to hold the reins of government for himself: the war was prosecuted with diligence, vigour, and success, and the spirit of Richelieu seemed still to impel the machine which his genius had set in motion. But victory could not check the progress of disease, and Lewis was sensible that the inevitable moment was rapidly approaching when his life and reign must terminate together. A fever had already worn him to a skeleton, and he prepared to meet with firmness and composure the last scene of human greatness. "When," says the historian, "his physician, at hisearnest desire, numbered the fleeting minutes that remained, and pronounced that his life could not exceed two or three hours; he received the intelligence with resignation, and even satisfaction; and looking fervently up to heaven, added, "Well! I content myself with all my heart." The prediction was strictly verified by the event, and he expired in the forty-second year of his age, and in the thirty-third of his reign. In estimating his character, he was devout, but his devotion shewed itself in minute observances and submission to his confessors. He was not greatly addicted to pleasure, and the indulgence on whom he bestowed his favours, were rather the objects of his jealousy than
L. E. W. I. S.

than of his love. He had a share of judgment and solid sense, and did not want decision. In the administration of justice, he was inclined to rigour, and thence acquired the epithet of "The Just!"; though it must be admitted that his administration of justice was frequently impeached by his severity, and sometimes by his cruelty.

L. E. W. I. S. XIV., son of the preceding, was born in 1638, and succeeded to the crown, under the regency of his mother, Anne of Austria, on the death of his father in 1643. She soon resigned herself to the influence of cardinal Mazarin, who had succeeded Richelieu in the last reign. In the early part of this reign, the kingdom was involved in a bloody and extensive war with the house of Austria. The peace of Munster, in 1648, relieved France from the greater of her foreign foes; but it was soon succeeded by the civil war of the Fronde, during which the royal family was obliged to leave the capital, and wander as fugitives from province to province. The education of the young king was much neglected, and he was left ignorant of the points of knowledge most useful and reputable to a prince. The most valuable part of his reading was the tragedies of Corneille, which improved his taste, and gave him ideas of true grandeur; but the want of solid instruction moral and literary, marked his character through life. The lesson most strongly impressed on his mind in his very childhood, was the sentiment of his own importance, which, though it led him to adopt a dignified propriety of conduct, nighed in him that pride and vanity, and that impatience of control, which were the leading features of his reign. Taught by flatterers that he himself was every thing, and that his subjects were nothing in the comparison; he was habituated to think no sacrifice of their's too great for the promotion of his glory and the gratification of his desires. The convulsions of the state had ceased when Lewis XIV. had attained the age fixed for his assuming the reins of government, and his majority was solemnly declared in parliament; but he was still in leading-strings, influenced wholly by the counsels of his mother, and he seemed to inherit her fond partiality for Mazarin, though he was shortly after, by the mitigation of his parliament, obliged to give him up, and offer him to retire into exile. No sooner was it known that Mazarin had left the city of Paris, than the king was welcomed by the inhabitants with the loudest acclamations, and he found himself freed from the clamorous importunities of a discontented parliament, and firmly fixed on his throne. Scarcely, however, was he expelled by the general voice of the nation, and by the royal declaration, than he was recalled by the king, and, to his own infinite surprize, entered Paris once more in full power, and without the least disturbance. The king received him as a father, and the people as a master; but the cardinal, amidst the satisfaction of this change, could not repress his contempt of the national levity. The minister applied himself with vigour to extinguish the sparks of revolt; and, in 1653, the war of the Fronde was terminated with his complete triumph. Condè, who had joined the Spaniards, continued to maintain a kind of civil war on the frontiers, where he was held in check by his rival in glory, the great marquis Turenne. In 1659, the peace of the Pyrénées advantageously concluded the long quarrel with Spain. One of its conditions was the marriage of the king with the infanta Maria Theréza, which took place in 1660. The king, during the life of Mazarin, interfered very little in public affairs; but after his death, in 1661, Lewis began to govern for himself, and from that moment the poet of prime minister became vacant: he had, however, able men about him; among these was Colbert, who had been recommended to him by Mazarin, as a most able financier. To his genius was owing the revival of commerce and the marine, and all the splendid establishments of arts and manufactures which adorned the early part of this reign. It was he who, though not learned himself, was capable of appreciating the true value of literature, and suggested to the king, his master, that plan of pensioning all the eminent men of letters throughout Europe, which, at a comparatively small expense, secured to him more adulation from persons of real learning, than any prince of modern times. His leading object was personal grandeur. In whatever point any other prince had attained to greatness, he was resolved to emulate him. He employed all the resources of a rich and flourishing country to enrich every competitor, in whatever could tend to his glory. This spirit led him to attempt many great and useful projects, but for want of limit and moderation, it defeated its own purposes, and exhausted its means before it had attained its end. The age of Lewis XIV. was that in which the reputation of France for arms, arts, literature, and magnificence, floated at its highest pitch; but the time, it was that which demonstrated its wretchedness and humiliation, and the impartial historian has held up the king rather as the squanderer of his country's prosperity, than as the author of it. Of the wars of this monarch we cannot pretend to give a detailed account; the merit that this article will allow will be a sketch of the principal events of the reign, as connected with the personal character of the king. A quarrel concerning the precedence between the French and Spanish ambassadors at London, gave occasion to Lewis to assert in such high terms the superiority of his crown, that the point was never after contended. Shortly after, the influence of the French ambassador's servants at Rome, having brought upon them an attack from the pope's Cortican guard, in which some were killed, and the French quarters violated, the king seized upon Avignon, and obliged the pope's nephew, a cardinal, to come to Paris and ask pardon; the Cortican guard was broke, and a column was erected in Rome as a memorial of the event. War with Spain was renewed in 1667; the king in person took the field, though the measures of the campaign were probably directed entirely by the great Turenne. The whole of Flanders was reduced in this campaign, and at the close of it Franche Comté was conquered. A triple alliance between England, Holland, and Sweden, checked the progress of the French arms, and produced the peace of Aix-la-Chapelle in 1668. In 1672 Lewis, with a vast army, commanded by the ablest generals, burnt upon the provinces of Holland; and Amsterdam, the capital, was reduced from his grasp only by laying the surrounding country under water. At this juncture, William, prince of Orange, raised the office of stadholder, revived the drooping spirits of his countrymen; and the principal potentates of Europe, alarmed at the success and ambition of France, league against her. Holland was now evacuated as fast as it had been over-run. The French arms were again turned upon Franche Comté; it was conquered a second time, and became inseparably annexed to the crown of France. War with Spain, the empire, and other powers, continued some years longer, but it was terminated, in 1678, by the peace of Nimeguen. Lewis, attended by all the pomp and luxury of a court, formed several sieges in person; he carried with him historiographers to record his exploits, and every art was employed to exalt him in his own estimation, and in the eyes of Europe. He received from his subjects the title of "Le Grand," which for a considerable time seemed durably attached to his name; but he lived to lose it in the estimation of foreigners, and it has, by the events of the last twenty years, finally become obsolete among his own countrymen.
countrymen. The peace of Nimigau did not terminate the projects of Lewis XIV.; he attacked, and brought to sub-
million, the piratical rates of Algiers, Tripoli, and Tunis; and next, upon very trifling grounds of offence, made war upon Genoa, and forced the doge to come in person and
acknowledge the dominion of the king. With pope Innocent XI. he
quarrelled respecting the suppos'd rights of the Roman
church, and because he insisted upon retaining the franchises of embassadors from Rome, which other powers had agreed to
renounce, as inconsistent with a safe and regular polity. On
this occasion Lewis declared to the nuncio, "that he would
never take the example of others as the rule of his conduct,
but that it was for him to give the example." He was now
ambitious of the fame that would attach to the extirpation of
heresy from his kingdom. Calvinism, in France, since the
victory over it by Richelieu, had become a peaceful separa-
tion from the national church, and its sectaries were useful
citizens chiefly attached to manufactures and commerce.
Lewis, animated by a spirit of intolerance and bigotry, under-
took to put an end to it. The privileges of the Protestants
were openly violated: missionaries were sent for their con-
version, supported by dragoons; and severity was exerted,
which excited the horror and indignation of all the
reformed states of Europe. In 1685 the revocation of the
edict of Nantes, first granted by Henry IV. and confirmed
by Lewis XIII. deprived the Protestants of all exercise of
their religion, and tore from them their children to be edu-
cated Catholics. The tyrant at the same time stifled his de-
crees against emigration, and placed guards on his coasts;
nevertheless vast numbers escaped from his machinations, and
carried their arts and industry to foreign and hostile nations.
Lewis, though a pretended votary to religion, and a zealous
fan of the church, was not free from that licentiousness which is regarded as highly culpable by persons of reason and
sense. Several mistresses, in succession, enjoyed his favours;
with one of whom, madame de Montespan, a married woman, he lived a long time, in the most open manner,
and indulging his haughty and capricious humour.
Her influence declined with her perfidious charms, and the
king's advancing years; and she was superceded by the
widow Scarron, elevated from that low condition to the
title of madame de Maintenon, a person who, by the powers
of her understanding, and consummate skill in the art of
pleasing, obtained a complete ascendancy over the king's
mind. On the death of the queen he privately married her,
but she was never acknowledged as queen. The league of
Auxbourg, formed in 1667, between the emperor and most
of the German princes, the king of Spain, the United Pro-
vinces, the duke of Savoy, and other Italian potentates, had
for its object the reduction of the power of France. The
great leader in this league was William, prince of Orange, who,
when he ascended the throne of England, contrived to add
that kingdom to the confederacy. The forces of France
had proved victorious in many quarters; marshal Luxen-
bourg, and other eminent generals, renewed the successes of
the former war, and the king in person took Namur.
The defeat at La Hogue was, however, a fatal blow to the
French marine; the finances of the country began to be dep-
rieved, a circumstance that led to much domestic diffi-

culties, and Lewis XIV. was obliged, in the midst of victory,
to sign the general peace of Ryswick in 1697. The declining
health of Charles II. king of Spain, who was without heirs,
became a subject of universal interefl; with respect to the
disposal of his vast inheritance; and Lewis, fearing lest it
should fall into the hands of the house of Austria, joined
England and Holland in a scheme for the partition of the
Spanish dominions. At length, however, the dying king
made his will, appointing, as his general heir, Philip, duke
of Anjou, second grandson of Lewis. The wary monarch
forewarned the danger of accepting the legacy, but was de-
cided by a regard for the glory of his house, and the wish
of uniting the interests of two great monarchies, which had
generally been at variance. The hopes of the king have
been completely disappointed, and every attempt to form
an union of interest and affection between two nations radically
opposite in character and circumstances, has been baffled.
Neither the intrigues nor the power of the present emperor
of France have, at present, been able to effect that which,
was unquestionably an object near the heart of Lewis XIV.

The jealousy excited in England and Holland by this ac-
cession to the influence of France, was converted into open
hostility by the imprudence of Lewis in declaring the son
of James II., king of England, at the decease of his father
in 1701. This step, contrary to the unanimous advice of
his council, and his own judgment, was taken in consequence
of a generous emotion of pity for the family of his royal
friend, enforced by the solicitations of madame de Main-
tenon; it was not only impolitic, but, in fact, it amounted
to a declaration of war, because an article in the peace of
Ryswick, explicitly acknowledges William's title to the
crown of England. A new league was immediately formed
between the maritime powers and the emperor of France;
and the death of king William, during the preparations for
war, did not prevent its being carried into execution under
his successor queen Anne. From this period to the year
1711, the reign of Lewis was one continued series of defeats
and calamities; and he had the mortification of seeing those
places taken from him, which, in the former part of his reign,
had been acquired at the expense of many thousand lives.
The domestick misery of Lewis had kept pace with the pub-
lie calamities; the court, the splendour and magnificent en-
tertainments of which had excited the admiration and envy
of Europe, had long been impreffed with a deep and settled
 gloom. The art of surgery, in Europe, was yet feeble and
crude; a fiflula, with which the king was attacked, spread
a general alarm; and though the operation was successfully
performed, yet he never recovered his accustomed spirits,
but led a more fercious and retired life, and chiefly devoted
his hours to the conversation of madame de Maintenon,
whose influence increased with his years. To his own pri-

vate afffeltions were added many family losses. The death
of the king's only fon, which happened in 1712; the duke
of Burgundy, the duchesf his wife, and their eldest fon, all
swayed away within a few months, and laid in the same tomb;
the only surviving child at the point of death; these private
woes, added to those of the public, mark the clofe of the
reign of Lewis, as an era of calamity; and a wretched peo-

dle, who conceived that their own happiness was concerned
in the glory of the king, awaited in silence to behold the
former greatness of their monarch extingiuifhed by the dark
cloud of misery which obscured his fetting fun. Another
mortification remained for the king; he had enlarged the
canal of Mardyke, and formed an harbour there, equal, it
was thought, to that of Dunkirk. The embassador for
England remonftrated againft this evasion of the treaty of
Utrecht, and Lewis was under the necessity of discontinuing
the works. At the age of seventy-seven, that vanity and
ambition which had agitated the years of manhood were
nearly extingiuifhed. He coolly listened to the solicitations of
the unfortunate James, who aspired to ascend the throne
of his late fife, queen Anne, already filled by the elector
of Hanover, under the title of George I. To the importu-
nities of the prince he granted a small supply of money, and
veffel fitted out in the name of an individual; but while
that
LEWIS.

that enterprise hung in suspense, Lewis was seized with a mortal disease which soon brought him to the grave. In his last hours he displayed a greatness of mind worthy of his exalted situation. "Why do you weep," said he to one of his domestics, "did you think me immortal?" His fortitude was tempered with humility; he recollected his own weaknesses, and had sufficient magnanimity to confess them; his advice to the infant that was to succeed him was to avoid that glory which he had hoped to attain by war, and to consider the happiness of the people as the principal object of his government. To madame de Maintenon he left no fixed stipend, but contented himself with recommending her to the care of the duke of Orleans. She retired to St. Cyr, which had been founded, at her persuasion, for the education of young ladies, and demanded but little more than 3000l. per annum during her life; this was regularly paid till her death, which happened in about four years. Lewis XIV. had the misfortune of outliving his popularity, and an indignant joy was manifested by the people at his funeral. As a monarch he had none of the commanding qualities which create a nation or an era, and would scarcely have been distinguished from common princes under common circumstances. The masculine beauty of his person was embellished with a noble air; the dignity of his behaviour was tempered with the highest affability and politeness; elegant without effeminacy; addicted to pleasure without neglecting business; decent in his vices, and beloved though reviled with arbitrary power. Nevertheless his qualities seemed those that rather attract a momentary regard, than command a permanent esteem. The talents, the fire of the statesman, and the hero were all wanting; vanity rather prompted him to infatuation, than ambition to enslave his neighbours. Though he frequently took the field, and reduced countries and the strongest towns, yet in all his campaigns he never exposed his life to the hazard of battle. The age of Lewis XIV. will always be a memorable period in his country and of Europe. His own intellectual acquisitions were very limited, but he was the patron of learning and science.

LEWIS XV., son of the duke of Burgundy, (grandson of Lewis XIV.) was born at Versailles in 1710, and succeeded to the crown on the death of his great grandfather, when he was but five years of age. By the last will of Lewis XIV., a council of regency was appointed during the minority of the young king, at the head of which was the duke of Orleans. That nobleman, however, digusted with an appointment which gave him only a casting vote, appealed to the parliament of Paris, who set aside the will of the late king, and declared the duke sole regent. His first acts were extremely popular, and gave the most favourable ideas of his government and character. He restored to the parliament the right which had been taken from them, of remonstrating against the edicts of the crown; and compelled those, who had enriched themselves during the calamities of the former reign, to restore their wealth. The young king was placed under the tutelage of Fleury, bishop of Tréoux, afterwards cardinal, who, by his inimitating and very gentle manners, acquired his affection and esteem. His minority ended in 1722, and he was solemnly crowned; but the regent retained his chief power during another year. He now resigned his high office as prime minister to the duke of Bourbon, who negotiated a marriage between the king and Maria Leszinski, daughter of Stanislaus, king of Poland, which took place in 1725. Shortly after this, Fleury became prime minister; which post, notwithstanding his great age, he held till his death in 1743. The spirit of his government was economical and pacific; and a war with the empire, in 1733, was the principal foreign occurrence. This terminated in the annexation of Lorraine and Bar to the crown of France. Lewis lived for some years in conjugal affection and fidelity with his queen, by whom he had one son and several daughters. At length, however, he was captivated by the allurements of some ladies of the court, and received, it is said, the favours of three mistresses at the same period; and from this time he indulged his propensities for the female sex without moderation and delicacy. On the death of the emperor Charles VI. in 1740, a new continental war was excited. France joined with Prussia and Poland, in rating to the empire the elector of Bavaria, in opposition to the interests of the house of Austria, whose cause was maintained by England, Holland, and Sardinia. In 1744 Lewis took the field in person, and was at the reduction of several strong places; but at Metz he was attacked with a dangerous illness, which occasioned a general confirmation through France. His recovery was celebrated with all those transports of joy which could proceed from the awakened sensibility of a nation, then remarkable for an enthusiastic attachment to its sovereigns. The surname of "Well-beloved" was given to the king on this occasion; and, in return for the affection of his people, he displayed the feelings of a good heart, and exclaimed very sincerely, as well as very naturally, "How fierce is it to be thus loved! What have I done to deserve it?" Soon after his recovery, he beheld at a distance the bloody battle of Fontenoy, gained by marshal Saxe. The French were generally successful in Austria and the Dutch Netherlands, but were defeated in Italy; and their marine was totally ruined by the English. The treaty of Aix-la-Chapelle, in 1748, restored peace to Europe; and, as far as the exhausted finances of France would allow, useful plans of domestic improvement were executed; and the most splendid establishment of the reign, the royal military school, was instituted in the year 1751. About this time, some warmly contended disputes between the magnificence and clergy occasioned the interference of the king, who, instead of making a firm decision between the contending parties, upon principles of justice and true policy, acted the part of a despot, by alternately banishing both. It was in consequence of the ferment produced by these quarrels, that a fanatic, named Damien, was induced, in 1757, to attempt the life of the king at Versailles, in the midst of his guard. He received a slight stab between his ribs. Damien was evidently insane: he was instantly seized by the soldiers, and put to the rack, in which he endured the most exquisite tortures, but the wit of the most savage hearts could invent. In the midst of these he perished in an obstinate manner to declare, that he had no intention to take away the life of the king; his only object was to wound him, that Almighty God might by that means affect his heart, and thereby incline him to restore peace to his dominions. These expressions had no weight with his merciless tormentors, who conformed him to the most terrible death which they could devise. This circumstance had probably some effect on the king himself; for he soon after banished the archbishop of Paris, and accommodated matters with his parliament. The war of 1755 had brought the nation to the brink of ruin, when Lewis implored the allegiance of Spain; and on this occasion the celebrated "Family Compact" was signed, by which, with the single exception of the American trade, the subjects of France and Spain were naturalized in both countries, and the enemy of one sovereign was, to be invariably regarded as the enemy of the other. At that time, the accession of Spain to her cause only added new laurels and acquisitions to Great Britain. Lewis's attachment to a selfish and imperious multrix, madame de Pompadour, who
was allowed to appoint and dismiss ministers and commanders at her pleasure, and sacrificed every thing to her avarice and ambition, was greatly instrumental in producing the dif-
affairs which followed one another at this period in rapid suc-
cession. The conclusion of the seven years' war, in 1763, gave the nation repose, but not without a considerable di-
munition of territory; and in the following year, the society of Jefuits, as celebrated for their great learning as famous for their unbounded intrigues, was abolished in France.

The death of madame de Pompadour did not free the king from female influence, who by this time had incurred all the habits of a confirmed debauchee. He fell under the dom-
inion of madame de Barre, who, by her dilatory arts, pro-
voked his languishing defires; and his latter years, as might have been anticipated by the conduct of the former part of his life, was disgraced by the groffet sensualty. At the same time, the government became more feverish and arbitrary.

The arms of Lewis had extinguhised the flame of freedom in Corsica, in France it was revived by the breath of the parltaments, and cherished with a fond regard that threatened the most important consequences. An edict flushed by the king, which transferred from the civil and extraordinary powers to the grand council, was strenuously op-
posed by the parliament of Paris. Sixty-four members of that affembly voted for utterly abolishing that council; and the question was left by a majority of two, though all the princes of the blood attended to support the court; and the duke de Choiefuel endeavoured to overawe the independent spirit of the patriotic party, by continuing in the affembly throughout the debate. The minifter, finding his exertions in the support of defpotism of no avail, attempted to con-
ciliate those whom he had vainly endeavoured to intimidate.

Hitherto the sovereign had refited the folicitation of the people to reform the parliament of Brittany: he now aspired to popularity, by doing of his own accord that which he had been frequently importuned to grant; and the duke de Duras was sent into that province to re-efabliff the par-
liament, and to recall the members from exile. But conceal,

which a short time before would have been ascribed to the bemegy of the monarch, was now attributed to his fears; and the parliament had fearfully affembled before they con-
vinced their countrymen, that oppression had confirmed, and not extinguhised their zeal for the public welfare.

The province of Brittany had long groaned under the iron rule of the duke d'Aiguillon; who for four years had perfe-
cuted with unremitting vengeance M. de Chalotais, the attor-
ney-general to the parliament. That unfortunate gentleman had opposed, with the indignation of a virtuous magistrate, the opprefive meafures of the duke; he was therefore driven into exile, and purfued from dungeon to dungeon, till at length a fentence was procured againft him that would have involved his life, and which his cruel perfeotor was hallet-
ingsly to carry into execution. The parliament of Brittany interfered, and prevented the perpetration of fo foul a deed. The refue of M. de Chalotais laid open a ap-
fence of the blackest inquity; and the parliament of the province, poffeffed of new proofs, commenced a process against the duke d'Aiguillon, whose trial was conducted in the prefence of the king, the princes of the blood, the peers, and the parliament of Paris. Before fo high a court thus specially affembled, the written proceedings carried on against M. de Chalotais were produced, and difclofed fuch a complicated fystem of guilt and cruelty as excelled every thing that could have been imagined. Amidst these do-
mestic difquiitudes, the dauphin, afterwards Lewis XVI., received the hand of Maria Antoniette, fitter to the emperor of Germany. The crowd that eagerly prefled forward to be spectators of the fire-works, displayed on this occa-
sion, was fo great, and the confufion that prevailed was fo completely overwhelming, that several hundred persons perifhed, by being literally trampled to death. This lofs, however, which was felt in one way or other by almost all the families of Paris, did not divert the public attention from the profeffion of the duke d'Aiguillon. But at the mo-
tent that the nation was expecting, with the moft earnest folicitude, the decision of this moft important caufe, Lewis thought proper, by a violent exertion of his power, to put a ftop to the whole courfe of juftice, and to all farther in-
quiries into the conduct of the duke. All the parlaments of the kingdom made a common caufe: the ordinary courfe of juftice was fuspended; and, in conclusion, the king, in 1771, overthrew the whole fystem of judicial administration, and eftabliffed a new one.

This was not efected but with force. The language of the parliament of Paris was worthy the ignodgent feelings of free men: "Your edict, fire," fay they, "is deftructive of all law: your parliament is sworn to maintain the law; and the law perifhing, they flould perifh with it: thefe, fire, are the lust words of your parliament." Lewis, unacclimated to fuch language, prepared to sup-
pport his authority by the moft violent meafures. In the de-
ad of the night, the members were roufed from their fumbers by parties of the guards fent into each house, who prefented to every individual a lettre de cachet, which en-
roned them to declare whether they would refume the ad-
miftration of justice. In the moment of confufion, feveral of them were surprifed into acquiefcence; yet they foon re-
tracted, and, in the end, the whole body of parliament was banifhed the capital. Here then was the foundation of that revolution, which must be touched upon in the next reign, and which has introduced fuch fenes into the political world which the wildeft imagination could not have con-
ceived. The exhausted state of the finances fuggelTed new and burdenfome imposts on the great body of the people, which augmented the public difcontents. In the midft of thefe, Lewis found no folemn even in the company of his miftrefs madame de Barre: her beauty proved insufficient to excite defire; and he became difcontented with himfelf, and with all about him. A fucceffion of miftrefles became necessary to foufe the languid appetites of the king. One of thefe, who was infected with the small-pox, communi-
cated the difeafe to the king, who in a fhort time died of it, unpitied and unlaunced, May 1774, in the sixtieth year of his reign. He had left his only fon in 1765, and his crown devolved upon his grandfon.

Such was the fate of Lewis XV., who at length fell a victim to thofe fenual appetites, in the gratification of which he had sacrifced his own fame, and the welfare of his subjects. The enviable appellation of well-beloved, which he was conficious, as we have feen, he had not merited, but which had been conferred in the moment of danger by a loyal and affectionate people, was completely oblitered from memory, by 30 years of lafievous excefs, profuion, and rapacity: his example had loofened the bands of mo-
ralitv; his prodigality had exhausted the credit and re-
ources of his country; and his wanton pride had trampled upon every form that had been held sacred in the confti-
itution. His affections seemed to have been confined within the narrow limits of his perfonal pleafance and fecurity. It was by the perpetuall fuggelTions of the courjefs de Barre, that his safety was at flake, which fiumulated him to deci-
cive meafures in suppressing the parlaments of France.

Though concealed from the public eye, the embers of freed-

om were still carefully cherished, and, as will be feen in due time, burft forth with accumulated force, and over-
whelmed
The humanity but which to of y-et graphy. degraded education their any being tive out recovery hoped, prudence paft for opinion. Lewis Auguft, his and Lewis, and of Maria Jolepha of Saxony, was born in Auguft, 1754. His father carefully superintended the education of his three sons, and placed them under the direction of preceptors, who were particularly attentive to their morals, and who inftilled into their minds found principles. With respect to the subject of the preient article their cares perfectly succeeded & he, whose title at that time was the duke of Berry, was naturally modest, timid, and docile, and repaid, by his virtues, the attention bestowed upon him. In his earlier years, though he did not manifeft any brilliancy of parts, he shewed a disposition capable of attaining useful knowledge, and manifefted a memory retentive of the minutest facts. He had a found judgment, great patience and application. He ascended the throne in 1774, being then in the 20th year of his age, and, to secure himself against the dire effects of that disease, which had proved fatal to his predecessor, submitted to inoculation, with several others of the royal family. Their quick and easy recovery contributed much to extend the practice throughout the kingdom. The king, as soon as he had gained his health, applied himself diligently to extinguish the differences which had taken place betwixt his predecessor and the people. He removed those from their employments, who had given cause of complaint by their oppressions; and he conciliated the affections of his subjefts, by disdifling the new parliaments and recalling the old ones. Though the prudence of Lewis had luggled these compliances, he was anxious to preserve the royal authority pure and entire: he avowed in one of his earfliest speeches, in the great chamber of parliament, that the steps he had taken were designed to enforce the tranquility and happiness of his subjefts; and he hoped, from the zeal and attachment of the preient assembly, for an example of submission to the reit of his subjefts; he farther said, he was defirous of burying in oblivion all past grievances, and that he should ever behold with extreme diapprobation, whatever might tend to create divisions and disturb the general tranquility. It was, however, the misfortune of this monarch, as it was that of Charles I., to come to the crown at a period when a great change in public opinion had long been preparing, and was now arrived at a point, which announced a speedy criifes in the political fytem. The defpotism of the lafl two reins had exasperated men's minds, and rendered them alive to the evils of arbitrary power, while the weaknesses and debauchery of Lewis XV. had accufled the nation to regard the crown with contempt. "The profligacy of the nobles, the rapacity of the courtiers, the disputes and vices of the clergy, had fapped the foundations of focial order; and, in the mean time, a set of able and eloquent writers had arisen, who, by the united powers of argument and ridicule, aggravatad all the faults of ancient fiftabiliments, and endeavoured to subvert public opinion." The finances were in a flate of derangement, and though the king himself was extremely moderate in his expences, his economical plans were thwarted by the queen and the princes of the blood.

The final conquest of the Corficans, who, provoked by the oppreffions of their governors, had once more attempted to regain their former liberty, was the firft event of importance which took place after the reforation of public tranquility; but the kingdom was a prey to disorder from other caufes. A scarcity of corn happening to take place juit at the time that fome new regulations had been made by M. Turgot the new financier, the populace rofe in great bodies, and committed fuch enormouf outrage, that a mili- tary force became absolutely necessary to quell them. The humanity of Lewis was fhewn in an edict, which he caufed to be registered in parliament, fentencing the defperers from the army, in future, to work as flaves on the public roads, instead of punifling them, as formerly, with death; and with equal attention to the general welfare of his subjefts, he feized the moment of peace to fulfil thofe promises of economy, which on his accession he had given to the people. Particular attention was paid to the flate of the marine; and the appointment of M. de Sartine, in 1776, to that department, did honour to the penetration of the sovereign. Shortly after this, notwithstanding the danger of the example, France took a decided part in the quarrel between England and her American colonies, permitting fome of her subjefts, men of high rank and fition in the country, to crofs the Atlantic, and ferve in the republican armies. The confefion of these measures was a declaration of war on the part of England. After a variety of fortune, France and her allies succeeded in detaching America from the British crown; yet the expence of fuch widely extended operations left the French finances in a flate of aggregated disorder, while the event could not fail to operate in behalf of antimonarchical principles. In the mean time successive minifteries had adopted various and contraditory fyllems with regard to external and internal policy; and, several projects of reform had been propofed and difcufTed, with no other advantage than that of accufuming the nation to debate with freedom all public topics, and open its eyes to exciting abufes. Without pretending to enumerate the events of the preient reign as they occurred, the record of which would fill a volume much larger than that of which we can only occupy a very few pages, in the defcription of an era more important to France and the world than can be found in history; we shall only refer to fome of the more prominent events, which led to the fatal, unjust, and cruel termination of the reign and life of Lewis XVI.

Of the minifteries employed by Lewis, feveral were dif- tinguifhed for enlarged and philosophical views, though, as it afterwards proved, they were very little accommodated to circumftances and the ancient constitution of the country. Among the more remarkable occurrences of the period of which we are speaking, was the appointment of M. Neckar to the adminiftration of the finances of the country. Hi- thero France had carefully excluded aliens from the country and eftablifhed faith from the controul of her revenue; nor was it left hofible to the feelings of the court, that a perfon without rank should be elevated to fo high an office in the state: nevertheless M. Neckar was a Siftif by birth; a Protestant in religion; and a banker by profession. In the year 1780, the king fixed on the anniversary of his birth to render the day memorable in the annals of his country by a new inftrance of humanity, and abdicated for ever the favage custom of "putting the question," as it was dene- nated, that is, of extorting confiffion from perfon's property, by the instrumentality of the rack and other engines of tor- ture—a custom which had been fo long eftablifhed by the practice of ages, that it feemed to be an ineparable part of the constitution of the courts of justice in France. At the
the same time, he rendered himself worthy of public esteem, by diminishing his own expenditure, and by sacrificing the magnificence of his court to the ease of his subjects. Unfortunately, however, the popular discontent was excited in the following year, by the dissipation of the then popular minister M. Necker. He had conceived the arduous project of supporting the war by loans without taxes; and the rigid economy which he had introduced into all the departments of the household, and the various resources which he prefigured to his fertile genius, had supported him amidst the difficulties that attended his fylem. The authority of his manners, increased probably by the difficulties with which he was surrounded and interrupted, rendered him exceedingly obnoxious to the queen and persons about the court, who took every opportunity of representing the reforms, which he had introduced, as inconsistent with the dignity of the crown; he was therefore dismissed from the high office, which he had held with great reputation. The effect of his dismissal was a vast abatement of public confidence in the permanency of the late; three different persons succeeded one another in rapid succession, as finance ministers; these, however, whatever might be their intentions, served only to increase the jealousy of the people, and the failure of the celebrated "CafLe d'Economie" completed the universal confusion. The floppage of this national bank was imputed to a scarcity of specie, but the real cause was probably owing to an immense loan advanced secretly to the government. Some successful expedients revived the credit of the bank, and its stock rose to above double the original subscription; by these means public credit was restored throughout the kingdom. In 1783 M. de Calonne, who had already succcessively filled with acknowledged reputation the office of intendant of Mentz, and afterwards of the provinces of Flanders and Artois, was nominated to the post of comptroller-general. This gentleman, whose name was accidentally omitted in the alphabetical arrangement of the Cyclopaedia, was born at Douay, in 1734, educated at Paris, and became an advocate of considerable reputation. After some attendance at the bar, he obtained, as we have seen, various important trusts, till he became prime minister. When he filled this office, it was said, he did not find a single crown in the treasury. In this important office he continued about four years, and by some frugal operations he restored an apparent prosperity to the affairs of the state, and maintained the public credit by a punctuality, till then almost unknown, in the payments from the royal treasury. He laboured with unwearied industry to restore the equities between the annual income and expenditure, and to provide a supply for the emergencies of the state, without vastly increasing the burdens of the people, which, even before his administration, they were scarcely able to sustain. For this purpose, he advised the king, to revive the ancient usage of convening national assemblies of the Notables, to whom he proposed the bold project of supressing the pecuniary privileges and exemptions of the nobility, clergy, and magistracy. This measure was too daring even for him to carry; it excited indeed so much ill-will and determined hatred from these powerful bodies, that M. de Calonne found it necessary to retire to England, where he wrote two defences in justification of himself and his measures. At the end of the war he returned to Paris, where he died in 1802. He was author of several other works, on the situation of his country, and on the fate of its finances.

The Notables, because there were to be selected by the king from the different orders of the state, and therefore it was expected they would the more readily submit to the guidance of the court. This assembly had been convened by Henry IV. and again by Louis XIII. and was now to be summoned by the authority of Louis XVI. The writs for calling them together were dated the 29th of December 1786; and they were addressed to seven princes of the blood, nine dukes and peers of France, eight field marshals, twenty-two nobles, eight counsellors of state, four masters of requests, eleven archbishops, thirty-seven persons high in the profession of the law, twelve deputies of the pays d'états, and twenty-five magistrates of the different towns in the kingdom. The first meeting of this assembly, in the month of February 1787, disclosed an enormous deficit which had hitherto been concealed. Great taxes were proposed to make good the deficiency, which the parliament of Paris refused to register, and thus refusing, that body was immediately banished the capital. The duke of Orleans, a man who disfigured the worst principles, and the most criminal ambition under the mask of patriotism, and who probably, from this moment, was perpetually engaged in intrigues to ruin the king and subvert the constitution, having entered a protest in favour of the parliament, partook of its punishment. Various measures, some harsh, some conciliatory, succeeded, all displaying the embarrassment of the government, and the progress of the public discontent. M. de Calonne was now dismissed; Necker was recalled; and at length, after a third convocation of the notables to no good effect, it was resolved to adopt the alarming expedient of calling together an assembly of the states-general, a circumstance that was looked on with anxious dread by the partisans of the court, and which was anticipated with pleasure and delight by those who were hoping for some radical change in the affairs of the state. On the dissolution of the notables, they were addressed in a moderate and very conciliatory speech from the throne. During the delay, the popular caufe had still been gaining ground in the public mind, by meetings held in the capital and provinces, at which the utmost freedom, and no small quantity of violence, in discussing political points, were indulged, and men of the inferior classes were accustomed to act in concert, and become familiar with their own strength.

The time appointed for the convention of the states-general was now approaching, and the means of assembling them formed a matter of difficult deliberation in the cabinet. The last meeting, in 1614, had been convened by application to the bailiwicks. This mode was liable to strong objections; the bailiwicks had been increased in number and jurisdiction, several provinces having, since that period, been united to France; and the numbers and quality of the members were no leas an object of serious attention; it was not, therefore, till the close of the year, that the proposal of M. Neckar was adopted, which fixed the number of deputies at 1200 and upwards, and decreed that the representatives of the third estate or commons should equal in number those of the nobility and clergy united. It remained now, as a matter of vast importance, for the popular party to carry the measure of the votes being taken, not by orders in three distinct houses, but by numbers in one house. As this would infallibly throw the whole power into the hands of the third estate, it was long and vigorously opposed by the royalists and aristocratic parties. At length the commons, thinking themselves sufficiently supported by the voice of the people, declared themselves "The National Assembly," and assumed the whole legislative authority. (For an account of the great operating and immediate
The events of the French Revolution, with which this account is primarily concerned, had their roots in the violent and momentous contentions which occurred in every part of the kingdom, and particularly in Paris, where the king, never ready to his purpose, fluctuated between the opposite councils. His chief desire was, evidently, to preserve tranquillity, and prevent the effusion of blood, and he was prepared on his own part to submit to any sacrifices for this purpose that might be required of him. The flates had been summoned to meet at Versailles on the 27th of April, and most of the deputies arrived at that time; but the elections for the city of Paris not being concluded, the king deferred the commencement of their sittings till the 4th of May. During this period, the members assembled, having little to do, spent their time in forming an intimacy with each other. Some of them united themselves into a club, into which none were admitted but those who were deemed zealous advocates for the popular cause. This society, originally formed at Versailles, was, hereafter, found sufficiently powerful to give laws to France, under the appellation of the Jacobin club, and to excite an almost universal terror and alarm through Europe. The flates-general commenced their business by going in solemn procession, preceded by the clergy, and followed by the king himself, according to ancient custom, to church, to perform an act of devotion. The nobles and superior clergy were splendidly arrayed; the commons appeared in black. The assembly was now opened by a short speech from the throne, in which the king congratulated himself on thus meeting the people assembled; and having alluded to the difficult circumstances in which they were placed, he concluded with the following prayer, "May an happy union reign in this assembly, and may this epocha become ever memorable for the glory and prosperity of the country. It is the wish of my heart; it is the most earnest desire of my prayers; it is the price which I expect from the sincerity of my intentions and my love for my people." Several weeks were spent in discussing mere matters of form; in the mean time the people from without were vexed that no important step was taken to remedy the evils under which they labour. They imputed this delay to the nobles and clergy, who became exceedingly unpopular. The leaders of the commons, called at that period the tiers etat, took advantage of the change which was taking place in the minds of their countrymen, and formed the project of seizing the legislative authority of France; they almost instantly declared that the representatives of the nobles and clergy were only the deputies of particular incorporations, whom they would permit to sit and vote among themselves, but who had no title in a collective capacity to act as legislators of France. Some of the clergy had joined them; and they then proceeded to announce themselves, by a solemn decree, the sovereign legislators of their country, under the name of the National Assembly. M. Bailly, the celebrated astronomer, was the first president; its earliest acts were decisively expressive of its own sovereignty. This was in the middle of June, and by the 19th a majority of the clergy voted for the verification of their powers in common with the national assembly, and they resolved to unite with them on the following day. At this important crisis the nobles perceived, that unless they could make a decisive stand all would be lost; they accordingly addressed the king, intimating him to dissolve the flates-general; and on the next day, the 20th, when the president and members were about to enter as usual into their hall, they found it surrouned by a detachment of the guards, who refused them admission, while the heralds at the same time proclaimed "A royal fession." Alarmed and irritated by this unexpected event, they instantly retired to a neighbouring tennis-court, where, in the vehemence of enthusiasm, they took a solemn oath, "never to separate till the constitution of their country should be completed." The royal fession was held in the most splendid form, but altogether in the style of the ancient deputations; the superior orders were seated while the commons were kept an hour in the open air, while it rained, before they were admitted. The king now assumed a high tone, delivered his speech, ordered the deputies to retire, and then left the assembly. He was followed by the nobles and part of the clergy, but the commons and those attached to them remained in gloomy silence, which being interrupted by an officer of the crown, who was left to see the intentions of his majesty carried into effect, the count de Mirabeau, flaring from his seat, indignantly exclaimed, "The commons of France have determined to debate; you, sir, who have neither seat nor voice, nor a right to open your lips here, are not to remind us of the king's intentions. Go tell your master, that we are here by the power of the people, and that nothing shall expel us but the point of the bayonet." The king gave way, and at first, anxious to spare the blood of his people, recommended the higher orders to join the deputies of the commons; but, in a few days, he saw, or was persuaded by the queen and her party, that the obvious tendency of the popular measures was the entire subversion of all monarchical power; he therefore gave orders for the assembling of troops around the capital, and ventured upon the step of dismistling Neckar, and commanding him instantly to quit the kingdom. Paris burst into a flame upon this unexpected event; commotions took place; the soldiers were commanded to suppress the turbulent assemblies; but they without hesitation grounded their arms instead of firing on the people; a vast body of national militia was organized, who supplied themselves with arms from the arsenal of the invalids, and on the memorable 14th of July, 1789, hostilities against the royal authority openly commenced by the storming of the Bastille. Resistance to the popular torrent was now in vain; the king recalled Neckar, who returned amid the acclamations of the whole nation, and resumed the reins of government. Schemes for a new constitution and new measures of finance were discussed with calms and composure, till a scarcity of provisions, joining with other causes of public agitation, inspired the populace with uncontrollable fury. In the beginning of October a dreadful insurrection took place, in which an immense armed mob marched to Versailles, broke into the palace, massacred some of the guards, and compelled the king, with the queen and his family, to accompany them to Paris. The triumph of the popular party was followed by the emigration of some of the most zealous friends to royalty, who carried into foreign countries a desire of exciting those hostile interferences on the part of the neighbouring powers in the affairs of France, which in the end proved destructive to the king and his family. On the 19th of October the national assembly, which had followed the king to Paris, opened its first session; and a constitution was speedily formed on the basis of a limited monarchy; a decree was passed, which put an end to all distinction of orders and immunities, so far as privileges were concerned, and the whole of the lands belonging to the church were confiscated for the purpose of supplying the exigencies of the state. This measure was proposed by M. Talleyrand, the bishop of Autun, who afterwards took a lead in the revolution. A provision was, at the same time, made for the national clergy, who were in future to be paid by the state. On the day following that, on which this important measure was adopted, a decree was passed, suspending the parliament of the kingdom.
dom from the exercise of their functions. During the winter the king had been strictly watched by numerous guards placed round his palace, so that he was regarded as in a state of captivity. To obliterate this impression, if possible, he appeared in the assembly, and in the presence of the deputies of the nation made a solemn declaration of his resolution to adhere to and defend the new constitution to the last moment of his life. On the 14th of July it was determined to commemorate the destruction of the Bastille, that fortress of despotism: never was a more splendid spectacle. The national assembly and the court joined in the procession that was made on the occasion, and when every thing was properly arranged to create effect, the king, after a serious invocation to God, approached the altar, and amidst the most solemn and awe-inspiring silence, took the following oath: "I, the king of the French, do swear to the nation, that I will employ the whole power delegated to me by the constitutional law of the state, to maintain the constitution, and enforce the execution of the law." The national assembly then took oath of fidelity to the nation: as did La Fayette and others in the name of the national guards. After this a "Te Deum" was sung, the performance of which was sublime beyond the power of description. "Never," says the historian, "was there before such an orchestra, or such an audience; their numbers baffled the eye to reckon, and their shouts in full chorus rent the skies. It is impossible to enumerate all the means which were employed to add splendour to this day. It ended with a general illumination, and no accident occurred to disturb the public tranquility."

Several new efforts were now making by the disaffected among the nobles and clergy to excite disturbances in various parts of the kingdom. Emigration became more frequent, and comprehended the king's aunts, and most of the princes of the blood, while troops were collected and openly formed into an army on the frontiers. The public fulminations were naturally kept awake by these circumstances, and popular ferment occasionally broke out in the capital and provinces. In April, 1791, the king and his family preparing to go to St. Cloud, to spend the Easter holidays, were forcibly stopped by the people, who were unfriendly to the king, and determined to quit the capital. La Fayette drew out the national guard, but they, with one consent, refused to act against the citizens: "We know," say they, "that we are violating the laws, but the safety of our country is the first law." The king went to the assembly and complained of the insult: he was answered respectfully by the president, and continued his journey. He now endeavoured to convince foreign courts that he was no longer in a state of thraldom, declaring his cordial assent to the new order of things.

About this period, M. de Bouillé, to whom the protection of the frontiers was entrusted, was employing every means in his power to render the country defenceless. The garrisons were left unprovided; diffusion was spread among the national troops, who were removed from the frontiers, and their place was occupied by foreigners, wherever it could be done. The emigrants abroad, and their friends at home, were lying in wait for an opportunity of revolt; when suddenly, on the 21st of June, it was announced from the Thilleries, that the king, the queen, their children, together with the king's eldest brother and his wife, had quitted the palace and the capital. The national assembly took upon themselves the government, and decreed their fittings to be permanent: they sent at the same time messengers in all directions to attempt to lay hold of the fugitives. At Varennes they were stopped, arrested, and brought back to Paris in triumph. The alleged reason for this departure was the danger and infilt to which the king, and more especially the queen, were exposed, from the licentious violence of the Parisian mob; but there is no doubt that it was connected with the plans of the emperor Leopold and the emigrants, who were prepared, by force of arms, to make a grand effort in behalf of a counter-revolution. The king's brother, with his comfort, who took a different route, made their escape. The national assembly proceeded with their labours, which they brought to a conclusion on the following September. The constitution, as fixed on at that time, was presented to the king, who solemnly accepted it, and swore to maintain it inviolate. On the 30th of September, the national assembly, which has been known since by the name of the "Constituent Assembly," dissolved itself, and gave place to the succeeding "Legislative National Assembly," which had been elected according to the rules prescribed by the new constitution. It was soon evident that France would have a foreign war to fulfill with the powers coalesced for the restoration of the ancient monarchy, and for the further purpose of making conquests upon the French territories. In proportion to the national danger, the fulminations of the people increased, and their loft confidence in the king could never be recalled. New jealousies were excited by the interposition of the royal negative, allowed by the new constitution, against two decrees of the assembly, one levelling at the emigrants, the other at the non-juring priests. War was declared by the assembly against the emperor in April, and armies marched to the frontiers. A decree paffed the assembly for forming a camp of 20,000 men near Paris, which Lewis, conceiving it a plan designed to overawe the more moderate party, and strengthen that of the Jacobins, refused to function, as he did likewise a severe decree against the refractory clergy. He also diminished some of the popular ministers who had been forced upon him. The discontent which these measures excited burst out into a furious insurrection on the 20th of June, in which an armed mob made their way into the Thilleries, and treated the royal family and their attendants with the grossest personal insults. The king displayed on this, as on all other occasions, great fortitude; and in reply to threats against his life, repeated in the lowest and coarsest language, he exclaimed, "Alas! would that my life could secure the happiness of the country, how readily would I offer it as a sacrifice." A calm now succeeded, in which the king and the national assembly appeared to unite in plans for the defence of the country: in the mean time dangers were accumulating, and the approach of the duke of Brunswick, with the Prussian army, preceded by a most menacing manifesto, in which the king's accession to the new constitution was represented as a mere involuntary compliance, incited the people almost to madness. The republican party determined to take advantage of this circumstance, with a view of deposing the king, and instituting a republic. At length, Petion, the mayor of Paris, appeared at the head of the factions, at the bar of the national assembly, to demand the deposition of the king. This was on the 9th of August; and at fix on the following morning the king was seen reviewing his troops. He was received at first with shouts of Vive le roi, which were shortly overwhelmed with those of Vive la nation. The king returned to the palace, and the multitude continued to collect. The national guard seemed undetermined what to do as they assembled in divisions near the palace, and, having a Zealous resistance been made from within, it has been thought they would have joined the royal party. The king was advised to seek protection in the hall of the national assembly: he was willing to comply;
but the queen opposed, with vehemence, the humiliating proposal, till actual danger surrounded her person and children; she then confounded, and the king, queen, the princes, Elizabeth, the king's sister, with the dauphin and princes of royal, went on foot to the hall of the assembly. "I am come hither," said his majesty, as he entered the doors, "to prevent a great crime. Among you, gentlemen, I believe myself in safety." By an article of the constitution, the assembly could not deliberate in presence of the king. The royal family were, therefore, placed in a box separated from the hall, where they remained 14 hours, without refreshment, obliged to hear discussions in which the royal character and office were treated with every mark of infult. At length the fatal decree was passed that the royal authority should be suspended, and the nation was invited to elect a Convention, to determine on the nature of its future government. On that fatal day a numerous body of insurgents attacked the palace of the Thulleries, which was defended by Swiss guards: a bloody engagement ensued, which terminated in the massacre of the greatest part of the Swiss, and several other regiments. As soon as the royal authority was suspended, the king and his family were sent to the Temple as a state prison. Maffeace succeeded upon massacre, till at length, on the second and third days of September, the most cruel and savage scenes were exhibited that were ever witnessed in a civilized country. More than a thousand state-prisoners were basely and infamous murdered by the ruffians of the capital, among whom was the beautiful princess of Lamballe, whose bleeding head was carried on a pike through the streets of the city, and under the windows of the room in which the queen was confined, whose intimate favourite she had been. These acts, to which the royal family could not be strangers, they might well regard as preludes to their own death; there was no party left in the country to espouse their cause; and no individual durst lift up his voice in their defence. The new convention was assembled on the 29th, and their first decree was the eternal abolition of royalty, which was carried by acclamation: this object being attained the house adjourned, and copies of the decree was sent into every village and commune of France. The most violent measures were adopted; nor could the moderate party in the convention restrain the madness of the Jacobins, who were bent on levelling all distinctions; to bring into contempt every thing in letters and in science that was in the least raised above the comprehension of the lowest of the people. The intention was soon avowed of bringing the king to trial. It was in vain that those, who were anxious to save his life, appealed to the inviolability of his person, declared by the constitution he had accepted: principles, however sacred, were made to yield, and a committee was appointed to give in a report upon his conduct. The result of this was, that various accusations were brought against him, and the convention resolved to take upon themselves the part of accusers and judges. On the 11th of December, the fallen monarch was brought to the bar to answer to the heads of accusation drawn up against him for the crime of tyranny and treason towards the nation. He defended himself with judgment and presence of mind, and received the advice and assistance of three eminent advocates, who generously and nobly undertook his cause, though with great hazard to themselves. The proceedings were carried on till the 26th of December, when M. Defeze, one of his advocates, read a defence of his client, which being finished, the king rose, and holding a paper in his hand, pronounced, in a calm and dignified manner, and with an impassive tone of voice, "Citizens, you have heard my defence; I now speak to you, perhaps for the last time, and solemnly declare that my counsel have afforded nothing to you but the truth; my conscience reproaches me with nothing." The discussion was finally closed on the 16th of January; and after a sitting of 34 hours, the punishment of death was awarded by a very small majority of the convention. M. Defeze then invoked the assembly, in the name of his colleagues, to consider by what a trifling majority the punishment was pronounced against the deposed monarch: "Do not afflict France," said he, "by a judgment that will appear terrible to her, when five voices only were presumed sufficient to carry it." He appealed to the eternal justice and sacred humanity, to induce the convention to refer their sentence to the tribunal of the people. "You have either forgotten or destroyed," said M. Tronchet, another of the king's advocates, "the lenity which the law allows to criminals, of requiring at least two-thirds of the voices to constitute a definite judgment." The sentence was ordered to be carried into execution without delay. The king and his family had been kept separate from each other; but he was now permitted to see them. The short interval allowed him employed in the preparations for death enjoined by his religion, to which he was sincerely attached. The final meeting and separation of the king from his family was affecting in the extreme. On the morning of the 21st of January, at eight in the morning, he was conducted to his fate. He ascended the scaffold with a firm and dignified step; and his behaviour there partook of the calm fortitude which had distinguished him through all his scenes of suffering. Raising his voice, he exclaimed, "Frenchmen, I die innocent; I forgive my enemies." He would have proceeded, but was prevented by the beating of the drums, placed on the spot purposely to drown his voice. The executioners came forward to perform the bloody deed, which being perpetrated, the bleeding head was held up to the view of the surrounding crowd, of whom some few exclaimed "Vive la Republique!" but the great mass of spectators was too deeply absorbed in thought to join in the shout which the leaders attempted to excite. The body of the deposed victim was thrown into a pit filled with quicklime, and a guard placed around it till it should be consumed. The unhappy monarch was in the thirty-ninth year of his age, and the nineteenth of his reign. He left two children, a son and a daughter, of whom the son died very miserably in 1795, and his father in the following year. The queen was brought to the scaffold in 1793, and his father in 1794. Such were the misfortunes to which this royal house was subjected. Lewis XVI. possessed from nature a good understanding, which, however, was blunted by the early indulgences of a court. He had a strong sense of justice, and his humanity was much superior to what could have been expected from a person in his high station in life. By polternity he will be regarded as one of the best and most virtuous of the French kings. He had acquired a large portion of general knowledge, and on some literary subjects he entered rather deeply. He wrote well, and excelled in clearness of expression and methodical arrangement. In vigour of mind he was unquestionably deficient: but in reviewing the history of the period, we cannot conceive how he could have acted so as to have successfully opposed the voice of the people. It was his misfortune to have fallen on difficult times; he could not stem the torrent of public opinion; and it is probable that few princes, if any, would have been capable of extricating themselves from such difficulties as surrounded Lewis XVI. during a great part of his calamitous reign. For farther particulars relating to Lewis's of France, the reader is referred to the Modern Universal History; to the History of France, London, 1790; and
and to the History of the French Revolution, by Rabaut St. Etienne.

LEWIS, JOHN, a learned English divine, was born at 
Bristol in 1675. He was educated in grammar learning at 
the free-school of Wincanton, in Dorsetshire, and received 
his academical education at Exeter college, Oxford, where he took 
his degrees. Having been ordained, he officiated some time 
as curate of St. John's, Wapping. In 1699 he obtained the 
rectory of Acri, in Kent, which he resigned in 1706, when 
he was presented by archbishop Tenison with the rectory of 
Saltwood in Kent, with the chapelry of Hythe annexed. He 
was afterwards collated to the vicarage of Minster, in 
the Isle of Thanet, and in 1719 archbishop Wake constituted 
him master of Ealdfrithe hospital, in the city of Canterbury. 
He died at Margate in 1746. He was author of 
a great number of publications, which reflected credit 
on his industry and learning; among these are "The Life of 
Wickliffe;" "Wickliffe's Translation of the New Testa-
ment;" "The History and Antiquities of the Isle of Than-
et;" "The History of the Abbey and Church of Fever-
ham;" "The Life of William Caxton;" "The History 
of the Translations of the Holy Bible and New Testa-
ment into English."

LEWIS, in Geography, is the most northern, and the largest 
of the Hebrides, or Western Islands, of Scotland. It is 
connected with the island of Harris by a narrow isthmus, 
which at low water is left entirely dry, and even at high 
water is not completely covered; whence the whole may be 
considered as one island. (See Harris.) The Isle of Lewis 
is of very irregular form and boundary; and extends about 
50 miles in length from north to south; by about twenty, on 
an average, in a transverse direction. Towards the centre 
the land is mountainous and boggy; but near the shore it is 
rather flat, and is intersected by numerous inlets or bays of 
the sea. The island is almost deftite of wood; a few 
birchles, hazels, and a little heath, being the only species of 
shrubs seen here; but it is said that Lewis was formerly 
covered with plantations; the decay and destruction of which 
contributed to form the peat-earth, with which the island 
abounds. Springs, lakes, and rivulets, scattered through 
the island, furnish in all parts abundance of fresh water. 
With respect to the climate, the spring is uncommonly cold 
and backward, the summer warm, the autumn accompanied 
by profuse rains, the winter without long or severe frosts, 
or very weighty falls of snow, but with constant winds, and 
thickly covered with snow, and the great cold and 
sharply cold. Among the wild animals, the stags 
produce deer or roes. Great numbers of wild 
owls of many different species frequent the shores, the lakes, 
and the cliffs of the mountains; among others, is the eider 
goose, the down of which is held in high estimation. 
Immense flocks of fife, of an innumerable diversity of kinds, 
haunt the coasts.

The island is intersected by arms of the sea, called lochs, 
which run to a considerable distance inland, both from the 
eastern and western sides. One of the chief is loch Roa; 
on the west, which is two leagues in breadth at the entry, 
and runs up, in a south-easterly direction, about twelve 
miles into the island. This loch contains several islands, 
some of which are inhabited; one, called Large Bernera, is 
eighty miles in length. The whole of this curious loch 
abounds with falls and burnes, sufficient to hold the 
whole of the island's water, or even that of all Europe. About 
140 tons of kelp, of a superior quality, are annually made 
from Loch Roa. On the eastern coast, loch Seaforth runs 
into the country to a great distance; loch Kyle and loch 
Leurbilt advance also far inland from the east; but loch 
Stornaway is most important, on account of the town which 
stands near it, and which is the capital of the island. On 
the coast, in this parish, is a large cave, into which the 
sea enters at high tide; this cavern is only accessible from the 
sea. When it was first noticed, a great number of seals were 
killed annually in it; and the practice is still continued. The 
entrance of the cave is very steep and narrow, and does not 
 admit more than the breadth of a fix-oared boat. The in-
terior is divided by a large pillar into two arches. Its whole 
length is about an English furlong.

The island of Lewis is divided into four parishes; named 
Barvas, Lochs, Stornaway, and Uig. It has various small 
fleets attached to it. In the parish of Barvas is the island 
of Rona, which is a mile in length, and half a mile in 
breadth; it is situated in the northern ocean, and is 
forgotten in the farthest to the north-west of any land in Eu-
rope. The parish of Lochs derives its name from the great 
number of lakes which are intersected over its surface. It is 
about nineteen miles in length and nine in breadth: along 
the coast it has a bold and rocky appearance; in the interior it 
is barren and inhospitable. About 50 tons of kelp are manu-
factured here annually; and the greater number of the in-
habits are employed in the fisheries on the coast. The 
parish of Stornaway is of very great extent; but the in-
habited part is of a triangular form, of which two of the sides 
are about ten miles, the other being the town of Storna-
way, from a very small origin, has, of late, by the exertions 
of lord Seaforth, arrived at a considerable extent. The 
harbour is excellent, and well frequented; the principal 
source of employment is the prosecution of the white and 
hering-fisheries in the bays, in which about 35 or 40 small 
vesseis are annually fitted out. It is a port of call for the 
fishermen, and has a post-office, and a regular weekly packet. 
The town of Stornawa-
way, in general, well built: here are a 
convenient culm-house, a town-house, a commodious 
chapel, an assembly-room, and two school-houses. On an 
early occasion, near the town, Stornaway lodge, the seat 
of lord Seaforth, who is the proprietor of the island. The 
parish of Uig is fifteen miles in length, and thirteen in breadth; 
the interior is hilly, covered with heath, and intersected with 
small lakes; the coasts are mostly level and cultivated. 
The fisheries and the manufacture of kelp are here also the 
chief sources of subsistence to the inhabitants. Near the hamlet 
of Calarnish, at a short distance from loch Roa, is a Druid-
tical temple, formed by a circle of twelve stones or obelisks, 
each about seven feet high, and six feet distant from each 
other; in the centre is one of a larger size, thirteen feet 
from the ground; directly south of the circle are three 
obelisks, standing in a line; another such to the west, and 
one to the east; each stone being nearly equal in size, and 
arranged at equal distances. Towards the north are two 
straight ranges of obelisks, forming an avenue to an opening 
between two of the stones which form the circle. Each of 
these ranges consists of six stones, regularly placed, one 
opposite to another. All the stones are in a rough natural 
itate, as taken from the stone. At Melita are the 
remains of a nunnery, still called in the Gaelic Teagh nan caill-
chun dou, "the house of the old black women." At Caila-
way is a Danish fort, quite circular, with a double wall of 
stone, thirty feet in height. This is broad at the base, and 
narrower at the top, like the frustum of a cone. In the 
year 1794, there was living in this parish a lady of the nature, of 
which Mr. Monro, the minister, gives the following account 
in his statistical report to Sir John Sinclair. — "Very near 
the manse there lives a woman, who has four dillent breasits 
or mamme. She has had several flouts, healthy children, and 
fucked them, and likewise one of the minister's children. 
She has nipples and milk in each of the four breasts; the
two upper are situated under the arm-pits, and by being diff
tended with milk, are very troublesome to her for the first
two or three months after delivery.

The population of Lewis, in the year 1796, was 8311;
which was an increase of 1925 from an enumeration which
was made in the year 1755. The inhabitants of the whole
island are scattered, for the most part, in single families, or
clusters of two or three families, around the coast, or through
the interior parts. Some large tracts are without inhabit-
ants; while upon others the population is more closely af-
fixed. There is scarcely any regular road: the moor,
which reaches across the island from Stornaway to Uig, is
so extensive and soft, that it would require the labour of
many ages to form a regular road through it. Martin’s De-
scription of the Western Islands of Scotland, 8vo. 1716.
Buchanan’s Travels in the Western Hebrides, from 1782
to 1790,” 8vo. 1795.

Lewis, a town of America, in Essex county, S.W. of
Leningtom adjoining, in Vermont; about 8 miles S. of
the Canada line.

Lewis Creek, a small stream in Vermont, which falls into
lake Champlain at Ferrisberg, a little N. of Little Otter
creek.

Lewis and Richford, a town in Sussex county, Delaware,
containing 1514 inhabitants.

LEWISBURG. See Louisburg.

Lewisburg, a county in Orangeburgh district, South Car-
fonia.—Alfo, a poft-town of North Carolina, and capital of
Franklin county, which lies on Tar river, and contains be-
tween twenty and thirty houses, a court-houfe, and gaol;
30 miles N. of Raleigh.—Alfo, a poft-town and chief
town of Greenbriar county, Virginia, on the north side
of Greenbriar river, containing about fifty houses, a court-
houfe, and gaol; 250 miles W. by N. of Richmond.
N. lat. 38° 8’.—Alfo, a poft-town of Northumberland
county, Pennsylvania, called alfo “ Taritown,” on the
W. side of the Susquehanna, 7 miles above Northumberland;
containing about 60 houses, and well situated for a good
trade with the N.W. part of the state; 30 miles E. by N.
from Aaronsburg.

LEWISHAM, a populous village, in the upper half-
hundred of Blackheath, lathe of Sutton at Hone, and
county of Kent, England, is situated 5 5 miles from London,
and extends nearly a mile in length on the road to Bromley.
Here was anciently a Benedictine priory, subordinated to
the abbey of St. Peter in Ghent, and most probably founded in
the Saxon times; this manor having been given to that
abbey by Ethelrude, niece to king Alfred. After the fup-
prefion of the alien priories, Henry V. made this a part of
the endowment of his newly erected Carthusian priory at
Shene. Lewisham is now the property of the earl of Dart-
mouth, whose seat on Blackheath is within the bounds of
this parish. The present church was erected in the year
1774; its form is that of an oblong square, with a semi-
circular recess at the east end for the altar. It contains two
handsome monuments: one to the memory of Anne, wife
of John Petrie, c(q.), was executed in Italy; it includes a
fine bas-relief in marbre, representing the deceased on her
death-bed, with her husband and children lamenting round
her. The other commemorates Margaret, relict of the
Rev. Robert Petrie, and was sculptured by Banks; it re-
presents Mrs. Petrie dying in the arms of Religion, sup-
sported by Faith and Hope. Many old monuments were
thrown carelessly into the vault, when the church was re-
built. An excellent free grammar school was founded by the
Rev. Abraham Colfe, who was rector of this parish from
the year 1610 to 1657. His will contains the regulations
of the school, and directs that it shall be for the education
of thirty-one boys of the several parishes therein named; one
scholar yearly to be sent to either of the universities. He
also founded an English school here for thirty-one boys,
and an almshouse for five “poor godly householders.”
The population of Lewisham, as returned under the act of
1800, amounted to 4007; the number of houses to 722.
In this enumeration was included the chapelry of Sydenham,
noted for its medicinal springs. Brayley's Beauties of Eng-

LEWISTOWN, a poft-town in Lincoln county, Maine,
on the east side of Androscoggin river, and bounded south-
west by Bowdoin; containing 948 inhabitants; 36 miles
N.E. of Portland.—Alfo, a poft-town, called “ Lewes,”
in Sussex county, Delaware, pleasantly situated on Lewes
creek, three miles above its mouth in Delaware bay; con-
taining a Presbyterian and Methodist church, and about 80
houses, in a tract more than three miles in length, extend-
ing along a creek which separates the town from the pitch
of the cape. Its situation is high. The court-houfe and
gaad are commodious buildings; the entrance of the bay is
crowded with vessels from all parts of the world, but during
part of the winter is closed with ice. The circumjacent
country is beautifully diversified with hills, woods, streams,
and lakes, but much infested with mosquitoes and sand-flies.

Northumberland county, Pennsylvania, was founded
in 1786 by the Rev. John Miller, D.D., and was incorpo-
rated in 1787. It contains 159 villages, and 15333
inhabitants.

—40° 32’ W. long. 75° 18’.
—Alfo, the chief and poft-town of Mislim county, Pennsyl-
vania, situated on the north side of Juniata river, on the
west side of, and at the mouth of, Cimicoquilis creek;
about 23 miles N.E. of Huntington; regularly laid out,
incorporated in 1795, and containing about 120 dwelling-
houses, 523 inhabitants, a court-houfe, and gaol; 150
77° 23’.

LEWUNAKANNEK, a town on the Ohio, in which
is a settlement of Christian Indians, formed by Moravian
missionaries.

LEX, LAW. See LAW.

Lex Amista, or legem amittere, in Law, is understood
of an infamous, injurious perfon, who is said to have
instead of the former. See In-
famous.

Lex Judicatius, is properly purgatio, per judicium ferris;
sometimes called simply judicium.

Lex Sacramentalis, purgatio per sacramentum. See OATH
and Purgation.

Lex Talionis. See TALIO.

Lex Terre, the law and custom of the land; by which
name it is distinguished from the civil law. See Common
Law.

LEX, Legem terra amittere. See AMITTERE.

LEXAWASCEIN, in Geography, a small river of
Pennsylvania, which rises by several branches in Northam-
ton county, Pennsylvania, on the east side of mount Ararat,
which unite about 10 miles from its mouth in Delaware
river. It joins the Delaware, after a south-east and east
course, about 174 miles above Philadelphia.

LEXEN, a town of Moravia, in the circle of Olimutz;
18 miles N.W. of Olimutz.

LEXIARCHI, Lexiarches, at Athens, the civil officers, as-
signed by thirty inferior ones, whose business it was to lay
the foundation upon which such as came not in the public assemblies, and also to make scrutiny among such as were present.

The lexarchi kept a register of the age, manners, and
abilities of all the citizens, who were always enrolled at the age of twenty. 
LEXICON, *λικον*, the same with dictionary.

The word is chiefly used in speaking of Greek dictionaries: it is derived from the Greek λικον, word, dictio; of λικον, I speak.

LEXINGTON, in Geography, a county of America, in Orangeburg district, South Carolina.—Alfo, a post-town of Virginia, and capital of Rockbridge county; situated on the post-road from Philadelphia to Kentucky, by way of the Wilderness, and about a mile south of the north branch of James’s river; containing a court-house, gaol, and about 100 houses. Its situation is agreeable and healthy, and the adjacent country highly cultivated. Near it is “Liberty-hall Academy,” now ”Washington College,” built of stone, and capable of containing forty or fifty students, and handsomely endowed by the distinguished perfonage whose name it bears. The town is 159 miles W. by N. of Richmond.—Alfo, a post-town of Kentucky, formerly the metropolis of that state; situated on a rich extensive plain, in Fayette county, on the north side of Town fork, a small stream, that falls into the south branch of Elkhorn river. The town is built on a regular plan, and contains about 350 houses, five places of public worship, a court-house, and gaol, and also an university, with several manufactories and store-houses. It is an agreeable flourishing town, on the head waters of Elkhorn river; 24 miles E. of Frankfort. The number of inhabitants is 1735. Near the town was found, upon digging five or six feet deep, a large flat stone, covering a well, artificially floored; and in its vicinity are also the remains of two ancient fortifications, furnished with ditches and bastions, overgrown with large trees.—Alfo, a post-town in Rowan county, North Carolina, 359 miles from Washington.—Alfo, a small post-town of Georgia, formerly called the “Great Falls,” situated on the south side of Ogeechee river, on a beautiful eminence which overlooks the falls of the river; 2 miles from George-town.—Alfo, a town in Middlesex county, Massachusetts, 11 miles N.W. of Boston, having a neat congregational church, and a number of compact houses. This town has been rendered famous by being the scene of a battle, fought April 19, 1775, which may be considered as the commencement of the American revolution. On the ground where this battle was fought is a stone monument, 10 feet high, with the following inscription: “Sacrificed to Liberty, and the Rights of Man-kind!! The freedom and independence of America sealed and defended with the blood of her foes, &c., &c.” Concluding, “The die was cast!!! The blood of these martyrs, in the cause of God and their country, was the cement of the union of these states, then colonies, and gave the spring to the spirits, firmness, and resolution of their fellow-citizens!!” More.

LEY, in Agriculture, a term used to signify land in the state ofward or grafts.

LEY, Sr James, in Biography, a learned English judge, who flourished in the seventeenth century, the son of Henry Ley, esq. of Jeflont, in Wiltshire, was, on account of his great merit, made lord chief judge, first in Ireland, and afterwards in England. He was likewise created baron Ley, lord high treasurer, and earl of Marlborough. His reports were printed in the year 1659.

LEY. See LIXIVIUM.

LEYBA, in Geography, a town of South America, in New Granada; 30 miles N.N.E. of Santa Fe da Bogota.

LEYBourNE, William, in Biography, a mathematician, was originally a printer in London. He published a course of mathematics, which was held in considerable estimation. He was author of a treatise on Surveying, a work on Dialling, and another work, entitled "The Trader’s Guide." He died about the year 1690.

LEYDECKER, Melchior, a Dutch divine, was born at Middleburg in 1652. Having received a good education, he officiated as pastor of a church in his native place; and in 1675 was appointed professor of divinity at Utrecht, and soon after took his degree of doctor in divinity. He died in 1721. He was deeply read in theology, ecclesiastical history, and rabbinical learning; but he had no taste for polite literature, and was exceedingly bigotryed to his own notions. Still he was deferous of uniting the Lutherans and Calvinists, and made some ineffectual efforts for the purpose. He was a voluminous writer, and his works are all written in Latin; of thefe the chief are, "A Treatise on the Republic of the Hebrews," in 2 vols.: "An Analysis of Scripture, with Rules for Preaching;" "A History of Judaism;" "A Continuation of the Ecclesiastical History of Horneas, with Notes;" and "A History of the Church of Africa,"

LEYDEN, in Geography, a city of Holland, the "Lug-dunum Batavorum" of Ptolemy, and the "Caput Germanorum" of Antoninus’s Itinerary, is the capital of a small district, called "Rhynd," comprehending 49 towns or villages, and, next to Amsterdam, the largest and most populous city of Holland; the number of inhabitants being estimated at about 50,000. It is situated on the ancient bed of the Rhine, which, by means of various streams, divides it into a number of islands, that communicate with one another by bridges, which are reckoned to be not fewer than 100. This city likewise carries on a daily intercourse by boats with Amsterdam, Haarlem, Utrecht, Delft, the Hague, &c. It has eight gates; and its ramparts are formed of earth, partly covered with turf, and partly faced with brick, and confifting of several bastions. The cloth manufactured at Leyden has been much celebrated, and it contains a staple-hall erected for the use of the manufacturers and merchants. The chief street of the town is constructed in the form of a crescent; and the principal public building is the town-houfe, which has many spires, and is a handsome structure, with a stone front. In the burgomaster’s chamber is a very capital painting of the Last Judgment by Lucas of Leyden, for which the emperor Rodolphus is said to have offered as many gold ducats as would cover it; together with several other capital paintings, and a representation of the famous siege of 1574, wrought in tapestry. The great church is one of the handsomest in Holland. The common council of the city, called "Vroedchaps," is composed of 40 persons, who are required to be natives of Holland, 28 years of age, and Protestant. Here are likewise four burgomasters, and eight echevins, and a grand bailiff, who admittance justice in civil and criminal cases, jointly with the echevins. The fair of Leyden is an ancient establishment, and still much frequented; it occupies by its booths, arranged under trees, and along the borders of canals, about a fourth part of the town. In proof of the antiquity of this city, some allege an ancient round tower, called the "Burgh," about 600 feet in circumference, said to have been erected either by the Romans or Saxons; but Joseph Scaliger contends that it was built five or six centuries ago by the comtes of Holland. This city was considerably enlarged towards the south in the year 1389; but it has suffered much from sieges and the plague. In the year 1574, the Spaniards laid siege to it; but it was obstinately defended by the inhabitants, and even by the women, who lined the ramparts, and performed the duties of soldiers.
During this resistance, the misery of the inhabitants was extreme: 6000 persons died of famine, and the difficulties attending it; so that for 14,000 who survived, there remained no more than 107 muids of wheat. The general of the Spaniards, apprized of their situation, summoned them to surrender; but they replied, that they could not want subsistence, as long as their left arms remained, on which they were determined to feed, whilst with the right they defended the city. The constancy and courage of Adrian de Werf, burgomaster of the city, deserve to be recorded; when he was solicited by some of the inhabitants to surrender, he told them, "My friends, since I must die, it is of little importance whether I fall by you or by the enemy; cut me to pieces, and divide them amongst you; I shall die satisfied, if by my death I can be the least useful." Just as they were preparing to surrender, they received notice from some pigeons, that relief was at hand; and the dykes of the Meuse and the IJssel having been opened, Louis Boisfoit, admiral of Zealand, advanced with a number of troops in flat-bottomed boats to their succour. The Spaniards, terrified by the inundation, abandoned the siege. In memory of this event the inhabitants have been accustomed every seven years to exhibit a spectacle of the siege. William Prince of Orange, just recovering from a dangerous illness, was carried to Leyden, that he might in person thank the citizens for their brave defence; he also liberally rewarded Boisfoit and Janus Douza, lord of Noortwijk, who commanded in the city, not forgetting the officers and soldiers; and besides granting several privileges to the city, he founded an university, and appointed Janus Douza the first curator. This university, says Mrs. Radcliffe, in her "Journey through Holland," etc., "would fearlessly be known to exist, if it had no more conspicuous objects than its buildings. The Dutch universities have no endowed foundations; so that the professors, who have their salaries from the states, live in private houses, and the students in lodgings. The library, to which Joseph Scaliger was a benefactor, is open only once in a week, and then for no more than two hours. To this, and other measures of Dutch policy, it is owing that the university has been of late years declining. There are students, however, of many nations and different religious professions, no oaths being imposed, except upon the professors. Physic and botany are cultivated with much success; and there is a garden to which not only individuals, but the East India company, contribute foreign plants. The salaries of the professors, exclusively of fees from the students, are nearly 200l. a-year. The government of the university is in the rector, who is chosen out of three persons, returned by the senate to the states; the senate confits of the professors; and, on extraordinary occasions, the senate and rector are directed by curators, who are agents for the states. The land adjoining to Leyden is very fertile and productive, and is much cultivated by gardeners, who supply Amsterdam with vegetables; and the rich meadows and pastures in the environs furnish excellent butter and cheese. Leyden is distant 14 miles N. of Rotterdam, and 19 S.W. of Amsterdam. N. lat. 52° 9'. E. long. 4° 20'.

The plays and players of the theatre of Leyden are not of the most refined sort; farce has not yet quitted tragedy, nor has Punch quitted farce; however, these exhibitions amuse persons, whose taste has not been formed upon refined models, and perhaps come more home to their humour and biases, than the tragedies of Sophocles, or comedies of Menander, would do, if they were now to be represented in the original Athenian manner.

As to music, mechanical chimes, every quarter of an hour; carillons at noon, two or three times a week; and huge organs, coarsely played, to more coarse plafmody, constitute all that Apollo and the Nine Muses have given to this place, in the way of harmony and melody, as far as we could discover. Burney.

Leyden, a small island in the East Indian ocean, near the coast of Java, within view from Batavia.—Alfo, a small island in the gulf of Manar, near the W. coast of Ceylon; 12 miles W. of Jaffnapatam.—Alfo, a small island in a bay of the Pacific ocean, on the N. coast of New Guinea. S. lat. 3° 58'. E. long. 135° 39'.—Alfo, a town of Prussia, 27 miles S.S.E. of Königsberg.—Alfo, a port-town of America, in Oneida county, New York; 330 miles N.E. from Washington.—Alfo, a township in Hampshire county, Massachusetts, between Colebrook and Bernardston; 29 miles from Northampton, incorporated in 1784, and containing 1095 inhabitants.

Leyden Phial, in Electricity, is a glaf phial or jar, coated both on the inside and outside with some conducting substance, for the purpose of being charged, and employed in a variety of entertaining and useful experiments. See Coating and Charge.

It was thus called because Mr. Cunzeus, a native of Leyden, was suppofed to have first contrived, about the close of the year 1745, to accumulate the electrical power in glafs by this method; and hence the operation of charging and discharging coated glafs, in general, has been denominated the Leyden experiment; and a vacuum produced in a jar of this kind has been called the Leyden vacuum. But Dr. Priestley, the historian of electricity, informs us, that the perfon who first made this great discovery was Mr. Von Kleist, dean of the cathedral in Camin; who, on the 4th of November, 1745, sent an account of it to Dr. Leibeknuh at Berlin; however, thofe, to whom Mr. Kleist's account was communicated, could not succeed in performing his experiments. The views which led to this discovery in Holland are flated by Dr. Priestley in the following manner: professor Muschenbroeck and his friends, observing, that electrified bodies, exposed to the common atmosphere, which is always replete with conducting particles of various kinds, soon lost their electricity, and were capable of retaining but a small quantity of it, imagined, that if the electrified bodies were terminated on all sides by original electrifies, they might be capable of receiving a stronger power, and retaining it a longer time. Glafs being the most convenient electric for this purpose, and water the most convenient non-electric, they first made these experiments with water in glafs bottles; but no considerable discovery was made, till Mr. Cunzeus, happening to hold his glafs vessel in one hand, containing water, which had a communication with the prime conductor by means of a wire; and with the other hand difengaging it from the conductor, when he imagined the water had received as much electricity as the machine could give it, was surprized by a sudden shock in his arms and breast, which he had not in the least expected from the experiment. This experiment was repeated, and the first account of it published in Holland by Mr. Allamand and Mr. Muschenbroeck; by the able Nollet, and M. Monnier, in France; and by Meffrs. Gralath and Rugger, in Germany. Mr. Gralath contrived to increase the strength of the shock, by altering the shape and size of the phial, and also by charging several phials at the same time, so as to form what is now called the electrical battery. He likewise made the shock to pass through a number of perffons connected in a circuit from the outside to the inside of the phial. He observed that a cracked phial would not admit of being charged; and he discovered what is now called the residuum of a charge. Dr. Watson, about
about this time, observed a circumstance attending the operation of charging the phial, which, pursued, would have led him to the discovery which was afterwards made by Dr. Franklin. He says, that when the phial is well electrified, and you apply your hand to it, you see the fire flash from the outside of the glass, wherever you touch it, and it crackles in your hand. He also observed, that when a single wire only was fastened round a phial, properly filled with warm water, and charged; upon the infant of its explosion, the electrical corruptions were seen to dart from the wire, and to illuminate the water contained in the phial. He likewise found, that the strokes, in the discharge of the phial, were \textit{eteris paribus}, as the points of contact of the non-electrics of the outside of the glass, which led to the method of \textit{coating} glases; in consequence of which he made experiments, that led him to conclude, that the effect of the Leyden bottle was greatly increased, if it was not principally owing to, not so much the quantity of non-electric matter contained in the glases, as the number of points of non-electric contact within the glases, and the density of the matter of which these points consisted; provided the matter was, in its own nature, a ready conductor of electricity. He farther observed, that the explosion was greater from hot water inclosed in glasses, than from cold, and from his coated jars, warmed, than cold. For his manner of explaining the shock of the Leyden phial, see \textit{Arc}.

Mr. Wilton, in 1746, discovered a method of giving the shock to any particular part of the body, without affecting the rest: he also increased the strength of the shock by plunging the phial in water, thereby giving it a coating of water on the outside as high as it was filled in the inside; he likewise found, that the law of accumulation of the electrical matter in the Leyden bottle was always in proportion to the thinnest of the glases, the surface of the glases, and that of the non-electrics in contact with the inside and outside thereof. Mr. Wilton made a variety of other experiments with the Leyden phial, which our limits will not allow us to recite.

Mr. Canton found, that if a charged phial was placed upon electrics, the wire and the coating would give a spark or two alternately; and that, by continuing this operation, the phial would be discharged; though he did not observe that these alternate sparks proceeded from the two contrary electrifications discovered by Dr. Franklin.

The abbé Nollet made several experiments with this phial. He received a shock from a bottle, out of which the air had been exhausted, and into which the end of his conductor had been inserted. He ascribed the force of the glases in giving a shock, to that property of it, whereby it retained it more strongly than conductors do, and was not so easily dissipated as they are. He also first tried the effect of the electric shock on brute animals, and enlarged the circuit of its conveyance. See \textit{Circuit}.

M. Monnier is said to have been the first who discovered that the Leyden phial would retain its electricity for a considerable time after it was charged, and to have found it to do so for thirty-six hours, in time of frost; and it is remarkable that the French as well as the English philosophers made several experiments, which, with a little greater degree of attention, would have led them to the discovery of the different quality of electricity on different sides of the glases. But this was referred for the ingenious doctor Franklin, who, in explaining the method of charging the Leyden phial, observes, that when one side of the glases is electrified positively, or \textit{plus}, the other side is electrified negatively, or \textit{minus}; so that whatever quantity of fire is thrown upon one side of the glases, the same is thrown out of the other; and in a phial not charged, none can be thrown into the inside, when none can be got out from the outside; and there is really no more electrical fire in the phial after it is charged than before; all that can be done by charging being to take from one side and convey to the other. Dr. Franklin also observed, that glases was impervious to electricity, and that therefore, since the equilibrium could not be restored to the charged phial by an internal communication, it must be done by conductors externally joining the inside and the outside. These capital discoveries he made by observing that, when a phial was charged, a cork-ball, fastened onfilk, would be attracted by the outside coating, when it was repelled by a wire communicating with the inside, and vice versa. But the truth of this maxim appeared more evident, when he beat the knob of the wire communicating with the outside coating, within a few inches of the wire communicating with the inside coating, and furnished a cork-ball between them; for, in that case, the ball was attracted by them alternately, till the phial was discharged.

Dr. Franklin also shewed, that when the phial was charged, one side lost exactly as much as the other gained, in restoring the equilibrium. Hanging a small linen thread near the coating of an electrical phial, he observed that whenever he brought his finger near the wire, the thread was attracted by the coating: for as the fire was taken from the inside, by touching the wire, the outside drew in an equal quantity by the thread. He likewise proved, that the coating on one side of a phial received just as much electricity as was emitted from the discharge of the other, in the following manner: he inflated his rubber, and took, hanging a phial to the conductor, he found it could not be charged, even though his hand was held constantly to it; because, though the electrical fire might leave the outside of the phial, there was none collected by the rubber to be conveyed to the inside. He then took away his hand from the phial, and forming a communication by a wire from the outside coating to the inflated rubber, he found that it was charged with fire. In this case it was plain, that the very same fire which left the outside coating, was conveyed by the way of the rubber, the globe and the conductor, and the wire of the fire into the inside. This new theory of charging the Leyden phial led Dr. Franklin to observe a greater variety of facts, relating both to charging and discharging it, than other philosophers had attended to. This maxim, that whatever the phial takes in at one surface it loses at the other, led Dr. Franklin to think of charging several phials together with the same trouble, by connecting the outside of one with the inside of another; whereby the fluid that was driven out of the first would be received by the second, &c. By this means he found, that a great number of bottles might be charged with the same labour as one only; and that they might be charged equally high, were it not that every bottle receives the new fire, and loses its old with some reluctance, or rather gives some small refilience to the charging. On this principle he constructed an electrical battery.

When Dr. Franklin first began his experiments upon the Leyden phial, he imagined that the electrical fire was all crowded into the substance of the non-electric, in contact with the glases; but he afterwards found that its power of giving a shock lay in the glases itself, and not in the coating, by the following ingenious analysis of the bottle. In order to find where the strength of the charged bottle lay, he placed it upon glases; then first took out the cork and the wire, and finding the virtue was not in them, he touched the outside coating with one hand, and put the finger of the
other into the mouth of the bottle; when the shock was felt quite as strong as if the cork and wire had been in it. He then placed the phial again, and pouring out the water into an empty bottle, inflated, expected that, if the force were refreshed in the water, it would give the shock, but he found it gave none. He then judged that the electric fire must either have been lost in decanting, or must remain in the bottle; and the latter he found to be true; for, filling the charged bottle with fresh water, he found the shock, and was satisfied that the power of giving it refixed in the glass itself. The same experiment was made with a panes of glass, laying the coating on lightly, and changing it as the water had been before changed in the bottle, and the result was precisely the same. He proved in other ways that the electric fire remain in the glass.

From the above account of Dr. Franklin's method of analyzing the Leyden phial, the manner of charging and discharging it, and the reason of the process, are easily understood. Thus, if a coated phial be placed near the prime conductor, so that the knob of its wire may be in contact with it; and the punch of the machine be turned, the index of the electrometer, fixed to the conductor, will gradually rise as far as 90 nearly, and then ret; which shows that the phial has received its full charge; then if the discharge be held by its glass handle, and one of its knobs be applied to the outside coating of the phial, and the other be brought near the knob of the wire, or near the prime conductor that communicates with it, a report will be heard, and luminous sparks will be discoovered between the discharge and the conducting substances communicating with the sides of the phial, and by this operation the phial will be discharged. If, instead of using the discharge, a person touches the outside of the phial with one hand, and brings the other hand near the wire of the phial, the same spark and report will be observed, and a shock will be felt, that affects the wrists and elbows; and, when the shock is strong, the breast likewise; and a shock may be given to any single part of the body, if that part alone be brought into the circuit. If a number of persons join hands, and the first of them touches the outside of the phial, and the last touches the wire communicating with the inside, they will all feel the shock at the same time. If the coated phial be held by the wire, and the outside coating be presented to the prime conductor, it will be charged as readily, only with this difference, that in this case the outside will be positive, and the inside negative; and if the prime conductor, by being connected with the rubber of the machine, be electrified negatively, the phial would be charged in the same manner; but the side that touches the conductor would be electrified negatively, and the opposite side would be electrified positively. But if the phial be inflated, and the same process repeated, the index of the electrometer will soon rise to 90; yet the phial will remain uncharged; because the outside, having no communication with the earth, &c., cannot part with its own electricity, and, therefore, the inside can acquire no additional quantity; but when a chain, or any other conductor, connects the outside of the phial with the table, the phial may be charged as before. Moreover, if a phial be inflated, and one side of it, instead of being connected with the earth, be connected with the inflated rubber, whilst the other side communicates with the prime conductor, the phial will be expeditiously charged; because, whilst the rubber exhausts one side, the other side is supplied by the prime conductor; and in this way the phial is charged with its own electricity; or the natural electric matter of one of its sides is thus thrown on its other side. This last experiment may be diversified, by inflating the phial, and placing it, with its wire, at the distance of about half an inch from the prime conductor, and holding the knob of another wire at the same distance from its outside coating; then turning the winch of the machine, and a spark will be observed to proceed from the prime conductor to the wire of the phial, and another spark will pass at the same time from the outside coating to the knob of the wire presented towards it; and thus it is seen, that as a quantity of the electric matter is entering the inside of the phial, an equal quantity of it is leaving the outside. If the wire presented to the outside of the phial be pointed, it will appear illuminated with a flash; but if the pointed wire be connected with the coating of the phial, it will appear illuminated with a brush of rays. See Charge, Electrical Experiments, &c. Electricity, Electrometer, &c.

Mr. Cavallo has described the construction of a phial, which, when charged by an electrical kite, in examining the slate of the clouds, or in any other way, may be put into the pocket, and which will retain its charge for a considerable time. Besides the coating on the inside and outside, which this phial has like others of the same kind, a glass tube open at both ends is cemented into its neck, and parallels, within the phial, having a small wire fastened to its lower extremity, which touches the inside non-electric coating. The wire, with the knob of this phial, is cemented into another glass tube, which is nearly twice as long, and smaller than the tube cemented into the neck of the phial. The wire is cemented in such a manner, that only its knob projects out of one end, and a small length of it out of the other end of the tube. If this piece, with the wire, be held by the middle of the glass tube, it may be put into the tube, which is in the neck of the phial, so as to touch the small wire at the lower extremity of it; and this may be done without discharging the phial, if it be charged. A phial of this kind has been kept in a charged state for fix weeks. Cavallo's Elec. p. 346. See Conductor.

We shall close this article with an account of the method by which Mr. Cavallo repairs coated phials, that have been cracked or perforated, either by a spontaneous discharge, or other accident. He removes the outside coating from the fractured part, and then makes it moderately hot by holding it to the flame of a candle; and whilst it remains hot, he applies burning sealing-wax to the part, so as to cover the fracture entirely; taking care that the thickest of this wax coating may be greater than that of the glass. Lastly, he covers all the sealing-wax, and also part of the surface of the glass beyond it, with a composition made with four parts of beer wax, one of resin, one of turpentine, and a very little oil of olives. This he spreads upon a piece of oiled filk, which he applies in the manner of a plaster. In this way several phials have been so effectually repaired, that, after being frequently charged, they were at last broken by a spontaneous discharge, but in a different part of the glass. Phil. Trans. vol. lxviii. part ii. p. 1011.

LEYGAGER is used for wager of law.

LEYMEN, or LEINEN, in Geography, a town of Germany, in the palatinate of the Rhine; eight miles S. of Heidelberg.

LEYPA, or LEPPA, a town of Bohemia, in the circle of Leitmeritz; 20 miles N.E. of Leitomeritz. N. lat. 50° 59'. E. long. 14° 43'.

LEYRE, a town of Spain, in Navarre; eight miles N.E. of Sangieta. LEYRIA,
LEYRIA, a city of Portugal, in the province of Évora, containing 3,500 inhabitants. Near it, on an eminence, is an ancient city built by the Moors; 57 miles N.N.E. of Lisbon. N. lat. 39° 59'. E. long. 8° 34'.

LEYSE, a town of Prussia, in Ermland; 18 miles N.E. of Hellberg.

Gen. Ch. Common Calyx ovate, imbricated; scales obtuse, concave, scarious. Cor. compound, radiated; florets of the disk sever, perfect, tubular, funnel-shaped, five-cleft, nearly erect; those of the radius sever, ligulate, lanceolate, entire. Stam. (in the perfect florets) Filaments five, capillary, very short; anthers united into a cylindrical tube. Pfd. (in the fame) Gernan small; flower thread-shaped; stigma notched. In the female ones the style is shorter, and the stigma more divided. Peric. none, except the unchanged calyx. Seed, in both kinds of florets, solitary oblong; down, in those of the disk, long, of five feathery bristles, surrounding a very short chaffy crown; in those of the radius the feathery bristles are wanting. Recept. naked in the disk, the florets of the circumference only being separated by narrow chaffy scales.

Obf. In Leysera pallescens the feathery bristles of the radius are wanting. Gartnert relines the genus of Leysera to such species, keeping Vaillant's name Afterotterus for those which have the two kinds of seed-down as above described; but such a distinction appears to us, as it did to Linnaeus, merely to separate a very natural genus, and it serves, among many other instances, displayed in this part of Gartnert's admirable work, to prove that technical characters must never be followed, without taking natural ones as a clue.

Eff. Ch. Receptacle chaffy in the circumference. Seed-down chaffy; in the florets of the disk mostly feathery also. Calyx scarious.

Linnaeus has three species of this genus. 1. L. gnaphalodes. Linn. Sp. Pl. 1249. Leyf. Hall. ed. 2.; frontispiece, inscribed "unicum premium, fed immutabile." (After aestopicus, afterochadis foliis, flore aureo; Herm. Lugd. Bat. 68. t. 71.)—Leaves linear-awl-shaped, downy and glandular. Calyx-scales lancolate.—Native of the Cape of Good Hope, as are all the known species hitherto discovered. The stem is shrubby, determinately branched, leafy, downy. Leaves copious, spreading every way, fan-shaped, bristle-shaped, hardly an inch long, downy, as well as be sprinkled with little prominent glandular bristles. Flowers mostly terminal, solitary, on long slender stalks, with yellow

LEY, in Geography, one of the Philippine islands, about 250 miles in circumference; the soil is so fertile as to yield two hundred fold; the mountains abound in deer, hogs, wild hogs, and fowls; cocoa grow spontaneously; the air is pure and healthy, and more temperate than at Luzon. The inhabitants are mild and peaceable in their disposition, and hospitable to strangers. Their number is estimated to be about 9000, who pay tribute in wax, rice, or cloth. N. lat. 10° 55'. E. long. 124° 40'.

LEZAISKO, a town of Austrian Poland, in Galicia; 58 miles W.N.W. of Lemberg.

LEZANDRIEUX, a town of France, in the department of the North Coafts, and chief place of a canton, in the district of Lannion, four miles E. of Tréguier. The place contains 1763, and the canton 17289 inhabitants, on a territory of 1424 kilometres, in 20 communes.

LEZERS, an Indian nation, which inhabits between the mouth of the Ohio and Wabash rivers. They can furnish 350 warriors.

LEZIGNAN, a town of France, in the department of the Aude, and chief place of a canton, in the district of Narbonne. The place contains 1565, and the canton 6827 inhabitants, on a territory of 250 kilometres, in 17 communes.

LEZOUX, a town of France, in the department of the Puy-de-Dome, and chief place of a canton, in the district of Thiers; seven miles W.S.W. of Thiers. The place contains 3307, and the canton 10581 inhabitants, on a territory of 1974 kilometres, in 12 communes.

LGOV, a town of Russia, in the government of Kursk. N. lat. 48. E. long. 53° 54'.

LHOTA, a town of Bohemia, in the circle of Konigigratz; six miles S.E. of Trutonan.

LHOTKA, a town of Bohemia, in the circle of Konigigratz; 14 miles W. of Konigigratz.

LHADOVA.
LIAADova, a town of Moldavia, on the Dniester; 56 miles E.N.E. of Chocrim.

LIAISON, Fr. in Music, connection, relation, combination. See RELATIVE.

LIALSKoi, in Geography, a town of Russia, in the province of Ural, on the Vim; 48 miles E. of Yarenk.

Liam, a town of Lower Saxen, on the E. side of the Gulf, N. lat. 12° 35'. E. long. 162° 18'.

Liamone, a river of Corsica, which runs into the sea; 10 miles N. of Ajaccio. It gives name to one of the two departments into which Corsica is divided; the other being Golfo. It is formed by the southern part of the island, in N. lat. 41° 50', containing 1,400 square leagues, and 63,437 inhabitants. It is divided into three circles, viz. Vico, containing 19,409 inhabitants; Ajaccio, 26,918; and Sarzeto, including 26,380 inhabitants. In the valleys and activities of the hills, the soil is fertile, yielding grain, fruits, vegetables, and, in some districts, delicious wines.

LiAM-PO. See Ning-ro.

LiamSA, a town of Russia, in the government of Archangel, on the coast of the White Sea; 36 miles N.N.W. of Oneg.

LIancourT, a town of France, in the department of the Oise, and chief place of a canton, in the district of Clermont; four miles S. of Clermont. The place contains 992, and the canton 10,365 inhabitants, on a territory of 125 kilometres, in 22 communes.

Lianga, a town on the E. coast of Mindanao. N. lat. 8° 21'. E. long. 126° 10'.

LiAnG-CHAN, a town of Corea; 40 miles S.S.E. of Kang-tehuen.

LiAngdal, a river of Sweden, which rises in the province of Harjedalen, and runs into the gulf of Bothnia, near Sundsvall.

LiaN-TchuAE, a town of Corea; 25 miles E.N.E. of Haimen.

LiAnderSake, a lake of Thibet, about 30 miles in circumference. N. lat. 34° 34'. E. long. 95° 44'.

Gen. Ch. Common Calyx oblong, imbricated, of numerous, somewhat ovate, unarmed, coloured secales. Cor. compound, uniform, tubular; flowers are perfect and equal, monopetalous, funnel-shaped; their tube indexed; limb in five recurved segments. Stam. Filaments five, capillary, very short; anthers united into an inferior tube. Fil. Gurnen to each floret, oblong; style thread-shaped, very long, divided as far as the top of the stamens, friggit; stigmas rather acute. Peric. none; except the permanent unaltered calyx. Seeds solitary, angular; down feathery, sometimes coloured. Recept. naked, flat.

This genus appears to have been originally separated from Serratula by Gartner, who altered the name by which he at first distinguished it, Suprao, to that which it now bears. Serratula differs from it in having a fealy or hairy receptacle, as well as in habit. Eight species are defined by Willdenow, of which the following are the most characteristic and remarkable.

L. fiscifolia. Willd. n. 2. (Serratula fiscifolia; Limn. Sp. Pl. 1147. Europario adnatis americana bulbofa. floribus fiscifolius calycibus contectis; Plek. Phnt. t. 177. f. 4.)

— Leaves lanceolate, tapering at each end, rough-edged. Flowers on long bracteated stalks. Calyx-seals obovate, spreading. — Native of North America; sometimes seen with us in curious gardens, where it is a hardy perennial. Root a bulb-shaped tuber. Stem three or four feet high, leafy, finely hairy, racemose at the upper part, each flower supported by a stalk from two to four inches long, bearing a few leafy bracts. The stigmas are long, purplish, as well as the florets. Calyx-seals more or less obtuse, leafy, widely spreading.

L. elegans. Willd. n. 3. (Stachelia elegans; Walt. Carol. 202. Serratula speciosa; Att. Hort Kew. v. 3. 138.)

— Leaves linear, dotted. Spike very long and dense. Calyx-seals lanceolate, acute, hairy; the innermost elongated, coloured, somewhat toothed. Florets few. — Gathered by Bortram, in Georgia, in 1757; by Walter in Carolina. The upper stem-leaves are widely spreading, or reflexed; lower longer, more dilated and upright; all finely dotted on both sides. Spike long, dense, erect, slender, of numerous, nearly sessile, bracteate flowers, whose long, leafy, fine pink, inner scales of the calyx are very beautiful.

L. pilosa. Willd. n. 4. (Serratula pilosa; Att. Hort Kew. v. 3. 138.)

— Leaves linear, hairy, somewhat dotted. Clutter long, loofe, hairy. Bracteate and calyx-seals obtuse, fringed. — Native of North America, from whence it was introduced, in 1783, into Kew garden, where we gathered it in flower two years after. It is perennial and hardy, blooming in the autumn. As there is no description nor figure extant, the following may be acceptable. The stem is three feet high, slender, leafy, angular, clothed with longish scattered hairs, it leafs in the upper part. Leaves narrow, reflexed, fringed with similar hairs, and irregularly dotted on both sides; the upper ones dilated at the base, and embracing the stem. Clutter terminal, simple, long, loofe, leafy, slightly hairy. Flower stalks about an inch long, axillary, bearing at their upper part two or three short, obtuse, fringed, dotted bracteate, resembling the lower scales of the calyx; whose inner-scales are gradually longer, with a membranous, fringed, white or reddish edge. Florets and stigmas pink.

We cannot but lament, that while so many well-known plants are figured over and over again in every publication, such curious and beautiful species as the last should remain neglected and unknown.

L. spicata. Willd. n. 6. (Serratula spicata; Limn. Sp. Pl. 1147. Cirrion tuberosum, laetus caputis spicatus; Dill. Eth. 85. t. 72. f. 83.)— Leaves linear, dustly dotted, fringed at the base. Spike leafy; dense above. Calyx-seals obtuse, smooth. — Native of various parts of North America, from whence it was brought to the English gardens about eighty years ago, and still remains at Kew. The nearly sessile flowers, and smooth-edged calyx, distinguish it from the last, to which it is otherwise nearly allied.

L. odoratifusa. Willd. n. 8. (Anonymus odoratifusus; Walt. Carol. 193.)— Leaves elliptic-oblung, smooth; the upper ones heart-shaped, clasping the stem. Panicle corymbose, spreading. Calyx-seals obovate, glandular. — Gathered by Walter in Carolina, from whence it was brought by the late Mr. Frazer in 1787. This species is remarkable for its fine scent when dried, which resembles that of the Woodward and Holcus odoratus. The radical leaves are flaked, three or four inches long, nearly elliptical; those of the item numerous, much smaller. Flowers small, purple, very numerous, in a smooth, spreading, bracteate, corymbose panicle. Florets not numerous.

LIBA,
LIB

LIBA, in Geography, a town of Bohemia, in the circle of Sätz; 10 miles E. of Eger.

LIBAN, a town of Bohemia, in the circle of Boleslaw; 12 miles E.S.E. of Jung-Buntzel.

LIBANUS, in Biography, a celebrated Greek sophist, or rhetorician, was born of an ancient family at Antioch, about the year 314. He devoted himself from his youth to the study of literature, and pursued his studies at Athens. Having finished his education he collected discip-les, and made himself known by various rhetorical com-positions. His reputation was so high at Constantinople, that some other professors, jealous of his fame, procured his banishment on the charge of magic. He then went to Nicomedia, where he obtained a great number of disciples, among whom, in a private manner, was Julian, afterwards denounced the Apollite. He finally returned to An-tioch, where he spent the remainder of his days. About the year 360, he was preceptor to Basili and Chrysostom, persons afterwards well celebrated in the church, though he was always zealously attached to the ancient religion; and on the accession of Julian, he was one of the first whom that emperor invited to be near his person. He declined the honours intended him, preferring a life of privacy to the baffle of a court. He was, however, warmly attached to a prince who patronized his flu-ids, and supported the same religious cause; and was enabled, by the influence which he had over him, to soften many of the emperor's refentments. Julian admitted him to the equality of a friend, and is thought to have derived some assistance from him in his compositions. He survived to an advanced age, but the time of his death is not known. The writings of Libanius were very numerous, consisting chiefly of orations, decla-mations, dissertations, and epistles; which are characterized by Gibbon as, "for the most part, the vain and idle compo-sitions of an orator who cultivated the science of words?" yet he admits that he had merit, and that his correspondence was various and elaborate; "he praised the virtues of his own times; he boldly arraigned the abuses of public and private life; and he eloquently pleaded the cause of Antioch against the just resentment of Julian and Theodosius." Some of the works of Libanius, consisting of his orations, declama-tions, &c., were published in two volumes, folio, in Greek and Latin, in the years 1626 and 1627; but the most complete collection of his epistles is that published at Amster-dam in 1738. A volume, containing seventeen of his ha-rangues, from the library of St. Mark, was printed at Venice in 1755. In reference to the conclusion of this writer's life, Gibbon observes, "it is the common calamity of old age to lose whatever might have rendered it desirable; but Libanius experienced the peculiar misfortune of sur-viving the religion and the sciences, to which he had consecrated his genius. The friend of Julian was the indig-nant spectator of the triumph of Christianity; and his bigotry, which darkened the prospect of the visible world, did not inspire Libanius with any lively hopes of celestial glory and happiness." The judicious and excellent Lard-ner has translated the whole of Libanius's oration to the emperor Theodosius, every part of which, he says, is of importance to Christians. The occasion of this oration was, that in the reign of Theodosius, several heathen temples had been pulled down and destroyed by the monks, with the consent or connivance, as Libanius thought, of the bishops, and without the orders of the emperor to that pur-pose. Of this Libanius complains and implies the protec-tion of Theodosius, that the temples may be preferred. Dr. Lardner, therefore, gives the oration at length, to shew that the testimony of this heathen writer went directly to prove the divine origin of Christianity. And he concludes by maintaining, that the greatest and splendid to which the Christian church had attained from small beginnings, by the force of truth against worldly terros and allurements, was a greater wonder and a work of greater power than the magnificence of Rome and the grandeur of her empire. Libanius has given an interesting detail of the private life of Julian, quoted and referred to by Gibbon; the mention of which affords us an opportunity of making an additional reference to the article Julian in our last volume. The works of Dr. Lardner should have been cited as containing a summary of the arguments respecting the extraordinary interpositions that prevented this emperor from rebuilding the Jewish temple. See Lardner's testimonies of Ancient Hea-thens, vol. iv. or vol. viii. edit. 1788. Gibbon, vol. iv.

LIBANUS, George, who flourished in the sixteenth cen-tury, was descended from a respectable family at Lignitz, in Poland, of which place he was a native. He pursued his studies for several years in the most celebrated German uni-versities; and coming to reside at Cracow, he was appointed one of the professors in the principal college of that city. He is said to have been the first person who introduced there the study of the Greek language. He published sev-eral works: as "Economicorum Aristotelis Libri Gracii et Latini Annotationibus illustrati;" "Carmina Sibylline Erithreae, &c.;" "Paracletis, id est adhortatio ad Graecarum Literram Radiovs, habita Caracovia;" "De Mu-tice Lanimus Oratio, &c." He also compiled an "Anthology," or choice Collections from the Works of St. Basili. St. Gregory Nazianzen, and St. Chrysostom. Moreiri.

LIBANOMANTIA, Ληβανομαντία, in Antiquity, a spe-cies of divination performed with frankincense; which, if it preferably caught fire, and sent forth a grateful odour, was esteemed a happy omen, and "vitae serenii.

LIBANOTIS, in Botany, the ancient appellation of a plant, supposed by some to have been the name of a boy, changed into the plant in question; but the most evident and generally received etymology is from λιβανος, frankincense, which the root is said to resemble in scent. The λιβανος of Dioscorides appears to be our Rosemary, as has been usually supposed; which is born by the modern Greeks called λεβανος, or Tree Libanos. Libanotis however has at different times, been employed to designate various umbelli-feros plants, of an aromatic quality, and generally of moun-tain origin, which may have been found under the genera of Abies, Picea, &c.

LIBANUS, in Geography. See Lebanon.

LIBATION, Libatio, a ceremony in the heathen fa-crifices, wherein the priest spilt some water, wine, milk, or other liquor, in honour of the deity to whom the sacrificie was offered; after having first tasted it himself.

Alexander is said to have sacrificed a bull to Neptune; and, for an offering to the sea-gods, to have thrown the golden veils used for the libation into the sea.

Libations were also in use under the law of Moses, being enjoined by God in Exodus xxix. and Numbers xv.

LIBAU, in Geography, a sea-port of the duchy of Courland, situated on the Baltic, built by the Lettonians, and deriving its name, as it is said, from the word "Leep-jaja," which, in the Lettonian language, signifies a piece of ground planted with linden-trees, suggested by the circum-stance that many of these trees formerly grew here. This etymology is further confirmed by the consideration that the Lettonians even now call the town "Leepaja." Some Germans intermixed with the inhabitants of this town in the
13th century, and about the close of the fifteenth, and commencement of the 16th centuries, many of that nation united together, and in 1625 it obtained the privileges of a city. In 1737, the harbour was cleared by Erniet John, and the future accumulation of mud and sand prevented, so that it is now a commodious port for vessels of light burden; a considerable number of which repair hither and are loaded with hemp, linseed, etc. This town was often taken by the Swedes, but ceded to Courland by the peace of 1660; 66 miles W. of Mitau. N. lat. 55° 28'. E. long. 21° 37'. In this part of the Baltic, as well as in the whole province of Courland belonging to Russia, accounts are kept by merchants, as at Riga, in Alberts dollars of eighty ferdings, or of ninety Alberts grochen; but retail traders mostly reckon two gulden of ninety current grochen, four of which are equal to three Alberts grochen. The coins chiefly circulating here are Dutch ducats, and Alberts dollars; and also pieces coined in the country of the same standard and value with these two coins. The ferdings is an old silver coin; but the grochofe is imaginary. The Russian coins are also current here. (See Riga.) The left of wheat, rye, barley or peas, contains 48 leofs; that of oats and malt 60 leofs, which are equal to 106 English bushels; so that a leaf of wheat contains about 10½ English quarters, and a leaf of oats 13½ English quarters: one hundred leaves of rye and malt are equal to 11,110 English bushels. Libau exchanges with London at four Alberts dollars fifty grochen, more or less, for ½ merling, at three months date. The old fyle is still used at Libau. Kelly's Un. Cambit., vol. 1.

LIBAVIUS, ANDREAS, in Biography, a physician and chemist, was born at Hall, in Saxony. He was professor of history and poetry at Jena, in 1588. But he removed to Rothenburg, on the Tauber, in 1591, and to Coburg, in Franconia, in 1605, in consequence of an appointment to the office of principal of the college of Calmin, at that place. He died at Coburg in 1616. Libavius obtained a considerable reputation in his time by his chemical works, having purposed that science upon better principles than most of his contemporaries. He employed many chemical preparations in medicine; nevertheless, he avoided the violence of Paracelsus and his disciples, whose principles he often refuted, and against whom he frequently defends the doctrines of the Galenical school. But, like the chemical philosophers of the age, he did not altogether escape the delusions of alchemy. He left his name long attached, in the laboratories, to a particular preparation of tin with mercuric acid, which was called "the fuming liquor of Libavius." It is unnecessary to enumerate the titles of his many works, which have now become obsolete, and are almost forgotten. His last work, published at Francfort in 1615, under the title of "Examen Philosophiae Nova, quae veteri abroganda opponitur," folio, is remarkable for the first mention of the transfusion of blood from the veins of one living animal to the veins of another, of which he speaks with great confidence. The suggestion, however, was not submitted to the test of experiment until the middle of the same century, when the subject made a great noise throughout Europe, and many physicians anticipated from it no less than a remedy against all diseases; nay, some of them felt a confident expectation of rendering life perpetual. But these notions were presently confuted by the numerous fatal terminations of the experiment. See Elyo Dict. Hist. Haller. Bibl. Med.

LIBAVIUS, Liquor of. See Liquor.

LIBEL, Famosus Libellus, a writing or report, unlawfully published abroad, containing injurious reproaches, or accusations, against the honour and reputation of any person, particularly of a superior or governor; or, it is defined to be a malicious defamation of any person, expressed either in printing or writing, signs or pictures, to aperce the reputation of one that is alive, or the memory of one that is dead. According to judge Blackstone, libels, in their most extensive sense, signify any writings, pictures, or the like, of an immoral or illegal tendency. Considered particularly as offences against the public peace, they are malicious defama- tions of any person, and especially a magistrate, made public by either printing, writing, signs, or pictures in order to provoke him to wrath, or expose him to public hatred, contempt, or ridicule.

Platina is of opinion, that a writing, how injurious soever it is, cannot be called a libel, if the author's name be to it. Libellers, among the ancient Romans, were punished with death, but in after-times they were only whipped. Augustus ranked "famosis libellis," defamatory libels, among the crimes "hac majestate," of high treason; and under the emperor Valentinian it was made capital, not only to write, but to publish or even omit destroying them. F. Baldwin has pub- lished a comment on the imperial laws against libels. Scandalous pictures are reckoned amongst libels.

A libel, the lawyers say, may be either in scriptis, or fine scriptis: in scriptis, when a writing is composed, or published to another's disgrace; which may be done either verbi aut cantione, as where this is maliciously repeated, or sung, in the presence of others; or else tradtiones, when the libel, or any copy of it, is delivered out, to scandalize the party. 3 Inst. 174.

A libel fine scriptis, may be twofold. 1. Picturis, as to paint the party in a shameful or ignominious manner: or, 2. Signis, as to fix a gallowa, or other ignominious signs, at the door of the party, or elsewhere.

Where a writing inveighs against mankind in general, or against a particular order of men, this is no libel; in order to make it a libel, it must descend to particulars and individuals. (3 Salk. 224.) But a general reflection on the government is a libel, though no particular person is reflected on; and the writing against a known law is held to be criminal. (4 St. Tr. 672. 903.) According to C. J. Holt, scandalous matter is not necessary to make a libel; it is enough if the defendant induces an ill opinion to be had of the plaintiff, &c. And if a man speak scandalous words, unless they are put in writing, he is not guilty of a libel; for the nature of a libel consists in putting the infamous matter into writing. (2 Salk. 437. 3 Salk. 226.) A defamatory writing, expressing only one or two letters of a name, in such a manner, that from what goes before and follows after it may be understood, by the natural construction of the whole, to signify and point at such a particular person, is as properly a libel as if the whole name were expressed at large. (1 Haw. P. C. c. 73. f. 4.) On application for information against this offence, some friend to the party complaining should in such case state by affidavit his having read the libel, and that he understands and believes it to mean the party. (3 Bac. Abr. 12.) And in the case of actions for libels by signs or pictures, it seems necessary always to shew, by proper inuendoes and averments of the defendant's meaning, the import and application of the scandal, and that some special damage has followed; otherwise it cannot appear that such libel by picture was understood to be levelled at the plaintiff, or that it was attended with any actionable consequences. (Bl. Com. iii. c. 8.) Although a private person or magistrate be dead at the time of making the libel, yet it is punishable, as it tends to a breach of the peace. (Hob. 215. 5 Co. 125. 1 Haw. P. C. c. 73.) But an indictment for publishing libellous matter
L I B E L.

matter reflecting on the memory of a dead, perfon, not alleging that it was done with a design to bring contempt on the family of the deceased, and to baffle the hatred of the king's subjects against them, and to excite his relations to a breach of the peace, cannot be supported; and judgment was in this cause accordingly arrested. (4 Term Rep. 126.)

No writing is efemned a libel, unless it reflect upon some particular perfon. And a writing full of obscene ribaldry is not punishable by any paffion at common law; but the author may be bound to good behaviour, as a perfon of evil fame. (1 Hawk. P. C. c. 73.)

It is certain that he who composes a libel, or procures another to compose it, and he who publishes or procures another to publish it, is in danger of being punished for it; and it is laid not to be material, whether he who composes a libel know any thing of the contents or effect of it, or not; for nothing would be more easy than to publish the most virulent papers with the greatest secrecy, if concealing the purport of them from an illiterate publisher would make him safe in dispersing them. (1 Hawk. c. 70.)

It hath also been faid, that if he who hath either read a libel himself, or hath heard it read by another, do afterwards maliciously read or repeat any part of it in the presence of others, or lend or fhew it to another, he is guilty of an unlawful publication of it. (Id.)

It hath also been held, that the copying of a libel shall be a conclusive evidence of the publication of it, unless the party can prove that he delivered it to a magiftrate to examine it. (Id.)

When any one finds a libel, if it be againft a private perfon, he ought to burn it, or deliver it to a magiftrate; and where it concerns a magiftrate, he should deliver it prefently to a magiftrate. (5 Rep. 125.)

If a libel be found in a house, the matter cannot be punished for framing, printing, and publishing it; but it is laid he may be indicted for having it, and not delivering it to a magiftrate (1 Vent. 31.); or it may, in some cafes, be considered as evidence of his being the author or publisher. (2 Saund. 478.)

It hath been ruled, that the finding of a libel on a book-feller's shelf is a publication of it by the book-feller, and that it is no excefs to lay, that the servant took it into the shop without the master's knowledge; for the law presumes the master to be acquainted with what the servant does. (1 Seff. C. 33. R. v. Dodd. 10 G.)

The fafe of the libel by a servant in a shop is prima facie evidence of publication, in a profecution against the matter; and is sufficient for conviction, unless contradicted by contrary evidence, fhewing that he was not privy, nor in any way affenting to it. (4 Term Rep. 126.)

It is faid to be immaterial, on a criminal profecution, with refpect to the offence of a libel, whether the matter of it be true or false, or whether the party againft whom it is made be of good or bad fame; for in a fettled state of government, the party grieved ought to complain for any injury done to him, in the ordinary course of law, and not by any means to revenge himself either by the odious course of libelling or otherwise. (5 Co. 125.)

But this is to be underftood, when the profecution is by information or indictment; but in an action on the cafe, which is to repair the party in damages, the defendant may juflify the truth of the facts, and shew that the plaintiff hath received no injury. (3 Term Rep. 25.) Although it hath been held, agreeable to the doctrine maintained by lord chief juftice Mansfield, for at least two centuries, that the truth of a libel is no juflication in a criminal profecution, yet in many inftances it is considered as an extenuation of the offence; and the court of king's bench

has laid down this general rule, viz. that it will not grant an information for a libel, unlefs the profeccor who applies for it makes an affidavit, affenting directly and pointedly that he is innocent of the charge imputed to him. This rule, however, may be dispofed of in particular cafes; as if the perfon libelled refides abroad, or if the imputations of a libel are general and indefinite, or if it is a charge againft the profeccor for language which he has held in parliament.

Where, on application for an information, the truth of the libel is not denied, the court, except in the inftances above mentioned, will leave the injury to be remedied in the ordinary course of fuit by action or indictment. (Sta. 493.)

But the court will not grant this extraordinary remedy by information, nor ought a grand jury find an indictment, unless the offence be of fuch signal enormity, that it be reasonably confidered to have a tendency to disturb the peace and harmony of the community. (1 Hawk. P. C. c. 73.)

There are authorities, that truth is not a jufification even in an action for a libel; and a very learned writer feems to doubt whether fuch a plea would now be admitted to the court, if the accufation in the libel did not amount to an indisputable offence. (3 Woodd. 182.)

It seems, however, that the contrary is the prevalent opinion; and that in every action for a libel, if specific inftances can be flated upon the record, fo as to support the general charge of the libel, the courts would determine them to be a fufficient jufification of the defendant. (1 Term Rep. 748.)

The punishment of libellers for either making, repeating, printing, or publishing the libel, is fine, and such corporal punishment (as imprisonment, pillory, &c.) as the court in its discretion shall infict; regarding the quantity of the offence, and the quality of the offender. (1 Hawk. P. C. c. 73.)

If a printer print a libel againft a private perfon, and much more againft a magiftrate, or againft the king and state, he may be indicted and punished for it; nor is it any apology to fay, that it was done in the way of trade, or to maintain a family. (1 St. Tr. 982. 986.)

Also, if book-fellers, &c. publish or fell libels, though they know not the contents of them, they are punishable. It has been refoled, that where perfons write, print, or fell any pamphlets, cuffading the public, or any private perfcns, fuch libellous books may be feized, and the perfons punished by law; and all perfons expofing books to fale, reflecting on the government, may be punished; alfo, writers of news (through not scandalous, feditious, or reflecting on the government, if they write false news) are indictable. (St. Tr. 477.)

With regard to libels in general, there are two remedies; one by indictment and another by action. The former for the public offence; for every libel has a tendency to break the peace, or to provoke others to break it; which offence is the fame, in point of law, whether the matter contained be true or false; and, therefore, the defendant on an indictment for publishing a libel, is not allowed to juflify the truth of it by way of jufification. In fuch profecutions the only facts to be confidered are, first, the making or publishing of the book or writing; and secondly, whether the matter be criminal. But in the remedy by action on the cafe, which is to repair the party in damages for the injury done him, the defendant may, as for words spoken, juflify the truth of the facts, and shew that the plaintiff has received no injury at all. Blackfl. Com. vol. iii. and vol. iv.

In information and law proceedings, there are two modes of describing a libel; viz. by the fene, and by the words; the fite is "cujus tenor fequitur," and the fecond "quae fequitur in hae Anglica verba, &c." in which the description
description is by particular words, and of which every word is a mark, so that if there is any variance, it is fatal; in the other description by the genus, it is not material to be very exact in the words, because the matter is described by the genus of them (2 Salk. 666.) It hath been adjudged, that libels, as having a direct and immediate tendency to a breach of the peace, are indictable before justices of the peace. (1 Hawk. c. 8.)

A libel must be proved to be written or published in the county laid in the indictment; all matters of crime being local. An information for a libel need not charge the offence to have been committed "vi et armis," or allege that the libellous matter is false. (7 T. R. 4.) The declaration for a libel must lay it to be "of and concerning the plaintiff," otherwise there can be no judgment.

(2 Strange, 924.) A very important subject of litigation has arisen from prosecutions for libels, and particularly for trade libels; and that is, whether juries are, or are not, judges of law as well as of fact. With regard to libels, it had for a long time been the usage for the judge to direct the jury, that if the fact of the publication of the paper charged to be a libel was proved, and if they believed the innuendoes in the indictment, they must find the defendant guilty; without advertising to any other circumstances, such as whether the paper were, in their opinion, a libel, or published with a malicious, seductive, traitorous, &c. intention. The counsel for the defendants in such prosecutions always maintained, that it was the province of the jury to judge whether the paper was a libel (a question of mere law); and also whether it were published with a malicious, seductive, &c. intention, as charged,—a complicated question of law and fact.

Mr. (now lord) Erskine was the most frenzied afferter of this latter doctrine; and by the indefatigable exertions of him and the late Hon. Charles Fox, the following act of parliament was obtained with a view expressly of settling this question by legislative authority; and in consequence of it a great, and, as many have deemed it, a very favourable, alteration has taken place in the trials for libels. The statute is that of 42 Geo. III. c. 6. After reciting that doubts had arisen whether on the trial of an indictment or information for making or publishing a libel, where an innuendo is joined on the plea of not guilty, it were competent to the jury to give their verdict upon the whole matter in issue, it enacts that on every such trial the jury may give a general verdict of guilty or not guilty upon the whole matter; and shall not be required or directed by the court or judge, before whom such indictment or information shall be tried, to find the defendant guilty merely on the proof of the publication by such defendant of the paper charged to be a libel, and of the innuendo ascribed to the same in such indictment or information. (f. 1.) Provided always, that on every such trial the court or judge before whom such indictment or information shall be tried, shall, according to their or his discretion, give their or his opinion and directions to the jury on the matter in issue between the king and the defendants, in like manner as in other criminal cases. (f. 2.) Provided also, that nothing herein contained shall extend, to prevent the jury from finding a special verdict, in their discretion, as in other criminal cases. (f. 3.) Provided also, that in case the jury shall find the defendant guilty, it shall and may be lawful for him to move in arrest of judgment on such ground, and in such manner, as by law he might have done before the passing of this act.

When a person is brought before the court to receive judgment for a libel, his conduct, subsequent to his conviction, may be taken into consideration, either by way of aggravation or mitigation of his punishment. (3 Term Rep. 432.) Judge Blackstone observes, that in all the instances where libelous, innominate, treasonable, schismatical, seductive, or scandalous libels are punished by the English law, some with a greater, and others with a less degree of severity, the liberty of the press, properly understood, is by no means infringed or violated. See Liberty of the Press. Libel, or libellata, a little book, in the spiritual court signifies the original declaration of any action in the civil law. (Stat. 2 Edw. VI. c. 53.) The libel used in ecclesiastical proceedings consists of three parts. 1. The major proposition, which shews a just cause of the petition. 2. The narration, or minor proposition. 3. The conclusion, or conclusive petition, which conjoins both propositions. Blackl. Com. vol. iii.

Libel, in the Law of Scotland, is used for a criminal accusation or indictment.

Libella, in Natural History. See Libellula.

Libellula, among the Romans, was the tenth part of the denarius.

Libellatici, an ancient kind of apollites from Christianity, under the persecution of Decius; who, to prevent their being obliged to renounce the faith, and sacrifice to idols in public, made application to the magistrates, and abjured their faith in private; obtaining certificates of them, either by treachery, or by money; by which they were attainted to have complied with the orders of the emperor; and were thereby sheltered from any farther molestation on account of their religion.

These certificates were called libelli; whence the people who obtained them came to be denominated Libellatici.

Others, particularly the centurions of Madgebourne, are of opinion, that the Libellatici were only such as furnished the magistrates with money, to secure them from prosecution, and from being obliged to renounce Christianity.

M. Tilllemont retains something of each opinion; he thinks, the Libellatici, applying themselves to the magistrates, bought off the sacrificing and abjuration; and obtained letters, by which they were declared to have renounced Christ, and sacrificed to idols; though, in effect, they had done neither.

Libellula, or Dragon Fly, in Entomology, a genus of the order Neuroptera; the character of which, according to Gmelin, reduced to the arrangement of the "Sylphes Naturae," consists in the mouth armed with jaws, more than two in number; lip trifid; antennæ very thin, filiform, and shorter than the thorax; wings expanded; tail (of the male insect) furnished with a forked process.

In this genus the antennæ are very short, being merely a pair of small hairs, the wings large and spreading, and the body lengthened. The libellula, or dragon-flies, exhibit an infus congrua less striking than the butterfly of that diffi-

mility in point of form under which one and the same animal is defined to appear in different periods of its existence. Persons not conversant with natural history, would fearlessly believe that these brilliant insects, flying with vast strength and rapidity, and pursuing other insects still smaller, after the manner and with the velocity of a hawk, had been inhabitants of the water, in which they resided a considerable time before they had assumed the flying form. The whole tribe, which is divided into fections, and one of which sections is subdivided, is exceedingly ravenous, and generally seen hovering over stagnant waters: the larvae are fix-footed, active inhabitants of the water, furnished with an articulate foreparted mouth; and prey with the utmost rapaciousness, upon aquatic insects and the larvae of others; the pupa resembles the larva, but, in the former state, it has the rudiments of wings. The libellulæ, or dragon-flies, are some-

sometimes,
times, though very improperly, called horse-flingers. There
are nearly sixty species; before, however, we come to the
enumeration of these, we may relate some facts common
to the tribe itself. The antennae of the male libellula to his
female from carried on in a rough but very efficacious man-
ner. He hovers about on this wing, till the object of his
amours makes her appearance; he then watches an oppor-
tunity of seizing her by the head with those pincers with
which his tail is armed. In this manner he travels through
the air, till the female, yielding either to superior strength
or inclination, forms her body into a kind of circle, adapted
to the purpose of nature; hence the libellulae are frequently
seen coupled in the air, exhibiting the form of a ring. The
female, at a proper period, returns to some stagnant water,
where, by the assistance of a dill or reed, the flowers herself
down, by moving backwards, till the tip of the tail is im-
merged a little in the water; she is then feized with a tre-
mor of the body, during which she deposits the egg in the
water. In this way the operation is repeated. The tail is
withdrawn from the water, by contracting the annuli; and,
by the pressure of these upon each other, the egg is gra-
dually forced from the ovary to the extremity of the tail;
whence it is separated by shaking that part in the water.
The eggs are of a white colour, resembling those produced
by the common blow-fly. The larvae are disgusting in ap-
pearance, but beneath the head is placed an instrument
excellently adapted for seizing and holding their prey. It
is furnished with a forceps at the end, and can be advanced
or drawn back with the agility of the human hand! The
larva remains in the same state about a year before it attains
its full size; when the period of its transformation has ar-
rived, it repairs to the margin of the pond in quest of a
convenient situation during the season of its incubation. It
takes up the plant or piece of wood, and the skin, which has gradually become parched and brittle, at length splits opposite the upper part of the thorax.
Through this aperture the winged insect quickly pushes its
way, and being thus extricated from confinement, begins to
expand its wings, to flutter, and finally to launch into the
air. The complete insect, in its winged state, continues to
pursue food similar to that by which it had been supported
before, and remains insectivorous. The lepidopterous in-
sects, the butterflies, and phalanges, are defined for the sup-
port of the larger libellula, which are a part of those nu-
merous tribes appointed to confine these prolific genera within
due bounds. The life of the libellula, in its winged state,
is short in comparison with that which it passed in its aquatic
form, the frolic of the early autumn destroying all those
that have not been devoured by birds in the preceding
months. It is impossible not to be struck with wonder in
contemplating the changes of the libellula, which, while
living in the water, would perish by a long exposure to the
air, while the winged insect, having escaped from the pupa,
would be destroyed by submersion under the water, of
which, not an hour before, it was the legitimate inha-
bitant.

The species are divided into the sections A and B. Sec-
A. Section A. Wings expanded when at rest: a Dorsal division
of the lip very minute; and 2 Divisions of the lip equal; constituting
the tribe Ephemna of Fabricius. B. Wings erect when at rest; eyes distinct; outer divisions of the lip bident. The tribe Agri on of Fabricius.

Species.

Section A. Wings expanded when at rest: a Dorsal division
of the lip very minute.

Vol. XX.

4-Maculata. Lower wings at the base, and all in the
middle on the fore-part with a blackish spot; abdomen
depressed, downy. It is an European insect, and described by
Reamur.

Depressa. All the wings blackish at the base; abdomen
depressed, yellowish at the sides. This also is an European
insect; figures and description are given by Edwards and
Dorovan. The male is of a bright sky-blue, with the sides
of the body yellow; the female of a fine brown, with yel-
loowish sides. The wings in both sexes are transparent,
cept at the shoulders, where they are each marked by a
broad bed of brown with a stripe of yellow: the tips of
each wing have also a small oblong-square black spot on the
outer margin. The larva is of a greenish-brown.

Thoicumulata. All the wings hyaline, with a ferru-
ginous spot at the base, and band in the middle. It inhabits
North Carolina.

Bifasciata. Wings hyaline, with a brown spot at the
base and two bands. It inhabits America. The thorax is
villous-brown, with two yellow lines under the wings; ab-
domen depressed, brown, the sides yellowish.

4-Punctata. Wings white; lower ones black at the
base with a yellow line; all with a black dot; abdomen
cylindrical. It inhabits America. Thorax is of a downy
green; front vescicular green; abdomen greenish at the base,
but towards the tip blackish; all the wings with a black
dot in the middle at the rib, and an oblong stigma at the
tip.

Flaveola. Wings pale yellow at the base. Inhabits
Europe. Its wings are sometimes without the yellow spot.

Limeata. Wings white with a yellowish base, and black
band and tip; abdomen yellow, with a lateral black line.
This species is found in India. Its head and thorax are yel-
loowish; abdomen compressed.

Stigmatisana. This is a yellowish insect; has wings
with a brown spot, the tip brown with a fowy stigma. It
is found in New Holland. Sir Joseph Banks has a speci-
men in his museum. The abdomen is marked with black
lines; wings hyaline.

Oculata. Like the last, this is of a yeowith colour;
the upper wings are hyaline at the tip, lower ones at the
margin, with a fowy stigma. It inhabits New Hol-
land.

Indica. This species has wings varied with yellow and
brown, and white at the tip; the lower ones have a blue
spot at the base. It is found, as its name imports, in India.
The body is brown; tip of the wings hyaline.

Murcia. Bronzved; wings are of a whitish colour
spotted with brown; the lower ones yellow at the base.
Inhabits India.

Vesicula. Wings white; takes its name from an ele-
vated vesicular front, and thorax yellow imaculate. Is
found in America, and is a large insect; the abdomen is
cylindrical, the segments pale at the base and black at the
tip; tail with cylindrical feales.

Rubicunda. Lower wings only blackish at the base;
body square. An inhabitant of Europe. In one sex the
back is spotted with red, in the other with yellow.

Vulgatisima. Thorax yellow, with eight black streaks.
It inhabits Europe.

Oncura. All its wings are ferruginous; the body of
a duney hue; an American insect; the abdomen is cylin-
drical; wings with an oblong brown marginal dot.

Vulcata. Wings hyaline imaculate; abdomen cylin-
drical and reddish. Inhabits Europe.

Siberica. Wings hyaline, with a transverse broad fer-
ruginous
ruginous band towards the tip; body reddish. Inhabits Siberia.

**Sinceton.** The wings of this insect are flat, longitudinally fluate, and black on the thicker margin, with a white stigma. The body is blueish. There is a specimen in the British Museum.

**Canaceata.** Wings immaculate at the base; back and sides of the abdomen interrupted by yellow. It inhabits Europe.

**Pseudomontanus.** Found among the mountainous parts of Italy; wings flat, cincereous, with a brown band at the tip. It is small, and the body of an obscure yellowish.

**Fasciata.** Wings flat, brown, with a white streak. It inhabits India.

**Umbrata.** Found in America. Wings flat, with a brown band.

**Serva.** Wings flat, white, with an oblong black spot at the base and band in the middle. It inhabits China. The body is cylindrical.

**Notata.** The wings of this are flat, with white spots and tips. It inhabits Africa. A specimen is in the museum of Sir Joseph Banks.

**Dimidiala.** Wings flat and black from the base to the middle. It is found in America.

**Equestris.** Wings half black, with a snowy band in the middle. It inhabits Africa. A specimen in the museum of Sir Joseph Banks. The head is brown, with a yellow dorifal line; all the wings are black from the base to the middle, then a snowy band; the tip hyaline with a common brown spot.

**Fluctuans.** Wings black t ipt with white. It inhabits India, is small, and brown; the front is vetcular yellowish.

**Nerula.** Wings white t ipt with black. It inhabits India; the body is black; mouth yellow; fides of the thorax and abdomen spotted with yellow; tail with yellow appendages.

**Chinensis.** The upper wings faint testaceous; lower ones green t ipt with brown. It inhabits China.

**Versicolor.** Wings flat, white with three black and three cincereous spots. It inhabits America. A specimen is in the museum of Dr. Hunter. The head is brown, spotted with yellow; thorax brown, with two yellow lines each side under the wings; the abdomen is brown.

**Vibrans.** Wings flat, white with a black spot in the middle, the tips ferruginous.

**Americana.** Notwithstanding the name, this species is found in India. Wings purplish, with a white band; upper pair t ipt with white, lower ones with a white line at the base.

**Marginata.** Wings black; upper pair with a white spot at the tip; lower ones edged with white. It inhabits Africa; may be seen in Sir J. Banks's museum. The front is blue; eyes brown, dotted with yellow; thorax black; abdomen brown, whitish at the base.

**Ferruginea.** Wings white, yellow at the base; body red. It inhabits China.

**Tolentina.** The wings of the insects of this species are also white; but the body is downy variegated with brown and green. It is found in America. The front is blue; abdomen cylindrical black, the segments with a greenish dot on each side.

**Annea.** Wings hyaline; thorax green bronzened. It inhabits Europe.

**Cyanea.** Wings white, with a snowy spot terminated by a brown one. The body is blue. It inhabits America.

6. **Maculata.** Wings with three black oval spots, the last with a snowy stigma; lower ones with yellowish bands. It inhabits China. The head is yellowish; thorax yellowish with black lines; abdomen flat and yellowish with black lines.

**Contaminata.** Yellowish; wings whitish, with a yellowish t hade in the middle. It inhabits India. The head, thorax, and abdomen yellowish.

**Epomina.** Wings yellowish, with about three black bands. Is found in Carolina. Head and thorax yellowish; abdomen cylindrical, with a yellowish dorsal and lateral line; all the wings have a white costal spot near the tip.

**Varia, or great variegated libellula, the most remarkable English species, makes its appearance towards the decline of summer, and is an animal of singular beauty; it is three inches long, and the wings, when expanded, measure about four inches from tip to tip. Wings varied with yellow and brown, the tip with a white spot terminated by a black one. The head is very large, and affixed to the thorax by an extremely slender neck; the eyes occupy by far the greatest part of the head, and are of a pearly blue-grey cast, with a varying luster; the front is greenish-yellow; the body is long, slender, and black, with rich variegations of bright blue, and deep grass-green. The wings are perfectly transparent, strengthened by numerous black reticular fibres, and exhibit a strongly iridescent appearance, according to the different inflections of light. This insect, in its motions, is extremely rapid, flying about in pursuit of its prey during the middle of the day, and is at this time taken with extreme difficulty, darting off on the slightest alarm from the spot where it settled, and in the space of a second or two flying to a great distance. During the early hours of the morning, and the late ones in the evening, it is easily taken; at such times it is observed to fit with its wings expanded, but in so inert a state, that it will suffer itself to be readily seized by one of its wings, without attempting to move from its place.

**Juncea.** Wings with a blackish necessary membrane; thorax with two yellow lines; abdomen tapering towards the base. Inhabits Europe.

**Carolina.** Wings whitish; lower ones indented ferruginous at the base; thorax brown. An inhabitant of America.

**Capeensis.** In this species the whitish wings are every where spotted and dotted with brown; it is found, as its name imports, at the Cape of Good Hope.

**Tricolora.** Wings variegated with brown, blueish, and yellow, the tip hyaline. An inhabitant of India.

**Rubra.** Is so named from its reddish colour; the wings with a ferruginous base and marginal lines. It inhabits Europe.

7. **Divisions of the Lip equal.**

**Forcipata.** This insect, like the varia, is very large, and expands full four inches and a half. Nose yellow, with a black line on the prominent part; thorax black, with several broad yellow stripes, two on the front, and two behind the ligaments of each pair of wings; abdomen black, with two breaks, resembling a cleft, on each segment; wings transparent and white, with a tuige of amber; tail with three curved claws.

**Grandis** is the largest of this genus found in Britain, and is, perhaps, not inferior in bulk to any insect which this country produces; the fore-part of the head is yellow; the eyes brown, and so large, that they meet at the top of the head. The thorax is of a dun colour, with four oblique bands on each side of a lemon colour. The abdomen
is reddish, often spotted with white and black upon the top and bottom of each segment; the small appendages which terminate the abdomen are very long; the wings have more or less of a yellow complexion, and are distiguished by a brown spot on the exterior edges. The colours of the insect vanish when dead.

**Variatius.** Thorax with two yellow lines on each side; wings with a white spot at the base. It inhabits Terra del Fuego. A specimen is in the museum of Sir Joseph Banks. The body is brown; mouth yellowish, with a black dot at the base; the abdomen is round and ferruginous, the segments are edged with black, and in each a white spot divided by a black line.

**Clavata.** Has a clavate abdomen, which is gibbous at the base, variegated with brown and green. It inhabits China. The head is velucinar green; thorax green with black lines; abdomen green with black flecks, the middle thinner and black with lateral yellow spots, the tip thickened black with a white tail.

**Minuta.** Abdomen yellow, with two black lines; lower wings yellow with two black spots. It is an inhabitant of China. The head is yellow, eyes brown; thorax with yellow lines beneath; abdomen with two black lines above and beneath; upper wings black at the base with a yellow spot.

**B. Wings erect when at rest; eyes distinct; outer divisions of the tip bifid.**

**Virgo.** This is one of the most elegant of the European insects, but is smaller than the *varia* or *grandis*, and is distinguished by its slender, long, cylindrical body, which, as well as the head and thorax, is usually either of a bright but deep golden-green, or else of a deep gilded green; the wings are transparent at the base and tips, but are each marked in the middle by a very large oval patch of dark violet blue, accompanied with indistinct hues, according to the direction of the light; sometimes the wings are entirely violet-black, without the faint appearance of transparency either at the base or the tips, and sometimes they are altogether transparent, without any appearance of the violet-black patch which distinguishes most of the individuals; lastly, the insect sometimes appears with transparent wings, but shaded with a strong call of gilded greenish-brown, each being marked by a small white speck at the exterior edge near the tips. The genus is divided into varieties, viz.:

a. Body shining green-blue; wings blueish in the middle, the base and tip whitish, the margin immaculate. Donovan.

b. Body emerald; wings blue-green, the tip brown, the margin immaculate. Raemaekers.

c. Body milky-green; wings brownish with a white marginal dot.  
d. Body milky; wings brownish with a black spot. It inhabits Europe, and is common about waters.

**Pulchra.** Wings hyaline, not coloured. This is a much smaller species than the *virgo*. It varies in colour, but is generally of a bright and beautiful sky-blue, variegated with black bars on the joints, and with the thorax marked by longitudinal stripes; the wings are transparent, and each marked near the tip with a small, oblong, square, black, marginal spot; the head in this species is broader and narrower in proportion than that of the *L. varia*, and the eyes are round, protuberant, and placed on each side at a distance from one another. From the brilliancy and richness of its colours, it has been called the king's-flyer; it frequents little rivulets of water overhaded with bushes. There are several varieties of this species, taken from the difference of spots and colours: as

1. Body red with yellow and black lines at each segment; thorax green with yellow lines; wings with marginal spots. This is given by Mr. Donovan.

2. Body flesh colour; wings with a brown marginal dot.

3. Body alternately blue and cinereous; wings with a black dot.

4. Body beneath blue-green, above brown; thorax with alternate brown and blueish bands; wings with a black marginal dot.

5. Body green with a flesh-colour blush; thorax with three black lines; wings with a brown marginal dot. It inhabits Europe, in almost endless varieties.

**Ciliata.** Green-bronze; abdomen brown; legs fringed black. Inhabits Coromandel. A specimen is in Sir Joseph Banks's museum. Head and thorax bronzed; abdomen cylindrical.

**Nobilitata.** Upper wings dusky; lower ones sky-blue with black. Is found in South America. Body glossy green; lower wings beneath black.

**Lineata.** Wings with a yellowish or black flaga; abdomen extremely long. Is found in India, and is figured by Drury; who, according to Dr. Shaw, has given a beautiful figure of a species not mentioned by Gmelin, viz. the

**Lucertia,** which is a native of the Cape of Good Hope, and is distiguished by the length of its slender body, which is about five and a half inches long, though scarcely the tenth of an inch in diameter. The wings of this species are transparent, slender, and narrow; they measure from tip to tip five and a half inches. The colour of the head and thorax is brown, with a yellowish stripe on each side, and the body is of a deep mazarine blue.

Having described the several species of the libellula, we shall close our account of this interesting genus of insects with some account of the eyes, as described in Adams' Essays. These are finely adapted for microscopical examination; and by the assistance of a good instrument, it will be seen that the eye is divided into a number of hexagonal cells, each of which forms a complete eye. The external parts of these eyes are so perfectly smooth, and so well polished, that when viewed as opaque objects they will, like so many mirrors, reflect the images of all surrounding objects. The figure of a candle may be seen on their surface multiplied almost indefinitely, shifting its beam to each eye according to the motion given to it by the hands of the observer. Luevenhock says, there are twelve thousand and fifty hundred and forty-four lentes on each eye of the libellula. If one of the protuberant substances be nicely taken from the head of the insect, washed clean, and placed before the microscope, its structure is elegantly seen, and it becomes an object worthy of the highest admiration. Each of the eyes is an hexagon, and has the same effect as a convex lens in forming the image of an object placed before it, as may be seen by turning the mirror of the microscope so as to bring the picture of some well-defined object under the eye. If turned to a single house, in the eye of the insect the house is diminished very much, but it is multiplied into a city; if turned to a folder, there will be seen an army of pigeons performing every motion at the same instant of time; if turned towards a candle, there will be a beautiful and splendid blaze from multitudes of regular flames. See Adams' Essays, 40. p. 195-6.
service, as well for his private amusement, as for the service of his chapel. See King's Band, Household, and Chapel Establishment. See also, N. 203, of the Harl. MSS., Brit. Mus. and N. 1457, 2, 3, 11. of the Ashm. Colléc. Oxford, for "ordnances touching the king's household," made in the time of Edward II. as well as in that of Edward IV. And in the Liber Niger published by Battman, with additions.

LIBERA, in Mythology, the name of a goddess, which Cicero, in his book of the Gods, represents as the daughter of Jupiter and Ceres. Ovid in his Fasti says, that the name was given by Bacchus to Ariadne.

LIBER is exhibited on medals, as a kind of female Baccus, crowned with vine-leaves.

LIBER, in Law, a writ or delivery of so much corn or grain to a customary tenant who cut down or prepared the said grain or corn, and received some part or small portion of it as a reward or gratuity. (Cowell.)

LIBERA Chasfa habenda, a judicial writ granted to a person for a free chalice belonging to his manor, after proof made by inquiry of a jury, that the same of right belongs to him. Reg. Orig. 26.

LIBERA Piscaria, a free fishery, which being granted to a person, gives him property in the fish, &c. (2 Salk. 637.) See Fishery.

LIBERAL Arts, are such as depend more on the labour of the mind than on that of the hand; or, that confine more in specification than in operation; and have a greater regard to amusement and curiosity than to necessity.

The word comes from the Latin lib. ralis; which, among the Romans, signified a person who was not a slave; and whose, whole, of consequence, was not checked by the command of any master. See Arts.

LIBERALE Veronese, in Biography. By this name Vafari speaks of an historial painter, born at Verona in 1451. He was at first a disciple of Vincenzo di Stefano; but afterwards he imitated the style and manner of Bellini of Venice, whom, while a youth, he saw painting in the chapel of St. Nicola at Verona.

He began to paint very early in life, and filled the churches and convents of his native city with highly wrought pictures, which were very much esteemed; and of which the author above-mentioned speaks with high encomiums.

His style appears by his account to be of the early dry manner in art. Compositions consisting of a number of figures, all finished with great minutefees; and frequently of small proportions.

LIBERIA, feasts celebrated by the ancient Romans, in honour of Liber, or Baccus, the same with those which the Greeks called Dionysus, and Dionysiana.

They took their name from Libra, i.e., free, a title conferred on Baccus, in memory of the liberty or freedom which he granted to the people of Bruttia; or, perhaps, because wine, whereof he was the reputed deity, delivers men from care, and sets their minds at ease and freedom. Varro derives the name of this feast from libra, considered as a noun adjective, and signifying free; because the priests were free from their fonction, and eased of all care, during the time of the liberia, as the old women officiated in the ceremonies and sacrifices of these feasts.

LIBERAM LEGEM. See Lex.

LIBERAN, in Geography, a small island of the East Indian sea, near the N.E. coast of the island of Borneo, on which are many dear. N. lat. 6° 2'. E. long. 116° 8'.

LIBERANDIS TERRIS. See Terris.

LIBERATI, in Law, a writ that lies for the payment of a yearly pension, or sum of money, granted under the great seal, and directed to the treasurer, chamberlains, and barons of the exchequer, &c. for that purpose.

In another sense it is a writ to the sheriff of a county, for the delivery of possession of lands, and goods extended, or taken upon the forfeiture of a recognizance.

Liberate is also used for a writ issuing out of the chancery, directed to a gaoler for delivery of a prisoner, who hath put in bail for his appearance. F. N. B. 142 6 Ind 116.

LIBERATI, Antimo, in Biography, a finger in the pontifical chapel at Rome in the 15th century. When a youth, he was a choir-singer in the chapel of the emperor Ferdinand III., and his brother Leopold, previous to his admission into the pope's chapel, where, besides his vocal abilities, he distinguished himself as a composer. He was, likewise, organist of the church of Trinita di Pellegrini, and maestro di cappella, and organist of the church of Santa Maria dell' Anima of the natione Teutonica at Rome. In this quality he wrote a letter, which is often quoted, particularly by Adamo, in his Offiziazio per ben reg. il cico de i Cantoci della Cap. Pont. This letter is addressed to Ovidio Perfepegi, in answer to some queries he had sent to him, concerning the state of music in the pontifical chapel; and the character of some musicians in its service, who were candidates for the place of maestro di cappella of the Metropolitan church at Milan.

This letter, printed at Rome 1683, contains characters of the great Roman masters, and descriptions of styles, more resembling found criticism than any musical work of the last century; but it is, unluckily, written in such a vein of general panegyric, as is more likely to generate scepticism in the minds of modern readers, than conviction. Liberati was a disciple of Benevoli, and his voice a soprano.

LIBERATUS, a deacon of the church of Carthage, flourished about the middle of the fifth century. In the year 534, he was sent to Rome by a council of African bishops held at Carthage for the purpose of consulting with pope John about some dubious points; and he was frequently employed respecting affairs of importance. He drew up an historical memorial of the contests which arose about the opinions of Nellorius and Eutyches, entitled "Brevisarum de Caufa Nellorii et Eutychetis, &c." The materials made use of on this occasion were collected from the relations of various credible persons, the history of the church, translated out of Greek into Latin, authentic acts of councils, and the letters of different bishops. An appendix to this Brevarium is given by father Crabbe, in the second volume of his edition of the Councils. Muratori.

LIBERGA, in Geography, a town of Prussia, in the palatinate of Culm; 26 miles E. of Culm.

LIBERHOF, a town of Prussia, in the province of Pommerelia; 18 miles S.S.E. of Danzig.

LIBERI Turri Libertas. See TAURI.

LIBERIA, a feat held among the Romans, on the day when their children laid aside their juvenile habits, and assumed the robe called toga liberia.

The liberia were kept on the 16th of the kalends of April; that is, on the 17th of March.

LIBERIUS, pope, in Biography, a native of Rome, who, having discharged the duties of different ecclesiastical offices with reputation, was chosen bishop in 352. Immediately after his election he wrote to Athanasius, summoning him to appear at Rome, and clear himself from the accusations preferred against him by the eastern bishops. It should seem he had afterwards a much better opinion of Athanasius, and undertook his defence with great zeal. With this view he sent legates to a council which the emperor Constantine had summoned to meet at Arles, but had
L. I. B

the mortification to hear they had betrayed the cause entrusted to them. When Liberius was told of the conduct of his deputies, he was filled with resentment and sorrow, and disfavored it in the strongest terms, as well in his declarations, as in his correspondence. He requested the emperor to assemble a new council, for the purpose of examining the matters in dispute between Athanasius and his opponents, and of restoring peace and tranquillity to the Catholic church. A council was accordingly held at Milan in 355, at which there were 300 western bishops, and a few from the east. So far from calming discussion into the merits of the question, the emperor infused upon it, as a preliminary measure, that they should give their signatures to the condemnation of Athanasius, and also to an edict containing the chief tenets of Arius, which had been published in his name. Those who had resolution to oppose the will of the emperor were threatened with infatant execution, and were actually banished. Such were the means used by Conflantius in obtaining the signatures of by far the greater part of the western bishops to the condemnation of Athanasius; but Liberius still declared in his favour, and exerted himself, by all the means in his power, to gain others to his party. At length, the emperor having failed, by threats and profcribed bribes, to gain the suffrages of the pope, he determined to apprehend him, and gave his order accordingly. This was executed in the dead of night, to prevent any commotion among the people, who were much attached to their bishop; he was carried first to Milan, and thence to Thrace. The hardships which Liberius experienced in exile, disfigured him to yield to conditions which at one time he would have rejected with the utmost indignation. He not only subscribed to the condemnation of Athanasius, but received, as Catholic, the Arian confession, and made other concessions still more disgraceful to his reputation as bishop of the holy Roman see. Before he could reach Rome, the emperor had embraced the doctrine of the Semi-Arians, and obliged Liberius to do the same; so that this pontiff, who, of course, was always the infallible head of the church, avowed himself an Athanasian, as Arius, and a Semi-Arian. On account of his obedience, he was permitted to return to Rome, on condition that he should govern the church jointly with Felix II. (See the article.) Liberius arrived at Rome in August, 358, and entered the city in a kind of triumph, being met on the road, and received by the people at large with loud acclamations of joy. He died in September, 366, after he had professed over the Roman see fourteen years; and notwithstanding his repeated change of religious opinions, he is honoured both by the Latin and Greek churches as a saint. "A Dialogue with the Emperor Conflantius" is ascribed to Liberius; so, likewise, are twelve "Letters," inserted in the second volume of the Collect. Concil. Bower. Moreri.

LIBERO, Ital. free, unconfined, in Musæ, the name ascribed to Hegesippus, contained in the canonists; fisco, fiscus, or Liberato, from Fugò perpetua. See SCIOLTA, and LEGATO.

LIBERTAS Ecclesiastica, Church Liberty, a frequent phrase in old writers, who treat of ecclesiastical immunities. The right of investiture, extorted from our kings by the papal power, was at first the only thing challenged by the clergy, as their libertas ecclesiastica, but by degrees under the title of church liberty, they contended for a freedom of their persons and possessions, from all secular power and jurisdiction; as appears by the canons and decrees of the councils held by Boniface, archbishop of Canterbury, at Merton, A. D. 1258, and at London, A. D. 1260, &c.

See Lord Littledon's Hist. of Hen. II., and Robertson's Hist. of Ch. V.

LIBERTATE PROBANDA, in Law, an ancient writ that lay for such as being demanded for villains, offered to prove themselves free; directed to the sheriff, that he should take security of them for the proving of their freedom before the justices of assize, and that in the mean time they should be unmolested. F. N. B. 77.

LIBERTATIBUS ALLOCANDIS, a writ lying for a citizen or burgess, implicated contrary to his liberty, to have his privilege allowed. Reg. Orig. 262.

If any claim a special liberty to be impeded within a city or borough, and not elsewhere, there may be a special writ de libertatibus allocandis, to permit the burgesses to use their liberties, &c., These writs are of several forms, and may be granted by a corporation, or by any single person, as the case shall happen. (New Nat. Br. 500, 510.) The barons of the Cinque Ports, &c., may sue forth such writs, if they are delayed in having their liberties allowed them.

LIBERTATIBUS EXIGENDIS IN ITINERE, an ancient writ by which the king commands the justices in eyre to admit of an attorney for the defence of another man's liberty. Reg. Orig. 19.

LIBERTATIS Anglæ Cujusque. See Custodes.

LIBERETE de la Musique, is the title of one of the late M. D'Alembert's Essays in his "Melange de Litterature," published in 1767. After being the champion of Rameau's fifth, and his baffe fondamente, he became his opponent, and a convert to Italian music. He enters into all the reasoning of Rouette against the French style of composition, but in a more guarded manner. Indeed, he appears never to have heard good Italian music well performed. The Suva Paderna of Pergolesi, executed by a troop of Italian burletta singers, not of the first clafs, was his standard of perfection. He tries hard to persuade the French that their music is bad, without knowing very well in what the Italian was superior. Rouette had resided at Venice a considerable time, and seems forcibly to have felt all the lyric beauties of Metafatto's poetry, as well as the merits of the great composers and enchanting powers of the great fingers of his time. This, D'Alembert only knows by tradition. It was easy for a man of his abilities to ridicule the old French music, and praise the Italian; but he was too little acquainted with its real beauties to know why Italian dramatic vocal music was superior to all other music, and the French inferior. But it may, perhaps, be roundly asserted that the French vocal music dost is, and probably ever will be inferior to the Italian from bad singing, as well as from the safful nature of their language, and the national expression founded upon it, by which the vocal organ is vitiated from infancy to age, and its tones in their expression rendered unpleasing to all ears but those of the natives.

The French, since the time of Rameau, have often had fine compositions performed in their theatres, and a well disciplined band to execute them instrumentally; yet, for want of good singers, the vocal part, which is the best and most interesting in an Italian opera, is the worst in the musical dramas of France. And for this there are two causes which affect the composition as well as the performance of French opera fongs: the composer, be he a Gluck, a Piazzit, or a Sacchini, having no great vocal talents to display, dares not give way to fancy, or aim at new passages, but, of necessity, underwrites the vocal part so much, that the productions of these great masters for the French stage are never in favour elsewhere with their greatest admirers. And even the simple
ample and common passages given to the voice, are so ill sung, that they give pleasure to no ears but those which are accustomed to nothing better.

In 1767, when D'Alembert wrote in favour of toleration in the religious religion of France, the accomplishments to what were called fongs at the opera were so bloody and so loud, that he compares the effect to twenty people reading different books at the same time.

Though D'Alembert and Rousseau quarrelled about the expediency of allowing plays to be acted within the walls of Geneva; yet the mathematician in his discours on the Liberty of Music, is but a commentator on the citizen of Geneva's "Letter concerning French Music."

On the subject of adapting Italian melody to French words, the great mathematician has not taken into his calculation all the objections to its success. In Italian poetry each verse is terminated by a double rhyme; and in the French poetry, the masculine and feminine rhymes are alternate. This must affect the melody. The mute syllables in French poetry (which are dogrel in English), can alone receive Italian melody: the masculine rhymes admit of no imitation.

M. D'Alembert, however, modestly says, that all his reflections are not worth, a single fine air in music; and adds (after Rousseau), that "inventing what succeeds is infinitely preferable to philosophical reasoning: a composer never thinks of giving precepts who is able to furnish models: Raphael produced pictures, not dissertations. In music, we (the French) write reveries; and the Italians compose and execute music." The two nations, in this respect, resemble the two architects who were candidates at Athens for the erection of a monument which the republic wished to raise to a deified hero; one of them spoke a long while with great eloquence on his art; the other, after listening with great attention, only uttered these words: "What he says, I have done."

LIBERTIES. See Franchise.

LIBERTINES, in Scripture History, the denomination of a class of Jews, or Jewish profligates, who had a synagogue at Jerufalem, which is mentioned in the book of Acts, ch. vi. 9. Libertinus, or Libertine, denoted a person who had been a slave, but who had obtained his freedom; or one who was the son of a person that had been a slave, and was afterwards made free. Several learned men have supposed, that the libertines above-mentioned were Jews, or profligates of the Jewish religion, who had been slaves to Roman masters, and had been made free, or the children of such. In proof of this, the learned Lardner alleges, that there was a great number of Jews at Rome; and, according to Philo, they occupied a large quarter of the city; and they were chiefly such as had been taken captive at several times, and had been carried into Italy, and were made free by their Roman masters. That these Jews were called Libertines, appears plainly from passages, which Lardner has cited from Tacitus, Josephus, and Suetonius, in which they speak of the banishment of the Jews from Rome in the reign of Tiberius. Josephus and Suetonius expressly call those Jews, whom Tacitus calls men of the Libertine race; and as there were many of them at Rome, it is not at all unlikely that they had a synagogue at Jerufalem. Such are the sentiments of Grotius and Vitringa, adopted by Lardner's Works, vol. i. p. 114.

LIBERTINES, Libertini, in Ecclesiastical History, a religious sect, which arose in the year 1525, whose principal tenets were, that the Deity was the sole operating cause in the mind of man, and the immediate author of all human actions: that, consequently, the distinctions of good and evil, which had been established with regard to those actions, were false and groundless; and that man could not, properly speaking, commit that religion consisted in the union of the spirit, or rational soul, with the Supreme Being; that all those who had attained this happy union, by sublime contemplation and elevation of mind, were then allowed to indulge, without exception or restraint, their appetites or passions; that all their actions and pursuits were then perfectly innocent; and that, after the death of the body, they were to be united to the Deity.

They likewise said that Jesus Christ was nothing but a mere "je ne sais quoi," composed of the spirit of God, and of the opinion of men.

These maxims occasioned their being called Libertines: and the word has been used in an ill sense ever since.

The Libertini spread principally in Holland and Brabant. Their leaders were one Quintin, a Picard, Pockefius, Ruffius, and another called Chopin, who joined with Quintin, and became his disciple.

This sect obtained a certain footing in France through the favour and protection of Margaret, queen of Navarre, and filter of Francis I., and found patrons in several of the reformed churches. This sect was probably a remnant of the more ancient Beghards, or Brethren of the Free Spirit. Motheın's Eccl. Hist. vol. iv.

LIBERTINES of Geneva, were a cabal of rakes rather than of fanatics: for they made no pretences to any religious system, but pleaded only for the liberty of leading voluptuous and immoral lives. This cabal was composed of a certain number of licentious citizens, who could not bear the severe discipline of Calvin, who purified with rigour not only dissolute manners, but also whatever bore the aspect of irreligion and impiety. In this turbulent cabal there were several persons who were not only notorious for their dissolute and scandalous manner of living, but also for their atheistical impiety and contempt of all religion. To this odious class belonged one Gruet, who denied the divinity of the Christian religion, the immortality of the soul, the difference between moral good and evil, and rejected with disdain the doctrines that are held most sacred among Christians; for which impieties he was at last brought before the civil tribunal, in the year 1530, and condemned to death. The Genevan spirit of reformation, improperly directed by the violence and zeal of Calvin, did at this time operate to a degree, which has marked the character of this great reformer with reproach. For, in 1544, Sebastian Cardano, master of the public school at Geneva, who was a man of probity and distinguished by his learning and talents, was, nevertheless, deposed from his office and banished the city, because he disapproved some of the measures that were purged, and some of the opinions entertained by Calvin and his colleagues, and particularly that of absolute and unconditional predestination. Jerome Bollee, also, a man of genius and learning, who became a convert to the Protestant religion, and fled to Geneva for protection, was cast into prison, and, soon after, sent into banishment; because, in 1551, he imprudently and indecently declaimed, in full congregation, and at the close of public worship, against the doctrine of absolute decrees. Motheın's Eccl. Hist. vol. iv.

LIBERTUS, or LIBERTINUS, among the Romans, a freedman, or a person set free from a legal servitude.

These still retained some mark of their ancient state; he who made a slave free having a right of patronage over the libertus; so that if the latter failed of shewing due respect to his patron, he was reduced to his servitude; and if the liber-
us died without children, his patron was his heir. See Slave.

In the beginning of the republic, libertinus denoted the son of a libertinus, or freedman; but afterwards, before the time of Cicero, and under the emperors, the term libertinus and libertin, as Suetonius has remarked, were used as synonymous.

LIBERTY, in Geography, a post-town of America, in Virginia; 15 miles from New London. This is the chief town of Bedford county; it has a handsome court-house, and contains 50 or 60 houses. —Also, a county of Georgia, bounded by N. by Brian, S. by Mackintosh, W. by Alabama, and N. E. by the ocean. It is 40 miles long, and 22 broad. The productions are cotton and rice. An acre of land yields 25 or 30 bushels of corn. It derives its name from the circumstance, that its inhabitants were the first in the state who declared for liberty, and sent a delegate to the congress at Philadelphia. It is divided into five towns, and contains 5313 inhabitants, of whom 3940 are slaves. —Also, a post-town of Maryland, in Frederick county; 12 miles N.E. of Frederickstown, and about 44 miles N.N.W. of the Federal city.

Liberty, Libertas, is usually understood of that state wherein a man acts freely; or that power by which he determines himself voluntarily either to good or evil, to this thing or that.

This is what some have denominated a liberty of indifference, natural liberty, philosophical liberty, or liberty of choice; defining it to be a power of doing an action or its contrary, all the previous circumstances remaining the same. In this sense it stands opposed to necessity, and is distinguished from external liberty, or liberty of action, which is defined to be the power of doing what we please or will; or, in other words, the power of carrying our volitions or purposes into effect. This external liberty is opposed to compulsion from external force, as philosophical liberty is to necessity, or the definite influence of motives, in definite circumstances. Accordingly it is said, that liberty of action may exist independently of liberty of choice; that is, the mind may be wholly untrained in the execution of its volitions, though in the same circumstances it could not have made a different choice. Liberty of choice, likewise, if it exists at all, is perfectly independent of liberty of action.

Most of the schoolmen confound liberty and the will together, and make one definition serve for both. Whereas Mr. Locke observes, that liberty does not belong to the will, but to the man or agent; and therefore, that the question, in the usual manner of stating it, whether man's will be free or not, is absurd and unintelligible. Liberty, which is but a power, belongs only to agents, and cannot be an attribute or modification of the will, which is also but a power. They distinguish liberty into a great many kinds; as liberty of contrariety, and liberty of contradiction. (See Freedom.) Also, next liberty, prioria, which is a full absolute freedom of doing any thing: remote liberty, which is a liberty that comprehends a natural power, though embarrased with obstacles, which it is in our power to remove, and to attain to a next liberty. Some writers have divided liberty into liberty, physical, or philosophical, or liberty of choice, which is that principle of spontaneity or self-determination, that constitutes us agents; or that gives us a command over our actions, rendering them properly ours and not effects of the operation of any foreign cause. Without this liberty, or being under a necessity of always following fores will different from his own, man would be a machine acted upon by mechanical springs, having no principle of motion in himself or command over events: and, therefore, incapable of all merit and demerit.

Whether man is endowed with this kind of liberty or self-determining power has been a subject of much controversy: it was agitated at the beginning of the last century, between Leibnitz, Collins, &c. on one side, and Clarke, Jackson, &c. on the other; and has been more lately reviewed by Dr. Prifley.

Cicero defines liberty the power of living after a man's own will, without any caufe or impediment to oblige him to do one thing rather than another.

F. Malebranche gives us a still more philophical definition: the will he defines to be that impression, or natural motion, which inclines towards good in the general; and by liberty, he understands, that power which the mind has of determining this general impression towards such objects as please us; and of directing our general inclinations to some particular things.

Whence it is easy to perceive, that though all natural inclinations be voluntary, yet they are not all free; not, we mean, with a liberty of indifference, which includes a power of willing, or not willing, or of willing quite the contrary to that which our natural inclinations lead us to. For though it is voluntarily and freely that we love good in general, it is absurd to suppose we should love any thing without the will, or that the will can ever be constrained; yet we do not love it freely (in the sense just laid down) because it is not in the power of the will not to desire to be happy.

It must be observed, however, that the mind, considered as determined towards good in general, cannot divert its motion to any particular good, unless the mind, considered as capable of ideas, have some knowledge of that particular good: that is, in plainer terms, the will is a blind power, that cannot direct itself to any thing but what the understanding represents to it; so that the power which the will has to determine its impression towards general good, or its natural inclinations, variously, conflicts in the power it has to command the understanding to represent some particular good.

Thus, a person, for instance, represents some dignity to himself, as a good to be wished for, immediately the will determines this good; that is, the impression which the mind continuously receives towards good in general, determines it to this dignity. But as that dignity is not the universal good, nor is perceived clearly and distinctly as such by the mind (for the mind cannot conceive a thing clearly which is not), the impression we have towards good in general, is not entirely exhausted by that particular good; the mind has an inclination to go farther; it does not love that dignity necessarily or invincibly, and in this respect is free.

Now its liberty consists in this, that, not being fully convinced that this good contains in it all the good it is capable of enjoying, it may suspend its judgment and its desire.

The case is nearly the same with regard to the knowledge of joy: we love this, as we do the enjoyment of good, by a natural impression; which impression is not invincible in the latter, excepting evidence be full, and our knowledge of the object complete. We have the same liberty in our false judgments, that we have in our irregular appetites. See Judgment and Will.

Mr. Locke defines liberty to be the power which a man has to do or forbear doing any particular action, according as its doing or forbearance has the actual preference in the mind, which is the same thing as to say, according as he himself wills it: and he observes, that so far as a man has power to think or not to think, to move or not to move, according
cording to the preference or direction of his own mind, so far is a man free. The will, he acknowledges, is always determined by some, and for the most part, by the most prevailing uneasiness or desire of happiness. The liberty for which he contends, and for the existence of which he appeals to experience, is a liberty of suspending our determination. The mind, he says, having, in most cases, as is evident in experience, power to suspend the execution and satisfaction of any of its desires, and so all, one after another, is at liberty to consider the objects of them, examine them on all sides, and weigh them with others. In this lies the liberty a man has. He has a power to suspend the execution of this or that desire, as every one daily may experience in himself. This seems to be the source of all liberty. In this sense to conțend, as he thinks, that which is improperly called free-will. And he adds farther, that perfect indiffERENCE in the mind, not determinable by its last judgment of the good or evil, that is thought to attend its choice, would be so far from being an advantage and excellency of an intellectual nature, that it would be as great an imperfection as the want of indiffERENCE to act or not to act, till determined by the will, would be an imperfection on the other side. Eff. vol. i. book i. chap. 21.

From these conclusions the advocates for necessity have pleaded the authority of Mr. Locke, though he does not seem to have been apprized of the confquences of his principles. Mr. Hobbes, who seems to have been the first who understood and maintained the proper doctrine of philosophical necessity, defines liberty to be the absence of all impediments to action, that are not contained in the nature and intrinsic quality of the agent. And Mr. Collins, the principal writer on the side of necessity, defines liberty to be a power in man to do as he wills, or pleases; though he denies, that we are at liberty to will, or not to will; or to will one or the other of two or more objects, between which, all things considered, we perceive a difference; or that we are free in our choice among things different or alike.

Dr. Clarke has remarked, that, in the above definition, there is an ambiguity in the words, "wills or pleases;" because they may either denote the last perception or judgment of the understanding, which is entirely passive; or the first exertion of the self-moving power, which is essentially active. Now, though the self-moving power is an adequate cause of action, yet understanding, or judgment, or affection, or approbation, or liking; or whatever name it is called by, can no more possibly be the efficient cause of action, than rest can be the cause of motion. Nothing can possibly be the cause of an effect more considerable than itself. Nothing that is passive can possibly be the cause of any thing that is active: an occasion indeed, it may be; and action may be consequent upon perception or judgment; it may easily be supposed to be always consequent upon it, and yet at the same time there may be no manner of physical or necessary connection between them. Besides, the word "do," in this definition of Mr. Collins, has no significations. For its meaning is not, that the man "acts" or "does" any thing; but the liberty or power in man to do as he wills or pleases, is with him exactly and only the same as the liberty or power in a balance to be moved as it wills or pleases; supposing the balance endued with such a sensation or intelligence, as enabled it to perceive which way the weights turned it, and to approve the motion, so as to fancy that it moved itself, when indeed it was only moved by the weights. Mr. Collins makes the difference between a man and a clock, to consist only in sensation and intelligence, not in any power of acting: whereas the whole essence of liberty consists in the power of acting: so that action and liberty are identical terms.

The liberty of a moral agent, according to Dr. Reid, is a power over the determinations of his own will. If, in any action, he had power to will what he did, or not to will it, in that action he is free. But if, in every voluntary action, the determination of his will be the necessary consequence of something involuntary in the state of his mind, or of something in his external circumstances, he is not free; he has not the liberty of a moral agent, but is subject to necessity. This liberty supposes the agent to have understanding and will; for the determinations of the will are the sole object about which this power is employed; and there can be no will without such a degree of understanding at least, as gives the conception of that which we will. The liberty of a moral agent implies, not only a conception of what he wills, but some degree of practical judgment or reason. For if he has not the judgment to discern one determination to be preferable to another, either in itself or for some purpose which he intends, what can be the use of a power to determine? His determinations must be made perfectly in the dark, without reason, motive, or end. They can neither be right nor wrong, wise nor foolish. Whatever the consequences may be, they cannot be imputed to the agent, who had not the capacity of foreseeing them, or of perceiving any reason for acting otherwise than he did. The author now cited restricts his attention to the liberty of moral agents, who are capable of acting well or ill, wisely or foolishly; and this liberty he calls, by way of distinction, "moral liberty." By necessity he understands the want of this moral liberty. This moral liberty a man may have, though it do not extend to all his actions, or even to all his voluntary actions. He does many things by instinct, many things by the force of habit, without any thought at all, and consequently without will. But in general this power over the determinations of his own will extends to every action for which he is accountable. This power may be impaired or lost, by disorder of body or mind, as in melancholy, or in madness; it may be impaired or lost by vicious habits; and, in particular cases, it may be restrained by divine interposition. In fact, man is a free agent in the same way as he is a reasonable agent. His reason is liable to be impaired or lost by his own fault, or by other means. It is also the case with respect to his freedom of action. The liberty above stated and explained has been represented by some philosophers as inconceivable, and as involving an absurdity. "Liberty," say Hobbes and others who have adopted this reasoning, "consists only in a power to act as we will, and it is impossible to conceive in any being a greater liberty than this. Hence it follows, that liberty does not extend to the determinations of the will, but only to the actions consequent to its determination, and depending upon the will. To say we have power to will such an action, is to say, that we may will it, if we will. This supposes the will to be determined by a prior will, and for the same reason, that will must be determined by a will prior to it, and so on in an infinite series of wills, which is absurd. To act freely, therefore, can mean nothing more than to act voluntarily; and this is all the liberty that can be conceived in man or in any being." The advocates of necessity maintain, that this is the only liberty that is possible, that is conceivable, and that does not involve an absurdity. Dr. Reid, however, mentions three other kinds of liberty, to which the term is very commonly applied: such are liberty, as opposed to external force or constraint of the body; liberty as opposed to obligation by law, or
LIBERTY.

by lawful authority; and liberty as opposed to necessity, in which latter sense it extends to the determinations of the will only, and not to what is consequent to the will. It has been a question among philosophers, whether, in every instance, the determination of the will, which is the first part of the action in every voluntary action, and upon which alone the moral elaboration of it depends, be the necessary consequence of the constitution of the person, and the circumstances in which he is placed; or whether he has not power, in many cases, to determine this way or that? This has, by some, been called the "philosophical" notion of liberty and necessity; but it is by no means peculiar to philosophers. The lowest of the vulgar have, in all ages, had recourse to this necessity for exculpating themselves or their kindred when they do wrong, though, in general, tenets of their conduct, they act upon the contrary principle. Whether the notion of moral liberty, above stated, be conceivable or not, every man must judge for himself. "To me," says Dr. Reid, "there appears no difficulty in conceiving it. I consider the determination of the will as an effect. This effect must have a cause which had power to produce it; and the cause must be either the person himself, whose will it is, or some other being. The first is as easily conceived as the latter. If the person was the cause of that determination of his own will, he was free in that action, and it is jutly imputed to him, whether it be good or bad. But if another being was the cause of that determination, either by producing it immediately, or by means and instruments under his direction, then the determination is the act and deed of that being, and is solely imputable to him." Should it be said, that nothing is in our power but what depends upon the will; and therefore the will itself cannot have power over power; it may be replied, that this is a fallacy arising from taking a common laying in a fork which it was never intended to convey, and in a fork contrary to what it necessarily implies. To say that what depends upon the will is in a man's power, but the will is not in his power, is to say that the end is in his power, but the means necessary to that end are not in his power, which is a contradiction.

The principal arguments in favour of liberty, as it is popularly understood, and as it is defined in the beginning of this article, are the following: this principle is necessary to constitute man an agent (see AGENT); for, as far as it is true of a being that he acts, so far he must himself be the cause of the action, and, therefore, not necessarily determined to act: but if he has no absolute power over his own actions, i.e. if he be not a free agent, the actions which he performs cannot properly be said to be his own, but must be ascribed to some other power, by which he is led on to perform them; as a good clock or watch performs the motions assigned to it by the artificer. This argument is excellently illustrated by Dr. Clarke: man, says he, either has within himself a principle of action properly speaking, i.e. a self-moving faculty, a principle or power of beginning motion; or he has not. If he has within himself such a principle, then he is a free, and not a necessary agent: for every necessary agent is moved necessarily by something else; and then that which moves it, not the thing itself which is moved, is the true and only cause of the action. That any other thing operating upon an agent, should efficiently and necessarily produce self-motion in that agent, is a direct contradiction in terms. If man has not within himself a principle or power of self-motion, then every motion and action of man is chiefly and properly produced by the efficiency of some extrinsic cause; which cause must be either what we usually call the motive or reason upon which a man acts; or else it must be some infensible subtle matter, or some other being or substance making an impression upon him. If the reasons or motives upon which a man acts be the immediate and efficient cause of the action, then either abstract notions, such as all reasons and motives are, have a real subsistence, that is, are themselves substances; or else that which has itself no real subsistence can put a body into motion; either of which is manifestly absurd. If infensible subtle matter, or any other being or substance, continually making impression upon a man, be the immediate and efficient cause of his acting; then the motion of that subtle matter or substance must be caused by some other substance, and the motion of that by some other, till at last we arrive at a free agent; and then liberty is a possible thing, and man possibly may have liberty: and if he may possibly have it, then experience will prove that he probably, nay, that he certainly, has it. If we never arrive at any free cause, then there is either in infinitum a progression of motions without any mover, of effects without any cause, of things acting without any agent; which is a manifest contradiction: or else motion exists necessarily of itself. If motion exists necessarily of itself, it must be either with a determination every way, or one certain way; if with a determination every way, this is no motion at all; if with a determination one certain way, then that determination is either necessary, and consequently all other determinations impossible, which is contrary to experience; or else there must be a particular reason of that determination, and so backwards in infinitum, which comes to the forementioned absurdity, of effects existing without any cause.

Further, liberty is the dictate of our own consciousnes; we have, really, the same constant and necessary consciousness of liberty that we have, that we think, choose, will, or even exist; and whatever men may say to the contrary, it is impossible for them, in earnest, to think they have no active self-moving powers, and are not the causes of their own volitions, or not to ascribe to themselves what they must be conscious they think and do. Mr. Hume, though he denies the reality of liberty, grants that we have a feeling of it; that the divine plan required that we should be so made, as to feem to ourselves free; that the whole constitution of things is as if we were free; and that being under a necessity of approving and disapproving actions and characters, we are so far under a necessity of believing ourselves and others free. After these concessions, it can hardly be imagined that the constitution of nature should be altogether imposition and deceit.

"We have by our constitution," says Dr. Reid, "a natural conviction or belief that we act freely; a conviction so early and so universal, that it must be the refult of our constitution, and the work of him that made us." And he adds, "the genuine dictate of our natural faculties is the voice of God no less than what he reveals from heaven; and to say that it is fallacious, is to impute a lie to the God of truth." Moreover, in favour of free-will an appeal has been made to "common sense," that is, to the irresistible conviction and universal consent of mankind. To this purpose it has been laid, that very few have denied the existence of liberty of choice even in theory; but this," says a necessitarian writer, "is only saying that there have been very few philosophers;" so as if the denial of liberty of choice were a sect of true philosophy. All men, it has been alleged, without excepting the professed necessitarians themselves, are under the necessity of acting upon the principle of liberty, whatever their hypothetical speculations may be.

All men agree in applauding some actions and condemning others,
others, which would be absurd upon the supposition that men were delitute of free will; all men make a distinction between harm and injury, e.g. between a blow given by design and another occasioned by accident; and the laws of all nations agree to punish an action performed by a man in possession of reason, when they excuse a lunatic; the former being free, and the latter not.

Besides, if man be not, in the strictest sense of the word, a free agent, he can be no moral agent. It is hard to say, what virtue and vice, commendation and blame, mean, if they do not suppost agency, voluntary motion, free choice, and an absolute dominion over our resolutions. Can we applaud or reproach ourselves for what we were no more the causes of than of our own beings, and what it was no more possible for us to prevent than the returns of the seasons, or the revolutions of the planets? On the system of necessity, conscience is an inexplicable principle: its cenures or applause are equally futile and groundless: the approbation of mankind is an infall with regard to those on whom it is beloved, because they can have no merit; and the reproach of men unjust and cruel, because there can be no demerit and ground of blame. Whatever difficulties, therefore, may attend the nature of that influence which we ascribe to motives. (see Motive,) they cannot be the efficient necessitating cause of human actions: since, on this supposition, there could but one agent in the universe; who must equally be the author of all the good and evil in the world, and on whom must ultimately be charged the sin and misery, as well as the virtue and happiness of his creatures.

Moreover, it has been urged by the advocates of liberty, that if men’s determinations and actions flow necessarily from the previous state of their minds and the motives or influences resulting from a nature or condition, imposed upon them without their own consent or choice, the idea of responsibility or accountableness must vanish, and there can be no propriety or use of rewards or punishments. God cannot reward without virtue, and there can be no virtue without a self-determining power: he cannot punish without guilt, and there can be no guilt when men do what they cannot avoid doing, and when their actions arise from circumstances in which their Creator placed them.

It is also equally unjust and useless to threaten punishment or inflict it on men to prevent crimes, when they are necessarily determined in all their actions. And if men are necessary agents, though we cannot well admit this verbal contradiction, it can be of no use to reason with them, to admonish or intreat them; and God must be inexcuseable in his addresses and invitations, and cruel in his requirements and commands. But such is the whole tenour of revelation, and, therefore, the conclusion is necessary, that man is a free agent, capable of good or evil, and of determining his pursuit of either, from the sole power of his own judgment or will.

If we adopt the system of necessity,” says Dr. Reid, “the terms moral obligation and accountableness, praise and blame, merit and demerit, justice and injustice, reward and punishment, wisdom and folly, virtue and vice, ought to be diffused, or to have new meanings given to them when they are used in religion, in morals, or in civil government; for upon that system, there can be no such things as they have been always used to signify.”

Another argument for proving that man has power over his own actions and volitions has been deduced from the consideration that he is capable of carrying on wisely and prudently, a system of conduct, which he has before conceived in his mind, and resolved to prosecute. If all the particular determinations, which concurred in the execution of the plan which such a person had formed, were produced, not by himself, but by some cause acting necessarily upon him, then there is no evidence left that he contrived this plan, or that he ever spent a thought about it. The cause that directed all these determinations to wisely, must be wise and intelligent. If it be said, that this whole course of determinations was produced by motives, motives fiercely have not understanding to conceive a plan, and intend its execution. We must therefore revert to some intelligent being, who had the power of arranging these motives, and applying them, in their proper order and seafon, so as to bring about the end. If man, then, had no concern in the execution, we have no evidence left, that he had any concern in the contrivance, or even that he is a thinking being.

Another argument from another system of necessity, is the fact of man being able to execute his designs. Man, with all his boasted faculties, is reduced to the state of a mere automaton or machine. Whereas, if wise conduct in a man demonstrates that he has some degree of wisdom, it demonstrates, with equal force and evidence, that he has some degree of power over his own determinations. We shall clofe this article with observing, that Mr. Abraham Tucker, the acute author of a work entitled “The Light of Nature purend,” by Edward Searle, eqq. after having argued strenuously against the existence of a liberty of indifference, contends for the existence of free-will, the exercise of which he conceives "to be only a particular species of action, performed in raising up ideas, or fixing them on the mind, which shall determine us to such volitions as we want." He expressly favours the doctrine of necessity. See on this subject Collins’s Enquiry concerning Human Liberty, first printed in 1717. Clarke’s Remarks, 1717, and Collection of Papers which passed between Mr. Leibnitz and Dr. Clarke, in 1715 and 1716. Jackson’s Vindication and Defence of Human Liberty, 1730. Reid’s Essays on the Active Powers of Man, eff. iv. Gregory’s Philosophical Essays. Edwards on the Will. Palmer on Liberty. Beattie on Truth. Belsham’s Elements of the Philosophy of the Mind, &c. For the objections against liberty, and the arguments in support of necessity, see Necessity.

Liberty of conscience, a right or power of making profession of any religion, or of serving God in any manner that a man sees fit. This seems to be a natural right; it is vigorously opposed by the generality of the Romanists, and even by many of the reformed, though it seems as if the reformation could scarcely subsist without it. See Toleration and Persecution.

Liberty, Moral, is the power of following, in all circumstances, our sense of right and wrong; or of acting in conformity to our reflecting and moral principles, without being controlled by any contrary principles or habits. See Liberty, supra.

Liberty, Religious, is the same with liberty of conscience, and signifies the power of exercising, without molestation, that mode of religion which we think best; or of making the decisions of our own consciences, respecting religious truths, the rule of our conduct, and not any of the decisions of others.

Liberty, Civil, is the power of a civil society or state, to govern itself by its own discretion; or by laws of its own making, without being subject to any foreign discretion, or to the impositions of any extraneous will or power. Civil liberty, says judge Blackstone, adopting the definitions of the Institutes, consists in the power of doing whatever the laws permit; or it is natural liberty, or a power of acting as one thinks fit, without any restraint or controul, unless by the law.
much liberty itself, as the safeguards and preservatives of liberty; e.g. a man's being governed by no laws but those to which he has given his consent, were it practicable, is no otherwise necessary to the enjoyment of civil liberty, than as it affords a probable security against the dictation of laws, imposing superfluous restrictions upon his private will. The same remark is applicable to the rest. We may farther observe, that in most of these definitions civil liberty and political liberty are confounded. Upon the whole we may remark, that whatever definitions of either kind of liberty we adopt, that people, government, and constitution is the freedom, which makes the best provision for the enacting of expedient and salutary laws.

to another and 4thly, every man, filled with the conscience of his own advantage and happiness. It is a man's civil liberty, which is originally in its full force, and part of which he sacrifices when he enters into a state of society.

Civil liberty, according to the definition of archdeacon Paley, is "the not being restrained by any law, but what conduces in a greater degree to the public welfare." To do what we will, he says, is nature's liberty; to do what we will, confidently with the interest of the community to which we belong, is civil liberty; that is, the only liberty to be defined in a state of civil society. The definition above laid down imports that the laws of a free people impede no restraints upon the private will of the subject, which do not conduce in a greater degree to the public happiness; by which it is intimated, 1st, that restraint itself is an evil; 2dly, that this evil ought to be overbalanced by some public advantage, 3dly, that the proof of this advantage lies upon the legislature; 4thly, that a law, being found to produce no sensible good effects, is a sufficient reason for repealing it, as adverse and injurious to the rights of a free citizen, without demanding specific evidence of its bad effects. This maxim, our author adds, might be remembered with advantage in a revision of many laws of this country; especially of the game laws; of the poor laws, so far as they lay restraints upon the poor themselves; of the laws against papists and dissenters; and amongst a people enamoured to excess, and jealous of their liberty, it seems a matter of surprize that this principle has been so imperfectly attended to. The degree of actual liberty always bearing, according to this account of it, a reversed proportion to the number and severity of the restraints, which are either unfelt, or the utility of which does not outweigh the evil of the restraint, it follows, among other conclusions of a more general nature, that we may hence be enabled to apprehend the distinction between personal and civil liberty. A citizen of the freeest republic in the world may be imprisoned for his crimes; and though his personal freedom be restrained by bolts and fetters, so long as his confinement is the effect of a beneficial public law, his civil liberty is not invaded. Another idea of civil liberty places it in security; making it to consist not merely in an actual exemption from the constraint of unfelt and noxious laws and acts of dominion, but in being free from the danger of having any such hereafter imposed or exercised. The definitions which have been framed of civil liberty are most of them adapted to this idea. Thus our political writer makes the very essence of the subject's liberty to consist in his being governed by no laws but those to which he hath actually consented; another is satisfied with an indirect and virtual consent; another again places civil liberty in the separation of the legislative and executive offices of government; another in the being governed by law, that is, by known, pre-constituted, inflexible rules of action and adjudication; a fifth in the exclusive right of the people to tax themselves by their own representatives; a sixth in the freedom and purity of elections of representatives; a seventh in the control which the democratic part of the constitution possesses over the military establishment. Of these and similar accounts of liberty, it may be observed, that they all labour under one inaccuracy, viz., that they describe not so
has suggested the difference between civil and political liberty, unnoticed by the learned judge and by other eminent writers. He defines political liberty to be the security with which, from the constitution, form, and nature of the established government, the subjects enjoy civil liberty.

The importance of liberty, civil and political, as well as religious, to the honour and prosperity of a nation, is sufficiently evinced by both ancient and modern history. It has been observed by the ancients, that all the arts and sciences arose among free nations; and that the Persians and Egyptians, notwithstanding their wealth, opulence, and luxury, made but faint efforts towards a republic in those finer pleasures, which were carried to such perfection by the Greeks, amidst continual wars, attended with poverty, and the greatest simplicity of life and manners. Greece, says Mr. Hume, was a cluster of little principalities, which soon became republics; and being united both by their vicinity, and by the ties of the same language and interest, they entered into the close intercourse of commerce and learning. There concurred a happy climate, a soil not unfertile, and a most harmonious and comprehensive language; so that every circumstance among these people seemed to favour the rise of the arts and sciences. Each city produced its several artists and philosophers, who refused to yield the preference to those of the neighbouring republics. Their contention and debates sharpened the wits of men: a variety of objects was presented to the judgment, while each challenged the preference to the reft; and the sciences, not being dwarfed by the restraint of authority, were enabled to make such considerable shoots, as are, even at this time, the objects of our admiration. Hence, and from other circumstances detailed by Mr. Hume, he concludes, that it is impossible for the arts and sciences to arise, at first, among any people, unless these people enjoy the blessing of a free government. It has been further observed, that when the Greeks lost their liberty, though they increased mightily in riches, by means of the conquests of Alexander; yet the arts, from that moment, declined among them, and have never since been able to raise their head in that climate. Learning was transplanted to Rome, the only free nation at that time in the universe; and having met with so favourable a soil, it made prodigious shoots for above a century; till the decay of liberty produced also the decay of letters, and spread a total barbarism over the world. From these two experiments, of which each was double in its kind, and viewed the fall of learning in absolute governments, as well as its rise in popular ones, Longinus thought himself sufficiently justified in ascertaining, that the arts and sciences could never flourish, but in a free government; and in this opinion he has been followed by several eminent writers in our own country, particularly Mr. Addison and Lord Shaftesbury, who either confined their views merely to ancient facts, or entertained, says Mr. Hume, too great a partiality in favour of that form of government established among us. This writer has alleged, as instances which serve to restrain the extent of the opinion maintained by the celebrated authors above cited, those of modern Rome and of Florence. The former carried to perfection all the finer arts of sculpture, painting, and music, as well as poetry, though it groaned under tyranny, and under the tyranny of prelates; while the latter made its chief progress in the arts and sciences, after it began to lose its liberty by the usurpation of the family of Medici. Ariosto, Tasso, Galileo, any more than Raphael and Michael Angelo, were not born in republics. And though the Lombard school was famous, as well as the Roman, yet the Venetians have had the smallest share in its honours, and seem rather inferior to the other Italians in their genius for the arts and sciences. Rubens established his school at Antwerp, not at Amsterdam. Dresden, not Hamburg, is the centre of polite and in Germany. France has, at a former period, to say nothing now of its present condition, furnished an eminent instance of the flourishing of learning in absolute governments. Although it had fearlessly enjoyed any established liberty, it has nevertheless carried the arts and sciences as near perfection as any other nation. The English are perhaps greater philosophers, the Italians better painters and sculptors, the Greeks more orators: but the French, says Mr. Hume, are the only people, except the Greeks, who have been at once philosophers, poets, orators, historians, painters, architects, sculptors, and musicians. With regard to the stage, they have excelled the Greeks, who far excelled the English. And in common life, continues the same author, they have, in a great measure, perfected that art, the most useful and agreeable of any, "le droit de vivre," the art of society and conversation. He adds, if we consider the state of the sciences and polite arts in our own country, Horace's observation, with regard to the Romans, may, in a great measure, be applied to the British.

"... Sed in longum tamen ærum
Manerunt, ludeaque mactant velutia ruris."

It has become an established opinion, that commerce can never flourish but in a free government; and this opinion seems to be founded on a longer and larger experience than the foregoing, with regard to the arts and sciences. If we trace commerce in its progress through Tyre, Athens, Syracuse, Carthage, Venice, Florence, Genoa, Antwerp, Holland, England, &c., we shall always find it to have fixed its seat in free governments. The three greatest trading towns in Europe now, says Mr. Hume at the time when he wrote, are London, Amsterdam, and Hamburg; all free cities, and protestant cities; that is, enjoying a double liberty. Hume's Effays, vol. i. Eff. xii. and xiv. See Literary Arts and Commerce.

Liberty, Personal, consists in the power of locomotion, or of changing situation, or removing one's person to whatsoever place one's own inclination may direct, without imprisonment or restraint, unless by due course of law. See Habeas Corpus, Imprisonment, and False Imprisonment.

Liberty of the Press. See Liberty of the Press.

Liberty of the Tongue, in the Manner, is a void space left in the middle of a bit, to give place to the tongue of a horse, made by the bit's arching in the middle, and rising towards the roof of the mouth. The bit, according to the various forms of the liberty, acquires different names; hence we lay a flat-mouth, a Pigantelli, &c. with the liberty after Pigantelli's fashion, and a canoes-mouth, with the liberty like a pigeon's neck.

In forging the bit, care must be taken not to make the liberty too high, left it hurt, or at least tickle the palate, and make the horse carry low. See Bits.

Liberty, in Mythology, was a goddess both among the Greeks and Romans. Among the former she was worshipped under the title Eleutheria; and by the latter she was called Libertas, and held in singular veneration: temples, altars, and statues, were erected in honour of this deity. A very magnificent temple was consecrated to her on mount Aventin, by Tiberius Gracchus, before which was a spacious court, called atrium libertatis. The Romans also erected a new temple in honour of Liberty, when Julius Caesar established his empire over them, as if their liberty had been secured by an event which proved fatal to it. In a medal of Brutus, Liberty is exhibited under the figure of a woman, holding in
LIB, in Geography, a town of Bohemia, in the circle of Konignitz; 13 miles E.S. of Konignitz.

LIBEBO, a small island in the East Indian sea; on the S.E. coast of Gilio. S. lat. 10° 48'. E. long. 128° 25'.

LIBOCH, a town of Bohemia, in the circle of Leitmeritz; 14 miles S.E. of Leitmeritz.

LIBONIA, in Ancient Geography, a town of Spain, in Caliberia. Ptolemy.

LIBONATI, in Geography, a town of Naples, in Principato Citra; four miles N.E. of Policastro.

LIBONGO, a town of Africa, in the kingdom of Congo, on the Lufuna, near the Ks; 50 miles S.S.W. of Bombi.

LIBONOTUS, in Physiology, one of the twelve winds of the ancients. See Wind.

LIBORA, in Ancient Geography, a town of Spain, in the Tarragonensis, in the country of the Carpentians; situated on the Tagus, N.E. of Angustobriga, and almost bordering on Lusitania.

LIBOURNE, in Geography, a town of France, in the department of the Gironde, and principal place of a district. The place contains 8076, and the canton 17376, inhabitants, on a territory of 1756, kilometres, in nine communes. N. lat. 44° 55'. W. long. 0° 9'.

LIBRA, BALANCE, one of the mechanical powers. See Balance.

Libra is one of the twelve signs of the zodiac; exactly opposite to Aries; so called because when the Sun is in this sign, at the autumnal equinox, the days and nights are equal, as if weighed in a balance.

The stars in this constellation, according to Ptolemy, are seventeen; Tycho ten; Hevelius twenty; and Flamsteed fifty-one. See Constellation.

Libra also denotes the ancient Roman pound, borrowed, as some have said, from the Sicilians, who called it libra, libras.

Mr. Pinkerton (Essay on Medals, vol. i. § 7.), though he allows that the Greek pound in Sicily was called libra, as it was in Greece, and divided into 12 styli, or ounces, and that the Roman word libra is derived from the Greek libra, will not admit the as or libra, a coin, to have been deduced from a Sicilian medal. The Sicilians had a coin called libra, but it was of silver, and equal to the obolus of the Eginian standard, ten of which constituted the Sicilian librarius.

The Syracusans, it is well known, were the chief people of Sicily, and they were a colony from Corinth. Gronovius takes pains to prove, that the standard of Egina was used at Corinth, and of course in Syracuse; but all the Corinthian coins now remaining are upon the Attic model, which circumstance at once confutes all his arguments; and it appears from Aristotle, as quoted by Pollux, that the Sicilians had a money talent, or standard, of their own. The libra, or Sicilian silver obolus, contained also, like the Roman primitive as, 12 styli, or shaeles, so called at first because they weighed an ounce, but afterwards because twelve of them went to the silver libra, as twelve ounces to the pound. It is of the Sicilian libra, or libella, says Mr. Pinkerton, that Varro speaks, when he says it was of silver; and not of the Roman libella, or as, which we may safely suppose was never struck in that metal. For after the Punic wars, of which Sicily was the grand scene, the Sicilian coins must have been frequent at Rome, and the Roman in Sicily. But the Greeks, or Phocicians, of which nations the chief towns of Sicily were colonies, never knew such coins as the as libellis, or any of its parts; and it is well known that the ancient colonies commonly followed the plan of their parent countries. And though it must be granted, that the Sicilians had their own standard, yet it bore a resemblance of the Greek; their being equal to the Eginian obolus, and their 50 being the drachma of Egina; and it is not to be supposed that when the Greek braid coinage was always of the most minute form, they should coin pieces of that metal.
weighing a pound. Mr. Pinkerton cannot agree in opinion with those, who strenuously maintain, that the Roman silver denarius owes its form to the Sicilian Δανίων. The Δανίων, containing 10 mos, or Egnia oboloi, would weigh about 170 grains, whereas the Roman denarius do not amount to above 63, or a third part. There seems, therefore, to be no connection between the two. Upon the whole Mr. Pinkerton is of opinion, that the Romans did not derive one idea of their coinage from Sicily; but that the Sicilians had their Δανίων divided into 12 νόμισματα, from the Etruscans: though, according to the more elegant Greek plan, they made the first a small coin in silver, and never struck any brass coin larger than the νόμισματα, or piece of an ounce weight; if, indeed, the Sicilians had not this idea of 12 νόμισματα to the λίρα of the Romans themselves, which is much more probable, than that the Romans had it from Sicily. It is a further and stronger argument against the opinion of the Roman coinage being copied from the Sicilians, that, though we have innumerable Sicilian coins in every cabinet, yet not one of them resembles the Roman As libra, or its early divisions, in the very smallest degree. This argument Mr. Pinkerton seems to be conclusive. Besides, in most cabinets there are Etruscan coins upon the exact scale of the As libra, and of its several parts; whence it follows of course, that these, and these alone, must have afforded a pattern to the primitive Roman coinage. The Etruscan, to whom the most ancient brass coins found in Italy are known to belong, are more a colony from Lydia, a country to which Herodotus ascribes the first invention of coinage. See COINAGE.

The libra was divided into twelve unciae, or ounces, and the ounce into twenty-four scruples.

The divisions of the libra were the onca, one-twelfth; the sextans, one-sixth; the quadrans, one-fourth; the triens, one-third; the quindecens, five ounces; the semis, five and one-fourth; the septemvices, seven; the as, eight; the dodecans, nine; the dextans, ten; the denarius, twelve; lastly, the as weighed twelve ounces, or one libra.

Learned writers are not agreed as to the true weight of the Roman pound. Villalpandus and Greaves, relying on the congers of Vepstan for its standard weight, have from hence attempted to determine this intricate question. This Roman conger contained ten pounds weight of wine; Villalpandus founded by filling it to the narrow part of the neck, with spring water, that it contained just ten modern Roman pounds, which are equal to 5260 Troy grains. Azout filled it to the same height, and, having weighed its contents twice, found a result very nearly agreeing with Greaves's measure, rated by Millet, in Phil. Transl. vol. i. p. 790. His greater weight was 63024 Paris grains, equal to 5169.2 Troy grains. His lesser, 62760 Paris grains, equal to 5148.2 Troy. The mean between both is 5150.1 Troy grains, which, divided by 10, give 515.01, such grains for the weight of the ancient Roman pound. Several objections have been made to this pound derived from the congers, which Mr. Raper, ubi infra, has collected into one view; from which he infers, that it is more probable, that this standard should give too great a Roman pound, than too small a one. But as the result from hence must be uncertain, he has recourse to the coins. Having weighed nine gold pieces in the Pembroke collection, containing 34½ Roman scruples, he found their weight to amount to 608 Troy grains, which divided by 34½ give 17½ for the scruple, whence the Roman pound should weigh 5075½ grains. From some other coins of the same kind, a scruple appears to be 17½ grains. Instead of this scrupular standard, another was introduced by Sylla; and from the heaviest of four pieces of this standard, allowing thirty of them to have been coined out of the Roman pound, its weight is found to be 5040 grains. The standard of forty in the pound, mentioned by Pliny, succeeded this of Sylla, and continued to the establishment of the monarchy under Augustus: and from ten different coins of this standard, he deduces a mean aureus of 126½ grains; and supposing the aureus of forty in the pound to weigh 126 Troy grains, the Roman pound must weigh 5040. In Pliny's time forty-five aurei were struck out of the pound; and the mean aureus from Nero to Titus, in whose reign Pliny died, was under 112 grains; and if the standard weight of the imperial aureus of forty-five in the pound did not exceed 112 grains, the Roman pound will weigh 5040 grains, as it is found from the confular aureus. Soon after the reign of Alexander Severus, in whose time the aureus came to be called solidus, the coinage became very irregular, till Constantine entirely modelled it anew, by coining seventy-two solidi of four scruples out of the pound of gold. From twenty-nine of these solidi in the interval from Constantine to Heraclius, it appears that the mean weight is 69 grains, which, multiplied by 72, gives but 4968 grains for the Roman pound. But if the standard weight of this coin amounted to 70 grains, the pound will weigh 5040, as before. If we take 5040 Troy grains for the weight of the Roman pound, the scruple will weigh 17½ grains; the confular aureus 126; the imperial aureus 112; and the solidus 75; and the confular denarius of 84 in the pound will weigh just 60 Troy grains. (Phil. Transl. vol. i. part ii. p. 463, &c.) The common Roman pound, still used at Rome, consisted of 12 ounces, of 458 grains each, equal to one ounce avoirdupois; but the money ounce seems to have had only 420 Troy grains in the pound 5040. See farther on this subject the articles DENARIUS and MILLARENSIS.

The Roman libra was used in France for the proportions of their coin till the time of Charlemagne, or perhaps till that of Philip I. in 1093, when their fols being so proportioned, as that twenty of them are equal to the libra. By degrees, it became a term of account; and every thing of the value of twenty fols, was called a four.

LIBRA PROFES, in our Law Books, denotes a pound of money in weight.

It was usual, in former days, not only to tell the money, but to weigh it; because many cities, lords, and bishops, having their mints, coined money, and often very bad too; for which reason, through the pound consisted of twenty shillings, they always weighed it.

LIBRARIUM, among the ancients, were a sort of copyists, who transferred in beautiful, or at least legible, characters, what had been written by the notaries in notes and abbreviations.

LIBRARY, an edifice or apartment designed for the placing of books; or the collection of books themselves lodged therein. See Book.

Some authors refer the origin of libraries to the Hebrews; and observe, that the care these took for the preservation of their sacred books, and the memory of what concerned the actions of their ancestors, became an example to other nations, particularly to the Egyptians. Ofand Paramon, king of Egypt, is said to have taken the hint first; who, according to Diodorus, had a library built in his palace, with this inscription over the door, Ὄ ΧΙΣ ΙΑΤΕΙΟΝ. Nor were the Ptolemies, who reigned in the same country, less curious and magnificent in books.

The
The scripture also speaks of a library of the kings of Persia, Ezra, xvi. 17, vi. 1, which some imagine to have consisted of the historians of that nation, and of keeping the affairs of state; but in effect it appears rather to have been a depository of laws, charters, and ordinances, of the kings. The Hebrew text calls it the house of treasurers, and afterwards the house of the rolls, where the treasurers were laid up. We may, with more justice, call that a library, mentioned in the second of Esdras to have been built by Nehemiah, and in which were preserved the books of the prophets and of David, and the letters of their kings.

The first who erected a library at Athens, was the tyrant Pisistratus; and yet Strabo refers the honour of it to Aristoëteles. That of Pisistratus was transported by Xerxes into Persia, and was afterwards brought back by Scelucus Niccanor to Athens. Long after, it was plundered by Sylla, and re-established by Hadrian. Plutarch says, that under Eumenes there was a library at Pergamus, containing two hundred thousand books. Tyrannion, a celebrated grammarian, contemporary with Pompey, had a library of three thousand volumes. That of Ptolemy Philadelphus, according to A. Gallus, contained seven hundred thousand, all in rolls, burnt by Cæsar’s soldiers. See Alexandrian.

Contantine, and his successors, erected a magnificent one at Constantinople; which, in the eighth century, contained three hundred thousand volumes, all burnt by order of Leo Haurus: and, among the roll, one in which the Iliad and Odyssey were written in letters of gold, on the guts of a serpent.

The most celebrated libraries of ancient Rome, were the Ulpian, and the Palatine. They also boast much of the libraries of Paulus Æmilius, who conquered Perusia; of Lucullus Lucullus, of Afranius Pollio, Atticus, Julius Severus, Domitian, Severus, Pamphilus Martyr, and the emperors Gordian and Trajan.

Anciently, every large church had its library; as appears by the writings of St. Jerom, Anastasins, and others. Pope Nicholas laid the first foundation of that of the Vatican, in 1450. It was destroyed by the contable Boarbon in theacking of Rome, and restored by pope Sixtus V. and has been considerably enriched with the ruins of that of Heidelberg, plundered by count Tilly in 1622. One of the most complete libraries in Europe, was said to be that erected at Florence by Cosimo de’ Medici; over the gate whereof is written, LABOR ASEQVE LABORE: though it has been since excised by that of the late French kings; begun by Francis I., augmented by cardinal Richelieu, and completed by M. Colbert.

The emperor’s library at Vienna, according to Lambcicu, consists of eighty thousand volumes, and fifteen thousand nine hundred and forty curious medals.

The Bodleian library at Oxford, built on the foundation of that of duke Humphry, exceeds that of any university in Europe, and is the most of all the sovereigns of Europe, except the emperor’s, and late French king’s, which are each of them older by a hundred years. It was first opened in 1603, and has since found a great number of benefactors; particularly sir Robert Cotton, sir H. Savil, archbishop Laud, sir Kenelm Digby, Mr. Allen, Dr. Pococke, Mr. Selden, and others. The Vatican, the Medecine, that of Bessarion at Venice, and those just mentioned, exceed the Bodleian in Greek manuscripts; which yet outdoes them all in Oriental manuscripts.

As to printed books, the Ambrosian at Milan, and that of Wolfenbuttel, are two of the most famous, and yet both inferior to the Bodleian.

Library, King’s, at St. James’s, was founded by Henry, eldest son of James I., and made up partly of books, and partly of manuscripts, with many other curiosities, for the advancement of learning. It has received many additions from the libraries of Isaac Caftabon, and others.

Library, Cottonian, originally consisted of nine hundred and fifty-eight volumes of original charters, grants, instruments, letters of sovereign princes, translations between this and other kingdoms and states, genealogies, historical registers of monasteries, remains of Saxon laws, the book of Genesis, thought to be the most ancient Greek copy extant, and said to have been writ by Origen in the second century, and the curious Alexandrian copy or manuscript, in Greek capitals. (See Alexandrian.) This library is kept in the British Museum, with the large and valuable library of Sir Hans Sloane, amounting to upwards of forty-two thousand volumes, &c. There are many public libraries belonging to the several colleges at Oxford and Cambridge, and the universities in North Britain. The principal public libraries in London, before that of the Museum, are those of the College of Heralds, of the College of Physicians, of Doctor’s Commons, to which every bishop, at the time of his consecration, gives at least 20l. sometimes 50l. for the purchase of books; those of the Gray’s Inn, Lincoln’s Inn, Inner Temple, and Middle Temple; that of Lambeth, founded by archbishop Bancroft in 1619, for the use of succeeding archbishops of Canterbury, and increased by the benefactions of archbishops Abbot, Sheldon, Tennison, and Secker, and said to consist of, at least, fifteen thousand printed books, and six hundred and seventeen volumes in manuscript; that of Red-Crofs Street, founded by Dr. Daniel Williams, a presbyterian divine, and since enriched by many private benefactions, and by an annual sum appropriated to its increase; that of the Royal Society, called the Arundelian or Norfolk library, because the principal part of the collection formerly belonged to the family of Arundel, and was given to the society by Henry Howard, afterwards duke of Norfolk; in 1666, which library has been increased by the valuable collection of Francis Aiton, &c. in 1715, and is continually increasing by the numerous benefactions of the works of its learned members, and others; that of St. Paul’s, of Sion College, the king’s library, erected by queen Caroline, in 1737; and the foreign’s library, kept in their hall in Lincoln’s Inn Fields; the Wellington library, the library of the Royal Institution, incorporated in 1805; the library of the London Institution, estabnished in 1805, the library of the Surry Institution and Ruffell Institution, &c. &c.

Where a library is erected in any parish, it shall be preserved for the use of the director by the founder; and incumbents and ministers of parishes, &c. are to give security for it, and make catalogues of the books, &c. None of the books shall be alienated, without consent of the bishop, and then only when there is a duplicate of such books. If any book shall be taken away and detained, a justice’s warrant may be issued to search for; and restore the same: alio, action of trover may be brought in the name of the proper ordinary, &c. And bishops have power to make rules and orders concerning libraries, appoint persons to view their condition, and enquire of the state of them in their visitations. (Stat. 7 Anne, cap. 14.) Dray’s Institution for parochial libraries is under the direction and management of a number of associates, a treasurer and secretary. See the biographical article THOMAS DRAY.

Library, Mufieal. Dr. Burney complains, in the second vol. of his General History of Music, p. 444, that in
his travels through France, Italy, Germany, Holland, and the Netherlands, in search of materials for his work, he was able to find no complete musical library. "Something like a chain or series of musical theorists (he says) may perhaps be found at Vienna, where the emperor Leopold I. began to form a musical library; and the elector of Bavaria another at Munich in the seventeenth century. But both have been long neglected, and are now in a very confused and imperfect state. Nor is a complete series of musical compositions by the best masters, from the earliest period of counterpoint to the present time, to be found in any public or private library in Europe, to which I have ever had access. Indeed the collectors of books for royal, collegiate, or public libraries seem never to have had an idea of forming any regular plan for making such a collection; and though many individuals have been possessed of a rage for accumulating musical curiosities, it has seldom happened that they have extended their ideas to musical productions in general; so that no more than one class or species of composition has been completed by them, and even this, at the death of the proprietor, is usually dispersed.

"In a library, formed upon so large a scale as that of the king of France at Paris, the Bodleian, and Museum in England, it seems as if music should be put on a level with other arts and sciences, in which every book of character is procured. In a royal or ample collection of pictures, specimens at least of every great painter are purchased, and no private library is thought complete while the writings of a single poet of eminence are wanting."

As the author, in a note upon this passage has given a sketch of such a musical library as he thinks wanting, and which has been inserted in the Encyclopædie Methodique, we shall give it a place here, in his own words.

"In forming such a musical library as would assist the student, gratify the curious, inform the historian, and afford a comparative view of the state of the art at every period of its existence, it was to be wished that the books, when collected, were clasped in a way somewhat like the following:

Maſses, Motets, Madrigals, Songs in parts, and fingle fongs From the infancy of counterpoint to the year 1500.

The fame continued to the year 1600; to which should be added:

Services and full anthems To English words, as well as those of other modern languages.

Verle and folio anthems To English words, as well as those of other modern languages.

Psalmody, in two or more parts. The faile clasps completed to the year 1700, with the addition of masques, intermezzi, serenatas,

Operas, serious and comic. Oratorios.

Cantatas. Pantalons and Recercari, for various instruments.

All the above continued to the present time, with an addition of full

Concertos, symphonies, and overtures.

Concertos, with solo parts for particular instruments. Quintets.

Quatuors.

Sonatas, or trios, duets, and Solos for every instrument for which music has been composed, including voluntaries for the organ, and lessons for every species of keyed instrument.

The music published in single parts should be scored, and that published in partition transcribed, in single parts; to be alike ready for the eye or the ear, for the theorist to examine, or the practical musician to perform.

And in order that science and criticism may keep pace with the mechanism and practice of the art, all the treatises, tracts, and essays, both in the dead and living languages, should be collected, arranged chronologically, and aligned to a particular portion of the library.

"The Bodleian library, the Museum, and Royal Society, with some other libraries, have copies of new books sent to them, by the Stationers' company, and by individuals either by law or by courtesy; and when once such a foundation of old music is laid as we have here sketched out, it would soon become a collection, or might be made one by the legislature, for copies of all music that is published in England, as well as books on the subject, to be presented by the authors or editors to the public library. And the same means should be used for procuring all foreign musical publications as are employed in accumulating books from all parts of the globe, where the press is at work.

The librarian, custode, or keeper of these books, should be a good practical musician, as well as theorist and scholar, in order to know the worth of the productions he has in charge, and to be enabled to give instructions at least how to draw single parts from a score, and score single parts; to explain difficulties to the ignorant, and display curiosities to the learned; to know the rank each composer should hold in every class, and perhaps record the degree of respect that has been paid to him by his contemporaries, and which is due to him from posterity.

LIBRATA TERRAE, a portion of ground, containing four oxgangs, and every oxgang thirteen acres.

It was anciently so much land as was yearly worth 20s. and in Henry III.'s time, he that had quindecim libras terrae, was to receive the order of knighthood.

Some say, that as money is divided into pounds, shillings, pence, and farthings, the same degrees are to be observed in the division of lands; and, therefore, as quadrans signifies a farthing, so quattuordecim quadrantes is the fourth part of an acre; obolus, an half; denarius, a whole acre; solidus, 12 acres; and libra, 20 times 12 acres; i.e. 240 acres.

This is the same with what in Scotland is called pound-land of old extent.

LIBRATION of the Moon, in Astronomy. Few persons are unacquainted with the remarkable circumstance, that the moon always presents nearly the same face to the earth. Sometimes, however, we see rather more of the calern, and sometimes rather more of the western hemisphere than at other times. The same occasional variation is likewise observable in the northern and southern hemispheres. This sensible oscillation, partly real and partly apparent, is called the libration of the moon.

Galileo was the first astronomer who observed and attempted to explain the libration of the moon; his explanation was, however, very imperfect, not being aware that the most considerable part of the libration arises from the unequal motion of the moon in its orbit, as was first discovered by Hevelius in 1654. Laplace gives the following popular explanation of the astronomical appearances connected with the libration. For the physical explanation the reader is referred
It is not the same with the inequalities of the lunar equator. In endeavouring to determine its position by observations of spots on the Moon, Dominique Caffini was led to this remarkable result, which contains all the astronomical theory of the real libration of the moon. If we conceive a plane to pass through the centre of the moon, perpendicular to its axis of rotation, which plane will coincide with that of the equator; if, moreover, we imagine a second plane parallel to that of the ecliptic, and a third plane, which is the mean plane of the lunar orbit, these three planes will always have a common intersection. The second plane, situated between the two others, forms with the first an angle of about 1° 30' 10", and with the second, an angle of 5° 8' 49". Thus the interferences of the lunar orbit with the ecliptic or its nodes, always coincide with the mean nodes of the lunar orbit, and, like them, have a retrograde motion, whose period is 18° 223° 7' 15' 17". In this interval the two poles of the equator and of the lunar orbit describe small circles parallel to the ecliptic, in such a manner, that these three poles are constantly situated on a great circle of the heavenly sphere.

Libration of the Earth, is a term applied by some astronomers to that motion, whereby the earth is so retained in its orbit, as that its axis continues constantly parallel to the axis of the world. See Parallelism.

This Copernicus calls the motion of libration; and may be illustrated thus: Suppose a globe, with its axis parallel to that of the earth, painted on the flag of a mast, moveable on its axis, and continually driven by an easterly wind, while it falls round an island; it is evident, the painted globe will be so librated, as that its axis will be parallel to that of the world, in every situation of the ship.

LIBSHAUSEN, in Geography, a town of Bohemia, in the circle of Leitmeritz; 15 miles S.W. of Leitmeritz.

LIBUN, a town of Bohemia, in the circle of Boleław; 16 miles N.E. of Jung-Bundetl.

LIBURNIA, in Ancient Geography, a province of Illyria, along the Adriatic sea, over-against Italy, between Dalmatia on the south, and Iliria on the north. This peninsula runs into the sea between the rivers Danubius and Titius, now the Zermagna and Kerka, the latter of which was in the Roman times the boundary between Liburnia and Dalmatia. Zara, anciently Jadera, and afterwards Diadora, was once the capital of Liburnia. The ruins of Burnum, the Liburnia of Strabo, are to be seen on the right hand of the Titius, or Kerka, in the defert of Bukoviza.

LIBURNII, or Liburnians, the denomination of one of the three nations which sprung from the Illyrians, having left the country which bore their name in Illyria. They were probably the first people who penetrated into Italy by its northern part, about the sixteenth century before the Christian era, and in process of time settled along the sea-coast. In Italy they were divided into three branches, viz. the Apuli, the Pediculi, or Paduli, and the Calabrini. The country which they inhabited was called Apulia by the Romans, or Japygia by the Greeks.

LIBYA, the name anciently given to that part of the world called Africa (which see), comprehending in its whole extent Egypt, Marmarica, Cyrenaica, the Sycitic region, Libya proper, Numidia, Mauritania, Libya or Africa interior, Ethiopia, &c.; and bounded on the N. by the Mediterranean, on the E. by the isthmus of Suez, the Red Sea or the Arabian gulf, and the Eastern ocean; on the S. by the Ethiopian sea; and on the W. by the Atlantic sea. In a more restricted sense, the name has been applied to that division of Libya or Africa called "Libya".

Vol. XX.
Libya Interior, which lay westwards with regard to the other divisions of Ptolemy denominated Ethiopia sub Aegypto. The line of division between these two parts, marked by this geographer, passes through Darmiana, a city on the confines of Cyrene. In this western part, called Libya interior, the inhabitants consisted chiefly of the Gazuli, Garamantes, Nigritae, and Heptarian Ethiopians, besides many other people, less considerable and less known. See GAZULI, GARAMANTES, and ETHIOPIA.

Libya Polis, a lake of Africa, properly so called. Ptolemy.

Libyarchae, a people of Africa, in Libya, and more particularly in Marmarica, of which they occupied the northern part. Ptolemy.

Libyctum Mare, or sea of Libya, a name given by the ancients to part of the Mediterranean sea, which adjacent the coast of the Marretida Libya; bounded on the W. by the sea of Africa, and on the E. by the sea of Egypt.

Libycus Mons, a mountain of Egypt, near the city of Thebes. The Nile ran between this mountain and the Sacred mountain.

Libyphænices, a name given by some authors to the Phoenician colonies established in Africa, in contradistinction to the Syro-phoenicians, or the Phoenicians of Asia.

Libyssa, a maritime town of Asia, in Bithynia, situated between Chalcedonia and Numidia. It was the place of Hannibal's retreat for avoiding the hatred of the Romans.

Licaavo, in Geography, a town of the island of Corfu; 20 miles E. of Ajazza.

Lice. See Louise.

Lice of trees. See Aphis.

Licea, in Botany, a genus of Fungi, Schrad. Nov. Gen. 16. Perf. Syn. 195, the species of which have been, some of them, referred to Trichia, Sphorocarpus, (not the true Sphorocarpus of Micheli, which belongs to the order of Age), and Didymium. Its character is thus given by Persoon.

Pcridium, (or cæsa,) naked, roundish, or somewhat indeterminate in shape, brittle. Internal membrane wanting. Seminal powder deftite of fibres.

The species he enumerates are five, all very minute productions, fearingly bigger than pins' heads, found chiefly on rotten wood of the fir kind.

1. L. bicoc, the frill species, (Didymium pareticium; Schrad. Nov. Gen. 24, t. 6, f. 1.) is singular for being found on white-washed mud walls. Its outer case is dark olive, enclosing a quantity of bright yellow powder, which, according to Schradar's generic character of Didymium, should be intermixed with fibres. Within is another, much smaller, brown, likewise globular, rather hard and rough cæsa, full of a coarser brown powder.

2. L. cirensfijmr, (Sphorocarpus fassili; Buillard. t. 417, f. 5.), is brown and clustered, opening by a circular division. Found in autumn or winter, between the bark and wood of the Aspen-tree.

3. L. pusilla, Schrad. Nov. Gen. 19, t. 6, f. 4, is hemispherical, polished, chestnut-coloured, with a blackish powder.

4. L. morisitli, ibid. 18, t. 6, f. 5, 6, is various in figure and colour, reddish-brown; the powder dirty yellow.

5. L. flexufa, is described by Persoon as creeping or oblong, shining red brown, somewhat wavy, with law-like incisions. These three last are found on fir wood.

Some of Schrader's species are removed by Persoon to other genera. Albertini and Schweinert, in their Confer- tis Fungorum, have described two new species.

L. fimbrijiffa, n. 503, t. 6, f. 5, found on the inner sides of the scales of cones of Pinus Pinea, growing regularly in clusters, brown, with a dull yellow powder.

L. incanata, n. 504, t. 10, f. 6, observed once only, on rotten fir wood in a moist forest, the beginning of October. It is crowded, flesh-coloured with a flecly glob; the powder at first white, then flesh-coloured, finally deep roff-coloured.

Licence, Licentia, in Law, a power or authority given to another to do some lawful act.

A licence is a personal power, and cannot be transferred to another; though a licence may be granted to a man and his assigns. (12 Hen. VII. 25.) There may be a parcel licence, as well as by deed in writing; but if it be not for a certain time, it passes no interest. (2 Nelf. Abr. 1123.) By licence a man may practice physic and surgery in London: licences are also necessary for carrying on various trades and professions, on which a duty is laid, for the purpose of raising a revenue to government. If a lessor licence his lease (who is restrained by covenant from aliening without licence) to alien; and such lessor dies before he alien, this is no countermand of the licence; so it is if the lessor grants over his estate. (Cro. Jac. 133.) But where a lord of a manor for life grants a copyhold tenant to alien, and dieth, the licence is destroyed, and the power of alienation ceaseth. (1 Init. 52.) Copyhold tenants leasing their copyhold for a longer time than one year, are to have a licence for it; or they incur a forfeiture of their estates. (1 Init. 63.) If any licence is given to a person, and he abuses it, he shall be adjudged a trespasser ab initio. 8 Rep. 146.

Licence to alien in mortmain. Alienations in mortmain to ecclesiastical persons, &c. are restrained by several statutes; but the king may grant licence to any person or bodies politic, &c. to alien or hold lands in mortmain. 27 Ed. I. 7 & 8 W. Iii. cap. 37.

Licence is also used, in the Civil Law, for a permission or leave granted by a superior.

Julinian appointed four years to be spent in the stud[y of the law; after which, those who had discharged this obligation, were paid to have licence or permission to retire from study.

Licence is also applied to the letters, or certificates, taken out in universities, whether in law, physic, or divinity.

Licence in the Sorbonne, denotes a period of two years, which the bachelors are obliged to pass in affilling at acts, and disputing in them, to qualify themselves for being admitted doctors. See Degree.

Licence, letter of. See Letter.

Licence to arise, in Law, Licentia surgendi, is a liberty, or space of time given by the court to a tenant, who is enjoined de malo leitu in a real action, to rise out of his bed, and go about his business.

Licence for election of bishops. See Conge d'Elire.

Licence of marriage. Bishops have power to grant licences for this purpose; and parsons marrying any person without publishing the banns of matrimony, or without licence, incur a forfeiture of 100l. &c. by 7 & 8 W. Iii. cap. 35. See also Stat. 26 Geo. II. c. 33. See Marriage.

Licence, in Painting, are the liberties which the painter takes
takes in dispensing with the rules of perspective, and the other laws of this art.

Licence, particular, is the liberty which poets claim of dispensing with the ordinary rules of grammar.

Anciently poets had much greater licences than are now allowed. The Greeks, by having recourse to the several dialects of their tongue, could lengthen out a word, if it were too short, or retrench something from it, if it were too long. The old poets did what they pleased with their language, and subjected it not only to all their necellicities, but their caprices too:

"Et data Romanis venia et indigna poetis."

But these became ridiculous in course of time; and the poets are now defpoiled of most of their ancient privileges.

Licence, in Music, a seeming breach of rule.

There are licences in harmony as well as in melody. As the laws of counterpoint were at first arbitrary, and formed of narrow and contracted principles, they became subject to change at the caprice of the composer, and at all times, the breach of an old rule by a great master became the establishment of a new one for a composer of inferior fame. At present, except the two fundamental prohibitions of two 5ths and two 8ths in regular progression, there is no rule that has not been happily infringed; at one time or other, by some man of genius; so that it may be said, perhaps, that whatever does not offend a cultivated ear in harmony or melody, is allowable in music. Of the disallowances of former times, there was none that seemed so inviolable as false relation, such as naturals against sharps, or sharps against naturals; in the perfect concords, as a redundant 5th, a diminished 4th, or a false octave. Yet these licences, of late years, have been so frequently practised, as to almost establish them into rules. The good or bad effect determines the expediency.

If the effect be good, it is a licence, if bad, a fault. Emanuel Bach, we believe, was the first who ventured to hazard a false 8th, or a sharp against a natural in melody. But Haydn and Mozart having once frequently violated the rule with effect, it almost ceases to be a licence, and every tonetor in composition assumes the same privilege. These licences, however, can only be defended on the principle of appoggiaturas, as they are certainly inharmonic.

LICENSED CURATE. See Curate.

Licentia Concordandi, in Law, is that licence for which the king’s silver is paid in palling a fine, mentioned in 12 Car. II. cap. 12.

Licentia hypendi. See Emparlane.

Licentia transfretandi, a writ or warrant directed to the keeper of the port of Dover, or other sea-port, commanding them to let such persons pass over sea, who have obtained the king’s licence for the purpose. Reg. Orig. 193.

Licentiate, or Licenciate, he who has obtained the degree of a licence.

Most of the officers of judicature in Spain are known by no other name than that of licentiates. To pass licentiates in the common law, civil law, or physic, they must have studied seven years; in divinity, ten.

Licentiate, among us, is usually understood of a physician, who has a licence to practise, granted him by the College of Physicians, or by the bishop of the diocese.

A person practising physic without such licence, in cafe his patient dies under his hands, is guilty of felony in the eye of the law.

Liceto, Portiunio, in Biography, a celebrated physician and philosopher, was born at Rapallo, in the state of Genoa, on the 3d of October, 1577, where his father, Joseph Liceto, was also a physician. His education was conducted with great care, and he afterwards spent four years in study at Bologna, which he quitted in 1599. He then settled at Pisa, where he soon obtained the professorship of philosophy, which he filled with so much reputation, that he was invited to the same chair in the university of Padua in 1609, which he occupied until 1636. He removed at that time to Bologna, in consequence of failing to obtain the professorship of medicine, which became vacant by the death of Cremonini. But the Venetian states very soon perceived, and acknowledged the loss which the university of Padua had sustained by the retirement of Liceto; and when a vacancy occurred in the first chair of the theory of physic in 1645, he was induced, by the prevailing invitations which were made to him, to return to Padua, where he held the professorship, at an advanced salary, till his death in 1657. He was a very copious writer, having published upwards of fifty treatises upon medical, moral, philosophical, antiquarian, and historical subjects; but they are no longer sufficiently interesting to require a detail of their titles. He was a man of considerable erudition, and an ardent admirer of the doctrines of Aristotle; but displayed little acuteness in research or originality of conception. He wrote a treatise "De Lucernis Antiquorum reconditis," in which he maintains the opinion, that the ancients were professed of a secret procès for making inconfumable lamps, by fome mode of condensing the vapour into oil, which returned to the reservoir, and was extremely credulous in respect to the pretended discoveries of sepulchral lamps of this sort. But his opinions were positively refuted by professor Ferrari of Padua, in a treatise, "De veterum lucernis sepulchralibus." Among his medical writings, his treatise, "De Monstrorum Caustis, Naturâ et Differentiis," is best known; but it is replete with infinaces of credulity, and with the fables and superstitions of his predecessors, and contains a classification of the monitors, which had been previously described, without any correction from his own observations. The best edition is that of Gerard Blafius, in 1668. Eloy Dict. Hist. Gen. Biog.

Liceto, in Ornithology. See Cenotna.

Lich, in Geography, a town of Germany, in the principality of Hohen-Salms, on the Wetter; 12 miles E.S.E. of Wetzlar. N. lat. 50° 31'. E. long. 8° 49'.

Li-chan, a town of Corea; 17 miles E.S.E. of He-tsin.

Lichanos, in the Ancient Music, is the name of the 3d found of the two lowest tetrachords in the system of the Greeks; as this found was produced by the index or forefinger, which was called ichanos. The 3d found of the lowest tetrachord ascending, was that of the hypate, and called lichanos-hypaton, sometimes lichanon-hypaton, or lichanos-hypaton, enharmonic, or chromatic, according to the genus. That of the 2d, or mean tetrachord, was called lichanos-melos, or Mykon diamos.

Lichen, in Botany, is a name borrowed by the Romans from the Greeks for the diaphæa called a tetter, or ringworm, and applied by both to some plant of a mossy nature, growing on flowers, which was thought a cure for such complaints. What the Lichen of the ancients may have been is very obscure, and the enquirey is given up by
Dillenius himself in despair. He has applied this name to the *Marchantia* of other writers, under which he comprehends the very distinct genera of *Turgonia, Riccia* and *Sphero-rocarnus*; see his t. 78. Linnæus much more happily adopts the *Lichen* of Tournefort and Micheli, whose crustaceous and feély nature, in many instances, is associated with the original idea of the word. This Dillenius terms *Lichenoides*, from which he distinguishes *Coralloides* and *Ufnæa*, but all these are comprehended in the Linnæan *Lichen*—Linn. Gen. 566. Schreb. 767. Mart. Mill. Dict. v. 3. HUD. 523. Juff. 7. Tourn. t. 325. Mich. Gen. t. 36–53. Hedw. Theor. 120. t. 30. 31. Lamarck. Histoire 878. (Lichenoides; Dill. Mucf. 124. t. 18–30. Coralloides; ibid. 75. t. 14–17. Ufnæa; ibid. 56. t. 11–13.)—A class and order, *Cryptogamia Alga*., Nat. Ord. Algæ, Linn. Juff.

Eff. Ch. Male, scattered powderly warts?—Female, shields or tubercles, in whose thick the seeds are lodged.

Ofb. Linnæus takes for male what are now known to be the female flowers, and, *vice verši*., takes for the female those powderly heads, warts or furrows in the frond, which are by some thought buds, by others the male blossoms. We have therefore ventured to reverse his character of this vast genus, which properly embraces an entire natural order. (See Lichen.) It is necessary here to give a compendious view of *Lichen*, as understood by Linnæus. The species defined in the 14th edition of his *Systema Vegetabilum* amount to 130; but the insufficiency of this catalogue, to comprise all the Lichens in the world, will be strikingly evident, when we consider that about 435 British species have already appeared in English Botany, and that several more remain to be published there. We shall on this occasion prefer illustrating the nine fections, into which Linnæus has divided his genus, by species of his own, rather than by new ones. Most of these exist in his herbarium, few or none of them being adopted from Dillenius or other cryptogamists, which cannot so generally be said of the *Linnæan* proper *Myceli.*

These consist of a leprous perennial crust, of more or less density, hardens and smoothens, its surface often granulated, sometimes powdery, of various colours, (white, grey, greenish, or yellowish,) in different species; the internal fibulation however is generally very white, often with a green stratum immediately below the actual surface. This crust spreads circularly, with more or less regularity, over stones, rocks, earth, the bark of trees, or even dead wood, to which it frequently adheres so strongly, that, being moreover in some cases very thin, it cannot be separated entire. Fibrous roots, of the cartilaginous or chalky fibulation of the crust, may be detected in species that grow upon uneven bodies, or on the ground. The circumference or border of the crust is always thin; often marked with a dark-coloured line; occasionally beautifully fibrous and branched. The central part first decays, and finally crumbling away, young plants, of the same or a different species, soon afterwards springing up there from seed; while the marginal boundary of the original crust, if its situation be convenient for the purpose, is sometimes extended to ten times its usual limits.

The crust of the thicker or sarceousic crusts, more especially, is liable to assume a red or purplish hue, from the access of volatile alkali; which is seen when certain animal substances fall upon these plants in their native situations. The observation of this has led to the use of some of them in dyeing; but several of the next and following sections are preferable for this purpose. The female fructification, or rather the fruit itself, of this first section, is, or ought to be, convex, without any border; except in a young state, when there is usually a thin margin of its own substance. The crust is most frequently black, in some brown, pale grey, or reddish; and in its solid internal fibulation are innumerable, vertical, closed cells, each containing about eight minute seeds. It may be observed that the increasing convexity of this disc seems well calculated to allow room for the swelling of the seeds; and finally, by separating or expanding the cells, to promote the escape of their contents. The subjacent crust, under each tubercle, is elevated into its core or centre, so as to form a nucleus there. Discoveries subsequent to the time of Linnæus have found this section to be rather heterogeneous, as to the affinities of the several kinds, as will be explained hereafter. (See Lichen.) Our purpose is now merely to indicate the most remarkable species, for the elucidation of our author.

L. *fruits.* Syll. Veg. ed. 14. n. 1. Linn. Sp. Pl. 1606. (Lichenoides crusatæ tenuilimbé, peregrinus velut literis inscripta; Dill. Mucf. 128. t. 18. f. 1.) Opegra pha scripta; Engl. Bot. t. 1813.)—Leprous, whitish, forming small, black, branched, letter-like lines. Common on the smooth bark of young trees. The crust is a fine, ineradicable, whitish film. The fruitification conveys an idea of Hebrew or Chineese writing, in a very striking manner. This plant however, as understood by Linnæus, Dillenius, and most of their followers till lately, embraces at least 30 known species, together constituting a most natural and distinct genus, of which we shall speak hereafter more than once, under the name of *Opegrapha*.

L. *geographicus.* n. 2. Sp. Pl. 1607. Engl. Bot. t. 245. (Lichenoides nigro-flavus, tabulns crassus, Dill. Mucf. 126. t. 18. f. 5.)—Leprous, yellowish, with black lines resembling a map. Frequent on the hard rocks of mountainous countries, and almost as hard itself, at least to the touch, forming broad ineradicable patches, of a vivid greenish-yellow, or lemon-colour, curiously streaked and dotted with black marks, composed of the tubercles, which are flat, not elevated above the crust, frequently confluent or crowded.

Of this species, *atroviridus*, n. 3, is thought to be a variety, or rather an early stage of its growth.

L. *fangamnaria.* n. 9. Sp. Pl. 1607. Engl. Bot. t. 157. (Verrucaria fangamnaria; Hoffn. Pl. Lich. t. 41. f. 1.)—Crust tartaceous, white, polished, uneven. Tubercles black, without a border; bright red within. Found on granite rocks; copiously upon Cronford Moor, Derbyshire; very rarely on the rugged barks of trees. This is extremely remarkable for the internal fusions of bright red, perceived when the tubercles, and even some parts of the crust, are broken; which resembling blood, gave occasion to the very apt name. Several species, distinct of that property, and which otherwise but imperfectly resemble this, are confounded with it by Linnæus, Hudfon, Lightfoot, and others.

L. *venexus.* n. 17. Sp. Pl. 1607. Engl. Bot. t. 906. (L. cruentus; Web. Goett. 184. t. 1. L. flavescens; Jacq. Mucf. v. 2. 79. t. 9. f. 1.)—Crust tartaceous, rugged, pale sulphur-coloured. Shells irregular, a little swelling, blood-red, with a narrow pale border. Found on large exposed granite or sand-stones, in mountainous places, forming patches as broad as the hand, easily pared from the rock when moist. The crust is of an elegant pale lemon or sulphur-colour, turning white the second year, but in either case it is strikingly contrived with the crimson *tubercle.* Thence having a permanent border, of a different substance and
colour from their disk, are *shields*, not *tubercles*, so that the plant belongs properly to the second section of its genus, of which we shall next give a few examples, and to which it is referred by Murray in Syst. Veg. ed. 14, under Jacquin’s name of *Heteromennia*, so that it occurs twice in that edition.

**Sect. 2. Leprōsi sectellati.** Twelve species.

The crust of these is almost universally tarantaceous, sometimes very thick, less hard than in several of the former, and more easily separable from the stones or bricks on which it may happen to grow. The essential difference resides in the fructification, which consists of flatish shields, or, as Dillenius terms them, fucces, whose elevated permanent margin is of the substance and colour of the crust, not of the disk.

(Lichenoides cruentaee et leprosum, acutabilis majoribus luteis, limbis argenteis; Dill. Mufc. 132. t. 18. f. 13.)—Crust tarantaceous, rugged, granulated, white. Shields tawny buff-coloured, with a white margin. —The largest of the cruentaee Lichens; very frequent upon rocks in the north, and important as an article of commerce. The diameter of the crust is six, eight or ten inches, and its thickest a quarter or half an inch. The *shields* are frequently half an inch wide, conspicuous for their full buff colour, and white, smooth, wavy border. This species is much used in dyeing, being scraped from the rocks when fully grown, which is about the fifth year of its age, and mixed with volatile alkali and alum. It is sold to the dyers in the form of a powder, called *Caldeur*, which being boiled with woollen yarn, communicates any shade of its own colour that may be desired, but does not dye vegetable substances. This colour is by no means permanent, being far inferior, in that respect, to what is given by the Orchall of the Levant, *Lichen Roscella*.

Engl. Bot. t. 1879, found on the Scottish mountains, is pretty generally believed to be a mere variety of *tartareus*, with a thinner crust; but it seems to differ in throwing out flender branched brilly processes, not found in the former.

*L. Perellus*. n. 52. Linn. Mant. 132. Engl. Bot. t. 727, is like *tartareus* on a smaller scale, with *shields* of the same white crust, and is used likewise for dyeing purplish colours, chiefly in the south of France.

(Lichenoides cruentaee et leprosum, sectellis fulciue; Dill. Mufc. 134. t. 18. f. 16.)—Crust thin, continued, smooth, brownish-white. Shields soft, fliadly convex, reddish-brown, with a timid, whitish, entire border. —This is one of the thinnest, and usually leaf tartartaceous, of the present section, and is very common everywhere on the smooth banks of trees, being distinguished by its copious, bay or chefnet *shields*, whose smooth border renders them conspicuous. Their disk is sometimes curiously proliferous, which happens also in *tartareus*. Sometimes it is part-coloured, or mixed with a pale waxy hue, as if withered or abortive there. Numerous species greatly resemble this, but have been distinguished from it and from each other, generally very successfully, by the acutenesses of the learned professor Acharius and others.

In this same section Linnæus places his *canadulium*, see Engl. Bot. t. 1794, but improperly; doubtless from his having, at one time or other, confounded it, as others have done; the *vitellinum* of authors, Engl. Bot. t. 1792, and *sitiens*, t. 1793. These are all yellow in their crust or frond, as well as the *shields* of their margins; and serve to give a golden colour to candles, used on festival days in the Swedish churches, by being mixed with the melted wax or tallow.

Some of the section have a lobed, though not easily separable, crust, as *Antigens*, n. 29. Engl. Bot. t. 871; and *giletus*, t. 699. The true *shields* of the latter, whole disk is of a fine pink colour, were not known to Linnæus, who never took the trouble to examine the crust. Hence the fructification of this rare species certain brown warts, or proliferous excrescences of the crust, which he termed *pelta*; see bis *Mans.*, 133. Having nevertheless true *shields*, it properly belongs to this second section. *L. magerum*, n. 31. Engl. Bot. t. 626, on the contrary, having only a black and evanescent border to its black convex tubercles, should have been placed in the first.

**Sect. 3. Imbricati.** Thirteen species.

The plants of this section do not consist of an adherent crust, but approach more or less to a leafy structure, being either of a membranous, cartilaginous or gelatinous texture. The segments spread from a centre, lying over one another like tiles, the central ones being most divided and elevated, the marginal part more depressed, rather plaited than deeply cut, and most dilated outwards. The two sides differ remarkably; the upper being usually either pitted, wrinkled, warty, or beprinkled with mealy cracks, but delitute of hairs, and frequently polished, variously coloured; the under opaque, sometimes pale or white, sometimes quite black, always beset with innumerable fibrous perpendicular radicles, by which it is firmly attached to the bark, wood, earth or stones on which the plants grow. The *shields* are horizontal, scattered over the upper surface, to which they are attached chiefly by their central part. Their border is of the substance and colour of the frond; the disk somewhat deeper in hue, and much inclined to a chefnet or tawny cast. The mealy warts or cracks in the upper side of the frond are presumed to be the male floiosoms, because no other are known. This is a miscellaneous and unnatural combination of species, as will be explained under the next section.

*L. centrifugus*. n. 34. Sp. Pl. 1609. Fl. Lapp. ed. 2. 337. n. 424. t. 11. f. 2.—Imbricated, membranous; greenish-white and smooth above; white, with brownish fibres, beneath; segments linear, divaricated, blunth. Shields scattered towards the circumference, reddish-brown, with an infixed, almost entire, border. —This is, according to Linnæus, extremely common on large stones throughout Lapland, where Lichens that grow on stones are more rare than in other places. It is of all others most remarkable for its centrifugal mode of growth, forming circles a foot or two in diameter, and indeed sometimes, as we are told, eight or ten feet, consisting of a whitish band two or three inches broad, while the central part is quite decayed and obliterated. Linnæus errs in citing under this *fructification* of Dillenius, t. 24. f. 75; which is the *conspicua* of Acharius and Engl. Bot. t. 269; a species found in various parts of Europe, of a more compact manner of growth and greener colour, with broader lobes and larger, concave, dark chefnet shields.

*L. faradis*. n. 35. Engl. Bot. t. 603; and *omphalodes*, n. 36. Engl. Bot. t. 604; are of more a lax and leafy habit than the lark, as well as different in colour. The former of them is very common; the latter confined to mountainous rocky heaths or moors. Both are used to dye browns or dull reds in the ruder states of human society, or amongst the inhabitants of the alps.

LICHEN.

(Lichenoïdes vulgare finusium, folis et feclulis luteis; Dill. Mufc. 180. t. 24. f. 76.) Imbricated, membranous, fracture, roundly lobed and crisped, orange-coloured; pale and fibrous beneath. Shields of the same colour, with a thin entire border.—One of the most common of its genus, very conspicuous on old walls, as well as on rocks, wooden buildings, trees and bushes. Its rich golden colour is most vivid in exposed situations; assuming an olive, greenish, or greyish cast in the shade and damp. Several species however are perhaps confounded under this by Linneus and his followers.

L. f Mit. n. 45. Sp. Pl. 1611. Engl. Bot. t. 1607, coloured too green. — Imbricated; leaflets oblong, laciniated, narrow, ash-coloured. Shields brown.” Linn. — Very common on trees. Under this a great number of species are undoubtedly confounded by Linneus, though Acharis may perhaps have gone too far in dividing them. Some are green when wet; others continue grey, whether moist or dry. The shields in all of them are of a greyish-black, not verging towards red, and are usually plentifully produced.

Sect. 4. Foliacei. Twenty-six species.

What Linneus refers to this section are all naturally allied to one or other species of the last, so that the two sections ought to form but one, those of the present being only more leafy, less imbricated, and in some cases quite erect. Nothing however can be more miscellaneous than this division of the genus.

L. Burgefield. n. 48. Light. Scot. 823. t. 26. Engl. Bot. t. 230. — Gelatinous, membranous, crisped and fringed, of a dark glaucous green. Shields depressed, dark brown, with a leafy, crested, elevated border. — Found on the trunks of old trees in Scotland and Wales. One of the most elegant of its tribe, consisting of dark-green patches as broad as the hand, of delicate pellicul crumpled and wavy leaves, bearing numerous shield, very remarkable on account of their leafy, complicated, wreath-like borders. L. ornatiss., n. 71, is the very fame species. When dry the whole frond becomes more opaque, verging towards a lead colour. This belongs to a tribe called gelatinous Lichens, which constitute a very natural genus, now named Collema. All agree in their peculiar dark-green colour, semi-pellucid pulpy texture, and reddish or tawny-olive, generally small, shields. Some of them are placed by Linneus in the former section, others in this. L. cataria. n. 49. Sp. Pl. 1611. Engl. Bot. t. 1572; is of the same natural family as f Mit. of the last order; only larger, more lax, and remarkably fringed. L. caperatus. n. 65. Sp. Pl. 1614. Engl. Bot. t. 653; is in like manner allied to f Mit., &c. and is properly an imbricated species.

L. ampullaceus. n. 54. Sp. Pl. 1613. (Lichenoïdes tinctorum gelinum velculoium; Dill. Mufc. 185. t. 24. f. 22.) See Hoffm. Pl. Lich. t. 13. f. 2; is only a morbid variety of the last, glaucus, caufed apparently by the wound of some insect, which produces a sort of gall. The original specimen of this, having been stolen by a foreigner, more curious than honest, from the Dillenian herbarium about thirty or thirty-five years ago, was detected by the late professor Sibthorp when abroad, in this person’s collection, and recovered. It is not however restored to its original place, where the figure only is now found. But this is of the kind consequence, as Mr. Menzie has gathered the plant in the very same state, which has been dissected in our presence, and its importance as a species thus falls to the ground. By the manner in which the history of this Lichen is related by our friend Mr. Turner, Tr. of Linn. Soc. v. 7. 112, it might seem that the excellent professor Von Jacquin was the thief, from which we think it essential to excuplate him, nor did Mr. Turner mean to imply any such thing.

To the fection in quilon belong several species of a very distinct tribe, named Phyllae by Acharis (but since fene in his Parmelia, the above Certania being separated from it), of which the following are examples.

L. fraxiniceps. n. 61. Sp. Pl. 1614. Engl. Bot. t. 1781, is so common on trees, conspicuous for its large size, and lanceolate figure, that nothing need be said of it.

L. fascicularis. n. 61. Sp. Pl. 1614. Engl. Bot. 728. (Lichenoïdes fasciforme tinctorum, corniculis longioribus et acutioribus; Dill. Mufc. 168. t. 22. f. 61.)—Leafy, divided, pointed, flat, nearly upright, tapering at each end, greyish-white, obscurely downy, with white nearly warts. Shields convex, blackish. — This is found on granite rocks upon the Cornish coast, but more plentifully in the Mediterranean, the Canary islands, and the East Indies, in which last climate it grows to the length of a foot. It is extremely important as an article of commerce, being used indiscriminately with, and according to some preferred to, the famous L. Racette, for dyeing. See section 8.

Sect. 5. Coriacei. Thirteen species.

This is in itself a very natural section, but Linneus has referred to it one or two species totally foreign to the nature of the rest; as perifolius, n. 82. Engl. Bot. t. 341. (Lichonoïdes glaucum perlatum, fruticos nigrum et cirrulum; Dill. Mufc. 147. t. 20. f. 39.) — This is in habit, texture, and natural affinity, closely allied to jadiffigus, in sect. 3; — L. aquaticus, n. 73. Sp. Pl. 1615; for which a synonym of Dillenius, t. 20. f. 44, is quoted with doubt, has always been involved in much obscurity. The plant of Dillenius is perifolius of Jacquin and others, well figured in Hoffm. Pl. Lich. t. 13. f. 1. That of Linneus, preferred in his herbarium, is laid in the Flora Suecica to have been found in mossy boggy places at Norby, near Upfal, his own country residence; but no one has ever discovered what was meant. On a careful examination of the same, it proves to be L. corrugatus, Sm. Tr. of Linn. Soc. v. 1. 83. Engl. Bot. t. 1652. Arch. Prod. 123. (Lichenoïdes acetabulis cuticularis et rugosis; Dill. Mufc. 185. t. 24. f. 79.), a plant found on trees throughout Europe, though long neglected by Linnaean botanists, none of the most distinguished of whom have mistaken it for olivaceus.

The real coriaceous Lichens, which constitute this fifth section, are, as their denomination implies, of a tough bastyer
thery texture; smoothish above; strongly veined and bearing numerous coarse radicles beneath. Their shields, called petia, or targets, are peculiar, perfectly fleshy, and as it were glued to the frond towards its margin, sometimes at its under side! They are oblong or kidney-shaped, often slightly convex; their border merely a thin film which, in a tender frond, covers their disk, and finally recedes to the edge as it withers. The plants of this section moily grow on the ground, either at the roots of trees, or on shaggy mossy banks.

L. rufuginatus. n. 74. Sp. Pl. 1615. Engl. Bot. t. 305. (Lichenoides fulceum, petia pollicis ferruginei; Dill. Mufc. 206. t. 29. f. 105.)—Coriaceous, creeping, lobed, brownish-grey. Targets oblong, at the under side of each small ascending lobe. Native of moist shaggy rocks, or of the mossy roots of trees in mountainous countries. The fronds are imbricated, smooth, of a dull brownish lead-colour, com¬posing broad depressed patches; the targets reddish-brown, concave, plentifully produced, but each solitary at the con¬cave extremity of its own small lobe.

L. arcticus. n. 77, and antarcticus. n. 78, both one species, are united by Acharius under the name of Petelidae polaris, being found in very high northern or southern latitudes only. They are remarkable for the great size of their targets, which grow at the back of the greenish-white frond, and are as big as the thumb-nail, orbicular, of a dark livid flesh-colour.

L. caninus. n. 79. Sp. Pl. 1616. Engl. Bot. t. 2290. (Lichenoides digitatum cinerum, lactuce folios ininosus; Dill. Mufc. 200. t. 27. f. 102.)—Coriaceous, dilated, ascending, furrowed, grey; white, with brown veins and fibres beneath; lobes very broad, with marginal fruit-bearing processes. Targets in front, vertical, revolute, roundish, red-brown, with a pale border. The largelt, most common, and most famous of its tribe, being the celebrated "Ash-coloured Ground Liverwort," so extolled by Dr. Mead as a cure for the bite of a mad dog, whence the above specific name. It was given with black pepper in milk, the patient being first bled, and afterwards bathed in cold water; but whatever accidental circumstances might confirm that famed physician in his opinion, the medicine has long been entirely laid aside.

L. croceus. n. 84. Sp. Pl. 1616. Fl. Lapp. t. 11. f. 3. Engl. Bot. t. 408. (Lichenoides subtilis croceus, petia ap¬prellis; Dill. Mufc. 221. t. 30. f. 120.)—Coriaceous, creeping, rounded at the extremities; green above; orange and veiny beneath. Targets scattered, round, flat. Found only in the most alpine situations, near the limits of perpetual snow, growing on the ground. These two half, elegant and rare productions, are not exactly of the habit of the rest. Acharius, in Schrader's New Journal, v. 1. f. 29, 21, has referred them to his new genus Arthenia (see Lichenens); from the true species of which they differ in their leafy, not crustaceous, habit, nor is it easy to say to what family they properly belong.

A most distinct and natural tribe, constituting the genus Gyrophora of Acharius, of which we have spoken in its proper place. (See Gyrophora.) Linnaeus defines these plants as umbilicate, or attached by their centre, and dirty as it were with foot. The latter perhaps may be their male parts. The fruit exhibits the most essential character in the concentric folds observable in its disk. The first species however, miniatns, n. 86. Engl. Bot. t. 593, though it agrees with the rest in its umbilicate habit, differs from them in fruitification, in which latter respect it accords with Endecarpon; see that article. True Gyrophora are

L. wellens. n. 87. Sp. Pl. 1617. (Lichenoides cornicarium, latifolium folio umbilicato et verrucoso; Dill. Mufe. 545. t. 82. f. 5.)—Umbilicate, flaked, dilated, wavy; brownish-grey and smooth above; covered beneath with black, branched, crowded fibres. Tubercles clustered, flat. Native of rocks in Lapland and North America. Often as broad as both the hands, tough and leathery, remarkable for its dense, black, hairy clothing beneath. In this last respect indeed it accords with the much smaller, green or olive-coloured, British petilis, Engl. Bot. t. 931, which Hudson mistook for wellens.

L. pygialis. n. 88. Sp. Pl. 1617. We need not repeat what is said of this under the article Gyrophora.

L. viridis. n. 96. Linn. Suppl. 451, gathered at the Cape of Good Hope by Thunberg, is Endecarpon Thun¬bergii. Ach. Meth. 129, has nothing of the character of a Gyrophora.

The natural family of cup-bearing Lichens, or psyllidat, being one of the most distinct and strongly characterized, has been separated as a genus of itself by moit who have considered the subject. (See Lichenens.) The species are extremely confined and difficult to define, being variable in themselves and much resembling each other. Their frond or basis consists of small, rounded, more or less dilated, horizontal scales, or leaflets; smooth and green or greyish above; pure white beneath, as well as at the edges and within. In some few instances they are dilated, and lobed or pinнатifid. From these arise upright stalks, terminating in a cup-shaped figure, of a large proportion compared with the leaflets, of a greenish-grey colour, and mealy or scaly surface; the edges of the cup producing the frucc¬tification, which consists of small globular tubercles, either brown, or of a more beautiful scarlet, fleshy, or variegately flaked. Sometimes the cup is proliiferous from its edges or centre; sometimes oblate, or, as it were, starred. These plants come under the Corallides of Dillenius, t. 14, 15.—Examples are

L. crucifer. n. 97. Sp. Pl. 1618. Engl. Bot. t. 2051. (Coralloides scyphiformis, tuberulis coccinis; Dill. Mufe. 82. t. 4. f. 7.)—Cup-shaped, leathery, pale greenish-grey, mealy. Cups dilated, somewhat toothed. Tubercules fun¬gous, scarlet. Leaves minute, lobed and crenate. A beautiful species, not uncommon in woods, or on heaths among ling, or in various dry sandy places. The large scarlet tubercetes render it very conspicuous. Several other species indeed have the same-coloured fruitification, but smaller, and they differ in other respects. The cups in this are shorter, broader, and more perfect than in any other with scarlet tubercles.

L. pyxidatus. n. 99. Sp. Pl. 1619. Engl. Bot. t. 1935. (Coralloides scyphiforme, tubereulis fuscis; Dill. Mufe. 79. t. 14. f. 6.)—Cup-shaped, leathery, greyish-green, scaly, often proliiferous. Cups dilated, nearly entire. Tubercles brown. Leaves minute, imbricated, crenate. The most common of this tribe, occurring everywhere in broad patches, on heaths, sandy banks, and under hedges. Its cup-like shape is usually pretty regular, at least before the tubercetes appear; but the edges of the cup, or its centre, occasionally throw up others, even to four or five ranks or.
ages, one another, in beautiful luxuriance. More frequently the first cup bears unequal and imperfect cups, or tubular flanks, crowned with the brown tubercles. The flanks of all are frequently leafy or feally, especially their lower part.

L. gracile. n. 101. Sp. Pl. 1619. Engl. Bot. t. 1284. (Corollioideae feryphorme serratum elatius, caulibus graci- libus globis; Dill. Muf. 88. t. 14. f. 13.)—Cup-shaped, long, slender, smooth, cariliiognous, greenish-brown; at length somewhat branched. Cups conical, sharply toothed. Tubercles brown. Leaves minute.—In healthy dry mountainous places, or in woods, in the north, not unfrequent. The character of this is widely different from the two preceding, displayed in its brown hue, tall fladder form, and sharp teeth or terminal branches. The tubercles are dark brown. Leaves very minute, and frequently obliterated.

L. flavum. n. 125. Linn. Suppl. 451. Hoffm. Fl. Lich. t. 3. f. 1; is very improperly referred to this section by Murray, merely, as it feems, on account of its tubular flanks and branches. It ought, according to the Linean arrangement, to stand in section 3, after particulatus, n. 43, and before physodes, n. 44; agreeing with the former in colour, with the latter somewhat in structure. We mean no; however, to say there is any considerable real affinity between these three species.

A vague section, comprising, though small, several discordant things, of which no general definition can be given, except that they are of an upright bushy habit.

L. rangiferinus. n. 106. Sp. Pl. 1620. Engl. Bot. t. 173. (Corollioideae montanum, fruticulosis specie, ubique candidans; Dill. Muf. 107. t. 16. f. 29; et corniculis rufescensius; 110. t. 16. f. 30.)—Buffy, tubular, very much branched, richly and hoary the little branches divaricating and drooping. Tubercles terminal, globose, mostly clustered, dark brown.—This is the Rendle Lichen, so celebrated by Linnæus, in his Flora Lapponica and Lapland Tour, as the food of that animal. In the wide heathy tracts and forests of those northern regions it covers the ground like snow, rising to the height of a foot or more; with us it is much humbler and more dispersed; always choosing the most fertile heathy soil, and not very generally producing fruit. Its texture is thin and brittle, sift to the grasp of the hand, and excellent for package, the only use for which it can serve in this climate. The branches are occasionally, not always, perforated at their divisions. The surface is hoary, or rough with minute warts. Tubercles very small, terminal, abundant when they occur at all.

L. fulvus. n. 109. Sp. Pl. 1621. (Corollioideae corni- culus longeriorius et rariorius; Dill. Muf. 102. t. 16. f. 26.)

These three are naturally akin to rangiferinus. The following are very different.

L. globiferus. n. 110. Mant. 133. Engl. Bot. t. 115. (Corollioideae cupreiforme, capitulis globosis; Dill. Muf. 117 t. 17. f. 35.)—Shrubby, solid, much branched, cylindrical, brownish and polished; branches with minute divaricating terminations. Fruit globular, smooth, enclosing a ball of black powder.—This very pretty coral-like production occurs on mountainous rocky heaths, or in dry flabby woods. Its flanks compose loose entangled tufts, of a tawny light polished brown, and are white and solid within; the ultimate branches are innumerable, short, slender, tufted, and divaricating. The fructification is altogether different from every thing we have hitherto described, consisting of terminal solitary balls, the size of a rathread, smooth, of the substance of the stem, opening by a wide irregular perforation at the top, and containing a globular mass of black condensed powder, presumed to be the seeds. This plant therefore, by its fructification and habit, has every right to constitute a distinct genus, and is now, with the two following, admitted as such by the name of Spherothoron.

See Lichenes.

L. fragilis. n. 113. Fl. Suc. ed. 2. 425. Fl. Lap. n. 442. t. 11. f. 4. (Corollioideae fragilis; Hoffm. Fl. Lich. 34 t. 33. f. 3.) Spherothoron fragilis; Ach. Meth. 135 t. 3. f. 5.—Shrubby, solid, brittle, ashy brown; branches level-topped, cylindrical, crowded, naked. Fruit globular, rugose, enclosing a ball of black powder.—Found in similar places with the last, with which most botanists, in Britain and elsewhere, have confounded it, taking the following for the true fragilis.

L. compactus. (Fragilis; Ach. Prod. 211. Hud. 558. Engl. Bot. t. 114. L. melanocarpus; Swartz Prod. 147. Spherothoron compactus; Ach. Meth. 135. Corollioideae alpinum, coralline minoris facie; Dill. Muf. 116. t. 17. f. 34.)—Shrubby, solid, cartilaginous, white, branched, compacted; branches clustered, somewhat palmate. Fruit depreessed, containing a cake of black powder.—The most elegant of this new genus, remarkable for its white corallike appearance, having the splendour of porcellan when fresh. The above characters mark it sufficiently. The fruit is rare, produced in moist flabby situations only. This species seems to prefer limestone rather than granite rocks.

To a very different family belongs:

L. pectoralis. n. 111. Sp. Pl. 1621. Engl. Bot. t. 282. (Corollioideae crithopum et betriformis alpinum; Dill. Muf. 114 t. 17. f. 33.)—Shrubby, solid, clothed with minute coralline leaves. Tubercles terminal, prominent, brown.—This Lichen, found on a peculiar alpine rocks, is destined to perform an important office in the economy of nature, being the first vegetable that takes to upon lava, whose porous surface will admit no extraneous species. Thus it composes a decaying portion of vegetable mould, fit for the reception of the seeds of other plants. Its roots and flanks are very tough and strong, and the affected leaf of greyish-brown leaves, that cover the whole, gives it a peculiar and distinct aspect. The tubercles are solid, white within, convex, without any border.

Three species only remain, having little or no affinity to any of the above, or to each other.

L. trilobis. n. 112. Web. Coct. t. 5. Swartz. Meth. Muf. 37. Engl. Bot. t. 720. This alpine Lichen has real thills. It occurs among the imbricated species, by Jacquin's name of rigidus, n. 42; and it is curious that Murray, the editor, has quoted in both places the same synonym of Haller. n. 1066 t. 47. f. 1.

L. verrucosus. n. 114. Suppl. 451. (Stereoconal tabular; Ach. Meth. 316 t. 7. f. 2.)—Found at the Cape of Good Hope: It consists of dense, broad, white tufts of low branched flakes, tumid and globose at their summits, and agrees altogether in genus, very nearly in species, with Mr. Dickson's oculatus, Engl. Bot. t. 1833. Yet Profesor Acharius considers the fructification of verrucosus as unknown, and refers the plant to his genus Stereocaulon, of which pectoralis, n. 111, above-mentioned, is a genuine example.

L. Roccella. n. 115. Sp, Pl 1622. Engl. Bot. t. 211. (Corollioideae corniculatum fuscicolare tinctorium, furi teretis facie; Dill. Muf. 120 t. 17. f. 39.)—This we have mentioned in speaking of tuturas, n. 253 and fuseiformis, n. 61.
It agrees very much with the latter, except in being cylindrical, and left soft or flexible, and their shields are exactly alike.—A Cape variety, as it is thought to be, of Roxcella, is partly cylindrical, partly flat, and much dilated.

Sec. 9. Filamentes. Fifteen species.

A very curious, striking, and, for the most part, very natural affemblage. Many of them hang in long, black, grey, or white clutters, from the branches of aged pines, oaks, or cheethuffs, in alpine forests, to which they give a singular and romantick aspect. Their fronds are filamentous, often a foot or more in length, repeatedly branched, either solid, or apparently jointed, in a beard-like manner, with a central tough fibre; sometimes they are compressed, sometimes tipped; in one undescribed species exquisitely reticulated like lace. The frutification is various and uncertain; in some perfect shields with a true disk; and a border like the frond; in others a spurious kind of shield, orbilis, is found, along with coloured feed-bearing tubercles; in others, again, powder warts only are discoverable.

A few examples will suffice.

L. pleniculatus. n. 116. Sp. Pl. 1622. Engl. Bot. t. 257. (Ufnea vulgaris, loris longis implexis; Dill. Mufc. 56. t. 11. f. 1.)—Filamentous, cylindrical, pendulous, whitish; branches entangled. Shields or dishes (spurious) whitish-green, radiated. Tubercles yellowish.—Found in ancient woods. The fronds are excessively and finely branched, a foot or two long, pendent in dense clutters from the trees. Their surface is minutely warty. The proper tubercles, described by Acharius, we have never seen. The spurious shields, his orbilis, are rare. The latter are improperly made reddish in English Botany.

L. druricatus. n. 119. Syl. Nat. ed. 12. v. 2. 713. (Ufnea mollis, ramis longis compressis; Dill. Mufc. 62. t. 12. f. 5. U. flaccida; Hoffm. Pl. Lich. t. 67.)—Filamentous, pendulous, angular, jointed, pale sulphur-coloured; branches discoloured. Shields felish, cheethnut-coloured, with a narrow border of the substance of the frond.—Native of fir woods on the alps of Savoy, Switzerland, &c. Often a foot and a half long, soft and flexible, coniposicus for its yellowish hue. The shields are those of an Acharian Parmelia. See LICHIENES.

L. aurantiacaster. n. 128. Jacq. Mufc. 359. t. 11. f. 2. (very badly drawn,) seems to us also a true Parmelia, though retained in Ufnea by Acharius; see his Methodus, 307.

L. capensis. n. 130. Suppl. 451. (Ufnea capensis; Hoffm. Pl. Lich. t. 10. f. 1.) is properly referred by Acharius to his Parmelia.

L. floridus. n. 129. Sp. Pl. 1624. Engl. Bot. t. 872. Ehrh. Crypt. 148. Ufnea vulgarisfilla tenueor et brevior, cum orbiculis; Dill. Mufc. 69. t. 13. f. 13.)—Filamentous, with a central thread, bushy, ereet, greenish-grey; branches round, fibrous, warty, with radiated spurious shields. Tubercles on the branches, lateral, flesh-coloured, rugged. —Not uncommon on dead branches of oaks in old woods, but the orbilis seldom occur except on the higher trees, and the real tubercles are extremely rare. The latter were supposed to have been published for the first time in Engl. Bot. vol. xiii. in 1801, but the celebrated Schrader appears to have deserved though not figured them two years earlier. They are coniposicus to what has long been known in other genuine species of this tribe. We cannot but think L. birinus, n. 125, Engl. Bot. t. 1554, specifically distinct from floridus, of which professor Acharius makes it a variety. The tubercles of birinus grow chiefly on the stem or large branches, which are continued straight beyond them, not strongly bent backwards, as in floridus. These species

boiled with wool, without alum, dye it of a rich tawny yellow.

The most minute species of this great genus, or natural order, hold a much more important place in the economy of nature than is apparent to superficial observers. They are the first beginning of vegetation on stones of all kinds exposed to the air, whose decomposing surfaces are the receptacle of their imperceptible feeds, and soon afford nourishment to the sprouting plants, whose minute fibrous roots still further infiltrate themselves. The larger species take possession of every cavity and fissure, both of stones and the decaying external bark of trees. In time they all decay, and furnish a portion of vegetable mould, capable of nourishing mosses, or still larger plants. The residuum of these, being still more considerable, is washed by rains into larger cavities, where even forest trees can scatter their feeds, by the penetrating power of whose roots, great masses are dislodged from the most lofty rocks. Thus the vegetable kingdom exercises dominion over the tributary foetal world, and, in its turn, affords the fame no lefs necessary aid to animal excellence. Nothing in nature is allowed to remain stationary, idle, or useless, and the most inconsiderable agents frequently appear, in the hands of Divine Providence, to be the most invisible.

L. floridus, in the Materia Medica. The Lichen floridus is a native of Britain, particularly on the mountains of Wales and Scotland. In Iceland this is used as food. For this purpose, a dish of it is prepared by boiling it in small, boiling it in three or four succeseive portions of water to take off its natural bitternesfs, and then for an hour or two in milk. When cold this preparation has the form of a jelly, which is eaten with milk or cream, and makes a very palatable dish. The medicinal qualities of this lichen have of late been so well established at Vienna, that the plant is admitted into the Materia Medica of the Edinburgh Pharmacopeia, and into the London Pharmacopeia of the year 1809. It is extremely mucilaginous, and to the taste somewhat bitter and astringent; but its bitternesfs, as well as the purgative quality which it manifests in its recent state, are in a great measure dilipated by drying, or, as we have already observed, may be extracted by infusion in water. An ounce of this lichen boiled a quarter of an hour in a pint of water, yielded seven ounces of a mucilage as thick as that procured by the solution of one part of gum arabic in three pints of water. Lord Dunleodnel (Phil. Mag. vol. x.) has given the following directions for preparing the mucilage from the lichen. The lichen has an outer skin, covering a green resinous substance; and the remainder of the plant consists chiefly of gum and of fibrous matter, on which water does not act. In order to separate the outer skin from the resinous matter, the plant must be scalded two or three times with boiling water, which causes the skin to crack, swell, and peel off. It is then put into a boiler with about three quarts of water for every pound of the plant, and about half an ounce of potash or soda, and the boiling should be continued till the liquor acquires a considerable degree of gummy consistency. The liquor is then to be taken out and strained from the plant, and fresh water added to the liquor for the purpose of further exhausting the gum. The several liquors, after standing some hours to settle, and then removing the dregs, are to be boiled down in a regulated heat to the consistency which is required for use, but no further, lest it should burn and become coloured. Two or three boilings will be necessary for entirely exhausting the lichen of its mucilage.

The medical virtues of this lichen were probably first learned

4 R
learned from the Icelanders, who employ it in its fresh state as a laxative; but deprived of this quality and properly prepared, it is said to be an efficacious remedy in consumption, coughs, diabetieties, and diarrhoeas. Dr. Crichton informs us (Med. Journ. vol. x.), that during a residence of seven months at Vienna, he had frequent opportunities of seeing the lichen illadonicus used in phthisis pulmonary at the General Hospital, and he confesses, "that by no means answered the expectation he had formed of it." He adds, however, "from what I have seen, I am fully convinced in my own mind, that there is only two species of this disease, and that this form of lichen promises a cure. The two species I hint at, are the phisitum hematoxylon, and the phisitum pitaicus, or mucosa. In several cases of these I have seen the patients to far get better of their complaints, as to be dismission the hospital cured; but whether they remained long or not, I cannot take upon me to say." That this lichen strengthens the digestive powers, and proves extremely nutritious, there can be no doubt; but the great medicinal efficacy attributed to it at Vienna will not readily, says Dr. Woodville, be credited at London. It is commonly given in the form of a decoction, an ounce and a half of the lichen being boiled in a quart of milk. Of this a tea-cup full is directed to be drunk frequently in the course of the day. If milk disagree with the stomach, a simple decoction of the lichen in water is to be used. Care should be taken to boil it over a slow fire, and not longer than a quarter of an hour. In the London Pharmacopoeia the decoction is directed to be prepared by boiling down an ounce of the lichen in a pint and a half of water to a pint, and then straining it.

The lichen caninus, or cineaeus terrestris, which grows on heaths, dry pastures, and woods, has a weak faint smell, and a sharpish taste. It was for a long time extolled as a medicine of singular virtue in preventing and curing that dreadful disorder which is produced by the bite of rabid animals. The "pulvis antilysin," a powder composed of equal parts of this lichen and black pepper, was first recommended as a preservative against the rabies canina by Mr. Dampier, brother of the celebrated circumnavigator, and by the authority of Sir Hans Sloane, it was published in the Philosophical Transactions, (vol. xx. p. 49.) The quantity of pepper having been found to render the medicine too hot, the powder was afterwards prepared of two parts of the lichen and one of pepper. This powder was afterwards adopted in the London Pharmacopoeia in 1731, at the desire of Dr. Mead, who seems to have had repeated experience of its good effects, and who declares that he had never known it to fail, where it had been used, with the assistance of cold-bathing, before the hydrophobia came on. He directed the patient to be blooded to the extent of nine or ten ounces; afterwards a dram and a half of the powder is to be taken in the morning fasting, in half a pint of cow's milk warm, for four mornings successively. After these four doses are taken, the patient is directed to go into the cold-bath every morning for a month, and then three times a week for a fortnight longer. On the character of Mead, the pulvis antilysin was long retained in the London Pharmacopoeia; but on the revision of that book in 1788, it was defervedly expunged. Woodv. Med. Bot. See Antilysus Pulvis.

Lichen, in Medicine, a cutaneous eruption, consisting of papule (pimples), affecting adults, connected with internal disorder, and usually terminating in fevers. It is not contagious.

Such is the character of an eruption, to which Dr. Willan has appropriated the term lichen, in his valuable treatise on cutaneous disorders. (Order 1. Genus ii.) In the writings of Hippocrates, he remarks, the term lichen, or lichenes, (Auriculai,) is employed to express an eruption of papule, and he did not include under that appellation any cutaneous disease. There is, however, an extreme confusion, as in the case of almost every other denomination of cutaneous affections, among the subsequent writers, in the acceptance of the word. The later Greek authors extend the application of it, so as to comprehend a cutaneous affection of the face, sometimes called fucosus, and likewise the lupus vulgaris, a contagious disease, together with the simple and rank lichen (Auriculai) of the Latins: he is, however, inconsistent with himself in other places. The only author to whom we can refer for a definition of lichen is Celsus; and his account of it does not, in any respect, correspond to that which the Greeks have given of the lichenes. Under the denomination of papula, Celsus has comprised, and accurately described, two varieties of lichen, the L. agricus, and L. circumscriptus; and he has correctly stated the real relation between the lichen and impetigo, when he says, that "the papula agris, through neglect or improper treatment, is often changed into impetigo." (De Med. lib. v. cap. 28.) Nevertheless, all the translators of the Greek medical writers have used impetigo as synonymous with the original term lichen; and their example has been followed by many respectable authors on the subject of cutaneous disorders.

By more modern writers, again, the lichen has been arranged under other genera of disease, with which it still less affinity than with impetigo. Thus Sauvages describes it under the title of herpes farinaceus; and Lorry confounds both lichen and impetigo with herpes; while Plater, Hafner, and others, arrange lichen under the gents scabae. By adopting the character of the lichen, flated by Dr. Willan, we may avoid this extreme degree of confusion.

An eruption, thus characterized, occurs under five or six varieties of form, to which Dr. Willan has appropriated the following titles: 1. Lichen simplex is preceded by symptoms of feverillness, or rather by a state of irritation not amounting to fever, which is relieved after five or six days, on the appearance of the eruption. This consists of distinct red papule, with but little inflammation round the base, first appearing on the face or neck, and spreading thence over the body and limbs. In about a week, the colour of the eruption fades, and the cuticle separates on the face. The duration of the complaint, however, is seldom in two cafes alike; from fourteen to twenty, or thirty days, sometimes intervene between the eruption and the renovation of the cuticle. It occurs, as well as some other of the species, annually about the beginning of summer, or in autumn, in persons of a very weak and irritable constitution. 2. Lichen pilaris is merely a modification of the foregoing species, the papula appearing only at the roots of the hairs of the skin. 3. In the lichen circumscriptus, or papulated ring-warm, the papule are arranged in clutters, or patches, which are of an irregular form, but with a well-defined margin, and appear in succession on the limbs or trunk of the body, sometimes by repeated eruptions, lasting for six or eight weeks. It is excited both by internal and external causes of irritation, and is at first attended with slight febrile symptoms for a day or two. 4. Lichen agricus is preceded by nausea, pain in the stomach and limbs, with shivering and depression of strength for several days, which sometimes diminishes when the eruption appears. The papule are distributed in great numbers in various parts of the body, face, and limbs, having a high red
red colour, and being attended with itching, heat, and painful tingling. The redness is augmented, and a lamination of burning and smarting is excited by the warmth of bed, by washing, especially with soap, by violent exercise, or wine. Its duration is uncertain. Women are more liable to it than men; and it affects those especially who have undergone long continued fatigue, watching, and anxiety. In men it is often produced by the intemperate use of spirituous liquors.

Cure.—Every thing heating or stimulat ing should be avoided, whether great exercise, or stimulant food and liquors; gentle laxatives should be used; and the skin should be washed with warm-water, or thin guild, by which the irritation and itching are alleviated. All strong applications are improper, and aggravate the complaint, producing intolerable smarting. Mild cooling ointments, as the rose-pomatum, relieve the uneasy sensations of heat and itching.

Two other varieties of lichen are noticed by Dr. Willan, one of which he terms lichen lividus, and the other L. tropicus. The former of these is characterised by papulae of a dark or livid hue, is more permanent than the species before described, and principally affords perons of weak constitutions, who live on a poor diet, and labour hard, or reside in close situations. The lichen is sometimes intermixed with petechia in the latter cafes, or larger purple patches, which point out its affinity with the purpura, and land-scurvy. It is cured also by the same means as are successful in the latter disorder; namely, by nourishing food, moderate exercise in the open air, with the use of cinchona and sulphuric acid, or the tincture of muriate of iron. The lichen tropicus signifies the eruption which is well known in hot climates by the appellation of prickly heat, of which we have already given some account. See Heat, Prickly.

LICHENASTRUM, in Botany, so called by Dillenius, from its affinity to Marchantia, his Lichen. See Jungermannia.

LICHENES, a Natural Order of vegetables of the Cryptogamic class, (Aspidofere of Wiggers's Holzf. 85.) allied on one hand to the Algae, in which it was included by Linnaeus, and on the other to the Fungi, with many of which it nearly agrees in habit, and with some of them very strikingly in the character and situation of its tours. This family has rifen gradually to the consequence it now holds among botanists, first by the labours of Dillenius and Micheli, and next by those of Linnaeus and his pupils; but the celebrated Dr. Acharius, professor at Vadilena in Sweden, has finally elucidated it fully, with respect to characters and synonyms, in several separate works; not merely as a genus, but as a natural order, comprising many genera. Professor Hoffmann indeed, and other German botanists, had already considered it in the same light; but none has so completely treated the whole subject as he has learned Sweden. For a general view of the nature of this family, with the leading feuctions to which its species have been reduced, see Lichens. We shall now proceed to explain what has been done towards its generic sub-division, the first attempt at which, by the fruit, was made in Wiggers's Prinaste Fl. Holzsates, a work of which Weber, in a copy before us, claims being the author.

It would be tedious and difficult to trace minutely every step in the progress of those who have at any time adverted to the generic distribution of Lichens. Weber's is but a rude attempt. The labours of Hoffmann, having led the way to Acharius, require some previous explanation.

That writer, in his Flora Germanica, v. 2, published in 1795, established an order of Cryptogamia Scutellata, as distinct from Alge, which is intended to embrace all the certain

Lichens, though it does not, in fact, admit all that are reckoned such by Acharius. It is thus defined.

Scutellata. Female fructifications in orbicular, flat or convex shields, radiated on naked, bordered or without a border, or spirally twisted, fixed to the frond either by their centre or their margin; and this frond with gelatinous, coriaceous, umbilicated, caulecent, frap-like, filamentous, leath, tartarose, or leprose; its duration perennial, throwing out various buds or offsets. Each frond contains seeds within its fibrous or spongy substance. This order contains nine genera.

1. Collema. Frond pellucid, gelatinous. Shields bordered. This comprehends the gelatinous Lichens of other authors, of which 26 species are here described as natives of Germany. (See Lichen; sect. 4. n. 48.) Collema is recently admitted as a genus in Engl. Bot. v. 32. t. 2284, where the essential character is, "Shields orbicular, horizontal, nearly felifie, superficial, with a gelatinous accceory border." There can be no doubt of its constituting one of the most natural genera to be found in any order.

2. Peligera. Frond coriaceous. Shields (or targets) comprised, attached by their margin.—The true coriaceous Lichens, sect. 5; as refufinatus, caninus, &c.; nine species in Germany.

4. Cladonia. Frond caulecent, cylindrical, hollow. Shields tubercular.—Thirty-seven species.—This genus embraces not only those of the Linnaean fruticosi, sect. 8, to which rangiferinus belongs, but likewise all the jdyphysyi (or pyxidi) sect. 7.—Thirty-seven species are described.

5. Stereocaulon. Frond caulecent, cylindrical, solid. Shields tubercular, globose.—This is, perhaps, the most excellent of the genus, confounding L. psclohali, (see Lichen; sect. 8. n. 106.) along with the powdery-fruited kinds, globifer, furcat, and commpress.; and with these the coral crusted tribe, which make the Acharian genus Ifdium here mentioned. Even L. niger of Hudson and Linneus, Engl. Bot. t. 1161, perhaps more akin to Collema, though its shields have no border, is joined with them. The whole however made but nine species.

6. Usnea. Frond frap-like, or filamentous. Shields radiated or naked.—Equivalent to the filamentoi, sect. 9, of Linnaeus. Sixteen German species.

7. Lobaria. Frond lobed, laciniated, much divided, erect, or deforeed. Shields bordered.—This large and rather multifarious genus, comprehending 63 German species, is divided into four sections, which perhaps run so much into each other as to justify the whole assemblage. They are

* Platina. Frond (molly) pitted.

To this belong many of Linnaeus's sect. 4. fojiacei, as the farinaceus, fraxinaceus, and their allies. To these rigidus, which is trifis, n. 112, of the Linnaean arrangement, is subjoined. Then follow iflandicu, &c.; then furfarceus, Linn. n. 53. Engl. Bot. t. 984, and ciliatus. All these are characterised as having a pitted or cellular frond, which is more or less erect. They are however very various tribe.

—Five species have a pitted deforeed frond, as faxatii, and palmonarius, Linn. n. 52. Engl. Bot. t. 52.—Twelve are defined as having a dilated frond, in which sarcus is included, with caperatus, perlati, pericas, and others, which are by no means naturally allied, nor is the character expressive, if it means absolutely that the frond is never pitted, or that it is more dilated than in the preceding ones.

** Physiata. Frond inflated, as in L. physodes, Linn. n. 44. Engl. Bot. t. 126.
LICHENES.

*** Squamaria. Frond narrowly divided, as in fllaris, and its numerous allies.

**** Placodium. Frond crustaceous, obscurely imbricated. In the beginning of this section, several species occur which are not really crustaceous, and which are closely akin to fllarris, though more depressed. True examples of Placodium are L. fivxioiia, Eng. Bot. t. 1693; as well as candidans, t. 1778; and gellius, Linn. n. 23.

8. Phora. Frond figured. Shields bordered, convex.—Twenty-six German species are enumerated under this genus, many of which are among the imbricated Lichens of Linnaeus, others amongst his leprous or crustaceous ones. In all of them the crust is either formed into leaflets, or pr. unciation of a determinate shape, leaved on a homogeneous white chalky bals, the outer surface being variously coloured.

9. Verrucaria. Frond leaflets, leprous, tarteaceous. Shields with or without a border.—This genus comprehends most of the leprous Lichens of Linnaeus. See Lichen, sect. 1 and 2. Seventy-one German species are defined, distinguished according to the colours of their shields.

Such is the method of Hoffmann, who in his acute and truly excellent work, entitled Planta Lichenographica, consisting of three thin folio volumes, with seventy-two coloured plates, has described and figured a great number of species from all parts of the world. This book however does not exactly agree in generic distribution with his Flora Germanica, but they are easily compared together. The same writer has left unfinished an Enumeratio Lichenum, in quarto, begun in 1784, of which we have 102 pages, and 22 uncoloured plates, very finely drawn by the author. In this book Lichen flabbas as one genus, divided into several sections improperly termed orders.

Professor Acharius, above-mentioned, having previously in several papers, with plates drawn by himself, in the Stockholm Transations, elucidated various species or tribes of Lichens, published in 1798 his Lichenographiae Sueciae Prodromus, in one volume octavo, with coloured figures of five species only. This work marks an era in cryptogamic botany. Though it professes to treat of Swedish Lichens only, it in fact indicates all of which the learned writer could discover any tidings, with their specific characters, synonyms, and places of growth, besides innumerable valuable observations. The whole are ranged under the name of Lichen, as one genus, but divided into twenty-eight tribes, or sections, of which the genin of Hoffmann form the bals. These tribes compose three families, under whose subdivisions we shall indicate them all. The peculiar terms which occur will be explained hereafter.

Family 1. Crustaceous Lichens.

Having a crustaceous, more or less expanded, bafe.

1. Lepraria. Receptacles scarcely known.—(Most of these come under the genus Byflura in Linnaeus.)

2. Verrucaria. Receptacles (thalamis) hidden in the crust, roundish, concave, opening by a perforation at the top.

3. Opegrapha. Clefts (thalline) closely attached to the crust, and opening longitudinally.

4. Variolaria. Powdery little mafles (glomeruli) attached to the surface of the crust.

5. Ureciolaria. Shields hollowed, funk in portions or quarters of the surface of the crust.

6. Patellaria. Shields attached to the surface of the crust, either concave or flat, with a border, or convex and hemispherical, with scarcely any.

8. Calicium. Tubercles stalked, lenticular, opening by a torn border, discovering a powdery elevated disk.

10. Fornia. Frond irregular, covered with minute somewhat imbricated scales. Shields lateral, as well as marginal.

Family 2. Leafy Lichens.

Without a stem, and consisting of a simple or multiple, sessile, divided, somewhat membranous leaf.

15. Umbilicaria. Receptacles (trices) convoluted, raised. See Gyrophora.

17. Steba. Shields scattered; or Targets marginal. Leaves somewhat coriaceous, laminal with little bals pits, amongst down.

18. Pelidea. Targets lateral and somewhat marginal, on the front or back of the leaf. Leaves coriaceous, mostly veiny, as well as downy, beneath.

F. Receptacles elevated far above the leaves, on the tops of stalks.

22. Helodinium. Tubercles fungous, on nearly solid, simply sub-divided stalks, scarcely dilated upwards.

23. Cladonia. Tubercles nearly globose, on taper-pointed, elongated, tubular, branched and shrubby stalks.

Family 3. Caulencous Lichens.

Stems either solid, branched, round and shrubby, or elongated and thread or leaf-like.

H. Filamentous, elongated.

28. Ufnea. Shields flat and radiated, or convex and slightly bordered, scattered; as well as powdery mafles. Branches with a crustaceous, somewhat jointed, cost.

It will easily be seen, by comparison, how far these sections answer to Hoffmann's genera. The first five have nothing corresponding with them. Patellaria is equivalent to his Ver
Verrucaria, at least in idea. Brumalces, Scyphophoros, Helpodium, and Cladonia, are included in his Cladonia. Psegora and Placodium are his Psegora. Colclera, Pelidice, (his Peligeria), Umbilicaria, and Ufnea, agree with his. Calicium, Iridium, Endocarpit, Spheora, and Conicularia, are not found in his section, except that Spherorlhus is, in his Pl. Lich., called Corallolidz. Imbricaria, Lobaria, Platypno, and Phylidia are nearly comprehended under his Lobaria.

It is to be remarked that, in his generic characters, Hoffmann takes the habit into consideration. To this perhaps Acharius, as a philosophical Linnaean, had objections, which induced him to consider these different affinements of species rather as sections of one great natural genus, the frutification being full much in the dark. In 1803 however he published his Methodus, in 8vo. with eight coloured plates, and, soon after, a supplement. In this new work, still keeping the Linnaean principle in view, he aimed at distinguishing the Lichenes, as a natural order, into several genera, by the frutification alone. Before we detail these, it is necessary to take a view of the physiology of the order, as explained in his able preface, as well as of his technical terms. Both these subjects are treated also, in the preface to his Prodomus; but it is best to consider here his latter view of them only, and they are so united together, that an explanation of the terms will sufficiently elucidate the physiological ideas of the author.

Thallus is used by Acharius for the whole plant, or herbage, of a Lichen, the frons of Linnaeus (see Frons) distinct from every thing belonging to the frutification. It is root, stem, flake, and leaf, all in one, its substance seeming to assume the nature of either, according to circumstances; but this is, in some measure, the cafe with every vegetable body, and by no means peculiar to a Thallus or Frons.

Acharius is unwilling to use the latter word for a mere filamentous crust, or mass of powder, but we confine ourselves unable to discover any use, or indeed any distinct meaning, in the new term, unless it was restricted to such crust or powder. Its meaning moreover, *pseudon*, a green bough, is precisely equivalent to frons; but this objection is not material. — Of the different forms and textures of this part, we have sufficiently spoken under the article Lichen. It is an essential part, though sometimes nearly or quite destroyed by age, though the frutification may still, for a while, remain.

Apophyseum (παρθένη, a receptacle), is the receptaculum of Linnaeus, the part where the seeds are formed and brought to maturity. Acharius defines it as "bearing, encompassing, or containing the organs subjacent to the propagation of Lichens; distinct in figure, generally in colour and nature, from the thallus, or frond, on which it is situated, and which sometimes furnishes it with an exterior covering." The ecuclation having taken place, in some manner unknown to us, within the frond, these receptacles, (as we must still beg leave to call them,) gradually increase, and finally expel their internal part, which is either occupied by a fibrous texture, more or less dense, or is, when moist, in some measure gelatinous, rarely appearing hollow. Their shape is most frequently roundish, but otherwise very various, as has been already explained. (See Lichen, sect. i.) When ripe they discharge their seeds, either naked, or contained in cles. Sometimes, though rarely, their under-side produces naked seeds. To the various situations of these receptacles, the generic characters already explained have sufficiently alluded; their various kinds have also been mentioned, but will now be more fully delineated. Hedwig and Gærtner differ about the seeds of Lichens; the latter supposing them (for it is entirely supposition) to be rather of the nature of buds or offsets, which he terms propagines, and not actual seeds produced by sexual impregnation. The reason for this opinion seems to be, that the mode of such impregnation has not been discovered, any more than in ferns or sea-weeds.

Acharius defines fifteen sorts of receptacle, or apophyseum.

1. *Stelula.* Shields. These are open, orbicular, compared by Dillenius to a faucer; their border, and under-side, of the substance, and usually of the colour of the crust, or leaf. Their disk, (fratum prolieterum of Acharius) almost always differing in colour, and totally distinct in substance from the margin, contains the seeds in the vertical parallel cells of its internal substance. Their border is termed an accetoty, not a proper, one. The shields are either thick, tumid, entirely sessile, or even sunk, as in many crustaceous Lichens; or membraneous, often elevated, somewhat flaked; very rarely they become perforated in the centre.

2. *Pellulnl.* Spangles. (See Dillenius, p. 133.) Open and orbicular, like shields, but sessile, and by no means formed of any part of the crust, from which they differ in colour, being most usually black. The seeds are lodged beneath the membrane that covers their disk, as in the former; and the disk is surrounded by a proper border, that is, of its own substance and colour. Their seeds are observed to be naked in the cellular substance of the disk, not inclosed in cles. The figure of the pellulula is not liable to much variation, except that the disk is sometimes concave, sometimes flat, but more frequently convex, and in an advanced state often globose, so that the border disappears. This kind of receptacle is properly that of the liruus tuberculatus Lichens of Linnaeus, and belongs to the genus Le- cidea of Acharius.

3. Cyphys. Pits. Open cup-like little naked, white or yellow spots, on the under, generally downy, side of the leaf, in the Acharian genus Sticta; see Eng. Bot. t. 2298. 2359. They are at first minute dots, globose, and immersed in the substance of the leaf; at length they burst, with an irregular margin, and discharge a powder, which Acharius, who has first defined and named them, supposse to be of a "permentic nature," by which we presume he means of the nature of pollen.

4. Lirells. Clefts. Open, elongated, sessile, black receptacles, with a somewhat spongy, very narrow, or quite linear disk, and a proper border, parallel to it on each side. Sometimes there is an accessory border from the crust besides. This is the peculiar frutification of the genus Opegrapha of Peroon; see Eng. Bot. v. 25 and 26 especially. The lirelle are either simple and solitary, or aggregate, confluent, and branched. These differences often occur in the same species. L. feriipes of Linnaeus is a specimen of this genus.

5. Pilidiz. (πασαβα, a little cap or hat.) Puffs. — Little round bordered knobs, whole disk, at first covered with a membrane, and often clothed with fine grey hoar fur, finally turns to powder. They are elongated below into a flaks, fixed to the crust, but totally different from it. Ca- lium of Peroon has this fort of frutification.

6. Orbilles. orbs. Flat, orbicular and dilated, of the substance of the frond, terminal, peltate, without a border, but often surrounded with radiating shoots. The membrane, or disk, under which the seeds are lodged, is smooth, mostly of the colour of the frond. These are seen in the filamentous Lichens, or Ufnea. Spurious orbilles, bordered like shields or spangles when young, are found in some Cornicularia of Acharius.

If orbilles produce real seeds, the filamentous Lichens have two kinds of fruit, for they bear also proper tubercules, or rather
rather cephalodia; see n. 12. But we cannot easily allent to this; see Utica hereafter.

7. Pelt. Targets. Flat, closely pressed, and attached by their whole under-side, as if glued, to the frond, sometimes at its back. They are broad, kidney-shaped or oblong, rarely irregular, covered with a thin coloured dillik, with no border, except occasionally a very minute acellulory one, which seems to circumferbe them. In an early stage they are concave, and concealed by a thin gelatinous fuculent membrane, or veil. (See Lichenes, lect. 5.)—The genus Cetraria is thought by Achauer to have fuscendent pelta, with a more evident border, entire, crepitate or lobed, which is不像 connected with the frond beneath, though the greater part of the receptacle is closely attached thereto, and sometimes sunk into its substance.

8. Trice. Buttons; (Dill.)—Roundish, fuscident, unexpanding receptacles, of a peculiar, compact, black, solid substance, continued along their whole surface. Their upper side is distinguished by concentric or plaited and twelked folds, covered by one common membrane through all their convolutions, and lodging in their inside naked feeves, deftitute of cafes, or cells. See Gyrophora, to which these buttons are peculiar.—Sometimes the presence of but one marginal fold gives this kind of receptacle the appearance of a patellula, see n. 2; but others will usually be found with more, on the same plant, even in Gyrophora pustulata. Engl. Bot. t. 1284.

9. Thalamia. Hollows.—Spherical, nearly clofed receptacles, lodged in the substance of the frond, lined with a proper coat, under which, in their spongy texture, are cells, each containing from two to four fseves. Each hollow finally opens by an orifice in the surface of the frond above, which sometimes supplies it with a fuscident border. These are the proper receptacles of Endocarpon; see that article.

10. Tubercula. Tubercles.—Spherical, or slightly conical, nearly clofed, crufmate, black, more or less immersed in the surface of the crufmate frond, or thallus, which they elevate; or sometimes they are exposed, being merely fquine. Each contains a ball or mass of connected feeves, deftitute of cells, but enveloped in one common membrane, and the whole are finally discharged together by an orifice at the top of the tubercle. Such is the fruit of Verrucaria, and if this account be correct, that genus is certainly as distinct in fructification as in habit from Endocarpon. The nature of these minute parts is very hard to determine, especially as the tubercles of Verrucaria often come under our inspection after they are emptied of their contents.

It must be remembered that Achauer here uses the term tubercle in a restricted fense, and not with that latitude habitual to Linnaeus and his followers, amongst whom it commonly, when applied to Lichens, means almost any thing that is not a shield.

11. Cellula. Cellules.—Globofe terminal receptacles, formed out of the substance of the frond, filled with uncoated feeves intermixed with fibres, and at length burfling irregularly; as in Spharophorum. See Lichenes, lect. 8.

12. Cephalidia. Knobs.—Convex, or more or less globular, covered externally with a coloured feed-bearing craft, and placed generally at the extremities of flakks originating from the frond (being rarely feline and scattered as in Stereocaulon), permanent. Such are seen in Dacrymyces, or the Cup-bearing Lichens. (See Lichenes, lect. 7.) In some of the filamentous tribe, Utica, they are at first like patellula, and feline, becoming afterwards convex and irregular. See orbile, n. 6. Cephalidia are sometimes simple, sometimes compound or conglomered.

15. Globuli. Globules.—Globose, solid and crufmate, formed of the substance of the frond, and terminating its points or branches, from whence they fall off entire, leaving a pit or cavity. They are supposed to be covered all over with a coloured feed-bearing membrane, and are taken for one of the modes of fructification in the Isidium of Acharius; see hereafter.

Acharius explains as follows certain terms used in his description of Lichenes.

These are the cases or cells containing the feeds, in the disk of most receptacles, at least in fopelle.

Spere are the feeds, of whose nature very little is known. This author declines calling them femina, because they are prefixed to have no cotyledons; but that is no sufficient reason. The question is, whether they are produced by sexual impregnation; if not, they are gemma (buds or offsets). We need not here repeat what is said under the article Gemma.

Propagula are those little roundish deciduous bodies, commonly termed powder in speaking of these plants, but which may be called the effervescence. These bodies are either difpered or clustered on the surface of the frond, and each of them is afforted by Schreber to be a hollow vehicle, and by Hofmann to discharge, through an orifice, a quantity of fine dust. They are also not infrequently powdery at their outside; sometimes interwoven with very short and fline threads, and finally pasa into what is supped by Achauer to be an amblage of minute buds, gemmae.

Achauer observes, that "some have taken these bodies for pollen, or male flowers; but that this conjecture is utterly contrary to the obervations of Micheli and Schmiedel, who faw them germinate, and produce offspring." Schmiedel's remarks we have not seen, but Micheli certainly afferta, in his Nova Plantarum Genera, 74, t. 41, Q, R, that he saw this powderly matter germinate, and produce plants, in the cup-bearing tribe of Lichenes. He therefore takes the shields and their contents, which he has delineated in his t. 52, for male blossoms, and this opinion was adopted by Linnaeus. Hedwig nevertheless, in his Theoria, p. 120, strongly combats this doctrine, affertaing that Micheli might easily be mistaken, as the real feeds, visible only with a very high magnifier, would escape observation, when fallen among the powder, and vegetating there, would cause the young plants to feed the offspring of the latter. Gartner thinks the powder is of the nature of buds; but his opinion is equally theoretical with that of Adanfon, who takes the contents of the shields for feeds. Achauer adopts both these opinions, and offers an ingenious conjecture of his own, which is, that the powderly buds may be defined to produce individual plants that propagate themselves subsequently by the same mode; while the feeds of the shields or tubercles may produce complete fructifying plants, which go on to increase by feed. Hence, his genus of Leparia, as he premuises, propagates itself by the former means, without any other. We confess this genre is very puzzling; but when so confpicuous a plant as Leucon has to long flowered and fruited without observation, and suppoed Leparia are from time to time detected with shields, we are disposed to attribute much to our ignorance. We certainly cannot agree with Dr. Acharius when he goes so far as to suggeft that the feeds, which originate from the shields, may sometimes produce shields alone, without any frond! The latter is well known to be now and then fugacious, and is invariably the root of Cystota, though absolutely effential to the young plant. It is very defirable that some perfon should see the germination of the feeds of Lichenes, taken from the shields; though there seems little reason to doubt their
their being fuch, whatever the powdery masses or warts may be. We are chiefly led by the obervation of Hoffmann, above-mentioned, to perfilt in the opinion of Hedwig. If the powdery granules in question be really vacular, and emit a duct, it is so analogous to the analyses of all other known plants, and fo unlike the nature of gemmae, that, if the contents of the fheds can be proved to be feeds, of which indeed we have no doubt, there would be little rea-
on to hesitate respecting the others. We do not mean that every granular appearance about the fronts of Lichens mutt be anthers. Much of it, doublefs, is gemmaceous, but anthers may accompany it; and the latter may in Leparia impregnate minute or folitary feeds, that also accompany the granules, and that have hitherto escaped detection.

Soredia are affemblages of the above powdery bodies, collected on a fort of receptacle. This Acharius exemplifies by Variolaria, as will be mentioned in speaking of that genus. Some Soredia originate from cracks in the frond.

Punctinula are excrescences found occasionally on the surface of the frond, often cluftered or branched, whose use and nature are unknown. They occur in Gyrophora pulu-
lata, but are most remarkable in Lichen glumiferus of Lightfoot. See Engl. Bot. t. 293.

Verrucose are varioufly-shaped protuberances, solid, and usually smooth, originating from the crust, and sometimes, though rarely, bearing or lodging the fructification, as in Lichen pertusus of Linnaeus. See Engl. Bot. t. 677; also t. 2317, 2336.

Podetia are stalks elevating the fruit, as in the Cup Lich-
ens, and are either solid or hollow.

Lorula are the long thread-like branches of the Usnea tribe.

We are now to take a compendious view of the genera of the Lichenes, as defined in the Methodus of Acharius, upon principles dependent on the parts of fructification, or, at least, propagation. These genera are 23, difpofed in three fections.

Seft. 1. STEREOITHALAMI; (from et, to deprive, and
Sororius, a bed.)

Receptacle none. Organs of propagation naked, scat-
tered or aggregate.

1. Pulveraria. Efflorefcence powdery, collected into tufts by fine, flender, interwoven threads. (Frond none.)

This genus is now reduced by its author to the following.
See Lepraria chlorina, Engl. Bot. t. 2038; a most beautiful production, which covers rocks with a coat many inches, or some feet, broad, resembling bright lemon-coloured cloth or velvet.

2. Leparia. Efflorefcence somewhat globular, scattered lofe over a crustaceous base, which it often entirely covers superficially. (Frond crustaceous, indeterminate.)

This, like Pulveraria, comes under the Byfus of Linnaeus, who has decribed some of its parts. The most common is L. botryoides, Ach. n. 7. Engl. Bot. t. 2148, seen every where on the trunks of trees, and on polts, to which it gives a green colour in winter. Another very common species, incana, n. 2, has been found with patellula, which make it a Leccia of Acharius. See Engl. Bot. t. 1683; as has his lepisma, n. 3, which is his Leccidea (or rather Parmelia) Stonei; Meth. 65; Lichen Hematoma; Engl. Bot. t. 486. Leparia rubens, n. 6, is Confera leche-
icola; Engl. Bot. t. 1609; and probably Mieheb's Lichen crustaceus, arboribus adnascens, tenuifilium, pulverulentus, ruber; Nov. Gen. 100. n. 73.

Wiggers, or rather Weber (see the beginning of this article), places this genus (under the name Lepra, by which Haller had previously distinguished it), in his order of Aipinaceae, defined as "destitute of fructification." But many of the plants, which he refers to that order, are now known to have feeds, and his genera are liable otherwise to much exception.

3. Spiloma. Efflorefcence? in shapeles, superficial masses, woolly and powdery, rigid. (Frond crustaceous, indeter-
minate, thin, uniform.)—Of this genus several species may be seen in Engl. Bot. v. 29 and 30. Notwithstanding the above character, the crust may be seen to be determinate, or limited, in Engl. Bot. t. 2150, where it has a very distant and curious border.

4. Variolaria. Efflorefcence globofe, collected in distinct affemblages (foredia). (Frond crustaceous, mostly deter-
minate.)—Great light has been thrown upon this genus since the publication of the Methodus of Acharius. See Turner Tr. of Linn. Soc. v. 9. 137—140, and Engl. Bot. v. 28. t. 2008 ; v. 29. t. 2061; so that it is now removed by Acharius himfelf to the second fection of his Lichenes, as having true receptacles. It seems indeed, in our opinion, to give no small support to the theory of the powdery efflorefcence (propagula), above-described, being the male part of the fructification. Variolaria has true receptacles, feated on a thick tartareous crust, which supplies them with an accufory border, of more or lefs thickness or regularity. Their diftk, or space within the border, is occupied with an affemblage of the powdery subflance in quifition, of which to much has already been faid, and under which has been obferved, in feveral species, a coloured fhefly or waxy diftk, lodging feeds (as we all prufe them to be) in vertical cells; like a true fheid. Here then the two fexes feem united in one receptacle. In some cafes the male is moft abundant and predominant, and the waxy diftk is scarcely difcernible; at leat at that period of growth when fuch specimens have happened to come under examination, which is when the powdery subflance renders them moft obvious; but it is moft likely, from analogy of other plants, that the diftk may subsequently increase. In other inftances, as in Lichen multipanus, Engl. Bot. t. 2061, the powdier is in lefs proportion, sooner almost disappears, and the diftk is very evident beneath it. Some traces of a diftk may be found, in what we would term the flowering state of the original Variolaria jaginae. See Engl. Bot. t. 1713.—The Hed-
wigian theory of the impregnation of Lichenes appears to us greatly confirmed by these obervations, and we cannot but think that the opinion of the germination of their pow-
dery efflorefcence has been too hastily admitted by recent naturalists.

Seft. 2. IDIOALTHALAMI; (from hio, proper, and Sclavus).

Receptacle compofed of a peculiar compact hardtiff sub-
flance, not in any manner formed out of the frond, from which it differs in colour (being moftly black).

The feeds are naked, not enclosed in proper cells, except in Endocarpon; upon which we shall offer some remarks hereafter.

* Receptacles open.

5. Opegrapha. Clefts black, fellefe, oblong or linear, simple, confluent, or branched, fhrilght or zigzag, bor-
dered; their diftk flat or flightly concave, naked or pow-
dery, narrow, linear, rarely dilated; their border (of their own subflance) often very narrow and scarcely perceptible, sometimes tumid, elevated, and somewhat inflexed. Some-
times there is a furpicious accufory border, or mere swelling of the crust. (Frond crustaceous, uniform, thin, generally indeterminate; occasionally leprous.)

Lichen scriptus of Linnaeus, with about thirty known spe-
cies
LICHENES.

We introduce this, as described by the author since the publication of his *Methodus.* A genuine example of it is *A. Swartziiana,* see above, p. 13. t. 4. f. 1. Engl. Bot. t. 2079. We conceive several plants are improperly referred to this genus by Acharius, as *Sphinctes wolverse,* or Engl. Bot. t. 2076, and *Opegrapha aldradiva,* Ach. Meth. 25. Engl. Bot. t. 1847; to say nothing of *Lichen crocatus,* t. 408, and *Jacidinia,* t. 288; whose shields or targets have no irregularity of shape, and whose fronds are of so totally different nature from the crust of *A. Swartziiana.* In short, we can scarcely find another certain species to associate with this; except possibly *A. gyrops,* Ach. as above, p. 14. t. 4. f. 3.

6. *Lecidea.* Spangles sifelline, with a flattish or convex disk. (Frond various: crustaceous, whether uniform and limited, or scattered and indeterminate; or even leafy, somewhat membranous, or sifellated. Acharius adds "rarely umbilicated;" from an idea now proved erroneous, that *Gyrophora pulvulata* was a *Lecidea.* See *GYRIPHORA.*

This is an extensive genus, excellent as far as only crustaceous species are admitted, sifell the genuine *Lichenes lepriei tuberculati* of Linnaeus. See *LICHEN,* section the 11; and the term *patellale* in the present article.—These constitute the first section named *caulata,* comprising 80 species. 45 of which have black or bluish receptacles, the rest red, yellow, or brownish.—The second section, *lepidota,* has a figured or lobed crust, often imbricated, and embraces 14 species, among which are *Lichen niger,* Engl. Bot. t. 1161, and *decipitum,* t. 870.—The third is a small section, with a leafy crust, *fophenaria,* into which should be admitted *Lichen daudelae,* Engl. Bot. t. 2129.—The fourth, *omphalaria,* contains only *Gyrophora pulvulata,* with its near relation *penyjuliana,* and ought to be abolished.

7. *Calicium.* Puffs (pilula) turbinate, lenticular, or nearly globose. They are generally elevated on a rigid simple stalk, of a totally different subsance from the crust. (Frond crustaceous, either leprous, or tartareous, uniform or sifellated, powdery and granulated, or solid and chequered, or somewhat lefthy and imbricated; see *Lichen phoebeaphus,* Turn. Tr. of Linn. Soc. v. 8. 260. t. 6.) Acharius describes 18 species, to which several have since been added by discoveries in Lapland and England. They are minute productions, long confounded with fungi, from which they were sifell distinguished by Perloos on account of their crust. It must be acknowledged that they bear the same analogy to several genera of fungi, that other Lichens, with proper shields, do to others, the *Ophiophora* of Hedwig. Examples of *Calicium* are seen in *Engl. Bot.* t. 1465; 1539; 1540. 1832. & c.

* Receptacles sifellate, at length opening.

8. *Gyrophora.* Buttons (trica) luperhicial, flattish. (Frond leafy, petate, between membranous and leathery.) See *GYRIPHORA,* in its proper place.

9. Basidiium. Receptacles sifellate, somewhat globose, opening by a deciduous lid, hollow, of one to three cells, lined with seeds. (Frond crustaceous, indeterminate, uniform.) This genus confis of only *R. majolicaeum,* Ach. Meth. 111. t. 8. f. 3; found on the bark of trees at Sierra Leone by Dr. Afzelius.

10. *Verruccaria.* Tubercles elevated, discharging their concatedated seeds by a terminal pore, or else falling out entire. (Frond thin crustaceous, uniform.)

A minute tribe, of which about 40 species are known. See *Lichen Schraderi,* Engl. Bot. t. 171; and *analectus,* t. 1848.

11. *Endocarpus.* Hollows (thalamia) hidden in the subsance of the frond, each opening by a little mouth. Seeds enclosed in cells. (Frond membranous, somewhat crifaceous, of a determinate figure.) See *ENOCARPS* in its proper place.

As the seeds are certainly enclosed in cells, like the genera of the next section, it seems desirable to range this genus with them. We are moreover now well aware that it differs sufficiently from *Verucaria* in having parallel cells, lodged in a disk lining the cavity of the receptacle; whereas, in that, the concatenated naked seeds, clustered into a ball, fill the cavity. Their habits indeed are also totally unlike.

The receptacles of *Endocarpus* are, moreover, so united to the subsance of the frond, that they may perhaps be considered as belonging to it, though somewhat different in colour; see Hedw. *Crypt.* v. 2. t. 20, A. Sect. 3. *CENOTHALAMIS;* (from knox, common or general, and *thalamos.*)

Receptacle formed of the frond itself, with which it agrees in subsance and colour. Seeds inclosed in proper cells, except in *Spherophorus.*

* Receptacles compound, either pierced or gaping.

12. *Thelotremum.* Receptacle compound; the outer one wart-like, elevated, of the subsance of the crust; inner somewhat globular, with a concave disk. (Frond a firm, continued, indeterminate crust.) Examples are *Lichen peritamus,* Linn. Mant. 151. Engl. Bot. t. 677; and *L. inclinyus,* t. 678. Acharius seems to have had the former in view when he defined the receptacles as "compound and opening by several little mouths." They are, in that species, generally aggregative or confluent, but each is internally distinct; and in others they are usually as distinct and separate as the shields of any other Lichen.

** Receptacles nearly globular, inclosed, of length burfting.

13. *Spherophorus.* Cells nearly globose, each enclosing a roundish ball of naked compact seeds, which turns to black powder, and is discharged by the torn orifice, leaving the cellule hollow and empty. (Frond sifell, branded, solid, rigid; tartareous or minutely fibrous within; with a smooth cartilaginous coat.)—This elegant genus is exemplified by *Lichen globiferus,* Engl. Bot. t. 115; and *fragilis,* t. 114; which, with the real *fragilis* of Linnaeus, make up the list of known species; see *Lichen,* sect. 8. *fructificus.*

14. *Idium.* Receptacle of the feeds terminal, somewhat discoïd, solid, various in thickness, covered with, and thinning through, the crust of the *papille* of the frond, which at length burfts, and each receptacle appears coloured, and partly exposed. Globules also either terminate each of the *papille,* or are nearly seiflle on the crust itself. They are coloured, and finally fall out, each leaving a little pit at the summit of the *papille* or branch. The globule is internally solid, and both lides are covered with a sifell-bearing coat. (Frond crustaceous, leprous and tartareous, cracked, rather indeterminate, either papillary only, or throwing up solid branches.)

Such is, as precisely as we can give it, the character of *Idium,* a genus founded by Acharius. He allows in a note that this genus is doubtful and ambiguous, near to *Spherophorus,* but differing in having a properly crustaceous frond, or bafs, and especially in the nature of its *frutatum proligeratum,* (disk, or receptacle of the feeds,) which does not turn to dust; as well as in the presence of terminal globules (see the explanation of this term, n. 13, among the kinds of receptacles,) even when the other receptacles are wanting.
Lichenese.

wanting. He adds that this double sort of fruit in *Ischnum* demands further enquiry, for he is firmly persuaded that these globules belong to the organs of fructification.—We presume that *Lichen scrobilus*, Engl. Bot. t. 1833, (see *Stratulina* hereafter) exhibits the former kind of receptacle, and L. Wulffringii, t. 2204, the latter; but of this we have no certain knowledge.—*Ischnum ganetes* of Acharius appears by his *Supplementum* to be a mere variety of the crust of *L. tartareus* of Linnaeus.

***Receptaculum orbiculare, open; their border of the colour of the frond, surrounding a variously-colored disk.***

15. *Urecaria.* Shields or spangles cup-shaped, variously coloured, sunk into the substance of the crust, or of its fragments or wars. Disk concave, rarely becoming flatish by age, but never elevated above the crust. Proper border often scarcely manifest, of the colour of the disk; the accesseory one sometimes formed of the crust, which is elevated like a ring, surrounding the disk of each shield; but it is generally purplish, not united to the shield throughout. (From crustaceous, tartaric, uniform, determinate, chqueered or cracked, rarely figured or lobate.)—Examples of this genus are the common *Lichen scrobilus*, Engl. Bot. t. 206; the rare *exanthematicus*, t. 1184. Tr. of *Linn. Soc.* v. 1. t. 4. f. 1; and *Urecaria calcaria*, Ach. Meth. 143. very common on grey marble tombstones, in exposed country churchyards, where it forms impenetrable hard white patches, two or three feet broad. This falt is *Patella multiformis*, Hoffm. Pl. Lieb. t. 63; f. 1—5; *Lichen cuneus*, Engl. Bot. t. 820, but not of *Linnaeus*. It is erroneously made a *Parmelia* in *Ach. Meth.* 158.

16. *Parmelia.* Shields superficial, or elevated, thick or somewhat membranous, flattish, convex, or concave, crowned with a free accessory border. (From varicous, crustaceous, leafy, branched or laciniated, cartilagineous, membranous or gelatinous.) This vast and various genus swallows up the greater part of the natural order; *Lecidea*, n. 6, being far inferior to it in number of species, though generally superior as a natural and confident genus. 204 *Parmelia* are defined in the *Methodus*, besides several in the *Supplementum* of Acharius. This author is often in doubt to which genus some species belong, for want of knowing them in every state of growth. The true *Parmelia* have an acceseory border of the colour and substance of their crust, but no proper border formed of the substance of the disk. The sections of this genus are eleven, distinguished by the nature of their frond, the first three being crustaceous, as in *Lichen tartareus* (see *Lichen*, sect. 2); the next two are leafy, more or less depreffed. The sixth section confits of Hoffmann’s *Colonna,* (see the early part of the present article,) and has been lately reforted to the rank of a genus in Engl. Bot. t. 2284, with this character. “Shields orbicular, horizontal, nearly fifeilie, superficial, with a gelatinous acceseory border.” The five remaining sections are the most miscellaneous possible, nearly as much so as the original genus *Lichen* in Linnaeus.

***Receptaculæ flattened, nearly defective of a border; their upper side entirely covered with a thin field of disk, of considerable solidity at the surface.***

17. *Stella.* Shields on the upper side of the frond, fifeilie, close-preffed, orbicular, membranous; their disk flat, rarely somewhat convex; their border acceseory, thin, entire, free, slightly tumid, rarely fringed, of the colour of the frond. Pits amongst the down of the upper side, fatter, fifeilie, minute, coloured; their disk roundish, poverdy; border elevated, a little inflexed, entire or jagged, sometimes obliterated. (From frond leafy, membranous or in some measure coriaceous, lobed or jagged, downy or flagggy beneath.)

A beautiful and natural genus, of which the pits (cyphile) at the back of the frond form the most essential character. *Acharius* seems to have admitted them as a part of the fructification. If so, they should seem to be the male blossoms. The species of this genus, however, often abound with powdery efflorescence. See *Lichen lindatus*, Engl. Bot. t. 1104; *allo fuscatus*, t. 1298; *crocutus*, t. 2110; and *curatus*, t. 2359. *Acharius* has fourteen species in all, several of them extra-europæan.

18. *Pelidæa.* Targets closely attached to the frond, about the margin, on the upper or under side, rarely lateral, or towards the middle, each entirely consisting of a flatish, very rarely concave, coloured disk; border acceseory, very thin and scarcely discernible, united with the frond, and of the same colour. (Frond leafy, rather leathery; with downy veins and fibres beneath, rarely naked; the circumference lobed. Its barren lobes depressed, fertile ones elongated, ascending, naked at the back.)

One of the most natural genera, the *Pelitigæ* of Hoffmann; most allied to *Stella* in habit, but wanting the cyphile, instead of which the prominent veins or ribs underneath are remarkable.—See *Lichen caninus*, Engl. Bot. t. 2299; *rufescens*, t. 2300; and the more rare *cæruleus*, t. 887; *abietifolius*, t. 1119; and *colonius*, t. 1834; which last Dr. Acharius now admits as distinct from *rufescens*, and the same plant with his *Pelitigæ cælesta*. He also informs us that his *P. chlorophyllus*, n. 7, is no other than his *Cetraria fìpina* &c. For mention of other species, see *Lichen*, sect. 5. *Lichen cæruleus*, Engl. Bot. t. 498; and *fucatus*, t. 258, form for us much better placed in this genus, as in *Ach. Meth.* 290, than in *Artenia* above-mentioned.

19. *Cetraria.* Targets shield-like, thickish, flat, close-preffed, fifeilie, near the margin; their circumference loose, rounded, deformed or wavy; disk coloured, slightly convex; border acceseory, very narrow, entire or crenate, of the colour of the frond. (Frond leafy, membranous or somewhat cartilagineous, rigid, smooth and naked on both sides; sometimes cellular or pitted; lobed and jagged, often cripped at the edges.)

The receptacles of this genus are, as it were, of an intermediate kind between shields and targets, rather moist akin to the latter. The nature of the frond however, its smoothness, polish, and membranous, somewhat rigid, texture, render *Cetraria* very distinct, on the score of habit, from the last. But eight or nine speicies are described; among which are *Lichen islandicus*, Linn. n. 50. Engl. Bot. t. 1330; *cætulus*, Sm. Tr. of *Linn. Soc.* v. 1. 84. t. 4. f. 7; *glaucescens*, Linn. n. 67. Engl. Bot. t. 1566. See *Lichen*, sect. 4.

20. *Caricaria.* Orbs shield-like, terminal, peltate, thickish, cartilagineous, orbicular, flat; at length rather convex, uneven, and irregular; disk generally of the colour of the frond; border scarcely any, except in a young state, a slight acceseory one, entire, naked, or radiated, at length reflected. (Frond cartilagineous, rigid, smooth, rather falky, pungy within, of a fuchby, tufted, branched habit, the branches acute.)—This genus is about as numerous in species as the last. It is conceived by Acharius to be intermediate between *Parmelia* and *Ujacea*, approaching the former most in the frond, the latter in the fruit, except that the occasionally deeper colour of the disks, and the presence of an early border, betray more affinity to the latter.—Examples of *Caricaria* are, *Lichen trifolius* of S. Weber.
LICHENES.

Weber, Linn. n. 112, described in Engl. Bot. t. 720; and L. sicula, t. 452; which last is C. ficica of Acharius: also L. bicolor, Engl. Bot. t. 1853, which has lately been shown by the Rev. H. Davies to be the Ufinea lane nigra isfilar fasis adpressos; Dill. M. 66. t. 13. t. 8, a long-difputed and uncertain plant; t. 13. f. 9, being L. lanatus, Engl. Bot. t. 845.

21. Ufinea. Orbs somewhat coriaceous, flattened, peltate, naked and smooth on both sides, mostly very much dilated; disk first concave, then flat, even; subsequently rather convex and cracked, or very, scarcely coloured; border either none at all, or an accessory one, which is entire or toothed in the circumference, very often radiated. Knobs (cephalodia) on the face, or on a different plant, in a manner, bordered, finally convex and white-coloured.

This apparently double mode of fructification in the Ufinea, or proper filamentous Lichens, see Lichen, sect. the last, involves as great a mystery as the propagula and seeds. Experiments a priori requisite to determine whether the orbicula produce seeds, as well as the cephalodia. Till this is proved, we cannot but feel persuaded that the former are more probably the male blossoms; or possibly they may be abortive or imperfect female ones. Being much the most frequent and conspicuous of the two, and greatly resembling fluids, they have been of course taken for the fruit; the cephalodia having nearly escaped obseration; till lately; see Sm. Tour on the Continent, ed. 2. v. 353, and Engl. Bot. t. 873.—(The frond of Ufinea is brachiated, with elongated, cylindrical, thread-like stems, either nearly erect, prostrate or pendulous, beft with very small fibres, and tapering towards the extremities; their coat crustaceous, more or less distinctly jointed like a necklace, and roughish, having a central thread which is semipellicel and elastic.

There can be little doubt of the natural disfinitives of the present genus, though some Parallels, (as L. divaricatus of Linnæus,) greatly resemble it in general aspect. The jointed frond is very curious, and we believe effential. See examples of Ufinea in Lichen florus, Engl. Bot. t. 782; hirtus, t. 1534; frutescens, t. 257; and articulatus, t. 258. Many species referred by Hoffmann and others to the same genus, as L. divaricatus; and jubatus, Engl. Bot. t. 1880; make a fection in the Paradilla of Acharius, called tricharia.—If the knobs be the true female fructification, Ufinea rather belongs to the following fection.

**Receptacle convex, more or left globose, clothed with a feed-bearing layer, or disk, of either either on the branches, papillate procious, or peculiar frutes, of the frond, terminal and permanent.

22. Stereocaulon. Knobs somewhat turbinate; at frist furnished with a proper border; then globose, without stalks, simple or clustered, coloured, permanent; disk at frist flat and small, but gradually occupying the whole; border of the same uninterrupted substance and colour, entire, at length obliterated. (Frond solid, almost woody, caudelent, eret, branched, mostly clothed with scales, rough and fibrous.)

This genus is more restricted than the Stereocaulon of Hoffmann, yet not much more certain or definite. Its proper type is Lichen psalchas, Engl. Bot. t. 283. Many others are doubtful. We can scarcely distinguish 8 tabular, Ach. Meth. 316. t. 1. 3, from Lichen acutus of Dickson, Engl. Bot. t. 1833. S. acutum of Acharius.

24. Bægmiæ. Knobs capitate, nearly globose, with reflexed, scarcely bordered, edges, terminating their own proper frutes, simple or clustered, coloured, permanent; disk properly none, the whole globose surface being covered with the thin, solid, feed-bearing coat; border none. (Frond either somewhat crustaceous, forthih, granulated, indeterminate, rarely figured; or confining of a cartilaginous, leafy and lobed crust; fruct-flakes elongated out of the very substance of the frond, simple or branched, tubular or nearly solid, either dilated or tapering upwards, sometimes baran.)

A great genus, very difficult for the determination of its species, of which about 20 are described. Acharius divides it into fix fections; in the first are Lichen byssides, Engl. Bot. t. 373; and the beautiful L. Beoomyces, t. 374; in the second L. Papilaria, t. 907; in the third L. rubiformis, t. 2112; and esculentus, t. 1756; and in the fourth L. deli- catus, t. 2552; and microphylus, t. 1782. These four fections comprise in all but 14 or 15 species. The fifth is by far more considerable, confining of the true cup-bearing Lichens, Scopifera or Pystilidi, which terms express the cup-like dilatation of their fruct-flakes upwards. We have already spoken of this tribe; see Lichen, sect. 7. Acharius defines 24 species, with numerous varieties. They seem to have engaged much of his attention. Beautiful specimens of them are his Beoomyces basillaris, (Lichen fictorum, Engl. Bot. t. 2551; L. eocicifrus, t. 2551; bulliformis, t. 1894; and alicosius, t. 1879.) The fifth fection, confining of 16 species, embraces the thorny and awl-shaped kinds of Hoffmann's Cladonia. Such are L. uncialis, Linn. n. 167, Engl. Bot. t. 174; rangiferinus, n. 156; t. 173; and vernacularis, n. 108, t. 2029.

By the above detail, this arrangement of the Lichens by their fructification will be sufficiently intelligible to any who will bend their attention to the subject; and the more it is fluided, the more honour will it be found to confer on its author. Whatever occasional laxity, or want of precision, may be observable in his use and adaptation of terms, will be found inevitable on too intricate a study, in which he was himself learning, as well as teaching, at every step. We have unfortunately not yet been able to procure a sight of his more recent publication, entitled Lichengraphia Universals; but from a manuscript scheme of the whole, and some information given by an intelligent friend, we learn that the great object of this work is the establishment of a new distribution of Lichenes, in which the genera are vastly multiplied. Most of the new ones seem formed out of the fections, or subdivisions, of those of his Mabedus; so that he has here given into the plan of taking habis into the generic character, to a great extent. How far this may be eligible, we dare not, without fearing his reasons, decide. The few plates of the book in question are, as we understand, entirely subversive to this object, and the synonyms, as well as every thing relating to specific illustration, are but cumbrously touched. Such subjects will receive a full and sufficiently diffuse exposition, in a new work, the fections of which we have lately been allowed to peruse, the Lichengraphia Brittanica of Mr. Dawson Turner, and Mr. William Borrer. This, when completed, will exhibit a finished history of the British species, the knowledge of which is nearly equivalent to an acquaintance with the characters of the whole order. An almost complete series of their figures is already before the public in the English Botany, to which we have so often referred. No other work, in any country, contains so many. The determination of the species in this, and the other tribes of British plants, has all along been a primary object of that publication; and the new genera of Lichenes having been very cautiously adopted; indeed scarcely at all till lately, they having been considered by the author as too
fluctuating a state, an idea which the above account will abundantly justify. The same reason, in addition to some inevitable impediments, has hitherto kept back the fourth volume of the *Flora Britannica*, where the Lichens will make a principal figure.

A very interesting work, on the dyeing properties of Swedish Lichens, is published at Stockholm, in 8vo. numbers, from the pen of Dr. Wehring. Seven numbers have reached us, in which 21 species of this natural order are illustrated by admirable coloured plates, with directions, drawn by the hand of Professor Achard himself, and accompanied by specimens of all the colours yielded by each species, the manner of procuring which is the chief subject of the Swedish letter-press. We regret that it is not given to the public in a language more generally understood. The variety of beautiful colours afforded by *Pulveraria* (or Lepraria) chlorina, t. 1, are very striking, and amount to 14, in which blue, green, and yellow are conspicuous. *Jullia* Wessingeri, t. 4, yields beautiful shades of red, which colour, with different browns, is derived from moss of the tartaraceous-clubbed tribe. The leafy membranous ones seem to excel in browns, as *L. laxitilla*, t. 2; *amphibole*, t. 7 1; and *encastus*, t. 10, Sm. Tr. of Linn. Soc. v. i. 37. t. 4. f. 6. The cup-bearing kind appears also by the common *L. spadjatus*, t. 17, to promise much in dyeing. When the high price of Orchall, *Lichen Roccella*, is considered, the investigation of different species under the guidance of improved chemistry, can hardly be thought an idle speculation, even by those who have no other motive for the study of nature.

We cannot conclude this article, without advertting to a subject, the consideration of which we have been disposed to put off as long as we could, because it is painful to differ decidedly from those who have made any subject their frequent and patient study, and to whom, moreover, natural science is too much devoted in other respects. We allude to the supposed transformation, for we can call it nothing else, of one species of this family into another. We can readily explain why *Licheniger*, Engl. Bot. t. 1161, may seem to be turned into *plumbeus*, t. 373, from the seeds of the latter falling into the decayed crust of the former, and finding there a most excellent situation for their germination; as an acorn might vegetate in a bed of rotten moss. But the transformation of a tuft of moss into a forest of oaks would scarcely be a less miracle than that supposed above, or than the change of *Lichen tricolor* or *conus*, into a *Spharia*. It is but justice, indeed, to the excellent botanist who has affected these changes, to declare, that we have no less extraordinary reports of the same kind from another quarter, respecting the progress from one species to another; in all which cases, doubtless, the intricacies of nature have deceived a most acute observer. We should fearlessly venture to speak on this subject, however clear to our reason, from the botany of the closet only. A slight degree of practical observation will serve to convince any one, that the dissemination of many far more obvious plants than these, is hardly to be explained, and that the shifting fancies of nature, in the animal as well as vegetable theatre, are almost a metamorphosis. But we affirm, with the confidence of experience, that the species of Lichens themselves, although undoubtedly liable to varieties like other plants, of which we have traced some curious instances amongst the alpine *Geopora* in particular, are as constant as those of any other plants, and even better defined than many of the most splendid. They differ indeed much in duration, somewhat in colour, and above all perhaps in luxuriance, according to favourable or unfavourable circumstances; for they are amongst the most hardy children of Flora, destined to thrive where others would perish, and to prepare the way for such as are left able to provide for themselves. To understand them well requires laborious research, and perpetual observation; but the curiosity and beauty of their structure will repay our toil, whilst, if we mistake not, the certainty of their characters and distinctions will afford satisfaction, as well as instruction to the scientific mind. 5.

**LICHENOIDES, Dill. Mufc. 124. See Lichen.**

**LICHFIELD, or Lichfield, in Geography, an ancient city situated in the hundred of Offlow, and county of Stafford, England.** According to the parliamentary returns of 1800, it then contained 873 houses, and 4712 inhabitants, of whom 1666 were found to be engaged in various trades and manufactures. The more ancient name of this city was Lichenfield, which, according to some antiquaries, signifies the "field of dead bodies," from a massacre of the Christians, said to have taken place here during their contest with the Pagans in the reign of the emperor Diocletian. Mr. Shaw, however, in his "History of Staffordshire," expresses his decided opinion against the truth of this tradition, and with greater probability considers it as deriving its name from its marshy or watery situation; the word *Loceum*, from which *lich* comes, signifying, in Saxon, land covered with water. Lichfield is supposed to have arisen on the ruins of a Roman station called *Licticum*, which lies about a mile from the present city. Whether this idea be correct it is not easy to determine; but it seems to be clear that Lichfield was totally unknown, or, more properly speaking, had no existence either in the time of the Britons, or Romans. The origin of it, according to the belt authorities, is attributed to the Saxons; and Mr. Shaw says, it was the first established seat of that people in England. In the year 669, when St. Chad was bishop of Lichfield, it was little more than a trilling village. Even after the Norman conquest, it was considered by the monks, then held at London, as too mean a place for the residence of a bishop; for till this time the bishops lived in an obscure manner; and seem to have done little towards adorning, or extending the town. However, trilling as it was, it received great honours and privileges from several of the Saxon kings. Borrocaophil, in the neighbourhood of this city, was in all probability one of the camps, or chief residences, of some Saxon princes; for, though no traces of building remain, the situation is too fine and commanding to have escaped the notice of those warlike people. In the reign of Henry I. Lichfield was accompanied with a duchy, and the castle was fortified by bishop Clinton. No part of the fortifications of the latter are now visible; but the field in which it stood is still denominated Caftlefield, and the site around the city may be easily traced by an attentive observer. The right of coinage was granted to the bishops of this diocese by King Stephen; but they did not enjoy this privilege for any considerable period. Bishop Langton, who flourished in the time of Edward I. was a great benefactor to this city, having built, among other things, an excellent bridge over the pool which separates the town from the clofe. In the twenty-third year of the reign of the last-mentioned prince, (1305,) Lichfield first sent members to parliament, which it ever after continued to do. Edward VI. constituted it a city by charter in the year 1549. This charter gave the corporation power to appoint bailiffs and other chief officers, who should be entitled to hold all pleas within the precincts of the city. Queen Mary, with the authority of parliament, confirmed these privileges in the year 1553, and added several others of importance. The city, which before that time formed a member of
Lichfield.

A parcel of Staffordshire, was then declared to be a county of itself for ever, from and after the ensuing feast of St. Thomas. All actions of whatever denomination arising within the city, were ordained to be held by the bailiffs and citizens, if they could determine them, and if not by the justices next coming into the city, and not on any account by any authority out of the city. These great privileges were conferred in consequence of the faithful services of the citizens in the time of rebellion. Both these charters were ratified by queen Elizabeth, and afterwards confirmed by her successor James I., who granted still further immunities to this city. Charles II. confirmed all the privileges of this city, by a charter dated the 5th of November 1664. The government at present is vested in two bailiffs, elected from the common council, one of whom is named by the bishop, and the other by the council themselves, a recorder, a sheriff, a steward, and other inferior officers. The burgesses are twenty-four in number. Lichfield sends two members to parliament, the right of election being in the bailiffs, magnates, freeholders of 400 a-year, the holders of burgage tenements, and such freemen as are enrolled and pay foot and lot. The number of voters is estimated at 650.

This city has been the seat of a bishop's see from a very early period. The famous St. Cedd was consecrated in the year 669. The great Offa, king of Mercia, of which Staffordshire formed a part, insisted upon his kingdom being governed by an archiepiscopal power, and that the bishop of Lichfield should be appointed to that dignity. Accordingly Alcuin, the successor of Sigebert, was created archbishop of Lichfield by pope Adrian, and the pall sent to him from Rome, about the year 785. Lichfield, however, did not long enjoy the pre-eminence it had thus acquired, for upon the death of Offa it was again reduced to a bishopric; at the earnest request of the archbishop of Canterbury, who presented pope Leo, the then pontiff of the papal chair, with a large sum of money, in order to give weight to his entreaties. For a considerable period the bishoprics of Coventry and Lichfield were united, but at the reformation they were again disjoined. In the town, built by bishop Chilton, king Richard II. is said to have kept his infamous Christmas festival, in the year 1397, when he conformed two hundred tons of wine and two thousand sheep. This fortress was likewise the place of his confinement, when on his way to the Tower of London as a prisoner, about two years afterwards. Here he attempted to effect his escape, by slipping from the window of the high tower into the garden, but being discovered was carried back to his confinement. Lichfield has ever been celebrated for the attachment of its citizens to the cause of royalty. When the civil war commenced between king Charles and the parliament, his majesty having sent an order to the inhabitants of his loyal city to bring in their arms, his order was not only willingly complied with, but many of the inhabitants voluntarily subscribed considerable sums of money for his use, and enrolled themselves as soldiers under the command of captain Richard Dyott, for the protection of their own city against the parliamentary forces. This officer being joined by many noblemen and gentlemen of the country under the earl of Chelmsfield, the cathedral and clofe were fixed upon as a proper place of defence from the height of its situation, and the strength of the fortifications around it. In a short time after the garrison was attacked by the republican troops. During this siege they maintained their post with great resolution, but the town as well as the cathedral suffered very material damage. In one assault, lord Brock, a most furious fanatic, who commanded the parliamentary army, lost his life in a manner somewhat singular. Having drawn up his army about half a mile from Lichfield, and prayed most devoutly for the deliverance of the cathedral, he ordered an immediate attack, and placed himself in a small house near the south gate, with the view of directing the operations of the gunners, whom he had stationed against this gate, in order, if possible, to open a breach. Upon some sudden accident which occasioned the soldiers to give a shout, lord Brock came to the door, and being perceived by a gentleman of the name of Dyott, who stood on the top of the tower, he levelled his piece at him, when the ball penetrated directly into the pocket of the eye and lodged in the brain, causing instant death. As this happened on the festival of St. Chad, the patron of the church, the ball was supposed to have been guided by the influence of that saint. The loss of their commander, however, did not dismay the besieging army, who continued to carry on the siege with great vigour, and at last succeeded in compelling the garrison to submit. The troops of the parliament left to secure this fortress were in their turn attacked by prince Rupert, about the year 1643. Colonel Rowswell then commanded the garrison, who vouched the utmost bravery in the defence of his post. The commanding situations chosen by prince Rupert, however, for erecting his batteries, and the explosion of a mine, soon effected an extensive breach, and the garrison was compelled to surrender. The prince conferred the government on colonel Harvey Basset, who maintained it for the king till the utter destruction of his majesty's affairs, when he very properly surrendered upon honourable terms.

Lichfield stands in a very pleasant and healthful valley, almost in the centre of England, at the distance of 150 miles from the metropolis. It is surrounded by hills of a moderate size, easy of ascent, and of very agreeable appearance. It is chiefly inhabited by gentry, being of little importance in a mercantile point of view. The buildings of this city have generally afforded the air and taste of modern times, and the spirit of improvement, fo conspicuous in the present age, is plainly manifested in many alterations which have taken place within these few years. This city was formerly divided into two portions, by three lakes or pools of water, one of which is now dried up. It contains the bathes, but part of the lands of St. Chad's and St. Michael's lie within the walls of the city. Lichfield is adorned with a number of buildings well worthy of notice, both on account of their antiquity and the splendid style of their architecture. Of these the most conspicuous in every respect is the cathedral, which stands in the close, and is said to have been fortified by bishop Clinton; though Dr. Shaw thinks he only repaired the fortifications which had existed there from the time of the Saxons. Some are of opinion, that the cathedral was first founded by king Olavey, in the year 655; but others attribute it to Peada, his son-in-law. Who was the first bishop is somewhat uncertain, but St. Chad is generally allowed that honour. The buildings of this cathedral, which was then called the Mercedarian church, were probably at first only covered with wood. The whole of them were pulled down, in the year 1148, by bishop Clinton, and another of enlarged dimensions, and more elegant design, commenced in the place of the Saxon structure. To this prelate the cathedral is indebted for that noble fore vault, which is at this day the admiration of architects, and is undoubtedly one of the finest works of its kind extant in England. The next benefactor to this cathedral was Walter de Langton, who laid the foundation of the choir. He expended the sum of two thousand pounds on a faneria for the reliques of St. Chad, and obtained many privileges for the vicars and canons, one of
of which was the right of hanging upon the next gallows, without trial, divers persons who withheld their lands from the church. This beautiful shrine continued in its full glory till the dissolution, when the cathedral was despoiled of this and many other valuable relics to satiate the avarice of the tyrannical Henry.

During the sieges which it sustained, as already mentioned, in the time of the civil wars, this noble building suffered much, being the first cathedral that fell into the hands of the parliament. The roof was stripped of its lead; and many of the curious statues, monuments, and other carved works, were demolished with axes and hammers. The costly and beautifully painted windows were battered to pieces. In short, little of this splendid structure escaped min, except the noble vaulted roof already mentioned. What did remain was ultimately destroyed in 1651, when Colonel Danvers, by authority of the Rump Parliament, employed workmen in order to effect this purpose. At this time, the remarkable bell, called "Jehu's bell," was knocked to pieces by a pewterer named Nicklin. During this perfecution of the established church, Dr. John Hacket rendered himself remarkable by his courage and resolution. When a soldier with a trooper were sent to flop the performance of the daily service, and, putting a pistol to his head, threatened to shoot him instantly if he did not desist, this noble prelate calmly, but resolutely, replied, "Soldier, I am doing my duty; do you yours?" a sentence which may justly be reckoned among the remarkable instances of the sublime, and which so impressed the minds of the soldiers, that they left him to the free exercise of the duty he thus evinced himself so worthy to perform. No sooner was he nominated to the bishopric of Lichfield, than he vigorously set himself to restore the ancient splendour of the cathedral. By his large contributions, the benefactions of the dean and chapter, and the money arising from his affluency in soliciting aid from the gentlemen of his diocese, he succeeded in restoring this building to the admiration of the country. The whole underwent a thorough repair in the bishopric of Dr. James Cornwallis, when it received its last fmit by the addition of a painted window at the east end of the choir, the execution of which reflects the highest honour on the artist Mr. Egin- ton. This cathedral is 411 feet in length, and 153 in breadth. From the centre rises a spire 255 feet high, of most elegant proportions. At the west front are two towers, terminated by spires, 66 feet in height. The portico can hardly be equalled by any thing of the kind in England. The chancel is paved with slabalter and channel stone, in imitation of black and white marble. The north door is particularly rich in sculpture. On the western front are a number of images, beautifully executed and arranged; the subjects of which are taken from the sacred writings. The statue of King Charles II. stands between the two western spires, where a figure of Adam, or of Chrift, was also formerly placed, beneath which the other statues are ranged. These figures were originally all richly gilt and painted; but the embellishments have suffered much injury from the action of the elements. With regard to the interior ornaments of this church, they are by far too numerous to admit of particular notice in a work of this kind. Every part of it is filled with statues and tombs, both ancient and modern. The nave, 60 feet in height, is supported by pillars formed from a number of slender columns, with neat foliated capitals. Along the walls of the aisles are rows of arcades, with seats underneath. The upper windows in the nave are of uncommon appearance, being triangular, and including three circles in each; and over the western door is a very beautiful one, raised by the duke of York in the reign of Charles II., and afterwards beautifully painted by a gift of the benevolent dean Akenbrooke. Behind the choir was the chapel of St. Mary, which contained a fine screen of the most elegant and splendid workmanship that can be imagined, embattled at the top, and adorned with several rows of niches most exquisitely finisbed. Each of these formerly contained a small statue. This fine screen was taken down during the late alteration, and the materials employed to fix the organ upon, and form pillars for the entrance into the choir. This chapel now forms part of the body of the church. It is neatly paved, and contains, besides, forty-eight flats, which are richly carved, and appropriated for the use of the members of the church. The altar is of fine stone very neatly sculptured. The government of the cathedral is vested in a dean and four residencia canons. The diocese of Lichfield, joined to Coventry, contains all the county of Stafford, (with the exception of Brome and Clent,) all Derbyshire, and nearly one-half of Shropshire. The archdeaconries are those of Coventry, Stafford, Derby, and Salop. The bishop's palace is situated at the north-east side of the close. The original building is said to have been founded by bishop Clinton, but it was probably of earlier date. This palace was quite destroyed in the civil wars, when bishop Hacket, having expended 1000l. on the presbendal house, fixed upon it as his residence. Whether the present palace is the same, or another wholly erected by his successor bishop Wood, is uncertain. It is now inhabited by different families; the bishop's residence having been for many years at Eccleshall castle.

The next building worthy of notice is the church of St. Chad, now called Stowe church, and is generally considered as the oldest foundation in or near the city. By some writers it is even supposed to have been erected by the Romans, towards the end of the second century. St. Ceadda or Chadda, the saint to whom the church is dedicated, had his cell here in the year 653. The interior of this fabric has been lately repaired and beautified. It contains a number of neat monuments. The church of St. Mary's stands in the market-place, near the Guild-hall. Leland says, "St. Mary's is a right beautiful piece of work, in the very market-place." The body of the present building is very neat, and is adorned with a handsome altar-piece, and a few ancient monuments to the memory of the family of the Dyotts. St. Michael's church is situated at the south-east extremity of the city, on the summit of Greenhill, and is remarkable for the extent of its burial-ground, which is fearcely to be paralleled in England. It contains within its limits not less than five or seven acres of excellent pasture land. This hill is remarkable for a court held here annually on Whitmonday, in a temporary stand of wood erected for the purpose. This court was anciently called the Court of Array, or view of men and arms. The high constables having assembled all the inhabitants, they perambulate the whole city; and the whole concludes with a procession through the principal streets to the market-place, where the town-clerk, in the name of the bailiffs and citizens, delivers an oration or charge to the high constables, thanking them for their attendance, and urging them to the due execution of their office. The origin of this remarkable custom is uncertain. On the top of the same hill a small edifice has been erected by subscription, with seats; from this spot there is a very beautiful and extensive view of the contiguous country, and of the many interesting objects it affords. South of Greenhill is Folly-hall, which also commands a very fine prospect. Not far from hence is the hospital and chapel of St. John, which was originally a monastery. When it was first founded is unknown. The front of the present building-
building is remarkable for the number and antique form of its chimneys. According to an inscription over the door it was erected by bishop Smith, who was also the founder of Bravenoote College, Oxford. The free grammar school, built at the same time with the hospital, stands nearly opposite to it.

This city can boast of having been the place at which some of the brightest ornaments of the two last centuries were educated. Among others were the unrivalled Garrick and his friend Dr. Samuel Johnson, whom Mrs. Barbauld designates as the Hercules of literature. The latter was born in a fluecoed house situated at the corner of Market-street, where his father kept a bookseller's shop. The Guildhall, the theatre, and the free English school, are situated in Broad-street. The latter is an ancient building, erected and endowed by Thomas Minors about the year 1670. At the back of the Guildhall is a gable for the confinement of debtors and felons apprehended within the boundaries of the city. To the west of Bird-street is a very pleasant seat called the Friary, having been formerly a monastery of Franciscan or Grey friars, founded about the year 1240. On the east side there still remains an antique monument in honour of a merchant named Richard. It is inscribed with a very singular epitaph, which the limits of this article, however, will not admit of being inserted. The residence of the late celebrated Dr. Darwin is situated in a street called Beacon-street, which was nearly burnt to the ground during the civil wars. Opposite to the funerary which surmounts Dr. Darwin's house is an hospital, built by Dr. Milley in the year 1504, for the support of fifteen poor women. Contiguous to this spot there formerly stood a very lately edifice, once the refectory house of the arch-deacon of Chester. Lithfield contains, besides these, many objects which deserve the attention of the inquisitive and curious. The museum and the botanical garden of Dr. Darwin are particularly interesting to all who have the slightest taste for the subjects of natural history. Lithfield was long the residence of Mis Seward.

The markets are held here on Tuesday and Friday; the fairs on the third Thursday after Twelfth day, Ash Wednesday, May 17, and the Friday before St. Simon and St. Jude. By means of canals this city communicates with a variety of rivers, some of which discharge themselves into the German ocean, and others into the Irish sea and St. George's channel. Harwood's History and Antiquities of Lithfield, 4to. 1805. Jackson's History of the City and Cathedral of Lithfield, 8vo. 1805. Shaw's History, &c. of Staffordshire, vol. i. folio.

LICHTENBERG, a town of Prussian Pomerelia; 57 miles S.W. of Danzig.—Also, a town of Germany, in the county of Heineberg; 8 miles S.E. of Meiningen.—Also, a town of France, in the department of Mont Tonnerre; 9 miles W.S.W. of Lauterneck.—Also, a town of Silesia, in the principality of Neisse; 3 miles N.N.W. of Groitzkau.—Also, a town of Germany, in the principality of Culmbach, on the Solnitz; having in its vicinity quarries of marble, and mines of copper and iron; 22 miles N. of Bayreuth. N. lat. 50° 22'. E. long. 11° 38'.—Also, a town of Saxony, in the circle of Erzgebirge; 5 miles S.E. of Freyberg.

LICHTENEBCK, a town of Carniola; 10 miles E.S.E. of Stein.

LICHTENFELS, a town of Austria, on the river Kamp; 7 miles E. of Zweit.—Also, a town of Bavaria, situated on the Main; 20 miles N.N.E. of Bamberg. N. lat. 50° 10'. E. long. 11° 38'.

LICHTENFELT, a town of Pfussia, in Pomerelia; 12 miles E.S.E. of Marienburg.

LICHTENHAGEN, a town of Prussia, in the circle of Natangen; 8 miles S.S.W. of Konigberg.

LICHTENSTEIG, a town of Switzerland, and capital of the county of Tockenburg, seated on the Thur, and the residence of a bailiff. It has places of worship for Roman Catholics and Protestants; 27 miles E. of Zurich. N. lat. 41° 17'. E. long. 9° 6'.

LICHTENSTEIN, a principality of Germany, on the E. side of the lake of Coifance, situated on the Rhine, betwixt the lordships of Pludenz and Feldkirch.—Also, a town of Saxony, and chief place of a lordship, belonging to the counts of Schonburg; 5 miles N.E. of Zwieka. N. lat. 50° 24'. E. long. 12° 31'.

LICHTENTHANEN, a town of Germany, in the principality of Culmbach; 7 miles N.W. of Bayreuth.

LICHTENWALD, a town of the duchy of Stiria; 12 miles S.E. of Citel.

LICHTENWALT, a town of Ruffia, in Ermland; 23 miles N.W. of Heilberg.

LICHTENBERG, a town of Ruffia, in the government of Kaluga, on the Oka; 28 miles S. of Kaluga. N. lat. 54°. E. long. 35° 42'.

LICHWE, a town of Bohemia, in the circle of Koniggratz; 6 miles W. of Geyerberg.

LICINIO, GIOVANNI ANTONIO, in Biogrophy. See PETROKOV.

LICINIUM, a word used by many chirurgical writers to express a tent.

LICINIUS, in Biogrophy, a Roman emperor, a native of Dacia, of an obscure origin, and accustoming from his infancy to the toils and hardships of rural life, became a Roman soldier, and rose through all the gradations of the service. He was raised to the rank of Augustus in the year 307. When the civil war broke out between Constantine and Maxentius, the former secured the friendship of Licinius by promising him in marriage his sister Constantia, which alliance took place in 315, when the two emperors had an interview at Milan, and joined in an edict in favour of the Christians. In the same year Maximin invaded the territories of Licinius, and took Byzantium and Heraclea; his success was very short lived, for Licinius advanced to meet him, and by his military skill obtained a complete victory. Maximin died soon after, and Licinius succeeded to his authority over the provinces of the East. The conqueror, who was harsh, ignorant, and brutal, knew not how to use his success with generosity, or even with humanity; he put to death a great number of persons, and among others Va-
Licinius, a Roman tribune, of a plebeian family, rose to that rank by his own aspiring temper; he was the first plebeian who was raised to the dignity of master of horse to the dictator. He was surnamed Statius, or utile Psyllus, on account of the law which he caused to be enacted during his tribuneship. By this law no person was permitted to hold more than 500 acres of land, it being alleged, that when more was held by one proprietor, he would not have leisure to pull up the useless shoots (Stolones) which grew from the roots of trees. He afterwards carried a law which permitted the plebeians to share the consulary dignity with the patricians, and was himself one of the first plebeian consuls, in the year 364 B.C.

Licinius, Tegetula, a comic Latin poet, flourished about 200 years before the Christian era. His fragments have been published by H. Stephens, and in the Corpus Poeticum, Maiitavia. There was an orator and poet of this name, who lived at the same time with Cicero, and who has been compared with Catullus. His orations are highly commended by Quintilian: he is supposed to have written annals quoted by Dionysius Halicarnassius. He died in the 30th year of his age.

Licinio, in Geography, one of the smaller Lipari islands. N. lat. 38° 54'. E. long. 15° 20'.

Lick, a town of Trussia, with a castle; 80 miles S.E. of Königsberg. N. lat. 53° 39'. E. long. 22° 38'.

Lick, a name given to the fall-springs in the western parts of the United States.

Licking, a navigable river of America, in Kentucky, which rises on the western confines of Virginia, interlocks with the head-waters of Kentucky river, runs in a north-west direction upwards of 180 miles, and by a mouth 150 yards wide through the south bank of Ohio river, opposite to Fort Washington. On this river are iron-works and numerous fall-springs. Its chief branch is navigable nearly 70 miles. From Limmelstone to this river the country is very rich, and covered with corn, rye-grafs, and natural clover. Morf.

Licking Creek, a river of Maryland, which runs into the Potomack, N. lat. 39° 38'. W. long. 78° 41'.

Licking Hole Creek, a river of Virginia, which runs into James river, N. lat. 37° 42'. W. long. 78° 5'.

Licknena, a town of Spain, in Arragon; 16 miles S.S.W. of Huesca.

Licky, the name of a small river in the county of Waterford, Ireland, which falls into the river Blackwater, a little above Youghal.

Licinon, in the Dionynian solemnities, the mythical van of Bacchus; a thing so essential to all the solemnities of this god, that they could not be duly celebrated without it. See Dionysia.

Licophori, in the Dionynian solemnity, those who carried the licinon.

Licodia, in Geography, a town of Sicily, in the valley of Noto; 18 miles S.W. of Lentini.

Liconda, a town of Africa, in the country of Trinopo, situated on the sea-coast. N. lat. 36° 56'. E. long. 18° 10'.

Licostamo, a town of European Turkey, in Thessaly, the fee of a bishop, suffragan of Larissa; 16 miles E.S.E. of Larissa.

Liques, a town of France, in the department of the straits of Calais; 10 miles S. of Calais.

Lictors, among the Romans, were officers established by Romulus, who always attended the chief magistrates when they appeared in public.

The duty of their office consisted in the three following particulars: 1. Subinaio, or clearing the way for the magistrate they attended: this they did by word of mouth; or, if there was occasion, by using the rods they always carried along with them. 2. Animadversio, or causing the people to pay the usual respect to the magistrate, as to a god, if on horseback, or in a chariot; to ride up, uncover, make way, and the like. 3. Praeitio, or walking before the magistrate: this they did not confudcdly, or all together, nor by
by two or three abreast, but singly following one another in a straight line. They also preceded the triumphal car in public triumphs; and it was also part of their office to arrest criminals, and to be public executioners in beheading, &c. The enigmas were the joces and secures.

As to the number of locators allowed to each magistrate, a dictator had twenty-four, a matter of the horse fox, a confurl twelve, a praetor six; and each Vestal virgin, when he appeared abroad, had one.

Gen. Ch. *Cal. Periandrum* inferior, three-leaflet, permanent, outwardly hairy. *Cor.* of one petal, cloven almost to the base into three equal, ovate, acute, concave segments; *Nectary annular*, truncated, twice as short as the corolla. *Stam.* Filaments fix, inserted into the nectary, erect, very short; anthers oblong, in pairs. *Pf.* Gerken superior, convex, three-leaflet, furrowed, smooth; *style* simple; *stigma* two. *Peric.* Drupa globose, the size of a large pea. *Seed* a hard nut.

1. *L. spinosa*, Linn. and Willd., is the only species known; a native of the Moluccas, and figured by Rumphius in his *Herk. Humb.* t. 44. t. 9, under the name of *L. arbor*. The trunk of this palm is from three to four feet in height, and about the thickness of a man’s arm, jointed, divided in the upper part into five or six foottalks, nearly so thick as a finger, triangular, their lower part furred at the angles with thick rows of teeth or spines. Each of the talk bears a *leaf* which is fan-shaped, and divided down to the base into about fourteen lateral, ribbed rays. *Flower-talk* rising from the trunk, in the midst of the leaves, of the same length with them, and involved from the bottom in sheaths, dividing at the top into about five smaller ones, which bear green heads, in three rows, expanding into flowers. *Fruit* green for a long time, then brown or blackish. *Nut* oblong, very hard, longitudinally fratated.

The natives of Macassar make use of the smaller leaves for tobacco pipes, after they are dried, rolled, and properly prepared. The larger leaves are used for packages, but the wood is not sufficiently durable to be considered useful.

LICZ, in Geography, a town of Austrian Poland, in Galicia; 30 miles W. of Przemyl.

LID, or *Lid*, a river of England, which runs into the Tamar, 4 miles N.W. of Tavistock.

LIDA, a river of Sweden, which runs into the Wener lake, at Lidköping.

LIDA, a town and castle of Lithuania, in the palatinate of Wilna, in which is held a provincial diet; 48 miles S. of Wilna. N. lat. 53° 52’. E. long. 27° 35’.

LIDDEL, Duncan, in Biography, a physician of the sixteenth century, was a native of Aberdeen; but he was elected professor of rhetoric in the university of Helmstäd in 1587. He afterwards taught geometry, and ultimately medicine, of which he was appointed professor in 1596. He was likewise made first physician to the duke of Brunswick. But he quitted these advantages, and returned to his native country in 1607. He left the following works: *De Facultate vegetante ejufque Functionibus*, Helmstäd, 1592; *Universae Medicinae Compendium*, ibid. 1605; 1620; *Ars medica succinécte et perficiculo explica*, Hamburg, 1607, several times reprinted; *De Febribus Libri tres*, ibid. 1616; *Operum Intro-Calencorum, ex intimis Artis medice adlytis et penetralibus erutorum*, a posthumous work, *Leyden*, 1624. Eloy *Dikt.* *Hift.*

LIDDEL, in Geography, a river of Scotland, which rises in Roxburghshire, and joins the Eik, three miles south of Longholm, in the county of Dumfries; giving to the valley in which it flows the name of Liddefdale, or Liddale.

LIDEN, a town of Sweden, in Angermanland; 60 miles N.N.W. of Hernoiland.

LIDENS, a town of Sweden, in the province of Medelpadía; 24 miles N.N.W. of Sundsvall.

LIDFORD, a village of England, in the county of Devon, near the forest of Dartmoor, situated in a parish laid to be the largest in England, including almost the whole of Dartmoor. It was formerly a fortified town, surrounded with walls and a moat, and having three gates, of which no trace now remains. It is supposed to have been destroyed by the Danes in the year 907. In this village is an ancient castle, in which courts are held for the duchy of Cornwall; and offenders against the flannary laws were here confined in a dreary and dismal dungeon, which gave rise to a proverb, *"Lydford laws punish a criminal first, and try him afterwards."* This village contains only about 15 houses, and its situation is bleak and dreary; 28 miles W. of Exeter. Cruttwell.

LIDHULT, a town of Sweden, in the province of Småland; 60 miles S. of Jonköping. N. lat. 56° 50’. E. long. 15° 14’.

LIDKIOING, a small, near, trading town of Sweden, situated in the midst of a plain near lake Wetter or Wenner, at the influx of the Lide, and containing the episcopal palace, the cathedral, and the palace in which resides the governor of East Gottland; 42 miles E.N.E. of Uddevalla. N. lat. 58° 33’. E. long. 12° 54’.

LIDL, in Biography, a native of Germany, who arrived in England about the year 1758, and was a remarkable fine performer on the violin da gamba. His taste and expression on this ungrateful instrument were exquisite; though he had embarrassed himself with the additional difficulties of base stringings at the back of the neck of his instrument, with which he accompanied himself, thrumming them in pizzicato with his left thumb; an admirable expedient in a defert, or even in a house, where there is but one musician; but to be at the trouble of accompanying yourself in a great concert, surrounded by idle performers who could take the trouble off your hands, and leave you more at liberty to execute, express, and embellish the principal melody, seemed at best a work of supererogation. The tone of the instrument will do nothing for itself, and it seems with music as with agriculture, the more barren and ungrateful the soil, the more art is necessary in its cultivation.
of Saxony, in the margravate of Meissen; 7 miles S.W. of Stolpen.

LIEBENWALD, a town of Brandenburg, in the Middle Mark, on the Havel; 24 miles N. of Berlin. N. lat. 53° 51'. E. long. 15° 30'.

LIEBENDA, a town of Saxony; 22 miles N. of Meissen. N. lat. 51° 28'. E. long. 12° 26'.

LIEBENZELL, or ZELT, a town of Wirttemberg, on the Neckar; having two warm baths in its vicinity; 35 miles E.N.E. of Strasbourg. N. lat. 48° 51'. E. long. 8° 45'.

LIEBERSE, a town of Lutatia; 17 miles W. of Cuben. N. lat. 57°. E. long. 14° 16'.

LIEBETEN, a town of Hungary; 65 miles N.E.E. of Gran.

LIEBHER, a town of Prussia, in the province of Oberland, with a castle; 66 miles S.S.W. of Königsberg. N. lat. 53° 42'. E. long. 19° 45'.

LIEBOSEE, a lake of Brandenburg, in the Ucker Mark; situated to the S. of Dolgen See.

LIEBSTADT, a town of Saxony, in Meissen; 14 miles S.S.W. of Dresden.—Also, a town of Prussia, in Oberland, with a castle; 48 miles S.S.W. of Königsberg. N. lat. 53° 57'. E. long. 20° 2'.

LIECHEN, a town of Brandenburg, in the Ucker Mark; 40 miles N. of Berlin. N. lat. 53° 12'. E. long. 13° 24'.

LIECHSTAL, or LIESTAL, a tolerably fruitful district of Switzerland, containing a small, regularly built, populous town of the same name, consisting of three parallel streets, in the canton of Bâle; 24 leagues S.E. of the capital, on the river Ergetz, which forms a cascade below it. In this district are the remains of a large Roman aqueduct.

LIEES, Fr., a musical term, equivalent to tied, bound, sustained. It likewise implies slurred, in music, for bowed instruments, when two or more notes are played with one stroke of the bow, or with one touch of the tongue on the flute or hautbois. What musicians call a flur is a semiflue, ~. The same character is used over or under two or any number of notes, in vocal music, that are sung to one syllable.

LIEFDE BAY, in Geography, a bay on the north coast of Schleswig. N. lat. 70° 32'. E. long. 12° 30'.

LIEGE, a bishopric and electorate of Germany, before the French revolution; bounded on the north by Brabant; on the east by Limburg, Juliers, and Luxembourg; on the south by Luxembourg and the French department of the Ardennes; and on the west by Brabant, Namur, and Hainaut; about 80 miles in length from north to south, and of an irregular breadth. The soil is fertile, yielding corn and pastures, and also wine that resembles the middle wines of Burgundy and Champagne. In this district are also considerable forests, and mine-works of copper, lead, iron, coal, flone quarries, and fome of marble. Its chief mineral waters are those of Spa and Claude-fontaine. Its principal rivers are the Meuse and Sambre. This bishopric is now united to France, and forms the department of the Ourte; which fee. Its chief exports are beer, arms, nails, forge, leather, and coal. It formerly contained 26 towns, divided into Walloon and Flemish.

LIEGE, a city of France, and capital of the department of the Ourte, and a bishop's see. It is large, populous, and rich, divided into four parts, each consisting of 12,500 inhabitants, and four cantons; the 1st containing 16,664 inhabitants, on a territory of 124 kilometres, in four communes; the 2d canton, including 13,926 inhabitants, on a territory of 20 kilometres, in two communes; the 3d comprehending 4
LIE

17,408 inhabitants, on a territory of 15 kilometres, in two communes; and the 4th containing 17,237 inhabitants, on a territory of 25 kilometres, in one commune. This city is situated on the Meuse, in a pleasant valley between hills, watered by the rivers Loofe, Ourte, and Amblevre, which discharge themselves into the Meuse, as it enters this city. It is proverbially called the hell of women, the purgatory of men, and the paradise of priests. Lisse has ten grand faubourgs, and two smaller, 16 gates, 17 bridges, and 174 streets, and also two quays planted with rows of trees. Before the revolution, it had within the city and faubourgs, besides the cathedral, seven collegiate and 50 parish churches, and 46 religious houses. The cathedral of St. Lambert is a large building, erected by St. Hubert in the year 712, on the spot where his predecessor St. Lambert, bishop of Maastricht, had suffered martyrdom. On the 2nd of November 1792, Dumourier, at the head of the French troops, took possession of Lisse; but in the following March they were driven out of Lisse and Brabant. In 1794 the French troops again entered Lisse, and it was annexed to the dominions of France. N. lat. 50° 40'. E. long. 5° 37'. Accounts are kept in this city in florins or gulden current; each florin being divided into 20 fous or fivers, and each fiver into 16 pénings. The fiver is sometimes divided into four ecaulins or liards. The patacon of account is four florins, eight ecavulins or schillings, or 80 flivers. The gold coins of Lisse are the ducat of 8½ current florins or 17 ecavulins, the florin d'or or gold gulden of 5 current florins or 10 ecavulins. The silver coins are the patacon of 4½ current florins or 8½ ecavulins, the ecavolin of 10 florins, and the blancafe of five fivers. The copper coin is a large silver. Since the year 1792 there has been no coinage at Lisse; the city and its territory having been soon after united to France, and the new French monies and coins introduced here. The commercial weight of Lisse is four livre. Of the gold coin, 21 lib. of Lissé being = 22 lib.avoirdupois nearly. A laff of corn contains 66 liers, the lier being 1837 English cubic inches, so that 20 liers are = 17 English bushels. The foot is 11½ English inches, the ell is 21½ English inches; so that 18 feet of Lissé = 17 English feet, and 63 liers of Lissé = 38 English yards. Since its union with France, Lisse has adopted the new French denominations of money in the business of exchanges. Kelly's Unit. Cambit. vol. 1.

Citizen Cretet, the eminent composer of French comic operas, a native of that city, in his Memoirs, vol. 1. p. 125, gives an account of the college established at Rome for the reception of students in all the arts from the city of Lisse. There was a time, before Rome was bequeathed of its mode of perfection, that we should have devoutly wished for an English college of arts, similar to that of France and Lisse, where our younger arts of promising talents, pining to visit Italy, but unable to bear the expense, might have an asylum in which they could be received and supported during a certain number of years, while they were pursuing their studies. Such an establishment would reflect honour on an opulent and learned nation, always disposed to patronize, and collect specimens in all the fine arts, particularly in painting, music, sculpture, and architecture.

LIEG, Ligiun, properly signifies a vaflal, who holds a kind of fee that binds him in a cloister obligation to his lord than other people.

The term seems to be derived from the French liez, to bind; an account of a ceremony used in rendering faith or homage; which was by locking the vaflal's thumb, or his hand, in that of the lord, to show that he was fast bound by his oath of fidelity. Cujus, Vigenere, and Bignon, choose rather to derive the word from the same source with levatus, or levati, loyal, faithful. But Du-Cange falls in with the opinion of others who derive it from levit, a kind of vaflal proper, so firmly attached to their lord, on account of lands or fees held of him, that they were obliged to do him all manner of service, as if they were his domestics. He adds, this was formerly called ligeum servitutem, and the perfon liege. In this sense, the word is used, Leg. Edw, cap. 29. "Judaei sub tutela regis liege debent effe," that is, wholly under his protection.

By liege hommage, the vaflal was obliged to serve his lord towards all, and against all, excepting his father. In which sense, the word was used in opposition to simple hommage; which last only obliged the vaflal to pay the rights and accrulements due to his lord; and not to bear arms against the emperor, prince, or other superior lord: so that a liege man was a person wholly devoted to his lord, and entirely under his command.

Omnibus, &C. Regionaldus, rex Inflarum, futam. Scias quod deveni homo liegen domini regis Anglie-Johannis, contra omnes mortales, quamdiu vixere; et inde e fidelitate et sacramento prasiti, &c." MS. pence W. Dugdale.

But it must be observed, there were formerly two kinds of liege hommage: the one, by which the vaflal was obliged to serve his lord against all, without exception even of his sovereign, the other, by which he was to serve him against all, except such other lords as he had formerly owed liege hommage to. See Homage.

In our old statutes, lieges, and liege people, are terms peculiarly appropriated to the king's subjects; as being fides, ligi, or ligati, obliged to pay allegiance to him; 8 Hen VI. 14 Hen. VIII. &c. though private persons had their lieges too.

LIEG-ville. See VASSALAGE.

LIEGNITZ, or Lignitz, in Geography, a town of Silesia, one of the belt as well as most ancient in the country, and capital of a principality of the same name; situated on the Katzbach. The palace, within the town, is surrounded with a moat and high wall. Here, in a very stately home, the states of the provinces assemble. The Lutherans have two churches in this town; and the Roman Catholics are in possession of the collegiate church, a magnificent college, and other religious foundations. The emperor Joseph founded here a spacious academy for the instruction of young gentlemen of both religions in military exercises. The trade of Lignitz in cloth and madder is considerable; 32 miles W. of Breslaw. N. lat. 51° 11'. E. long. 16° 10'.

LIE, Fr., a word used in the law, of two significations: personal lien, such as bond, covenant, or contract; and real lien, a judgment, fiatute, recognizance, which oblige and affect the land. Term de Ley.

Lign signifies an obligation, tie, or claim annexed to, or attaching upon any property; without satisfying which such property cannot be demanded by its owner. Thus, the claims of an attorney are a lien upon deeds and papers in his hands; a factor has a lien on goods in his hands for balance due from his principal.

LIEN-CHAN-POU, in Geography, a town of Chinese Tartary; 12 miles N.N.E. of Ning-yaen.

LIENIS,
LIE

LIEUS INFARCTUS. See spleen.

LIEU-TCHEOU, in Geography, a city of China, of the first rank, in the province of Quan-tong, seated on the river Lien-kiang, which forms a very convenient harbour for Chinese barks. The territory of this city borders on the kingdom of Tong-king, from which it is separated by inaccessible mountains. It has under its jurisdiction one city of the second class, and two of the third. N. lat. 21° 40'. E. long. 108° 36'.

LIENTERY, in Medicine, signifies that variety of diarrhoea, in which the alimentary matters pass off by stool, in an undigested or almost undigested state. The term is derived from λυσις, smooth, or पोल्ली, and इन्तल, intestines, the ancients having been of opinion, that this affection was owing to the too great smoothness and lubricity of the internal membrane of the intestines, which allowed the food to slip off in an undigested state.

Some writers have treated of the lientery as a disease altogether distinct from diarrhoea; but Dr. Cullen properly considered it as only a variety of that complaint. The principal cause of the lienteric diarrhoea appears to consist in a morbid state of irritability of the stomach and bowels; whence the former organ is excited to an excessive motion of its muscular coat, by the stimulus of whatever aliment is introduced into it, and consequently expels it into the bowels in an undigested state; and the latter, being likewise morbidly sensible to the same stimulus, becomes upon the undigested matter speedily through the whole canal. The motions are at the same time loose or liquid, because, on the one hand, the undigested matter is not taken up by the lacteals, and, on the other, the irritation of this matter, thus rapidly passing, excites the exhalent vessels, and the excretories of the mucous glands to pour out a more abundant quantity of their fluids. This affection is generally accompanied with a great weakness of the digestive power, as well as a morbid irritability of the stomach.

From this view of the subject, two indications present themselves with a view to the method of cure in lientery; namely, first, to lessen the irritability of the whole alimentary canal; and secondly, to strengthen the digestive power of the stomach. For it must be observed, that, although food, when converted into a proper bland chyle by the process of digestion, passes through the bowels without producing any irritating effect; yet the same food, when it is transmitted into them from the stomach in a crude and unaltered condition, operates as an extraneous and foreign matter on the irritable villous lining of the bowels, and excites them to an extraordinary peridiatatic action.

The first indication, of allaying the irritability of the stomach and intestines, is to be fulfilled by the administration of opiates, or other narcotic medicines, and of astringents. Opium itself is the most effectual manner of morbid irritability that we possess; and in cases, like that under consideration, its operation is improved by the union of some aromatic substance; hence the form of the opiate confection, according to the formula of the London pharmacopoeia, is a grateful and efficacious medicine for this purpose. But the irritability is still more effectually allayed, when astringents and absorbents are employed at the same time with the opiates; the belt of these are the catechu, kino, and the tannaceous powders, or chalk. The confectio catechu of the Edinburgh pharmacopoeia, which combines the opiate, astringent, and aromatic in one substance, is a valuable medicine for the fulfilment of this indication. These substances may be administered in a little distilled water of some aromatic vegetable, as of mint, cinnamon, piments, &c.

Or, with a view to the second indication, of strengthening the digestive power of the stomach, the same medicines may be combined or alternated with the tonic bitter medicines; such as the infusion of cefailla, gentian, or orange peel, or the decoction or infusion of the cinchona. At the same time moderate exercise, especially on horseback, will aid in re-establishing the functions of the stomach; and all cold and debilitating articles of diet, or substances of difficult solubility, should be studiously avoided. Of the former are ice, fallads, water-cresses, cucumbers, or other raw vegetables, vegetable acids, &c. We once witnessed a severe influence of lientery, which was brought on by eating a little ice-cream, at a time when a considerable degree of indigestion already prevailed; it appeared at once to sink the feeble digestive powers of the stomach, and the food was discharged almost unchanged. Of the latter, or food of difficult solubility, we may mention cheese, hard or salted meats, fatty substances, &c. which require all the energy of the healthy stomach to subdue them into chyle. When the alimentary canal is in the irritable condition above-mentioned, it is advisable for the invalid to avoid active exercise immediately after his meals, which is liable to hurry on the food into the intestines before the digestion is completed, and thus to occasion a lienteric attack. We have known persons, subject to habitual indigestion, or at least great feebleness of stomach, who at those times certainly brought on a diarrhoea of the lienteric kind, unless they remained quiet for some time after every meal.

See DIARRHEA.
these islands; but this fleet proceeded no further than the
isles of Pong-hou, and the western coast of Formosa, from
whence, under various pretensions, they returned to Fo-kién.
It was not till the year 1372, under the reign of
Hong-vou, founder of the dynasty of Ming, that these
islands voluntarily submitted to the Chinese government.
Tay-tou, the prince, was solemnly declared a vassal of the
empire; and when Hong-vou had received his first tribute,
consisting of valuable horses, aromatic wood, sulphur, tin,
&c. he lent to this prince a golden seal, and confirmed the
choice he had made of one of his sons for a successor.
The emperor afterwards sent 36 families, almost all from the pro-
vince of Fo-kién, to Lieou-kieou. These families were hol-
pitably received, and had lands assigned to them near the port of
Napa-kiang, and certain revenues were appointed for their
use. These families first introduced into Lieou-kieou the
learned language of the Chinese, the use of their characters,
and the ceremonies practised in China in honour of Confucius.
On the other hand, the sons of several of the grandees of the
court of Tay-tou were sent to Nan-kiing to study Chinese in
the imperial college, where they were treated with distinction
and maintained at the emperor’s expense. As these isles had
neither iron nor porcelain, they were supplied by Hong-vou.
Commerce, navigation, and the arts soon began to flourish.
These islanders learned to cast bells for their temples, to manu-
ufacture paper and the finest flutes, and to make porcelain,
with which they had before been supplied from Japan.
The subsequent revolution, which placed the Tartars on the im-
perial throne of China, produced no change in the conduct of
the kings of Lieou-tehou. The emperor Kang-hi (about
A.D. 1729) paid a more marked attention to these isles than any
of his predecessors. He caused a superb palace to be
ereeted in honour of Confucius, and a college, where he
maintained masters to teach the sciences and the Chinese char-
acters. He also instituted examinations for the different
degrees of the literati. He ordained that the king of Lieou-
kieou should never send in tribute rosewood, cloves, or any
other production which was not of the growth of the coun-
try; but that he should find a fixed quantity of sulphur,
copper, tin, shells, and mother-of-pearl, which is very
beautiful in these isles. He permitted, that, besides the
usual tribute, he might present him with horse furniture,
pilol-cafes, and other things of the same kind, which these
islanders are fad to manufacture with great taste and neatness.

It is more than 500 years, says Grolier, since the bouses
of China introduced at Lieou-kieou the worship of Fo, and
the principal books belonging to their faith. This worship is
at present the established religion both of the grandees and
of the people. In the royal city there is still to be seen a
magnificent temple, erected in honour of another idol bor-
rrowed from the Chinese, named Tien-fei, which signifies
“celestial queen, or lady.” These islanders do not swear
or make promises before their idols. For this purpose they
burn perfumes, present fruits, and stand respectfully before
some stone, which they call to witness the solemnity of their
engagements. Of these stones many are to be seen in the
courts of their temples, in most public places, and upon the
mountains; and they are appropriated to this use. They
have also among them women consecrated for the worship of
spirits, who are supposed to have great influence over these
beings. They visit the sick, distribute medicines, and write
prayers for their recovery. They respect the dead as much
as the Chinese, but their funerals are less pompous. They
burn the flesh of the deceased, and preserve only the bones.
They place round lamps, and burn perfumes, and dif-
ferent families are distinguished by surnames, as in China;
but a man and woman of the same surname are not allowed
to marry. The king is not at liberty to marry except in the
tree grand families, among which the highest offices are
distributed. A plurality of wives is allowed in these isles.
The women are very reserved; they neither use paint, nor
wear pendants in their ears; they collect their hair on the
top of their heads, in the form of a curl, and fix it in that
manner by long pins made of gold or silver. Besides the
colours and points which the king po|lettes, he receives the
produce of all the sulphur, copper, and tin-mines, and of the
felt-pits, together with what arise from the taxes; and from
these revenues he pays the salaries of the mandarins and of-
ers of his court. Of the mandarins there are, as in China,
three orders, distinguished by the colour of their caps, or by
their girdles and costumes. In the royal city tribunals are
established for managing the revenue and affairs of the prin-
cipal isle, and of all the others dependent upon it. There
are also particular tribunals for civil and criminal matters,
for the affairs of religion, for manufactures, commerce, navi-
gation, &c. The vessels built in this country are highly valued
by the people of China and Japan. In these the natives sail
not only from one isle to another, but also to China, Ton-
quin, Cochinchina, Corea, &c. Besides those articles of
commerce, which their manufactories of silk, cotton, paper,
arms, copper utensils, &c. furnish them, they also export
mother-of-pearl, tortoise and other shells, coral and whet-
stones, which are held in high estimation both in China and
Japan. Three languages are spoken in the isles of Lieou-
kieou, different from those of China and Japan. The
language of the large isle is the same as that of the neigh-
bouring isles; but it differs from those of the isles which lie
to the S.W. and N.E. Letters, accounts, and all the king’s orders are written in Japanese characters, not in the
language of the country; books of morality, history, medi-
cine, astronomy, and astrology, are written in Chinese char-
acters. The distribution of time, and the division of the
year, are the same in Lieou-kieou as in China. The edifices,
temples, and palace of their kings are built after the Japanese
manner; but the houses of the Chinese, the hotel of the em-
basilard, the imperial college, and the temple of the goddess
“Tien-fei,” are built after the fashion of China. The
natives of Lieou-kieou are, in general, mild, affable, and
temperate; they are active and laborious, enemies to slavery,
and detest falsehood and dishonesty. Excepting the grandees,
bones, and Chinese established in Lieou-kieou, few of the
inhabitants of these isles can either write or read. The
people are fond of games and diversions. They celebrate
with great pomp and splendour, those festivals that are insti-
tuted in honour of their idols, and those which are appointed
for the termination and commencement of the year. Great
harmony prevails among families and individuals, which
they take care to preserve by frequent repasts, to which they
invite one another. Suicide is unknown among these islanders;
and they are free from those crimes that are common in the
isles situated to the N.E. of them, which being nearer to
Japan, have adopted the vices of its inhabitants, as well as
their manners and customs. Grolier’s China, vol. i. The
capital is in N. lat. 26° 2’ E. long. 128° 40’.

LIEUREY, a town of France, in the department of the Eure; 7 miles S. of Calais.

LIEUTAUD, JAMES, in Biography, a French mathematician, who flourished in the former part of the eighteenth century, was the son of a gun-smith at Arles, and died at Paris in the year 1733. He particularly attached himself to the study of astronomy, and from the great proficiency which he made in this branch of knowledge, he obtained a seat in the French Academy of Sciences. He published twenty-seven volumes of the "Connaissance des Temps," from the year 1703 to 1739.

LIEUTAUD, JOSEPH, a celebrated physician and anatomist, was born at Aix, in Provence, on the 21st of June, 1703. His family had been established from time immemorial at Aix, and had produced a great number of distinguished officers, ecclesiastics, lawyers, and useful citizens. He was at first intended by his parents for the church; but the reputation of his maternal uncle, Garidel, the professor of medicine in his native place, gave him a bias to the study of medicine. Botany was the first object of his pursuits. He travelled into the countries where Tournefort had surveyed before him, and brought back many plants which had escaped the observation of that distinguished botanist. This success gained him great applause in the universities of Aix and Montpellier, and he soon obtained in the former the reversion of the chairs of botany and anatomy, which his uncle had long held. Being appointed physician to the hospital at Aix, the necessity of purifying his anatomical studies presented itself to his mind, together with the greater facilities which this appointment afforded, and he thenceforth nearly abandoned the subject of botany. His audience soon became numerous, comprising many persons not engaged in the study of medicine, and among others the marquis d'Argens, the intimate friend of the king. M. Lieutaud published, in 1743, a syllabus of anatomy for the use of his pupils, entitled "Élais anatomiques, contenant l'Histoire exacte de toutes les Parties qui composent le Corps humain;" it was several times reprinted, with improvements, and in 1777 was edited by M. Portal, in two volumes. He communicated also several papers on morbid anatomy, to use a common phrase, and on physiology, to the Academy of Sciences, of which he was elected a corresponding member. In 1749, however, he quitted his post at Aix, and went to Verfailles, at the instance of the celebrated Senex, who then held the highest appointment at court, and who obtained for Lieutaud the appointment of physician to the Royal Infirmary. This act of friendship is said to have originated from the private communication of some errors, which Lieutaud had detected in a work of M. Senex, and which he did not deem it proper to publish. At Verfailles he continued his anatomical investigations with unabated zeal, and was soon after his arrival elected anatomist to the Royal Academy, to which he continued to present many valuable memoirs. He also printed a volume, entitled "Elementa Physiologica, &c." Paris, 1749, which had been composed for the use of his elys at Aix. In 1755, he was nominated physician to the royal family, and, twenty years afterwards, he obtained the place of first physician to the king, Louis XVI. In 1759, he published a system of the practice of medicine, under the title of "Precis de la Medicine pratique," which underwent several editions, with great augmentations, the bulk of which is that of Paris, 1770, in two volumes. In 1766, he published a "Precis de la Materie medecinale," in 8vo. afterwards reprinted in two volumes. But his most important work, which still ranks high in the estimation of physicians, is that which treats of the feasts and causes of diseases, ascertained by his innumerable dissections. It was entitled "Histoire Anatomique-medecin, fitiens numerosissimi cadaverorum extefficia," Paris, 1769, in two volumes, 4to. M. Lieutaud died on the 6th of September, 1780, after an illness of five days. Eloy Dict. Hist. Hist. de l'Acad. Roy. des Sciences, for 1780, p. 48.

LIEUTENANT, LOCUMTENENS, a deputy, or officer, who holds the place of a superior, and discharges in his absence the duties of the office which he ought to exercise in person. The term is originally derived from legatus (which see), and more immediately from the French lieutenant, supplying or holding the place of another.

Of these, some are civil; as lords lieutenants of kingdoms; who are the king's viceroys, and govern in his stead, such as the lord lieutenant of Ireland; and lords lieutenants of counties. See Lords Lieutenants.

But the term is most frequent among military men, among whom there is a variety of lieutenants.

Lieutenant is the second commissioned officer in every company of both foot and horse, and next to the captain, who takes the command upon the death or absence of the captain. Fuzilee corps, grenadiers, and light infantry, have second lieutenants and no ensigns. See Captain.

Lieutenant of Artillery, is an officer of the artillery in each company, of which there are one first and three second lieutenants. The first lieutenant has the same duty as the captain, because in his absence, he commands the company. The second lieutenant is the same as the ensign in an infantry regiment, being the youngest commissioned officer in the company, and it is his duty to assist the first lieutenant.

Lieutenant-General of Artillery. See Lieutenant-General of Artillery.

Lieutenant-Captain. See Captain.

Lieutenant-Engineer. See Engineer.

Lieutenant-General. See General, Lieutenant.

In France they have also lieutenant-generals of their naval forces, who command immediately under the admirals.

In Holland they have a lieutenant-admiral, which is the same with what we call a vice-admiral.

Lieutenant-General of the Ordnance, is he who has the charge of the artillery, batteries, &c. under the maiter-general, or in his absence. This officer was first established in 1597. See Ordnance.

Lieutenant-Colonel of Foot. See Lieutenant-Colonel.
The dragoons have also a lieutenant-colonel; but the horse have not, properly, any; the first captain of the regiment supplies the office.

Lieutenant-Colonel of Horse, is only the first captain of the regiment, who commands in the absence of the colonel, taking place of all other captains.

Lieutenant of a Ship of War, is the officer next in rank and power to the captain, in whose absence he is charged with the command of the ship, and also the execution of any orders which he may have received from the commanders relating to the king's service. The lieutenant, who commands the watch at sea, keeps a list of all the officers and men belonging to it, in order to muster it, and report to the captain the names of those who are absent from their duty. During the night-watch he occasionally visits the lower deck, or sends thither a proper officer to see that order is observed. He is always to be upon deck in his watch, to give orders for trimming the sails and superintending the navigation, and for preferring order; but he is never to change the ship's course without the captain's direction, unless it be to avoid an immediate danger. In time of battle he is to see that all the men are present at their quarters, to order and exhort them to perform their duty, and to inform the captain of any misbehaviour. The youngest lieutenant of the ship, who is also called lieutenant at arms, is, besides his common duty, to train the seamen to the use of small arms, and in time of battle to attend and direct them for this purpose.

Lieutenant de Roy, the deputy governor of all strong towns in France before the revolution, who is a check upon the governor, and commands in his absence.

Lieutenant Reformed, is he whose company or troop is broke or disband, but continued in whole or half-pay, and still preserves his right of seniority and rank in the army.

Life, in Physiology, is the peculiar condition or mode of existence of living beings. Surrounding matter we observe to be divided into two great classes, living and dead: the latter is subjunct to physical laws, which the former also obeys in a great degree: it exhibits also physical properties, which we find equally in the latter. But living bodies are endowed moreover with a set of properties altogether different from these, and contrasting with them in a very remarkable way; these are the vital properties, powers, faculties, or forces. They animate living matter so long as it continues alive, and are the source of the various phenomena which constitute the functions of the living animal body, and which distinguish its history from that of dead matter. The study of life, then, which is the object of the science of physiology, as organization is of anatomy, includes an inquiry into the properties that characterize living matter, and an investigation of the functions which the various organs, by virtue of these properties, are enabled to execute.

As the animals, which belong to the different classes of natural history, differ greatly in the number of functions, which they can execute, as we have every gradation from that of the greatest simplicity, to as great a complication in structure and functions; life includes very different notions in the different instances. Our view would be very imperfect if we observed it only in one example; we shall, therefore, extend our survey in a very general manner, through all the orders of animals. For this purpose we shall avail ourselves of the very excellent introductory lecture to the Leçons d'Anatomie comparée of Cuvier, which exhibits a luminous and philosophical view of life in general, and of its principal modifications in the different classes of animals. We shall subjoin a general account of Bichat's division of the animal functions, and of the vital properties by which they are executed, from his Recherches sur la Vie et la Mort.

The idea of life is one of those general and obscure ideas produced in us by observing a certain series of phenomena pitting mutual relations, and succeeding each other in a constant order. We know not indeed the nature of the link that unites these phenomena, but we are sensible that a connection must exist; and this conviction is sufficient to induce us to give it a name, which the vulgar are apt to regard as the sign of a particular principle, though in fact that name can only indicate the totality of the phenomena which have occasioned its formation.

Thus, as the human body, and the bodies of several other animals resembling it, appear to refit, during a certain time, the laws which govern animate bodies, and even to act on all around them in a manner entirely contrary to those laws, we employ the terms life and vital force to designate what are at least apparent exceptions to general laws. It is therefore by determining exactly in what the exceptions consist, that we shall fix the meaning of those terms. For this purpose, let us consider living bodies in their active and passive relations with the rest of nature.

For example, let us contemplate a female in the prime of youth and health. That elegant voluptuous form, that graceful flexibility of motion, that gentle warmth, those cheeks criminated with the roses of delight, those brilliant eyes, darting rays of love, or sparkling with the fire of genius, that comeliness, enlivened by fallies of wit, or animated by the glow of passion, seem all united to form a most fascinating being. A moment is sufficient to destroy this illusion. Motion and feme often cease without any apparent cause. The body loses its heat; the mufcles become flat, and the angular prominences of the bones appear; the luftre of the eye is gone; the cheeks and lips are livid. These, however, are but preludes of changes still more horrible. The flesh becomes successively blue, gree, and black: it attains humidity, and while one portion evaporates in infectious emanations, another dissolves into a putrid fumes, which is also speedily disintegrated. In a word, after a few short days there remains only a small number of earthy and saline principles. The other elements are dispersed in air, and in water, to enter again into new combinations.

It is evident that this separation is the natural effect of the action of the air, humidity, and heat,—in a word, of external matter upon the dead body; and that it has its cause in the elective attraction of those different agents for the elements of which the body is composed. That body, however, was equally surrounded by those agents while living, their affinities with its molecules were the same, and the latter would have yielded in the same manner during life, had not their cohesion been preserved by a power superior to that of those affinities, and which never ceased to act until the moment of death.

Of all the phenomena, the particular idea of which enters into the general idea of life, this is what at first light appears to constitute its essence, since we can form no conception of life without it, and since it evidently exists without interruption until the instant of disolution.

But a further study of any living body convinces us, that the power which preserves the union of the molecular, notwithstanding the external forces which tend to separate them, does not confine its activity to this tranquil operation, and that the sphere of its action extends beyond the bounds of the living body itself. At least it does not appear that this power differs from that which attracts new molecule
molecule to deposit them between those that already exist; and this action of the living body, in attracting the surrounding molecule, is not less constant than that which it exercises in retaining its own; for, besides that the absorption of the alimentary matter, its conversion into nutritive fluid, and its subsequent transmission to all the parts of the body, experience no interruption, and continue from one re- pa rt to another; another absorption conflantly takes place at the external surface, and a third by the effect of respiration. The two latter are those only which exist in all living bodies which do not digest, that is to say, in all plants.

Living bodies, however, do not increase indefinitely. Nature has assigned to each limit which it cannot exceed. It follows, therefore, that they must lose, in one way, a great part of what they gain in another; and indeed an attentive observation has convinced us, that transpiration, and a number of other causes, tend continually to diminish their substance.

This consideration must modify the notion which we at first formed from the principal phenomenon of life. Instead of a constant union in the molecule, we cannot avoid observing, that there is a continual circulation from the exterior to the interior, and from the interior to the exterior of bodies; a circulation which, though uniformly preferred, is notwithstanding fixed within certain limits. Thus living bodies may be considered as a kind of receptacles, into which inert substances are successively thrown, in order to combine among themselves in various manners, maintain a certain place, and perform an action determined by the nature of the combinations they have formed; and from which they escape in order to become again subject to the laws of inanimate nature.

It must be observed, however, that there is a difference, depending on age and health, in the proportion of the parts which enter into this kind of circulation, and those which abandon it; and that the velocity of the motion usually varies according to the different conditions of each living body.

It appears, at the same time, that life is terminated by causes similar to those which interrupt all other known motions, and that the hardening of the fibres, and the obstruction of the vesseIs, render death the necessary consequence of life, as repose is of motion, even though the crises were not accelerated by innumerable causes which are foreign to the living body.

This general and common motion of all the parts forms so peculiarly the essence of life, that the parts which are separated from a living body soon die, because they possess no motion of their own, and only participate in the general motion produced by their union. Thus, according to the expression of Kant, the reason of the mode of existence of each part of inanimate bodies belongs to itself, but in living bodies it resides in the whole.

The nature of life, as above described, being once well ascertained by the observation of the most constant of its effects, a wish would naturally arise to investigate its origin, and to inquire how it is communicated to the bodies it animates. Living bodies have, therefore, been traced to their infancy; and it has been endeavoured to carry this examination as near as possible to the moment of their formation. But they have never been observed otherwise than completely formed, and already enjoying that vital force, and producing that circulatory motion, the first cause of which we are desirous of knowing. In fact, however feeble and minute the parts of an embryo, or of the seed of a plant, may be at the moment we are first capable of perceiving them, they then enjoy a real life, and possess the germ of all the phenomena which that life may afterwards develop. These observations, extended to all the classes of living bodies, lead to this general fact, that there are none of those bodies which have not herefore formed parts of bodies similar to themselves, from which they have been detached. All have participated in the existence of other living bodies, before they exercised the functions of life by themselves; and it was even by means of the vital force of the bodies to which they formerly belonged, that they were enabled to develop themselves to completely as to become capable of enjoying separate vitality; for though the particular action of copulation is necessary for the production of a number of species, many are produced without it; copulation, therefore, is only a circumstance belonging to certain cases, and does not change the essential nature of generation. It appears then that the motion proper to living bodies has really its origin in that of their parents. It is from them they have received the vital impulse; and hence it is evident, that, in the actual state of things, life proceeds only from life, and that there exists no other except that which has been transmitted from one living body to another by an uninterrupted succession.

Unable to ascend to the origin of living bodies, there remains then within our reach no source of information respecting the real nature of the powers which animate them, except the examination of the composition of those bodies, that is to say, of their texture, and the union of their elements; for, though it may be truly said, that this texture, and this union are in some manner the result of the action of the vital impulse which has given them being, and which maintains them; it is also evident, that in them only this impulse can have its source and foundation: and if the first union of the chemical and mechanical elements of any living body has been effected by the vital force of the body from which it descended, we ought to find in it a similar power, and also the cau ses of that power, since it has to exercise a like action in favour of the bodies which are to descend from it.

But this composition of living bodies is too imperfectly known to enable us to deduce clearly from it the effects they exhibit. We observe, in general, that they are composed of fibres or laminae, forming altogether a series of reticulated substances more or less complex, which form the bafilis of all their solids, as well as of them that are innately, as of those that present the appearance of laminae and filaments. We are acquainted with the form, the consti tution, and the position of the larger of those filaments, the ramifications of the most considerable of their vessels, and the course of the fluids they contain: but their minute branches, and their more secret texture, cannot be traced by our instruments. We likewise know the chemical characters of the most apparent of the different fluids and concrete substances; we can even decompose them to a certain point. This investigation, however, is not only imperfect, since we cannot reconstitute them, but the phenomena indicate, that there must exist several other fluids which we have not yet been able to discover.

The efforts hitherto made by naturalists to prove a connection between the phenomena of living bodies and the general laws of nature, have doubtless been unsuccessful. It would, however, be wrong, on that account, to conclude that those phenomena are absolutely of a different kind; but on the other hand, there would be much temerity in refusing this task, while our knowledge of the bodies in which the phenomena appear is so limited. We should be able to give only an empirical exposition, instead of a rational
rational system. All our labours on organic economy must therefore be confined to its history.

If, however, our knowledge of the composition of living bodies be not sufficient for the explanation of the phenomena they exhibit, we may at least employ it in recognizing those bodies when out of a state of action, and in distinguishing their remains long after death; for we find in no inert body that fibrous or cellular texture, nor that multiplicity of volatile elements which form the characters of organization and organized bodies, whether in those that are alive, or in those that have lived.

We know that inert solids are composed only of polydrous molecule, which attract each other by their sides, and never move except to separate—that they are resolvable into a very small number of elementary substances—that they are formed of the combination of those substances, and the accumulation of those molecules—that they grow only by the juxtaposition of new molecules, the strata of which envelope the preceding mass—and that they are destroyed only by some mechanical agent separating their parts, or some chemical agent altering their combinations; but organized bodies, which are tules of fibres and lamiae, and have their interfaces filled with fluids, resolve almost entirely into volatile substances, are produced by bodies similar to themselves, from which they do not separate until they are sufficiently developed to act by their own force; constantly affinable foreign substances, and deposit them between their particles, grow by an internal power, and finally perish by that internal principle, or by the effect of life itself.

Origin by generation, growth by nutrition, termination by death, are the general and common characteristics of all organized bodies: if, however, there are bodies which perform only these functions, and those which are subsidiary to them, and those of the organs necessary for such operations, there is a great number of others which perform particular functions, that not only require appropriate organs, but necessarily modify the manner in which the general functions are performed, and the organs proper to those functions.

Among the less general faculties which indicate organization, but which are not the necessary concomitances of it, the faculty of sensation, and that of voluntary motion, in whole or in part, are the most remarkable, and thence which have the greatest influence on the other functions.

We are conscious that these faculties exist in ourselves, and we attribute them, by analogy, and from their apparent existence, to a number of other beings, whom we therefore name animated beings, or, using a single word, animals.

It appears that these two faculties are necessarily connected, the idea of sensation is even included in that of voluntary motion: we cannot conceive volition without desire, and unaccompanied by the sentiment of pleasure or pain. There may indeed exist inanimate bodies, that manifest external motion produced by an internal principle; but their movements are not of the same nature as those which constitute the functions essential to life, and do not merit the name of voluntary.

On the other hand, the bounty which nature displays in all her productions, does not permit us to believe that the has deprived beings susceptible of sensation, that is to say, of pleasure and pain—of the power, in a certain degree, of avoiding the one and pursuing the other. Among the misfortunes which afflict our species, one of the most painful is the situation of a man of courage withheld by a superior power from resisting oppression; and the poetic fictions best calculated to excite compassion, are those which represent sentient beings inclosed within immoveable bodies. The sighs of Clorinda sufficing, with her blood, from the trunk of a cypress, would arrest the fury of the most savage of mortals. La Gierusalemme Liberata, canto xiii.

But, independently of the chain which connects the two faculties, and the double system of organs they require, they are accompanied by several modifications in those faculties which are common to all organized bodies: these modifications, joined to the two first mentioned faculties, are what more particularly constitute the nature of animals.

With respect to nutrition, for example, vegetables, which are attached to the soil, absorb immediately, by their roots, all the nutritive parts of the fluids which they imbibe. These roots are subdivided into extreme minutest; they penetrate into the smallest interstices, and proceed, if it may be so said, to seek at a distance food for the plant to which they belong. Their action is tranquil and uniform, and never is interrupted except when deprived by drought of the juices which they require.

Animals, on the contrary, which are not fixed, and which frequently change their place, can transport with themselves a portion of the substanices necessary for their nutrition; they have therefore received an internal cavity, into which they deposit the matters defined for their aliment; and the inward surfaces of this cavity are furnished with innumerable absorbing pores or vessels, which, according to the energetic expression of Boerhaave, are real internal roots: the magnitude of this cavity, in a number of animals, permits them to introduce solid substanices into it. It was necessary, then, that they should have instruments for dividing those substanices, and liquors for dissolving them. In a word, with fuch animals nutrition does not immediately commence upon the absorption of the substanices which the soil or the atmosphere furnish them. It is necessarily preceded by a vast number of preparatory operations, the whole of which constitute digestion. See Digestion.

Thus, it appears, that digestion is a function of a secondary order, proper to animals, the existence of which, as well as of the alimentary canal in which it is performed, is rendered necessary by the faculty they possefs of voluntary motion; but this is not the only conqueissance of that faculty.

The faculties of vegetables being very few, their organization is very simple; almost all their parts are composed of fibres, which are either parallel, or diverge very little. Further, their fixed position admits, that the general motion of their nutritive fluid may be preferred by simple external agents. It appears that it proceeds upwards, by the effect of the suction of their capillary or capillary texture, and the evaporation which takes place at their top, and that its motion in that direction is the more rapid in proportion as the evaporation is great. It appears also that the motion of this fluid may even become retrograde, when it ceases to flow in its usual course, or changes into absorption by the coolness and humidity of the air.

It is not only necessary that animals defined continually to change their place of existence, and to live in all kinds of situations and temperatures, should possefs within themselves an active principle of motion for their nutritive fluid; but their more numerous and more developed faculties requiring a much greater complication of organs, their various parts being differently formed, often at a distance from each other, and even capable of changing their respective positions and directions, means more powerful, and otherwise diposied than in vegetables, are necessary for transmitting this fluid through such a multiplicity of intricate windings.

In the greater part of animals, therefore, this fluid is contained in innumerable canals, which are the ramifications of two trunks communicating with each other, in such a manner,
ner; that the one receives in its roots the fluid which the other
has pushed into its branches, and carries it back to the centre,
to be again driven forward from that point.

Where the two great trunks communicate, the heart is
placed; it is merely an organ, the contractions of which
drive this fluid forward with great force into all the ramifi-
cations of the arterial trunk. It has two orifices, the valves
of which are so disposed that the fluid contained in the whole
vessel system can proceed in no other manner than that
we have pointed out; that is to say, from the heart towards
the other parts of the body by the arteries, and from those
parts back to the heart by the veins. See CIRCULATION
and HEART.

In this movement, by rotation, confilts the circulation of
the blood, which is another function of a secondary order,
proper to animals, and of which the heart is the principal
agent and the regulator; but this function is not to necessa-
riely connected with the faculties of digestion and motion as
the function of digestion is; for two numerous classes of
animals are completely deprived of circulation, and are
nourished like vegetables, by simply imbining a fluid which
is prepared in the intestinal canal.

In the animals that have a circulation, the blood appears
to be merely a vehicle which is continually receiving from
the alimentary canal, from the external surface of the body,
and from the lungs, different substances, which are in-
timately incorporated with it, and continually furnishing sub-
fances to all the different parts of the body, for their pre-
ervation and growth. In its palfage through the extremi-
ties of the arteries the blood effects the real nutrition of the
parts; at the same time it changes its nature and its colour:
and it is only by the accession of the different substances,
which have just been pointed out, that the venous blood is
rendered proper for nutrition, or, in one word, becomes
arterial blood.

It is by particular vessels, called lymphatics, that the
venous blood receives the substances with which the skin
and the alimentary canal supply it. By them, also, it re-
ceives even the residuum of nutrition, and the particles which
are detached from different parts, to be carried out of the body
by various excretions. See ABSORBENTS and ABSORPTION.

With respect to the lungs, the air that penetrates into
them produces, with the venous blood, a kind of combus-
tion, which appears to be necessary to the existence of all
organized bodies: for it takes place in them all, though in
very different ways. See RESPIRATION.

Vegetables, and animals which have no circulation, re-
spire throughout the whole of their surface, or by vessels
which introduce the air at different points into the interior of
their bodies. No animals respire by a particular organ,
except those that have a real circulation, because, in them,
the blood coming from one common source, the heart, to
which it constantly returns, the vessels containing it are so
dispersed, that it cannot arrive at the other parts until it has
passed through the lungs. This, however, cannot take place
in vegetables, or in thole animals in which this fluid is every
where diffused in an uniform manner, without being contained
in vessels.

Hence it appears that pulmonarv or branchial respiration
is a function of a third order, the existence of which de-
Pends on that of circulation, and that it is a remote con-
sequence of thole faculties that characterize animals.

Even the mode in which the gills are used is so far
as the fecundation of the ova is concerned, depends on their
particular faculties; for the faculties they possess of moving
and advancing towards each other, of deliberating and enjoying,
has fitted them for taking all the delights of love: while
with respect to the purely mechanical part, their spermato-

genate fluid has no occasion for any envelope, and is capable
of being transmitted directly to the ova; but in vegetables,
which do not possefs within themselves the power of direct-
ing this fluid, it was necessary that it should be enclosed in
little capsules, which are susceptible of being transported
by the winds, and which form what is called the pollen of
the stamina. Thus, while animals, for the performance of
most of their other functions, have, in consequence of fa-
culties peculiar to themselves, received more complicated
organs, they are enabled, by those characteristic faculties,
to exercise the function of generation in a manner more
simple than vegetables.

These examples shew how much influence the faculties of
fecundation and motion, which animals possess; in addition
to those of vegetables, have over the organs of all the other
faculties which are common to both these kinds of beings.
The comparison which we shall hereafter make of the dif-
ferent orders of animals, will, in the same manner, demon-
strate that the modifications of their principal functions exer-
cise a similar influence on all the others:—that is the union
and harmony, which prevails in all the parts of living bodies.

We have thus described the principal functions which
compope the animal economy. It is obvious that they may
be divided into three distinct orders. There are some which,
in constituting animals what they are, fit them for fulfilling
the part that nature has assigned to them in the general ar-
rangement of the universe,—in a word, which would be
sufficient for their existence, if that existence were only mo-
motary. These are the faculties of fecundation and motion
which the latter enables them to execute certain actions, and
the former determines their choice of the particular actions they
are capable of performing.

Each animal may be considered as a partial machine, co-operating with all the other machines,
the whole of which form the universe: the organs of motion
are the wheels and levers, in short, all the passive parts; but
the active principle, the spring which gives the impulse to
every part, resides only in the sensitive faculty, without which
the animal, plunged in a continual slumber, would be re-
duced to a state purely vegetative;—plants themselves,
which Buffon has observed, may be called animals which sleep.
These two functions form the first order, and are termed
animal functions. But animal machines, unlike those we con-
struct, poiffes an internal principle of preservation and repa-
ration. This principle consists in the union of the different
functions which serve to nourish the body, that is to say,
digestion, absorption, circulation, respiration, transpiration,
and the excretions. These form the second order, and are denomi-
nated vital functions.

Finally, the duration of each animal's life being determined
according to its kind, generation is a function of a third
order, by which the individuals that perish are replaced by
others, and the existence of each species maintained. See
FUNCTION.

Having considered these functions with respect to them-
selves, and to their reciprocal relations, we shall next exa-
mine the organs by which they are performed.

General idea of the organs of which the animal body is
composed.—No part of the animal body is composed entirely
of solid particles; they all yield fluids by expiration, or lose
them by exspection; and they all exhibit the appearance of
an organised or reticular texture.

The mechanical division of the solilis conduces us, in the
last result, to lamellae, or filaments, which seem to be the
elementary molecule. When the lamellae are separate, and
Vol. XX.
interrupted by sensible vacuities, they form what is called celluloidity. This celluloidity not only envelopes and pervades the most dense parts, but it appears to form almost always their basis; for membranes consist only of a more compact celluloidity, the lamella of which are more closely approximated, and placed more exactly above each other, and are resolved into an ordinary celluloid by maceration. (See Cellular substance, and Membranes, cellular.) The vessels are merely membranes rounded into cylinders. All the soft parts of the body, the fibres excepted, seem to be an assemblage of vessels, differing from each other only according to the nature of the fluids they contain, by their number, their direction, and the structure of their coats.

The chemical analysis of these substances, solids as well as fluids, exhibits only a few principles, almost all of which are to be found in each of them, though in very different proportions. Some earths, some salts, phosphorus, carbon, azote, hydrogen, oxygen, a little sulphur, and a little iron, combined in a great variety of ways, produce different compositions, i.e., gelatine, albumen, and fibrous matter, &c. which, uniting in their turn, form animal solids and fluids, such as we know them. But, distant as we are from a complete analysis, we see enough to convince us, not only that we alter these compositions by our experiments, but also that several of their principles entirely escape our inferences. For a more particular account of the elementary filaments, into which the body can be resolved, see the article Fine.

The general organ, by which we exercise the faculty of sensation, is the medullary substance. In all the animals in which we can distinguish it, that substance is divided into filaments, which arising from certain centres, distribute themselves over most parts of the body, where they appear to serve other purposes besides that of procuring sensations. The centres from which those nervous cords proceed, communicate with each other in a manner more or less intimate, and several of the filaments seem of no other use than to establish those communications.

A nerve, when touched by a foreign body, causes the sensation of pain, though its contact with the parts of the body which are naturally contiguous to it, produces no sensible effect in a state of health. The nerves, by which we discern external objects, are provided, at their extremities, with organs, each of which is disposed in a particular manner, and always possesses an admirable relation to the nature of the objects, a knowledge of which each of these senses is designed to convey to us. See Nerve and Brain.

The general organ of motion is the fibrous or muscular fibre. This fibre contracts itself by volition; but the will only exerts this power through the medium of the nerves. Every fibrous fibre receives a nervous filament; and the obedience of the fibre ceases, when the communication of that filament with the rest of the system is interrupted. Certain external agents, applied immediately to the fibre, likewise cause contraction; and they prefer the action upon it, even after the cessation of its nerve, or its total separation from the body, during a period which is longer or shorter in different species of animals. This faculty of the fibre is called its irritability. Does it in the latter case depend upon the portion of the nerve remaining in the fibre after its section, which always forms an essential part of it? Or is the influence of the will itself only a particular circumstance, and the effect of an irritating action of the nerve on a faculty inherent in the muscular fibre? Haller and his followers have adopted the latter opinion; but every day seems to add to the probability of the opposite theory. See Muscle.

Be this as it may, all the internal parts of the body delineated to produce a compression on the substances they contain, have their parietes furnished with fibrous fibres, and receive nervous filaments; such as the face with the bladder, the intestines, the heart, &c. But the principal use of these fibres is the formation of muscle. This is the name given to the bundles of fibrous fibres, the extremities of which are attached to the movable parts of the animal body. When the fibres which compose the muscle shorten, the two points to which it is attached are brought towards each other; this is the sole means by which all the external motions of the body and the members, even those which are necessary for removing the body entirely from one place to another, are produced.

Animals that can only crawl have their muscles attached to different parts of their skin, on which they alternately produce dilatations and contractions, which are the only motions of which they are susceptible; but those which are capable of moving themselves by steps or otherwise, either wholly or partially, have their muscles attached to hard parts placed externally or internally. Those parts perform the office of levers, and have points of support on each other, which are called their articulations.

All the hard parts taken together form the skeleton. When they are covered by the muscles, they receive the name of bone; when they cover muscles, they are denominated stiff, cartilaginous, or scale, according to their degree of firmness. In both cases they always enclose vasa, and determine the exterior form of the body, and the proportions of its different parts.

The articulations are provided with as many muscles as are necessary for the different movements of which they are susceptible; each muscle moving the body to which it is attached, in its proper direction. They may be regarded as the moving powers. Their force, the point of their infection, and the length and weight of the parts attached to the lever they have to move, determine the velocity and the duration of the motion they are capable of producing. On these different circumstances depend the force of leaping, the extent of flight, the rapidity of running, and the prehensile power displayed by different species of animals; but, as we have already observed, all this organization would remain immovable, were it not animated by the nervous system.

The soft white substance which forms the essence of this system, is divided into filaments that approach each other, and unite in bundles, which contain more filaments in proportion as they are traced nearer to the common fasciculus of all the nerves, called the spinal marrow, the anterior extremity of which is joined to the brain, that is to say, to a medullary mass of more or less magnitude, and differently formed according to the various kinds of animals.

From the action of external bodies on our own, we perceive that the nerves affected by that action communicate with the common fasciculus, and that it communicates with the brain. A ligature or a rupture intercepts the physical communication, and destroys sensation.

The only sense which belongs generally to all animals, and which pervades almost the whole surface of the bodies of each of them, is that of feeling. It resides in the extremities of the nerves which are distributed to the skin, and makes us sensible of the resistance of bodies, and their temperature.

The other senses seem to be only modifications of this one.
LIFE.

One, but more exalted, and capable of receiving more delicate impressions. Every one knows that the other senses are feeing, which resides in the eye; hearing, which belongs to the ear; smelling, which is attached to the membranes within the nose; and tasting, the feel of which is in the surface of the tongue. These senses are almost always situated in the same extremity of the body which contains the brain, and which we call the head.

Lights, the vibrations of the air, the volatile emanations which float in the atmosphere, and falling particles soluble in water, or saliva, are the substances which affect these four senses; and the organs, which transmit the action to the nerves, are appropriate to the nature of each. The eye presents transparent lenses to the light, which refract its rays. The ear offers membranes and fluids to the air, which receive its concussions. The nose inhales the air which is to go to the lungs, and senses, in their passage, the odorous vapours it contains. Finally, the tongue is covered with fpongy papilla, which imbibe the savoury liquids that are taken into the mouth.

By these means we obtain a knowledge of what passes around us: but the nervous system likewise makes us acquainted with a great deal of what passes within us. Independently of those internal pains which indicate some disorder in our organization, and the disagreeable state in which we are placed by hunger, thirst, and fatigue, it is in consequence of the operation of this system that we experience the agonies of fear, the emotions of pity, the desires of love. Sensations of this kind often, however, to be rather the effect of the re-action of the nervous system, than immediate impressions; though, at the sight of any imminent danger, we hasten to avoid it before it appears that the mind has time to act; and the same observation applies to the transports we feel on the presence of a beloved object, or to the tears we shed over the spectacle of suffering virtue. Those effects of the nervous system are produced by numerous communications which particular nerves, called lymphatics, establish between different branches of the general trunk, by means of which the impressions are transmitted more rapidly than by the brain. The knots called ganglia, when they are considerable, are each a kind of secondary brain; and it is observable, that they are larger and more numerous in proportion as the principal brain is less.

The faculty of sensation, and that of contraction, the first of which, in most animals, is exclusively appropriated to the nervous substance, and the second to the fibrous system, appear to be equally diffused in all the parts of certain gelatinous animals, in which we cannot perceive either fibres or nerves.

It is by the means of these two faculties that animals feel, define, and are enabled to provide for their wants. The most irremediable feeling of all is that of hunger, which constantly reminds the animal of the necessity of procuring new materials for its nutrition. This third function commences in the mouth, into which the aliment is taken, and, when they are solid, macerated and moistened with dissolving liquids; thence they traverse the alimentary canal, which is longer or shorter, and more or less convoluted and dilated in different animals, and the parietes of which are composed of several continued tunics, analogous to those which form the external extremity of the body.

These cuts act in a mechanical manner, on the sublunates which they contain, by flight contractions of their fibres; and in a chemical manner, by the liquors which are poured out within them.

The first dilatation of the alimentary canal is called the stomach. There are sometimes several stomachs, or several divisions of that organ; its parietes yield a liquid which reduces the aliments to a homogeneous pulp, during the time they remain in it. The remainder of the canal is more particularly called bowels or intestines. Independently of the juices, which the different coats of the bowels produce, there are some which are separated from the nafs of the blood by glands, and which penetrate the intestinal canal by particular conduits. The most remarkable and the most general of these glands are the liver and the pancreas. The first, which secretes the bile, is always of a considerable size; and besides the effect of its liquid on the intestines, produces another very remarkable effect on the blood itself, from which it removes several principles. See STOMACH, INTESTINES, LIVER, AND PANCREAS.

It is in the intestines that the aliments undergo that change which fits them for nutrition. The nutritive part is absorbed, during the act of digestion, either by the pores of the canal itself, in animals that have no circulation, or, in those that have, by very small vessels which conduct it into the general system of nutritive vessels. Those small vessels are called lymphatics. They are very distinct from the veins, in animals whose structure most resembles that of man; in the more inferior animals they become gradually more like the veins, and cannot be distinguished from them in those which have white blood. The membranes which compose the lymphatic vessels and veins are thin, and without apparent fibres. Internally they are furnished with valves, all opening in the direction in which the fluid they convey has to flow, that is to say, towards the heart. The arteries, on the contrary, are strong and muscular, but have no valves; the vigorous impulse of the heart is sufficient to impress a constant direction on the blood they contain.

But the chyle, or the liquor produced by digestion, is not sufficient for renewing the venous blood, and rendering it fit for the nutrition of the different parts of the body. It is necessary that it should experience the contact of the air before it enters into the arterial system. This is effected by respiration. The organs of respiration, in animals which have blood-vessels, consist in a ramifications of those vessels, which increases their surface to such a degree, that almost all parts of the fluid are separated from the surrounding element only by a very thin pellicle, which cannot obstruct its action. This ramifications takes place on the surface of certain folds or lamellae in aquatic animals, and on that of certain cells in aerial animals. In the first case the organ is denominated branchia, in the second lungs. In animals which have no vessels, the air reaches all parts of the body, and acts on the nutritive fluid at the same moment in which that fluid combines with the parts of the body which it is destined to nourish. This is the case with insects that have trachea. It will be easily conceived that there must be muscular organs, appropriated to each of those species of respiration, destined to attract or impel the ambient fluid towards the place where it has to act upon the blood. This office is performed by the ribs, the diaphragm, the muscles of the abdomen, the flaps of the gills, and several other parts, according to the nature of the animal. See LARYNX.

The air cannot be employed in the formation of the voice, except in the animals that respire by cellular lungs, because it is in them only that it enters by a single and lengthened tube. At one or two parts of this tube there are membranes susceptible of tension, which vibrate when the air acts upon them, and thereby produce the various sounds which we call the voice. The animals which have no voice, properly so called, are not, however, deprived of the power of producing certain sounds, but they are produced in them by other means. See LARYNX.
The blood, on its passage into the organ of respiration, experiences a kind of combustion, which removes a part of its carbon, carrying it off under the form of carbonic acid, and which thereby augments the proportion of its other elements. The effect of this proceeds on the expired air, is to deprive it of its oxygen, which is the only aeriform fluid that is capable of respiration. Its effect on the blood is left unknown; we know that it heightens the power of the blood in red-blooded animals, and gives it the power of exciting the heart to contraction. There is every reason to believe that it is this action of the air on the blood which gives, indirectly, to the fleshy fibres their contractile power.

It is still necessary that the blood should lose several other principles: some are carried off by the kidneys, which secrete the urine, and which are found in all animals that have red blood. The matter which transpires through the pores of the skin, and the substances which pass through the intestinal canal, a great part of which are carried away with the excrements, relieve the blood of other principles. These three kinds of excretions, to a certain degree, supply the place of each other, and appear, therefore, to tend towards one common object. See Integuments, Kidney, and Respiration.

These are all the organs which constitute the animal, considered individually, and which are sufficient for its separate existence, while the object is not the multiplication of the species; such are the whole of the organs in the higher orders of animals. We shall see that, in proportion as we descend in the scale of being, they successively disappear, and that at last we shall find, in the lowest classes, only what is necessarily connected with the idea of an animal; that is a fæce, sensible, moveable, and capable of digesting.

Upon a close observation of the action of all these organs, it will appear, that all the operations which take place in the animal body, depend on the combination and decomposition of the fluids contained within it. To the animal processes, by which one fluid is separated from another, or is formed from a part of the elements of one, mixed with a part of those of another, we give the name of secretion; this term, however, is usually confined to the changes which take place in different kinds of glands, that is to say, in bodies more or less thick, in which the blood-vessels, being infinitely subdivided, permit the liquid which the gland separates from the blood to transude from their extremities. (See Gland.) But the animal economy exhibits a number of other transformations, or separations of humours, which equally merit this name. It cannot be supposed that the nerves act on the muscular fibres without producing a chemical change on the fluid that may be contained in the one, by the accession of that which the organs may transmit, or that external objects act upon the nerves otherwise than by producing a change of the same kind. The fluid contained in the nervous system may have been separated from the blood in the brain, and, in general, in all the medullary organs. The blood itself does not attain its state of perfection until a multitude of substances have been detached from it by the lungs, the kidneys, the liver, &c. and until after it has received a number of others which have been separated from the alimentary mass by the blood-vessels: on the other hand, this mass is not capable of yielding chyle until it has in its turn received different liquors which have been secreted from blood by several organs; and the blood only nourishes the parts to which it is distributed, by the particles that are detached from its mass, while other particles are separated from these parts to return into the mass of the blood through the medium of the lymphatic vessels.

In a word, all the animal functions appear to reduce themselves to the transformation of fluids. In the manner in which these transformations are produced, the real secret of the admirable economy of animals consists, as health depends upon their perfection and regularity.

If we do not perceive this process in a manner sufficiently clear when the embryos of new individuals begin to develop themselves within or without the bodies of their mothers, than at least discover in the preparation of the male liquor, which, by its presence, excites or occasions this development in all the species in which copulation is necessary. This development takes place in the same manner as the ordinary growth. It, therefore, comes under the general rule. The organs of generation, which alone remain to be noticed, are those which prepare the prolific liquor, and convey it to the ova, and those which are destined to contain and protect the embryo during its development. The first constitute the male, the second the female.

The testicles are the glands which secrete the seminal fluid; several other glands prepare liquors which mingle with it. The penis contains the seminal canal; it swells by the accretion of blood when the nerves are excited by desire; by that means, it is rendered capable of penetrating the vagina, which leads to the matrix, or to the oviductus, and of conveying thither the fluid defined to vivify the ova. The oviduct or tube receives the ovum at the moment in which it is detached from the ovary; and conducts it without the animal if it be of the oviparous kind, or into the matrix if it be viviparous. The little embryo develops itself, and grows its nourishment, either from the body of its mother, by the absorption of a large tisue of vessels connected with those of its own body, or from an organized mass attached to it in the same manner, and which forms the yolk of the egg, or the vitellus. When the embryo attains a certain state, the matrix expels it; or it breaks the shell of the egg in which it is contained, and escapes from its prison. See Generation.

View of the principal differences which animals exhibit in their several organs.—It appears from the preceding account, that what is common to each kind of organs, considered in all animals, resolves itself into a very small compass, and that frequently they only resemble another in the effects they produce. This is particularly obvious with respect to respiration, which is performed in the different classes of animals by organs so various, that their structure presents no common point of comparison. Those differences in the organs of the same kind are precisely the object of comparative anatomy; and the short exposition we are about to make, of the principal of these differences, may be regarded as a general view of this subject. We shall, therefore, return to each of the functions of which we have treated, and examine the different degrees of energy it possesses, and the particular means by which it is carried on in different animals.

The organs of motion present us at first sight with two important distinctions with respect to their situation. Sometimes the bones form an internal skeleton, articulated and covered by the muscles; sometimes there are no internal bones, but merely scales or shells which cover the skin, within which are the muscles; in other cases there is no hard part that can serve as a lever, or point of support for the motions of the animal's body.

Animals of the first kind have the whole body supported by a strong pillar, formed of several bony pieces, placed one above the other, and called the spine of the back, or the vertebral column. They are, therefore, denominated vertebrated animals. These are the mammalia, birds, reptiles, and fishes.

The animals without vertebrae are either entirely soft, or
have their bodies and members enveloped in scales articulated on one another, or, finally, are enclosed in shells. These are the soft worms, infects, and the tettecas.

It is by the greater or less perfection of certain parts that the animals of these different classes become susceptible of various kinds of motion.

The organs of sensation present considerable varieties; some have a relation to the internal part of the nervous system, others to the external sense. The first give rise to three classes:—that of animals which have no apparent nervous system, and in which we discover neither vessels nor nerves; such are the zoophytes or the polyphyes;—that of animals in which there is only the brain above the alimentary canal, and which have all the remainder of the common bundle of nerves situated underneath, and contained in the same cavity with the other viscera; these are the mollusca, the crustaceas, infects, and a part of the articulated worms;—lastly, that of animals in which the common fasciculus of the nerves is situated entirely in the back above the alimentary tube, and enclosed in a canal which passes through the vertebral column; these are all the vertebral animals. Their ganglia are placed on the sides of their medullary cord, or dispersed in the large cavities. Among the invertebral animals there are some that have ganglia only in the large cavities, as the mollusca, and others, which have them all on the medullary cord itself, of which they appear to be swellings; these are the infects, and some articulated worms.

The differences in the external sense in their number, and in the degree of energy that belongs to each.

All vertebral animals possess the same sense as man.

Sight is wanting in the zoophytes, in several kinds of articulated worms, in several classes of infects, and in the acipenserian mollusca. Hearing does not exist, at least we have not yet discovered its organ, in some mollusca and infects. The other three senses, but particularly those of taste and touch, appear never to be wanting.

But each of these senses may vary considerably in the degree of its susceptibility, and the complication of its structure. The perfection of the sense of touch, for example, depends upon the delicacy of the external teguments, and on the division of the extremities that more particularly enjoy that sense; their formation rendering them capable of being applied more or less exactly to the bodies of which the animal wishes to acquire a knowledge. Above all, it is in the number and flexibility of the fingers and toes, and the smallness of the claws or nails, that the anatomist discovers important characters.

The eyes may be more or less moveable, more or less covered, and more or less numerous. The ears may be sunk within the cranial, or exposed outwardly; or they may be provided with an external trumpet, which collects the rays of sound. The membranes in which the sense of smelling rediles, may be more or less extensive: these are the heat of taste, may be more or less delicate and humid; but it is only by particularly considering each of those senses, that we can take a comprehensive view of the differences that exist in the various classes of animals.

The organs of digestion exhibit two important differences in their general dispositions. In certain animals, (in the greater part of zoophytes,) the intimeles form a lace with only one aperture, which serves at once for the entrance of the aliment, and the issue of the excrements; all other animals have two distinct apertures, for those purposes, at the two extremities of the same canal; but the convolutions of this canal may be such as to remove these openings to a greater or less distance from each other. Another difference which has much influence on the nature of the aliments appropriated to each species, is, that in certain animals the mouth is armed with teeth, or hard parts proper for grinding solid substances, while in others they do not exist. In the latter case, the animal can only swallow whole bodies if its mouth be large, or merely suck in fluids if its mouth be in the form of a tube. The structure of these teeth has itself much influence on the substances the animal can submit to mastication. The remainder of the alimentary canal varies also considerably in its structure, according to the different substances which the mouth conveys to it. On this likewise depend the length of the canal, and the number of stomachs, ceca, &c.

The chyle produced by the action of the digestive organs on the alimentary substances is transmitted to the various parts of the body in two different ways. It either simply transeides through the parietes of the intestinal canal, to bathe all the interior of the body, or it is absorbed by particular vessels which convey it into the mafs of the blood. The first is the mode in which this operation is performed in zoophytes, and, probably, also in common infects, which appear to have no kind of vessels proper for circulation. As to the other animals, viz. the mollusca, and the vertebral animals, that have abundant vessels, they exhibit two new differences. The latter have red blood, and the lymph and chyle white. Almost all the others have these two fluids of the same colour.

Vertebral animals differ among themselves, with regard to the colour of the chyle, which is white and opaque in the mammalia, and transparent, like the other lymph, in birds, reptiles, and fishes. The three last classes, therefore, have no coagulate glands in their chyliferous vessels, while they are very numerous in the first.

The circulation of the blood is accompanied with very important differences in its organs. In the first place, there are animals which have no circulation whatever, viz. infects and zoophytes: others have a double, and others a single circulation. We call that a double circulation in which no part of the venous blood can enter the arterial trunk, until it has passed through the organ of respiration, which is generally formed of the ramifications of two vessels; the one arterial, the other venous; each nearly as large, but not so long, as the two principal vessels of the body. Such is the circulation of man, of all mammalia, of birds, fishes, and a number of mollusca.

In the single circulation a great part of the venous blood re-enters the arteries without passing through the lung; because only one branch of the arterial trunk is expanded upon that organ; such is the circulation of the amphibia. There are, besides, other differences in the hearts, or muscular organs, destined to give impulse to the blood. In the single circulation there is only one heart; but when the circulation is double, there is sometimes an organ at the base of the aorta, and also at that of the pulmonary artery. At other times it is at one of the two only.

In the one case, the two hearts, or rather the two ventricles, may be united, as in man, mammalia, and birds; or they may be separate, as in the cuttle-fish.

Where there is only one ventricle, it may be placed at the base of the artery of the body, as in snakes, and other mollusca; or at the base of the pulmonary artery, as in fishes.

The organs of respiration are likewise distinguished by a number of remarkable differences. When the element that acts on the blood is the atmospheric air, it penetrates even
into the interior of the respiratory organ; but when that
element is water, it simply glides over a surface more or less
multiplied.

The lamellæ which compose the organ, in the latter case,
are called branchia. They are found in fishes, and in a
number of molluscs: instead of lamellæ, we sometimes find
fringes or tufts.

The air either enters the body by a single aperture, or
by several. In the first case, which is that of all animals
that have what is properly called lungs, the canal which
receives the air divides into a number of branches, terminat-
ing in as many small cells, that are usually united into two
masses, which the animal has the power of compressing or
dilating at pleasure.

When there are several apertures, which is the cafe only
with insects, the vessels that receive the air are ramified ad
infinitum, and convey it to all parts of the body without
exception. This we call respiration by tracheæ.

Lately, the zoophytes, if we except the echinoderma,
have no apparent organ of respiration.

The organs of the voice present only two differences,
which may be regarded as general. They depend on the
position of the glottis, in which the sound is formed. In
birds, it is at the lower part of the trachea or tube, which
conducts the air, where it divides into its two branches to
pafs into the lungs. In quadrupeds and reptiles it is situa-
ted in the beginning of the tracheæ, at the root of the
tongue.

Only these three classes have a glottis; but the other ani-
mals produce sounds by different means. Sometimes they
employ the friction of certain elastic parts; sometimes they
beat the air with other parts, or produce a rapid motion in
certain portions of air, which they somewhere retain in their
bodies.

Generation gives rise to varieties of two kinds. The
one relates to the actions which occasion it, the other to the
result.

In a small number of animals, belonging almost entirely
to the clas of zoophyta, generation is performed without
copulation, and the young animal grows on the body of the
parent, like a flint on a tre: others only produce in conse-
quence of copulation, and are therefore provided with two
sexes; but these two sexes may be separate in different
individuals, or united in the same. It is only in the mollusæ
and zoophyta that this last case occurs: all animals with
vertebræ, and insects, have the sexes separate.

Hermaedrectic animals, such as the bivalve shell-fish, ge-
nerate finely; in others, a reciprocal copulation takes place,
each of the two individuals performing the functions of male
and female: this is the case with the snails and other mollusca
that crawl on the belly.

The produce of generation is either a bud which de-
velops itself into an animal, remaining some time on the body
from which it proceeds, and of which it forms as it were a
branch; or it is a form, which unfolds itself in the uterus
of its mother, to which it is connected by a plexus of vessels,
and from which it comes forth alive; or, finally, it is a
fetus inclosed in a shell, with a substance adhering to it by
vessels which it must absorb before it is discharged. Theze
are the gemmiparous, viviparous, and oviparous modes of
generation.

The first occurs in some zoophytes, and in some articu-
larated worms; the second in man and other mammals only;
the third is common to all other animals; and when their
young come forth alive from the body of the mother, as is
the case with the viper, it is because the eggs are hatched in
the oviduct.

Lastly, if we consider the states through which the young
animal is obliged to pass before it becomes, in its turn,
capable of perpetuating its species, we again discover two
principal differences. Some have at their birth the form
which they will always preserve, with the exception of a
few considerable parts which have yet to grow and develop
themselves, and to change their proportions: the others, on
the contrary, have a form altogether different from their perfect
state, and not only have to produce and unfold new parts,
but must lose their old ones: these are the animals which
undergo a metamorphosis. Hitherto this change has only
been observed to take place among insects, and among the
reptiles without scales, that is, frogs, and salamanders.

Such are the chief varieties which the organs belonging to
the several functions of animals exhibit.

We have, however, yet to notice one very important vari-
ety which extends to several of these functions: it relates
to the organs of secretion. In the four classes of vertebral
animals, and in some molluscs, these organs are glands,
or at least expansions of blood-vessels; the name of gland
being particularly applied to them when they form mounds of
some thickness.

It is not so in insects, which, instead of secretory
organs, have only tubes more or less long, which attract
into the spongy texture of their parietes, that portion
they have to separe from the mafs of the nutritive
fluid.

We are as yet little acquainted with the organs of secre-
tion in zoophytes, if indeed they can be said to have any
particular organ for that purpose.

Division of life into the animal and organic.—The preceding
flech has exhibited to us a general view of life; when
we come to examine it more in detail, it offers us two
remarkable modifications. One is common to vegetables
and animals, the other peculiar to the latter. Compare to-
gether two individuals, one taken from each of these king-
doms: one exits only within itself, has no other relations to
surrounding objects than those of nutrition, is born, grows,
and perishes, attached to the soil, which received its germ:
the other joins to this internal life, which it perpusses in a
full higher degree, an external life, which establishes numerous
relations between it and the neighboring objects, uniting its
existence to that of other beings, and draws it near to or
removes it from them according to its wants or fears. We
might say that the vegetable is the skeleton of the animal,
and that, in order to form the latter, it was only necessary
to clothe the skeleton with an apparatus of external organs,
calculated to establish the necessary relations. Hence it fol-
lows that the functions of the animal form two very distinct
classes. One of these consists of an habitual succession of
affirmation and exertion; by which it is constantly trans-
forming into its own substance the particles of other bodies,
and then rejecting them, when they have become useless.
By the other he perceives surrounding objects, reflects on
his faculties, performs voluntary motions under their influ-
ce, and generally can communicate, by the voice, his pla-
ughters or pains, his desires or fears. By the one he lives
only within himself; by the other he carries his existence out
of the sphere of his own body.

I call, says Bichat, the functions of the former clas,
taken altogether, the organic life, because all organized be-
ings, whether vegetable or animal, enjoy it in a more or less
marked degree, and because organic structure is the only
condition
I L E.

condition necessary for its exercise. The assembled functions of the second class form the animal life, so named because it is the chief attribute of the animal kingdom.

Generation does not enter into the series of phenomena of these two lives, which relate entirely to the individual; while that function regards the species, and is consequently connected only in an indirect manner to most of the other functions. Its exercise does not begin until the others have been for a long time in action; and it is extinguished long before they cease. In most animals its periods of activity are separated by long intervals of entire inaction; and in man, where the remissions are less durable, its relations to the other functions are not more numerous.

Each of the lives is composed of two orders of functions, succeeding each other, and mutually connected. In the animal life, the first order takes place from the exterior of the body to the brain; and the second, from the latter organ to those of locomotion and the voice. Objects affect successively the senses, the nerves, and the brain. The first receives, the second transmits, and the last perceives that impression which constitutes a sensation. The animal is nearly passive in this first order of functions; he becomes active in the second, which results from the successive operations of the brain, where volition arises in consequence of sensation, of the nerves, which transmit that volition, and of the locomotive and vocal organs, which are the agents of its execution. A double movement of composition and decomposition exists also in the organic life. Hence the animal is not the same at one time as at another; his organisation is unchanged, but the component elements are constantly varying. The order of functions, which affinitiate to the animal nutritive labours, consists of digestion, circulation, respiration, and nutrition. All foreign matters undergo the influence of these four functions, before they belong to the elements of the body. After a certain time absorption removes them, and conveys them into the circulation, from which they are separated by the cutaneous or pulmonary exhalation, or by the various secretions. Thus absorption, circulation, exhalation, and secretion, form the second order of functions in the organic life; or the order opposed to assimilation. The circulating system is the common centre in the organic, as the brain is in the animal life. The blood consists of two parts; one, furnished principally by the food, affords the materials of nutrition; while the other, constituting the flesh or residue of all the organs, supplies with materials the secretions and external exhalations. Yet the latter functions sometimes convey out of the body the products of digestion where they have never been employed in nourishing the organs. This is exemplified in the urinary and cutaneous discharges consequent on copious drinking.

The most essential difference that appears to exist between the organs of the animal and those of the organic life, is the symmetry of the one and the irregularity of the other. This observation, indeed, does not apply to all animals; nor is it invariably true in man; but it holds good generally in the latter, and forms a striking general feature. Two globes exactly alike receive the impression of light. Sounds and odours have each their double organ. The median line is clearly marked on the tongue, and its two halves exactly resemble each other. This line is not very manifest in the skin. The nerves, which transmit impressions from the sensitive organs, are arranged in symmetrical pairs. And the brain, in which the impression is received, has a regular form; its double parts resemble each other on the opposite sides; and its single organs are all symmetrically divided by the median line into two exactly corresponding halves. The nerves, which transmit our volitions from the brain to the agents of locomotion and the voice; and the locomotive organs, composed of a great part of the muscular system, of the bony skeleton and its dependences; and the apparatus of respiration, and its various organs; the double agents for the execution of motions, have a symmetrical structure throughout.

The muscles and nerves, when they do not belong to the animal life, no longer exhibit this regularity of form. The heart, and the muscular coverings of the digestive viscera, prove this with respect to the muscles; and the great sympathetic nerve, everywhere employed in the internal life, clearly shew the irregularity in the nerves.

On surveying the parts concerned in the organic life, we shall find that an exactly opposite character is applicable to them. The stomach, the intestines, the spleen, liver, &c. are all irregularly formed in the digestive system. In the circulating apparatus, the heart, and the large vessels, such as the aorta, the axillary, the vena portarum, &c. exhibit no trace of symmetry. Continual variations are observed in the blood-vessels of the extremities, and the disposition of one side is often by no means the same with that of the other.

The respiratory apparatus, at the first glance, appears regular; but we find the two branches of the trachea differing in size, length, and direction; the two lungs differing in size and in the number of their lobes, &c. The organs of exhalation and absorption, the serous membranes, the thoracic duct, and the right lymphatic trunk, as well as the other absorbing vessels, have every where an irregular distribution.

Among the glands we see the mucous follicles every where scattered irregularly. The pancreas and liver are out of all symmetry; the kidneys differ in position, size, &c.; &c. It is apparent, from these considerations, that the organs of the animal life in man are essentially characterised by symmetry; while those of the internal life have the constant character of irregularity in their external forms.

It follows from this view, that the animal life is in a manner double; that its phenomena, executed at the same time on the two sides, form an independent system on each side, of which one may go on while the other ceases. This happens in those cases of paralysis called hemiplegia, where the animal life is annihilated on one side of the body, so that the individual has no relation to surrounding objects; while the preservation of sensation and motion on the other side given him all the usual powers. The median line in these cases accurately divides the sound from the affected side.

In the organic life, on the contrary, all the parts conspire to form one system, so that the functions of one side cannot be interrupted without those of the other being affected. The liver on the left influences the flate of the stomach on the right; if the colon cease to act on one side, that of the other cannot go on; the same cause that should arrest the circulation in the large venous trunks and the right side of the heart, would stop it also in the left side, and in the arteries, &c. Hence, if all the organs of the internal life on one side should have their functions stopped, those of the opposite side would necessarily remain inactive, and death must follow. This effect, however, is general, and applies to the organic functions collectively; some of the organs are in fact double, and may supply each other's places, as the kidney and lung.

Bichat proceeds to point out the differences by which the animal and organic lives are distinguished when in a state of action. He observes that harmony is to the functions of the organs, what symmetry is to their conformation; it
supsposes a perfect equality of force and action, as symmetry indicates an exact analogy between the external form and the internal structure. It is a consequence of the law of symmetry; for two parts, essentially alike in their structure, cannot act differently. This reasoning would lead to the general position, that harmony is the character of the external functions, and discordance the attribute of the internal ones. He then enters at considerable length into a detailed consideration of this subject; but does not succeed in proving the point to the extent attempted.

A more important distinctive character of the two lives is drawn from the periodic interminitions of the external functions, and the uninterrupted continuity of the internal ones. Whatever suspends respiration and circulation, suspends and even annihilates life if it be continued. All the secretions go on uninterruptedly; if some periods of remission are observed, as in the bibe and taliva, when digestion and malaciation are not going on, these affect only the degree of activity and not the entire exercise of the function. Exhalation and absorption succeed each other without ceasing; nutrition is never inactive; the double motion, of composition and decomposition, from which it results, ends only with life.

In this concatenation of the organic phenomena, each function depends immediately on those which precede it. The circulation is the centre of the whole, and immediately connected with their exercise; if that is disturbed, the others languish; they cease if the blood no longer moves. Thus, the numerous wheels of a clock stop as soon as the pendulum, which sets them all in motion, is at rest. Not only is the general action of the organic life connected to the particular action of the heart, but each function is also separately connected to all the others. Without secretion there would be no digestion; without exhalation, no absorption; without digestion, no nutrition. We may, therefore, lay down as a general character of the organic functions, their continuity of action and mutual dependence on each other.

On the contrary, consider each organ of the animal life in its separate exercise of its functions; you will see constantly alternations of activity and repose, complete intermissions, and not remissions like what may be seen in some of the organic phenomena. Each sense, fatigued by a long continuance of sensations, becomes momentarily unfit for the reception of new ones. The ear is not excited by sounds, and the eye is closed against the light, merely because the respective functions have been exerted for some time. Fatigued by a long exercise of the perception, the imagination, memory, &c., the brain requires a suspension of action proportioned to the duration of the preceding activity, in order to recruit the powers, without which it could not again become active.

When a muscle has been contracted strongly, and for a considerable time, it cannot perform new contraction until after a certain interval of relaxation. Hence there are intermissions in the exertions of the locomotive and vocal powers.

This intermission in the animal life may be either partial or general. The former is seen when a particular organ has been a long time in exercise, the others remaining inactive; this organ then relaxes; it sleeps while the others are awake. Each animal function, therefore, is not in an immediate dependence on the others, as is the case with the organic functions. When the senses are closed against external objects, the action of the brain may still continue; memory, imagination, and reflection, are then often exercised. Locomotion and the voice may still remain; when the latter are interrupted, the functions of the senses still go on. The animal can fatigue any part separately. Each, therefore, should have the power of retiring in order to recruit its forces separately; this is the partial sleep of the organs. General sleep is the assembled of the acting particular acts, and arises from the law which we have just illustrated.

Differences of the organic and animal lives in respect to the vital properties.—Physicians and physiologists, in their writings on the vital powers, have generally begun by searching for the principle on which they depend; they have wished to descend from the study of its nature to that of the phenomena, instead of ascending from the result of observation to the conclusions which theory may suggest. The soul of Stahl, the archetypal of Van Helmont, the vital principle of Bartholomew, the materia medica of Hunter, with a long train of et cetera, have been regarded in their turns as the single centres of all those actions which bear the character of vitality, and have successively afforded the bases on which all physiological explanations rest in the last result. Each of these has been successively destroyed, and nothing has been preferred from their wrecks, except the facts afforded by experiment on the powers of sensation and motion. So narrow are the limits of the human understanding, that the knowledge of first causes seems placed for ever beyond our reach. The thick veil which covers them, envelopes in its innumerable folds whoever attempts to break through it. In the study of nature, principles are certain general results of first causes, from which innumerable secondary results proceed; the art of discovering the connection between these primary and secondary results is the object of every judicious mind. To seek the connection between first causes and their general effects, is like walking blindfold through a road from which we may stray by a thousand paths.

Moreover, how are we interested in knowing these causes? is it necessary that we should understand the nature of light, oxygen, caloric, &c., in order to study the phenomena? Let us imitate, in the science of physiology, the examples of modern metaphysicians in their investigations of the intellectual phenomena; let us suppos the causes, and fix our attention entirely on the grand results.

We may observe in nature two classes of beings, two classes of properties, and two classes of sciences. Beings are either organic or inorganic, properties vital or not vital, and sciences physiologica] or physical. Animals and vegetables are organic; minerals, inorganic. Sensibility and contrariety are vital properties; gravity, affinity, elasticity, are non-vital properties. Animal and vegetable physiology, and medicine, compose the physiological sciences; alronomy, chemisty, &c. are physical sciences. These two classes of sciences relate merely to phenomena. Two others, relating to external and internal forms, consequently descriptive, correspond to them; these are botany, anatomy, zoology, for organic; mineralogy, &c. for inorganic bodies.

From these properties are derived all the phenomena in each class of sciences. Whatever we see in alronomy, hydraulic, dynamics, &c. must be ultimately referred through the concatenation of causes, to gravity, elasticity, &c. In the same way the vital properties are the manifesting at which we arrive, whatever phenomena we may be contemplating in respiration, digestion, secretion, inflammation, &c.

Each body possesses a certain number of properties, which especially characterize it, and by virtue of which it concurs in its own manner in the production of the phenomena, which are successively developed in the universe.

Observe...
LIFE.

Observe surrounding objects; carry your view towards the most distant; use the telescope on the celestial bodies moving in space, or penetrate with the microscope into the world of those concealed from our view by their minute-ness; you will continually see inanimate bodies gravitating towards each other, living bodies also gravitating, but moreover feeling and performing a motion, which they owe only to themselves. These properties are so inherent in both, that we cannot conceive the bodies without them; to enjoy them and to exist mean the same thing. Suppose that they should be suddenly annihilated, all the phenomena of nature would instantly cease.

Differences between the vital properties and the physical powers.—The extent of this difference cannot fail to strike us on the first glance. The vital properties, constantly variable in their intensity, often pass with the greatest rapidity from the lowest to the highest degree of energy, are successively exalted and weakened in the different organs, and assume, under the influence of the lightest causes, a thousand different modifications. Sleep, exercise, rest, digestion, hunger, the passions, the effect of surrounding agents, &c. expose them at every instant to numerous revolutions. The others, on the contrary, constantly the same at all times, give rise to a series of phenomena always uniform. Compared to sensitivity to attraction; the latter is always in proportion to the mass of the body, in which it is observed, while the former is constantly changing in the same organ, in the same mass of matter.

The invariable nature of the laws which predominate over the physical phenomena, enables us to submit to calculation all the sciences of which they are the objects; but the application of the mathematics to vital action can only lead to a very general formule. The resistance experienced by a fluid in passing through a dead tube, the velocity of a projectile, &c. may be easily reduced to a fixed law; but to calculate with Borelli the power of a muscle, the velocity of the blood with Reil, the quantity of air entering the lungs with Irwin and Lavosifier, is like building on a moving-fand an edifice which is solid in itself, but which quickly falls from the insolvency of its foundation.

From the circumstances just explained, the vital and physical phenomena derive respectively the characters of irregularity and uniformity. Inert fluids are known, when they have once been accurately analyzed; but one, or even many examinations do not inform us of the nature of the living fluids. Chemical analyses give us, says Bichat, the anatomy (Anatomic cadaverique) of them; but their physiology consists in a knowledge of the innumerable variations which they exhibit according to the condition of the respective organs. The urine differs as it is voided after a meal or after sleep; in winter and in summer: the mere passage from a warm to a cold temperature alters its composition; it is not the same in the child, the adult, and the old man; in the male and in the female; in a quiet state of the mind and in the agitation of passion. Add to these differences the innumerable alterations produced by disease. These facts prove that the organs must undergo continual changes in their mode of action, to produce correspondent variations in the substanses separated from the blood.

The science of organized bodies should be treated in a manner entirely different from those, which have inorganic matter for their object. We should employ a different language; finer words transported from the physical sciences to the animal or vegetable economy confantly recall to us ideas not at all connected with the phenomena of that science. If, says Bichat, men had cultivated physiology before natural philosophy, instead of after it, we cannot doubt that they would have discovered numerous applications of the former to the latter; that they would have described rivers flowing by the tonic action of their banks; crystals formed by an excitement of the reciprocal sensibilities of the particles; planets moving by their mutual irritation at great distances, &c. All this would appear to us very unreasonable, and we see gravity only at the bottom of these phenomena: is it more rational to have recourse to gravity, chemical affinity, and a language entirely founded on the fundamental data, in a science where their influence is most obscure? Natural philosophy, chemistry, &c. are connected, because the same laws regulate their phenomena: but a small interval separates them from the science of organized bodies, because a wide difference exists between their laws and those of life. To call physiology the natural philosophy of animals can only lead to inaccurate notions: as well might we denominate astronomy the physiology of the stars.

Differences between the vital properties and those which arise from organization.—The properties of any living organ are of two kinds: the one immediately connected with life, beginning and ending with it, or rather forming its principle and essence; the other connected to it only indirectly, and appearing rather to depend on the organization, on the texture of the part.

Sensibility, and the power of contracting, are vital properties. Extensibility (the capability of being stretched), and the power of recovery, when the extension has ceased, are properties resulting from organization. The latter derive an increased energy from life; but they still remain in the organs when life has ceased, and decomposition is the only termination of their existence. We shall consider first the vital properties.

Of the animal and organic sensibilities.—The vital properties are reduced to those of perceiving or feeling (sensibility), and moving (contractility): each of these has a different character in the animal and organic lives. In the latter, sensibility is only the capability of receiving an impression: in the former, it is the capability of receiving an impression, with the additional power of referring it to a common centre, or consciousness. The viscus is sensible to the presence of food; the heart to that of the blood; and an excursive tube to the contact of its proper fluid: but this power ends in the organ itself. The organs of fission, the mucous surfaces at their origins, the nerves, &c. are sensitive to the impressions of bodies which touch them, and moreover transmit these impressions to the brain, which is the general centre of the sensibilities of these various organs.

Thus we have an organic and an animal sensibility. On the former depend all the phenomena of digestion, circulation, secretion, exhalation, nutrition, &c. it is common to plants and animals: the zoophytes enjoy it as well as the most perfectly organized quadruped. From the latter flow the sensations, perception, and pleasure and pain, which modify them. The perfection of an animal is in proportion to the degree in which he enjoys this sensibility. It is not an attribute of vegetables.

The difference in these two modifications of sentient power is well marked in the mode of their termination in sudden death. The animal sensibility is immediately extinguished. There is no trace of this faculty left in the inanimate which succeeds a powerful concussion of the brain, a great hemorrhage, or an asphyxia; but the organic sensibility still subsists for a longer or shorter time. The lymphatics still absorb the muscle quivers when pricked; the nails and hairs even seem to grow. All traces of this sensibility are not destroyed until after an interval, occasionally of considerable length.
LIFE.

Yet the essential nature of these two powers is probably the same. In many parts they are connected together and succeed each other in an intangible manner; as we may observe in the origins of the mucous membranes. We are senile of the passage of the food through the mouth and the pharynx; this sensation becomes weaker in the beginning of the chest, almost ceases in the middle of that tube, and disappears at its lower extremity and in the stomach, where the organic sensibility alone remains. The urinary and generative organs exhibit exactly the same phenomenon; there is an animal sensibility near the skin; it gradually diminishes, and becomes at last organic in the interior of the organs.

Different stimuli, applied to the same organ, excite in it one or the other of these sensibilities. When ligaments are cut, or irritated by acids or alkalies, they do not transmit to the brain the strong impressions which they receive. But, if they are twisted, distended, or torn, acute pain is the consequence. The blood circulates in the arteries without our feeling it, but inject an extraneous fluid, and the cries of the animal show he is senile to the impression.

We daily observe inflammation, by increasing the organic sensibility of a part, transform it into animal sensibility. Cartilages, serous membranes, &c., which, in their ordinary state, have only the obscure sensibility necessary for their nutrition, become endued, when inflamed, with animal sensibility, often more acute than that of the organs, in which it resides habitually. Inflammation accumulates the vital properties in a part, and thereby changes the organic into animal sensibility, which differs from it only in degree.

The distinction now explained does not arise from the nature of the faculty, which is everywhere the same, but is founded on the different modifications of which it is susceptible. The power is common to all organs, and forms their true vital character; but it is distributed in different proportions, and beffows a different mode of existence on each. In the varieties there is a certain measure, below which the excited organ alone receives and perceives the sensation; and above which it is transmitted to the brain.

Although each organ exhibits continual varieties in its sensibility, yet it seems possible originally a certain proportion, to which it always returns after these alternations of augmentation and diminution. This proportion constitutes the proper life (vita propria) of each part, and fixes the nature of its relations to those bodies, which are foreign to it, but which often come in contact with it. The salivary, pancreatic, and biliary ducts, having a proportion of sensibility exactly analogous to the nature of the fluids which pass through them, admit those readily, but reject all others. The larynx refuses admission to every thing except the air. The excretory tubes are in contact, on the mucous surfaces, with various fluids that pass over these surfaces, but they never allow them admission. In the same way the lacteals, which open on the surface of the intestinal canal, absorb chyle only, and not the fluids which may be mixed with it. These relations do not exist only between the different proportions of sensibility in the organs, and the various animal fluids; they may also take place between external matter and the parts of the animal frame. The particular sensibility of the bladder and kidneys, and of the salivary glands, establishes the relations between these organs and carbonated, mercury, &c.

It may be enquired, why nature, in the distribution of the different proportions of sensibility, has bestowed this property only in inferior degrees on the internal organs, or those of the interior life, while the has so abundantly provided with it the external organs? why, consequently, each organ concerned in digestion, circulation, respiration, nutrition, absorption, does not transmit to the brain the impressions which it receives, while all the acts of the animal life suppose this transmutation? The reason seems to be, that all the phenomena, which establish our relations to surrounding beings, must be, and are in effect, under the influence of the will, while those, which are subordinate to the purposes of suffocation, ought to be exempt from that influence. To make a phenomenon dependent on the will, we must be conscious of it: to exempt it from the influence of that power, this consciousness must not exist.

Of the animal and organic contractions.—Contraction is the most common form of motion in the animal organs. Some indeed move by dilatation, as the iris, conjunctiva ciliata, &c.; but we know as yet too little of this kind of motion, that we shall confine our remarks entirely to the former.

Spontaneous motion, a faculty inherent in living bodies, presents, like sensibility, two great modifications distinct from each other, as we observe it in the phenomena of the two lives: these are the animal and the organic contractions. The former, subject to the will, has its origin in the brain, ceases to exist when the organs no longer communicate with the brain, and participates in all the sensations of that part. It refires exclusively in the voluntary muscles, and precedes over the function of locomotion and the other movements, and the voice. The latter, not dependent on any common centre, has its origin in the part, is not connected with any voluntary acts, and produces the phenomena of digestion, circulation, secretion, &c. Like the corresponding sensibilities, they are essentially distinguished in violent deaths, which suddenly annihilate the animal contractions, allowing the organic fluid to exert itself for a longer or shorter time. The same difference is observed in asphyxia, which so much resembles death: the animal contractions are entirely suspended, the organic still continuing active. In paralysis also, voluntary motion is destroyed, while the organic movements still go on.

These two kinds of contraction are connected to their corresponding species of sensibility. The sensations produced by external objects bring the animal contraction into exercise; and before the organic contraction of the heart takes place, its sensibility has been excited by the contact of blood.

Yet the connection is not the same in the two cases. The animal sensibility may be excited, without the analogous contraction being necessarily brought into action; but the two other powers are never separately exercised. The excretory tubes immediately re-act when the secreted fluids are brought into contact with them: the arrival of blood in the heart is necessarily followed by its contraction. This conjunction is so constant that authors have included both powers in one name. Irritability designates both the sensation excited by the contact of any body, and the contraction of the organ when it re-acts.

There is a very simple reason for this difference. In the organic life nothing intervenes between the two faculties in their exercise; the animal organ is the point at which the stimulation terminates and the contraction begins. In the animal life, on the contrary, the two acts are separated by middle functions, those of the nerves and brain, which, if they are not entered, interrupt the communication. In the same way we explain this further difference; viz. that there is always a strict proportion between the sensation and the contraction in the organic life, while they may be separately excited or diminished in the animal.

Two varieties of the organic contraction. —The animal contractions
but the organic displays two essential modifications, which might seem to indicate a difference of nature, although there is only a diversity of external appearance. Sometimes it may be observed very distinctly, while, on other occasions, although it really exists, inspection alone cannot appreciate it.

Sensible organic contractility may be seen in the heart, stomach, intestines, bladder, &c.; its action is exerted on the animal fluids in considerate masses. It is by virtue of the inelastic organic contractility, that the excretory tubes act on their respective fluids, the secretory organs on the blood which they receive, all parts that are nourished on their nutritive juices, the lymphatics on the substanzes applied to these orifices, &c. Whenever the fluids exist in small masses, where they are minutely divided, this second kind of contractility is developed.

We may illustrate the difference between them, by comparing one to the attraction, which is exerted between large masses of matter, and the other to the chemical affinities, which take place between the component particles of an aggregate. Barthez compares them to the motions of the hands of a watch: that, which marks seconds, moves round the circumference in a very obvious manner; the hour hand moves also, although we cannot perceive its motion.

The sensible organic contractility corresponds nearly to what has been called irritability; the other to the tonic power, or toxicity. These two words are objectionable, because they indicate a diversity of nature in the two properties. The common term which we employ, designates their general character, that of belonging to the internal life, and of being independent of the will; while the additional epithet expresses the peculiar attribute of each. This view of the matter is confirmed by the fact, that the two properties are connected by inelastic gradations. Between the obscure, but real contractility necessary for the nutrition of the hair, nails, &c. and that which we feel exerted in the motions of the intestines, stomach, &c., there are many shades which form the transition; such as the motions of the darts, of the arteries, of some parts of the skin.

The circulation will serve to give us an idea of the gradual transition from one to the other kind of organic contractility. In the heart and large vessels, this function is regulated by the sensible kind; it becomes less and less apparent, in proportion as the diameter of the vessels diminishes; and it is lastly inelastic in the capillaries where toxicity alone is observable.

To consider, with most authors, irritability as a property exclusively belonging to muscles, and constituting a character by which they are distinguished from other organs, and to express this property by a name indicating this exclusive feat, is taking a confused and erroneous view of the matter. The muscles undoubtedly occupy the first rank in this respect; they possess the greatest share of organic contractility. But every living organ acts, like them, though in a less apparent manner, on fluids artificially applied, or on the fluids which it receives, and which bring to it the materials of secretion, nutrition, exhalation, or absorption. Hence nothing can be more uncertain than the rule commonly adopted for deciding whether a part be or be not of a muscular nature; a rule which confides in examining whether it contracts under the action of natural or artificial stimuli. From this mode of judging, a muscular coat has been assigned to the arteries, although their organization is throughout unlike that of the muscles; the uterus has been pronounced to be muscular, although there are great differences between it and any muscles; and a muscular texture has been admitted in the dartos, iris, &c.

This faculty of contraction, like sensibility, is unequally distributed in the organs; and these differences, like those of sensibility, appear to be only differences in degree. If we were to designate any kind of contraction in the muscles by a particular term, it would be their animal, rather than organic contractility; since they alone, of all parts in the body, move under the influence of the brain. This property is foreign to their tissue, and is derived entirely from the latter organ.

The two kinds of contractility cannot be changed, like the two species of sensibility. The organic is never transformed into animal; however its intensity may be increased, it is still of the same nature. The stomach and intestines are often so susceptible, that the slightest cause will produce violent motions; but these are never influenced by the brain.

The extensibility and contractility arising from organization.— These properties depend entirely on the organic arrangement of the parts of the frame. They succeed and are connected to each other, and are in a state of mutual dependence, like the vital phenomena of sensibility and contractility.

The extensibility of tissue, or the power of elongation beyond the ordinary state, from a foreign impulse, belongs in a very sensible manner to a great number of organs. The extensor muscles are remarkably lengthened where the limbs are bent to the greatest degree; the skin gives way and is stretched to envelop tumours; aponenoeus are diffused by fluids accumulated under them, as in ascites and pregnancy. The mucous and serous membranes present analogous phenomena. The fibrous membranes and even the bones are susceptible of this distention; as, for instance, the dura mater, cranium and pericranium in hydrocephalus, the extremities and middle of the long bones in the various affects of those organs; the kidneys, brain, and liver, in abceses of their interior, the spleen and lung when distended with blood, the ligaments in hydrops articular; in a word, all organs, under a thousand circumstances, offer to us innumerable proofs of this property, which is inherent in their tissue, but not dependent on life. It subsists, as long as the organic structure remains, even for a long time after life has been extinct. Pertraction, decomposition, and whatever affects the organic tissue, are the only causes that destroy the exercise of this property, in which the organs are always passive, and experience a mechanical influence from the various bodies which act on them.

We may draw out a scale of extensibility for the different organs. At the top are placed those which have the most softness in the arrangement of their fibres, as the muscles, skin, cellular tissue, &c.; at the bottom those characterized by considerable density, as the bones, cartilages, tendons, nails, &c.

A particular mode of contractility corresponds to this extensibility; it may be called the contractility of tissue, or contractility through the effusion of extension. For its exertion in any organ, it is only necessary that the extension should cease. Ordinarily, most of our organs are maintained in a certain state of tension by particular causes; the locomotive muscles by their antagonists; the hollow muscles, by the various fluids which they enclose; the vessels by the fluids which circulate in them; the skin of one part, by that of the neighbouring organs; the alveoli of the jaws by the teeth, &c. Now, if any of these causes cease to act, contraction immediately takes place; divide a muscle, and its antagonist
antagonift will be shortened; empty a hollow muscular organ, and it will contract; prevent an artery from receiving blood, and it will be converted into a ligament; cut the skin, and the edges of the incision will be drawn asunder; remove a tooth, and the socket will be obliterated.

In all these cases contraction follows the effusion of a natural extension; in other instances it is the effusion of the effusion of an unnatural extension. Thus the abdomen is reduced after parturition or paracentesis; the cellular tisue after the opening of an abcess; the tunica vaginalis after the operation for hydrocele; the skin of the feromum after the removal of a large diseased tillicule; and aseptic wounds after the evacuation of the contained fluid.

This kind of contractility is perfectly independent of life; like the extensibility, it is connected only to the tisue or organic arrangement of parts; but the vital powers bestow on it increased energy; thus a divided muscle retracts much less in the dead than in the living state. It terminates only by the disorganization of the parts from decomposition, &c., and not by the annihilation of their vital properties.

Most authors, as Haller, Blumenbach, Barthéz, &c., have confounded the phenomena of this contractility with those of the organic sensible kind, or tonicity; they refer the reduction of the abdomen after its dilatation, the retraction of the divided skin, and the corrugation of the feromum by cold, and the cripitation of parts by certain poifons, uulcrtics, &c., to the same principle. The two former phenomena belong to the contractility of tisue, which never supposes the application of irritants; the latter to tonicity, which is never exerted without their influence.

In order to render the distinctions, which we have made on this subject, more clear, let us select for observation an organ in which all the kinds of contractility are united; a voluntary muscle for example. This muscle acts, viz., through the influence of the nerves, which it derives from the brain; this is the animal contractility; z.dly, by the application of a chemical or phusical stimulus, which produces in it a general movement analogous to those which naturally belong to the heart and other involuntory muscles; this is the organic sensible contractility or irritability; z.dly, by the arrival of fluids, which convey the materials of nutrition to all its parts, and which excite motion in every fibre and particle—a motion indistinguishable to the function of nutrition, as it is in the glands to secretion, in the lymphatics to absorption, &c.; this is the inensible organic contractility or tonicity; zthly, by the transverse section of its substance, producing retraction of the divided ends towards their points of infection; this is the contractility of tisue. Each of these properties may be separately destroyed in a muscle; divide its nerves and the animal contractility ceases; although the two organic kinds still subsist. Apply opium to it, and it will no longer excite it to motion, although the tonic movements determined by the contact of the blood will remain. Kill the animal, or intercept all the vessels which go to the limb, and the tonic powers will be destroyed, leaving only the contractility of tisue, which does not cease until gangrene or putrefaction, the consequences of destroyed vital action, appear.

This example will enable us to appreiate the different kinds of contractility in organs, where they exist in smaller number than in the voluntary muscles, as in the heart or intestines, which have all the kinds except the animal; in the white organs, as the tendons, aponeuroses, bones, &c., where the inensible organic contractility and that of tisue only are found. In general, the two latter belong to all organs, the former belonging exclusively to some particular ones. We may therefore select tonicity, or inensible organic contractility, as the general charater of all living parts; and the contractility of tisue as the common attribute of all parts, whether living or dead, which are organically composd. The latter property, like the extensibility of tisue, to which it corresponds, has its different degrees; the muscles, skin, cellular tisue, &c., on one part, and the tendons, aponeuroses, and bones, on the other, form the two extremes of the scale.

It will be easily seen, from what we have just said, that in the contractility of any organ two things are to be considerd; viz., the power and the cause which brings that power into exercise. The power or the contractility is always the same, connected to, and inherent in the organ; but the cause which determines its exercise varies greatly, and hence the various kinds of contraction. Consequently, the distinctive epithets should be applied rather to the contraction, which expresses the effect produced, than to the contractility which indicates the principle or cause.

The general result of the preceding remarks on the vital properties, is exhibited in the following table, which presents all these properties in one point of view.

Wherever the vital properties are in activity, a disengagement of caloric takes place, peculiar to the animal, and compoing for it a temperature independent of that of the medium in which it lives. The word caloricity, or calorification, is improper to express this phenomenon, which is a general effect of the two great vital powers in exercise, and does not flow from any particular faculty. We do not say digestibility, respribilhity, &c, because respiration, digestion, and other procees, are the results of functions deduced from the common laws: the production of heat is in the same case. The digestive force of Grimaud is an expression
preliminary equally objectionable. The assimilation of heterogeneous substances to our organs is one of the grand results of sensibility and contrariety, and not a peculiar property. The same observation will apply to the formative power of Blumenbach, that of fixed situation of Barthez, and to the various principles admitted by numerous authors who have attributed to functions, or results, names that indicate laws, or vital properties.

In the article EMBRYO we have given a sketch of the state of the two lives in the fetus: we shall add here a short view of the changes which occur after birth.

A new mode of existence commences as soon as the child has quitted the uterus: various functions are added to the organic life, and the animal, which has not yet begun, comes into exercise, establishing relations, hitherto unknown, between the individual and surrounding objects. While the organs of the internal life act at once in a perfect manner, those of the external require a kind of education, and arrive only by degrees at that perfection which they exhibit in the sequel. The sensations are at first confused, and offer only general images: habit gradually deadens these first impressions, and then the particular sensations come to be distinguished, after long and repeated exercise. Thus a man, introduced for the first time to the magic spectacle of an opera, perceives only a whole which pleases him; and he gradually separates the sources of pleasure arising from the dancing, the music, the decorations, &c.

The education of the mind in this respect resembles that of the senses: all the mental faculties depend on its action acquire very gradually the degree of precision to which they are entitled. Perception, memory, and imagination, which are always preceded and determined by sensation, are enlarged in proportion to their employment. The judgment, of which they are the triple balls, at first associates irregularly notions which are themselves irregular: its exertions are soon distinguished by greater clearness; and they become at last rigorous and precise.

The voice and locomotion present the same phenomena: the cries of young animals confine, at first, of one unformed found, without any distinct character. Age gradually modifies them; and, after repeated exercise, they acquire the characters peculiar to each species. It is unnecessary to mention speech, as that is so evidently the result of education.

The muscles of the newly born animal are in continual action; but progression, or even standing, cannot be effected. Habit must teach the art of connecting together particular contractions for the production of certain effects. Until this period has arrived, there is a vacillation in all the motions, particularly the general ones, which almost deprives the child of the power of locomotion.

It is obvious, then, that we are obliged to learn the art of extending our existence beyond ourselves; that the exterior life acquires fresh development every day, and demands a kind of apprenticeship, which is not observed in the organic life.

Society exercises a remarkable influence on this kind of education which the external organs undergo: it enlarges the sphere of action in some, contracts it in others, and modifies it in all. The occupation in which an individual is habitually employed, almost always exercises one particular organ more than the others. The ear of the musician, the palate of the cook, the brain of the philosopher, the muscles of the dancer, the larynx of the singer, &c., have, besides the general education of the external life, a particular education, which frequent exercise carries to a high degree of perfection. Hence, the musician and painter become able to distinguish in a harmony, or a picture, what escapes vulgar observation. In some instances, this perfection of action in an exercised organ is accompanied by an excess of nutrition, as in the occupations where particular members are exerted greatly and habitually.

It is no less true, that when the organ is continually occupied, the others are inactive, and appear to lose in capacity what the other gains. The philosopher who spends his life in his study, and devotes himself to abstract meditations, condemns his locomotive organs to inactivity, and hence loses the facility of exerting them: the dancer is in the opposite state. The observation of man in society will lead us every moment to similar remarks: perfection of action in the locomotive organs scarcely ever coincides with that of the brain or senses; and vice versa. This observation naturally leads to a fundamental principle of social education; viz. that we should never direct the attention to several studies at once, if we wish to succeed in each; that it is vain for any individual to cultivate various departments of human knowledge and exertion with an expectation of shining in each; and that in general the secret of excelling in any one, is, to be inferior in all the rest. For a more detailed account of these views, which are not, perhaps, strictly physiological, see Bichat, sur la Vie et la Mort, p. 121-130.

When the child quits the womb of the mother, its organic life undergoes a remarkable development; several functions, which did not exist before, are now brought into exercise; and those which had begun become more enlarged. But the organs, in either case, require no education: they exhibit at once a degree of perfection, which those of the animal life arrive at only after frequent exercise. Digestion, respiration, a great part of the exhalations, and absorptions, begin at birth: after the first acts in the respective organs, they proceed with as great facility as they will ever after. The glands, which had been hitherto inactive, or at least had produced a very small quantity of fluid, are excited by various applications to their excretory ducts.

The passage of food over the openings of the salivary ducts, of the tongue over the pancreatic and biliary tubes, &c. stimulates the respective glands. The excretions now also begin: all these phenomena are at once executed with precision, and no education is required in the organs which exhibit them.

As all the organs of the internal life act perfectly at once, none can acquire in the sequel a superiority over the others, as in the animal life. Yet it is common, even here, for one system to predominate over the rest: sometimes the blood-vessels, sometimes the pulmonary systém, sometimes the gastric organs, and particularly the liver, are excited beyond their due proportion, and give a peculiar character to the temperament. But the foundation of these differences seems to be laid in original difference of structure; and the fame is the case where one system is remarkably weak.

"Such, then, concludes Bichat, is the leading difference of the two lives, in respect to the degree of perfection of the various systems of functions of which each consists: in the animal, predominance or inferiority of one system arises from the greater activity or indolence of that system; in the organic, the original conformation is the cause. Hence, the physical temperament and the moral character cannot be changed by education, which has to vail an effect in modifying the animal life. The character, if I may use the expression, is the physiognomy of the passions; the temperament is that of the internal functions: as both are constantly the same, and not influenced by habit and exercise, they cannot be affected by education. That may, indeed, below their perfection on the judgment and reflections, and thus make them more powerful than the passions; it may fortify the animal life, and make it superior to the impulses of the
organ. But to attempt altering the character, softening or exalting the passions, of which it is the habitual expression, or enlarging or contracting their sphere, would be an enter-prise analogous to that of permanently raising or diminishing the extraordinary force of the heart, or accelerating or re-}
cording the motions of the arteries in the state of health. We should inform any person who entertained the latter project, that circulation and respiration are not under the influence of the will, and cannot, therefore, be modified by the individual, without the occurrence of disease. The same observation will apply to those who think they can change the character, and consequently the passions; since the latter are the produce of the actions of all the internal organs, or, at least, are especially feated in them.

For the mode in which the functions escape, the connec-
tions of the animal and organic life to each other, and the reciprocal influences of the heart, brain, and lungs, see

Cuvier, Leçons d'Anatomic comparée, tom. i. Bichat, Recherches Physiologiques sur La Vie et la Mort; and his Anatomic Generale, in the Considerations Generales.

Life of Mind, vita mentis, as contra-distinquiished from life of body, vita corporis, is held, by the Cartesians, to consist in a perpetual cogitation, or uninterrupted course of thinking; which seems likewise to have been Aristotle's meaning, when he calls the soul \textit{dunameis}, which his interpreters call \textit{actus} thinking being the only proper act of the mind. But Mr. Locke endeavours to refute this principle. See \textit{Thinking} and \textit{Soul}.

Life of Man, vita hominis, consists of a continued communication of body and mind; or in operations, to which both the motions of the body and ideas of the mind contribute.

Thus, \textit{e. g.}, the mind now thinking of something, on occasion of that thought there arises a certain motion in the body; and now, again, the body moves itself, which motion is followed by some thought of the mind.

In such alternate or reciprocal operation does the life of man consist; considered, that is, as a compound of body and mind. See \textit{Sensation} and \textit{Motion}.

Life is more particularly used for the duration of an animal's being; or the space of time that passeth between its birth and death.

Life, considered as an object of Law. See \textit{Rights}. See also \textit{Homicide}.

Life-Annuities, are annuities, the payments of which depend on the continuance of any given life or lives, and they may be distinguished into annuities to commence immediately, and annuities to commence at some future period, or reversionary life-annuities.

The value of a life-annuity is properly the sum that will be sufficient to enable a feller (allowing for the chances of mortality) to pay the annuity without loss; and, supposing money to bear no interest, it is always equal to the expectation of the life.

For example:—Observations shew, that according to the \textit{mean} probabilities of the duration of human life, the expectation of a life aged ten is nearly forty years; or, in other words, that a life of lives at this age will, one with another, enjoy forty years each of existence, some of them enjoying a duration as much longer as others enjoy a shorter. It is obvious, therefore, that supposing money to bear no interest, 40l. in hand for each life, would be sufficient to enable a feller to pay to any number of such lives 1l. per annum for their whole duration; or, in other words, that 40l. is, on this supposition, the value of a life aged ten.

But if any improvement is made by putting it out to interest this will be more than the value; because it will be more than sufficient to pay the annuity; and as much more than sufficient as the improvement or interest is greater. If, for instance, any sum now in hand may be so improved, by being put out to interest, at 4 per cent. as to double itself in eighteen years; the feller of such an annuity will (in consequence of putting out half the purchase-money to interest) find himself, at the end of eighteen years, a possessor of 42l. or of 20l. more than is sufficient to pay the remainder of the annuities, though he should make no further improvement of the purchase-money. If he puts out the money to higher interest he will be a greater gainer; if to les, he will be a less gainer; but at any rate of interest he must be a gainer. The truth is, that supposing the interest to be that just mentioned, or 4 per cent. and all the improvement possible made of the money at this interest, he will find 17l. 10s. 6d. for each annuity (instead of 40l.) to be sufficient to enable him to make all his payments. (See the tables at the end of this article.) But that if he improves the money at 5 per cent. he will find 15l. to be sufficient.

It may seem to follow from hence, that we have nothing to do to find the value of a life-annuity, but to find the expectation of the life, and then to take out of the common tables the value of an annuity certain for a term of years equal to the expectation; and it may appear strange that this should give the true value.

The truth is, that it will give the value greater than it is; or that a less sum than that found in this way will be sufficient to pay the annuity. Supposing the interest 4 per cent. the value of an annuity certain for forty years is 19l. 16s. (see Tab. III. ANNUITIES); but the value of a life aged ten, at this rate of interest is, as hath been just said, no more than 17l. 10s. 6d. The principal reason of this is the difference between the value of forty payments of an annuity to be made every year regularly one after another, till in forty years they are all made; and the value of the same number of payments to be made at greater distancies of time from one another, and not to be all made till the end of seventy or eighty years. In this last case there is more time given for the improvement of the purchase-money, and therefore a less sum will be sufficient to enable a feller to make his payments. All that is learned from knowing the expectation of a number of lives, is the mean number of payments that will be made to each of them, and not the time in which they will be made. For example:—The expectation of a life at ten being forty years, it follows that to a hundred lives at this age, forty payments for each life, or four thousand in all, will be made. But, as all the lives will not be extinct in less than seventy or eighty years, many of the payments will not be made till after the expiration of forty years; and therefore, a part of the purchase-money will be improved for a longer time than forty years. In general, it may be observed that \textit{one-half} nearly of the payments of a fet of life-annuities will be made after the expiration of a term of years equal to the expectations of the lives; and that this half having a longer time for accumulation than the expectations of the lives, the value of the lives must be less than the value of annuities to be paid regularly every year for a time equal to the expectations. Thus 1980l. will, in consequence of being improved at 4 per cent. pay a hundred annuities of 1l. for forty years. But a less sum (or 1750l.) will pay a hundred such annuities to a set of lives whose common expectation is forty years; because \textit{one-half} nearly of the payments will not be made till after the end of forty years, and some not till after the end of seventy or eighty years; and consequently \textit{one-half} nearly of the purchase-money will be improved for more than forty years, and some of it for more than seventy or eighty years.

These observations demonstrate, that it is a mistake to reckon the value of a life-annuity the same either with the value of an annuity certain for a term of years equal to the expectation.
LIFE-ANNUITIES.

Expectation of the life; or with the value of an annuity for a term certain, equal to that which a life has an even chance of existing. This is an error into which some have fallen, but it only proves their utter ignorance of the subject.

The true method of computing the values of life-annuities may be explained in the following manner. Let us suppose that the duration of the annuity is to be only one year. That is, that $1l$ is to be paid a year hence, provided a life now of a given age should be then in being. Were it certain that this life would not fail in the year, the value of the annuity would be the fame with the value of it payable a year hence, or with the fund which, now put out to interest, would increase to $1l$ in a year; and this fund, supposing interest at 4 per cent. is $192.3d$. See Tab. II. Annuities.

But the payment not being to be made, should the life happen to fail in the year, this sum ought to be diminished in proportion to the degree of the uncertainty of the life's continuing to exist through the year; and it is easy to see that this uncertainty or chance is in the proportion of the number of persons at that age living at the end of the year, to the number living at the beginning of it, as shown by observations. For example:—if it has been found in any situation that but half the number of persons of the given age living at the beginning of the year, are living at the end of it, the uncertainty will be as half; and the value just mentioned ought to be lessened one-half. If it appears that two-thirds, or nine-tenths, or ninety-nine hundredths, are living at the end of the year, the same value must be diminished only one-third, one-tenth, or one-hundredth. That is, it will be necessary to multiply it by $\frac{1}{3}$, $\frac{9}{10}$, or $\frac{99}{100}$.

Univerally then, the present value of any sum to be paid a year hence, provided a given life should be then existing, is that sum multiplied by the value of $1l$ payable at the end of the year (taken out of Tab. II. under the article Annuities), and also by the fraction formed by making the number of the living at the age of the given life (taken out of the Table of Observations) the denominator, and the number of the living at the next succeeding age (or at the end of the year) the numerator. For example:—let the value be sought of $1l$ payable a year hence, if a child aged ten should be then living, reckoning interest at 4 per cent. The value of $1l$ reckoning this interest, and payable a year hence, is, (as hath been just said) $192.3d.$ or (in decimal parts of a pound), $\frac{9615}{100}$. (See Tab. II. under the article Annuities.)

The number of the living at the age of ten (in Tab. III. at the end of this article) is 5675; and at the next succeeding age (or eleven) is $\frac{5623}{100}$. It follows, therefore, that according to this table, out of 5675 living at the age of ten, only 5623 are living at the end of the year; or, in other words, that the chance or probability of a life aged ten existing through the year is $\frac{5623}{5675}$, which fraction, therefore, multiplied by $\frac{9615}{100}$, gives the value sought, or $\frac{5526}{100}$ equal to 192.6d.

Again, let us suppose that the duration of a life-annuity of $1l$ is to be two years, or that one payment of $1l$ is to be made a year hence, provided a given life should exist a year, and a second payment of the same sum at the end of two years, provided the same life should be in existence at the end of two years. The method of finding the value of the first payment has been already explained; and by the very same reasoning it may be easily discovered, that the value of the second payment must be the value of $1l$ payable at the end of two years, diminished in proportion to the uncertainty that the given life will exist two years; or (which is the same) multiplied by the fraction formed by making the numerator of the living at the given age the denominator, and the number of the living at the next succeeding age but one, or at the end of two years, the numerator.

Thus. Let the value be required of $1l$, payable yearly for two years, provided a child aged ten should live two years, reckoning interest at 4 per cent.

The value of the payment at the end of the first year has been just found to be $\frac{5526}{100}$ in decimal parts of a pound, or 192.6d.

The value of the payment at the end of the second year is the value of $1l$ payable two years hence, lessened by the uncertainty that a life aged ten will live two years; or in the proportion of the number of the living in the Table of Observations at the age of twelve to the number of the living at the age of ten. That is, it is $\frac{5245}{100}$ the said value of $1l$, payable at the end of two years, taken out of Tab II. under the article Annuities) multiplied by the fraction $\frac{5575}{5626}$ or $\frac{575}{5978}$, equal to 182.2d. (See Tab III. at the end of this article.) To this, add the former value, or $\frac{5245}{100}$ and the total, or 18604d. will be the value of both payments, or of an annuity of $1l$ on a life aged ten for two years.

By proceeding in this way it will appear that the value of the same annuity for three years is $\frac{5526}{100} \times 18604d.$ = 2735l. and for eighty-six years (or the whole duration of life, according to the Table of Observations) 175238l.

It is evident, that in the same method the value of an annuity of $1l$ on a life at any other age is to be found; and that supposing the annuity any other sum than $1l$, its value will be this sum multiplied by the value of an annuity of $1l$.

The calculations of the values of life-annuities may be otherwise explained in the following manner. Suppose a life-annuity of $1l$ payable yearly to every one of 5075 persons, all now aged ten, the first payment of which is to be made a year hence. It appears from the Northampton Table of Observations (or Table III. under the article Expectation), that only 5623 of these persons will be living at the end of the year; and consequently, that the money then to be paid will be only 5623l. The present value, therefore, of the first payment of the annuities will be the sum which being now put out to interest will increase in a year to 5623l. That is, it is 5623l. discounted for a year, or $\frac{5406}{100}$. or $\frac{5675}{100}$. for this sum added to its interest for a year (reckoned at 4 per cent.) will just make up 5623l. From the same Table of Observations, it appears further, that of 5675 persons living at ten years of age, only 5575 will be living at the end of two years. The present value, therefore, of the second payment of the annuities will be the sum, which being now put out to compound interest at 4 per cent. will increase to 5573l. in two years. The sum is $\frac{5152}{100}$ or $\frac{5473}{100}$ or $\frac{5423}{100}$ &c. being the number living at the end of three, four, five, &c. years, the value of the third, fourth, fifth, &c. payments of the annuities will be $\frac{5523}{100}$. $\frac{5473}{100}$. &c. discounted for three, four, five, &c. years respectively, and continued to the year in which all the lives became extinct. The total of all these values is 5915l. which, therefore, is the sum that would be sufficient, if improved at 4 per cent., to make good the payment of an annuity for life to every one of 5675 persons aged ten, according to the Northampton Table of Observations. The value, therefore, of such annuity payable to only one of this number, must be the 5675th part of 99443l. or 17l. 10s. 6d.
LIFE-ANNUITIES.

In the Table of Observations, from which the examples here given have been taken, and also in the tables framed by Dr. Halley, from the bills of mortality at Breslaw in Silesia, it may be observed, that the numbers dying every year out of a given number born, continue in the middle stages of life nearly the same for many years together. It was this circumstance that led M. De Moivre to form his hypothesis of an equal decrement of life through all its stages after ten. In this hypothesis, the limit or utmost probable extent of life is fixed to the age of eighty-six; and out of any number living at a given age an equal number is reckoned to die every year, till at eighty-six all the lives become extinct. Thus, for instance, if there are seventy-six persons living at ten, one of them by this hypothesis will die annually during the term of seventy-six years, at the end of which time the last surviving life will have failed. Or, in other words, seventy-five will be living at the end of the first year, seventy-four at the end of the second year, seventy-three at the end of the third year, and so on for seventy-six years; from whence it follows that the probability of one person's living to the end of the first, second, or third year will be \( \frac{75}{76}, \frac{74}{76}, \frac{73}{76}, \) &c. respectively, where it appears that the fractions, and consequently the probabilities they express, decrease arithmetically. The number of years which a life wants of the age of eighty-six is in this hypothesis called the complement of the life, and half this complement is always the expectation of the life. That is, according to what has been already said, it is the number of years which one with another form a set of lives at that age will exist; or, as the writers on this subject sometimes speak, it is the share of life due to each of them.

It is extremely easy to calculate the values of life-annuities on this hypothesis. For by what has been just said, the value of an annuity on a life aged ten, is the sum of the series

\[
\frac{75}{76} \times .0615 + \frac{74}{76} \times .0245 + \frac{73}{76} \times .0859 + \text{etc.}
\]

This series is continued

\[
\frac{1}{76} \times .0527 + \frac{1}{76} \times .0615 + \frac{1}{76} \times .0245 + \text{etc.}
\]

and is equal to the perpetuity, and \( \frac{1}{r-1} = \frac{1}{r-1} \) is equal to an annuity certain for \( n \) years, therefore we have the following rule:

"Find in Table III, under Annuities, the value of an annuity of \( 1l. \) certain for a number of years equal to the complement. Multiply this value by the perpetuity increased by unity, and divide the product by the complement. The quotient subtracted from the perpetuity will be the value."  

The complement in the present case being 76, the value of an annuity for 76 years being (see Tab. III. Annuities) 23.7311, and the perpetuity 25, the value of a life aged 10, will come out 16.884. In the same manner may the value of a life at any other age be computed according to this hypothesis: and these values are the same with those in M. De Moivre's table of the values of lives.

But it is a necessary observation, that in the first and last stages of life, this hypothesis differs too much from fact; which may be easily seen, by comparing it with the following tables of the probabilities of human life. It had better therefore be entirely rejected from the doctrine of annuities, especially as we are now furnished with correct tables, deduced from real observations, of the values both of single and joint lives. The labour and difficulty of forming such tables are also greatly lessened by means of an easy theorem given by Mr. Simpson in his book on the Doctrine of Annuities; and since by Dr. Price in his Treatise on Reversionary Payments. We shall here give the explanation and proof of this theorem from Mr. Morgan's Treatise on Annuities and Assurances, chap, ii. § 2. p. 56.

"Were it certain that a person of a given age would live to the end of a year, the value of an annuity of \( 1l. \) on such a life would be the present sum which would increase in a year to the value of a life one year older, together with the value of the payment of \( 1l. \) to be made at the end of a year; that is, it would be \( 1l. \) together with the value of a life aged one year older than the given life, multiplied by the value of \( 1l. \) payable at the end of a year. Call the value of a life one year older than the given life \( N, \) and the value of \( 1l. \) payable at the end of a year \( \frac{1}{r}; \) then will the value of an annuity on the given life, on the supposition of a certainty that it will exist a year, be \( \frac{1}{r} + \frac{1}{r} \times N. \) But the fact is, that it is uncertain whether the given life will exist to the end of the year. This last value, therefore, must be diminished in the proportion of this uncertainty; that is, it must be multiplied by the probability that the given life will survive one year, which supposing \( \frac{b}{a} \) to express this probability, will make it \( \frac{b}{ar} \times \frac{1}{1 + N}. \"

The great utility of this theorem will appear from the following examples. Suppose the probabilities of life as they are given in the third of the following tables, or the tables of observations for Northampton, and the rate of interest 4 per cent., or \( r = 1.04. \) By reasoning in the manner already explained, the value of a life aged 95 will be expressed by the single fraction \( \frac{4}{9} \times .0615 = .2403. \) The value of a life one year younger, will, by this theorem, be \( \frac{4}{9} \times 1.04 \times 1 + .2403 = .5300. \) The value of a life two years younger, by the same theorem, will be \( \frac{2}{10} \times 1.04 \times 1 + .5300 = .8270. \) The value of a life three years younger, or at the age of 92, will be \( \frac{16}{24} \times 1.04 \times 1 + .8270 = 1.171. \) If we proceed in this manner, the value of every younger life will be deduced from that next preceding; nor will the number of multiplications necessary to determine the values (agreeably to any table of observations) of all lives, at all ages, much exceed the number of those which must otherwise have been used for finding the single value of the youngest life. See Table VI.

Mr. Morgan, after having given this account of the foregoing
LIFE-ANNUITIES.

The going theorem, and explained the method of verifying all the operations in proceeding by it from one life to another, applies the theorem to the calculation of the values of joint lives, and gives a similar method of verifying all those operations.

But instead of following him in this, we shall resume our account of the general principles on which the values of life-annuities are calculated. We have already explained these, as far as annuities on single lives are concerned. From the same principles the method of finding the value of annuities on the joint continuance of any two lives, may be understood.

Suppose the ages of two persons to be 50 and 60. It appears in Table III. that of 2857 persons living at 50, only 1776 will live to be 51; or in other words, that the probability that a person at this age will live a year, is \( \frac{2776}{2857} \). Also, it appears from the same table, that the probability that a person aged 60 will live to 61, is \( \frac{1956}{2038} \).

The probability, therefore, that they will both live a year, (or the former to be 51, and the latter 61,) is the product of these two probabilities, or \( \frac{2776}{2857} \times \frac{1956}{2038} = \frac{549856}{582266} \).

For it is well known, that the probability that any two independent events will both happen, is always the product arising from multiplying the probability of one event by the probability of the other.

In like manner, the probability that the former of these lives will live to be 52, 53, 54, &c. and the latter to be 62, 63, 64, &c. or that they will both live two, three, four, &c. years, is by the same table \( \frac{2694}{2857} \times \frac{1974}{2038} \). And according to the reasoning already used, if these probabilities multiplied by the values (in Table II. ANNUITIES) of \( n \) payable at the end of one, two, three, four, &c. years, will give the present value of the first, second, third, fourth, &c. payments of an annuity dependent, on the joint continuance of the two lives; and the sum of these products for one, two, three, four, &c. years, will be the value of an annuity of \( 1 \) on the joint continuance of the two lives for one, two, three, four, &c. years; and if the products are continued to the extremity of the oldest life, their sum will be the value of an annuity on the whole duration of the joint lives.

The values of annuities on the joint continuance of three, or any other number of lives, are found in a similar manner. The several fractions expressing the respective probabilities of their continuing one, two, three, four, &c. years, being multiplied into one another, and also into \( 1 \) discounted as before; and the sum of the products arising from these multiplications continued to one, two, three, four, &c. years, or to the extremity of the oldest of the lives, will be the value of the annuity for one, two, three, four, &c. years, or for the whole duration of the joint lives.

With respect to annuities on the longe of any number of lives, the reasoning is not so simple. The following explanation, however, of the method of determining their values, when only two lives are concerned, will be easily understood.

Suppose the ages of the two persons to be 50 and 60; and for the sake of more perspicuity, let \( a, b, c, d, e, \) &c. be the number of persons living in the table at the age of the younger life, at the beginning of the first, second, third, &c. years; and, in like manner, let \( m, n, o, p, \) &c. be the number of persons living in the table at the age of the older life. From what has been already observed, the chances of the younger life's surviving the first, second, third, &c. year, will be \( \frac{b}{m}, \frac{c}{m}, \frac{d}{m}, \) &c.; and the chances of the older life's surviving those years respectively will be \( \frac{n}{m}, \frac{o}{m}, \frac{p}{m}, \) &c.; and the chances that they will not survive the first, second, third, &c. years, will be \( 1 - \frac{b}{m}, 1 - \frac{c}{m}, 1 - \frac{d}{m}, \) &c. and \( 1 - \frac{n}{m}, 1 - \frac{o}{m}, 1 - \frac{p}{m}, \) &c.

The chance, therefore, that both will die in the first year will be \( 1 - \frac{b}{m} \times 1 - \frac{n}{m} = 1 - \frac{b}{m} - \frac{n}{m} + \frac{b n}{m^2} \) that both will die in the second year \( 1 - \frac{c}{m} \times 1 - \frac{o}{m} = 1 - \frac{c}{m} - \frac{o}{m} + \frac{c o}{m^2} \) and so on for the other years.

If each of these expressions be subtracted from unity, we shall have \( \frac{b}{m} + \frac{n}{m} - \frac{b n}{m^2} \) for the chance that they will not both die, &c., that is, that one or other of them will live to the end of the first year, \( \frac{c}{m} + \frac{o}{m} - \frac{c o}{m^2} \) for the chance that they will not both die in two years, &c. By continuing these expressions for as many years as are equal to the difference between the age of the younger life and of the oldest life in the table, and multiplying them respectively into \( 1 \) discounted for one, two, three, &c. years, we shall have the whole value of an annuity on the longevity of the two lives.

Let \( \frac{1}{r}, \frac{1}{r}, \frac{1}{r}, \) be \( 1 \) discounted for one, two, three, &c. years, and the series expressing the annuity will be \( \frac{b}{a r} + \frac{c}{a r^2} + \frac{d}{a r^3} + \&c. \) &c.

\[ \frac{b n}{a m r^2} - \frac{c o}{a m r^3} - \frac{d p}{a m r^4} - \&c. \]

But the first of these series is the value of an annuity of \( 1 \) on the younger life, the second the value of the like annuity on the older life, and the third the value of the sum of the two joint lives: whence it follows, that if \( 1 \) from the sum of the values of the two single lives we subtract the value of the two joint lives, the remainder will be the value of an annuity on the longevity of the two lives.

Example.—Let the ages of the two lives be 20 and 30, and let interest be reckoned at \( 4\% \) per cent. The value by Table VI. of a life of 20 is \( 1663 \), and of a life of 50 is \( 113873 \). The sum of these two values is \( 30814 \). The value of the joint lives by Table IX. is \( 113873 \); and this value subtracted from \( 30814 \), leaves \( 18941 \) for the value of an annuity on the longevity of the two lives.

This account leads to an easy explanation of the method of finding the value of reversionary life-annuities mentioned at the beginning of this article, that is, of life-annuities which are to commence on the survivorship of one or more lives beyond others. See REVERSIONS and SURVIVORSHIPS.

Problem I.—To approximate to the value of a given life according to any given table of observations.

Solution.—Take the difference between twice the expectation...
tion of the given life by the given table, and $6$; and the
value deduced from M. De Moivre's Table of the values of
lives corresponding to that difference, provided it is not less
than ten, will be the value of the life.

Example.—The expectation of a life aged 15 is, by the
Northampton Table of Observations, (or Table IV. under
the article Expectation,) $361$. The difference between
twice this number and $86$ is $13$. And the value cor-
responding to the age of $13$ in M. De Moivre's Table of
the values of lives (or Table IV.) is $10.503$, reckoning
interest at $4$ per cent.; and this is nearly the value of a life
aged $15$, by the Northampton Table.

Scholium.—It must be remembered that this rule is only an
approximation, and should not be used except when records
cannot be had to tables giving the values of lives agreeable
to given observations. The method of calculating such
tables has been before particularly explained.

Problem II.—To determine the value of any two joint
lives by M. De Moivre's hypothesis, or on the supposition
of an equal decrement of life, through all its stages.

Solution.—This value is expressed by the series

$$\frac{n-1}{n} \cdot \frac{m-1}{m} + \frac{n-2}{nm} + \frac{m-2}{nm} + \frac{n-3}{nm} + \cdots \cdots (m)$$

is to be the complement of the younger, and $m$ the com-
plement of the older life, which Mr. Simpson has given in his
Treatise Annuities, and Mr. Morgan in his edition of
Dr. Price's Treatise on Reversionary Payments, note L
appendix, has demonstrated to be $V - \frac{V+1}{n}$

\[ n - m - 2V - 1 \times \frac{p}{m} = 2, V \text{ being the perpetuity,} \]

and $p$ the value of an annuity certain for $m$ years. From
this theorem may be deduced the following rule. Refere
the difference between the complement of the young life
and the complement of the old life increased by unity and
by twice the perpetuity. Multiply this difference by the
value of an annuity certain for a time equal to the comple-
ment of the old life; and by this complement divide the
product, referring the quotient. From twice the perpetuity
subtract the referred quotient, and multiply the remainder
by the perpetuity increased by unity. This last product
divided by the complement of the young life, and then
subtracted from the perpetuity, will be the required value.

Example.—Let the joint lives be $10$ and $15$. Their
complements by M. De Moivre's hypothesis are $76$ and $71$.
The complement of the old life, increased by unity and
twice the perpetuity, (or twice $25$, reckoning interest at
$4$ per cent.) is $122$; which divided by $76$, the comple-
ment of the youngest life, leaves $40$ for the referred difference.
This difference multiplied by $23.456$, (the value of an an-
nuity certain for $71$ years, by Table III. Annuities),
and the product divided by $71$, (the complement of the
old life,) gives $15.109$, the quotient to be referred;
which subtracted from double the perpetuity (or from $50$),
and the remainder (or $34.890$) multiplied by the perpetuity
increased by unity (or by $26$), gives $904.878$; which di-
vided by $76$ (the complement of the young life), and the
quotient subtracted from the perpetuity, we have $13.063$ for
the value of two joint lives aged $10$ to $15$, by M. De
Moivre's hypothesis.

By this rule, Table V. in the following collection of
tables, was computed by Dr. Price. (See his Treatise on
Reversionary Payments.) To this he was induced by the
consideration, that there was no table extant at that time of
the values of joint lives, except Mr. Simpson's for London,
(Table III. in this collection,) which being founded on the
rate of human mortality in one of the worst of all situations,
or among the inhabitants of London taken in the gros,
was by no means fitted for general use. The truth also is,
as hath been before observed, that neither do the tables
formed from M. De Moivre's hypothesis give the values of
single and joint lives with the exactness necessary to adapt
them properly to general use; nor can it indeed be ever nec-
necessary to have recourse to them, as we are now possesse-
of tables, deduced from real observations, which are in-
ferior to the end of this collection.

Problem III.—To determine the value of an annuity on a
given life for any number of years.

Solution.—Find the value of a life as many years older
than the given life as are equal to the term for which the
annuity is proposed. Multiply this value by $1/10$, payable
at the end of this term, and also by the probability that
the life will continue to live. Subtract the product from
the present value of the life; and the remainder multiplied
by the annuity will be the answer.

Example.—Let the annuity be $10/10$, the rate of interest
$4$ per cent., the age of the given life $30$ years, and
the term proposed $15$ years. The value of a life aged $45$
(or $15$ years older than the given life) appears by Table VI.
to be $12.829$. The value of $1/10$, payable at the end of
$15$ years (by Table II. under Annuities) is $5.5553$, and
the probability that the life will exist to live is (by
Table III. under the article Expectation) $3243$. These
three quantities multiplied into each other are equal to
$5.051$, which being subtracted from $14.781$, (the per-
net value of the given life by Table VI.) we have $9.730$; and
this remainder multiplied into $10$ (the annuity) gives
$97.30$, for the value required.

Problem IV.—To approximate to the value of an annuity
for three joint lives, $A$, $B$, and $C$.

Solution.—Let $A$ be the youngest, and $C$ the oldest of
the three proposed lives. Take the value of the two joint
lives $B$ and $C$, and find the age of a single life $D$ of the
same value. Then find the value of the joint lives $A$ and $D$,
which will be the answer.

Example.—Let the three given ages be $20$, $30$, and $60$.
The value, reckoning interest at $4$ per cent., of the two
joint lives $B$ and $C$ (by Table XIII.) is $7.802$, an-
fwering nearly to a single life $D$ of $65$ years (by Table VI.);
and the value of the joint lives $A$ and $D$ (by Table XVI.)
is $6.968$, which will be the value required.

This rule was first given by Mr. Simpson in his Select
Exercises; and the following comparison, taken from Dr.
Price's Treatise on Reversionary Payments, will shew its
correctness.

Problem V.—To find the value of an annuity on the
longest of three lives, $A$, $B$, and $C$.

Solution.—Let $a$, $b$, $c$, $d$, &c. be the number of perons
living in the table at the age of $A_1$, at the beginning of the
first, second, third, &c. years; $m$, $n$, $o$, &c. the same
numbers at the age of $B$; and $t_1$, $t_2$, $t_3$, &c. the like
numbers at the age of $C$, the older of the three lives. By
reasoning as in the case of the longest of two lives, the
probability that $A$, $B$, and $C$ will die in one, two, three, &c.
years, will be
\[
\frac{1}{a} - \frac{b}{m} \times \frac{1}{n} - \frac{c}{r} - \ldots - \frac{1}{t}
\]
and
\[
\frac{b}{a} + \frac{c}{m} + \frac{d}{r} + \ldots + \frac{1}{t}.
\]

The sum of these three values are respectively equal to $AB - ABC$, $AC - ABC$, and $BC - ABC$. (See article Reversions.) Consequendy
the whole value will be $AB + AC + BC = 2AB$; therefore
find the value of each pair of joint lives, viz. of $A$ and $B$, of $A$ and $C$, and of $B$ and $C$. Then from
the sum of these three values let twice the value of the three
lives, $A$, $B$, and $C$, be deducted, and the remainder
will be the answer.

Example.—Let the ages of $A$, $B$, and $C$ be 20, 30, and 60. By Tables IX. and XIII. the value of the joint lives,

\[
\begin{align*}
A, B & \{ 11.873 \\
A, C & \{ 7.995 \\
B, C & \{ 7.822
\end{align*}
\]

the sum of which three numbers is 27.690. Moreover, the
value of the three joint lives, $A$, $B$, and $C$, by problem V
is 6.996; therefore $13.693$ is the value required.

See on this subject Simpson’s Doctrine of Life Annuities,
Dr. Price’s Treatise on Reversionary Payments, Mr. Baron
Maferes on Life Annuities, and Mr. Morgan on the
Doctrine of Life Annuities and Assurances.

Table I.

Shewing the probabilities of the duration of life, as deduced
by Dr. Halley from observations on the bills of mor-
tality at Breflau in Sileia.

</table>

Then, \( Y = P \times \frac{1 + \frac{r}{n}}{\frac{n}{r}} \times y \)

\( H = P \times \frac{1 + \frac{r}{n}}{\frac{n}{r}} \times b \)

\( Q = P \times \frac{m}{n} \times q \)

\( M = P \times \frac{m}{n} \times r \)

Example. — Let the life supposed be the age of 36. The complement of such a life is (by what has been already said) 50, according to M. De Moivre's hypothesis; therefore, \( n \) will be 50. Let the rate of interest be 4 per cent., or \( r = 0.04 \), \( P = 25 \), \( Y = 21.482 \) (see Table III. Annuities), \( k = 21.5499 \) (by the theorem given under Annuities), \( q = 21.582 \), by the same theorem, and \( m = 21.610 \). Therefore,

\( Y = 25 \times \frac{1.04}{50 \times 0.04} \times 21.482 = 13.829 \)

\( H = 25 \times \frac{1.02}{50 \times 0.04} \times 21.049 = 14.010 \)

\( Q = 25 \times \frac{1.01}{50 \times 0.04} \times 21.582 = 14.101 \)

\( M = 25 \times \frac{1.01}{50 \times 0.04} \times 21.610 = 14.191 \)

These theorems, though founded on the hypothesis of an equal decrement of life, give the differences between the yearly,
LIFE

yearly, half-yearly, and quarterly values, almost exactly the
same, whether those values be deduced from real observations
or from this hypothesis.

For determining the differences between the values of
annuities on two joint lives, when payable half-yearly,
quarterly, or quarterly, Mr. Morgan, in the 6th edition of
Dr. Price's Treatise on Reversionary Payments, (note L,
appendix,) has given the following theorems. Let \( b, m, n, \)
denote the same quantities as above for \( t \) years. Let \( n \) be
the complement of the younger, and \( r \) the complement of
the older life. Let \( s \) also be the interest of \( l \) for a year,
and \( V \) the perpetuity: then will the value of the annuity be

\[
V = \frac{V + \frac{1}{n} \times n - t - \frac{1}{2} - 2V \times \frac{b}{t} + 2V, \text{ or } V-
\]

\[
\frac{V + \frac{1}{n} \times n - t - \frac{1}{2} - 2V \times \frac{b}{t} + 2V, \text{ or } V-
\]

\[
\times n - t - 2V \times \frac{m}{t} + 4V, \text{ according as it is payable}
\]

half-yearly, quarterly, or momentarily.

Thus, if the ages of the two lives be 20 and 36 years,
the value of the annuity at \( \frac{1}{4} \) per cent., when payable
yearly, may be found by the theorem in the preceding
article to be equal to 11.227; and its value, when payable
either half-yearly, quarterly, or momentarily, may be found
by these theorems to be either 11.427, 11.565, or 11.629.
If the ages of both lives be 36, these values respectively
will be 10.994, 10.600, 10.703, and 10.808. It may be
observed, that the differences between the values of two
joint lives are always greater than the differences between
the values of the single lives, when payable at shorter in-
tervals than a year; and therefore, that the addition, in this
case, to be made to the value of an annuity on the longest of
two lives will be less than the addition to be made either to
the joint or single lives.

LIFE-Annuites secured by land, differ from other life-an-
nuities only in the single circumstance, that the annuitant,
whenever he dies, is entitled to a payment for the time which
has lapsed between the payment last due, and the moment of
his death; whereas other annuities fappose nothing due for
this time. In order to obtain the value of such an annuity,

\[
\frac{V}{2n} \text{ must be added to the expression in the first theorem, if it is}
\]

is payable yearly; \( \frac{V}{4n} \) must be added to the expression in the
second theorem, if it is payable half-yearly; and \( \frac{V}{bn} \)
be added to the expression in the third theorem, if the an-
nuity is payable quarterly. For since \( \frac{1}{n} \) is the proba-
ability that a life, whose complement is \( n, \) fails in any year of
its duration, and it is an equal chance whether more or less than
half the yearly, half-yearly, or quarterly payment is due at
the death of the annuitant, it follows that the additional
value of the annuity will be either \( \frac{1}{n} \times \frac{V}{2}, \text{ or } \frac{1}{n} \times \frac{V}{2} \times
\]

\[
\frac{b}{2}, \text{ or } 1 \times \frac{1}{2} \times \frac{q}{2}, \text{ according as the payment is payable}
\]

either yearly, half-yearly, or quarterly. See Dr.
Price's Esay, before quoted.

The value, therefore, in the last example, of an annuity
payable yearly on a life aged 36, being 13.829; its value,
Vol. XX.

if secured by land, or to be enjoyed to the last moment
of life, will be \( 13.829 + \frac{21.549}{100} = 14.043 \); if secured by
land, and payable half-yearly, its value will be \( 14.010 +
\frac{21.549}{200} = 14.117 \); if secured by land, and payable quar-
terly, its value will be \( 14.101 + \frac{21.583}{400} = 14.155 \).

LIFE-Annuites, in the contemplation of Law, are, in
some cases, hold and purchased in an improvident manner,
and with great privacy; and therefore, in order to throw
some check on transactions of this kind, the statute 17 Geo.
III. c. 26 has directed, that upon the sale of any life-annuity
of more than the value of 10L per annum, (unless on a suffi-
cient pledge of lands in fee-simple, or flock in the public funds,) the
true consideration, which shall be in money only, shall be
set forth and described in the security itself; and a memo-
ral of the date of the security, of the names of the parties,
executor que trufis, executor que vice, and witnesses, and of the
consideration money, shall, within 21 days after its execution,
be enrolled in the court of chancery, else the security shall
be null and void; and in case of collusive practices respect-
ning the consideration, the court, in which any action is
brought, or judgment obtained upon such collusive security,
may order the same to be annulled; and the judgment, if
any, to be vacated; and also all contracts for the purchase of
annuities from infants shall remain utterly void, and be
incapable of confirmation after such infants arrive to the age
of maturity. By 29 Geo. III. c. 41, § 27, and other acts
that respect life-annuites, oath of an annuitant's life may be
made before a justice of the peace, who shall give a certificate
thereof, without fee or stamp-duty, in order to entitle such
person to receive his annuity.

LIFE-Boat. See BOAT.

LIFE-Complement of. See COMPLEMENT.

LIFE-Estates, in Law, are such estates of freehold as are
only for life. (See ESTATE.) Of these some are con-
ventional, and others merely legal. Estates for life of the first
kind, expressly created by deed or grant, are where a lease is
made of lands or tenements to a man to hold for the term of his
own life, or that of any other person, or for more lives than
one; in any of which cases he is styled tenant for life; only
when he holds the estate by the life of another, he is usually
called tenant for another vie. These estates for life are like i-
heritances, of a feudal nature; and for some time were the
highest estate that any man could have in a feud, which was
not in its original hereditary. They are given or conferred
by the same feudal rights and solemnities, the same invi-
lence or livery of seisin, as fees themselves are; and they are
held by fealty, if demanded, and such conventional rents and
services, as the lord or lessor, and his tenant or lessee, have
agreed on. Estates for life may be created, not only by
express words, but also by a general grant, without
binding or limiting any specific estate. As if we grant
to A. B. the manor of Dale, this makes him tenant for
life. (Co. Litt. 41.) Such estates for life will, generally
speaking, endure as long as the life for which they are
granted; but there are some estates for life, which may de-
termine upon future contingencies, before the life for which
they are created expires; as an estate granted to a woman
during her widowhood, or to a man till he be promoted to
a benefice. These, while they subsist, are reckoned estates
for life; because the time for which they will endure being
uncertain, they may by possibility last for life, if the con-
tingencies upon which they determine do not sooner happen.

5 A
The

Life.

inhabitants to an effate for life are principally the following; and they are applicable not only to that species of tenants for life which are expressly created by deed, but also to those which are created by act or operation of law.

1. Every tenant for life, unless restrained by covenant or agreement, may of common right take upon the land, demised to him reasonabe dflowers, or botes. (Co. Litt. 43.) But he is not permitted to cut down timber or do other waste upon the premises. (Id. 53.) 2. Tenant for life, or his representatives, shall not be prejudiced by any sudden determination of his estate, because such a determination is contingent and uncertain. (Ibid. 55.) The advantages also of emblements are particularly extended to the parochial clergy by Stat. 25 Hen. VIII. c. 11. 3. Another incident to estates for life relates to the under-tenants, or lesees. For they have the name, and greater indulgences than their lessors, the original tenants for life.

The second estate for life is of the legal kind, as contradistinguished from conventional; viz. that of tenant “in tail after possibility of issue extinct.” This happens where one is tenant in special tail, and a person, from whose body the issue was to spring, dies without issue; or, having left issue, that issue becomes extinct; in either of these cases, the surviving tenant in special tail becomes tenant in tail after possibility of issue extinct. This estate must be created by the act of God: that is, by the death of that person out of whose body the issue was to spring; for no limitation, conveyance, or other human act can make it. A possibility of issue is always supposed to exist in law, unless extinguished by the death of the parties; even though the issue be each of them 100 years old. (Litt. § 54. Co. Litt. 28.) This estate is of an amphibious nature, partitioning partly of an estate-tail, and partly of an estate for life. In truth, the tenant is only tenant for life, but with many of the privileges of a tenant in tail, as not to be punishable for waste, &c. (Co. Litt. 27.) Or, he is tenant in tail, with many of the restrictions of a tenant for life; as, to forfeit his estate if he alienate it in fee-simple (Ibid. 28.); whereas such alienation by tenant in tail, though voidable by the issue, is no forfeiture of the estate to the receiver; who is not concerned in interest, till all possibility of issue be extinct. But, in general, the law looks upon this estate as equivalent to an estate for life only; and, as such, will permit this tenant to exchange his estate with a tenant for life: which exchange can only be made of estates that are equal in their nature. (Blackl. Com. b. ii.) See Lease and Tenant.

Life, Expectation of. See Expectation.

Life-everlasting, a name by which the Ichthyom, or Gaphalium of botanical writers, is sometimes called. See Cudweed.

Life Guards. See Guards.

Life Preserver, against drowning. Many different articles under this denomination have been made, particularly within these few years, by Collins, Spencer, Daniels, and others. But we believe they have all been copied, in a greater or less degree, from an apparatus constructed by John Bentley, esq. about the year 1707. It is however remarkable, that although he exhibited it in public several times, some very important parts of it seem to have escaped their notice, or at least their application of them to their own purposes. The following is his account of it.

The human body in most inundations is of the same specific gravity as water; therefore, any substance which is lighter than water, being attached to the body, must cause it to float. The situation best adapted for fixing it is round the body, immediately under the arms; and as it is desirable to able to keep the head, neck, shoulders, and arms above water without any exertion, the article used must displace a bulk of water equal in weight to these parts. The next thing to be attended to, is to enable a person who cannot swim to make progress through the water. The hands and feet are too narrow to accomplish this without a knowledge of the art of swimming, therefore the fingers and feet must be artificially webbed. Thus the whole apparatus, which he calls a nautilus, consists of three distinct parts, and are to be thus constructed.

The buoyant is made of copper, in the form of a tube, to fit the round of the body, about six inches diameter, the seam brazed with hard solder. It should be made in three lengths, the ends quite flat, to fit each other exactly, so that, when put together, they form a ring or belt. This is in case of accident happening to one part by leaking, that it may not extend to the other two, which will be sufficient to prevent sinking. Each of these parts is sewed up in baiine, with three strong tapes near the end of each piece, by which all of them are securely tied together. A flexible pipe, of the thickefs of a quill, is inserted in each piece, from the upper side to the bottom, so that if any leakage happens, the water is readily drawn out by the mouth and discharged. The buoyant, thus prepared, must be securely tied with strong tapes, cross-rod and over the shoulders, to prevent it getting down. It cannot get over the arms. When it is thus fixed, the body will, by its own gravity, be carried in the water, with the feet downwards, and will always retain this position unless force is applied to alter it, and which it will again recover when the force ceases to act. The second part, which is for the hands, is a pair of oil skin gloves, which, after being made to the usual way, the fingers are opened to their full extent breadthwise, and a piece of the same material sewed over them on the under side. Tapes are sewed at the top to tie them round the wrist.

The third part, being for the feet, is made thus: take a piece of half-inch wainscot or mahogany, 11 inches long, and 10 inches wide. Cut it longitudinally into three pieces, two of them 3 1/4 inches broad, and the other 2 1/4 inches. Fasten them well together with two pairs of brass hinges, and rule joints to fall and rise like a two-leaved table, the narrow piece being in the middle. On the under-side of the middle-piece, in the centre, a wooden turn buckle must be screwed to prevent the side-pieces from falling down, when walking to or from the water. Two wooden stops are fixed upon this piece as to prevent the sides, when down, coming to a right angle with the middle-piece, that the rising and falling may be duly performed with the action of the feet. To the upper side of the middle-piece, a common leather lace, (to fit the person) must be fastened on with two screws through the sole, and near each end of this middle-piece two small holes are made with a centre-bit, through which good tapes are passed, to tie round the instep and over the foot. A pair of these must of course be provided, and a person thus equipped, being perfectly buoyant in water, and web-footed and web-fingered, will be able to outswim any other person, and may exit in the water as long as cold and hunger will permit.

By increasing the dimension of the buoyant, a proportionate quantity of provisions, or any other article, may be carried. The inventor has wrote a letter, and otherwise described himself on the sea, with this apparatus, and believes he could cross from Dover to Calais in perfect safety. It is very convenient for crossing deep rivers, where there are neither boats nor bridges. It is procured at little expence, very portable.
Ligament. The annular ligament of the fore-arm, which contains the extensor tendons, is described in the articles Extensor communis digitorum, and Fascia. The description of the annular ligaments of the cord will be found under Fascia.

Ligamentum Articulorum, is the fibrous cord connecting together the trunks of the pulmonary artery and the artorta, containing the remains of the canalis arteriosus of the foetus. See Embryo.

Ligamentum Colli, in the eye, is the white union of the sclerotica and choroid coats. See Eye.

Ligamenta Cofii. See Intestine.

Ligamentum Dentale in the spinal marrow. See Brain.

Ligamentum Nuchae. See Head.

Ligamentum Palpebrae, or Poupart's Ligament. See Obliquus externus abdominis.

Ligamentum Latum, or Suprarenal Hepatis lig. coronarium hepatis, et ligamenta lateralia hepatis. See Liver.

Ligamentum Latum Uteri, et lig. rotundum uteri. See the description of the uterus in the article GENERATION.

Ligamentum Tendineum of the hip-joint. See Extremities.

Ligamentum, in Lazo, denotes a wretch confounding of goods funk in the sea, but tied to a cork or buoy, in order to be found again. Over these, as well as flotaam and jetam, the high-admiral hath jurisdiction, as they are in and upon the sea. 5 Rep. 196.

Ligani, in Geography, a town of Turkish Armenia; 30 miles E. of Upira.

Ligardes, a town of France, in the department of the Gers; 7 miles N.E. of Condom.

Ligature, among Mythic Divines, signifies a total fulpension of the superior faculties, or intellectual powers of the soul. They pretend, that when the soul is arrived at a perfect contemplation, the remains deprived of all her operations, and cease to act in order to be more ready and prepared to receive the impulse and communications of divine grace. This paffive state of these contemplative people they call their ligature.

Ligature is also used for a state of impotency, in respect to venery, pretended to be caueld by some charm, or witchcraft.

Kempfer tells of an uncommon kind of ligature, or knotting, in ufe among the people of Maffacar, Java, Malaya, Siam, &c. By this charm, or spell, a man binds up a woman, and a woman a man, fo as to put it out of their power to have to do with any other perfon; the man being thereby rendered impotent to any other woman, and all other men impotent with respect to the woman.

Some of their philosophers pretend that this ligature may be effected by the fluting of a lock, the drawing of a knot, or the flicking of a knife in the wind, at the point of time wherein the priest is joining a couple together; and that a ligature, thus effected, may be dissolved, by the spouse's turning through a ring. This piece of superition is said to obtain also among the Chriftians of the East.

The fame author tells us, that during the ceremony of marriage in Ruffia, he observed an old fellow lurking behind the church-door, and mumbling over a fling of words; and, at the fame time, cutting a long rod, which he held under his arm, into pieces; which, it feems, is a common practice at the marriages of great perffons, and done with design to clude and counter-work any other perfon, that might possibly be inducing the ligature.

The secret of inducing a ligature is delivered by the fame author, as he was taught it on the spot by one of their adepts; which, being a curiosity, we shall not feruple to add in his own words.

Portable, and can be put on in one minute. Persons provided with it, and being shipwrecked near the coast, would seldom be lost.

Livy-Rent, in Law, a rent which a man receives for a term of life, or for sustentation of it. Skenie.

Liffamatula, in Geography, an island in the East Indian sea, 25 miles long and fix broad. S. lat. 2°. E. long. 126° 18'.
own words; not daring to make it speak English. “Puella
amataum, vel conjux maritum ligaturus, ableget a conubitis
actu, priapum, individi—ut feminis quantum potest exspectet.
Hoc probe convolutum fulb limine domus fur in terram
sepeliat. Ibi quamdui feptulm reliquit, tamdu ejus
handa in nullius praeter quam fui (facinantis) servitium ob-
diet, et prius ab hoc nexe non liberabitur quam ex clantbro
liminis liberetur ipsum linteum: vice verfa, vice fecit fociam
ligaturum, mensuratum ab eo linteum combirit; ex cine-
ribus cum propria urina fudatis, efformato vigurum priapi,
vel, si cinere inueni unt fingendi: non sufficiant, confem subi-
gito cum parte terra, quam recens permincet. Formatam
iconem exusta exscticato, ficcamque afferit loco fcco, ne
humorem contrahat. Quamdui fic fervaveris, omnes artus,
dum ad fcofan focize colhseverint, momento contabefcet:
ipf vero dominus. Aburum hunc fium prius imuscateto,
quamdui fic manebeat, tamdu sufuno nexe priapus ipiti
parebit, quis & alios quotquot femina properantes admi-
erit.”

M. Marshall mentions another ridiculous form of ligature,
which he received from a Branim at Hindoo deline: “I
fays he, “the little worm in the wood hokerara kara be cut
into two, and the one part firs, and the other not, if the
ftirring part be bruifed, and given with half a beetle to a
man, and the other half to a woman, the charm will keep
each from ever having to do with any other person.” Phil.
Tranf. No. 268.

Ligature, Ligatura, in the Italian Music; signifies a tying
or binding together of notes.

Hence syncopes are often called ligatures, because they
are made by the ligature of many notes. There is another
form of ligatures for breves, when there are many of these
on different lines, or in different spaces, to be sung to one
 syllable.

To understand this, it must be observed, that only breves
are capable of this species of ligature, becaufe their figure
admits of their being placed fo close together, as to feem
one character only, though placed on different degrees, unlefs
there be occlusion to place a femicie rete either above or below
them, to shew that they are tied. This kind of ligature
regards common time only. Breves again must be con-
dered as fimple, as having a tail, and as being of different
colours. First, if they be fimple and affcnd, they con-
tain their natural quantity, i.e. each two femi-breves, as in
example A. But if they defcend, then each is equivalent
to four femi-breves, if only two follow one another, as in B.
If there are three or four following ones, the firft and laft
contain each four femi-breves, and thofe in the middle but
two, as in C.

![Diagram](image_url)

Secondly, if they have tails, and the tail be turned
upwards, the breves contain only one meafure, as well
ascending as defcending. See Ex D. But if it be marked
downwards, the breve then contains its natural quantity.
See Ex. E. This fpecies of ligature was invented only
because the minim, being round, could not be used in this
manner. And the femicie rete was not at that time in ufe.

It may be refurred, that ordinarily the firft breve
alone of every ligature has a tail, and that usually placed on
the left fide. Laiily, if they be of different colours, i.e. if
the firft be white, or open in the middle, and the second black,

the firft contains a femi-breve, and the second a pointed
mini. Example F.

![Diagram](image_url)

These are the principal ligatures, besides which there are
many others, for which fee Character. See also Lega-
tura.

Ligatures, among Printers, are types consisting of two
letters or characters joined together, as B, E, F, A, F. The
old editions of Greek authors are extremely full of ligatures;
the ligatures of Stephens are, by much, the moft
beautiful.

Some editions have been lately printed without any ligatures
at all; and there was a design to expofe them quite
out of printing. Had this proceeded, the finest ancient edi-
tions would, in time, have grown useless; and the reading
of old manuscripts would have been rendered almost imprac-
ticable to the learned themselves.

Ligature, in Surgery, is the only means to be depended
upon for putting a permanent stop to all bleedings from
arteries of conliderable size. In ordinary cases, the mouth
of the bleeding vefsel being exposed, is taken hold of with
the tenaculum, or forceps, and tied. In fonie infances, the
artery being only punctured, and not cut through, nor
brought into view, the surgeon has first to cut down to the
wounded portion of the vefsel, and then passes a double li-
gature under it by means of an anermif-needle, or an eye-
probe. The latter instrument, having fulfilled its office, is
to be removed by dividing the double ligature with a pair
of fciIors. One part of the ligature is then to be applied
round the artery in a firk knot above the opening from
which the blood issues, and the other below it. In cafes of
anermif, the ligature is introduced under the artery in a
very fimilar way.

Whoever is acquainted with the history of surgery, must
be fully fenfible of the immense advantage which the
moderns have over the ancients in the familiar employment
of ligatures for the fopppage of hemorrhage. But, although
many years have elapsed fince this important improvement
in practice began, it was not till very lately that feveral meft
interesting circumftances, relative to the ufe of the ligature,
were brought to light. For this elucidation of a difficult,
though highly momentous, subject to the practical surgeon,
we are indebted to the judgment, accuracy, and talents of
Dr. J. F. D. Jones, whose Treatife On Hemorrhage de-
mands the earnest attention of every enlightenedit practitioner.
Before this work appeared, scarcely any surgeon had a jut
conception of the manner in which ligatures effected the
suppofition of hemorrhage; nor were the principles on
which they ought to be made and applied properly under-
fstood. One of the firft and moft material effects of a li-
gature applied to an artery, is to produce a division of the
middle and internal coats of the veffel. This fact was com-
municated to Dr. Jones by Mr. Thomfon of Edinburgh,
and is alleged to have been known to the celebrated M.
Default of Paris. The inner coats of the artery, thus cut
through by the pressure of the ligature, are in the fitter
state for inflaming and effufling coagulable lymph, and, in
flert, for undergoing that process, by which the permanent
oclufion of the veffel is to be accompanied. Hence, li-
gatures should not be thick, irregular, and clumpy; but small-

LIGHT, that sensation occasioned in the mind by the view of luminous bodies; or that property in bodies, whereby they are fitted to excite those sensations in us.

LIGHT is also used to denote a certain action of the luminous body, on a medium between it and the eye; by means of which, some suppose the one to act on the other. This they call secondary, or derivative light: to distinguish it from that of luminous bodies, which is called primary, or innate.

Aristotle explains the nature of light, by supposing some bodies to be transparent, as air, water, ice, &c.; but since, in the night-time, we do not see any thing through those bodies, he says, they are only transparent potentially; whereas, in the day, they become really and actually transparent: and since it is light alone that can reduce that power into act, he defines light to be the act of a transparent body, considered as such. He adds, that light is not fire, nor is it any thing bodily radiating from the luminous body, and transmitted through the transparent one; but the mere presence of fire, or some other luminous body, at the transparent one.

This is Aristotle's doctrine of light, which his followers mistaking, have charged on him another, very different; making light and colours to be qualities of the luminous and coloured bodies themselves, and in all respects like those sensations which they occasion to us: aduing, that things lucid, or coloured, could not produce any sensation in us, unless they had something similar in themselves, since nihil dat quod in fac non habet.

But the sophism is apparent; for we find, that a needle, in pricking the flesh, gives us pain, which nobody ever imagined to exist in the needle. But that it is not necessary there should be any similitude between the quality of the object, and the sensation it produces, appears still more evident from a glass prism, which is found to exhibit blue, yellow, red, and other colours extremely vivid; and yet no body will lay there is any thing in the glass prisms like to those sensations.

The Cartesians have refined considerably on this notion; and own that light, as it exists in the luminous body, is nothing but a power or faculty of exciting in us a very clear and vivid sensation; adding, that what is required to the perception of light, is, that we be so formed, as to be capable of such sensations; that in the hidden pores of transparent bodies, there be a certain subtle matter, which, by reason of its exceeding smallness, may penetrate even glas, and yet be strong enough to shake certain capillaments at the bottom of the eye; and lastly, that this matter be impelled by the luminous body, so as to move the organ of light.

Primary light, therefore, they say, consists in a certain motion of the particles of the luminous body, whereby they are enabled to propel, every way, the matter subtiliss, lodged in the pores of transparent bodies; and secondary or derivative light, in a conatus to motion, or an inclination of that matter to recede from the centre of the luminous body in right lines.

Father Malebranche explains the nature of light, from a supposed analogy between it and sound.

Thus he supposes all the parts of a luminous body are in a rapid motion, which, by very quick pulses, is constantly compressing the subtilis matter between the luminous body and the eye, and excites vibrations of prelision. As these vibrations are greater, the body appears more luminous; and as they are more quick, or more slow, the body is of this or that colour.

This hypothesis, how ingenious soever, is now deferredly discarded, since the great discoveries made by Sir Isaac Newton on the nature of light. The primary light they talk of, we now know, consists wholly in a certain motion of the particles of the lucid body, whereby they do not propel any fictitious matter, supposing to be lodged in the hidden pores of transparent bodies; but throw off from the luminous body certain very small particles, which are emitted with great force; and the secondary or derivative light consists not in contumus, but a real motion of these particles, receding every way from the luminous body, in right lines, and that with an incredible velocity.

The most distinguishing property of light is that by which it renders objects visible by some power, which transfers their exterior figure to the retina of the eye.

We obtain light from three distinct sources, which will divide our subject into three heads; namely, solar light, light of combustion, and phosphorescent light.

Very little was known of the nature and properties of light before the experimental researches of Newton; and it is remarkable that at this time so little should have been added to the labours of that acute philosopher. It is strange, that after the evidence of his experiments there could have been two opinions respecting the nature of light. Hypo- gens supposes the phenomena of light to be caused by an undulatory motion, excited in a supposed subtile and elastic medium, pervading all space; that these waves or pulses are propagated, first at the luminous body, such as the sun or a candle, and transmitted in all directions. The impression made by these waves upon the eye is the cause of vision. This doctrine has since been taken up by Euler, who, with much zeal and mathematical labour, supported it to his death. Newton, however, had given an hypothesis, supported by clear and striking experiments; and at the same time had pointed out insurmountable objections to the undulatory hypothesis, so that the labour and great talents of Euler were exhausted to little purpose.

Sir Isaac Newton argued, with great propriety, that the undulatory motion was inconsistent with the phenomena of light. The passage of light would not be confined to straight lines, but might, like sound, be conveyed through crooked tubes, which is contrary to the fact.

Besides, if light consituted in a mere prelision, or pulse, it would be propagated to all distances in the same instant of time; the contrary of which appears from the phenomena of the eclipses of Jupiter's satellites, which we shall presently mention.

We shall therefore, with Newton, consider light as a material agent, moving with an immense velocity from the point where it is liberated. If its motion be in free space, it moves in straight lines in the form of rays, and would continue for ever in the same direction, if not changed in its course by the attraction of other matter. Light, therefore, like electricity and caloric, appears in a high degree to be repellent.
repellent of itself, although it possessions attraction for ponderable matter. Indeed, it is to this great repulsion of the particles of light that we are to attribute its progressive velocity, which, therefore, is as the force by which its particles are separated.

The small extent of the limits of vision upon the surface of our globe does not enable us to appreciate the velocity with which light moves.

Roemer, a Danish philosopher, at length found the means of determining this point by the difference of time in the eclipses of Jupiter's satellites, when the earth was on the same, or on the contrary side of the sun, with that planet. The imminence of these satellites, as the earth approaches towards Jupiter, are found to anticipate somewhat on the true time, and to commence sooner; and again, as the earth retires from Jupiter, their emissions, which alone in that case can be observed, happen later and later, or lose time; deviating thus, very considerably on either side, from the true time marked by the tables.

This was first observed by M. Roemer, and since by other astronomers; the reason of which is not owing to any eccentricity; but apparently follows from this circumstance, that the light of the sun, reflected from the satellites, has farther to travel, before it reaches the eye, in the one case than in the other, by a space equal to the diameter of the earth's annual orbit.

The observations, whence this conclusion was deduced, were made at the observatory belonging to the Royal Academy of Sciences at Paris, from 1670 to 1675: the principal fact was, that the first satellite sometimes emerged exactly at the times calculated by the tables, and sometimes not, so that the greatest variation was about fourteen minutes. The particular observation that was the most striking, was the emission of this satellite observed at Paris, Nov. 9, 1676, ten minutes later than it had been observed in the month of August, when the earth was much nearer to Jupiter. Hence Cassini and Roemer both concluded, that this circumstance depended on the distance of Jupiter with respect to the earth; and that in order to account for it, they must suppose that the light was about fourteen minutes in crossing the earth's orbit.

But the conclusion was afterwards abandoned and attacked by Monsieur Cassini. M. Roemer's opinion found an able advocate in Dr. Halley; who removed Cassini's difficulty, and left M. Roemer's conclusion in its full force. In a memoir presented to the academy in 1707, Monsieur Maraldi endeavoured to give a new force to Cassini's arguments; but Monsieur Roemer's doctrine found a new defender in Mr. Pound. See Phil. Trans. N. 156. Phil. Trans. Abr. by Lowth, vol. i. p. 409, 412. S'Grav. Phys. Elem. N. 1636, seq.

It has been since found, that when the earth is between the sun and Jupiter, his satellites are eclipsed about eight minutes sooner than they could be according to the tables, and that when the earth is nearly in the opposite point of its orbit, these eclipses happen about eight minutes later than the tables predict them. Hence it is undeniably certain, that the motion of light is not instantaneous, since it takes about 16' (or 10 10") minutes of time to go through a space equal to the diameter of the earth's orbit, which is at least 100 millions of miles in length; and consequently the particles of light fly about 191019 or 200000 miles every second of time, which is near a million of miles swifter than the motion of a cannon-ball. And as light is 16' minutes in travelling across the earth's orbit, it must be 8' (or 8' 5") minutes in coming from the sun to us; therefore, if the sun were annihilated, we should see him for 8' minutes after; and if he were again created, he would be 8' (or 8' 5") minutes old before we could see him. In order to explain this progressive motion of light, let A and B, Plate IX. Optics, fig. 1, be the earth in two different parts of its orbit, whose distance from each other is 95 millions of miles, equal to the earth's distance from the sun.

It is plain, that if the motion of light were instantaneous, the satellite 1 would appear to enter into Jupiter's shadow 1 F, at the same moment of time to a spectator in A, as to another in B. But it is now well known that the immersion of the satellite into the shadow is seen 8' (or 8' 5") minutes sooner when the earth is at B, than when it is at A. As the earth moves from D to C, through the side A B of its orbit, it is constantly meeting the light of Jupiter's satellites sooner, which occasioning an apparent acceleration of their eclipses; and as it moves through the other half H of its orbit, from C to D, it is receding from their light, which occasions an apparent retardation of their eclipses, because their light is then longer before it overtakes the earth. That these accelerations and retardations are not occasioned by any inequality arising from the motions of the satellites in eccentric orbits is plain, because it affects them all alike, in whatever parts of their orbits they are eclipsed. Besides, they often round their orbits every year, and their motions are thus very little constant towards the earth's position not to be accounted for from the real motions of the satellites, but so easily deducible from the motion of the earth, and so answerable to it, must be allowed to result from it. And this affords one very good proof of the earth's annual motion. See the sequel of this article.

We shall here observe, that the first person, who conceived the thought of measuring the velocity of light was Galileo, who has given a particular description of his contrivance for this purpose, in his Treatise on Mechanics, p. 39. He had two men with lights, one of whom was to observe when the other uncovered his light, and to exhibit his own the moment that he perceived it: the experiment was tried, as may naturally be imagined, without success, at the distance of one mile; but the members of the academy Del Cimento refused the experiment, and placed the observers, to as little purpose, at the distance of two miles. However, the method used by M. Roemer, already mentioned, was the only one adequate to the discovery of the velocity of light.

Our excellent astronomer, Dr. Bradley, has found nearly the same velocity of light, from his accurate observations, and most ingenious theory, to account for some apparent motions in the fixed stars. Phil. Trans. N. 406, or Abridg. vol. vi. p. 150. And for a summary account of these observations, &c. see EARTH and STAR.

To understand this, it must be premised, that the fixed stars are luminous bodies, and at rest, with respect to our planetary system, from which they are vastly remote. In this system also the earth is considered as one of the planets, and moving about the sun.

Suppose the sun represented in S, (Plate IX. Optics, fig. 2,) and that the circle A B C D represents the path of the earth, or the ecliptic. At the centre S suppose a perpendicular S P raised to the plane of the ecliptic, and that this perpendicular passes through any fixed star. If a spectator were placed in S, he would see the star in the same perpendicular, but if the spectator passes over the circle A B C D, the diameter of which is supposed to bear a sensible though small proportion to the distance of the planet, it will be perceived to change its situation in the heavens. For a spectator in A would see the star in the line A P S; in C he would see the same star in the line C D P S;
and so in any other point of his progress; whence it follows, that the star would seem to describe a circle in the heavens represented by \( a b c d \). If the distance of the star was so very great, that in respect of it the diameter of the earth's orbit \( A C \) might be esteemed a point; in this case, the fore- 
faid circle would be entirely insensible; all the lines drawn from the point of the orbit to the star might pass for per- 
pendiculars to the plane of the ecliptic, and in appearance 
would correspond to the same point in the heavens with the 
perpendicular in \( S \), in which point the star would always 
appear, if its light could reach us in an instant. But if in 
this case, where the star is so remote, the light is supposed 
to be propagated from the star with a certain velocity, at 
the same time that the earth proceeds in its orbit, the star 
will be seen in an oblique direction to the plane of the orbit; 
because of the motion compounded of the motion of light, 
and that of the spectator. 
Suppose the light to move in the line \( E G \) (fig. 3.) making 
an angle with the line \( F G \), in which the spectator is 
carried along; whom we shall conceive placed in \( F \). Let 
the velocity of the spectator be to the velocity of the light, 
as \( F G \) to \( EG \). While the spectator moves along \( F G \), 
the light does the same along \( EG \); and the particle of 
light, which is in \( E \) when the spectator is in \( F \), enters 
the eye only when he arrives at \( G \). Now the direction of 
the light, with respect to the eye, makes with the line \( FG \) 
the angle \( EFG \). For if we conceive the line \( FE \) drawn, and 
to be carried with a parallel motion along with the eye, so 
that in respect thereof it be at rest, while this continues 
moving, the light will reach the eye in the direction of 
the said line; for when the eye shall be in \( f \), the middle 
point between \( F \) and \( G \), the transferred line, will cut \( EG \) 
in its middle point \( g \), to which the particle of light has reached, 
and which is likewise the middle point of the transferred 
line \( fe \); wherefore the particle of light, which was in \( E \), 
in the extremity of the line \( EF \), arrives at, and will enter 
the eye in the direction \( eg \). 
Let the angle \( EGF \) (fig. 4.) be a right one, and \( EG \) to 
\( FG \) as the velocity of the light to the velocity of the 
earth in its orbit; then \( EFG \) will be the angle, which the 
ray of light entering the eye, makes with the plane in which 
the earth moves round the sun. 
If the earth be in \( B \) (fig. 5.) it moves in the direction 
of the tangent to its orbit in this point; that is, if we sup- 
pose the spectator in the sun, the direction of the earth's 
motion is parallel to \( SC \); and making the angle \( a S C \) 
equal to the angle \( EGF \) in the former figure, the line 
\( Sa \) will represent the line in which the spectator would see 
the star. 
In the same manner when the earth is in \( D \), the spectator 
in the sun will see the star in \( S \), the angles \( P S C \) and \( PSa \) 
being equal; and the line \( S a \) or \( Sc \), by its revolution about 
\( PS \), would describe a cone, whose base in the heavens 
would be a circle representing the apparent path of the star 
through a whole year. Let us suppose this circle to be 
\( a b c d \) as in fig. 5. 
When the star is not in the perpendicular to the plane of 
the ecliptic, but the line \( PS \) (fig. 6.), is inclined to that 
plane, the lines which determine the apparent motion of the 
star in the heavens will form cones, as in the case already 
explained; only they would be oblique, and in both cases 
the apparent path of the star in the heavens would be 
determined as above; but in this last case it would be an ellipse, 
the greater diameter of which would be equal to the diam- 
eter of the circle \( a b c d \) of the former figures; so that 
knowing this ellipse, the circle might easily be found which 
the star would describe, if placed in the perpendicular to the 
plane of the ecliptic. 
The only way to determine, whether the stars describe 
such ellipses, is by observations; in making which there are 
great difficulties, which, however, Dr. Bradley has with in-
comparable industry surmounted. 
Nothing can immediately be determined concerning the 
forefaid elliptic motion. The distance of the star from the 
pole of the world must be measured at different times of the 
year, and from the different distances the elliptic motion is 
to be determined by calculation, allowing for the motion of 
the pole itself during the space of time between the observa-
tions; for the pole moves in a leffer circle, one degree of 
it passes over in seventy-two years. 
Dr. Bradley, making all necessary allowances, observed 
several stars at different times of the year, whereby he im-
mediately discovered, that their distances from the pole of 
the world varied; and was convicted that this variation 
could not be attributed to the rotation of the pole; for he 
examined two stars at equal distances from the pole, but to 
the opposite, that the one ought to have receded from the pole 
as much as the other advanced to it, if the motion was in the 
pole itself. But this did not fall out so; for the change of 
the one star was double of that of the other; a proper 
allowance being always made for the pole's motion arising 
from the above revolution. However, this indefatigable 
observer inferred from his observations, that the stars in cer-
tain times receded from, and acceded to, the pole of the 
world with a motion entirely analogous to that which is per-
formed in an ellipse; and also that they move in such curves, 
for each of which the motion in the same little circle, as 
\( a b c d \) (fig. 6.) answers, when the stars are referred to the 
perpendicular in \( S \) to the plane of the ecliptic; and the di-
meter of this minute circle for them all is \( 40^1/2 \). 
It is plain from observations, to which of the above men-
tioned causes we are to ascribe the motion of the star. For 
if the first takes place, the star would be carried from \( a o e \), 
while the earth passed over the part \( A B C \) of its orbit; 
but this, being contrary to observation, cannot be the true 
cause. But this change in the situation of the star takes 
place according to the observations, while the earth describes 
the part \( B C D \) of its orbit, which is just what the second 
cause requires. 
If both the causes took place at the same time, the are 
described by the earth would differ from that indicated by 
either of them; besides, this concurrence of the causes is 
contrary to the observations; unless, perhaps, it may be 
thought reasonable to attribute a little influence to the first 
cause; but so very small a portion, as not to be sensibly per-
ceived in the observations. 
Dr. Bradley himself considered this matter in the follow-
ing manner: he imagined \( C A \) (Plate IX. Optics, fig. 7.) 
to be a ray of light falling perpendicularly upon the line 
\( BD \); that, if the eye is at \( A \), the object must ap- 
ppear in the direction \( AC \), whether light be propagated in 
time or in an instant. But if the eye is moving from \( B \) towards 
\( A \), and light is propagated in time, with a velocity that is 
to the velocity of the eye as \( CA \) to \( BA \), then light, mov- 
ing from \( C \) to \( A \), whilst the eye moves from \( B \) to \( A \), that 
particle of it by which the object will be discerned when 
the eye comes to \( A \), is at \( C \), when the eye is at \( B \). 
Joining the points \( B, C, \) he supposed the line \( CB \) to be a 
tube, inclined to the line \( BD \) in the angle \( DBC \), of such 
a diameter as to admit but one particle of light. Then it 
was easy to conceive, that the particle of light at \( C \), by 
which the object must be seen, when the eye, as it moves 
along, arrives at \( A \), would pass through the tube \( BC \), if
L I G H T.

it, is inclined to $BD$ in the angle $DBC$, and accompanies the eye in its motion from $B$ to $A$; and that it could not come to the eye placed behind such a tube, if it had any other inclination to the line $BD$. If, instead of supposing $CB$ to be a small tube, we imagine it to be the axis of a larger; then, for the same reason, the particle of light at $C$ would not pass through that axis, unless it is inclined to $BD$ in the angle $CBD$. In like manner, if the eye move the contrary way; from $D$ towards $A$, with the same velocity, then the tube must be inclined in the angle $BCD$. Although, therefore, the true or real place of an object is perpendicular to the line in which the eye is moving, yet the visible place will not be so, since that, no doubt, must be in the direction of the tube; but the difference between the true and apparent place will be, $ceteris paribus$, greater or less, according to the different proportion between the velocity of light and that of the eye. So that if we suppose that light was propagated in an instant, then there would be no difference between the real and visible place of an object, although the eye were in motion; for in that case, $AC$ being infinite with respect to $AB$, the angle $ACB$, the difference between the real and visible place, vanishes. But if light be propagated in time, it is evident, from the foregoing considerations, that there will be always a difference between the true and visible place of an object, unless the eye is moving either directly towards or from the object. And in all cases the fine of the difference between the real and visible place of the object will be to the sine of the visible inclination of the object to the line in which the eye is moving, as the velocity of the eye is to the velocity of light.

He then shews that if the earth revolve round the sun annually, and the velocity of light be to the velocity of the earth's motion in its orbit, as one thousand to one, that a star really placed in the very pole of the ecliptic, would, to an eye carried along with the earth, seem to change its place continually; and neglecting the small difference on the account of the earth's diurnal revolution on its axis, would seem to describe a circle round that pole every way distant from it $3\frac{1}{2}$; so that its longitude would be varied through all the points of the ecliptic yearly, but its latitude would always remain the same. Its right ascension would also change, and its declination, according to the different situation of the sun with respect to the equinoctial points, and its apparent distance from the north pole of the equator, would be $7'$ east at the autumnal than at the vernal equinox.

The greatest alteration of the place of a star in the pole of the ecliptic, or which, in effect, amounts to the same thing, the proportion between the velocity of the light and the earth's motion in its orbit being known, it will not be difficult, he observes, to find what would be the difference, upon this account, between the true and apparent place of any other star at any time; and, on the contrary, the difference between the true and apparent place being given, the proportion between the velocity of light and the earth's motion in its orbit may be found.

From all which the following conclusions may be deduced: 1. That the second cause above-mentioned alone takes place in this case; viz. that the distance of the stars is so great, that the diameter of the earth's orbit has no sensible proportion to it. 2. That the angle $FEG$ (fig. 3.) in the above mentioned triangle, is $20^{2}$; or, since the apparent declination of the star $\gamma$ Draconis, observed by Dr. Bradley, on account of the fictitious propagation of light, would be to the diameter of the little circle which a star would seem to describe about the pole of the ecliptic as $39^{9}$ to $40^{0} 4$; the half of this is the angle $ACB$ (fig. 7) which is equal to $20^{2}$; and consequently the ratio of $EG$ to $FG$ (fig. 3.) or of $AC$ to $AB$ (fig. 7) or the velocity of the light to the velocity of the earth in its orbit, as $10210$ to $1$; whence it follows, that the light comes from the sun to the earth in $8'12"$. This, Dr. Bradley observes, is very probably the truth, because it is a medium between $7$ and $11$, which were the times which it had before been supposed to take up, according to different observations of the eclipses of Jupiter's satellites. Comparing his observations on other stars, he afterwards concluded, that light is propagated from the sun to the earth in $8'13"$; and the near agreement of his observations induced him to think, that this supposition could not differ so much as a second of a degree from the truth; so that the time which light spends in passing from the sun to us may be determined by these observations within $5''$ or $10''$, which is such a degree of exactness as we can never hope to attain from the eclipses of Jupiter's satellites. 3. That the light proceeds with the same velocity from all the stars; for all have the same angle $FEG$. Whence (if we suppose that all the stars are not equally distant from us, as many arguments prove) it will follow, that the motion of light, all the way it passes through the immense space above our atmosphere, is equal or uniform. And since the different methods of determining the velocity of light thus agree in the result, it is reasonable to conclude, not only that the phenomena above recited are owing to the causes to which they are ascribed, but also that, in the same medium, light is propagated with the same velocity after it has been reflected, as before. 4. Lastly, it must be considered, that very small differences cannot be perceived; and nobody will deny, but that in measuring a small angle, an error of a second may be committed, whatever care is used to prevent it; and therefore, although we have said, that the first cause is to be rejected, we do not deny that the stars may possibly by its influence describe a minute circle, whose diameter is $1''$, or even a little more. S'Gravefande's Phys. Elem. Math. lib. ii. cap. 1. p. 708, &c.

Hence it appears, that the successive propagation of light will cause an aberration in the appearances of the stars, planets, and comets. (See Aberration.) After Dr. Bradley had discovered this cause of error in the apparent places of the fixed stars, M. Clairaut and others investigated several rules for the computation of this aberration. M. Euler also has given us a paper on this subject. Mem. Acad. Scienc. 1756. Mr. Simpson, in his Essays. Mem. de l'Acad. de Berlin, tom. ii. p. 141, &c.

See remarks on the effect of the aberration of light on the time of the transit of Venus over the sun, by Dr. Price, in Phil. Transf. vol. 18. art. 47. p. 536.

For an account of Mr. Melville's hypothesis of the different velocities of differently coloured rays, see Refrangibility.

Whether the light, emitted by candles and other luminous bodies acquires the same velocity it is difficult to determine. So far as our knowledge extends on that head, it does not appear inferior to solar light. But to return to the hypothesis of pressure, by which some have accounted for the propagation of light, it might be observed farther, if light were not a body, but consisted in a mere pressure, or pulsion, it would never be propagated in right lines, but would be continually refracted at umbra. Thus Sir Isaac Newton: "A pulsion on a fluid medium, \textit{i.e.} a motion propagated by such a medium, beyond any obstacles, which impedes any part of its motion, cannot be propagated in right lines, but will be always intersecting and diffusing
L I G H T.

diffusing itself every way, to the quiescent medium beyond that obstacle. The power of gravity tends downwards; but the prelude of water arising from it tends every way with an equal force, and is propagated with equal ease, and equal strength, in curves, as in straight lines. Waves, on the surface of the water, gliding by the extremities of any very large obstacle, infect and dilate themselves, still diffusing, gradually, into the quiescent water beyond that obstacle. The waves, pulses, or vibrations of the air, wherein sound consists, are manifestly infected, though not so considerably as the waves of water; and sounds are propagated with equal ease, through crooked tubes, and through straight lines; but light was never known to move in any curve, nor to infect itself ad umbram. The rays of light, therefore, are small corpuscles, emitted with exceeding celerity from the luminous body. As to the force wherewith these corpuscles are emitted, so as to enable them to move at the inconceivable rate of 200,000 miles a second; the fame great author observes: “Among bodies of the same kind and virtue, by how much any one is smaller, by so much is its attractive power greater in proportion to its bulk. This power we find stronger in small magnies, than in large ones, regard being had to the difference of their weights: and the reason is, that the particles of small magnies being nearer each other, more easily unite their forces intimately together, and act conjunctly. For the same reason the rays of light, being of all other bodies the most minute, it may be expected that their attractive powers should be, of all others, the strongest; and how strong in effect they are, may be gathered from the following rules: the attraction of a ray of light, according to the quantity of its matter, is to the gravity which any projected body has, according, likewise, to the quantity of its matter, in a ratio compounded of the velocity of the ray of light, to the velocity of that projected body, and of the bending or curvature of the line which the ray describes in the place of refraction, to the bending of the curvature described by that projected body; provided, however, the inclination of the ray to the refracting surface be the same with that of the projected body to the horizon. From which proportion I gather, that the attraction of the rays of light is above 1,000,000,000,000,000 times greater than the gravity of bodies on the surface of the earth, in proportion to the quantity of matter in each, if the light pafs from the fun to the earth in the space of seven minutes. But now, as in algebra, where affirmative quantities eafe, there negative ones begin; fo in mechanics, where attraction eases, there the repelling power must succeed; therefore a ray of light, as soon as it is call’d off from the luminous body, by the vibrating motion of its parts, and is got out of the sphere of its attraction, is propelled with an immense velocity.”

The wonderful divisibility of the parts of matter is nowhere more apparent than in the minuteness of the particles of light. Dr. Nieuwenh and has computed, that an inch of candle, when converted to light, becomes divided into 269,517,540 parts, with 40 ciphers annexed; a which rate there must flue out of it, when burning, 418,660, with 39 ciphers more, particles in the second of a minute; vailly more than a thousand times a thousand million times the number of sands the whole earth can contain; reckoning ten inches to one foot, and that 100 sands are equal to one inch. See Relig. Philof. vol iii. p. 865.

It must be acknowledged, that many difficulties and objections have been urged against the materiality of light, or the hypothesis of light’s consisting of small particles emitted from luminous bodies; and that many eminent philosophers, both foreigners and English, have recurred to the opinion, that light consists of vibrations propagated from the luminous body through a subtile ethereal medium.

The ingenious Dr. Franklin, in a letter dated April 23, 1752, expresses his dissatisfication with the doctrine, that supposes particles of matter, called light, continually driven off from the fun’s surface, with a swiftness so prodigious. “Milt not,” says he, “the smallest particle conceivable have, with such a motion, a force exceeding that of a twenty-four pounder discharged from a cannon? Milt not the fun diminish exceedingly by such a waste of matter; and the planets, instead of drawing nearer to him, as some have feared, recede to greater distances through the deftead attraction? Yet these particles, with this amazing motion, will not drive before them, or remove, the leaf and lighted dust they meet with; and the fun appears to continue of his ancient dimensions, and his attendants more in their ancient orbits.” Accordingly, he conjectures, that all the phenomena of light may be more conveniently solved, by supposing universal space filled with a subtile ethereal fluid; which, when at rest, is not visible, but whose vibrations affect that fine sense in the eye, as those of air do the grofer organs of the ear: and that different degrees of the vibration of this medium may occasion the appearances of different colours. The ethereal fluid, he says, is always the same, and yet weaker and stronger sparks differ in apparent colour, some white, blue, purple, red; the strongest, white; the weak ones, red. Franklin’s Exp. and Obs. &c. p. 324, &c. ed. 1769.

The celebrated Mr. Euler (as we have already observed), has also irreduciably maintained the fame hypothesis, in his Theoria Lucis & Colorum. In the summary of his arguments against the common opinion, recited in Acad. Berl. 1752. p. 271, besides the objections above-mentioned, he disputes the possibility, that particles of matter, allowed to move with the amazing velocity of light, should penetrate transparent substances with so much ease. In whatever manner they are transmitted, those bodies must have pores, disposed in right lines, and in all possible directions, in order to form canals for the passage of the rays; but such a structure must take away all solid matter from those bodies, and all coherence among their parts, if they do contain any solid matter.

Dr. Horlby has taken considerable pains to obviate the difficulties suggested by Dr. Franklin; and supposing that the diameter of each particle of light does not exceed one millionth of an inch; and that the density of each particle is three times that of iron, that the light of the sun traverses the semi-diameter of the orbis magnus in 7, and that this semi-diameter is 229,150, semi-diameters of the earth, he calculates, that the momentum or force of motion in each particle of light coming from the sun, is less than that in an iron ball of 4 inches in diameter, moving at the rate of less than an inch in twelve thousand millions of millions of Egyptian years. Hence, he concludes, that a particle of matter, which is probably larger than any particle of light, moving with the velocity of light, has a force of motion, which, instead of exceeding the force of a twenty-four pounder discharged from a cannon, is infinitely less than that of the smallest shot discharged from a pocket-pistol, or less than any that art can create. Moreover, he thinks it possible, that light may be produced by a continual emulsion of matter from the sun, without any such waste of its substance as should sufficiently contrat his dimensions, or alter the motions of the planets, within any moderate length of time. In proof of this, he observes, that it is not necessary to the production of any of the phenomena of light, that the emanation from the sun should be continual in a strict mathematical sense, or without any interval; and likewise that...
part of the light which issues from the sun is continually returning to him by reflection from the planets, and other light is continually coming to him from the funs of other systems. He proceeds by calculation to show, that in 385,130,000 Egyptian years, the sun would lose 17,760 of his matter, and, therefore, that the gravitation towards the sun, at any given distance, would diminish in the same proportion. But this alteration is much too small to discover itself in the motion of the earth, or of any of the planets. He also computes, that the greatest stroke which the retina of a common eye sustains, when the eye, in a bright day, is turned up directly to the sun, does not exceed that which an iron that. 4th of an inch diameter, would give, moving only at the rate of 16.16 inches in a year; but the ordinary stroke is less than the 3,54th part of this. (Phil. Trans. vol. ix. art. 35. vol. lxxi. part ii. art. 50.) One of the principal difficulties attending the hypothesis of the mortality of light, is the non-interference of its particles with each other. There is, probably, says Mr. Melville, Edinb. Edi. vol. ii. p. 17, &c. no physical point in the visible horizon, that does not send rays to every other point, unless where opaque bodies interpose. Light, in its passage from one system to another, often pales through torrents of light issuing from other suns and systems, without ever interfering, or being diverted from its course either by it, or by the particles of that elastic medium, which some have supposed to be diffused through all the mundane space. In accounting for this fact, he supposes that the particles of light must be incomparably rare, even when they are the most dense; that is, that the semidiameters of two of the nearest particles, in the same, or in different beams, soon after their emission, are incomparably less than their distance from one another. This consideration obviates the objection urged by Euler and others against the mortality of light, from its influence in disturbing the freedom and perpetuity of the celestial motions. Boscovich and others solve the difficulty concerning the non-interference of the particles of light, by supposing that each particle is endowed with an insuperable impulsive force; but in this case, their spheres of impulsion would be more liable to interfere, and they would, on that account, be more likely to disturb one another. This difficulty, attending the supposition, that particles of light move through other light, in all imaginable directions, without perpetual collisions among the particles, and continual deflections from a rectilinear course, is, in a great degree, obviated, by an easy computation of Mr. Canton. He observes, that it is necessary to allow only a very small portion of time between the emission of every particle, and the next that follows in the same direction. Suppose, for instance, that one lucid point of the sun's surface emits 150 particles in one second, which are more than sufficient to give continual light to the eye, without the least appearance of intermission; yet still the particles of which it consists will, on account of their great velocity, be more than a thousand miles behind one another, and thereby leave room enough for others to pass in all directions. Phil. Trans. vol. lxxi. art. 45. p. 344.

If we adopt the conclusions drawn from the chevalier d'Arca's experiments on the duration of the sensations excited by light, which states it at the seventh part of a second (Hill. Acad. Sc. 1765. Mem. 2.) we may admit an interval of more than 20,000 miles between each particle. Some, in order to answer the chief objections of this kind against the mortality of light, have adopted the hypothesis of M. Boscovich; who advances, in his Theoria Philosophica Naturalis, that matter is not impenetrable, but that it consists of physical points only, endowed with powers of attraction and repulsion, taking place at different distances; that is, surrounded with various spheres of attraction and repulsion, in the same manner as solid matter is generally supposing to be; provided, therefore, that any body move with a sufficient degree of velocity, or have sufficient momentum, to overcome any powers of repulsion it encounters with, it will find no difficulty in making its way through any body whatever; for nothing will interfere or penetrate one another, but power, such as we know, do, in fact, exist in the same place, and counterbalance or overrule one another. Priorley's Hist. &c. of Light, &c. p. 394.

That light is a real substance, notwithstanding the objections that have been urged against this hypothesis, seems to be established by the phenomena of the Bolognian stone, and of other substances, which possest the remarkable property of imbibing light, of retaining it for some time, and afterwards of emitting it. See Prosp. &c. and the sequel of this article.

The doctrine of the mortality of light is farther confirmed by those experiments, which demonstrate, that the colour and inward texture of some bodies are changed, in consequence of their being exposed to the light.

The first observation of this kind appears to have been made by M. Duhamel, who found that the juice of a certain shell-fish in Provence contracted a fine purple colour when it was exposed to the light of the sun, and that the stronger was the light, the more splendid was the colour. Pieces of cloth dipped in this liquor, and exposed to the sun, became red, though they were inclosed in glasses; but they acquired none of this colour in the same exposure, if they were covered with the thinnest plates of metal. It was afterwards observed by Beccarius, Com. Bonon. vol. iv. p. 75, that a quantity of luna cornes, exposed to the rays of the sun, became of a violet colour, whilst part of the same composition, covered with black paper, remained white. This effect was found by M. H. Schulze to depend on the silver that happened to be in it. (Ac. Cesar. vol. i. p. 525, &c.) G. Bonzius was thus led to some subsequent experiments, which seem to prove that various colours are considerably affected by light, exclusive of heat or any thing else.

By exposing ribbons of different colours to the rays of the sun for several days in the open air, he found that all, except the yellow and light green, lost part of their lustre, and were considerably faded; but when the same ribbons were exposed to a much greater degree of heat in a dark room, none of the colours were affected, except that a small part of their lustre was lost; nor was any sensible change made in them after remaining for a considerable time in a room that faced the north. By inclining them in an exhausted receiver, he found that the change was not occasioned by the air; but no change could be produced in them by the light of torches. Beccarius also found by experiments on paper, and a great variety of substances, mineral, vegetable, and animal, that the light of the sun produced many changes in the internal structure of bodies, and that those substances which imbued light were much injured. The stronger the light, and the longer they were exposed to it, the more injury they received; and the injury thus sustained was found to be lifting. Com. Bon. vol. vi. p. 77, &c. See Prieirlay's History, p. 376, &c.

Some writers have attempted to prove the mortality of light, by determining the momentum of their component particles, or by walking that they had a force, so as, by their impulse, to give motion to light bodies. M. Homberg, Ac. Par. 1708. H. p. 25, imagined, that he could not only disperse pieces of amiantus, and other light substances, by the impulse of the solar rays, but also that by throwing them
L I G H T.

them upon the end of a kind of lever, connected with the spring of a watch, he could make it move sensibly quicker; whence, and from other experiments, was inferred the weight of the particles of light. But M. Du Fay, and M. Mairan, made other experiments of a more accurate kind, which exhibited no such effects as M. Homberg imagined. However, Dr. Priestley informs us, that Mr. Mitchell endeavoured to ascertain the moment of light with still greater accuracy, and that his endeavours were not altogether unsuccessful. Having found that the instrument which he used acquired, from the impulse of the rays of light, a velocity of one inch in a second, he inferred, that the quantity of matter contained in the rays falling upon the instrument at that time, amounted to no more than one twelve hundred millionth part of a grain. In the experiment, the light was collected from a surface of about three square feet; and as this surface reflected only about half what falls upon it, the quantity of matter contained in the rays of the fun, incident upon a square foot and half of surface in one second of time, ought to be no more than the twelve hundred millionth part of a grain, or upon one square foot only, the eighteen hundred millionth part of a grain. But the density of the rays of light at the surface of the fun is greater than at the earth, in the proportion of 45000 to 1; there ought, therefore, to issue from one square foot of the fun’s surface in one second of time, in order to supply the waist by light, one forty thousandth part of a grain of matter; that is, a little more than two grains a day, or about four millions seven hundred and fifty-five thousand grains, which is about fix hundred and seventy pounds, avoidopius, in fix thousand years; a quantity which would have shortened the fun’s semi-diameter no more than about ten feet, if it was formed of matter of the density of water only. Priestley, ubi supra, p. 389.

The nature of light has not been satisfactorily ascertained by any of the experiments and investigations of philosophers. Some incline to the Newtonian hypothesis, which ascribed it to the emission of very minute particles from luminous substances, as we have already stated; and others to the excitation of an undulatory motion, analogous to that which constitutes sound, in a very rare and elastic medium, which pervades the universe. There are also some circumstances which induce those who entertain the first hypothesis, either to believe, with Newton, that the emanation of the particles of light is always attended by the undulations of an ethereal medium, accompanying it in its passage, or to suppose, with Ecochecu, that the minute particles of light themselves receive, at the time of their emission, certain rotatory and vibratory motions, which they retain as long as their projectile motion continues. These additional suppositions, however necessary they may have been thought for explaining some particular phenomena, have never been very generally understood or admitted, although no attempt has been made to accommodate the theory in any other manner in these phenomena. Dr. Young, in his “Course of Lectures on Natural Philosophy, &c.” has examined in detail the manner in which the two principal hypotheses respect light may be applied to its various aforesaid and properties; for which we refer to vol. i. p. 438, &c. to the sequel of this article, and to other appropriate terms that occur in the Cyclopaedia.

The expansion or extension of any portion of light is inconceivable. Dr. Hook shows it is as unlimited as the universe; proving it from the immense distance of some of the fixed stars, the light whereof becomes sensible to the eye by means of a telescope; nor, adds he, are they only the great bodies of the fun or stars that are thus liable to disperse their light through the vast expanse of the universe, but the smallest spark of a lucid body must do the same, even the smallest globule struck from a steel by a flint.

The method of measuring the intensity of different lights, or of the same light in different circumstances, affords a curious subject of investigation. M. Bouguer pursed it with particular attention, and devised an apparatus which he has contrived for this purpose, in his Traité de Optique, published in Paris, 1760. Dr. Priestley (ubi infra) has given an abridged account of the two methods used for this purpose by M. Bouguer. The first of these two methods has been used by others since, and probably before that time, and particularly by count Rumford. See Photometer.

It is well known that the action of a strong light upon the eye, and also the impression which it leaves upon the eye, makes it insensible to the effect of a weaker light. M. Bouguer found, that when one light is sixty-four times less than another, its presence or absence will not be perceived; and, allowing for different effects on different eyes, he supposes that the boundaries, with respect to different persons, may lie between sixty and eighty. Being unable to determine the variation of the light of the sun, because it is too strong, and that of the stars, because it is too weak, at different altitudes, he made his observations on the moon, the diminution of the light being in the same proportion in this case and in the others, and found that its light at 19° 16' is to its light at 60° 11', as 1681 to 2500; or the one is nearly two-thirds of the other. When one limb of the moon touched the horizon of the sea, its light was two thousand times less than at the altitude of 60° 11'. But this proportion, he says, is liable to variations, as the atmosphere near the surface of the earth varies so much in its density. Hence he concludes, that, at a medium, light is diminished in the proportion of about 2500 to 1681, in traversing 7460 toises of dense air. He also found, that the centre of the sun is considerably more luminous than the extremities of it; whereas, both the primary and secondary planets are more luminous at their edges than near their centres. In a comparison of the light of the sun and moon, he compared each of them to that of a candle in a dark room, one in the day time, and the other in the night following, when the moon was at her mean distance from the earth, and, after many trials, he concluded, that the light of the fun is about three hundred thousand times greater than that of the moon; and, therefore, it is no wonder that philosophers have had so little success in their attempts to collect the light of the moon with burning-glasses; for the largest of them will not increase the light a thousand times, which will still leave the light of the moon, in the focus of the mirror, three hundred times less than the intensity of the common light of the fun. Dr. Smith, in his Optics, vol. i. p. 29, thought that he had proved, from two different considerations, that the light of the full moon would be to our day-light as 1 to about 90,000; if no rays were lost at the moon. His method of calculation follows, as far as it is jufi, says Mr. Robins, Math. Tracts, vol. ii. p. 255, directly from the proportion for the same purpose of that excellent geometer, James Gregory, in his Geom. Par. Univer. p. 144; and the general proposition there mentioned for distinguishing the proportion between the degrees of light received from any planet, and from the sun, as repeated in David Gregory’s Almanon, lib. iii. prop. 58. Mr. Robins remarks, that though his estimate is founded on the supposition, that the moon reflects all the light it receives from the sun; yet his argument is drawn from com-
comparing the light of the moon seen in the day with the light of the clouds; that is, is deduced from the quantity of light actually reflected by the moon. In the first place, he supposes that the moon, enlightened by the sun, is as luminous as the clouds are at a medium. He, therefore, supposes the light of the sun to be equal to that of a whole hemisphere of clouds, or as many moons as would cover the surface of the heavens. But upon this it may be observed, that the light of the sun shining perpendicularly upon any surface, would be equal to the light reflected from the whole hemisphere, if every part of it reflected all the light that fell upon it; but the light that would, in fact, be received from the whole hemisphere (part of it being received obliquely) would be only one-half as much as would be received from the whole hemisphere. If every part of it shone directly upon the surface to be illuminated. In his Remarks, &c. p. 17, he draws the same conclusion from a different method of induction; but in this case also he made a mistake of one-half, supposing all the enlightened hemisphere of the moon to receive the direct rays of the sun; whereas, in fact, no more can be received than would fall perpendicularly upon the superficial section of one great circle, which is just one-half of the surface of the hemisphere. Prieaffy, ubi supra, p. 540, &c.

Mr. Mitchell made this computation in a more easy and accurate manner. Considering the distance of the moon from the sun, and that the density of the light must decrease in the proportion of the square of that distance, he calculated the density of the sun's light at that distance, in proportion to its density at the surface of the sun: and in this manner he found that, if the moon reflected all the light it receives from the sun, it would be only the 45000th part of the light we receive from that greater luminosity. Admitting, therefore, with M. Bouguer, that the moon reflects only a 300000th part of it, Mr. Mitchell concludes, that it reflects no more than betwixt the sixth and seventh part of the light that falls upon it. Phil. Trans. vol. lvi. art. 27, p. 234, &c.

Dr. Pemberton, in his Course of Chemistry, sect. 2, states the greatest light which we can receive from the moon, when at the full, and nearest to the earth, to exceed the light of the sun more than 87,000 times, supposing that the moon reflected all the light of the sun which falls upon it; but if it reflects only half the light that falls upon its surface, which is the most that can be supposed, then the light of the moon will be exceeded by the sun's light more than 179,000 times: and in the mean distance of the moon from the earth, her light will be exceeded by the sun more than 290,000 times.

The mutual action between light and other matter is productive of numerous phenomena. These of late have constituted two distinct branches of science. The one has for its object the investigation of the physical properties of light, for which we are principally indebted to Newton, and which forms the basis of the science of optics. The other is confined to the chemical agency of light, resting upon facts discovered since the time of that great genius, and which has hitherto occupied the attention of the chemical philosopher.

When a ray of light falls upon the surface of a body, it is either reflected, absorbed, and extinguished, or transmitted. And under some circumstances all these effects take place.

The reflection of the ray depends, first, upon the nature of the body; secondly, upon the state and colour of the surface; and, thirdly, upon the quantity of the angle of incidence. Under all these circumstances, however, the angle at which the ray is reflected is equal to the angle of incidence. The same laws, therefore, which govern the collision between perfectly elastic bodies and absolutely hard surfaces, may be applied to the reflection of light. Of the different bodies which reflect light, metals possess this power in the greatest degree, and perhaps in proportion to their density and hardness. Smooth or polished surfaces reflect more light than rough ones.

Of coloured surfaces the lightest colours reflect the most; hence the whitest metals make the best reflectors. The order will therefore, in all probability, be as follows, beginning with the best reflectors, white, yellow, red, blue, black. The two extremes are very striking, in the well-known experiment of two pieces of cloth, one white and the other black, laid on the surface of snow in the sun. The black piece very soon sinks into the snow, from absorbing a greater quantity of light, which causes the heat. The white piece reflects a greater portion, and is longer in becoming heated. With regard to the quantity of reflection, as affected by the angle of the incidence; it is found that opaque bodies are more heated as the rays strike their surfaces more perpendicularly, and the quantity of light which enters transparent bodies is as the same. In both instances, therefore, more light enters the bodies, and less is reflected. In the first instance, the light which is not reflected becomes extinguished, producing heat; in the second it is transmitted, still retaining the property of light. Hence, therefore, we ought to conclude that the reflection will be inversely as the angle of incidence, supposing the angle to be formed by the ray and the surface of the medium.

M. Bouguer has informed us, that the light reflected from a surface of mercury, when the angle of incidence was 114° 3', was only equal to 9th of the whole; and he thinks it probable that no body reflects more. It is certain, however, that polished silver reflects much more. The same philosopher observes, that metallic reflectors change less in their power of reflection with the angle of incidence. He made the following experiment with polished black marble. At an angle of 3° 33' with the reflecting surface, .6 were reflected, the whole being unity; at 15° of incidence, .150 were reflected; at 30°, .051; and at 85°, .023. The rest of course became extinguished, and would heat the marble.

A similar diminution of the reflective power, with the angle of incidence, is observed in transparent bodies, by the same author. The following Table gives the results with water and plate-glass.

The reflections in this instance are partly made from the upper, and the rest from the under surface. The remainder of the thousand parts are transmitted, with the exception of a few, which are in all probability extinguished.

That under certain circumstances, the rays of light are extinguished, even in transparent bodies, is rendered highly probable by the above inquirer.

Light becomes so far extinct, by passing through 679 feet of sea-water, as to render it opaque; and a length of seven feet of water has been found to intercept one-half of the light which enters it.

M. Bouguer tells us, that if our atmosphere were 518,385 toises in height, we should have no light from the sun, even in his meridian splendour. It has been estimated, that of the horizontal fun-beams passing through about 200 miles of air, one two-thousandth part only reaches us.

In all the instances in which light is extinguished, it will doubtless be so found that a certain quantity of heat will be generated. Sir Isaac Newton seems perfectly aware of this fact. In his time, however, heat was supposed to arise from motion, and hence he concluded that the light, when it was neither reflected nor transmitted, so acted upon the body it entered, as to put its particles into a vibratory motion, in which he believed the heat to consist.

Dr. S'Graveande afflicts, a lucid body to be, that which emits, or gives fire a motion in right lines; and makes the difference between light and heat to consist in this, that to produce the former, the fiery particles must enter the eye in a rectilinear motion, which is not required in the latter: on the contrary, an irregular motion seems more proper for it, as appears from the rays coming directly from the sun to the tops of mountains, which have not near that effect with those in the valley, agitated with an irregular motion, by several reflections.

Whether or not there be always light, where there is fire, has been disputed among authors; as also, whether or not there be any luminous body without heat; heat being considered by them as a motion that may be infinitely diminished, and light a matter that may be infinitely rare; to which we may add, that no heat is sensible to us, unless it be more intense than that of our organs of sense. M. De Luc, in his Lettres Physiques et Morales, &c. 1780, observes, that the rays of the sun, though not warm in themselves, occasion heat, by giving activity to a substance, which reflects in all bodies, and constitutes a part of their mass, and which in certain circumstances is capable of producing heat, and that in consequence of this influence, this substance becomes an elastic or igneous fluid. (See Heat.) Caloric, however, is now considered material, and a distinct fluid from that of light.

Solar heat is at present accounted for in a different way to that of considering the heat as extinguished by light. Dr. Herchel has, from a series of experiments, of which we shall soon give an account, concluded, that the rays of caloric, or rays solely producing heat, are emitted from the sun, as well as from terrestrial bodies, affording light and heat; while the rays of light, or such as are essential to vision and colour, have not the property of producing heat. How far this conclusion is warranted, we shall have occasion hereafter to consider.

Besides the properties of light to be reflected and transmitted, and that of being absorbed and extinguished, we are presented with curious phenomena, arising from the attraction between this substance and other matter, which is the cause of the refraction and refraction of light. When a ray of light enters any transparent medium, in a direction perpendicular to the surface of the same, the ray will maintain its course in the same direction; but if the ray of light make any angle less than a right angle with the surface of the medium, it will not continue in the same direction, but will be drawn towards a straight line, perpendicular to the same surface, and passing through the medium at the point where the oblique ray enters. This line, in optical language, is called the perpendicular. The angle which the incident ray makes with the perpendicular is called the angle of incidence, and the angle which the ray makes with the same perpendicular, after it enters the medium, is called the angle of refraction. In all the degrees of obliquity with which a ray enters any medium, the sine of the angle of incidence has the sine of the angle of refraction.

The refracting power of different transparent bodies is not dependent upon one property alone; it appears, however, to be directly as their density, all other things being equal.

Inflammable bodies are found to refract light much more than bodies not inflammable. Sir Isaac Newton divided diaphanous bodies into two classes, each of which refracts light as their density. The first consisted of the inflammable, in which it was much more than according to the ratio of their density.

The other classes, which were not inflammable, appeared to obey the same law as to density, with the exception of the diamond and water. The former of these refracted in the compound ratio of inflammability and density; and although it was then not known to be inflammable, Newton strongly suspected it to be entirely an inflammable body, and that water which appeared to have an intermediate power between the two classes, he supposed, was partly inflammable, be.
Thee prophetic observations have been verified in the discovery of the diamond being pure carbon, and in the decomposition of water.

The late discoveries of Mr. Davy render it very probable that all compound bodies are composed of inflammable matter and oxygen. Hence it would seem, that the refractive power of bodies is less in proportion to the oxygen they contain. Sir Isaac Newton suspected that refraction was caused by inflammable matter alone, from which it would follow, that all diaphanous bodies contained inflammable matter. This, in all probability, is the case with the exception of oxygen. It has, however, been proved by Mr. Biot, that the refractive power of oxygen, although less than any substance in proportion to its density, is nevertheless appreciable. The same philosopher also ascertained that hydrogen refracts light in a ratio, independent of its density, higher than any other substance.

From the above facts we may, with some certainty, conclude, that the refractive power of bodies, or, in other words, their attraction for light, is in the compound ratio of their inflammability and density.

Light is not only attracted in passing through different media, constituting refraction, but it is attracted towards the sides of bodies by which it passes, and is then said to be reflected. When a beam of light is let through a small hole into a dark room, the rays are found to be drawn towards the sides of the hole, by which means they acquire a certain degree of divergence. In consequence of this change in the direction of the rays, the shadows of hairs, and other slender substances held in the beam of light coming through the aperture, are found to be enlarged in proportion to the distance of the place on which the shadow is cast.

See Inflexion.

From this circumstance Sir Isaac Newton concluded, that the rays of light must have passed as they are represented in Plate IX. Optics, fig. 8, in which X represents a section of the hair, and A, D, B, E, &c. rays of light passing by at different distances, and then falling upon the wall QQ. Since, when the paper which receives the rays is at a great distance from the hair, the shadow is broad, it must follow, as he observes, that the hair acts upon the rays of light at some considerable distance from it; the action being strongest on those rays which are at the least distance, and growing weaker and weaker on those which are farther off, as is represented in the figure; and from hence it comes to pass, that the shadow of the hair is much broader in proportion to the distance of the paper from the hair, when it is nearer than when it is at a great distance. It is of no moment, whether the hair be surrounded with air, or with any other pellicul substance. The shadows of fringes made in polished plates of glass, and the veins in the glass, cast the like broad shadows; so that the breadth of shadow must proceed from some other cause than the refraction of the air.

The shadows of all bodies, metals, flumes, a glass, wood, horn, &c. in this light, were bordered with three parallel fringes, or bands of coloured light, whereof that which was contiguous to the shadow was the broadest and most luminous, while that which was the most remote was the narrowest, and so faint, as not easily to be visible. The first or innermost fringe was violet, and deep blue next the shadow, light blue, green, and yellow in the middle, and red without. The second fringe was almost contiguous to the first, and the third to the second; and both were blue within, and yellow and red without; but their colours were very faint, especially those of the third. The colours, therefore, proceeded in the following order from the shadow: velvet, indigo, pale blue, green, yellow, red; blue, yellow, red; pale blue, pale yellow, and red. The shadows made by scratches and bubbles in polished plates of glass, were bordered with the like fringes of coloured light. He also observes, that by looking on the sun through a feather, or black ribbon, held close to the eye, several rainbows will appear, the shadows which the fibres or threads cast on the retina being bordered with the like fringes of colours.

From comparing other experiments, in which a ray of light was made to pass through a hole into a darkened chamber, and then through a hole in a pale board, first by the edge of a single knife, and then by the edges of two knives placed parallel to one another, Sir Isaac Newton concluded, that the light of the first fringe passed by the edge of the knife at a distance greater than the eight hundredth part of an inch, that the light of the second fringe passed by the edge of the knife at a greater distance than the light of the first fringe, and that of the third at a greater distance than that of the second; and that the light, of which the fringes, observed in these experiments, consisted, passed by the edges of the knives at less distances than that of any of the fringes.

In another experiment, he placed at the hole a prism to refract the light, and to form, on the opposite wall, the coloured image of the sun; and he found that the shadows of all bodies, held in the coloured light between the prism and the wall, were bordered with fringes, of the colour of that light in which they were held; and comparing the fringes made in the several coloured lights, he found, that those made in the red light were the largest, those made in the violet the least, and those made in the green were of a middle size. Whence he inferred, that the rays which made the fringes in the red light, passed by the hair at a greater distance than those which made the like fringes in the violet; so that the hair, in causing these fringes, acted alike upon the red light, or least refrangible rays, at a greater distance, and upon the violet or most refrangible rays at a less distance, and thereby occasioned fringes of different sizes, without any change in the colour of any fort of light. It may, therefore, he concluded, that when the hair in the first observation was held in the white beams of the sun's light, and cast a shadow, which was bordered with three fringes of coloured light, those colours arose not from any new modifications impressed upon the rays of light by the hair, but only from the various inflections, whereby the several parts of rays were separated from one another, which, before separation, by the mixture of all their colours, composed the white beam of the sun's light; but when separated, composed lights of the several colours which they are originally disposed to exhibit. But for a fuller account of the author's curious experiments, and the conclusions drawn from them with regard to the inflection of light, we must refer to his well known treatise on Optics, p. 293. &c.

This action of bodies on light is found to exert itself at a sensible distance, though it always increases as the distance is diminished; as appears very febibly in the passages of a ray between the edges of two thin plates at different apertures; in which there is something very peculiar; the attraction of one edge being increased as the other is brought nearer it. The rays of light, in their passage out of glass into vacuum, are not only inclined towards the glass, but, if they fall too obliquely, they will revert back again to the glass, and be totally reflected.

The cause of which reflection cannot be attributed to any resistence of the vacuum, but must be entirely owing to some force or power in the glass, which attracts or draws back the rays as they are passing into the vacuum. And this
LIGHT.

This appears farther from hence, that if you wet the posterior surface of the glass with water, oil, honey, or a solution of quicksilver, then the rays which would otherwise have been reflected, will pass into, and through that liquor; which shows that the rays are not reflected till they come to the posterior surface of the glass, nor even till they begin to go out of it; for if at their going out, they fall into any of the foresaid mediums, they will not then be reflected, but persif in their former course, the attraction of the glass being in this case counterbalanced by that of the liquor.

Experiments, similar to those of sir Isaac Newton on reflected light, were prosecuted by M. Maraldi, whose observations chiefly respect the inflection of light towards other bodies, whereby their shadows are partially illuminated. Ac. Paris. 1723. M. p. 159. For an abstract, see Priestley's History, &c. of Light, &c. p. 521, &c. M. Mairan, without attempting the discovery of new facts, endeavoured to explain the old ones, by the hypothesis of an atmosphere surrounding all bodies; and consequently made two reflections and refractions of light that impinges upon them, one at the surface of the atmosphere, and the other at that of the body itself. This atmosphere he supposed to be of a variable density, and refractive power, like the air. M. du Tour succeeded Mairan, and imagined, that he could account for all the phenomena by the help of an atmosphere of an uniform density, and of a less refractive power than the air, surrounding all bodies. Du Tour varied the Newtonian experiments, and discovered in the colours produced by the inflection of light more than three fringes, which he exhibited distinctly in the following manner. He took a circular board, A B D E (Plate IX. Optics. pl. 9.) thirteen inches in diameter, the surface of which was black, except at the edge, where there was a ring of white paper, about three lines broad, in order to trace the circumference of a circle, divided into 360 degrees, beginning at the point A, and reckoning 180 degrees on each hand to the point E; B and D being each of them placed at 90 degrees. A slip of parchment three inches broad, and difpofed in the form of a hoop, was fastened round the board, and pierced at the point E with a square hole, each side being four or five lines, in order to introduce a ray of the fun's light. Lastly, in the centre of the board C, and perpendicular to it, he fixed a pin, about three-quarters of a line in diameter.

This hoop being so disposed, that a ray of light entering the dark chamber, through a vertical cleft of two lines and a half in length, and about as wide as the diameter of the pin, went through the hole at E, and passing parallel to the plane of the board, projected the image of the fun and shadow of the pin at A. In these circumstances he observed, £1, that quite round the concave surface of this hoop, there was a multitude of coloured frisks; but that the place M A N, of about eighteen degrees, the middle of which was occupied by the image of the fun, was covered with a faint light only.

2. The order of the colours in these frisks was generally such, that the most refrangible rays were the nearest to the incident ray E C A; so that, beginning from the point A, the violet was the first, and the red the last colour in each of the frisks. In some of them, however, the colours were disposed in a contrary order.

3. The image of the fun, projected on each side of the point A, was divided by the shadow of the pin, which was bordered by two luminous frisks.

4. The coloured frisks were narrower in some parts of the hoop than others, and generally decreased in breadth as receding from the point A.

5. Among these coloured frisks, there were sometimes others which were white, a line, or a line and a half in breadth, which were always bordered on both sides by a streak of orange colour, at least when the light of the sun was intense, and the chamber sufficiently dark.

From this experiment he thought it was evident, that the rays which passed beyond the pin were not the only ones that were decomposed; for that those which are reflected back from the pin were decomposed also: from which he concluded that they must have undergone some refraction. He also thought that those which went beyond the pin suffered a reflection, so that they were all affected in a similar manner.

In order to account for these facts, our author describes the progress of a ray of light through an uniform atmosphere which he supposes to surround the pin, and shows that the differently refrangible rays will be separated at their emergence from it; but he refers to some experiments and observations in a future memoir, to demonstrate that all the coloured frisks are produced by rays that are both reflected and refracted. Mémoires Présentés, vol. v. p. 636. 641.

From other observations, M. Du Tour concludes, that the refracting atmospheres, surrounding all kinds of bodies, are of the same size; for when he placed a great variety of substances, and of different sizes also, he always found the coloured frisks of the same dimensions. He also observes, that this hypothesis contradicts an observation of Sir Isaac Newton, viz. that those rays which pass the nearest to any body are more inflected. Mem. de Mathem. and de Phys. vol. v. p. 650, &c. or Priestley, ubi supra, p. 531, &c.

M. Le Cat found that, in some cases, objects appear magnified by means of the inflection of light. Looking at a distant steeple, when a wire of less diameter than the pupil of his eye was held pretty near to it, and drawing it several times betwixt his eye and that object, he was surprized to find that, every time the wire passed before his pupil, the steeple seemed to change its place, and some hills beyond the steeple seemed to have the same motion, just as if a lens had been drawn betwixt his eye and them. This discovery led him to several others depending upon the inflection of the rays of light. Thus, he magnified small objects, as the head of a pin, by looking at them through a small hole in a card; so that the rays which formed the image, must necessarily pass so near the circumference of the hole, as to be attracted by it: he also exhibited other appearances of a similar nature. Traité des Sens, p. 299, &c. Priestley, ubi supra, p. 537, &c.

Several coincident facts induced Sir Isaac Newton to believe that reflection, refraction, and inflection resulted from the same cause, namely, attraction. Of the two latter of these properties resulting from this cause there can be little doubt; but the laws by which the first is governed appears to depend rather upon the repulsion than the attraction of the medium. The greatest mystery attending reflection, is in the circumstance of the under surface reflecting light equally with the upper surface. This part certainly goes far to prove, that the reflection of light is not to be explained by considering the reflecting surface as a hard substance, from which the elastic particles of light are repelled, particularly since the reflection from the under surface of any medium is in the inverse ratio of the density of the medium, beyond the reflecting surface, and is greatest when the surface is bounded by a vacuum.

Although
Although Sir Isaac Newton does not attempt to explain the reflection from the upper surface by the attraction of the medium, he seems to be of opinion, that the light reflected from the under surface is attracted by the same medium in a contrary direction.

Hence he concludes, that this reflection is less as the density of the under medium is greater, the attraction of the first medium being counteracted by that of the second.

This explanation does not appear satisfactory. If the reflection of the rays from the under surface depended upon the attraction of the same medium, it would not produce the same phenomena which result from the reflection at the upper surface, and which is clearly caused by something like repulsion.

When a ray of light falls upon any reflecting surface, we cannot for a moment suppose that any attraction of the medium could cause it to be reflected, since the effect produced can arise only from a repelling force, exerted in a direction perpendicularly from the surface of the body. And that the elastic force existing between the body and the light is so perfect, as to make the angle of reflection equal to the angle of incidence. Newton very properly argued, that the reflection could not take place from the particles of light striking the hard parts of bodies, on account of the numerous interstices existing between their molecules; on the contrary, he supposed the light which struck the solid parts became extinguished.

It may here be observed, that it is equally difficult to explain the action of one solid body upon another, as it may easily be proved that they do not come into absolute contact in any instance. When we attempt to unite the surfaces of fractured bodies, we cannot, in most instances, bring the parts within the sphere of attraction; and even where this can be effected, as in two bright surfaces of lead, it may be proved that the parts do not touch.

It seems difficult to conceive how an atmosphere of hydrogen should by its pressure support a column of mercury, by the mere action of the solid parts of the two surfaces, since every particle of hydrogen would be required to act upon seven thousand particles of mercury.

We may, without much irregularity, consider all solid bodies as composed of two species of matter; the one possessing so great an attraction as to bring the particles into absolute contact, and the other so completely repelling itself, as to be infinitely dilated, if it were not for its attraction for matter with which it combined. The former of these properties is peculiar to all ponderable matter, the latter to the repelling matter denominated light and caloric, and perhaps electricity and magnetism. Daily experience shows, that the constitution of solid and liquid bodies is dependent upon a certain quantity of caloric, opposed to the opposite and contending force of the attraction of the particles of the solid body, by which also their volumes and relative gravities are governed. Hence we may expect, that when the attraction of the body for caloric is greater than the repelling force of the caloric, the body will possess what is called a greater capacity for heat, and the reverse of this will take place from a contrary change.

Conceiving the above to be the case, it will be easy to infer, that the surfaces of bodies must be surrounded by atmospheres of caloric, and it doubtless is by these atmospheres that we are to account for the difficulty of bringing two surfaces together, and by which we may also explain the action of the hydrogenous atmosphere upon the mercury. May not we, therefore, draw this general conclusion, that the particles of all solid matter can never be brought into contact, either in their internal arrangement or on the surfaces; and that the repulsion existing between the particles of bodies, whether in the same or in two different bodies, is solely to be attributed to the repulsion between the particles of caloric? And may we not further conclude, that the particles of bodies, in all situations, and under all circumstances, are constantly exerting an attractive force tending to their ultimate contact? If it should be admitted that caloric is the cause of repulsion, ethereal must be therefore dependent upon its presence, acting in a contrary direction to the attractive force. Hence it would be very absurd to say that caloric itself should be elastic, because this property depends upon two forces. When caloric, therefore, is reflected from the surface of a body, we are to attribute its return to the repulsion between itself and the caloric of the body, the solid matter having nothing to do with the reflection. The rays of caloric, passing from one body to another, may, from what has been observed, be caused by the joint action of two forces. The one arising from the repulsion of the particles of caloric for each other at the heated body, and the other from the following force of the attraction between the caloric and the receiving body. When, however, the repulsion between the radiant caloric and the caloric of the receiving body increases in a greater ratio than their attraction, the radiant caloric will be reflected. A contrary effect would cause them to be absorbed.

When the direction of the radiant caloric is perpendicular to the receiving surface, its projectile force conspires in the greatest degree with the attraction of the body, and less of course in proportion to its obliquity. Does not this agree with the established fact, that the reflection of both light and heat is inversely as the angle of obliquity the ray makes with the surface.

Light and caloric, so far as their reflection is concerned, are so similar, that we may with great propriety apply the same reasoning to the reflection of light, and the same absurdity would arise in considering light as consisting of elastic particles, because this would imply the existence of attractive matter in its composition. When, therefore, light is reflected, we are to consider with Sir Isaac Newton, that no action takes place between the particles of light and the solid matter to produce the effect; but, agreeably to our hypothesis, we must conclude that the reflection is caused by the repulsion between the particles of light and the caloric of the body.

If the reflection is caused by the caloric atmosphere on the surface of the body, we may perceive an easy way of explaining why the reflection of light is confined to the surface of bodies, and why the under surface should reflect as much as the upper one.

This hypothesis does not disagree with the fact, of the reflection being, like the refraction, as the density of the medium, because the increase of density will be attended with increase of attraction between the particles, and it will be evident, that the density of the caloric atmosphere will be in the same proportion, therefore reflection will be as the density.

What we observed respecting the obliquity of the rays of caloric, will hold good with respect to light. When the obliquity of rays of light, which fall upon transparent bodies is such, that the repulsion between the light and the caloric of the body is greater than the projectile force of the ray added to the attraction, the medium of the angle of obliquity is called the angle of total reflection. When the reflection is from the under surface, the attraction of the medium
The properties of light have been extensively studied, and we find that light is attracted by ponderable matter, as it is affected by gravity. The refraction and reflection of light are caused by the medium in which the light travels. The angle of total reflection also plays a crucial role in determining how light behaves when it encounters a new medium.

Solar Light. — We have already noted the immense velocity with which light is emitted from the sun's body, and it is easy to conceive that it cannot suffer any change in velocity or direction, till it meets with some ponderable matter. In approaching any planetary body, such as our earth, we have reason to believe that they are mutually attracted. Rays falling perpendicularly upon the atmosphere are equally attracted on every side, and come in a straight line to the earth; while those rays which fall obliquely are bent out of their original direction, and since the atmosphere is not of uniform density, such oblique rays will come to the earth in curved lines. If our atmosphere were of uniform density, the refraction would not be altered; but the oblique rays falling upon its surface, would be reflected in a very great degree; a circumstance which would deprive us of much of the sun's light. No doubt a great quantity of light becomes extinguished in its passage through the aerial medium, as we may justly learn from the difference of intensity in the light, at different altitudes of the sun; for much must this loss of light appear, when we recur to the statement already made, namely, that the whole effect of the sun's light would be lost by passing through 679 feet of water, and that the same effect would take place by its passage through 3,110,310 feet of air.

The following is a table from M. Bouguer, showing the intensity of the sun's light, at different altitudes, and the thickness of air it has to penetrate at each angle:

Vol. XX.
The property of light to be refracted had been known long before the time of Newton; but this philosopher was the first who discovered that the light of a fun-beam was not refracted uniformly. If light were uniformly refracted, the rays which enter any plane surface would retain their relative inclination to each other, while they pass through the diaphanous medium; and the same after their emergence, if the surface were a plain. Sir Isaac Newton, however, has proved, by a series of elegant experiments, strengthened by able reasoning, that the different parts of a solar beam are not refracted in the same degree. He caused a beam of light to pass through a small hole in the window-shutter of a dark room, making the pencil of rays to fall upon one side of a triangular prism. These rays were so refracted as to come out at another side of the prism. These emergent rays, however, were not parallel as they entered the other side; but each made a certain angle with the other, in consequence of some being more bent or refracted than the other. The image, or spectrum, formed by these rays upon a sheet of white paper, instead of being round, which would have resulted from uniform refraction, was of an oblong shape. Those rays which had been the least refracted occupied one end of the spectrum; and those most refracted, the other. The former tinged the paper of a red colour, the latter a violet colour; the intermediate rays exhibiting different colours, which were in the following order: red, orange, yellow, green, blue, indigo, and violet.

In order to shew that each of these rays had specific properties, not depending upon the medium they passed through, he caused them to pass through a second prism, sometimes together, and sometimes separately; but he always found them to retain their original properties.

By means of two contiguous spectrums, he caused a ray of one colour in the one to unite with a different colour in the other, and produced different compound colours. The yellow of one with the red of the other produced orange, which had the appearance of the primitive orange ray, and differed from it only in being decomposable into its original elements.

He ascertained by direct experiment, that those rays which were most refrangible were also most refrangible. In consequence of this property, he could reflect the different coloured rays separately. He caused the light to fall upon a prism, so laid upon a similar prism as to constitute a paralleloipied, so that the rays were parallel at their emergence; but upon turning the two prisms round their common centre, the light became reflected from the upper contiguous surface, and all the rays in their turns arrived at the angle of total reflection. But he observed that those which had been most refracted were first reflected; the least refrangible being the last.

These valuable facts were used by this able philosopher to explain the colours of natural bodies. He has shewn that colour is not a specific property of bodies, but is caused by the different rays of light being reflected from the surface of the body; the rest of the rays passing into, or through the body. Since the time of this philosopher, it has been objected that the seven colours above mentioned are not primitive. It seems very obvious that there can be only three primitive colours, namely, red, yellow, and blue; since all the colours can be made by means of these. It has lately been advanced by Prieur, that the primitive colours are violet, green, and red; that the yellow is formed with red and green, the latter being in excess; and that when the red is in excess, they form orange; the green and violet form blue.

The colours excited by the different refrangible rays do not appear to determine what are the primitive colours, since we find that different rays are capable of producing the same colour, as a mixture of the yellow with the red produces orange. And it must be admitted, that the violet rays excite, to some degree, the idea of red along with the blue; as in the green, the yellow and blue may be discerned, but none of the red.

When the different coloured rays are mixed together, either by recomposition, or by getting each colour from a separate

</table>
separate spectrum, the result will be white light. Hence Sir Isaac Newton concluded, that when the rays are profusely reflected from any surface it will appear white. It was found by Sir Isaac Newton, and has since been confirmed by the experiments of Dr. Herschel, that the different coloured rays have not by any means the same illuminating power. The violet rays appear to have the least luminous effect, the indigo more, the blue a little more, the green very great, between the green and the yellow the greatest of all, the yellow the same as the green, and the red less than the yellow. When the solar rays are passed through a convex lens, or reflected from a concave, a very intense heat is produced by the concentration of the rays. Count Rumford has shown, that when the rays of the sun are made to pass through a certain aperture, and fall upon any substance to be heated, while the same area of light is made to pass through a lens, in the focus of which the same quantity of matter is to be heated, they become heated in the same time to the same degree. Nothing is better known, in short, than that the rays of the sun are capable of exciting sensible heat. Newton, and the philosophers of his age, accounted for heat by the motion excited in the parts of the body by the agitating power of the absorbed light. Melville supposed that the heat was expelled from the terrestrial matter by the light. At present, it is generally admitted, on the strength of some valuable experiments made by Dr. Herschel, that the rays of light and calorific heat are separately emitted from the sun, the luminous rays producing light, and the calorific, heat.

This philosopher introduced a beam of light into a dark room, which was decomposed by a prism, and then exposed a very sensible thermometer to all the rays in succession, and observed the heights to which it rose in a given time. He thus determined, that the heating power of the red to that of the green rays was 2:2 to 1, and 3:2 to 1 in red to violet.

On repeating these experiments, he found that the greatest quantity of calorific rays were even beyond the co-oured spectrums at about ½ inch, from the commencement of the red rays. At a greater distance from this point it began to diminish, but was very perceptible even at the distance of ½ inch.

It will appear from what has been stated, that these calorific rays are less refrangible than the rays of light; hence the calorific focus will fall beyond that of the luminous. Dr. Herschel made an experiment to verify this inference, but did not come at any thing very conclusive. He afterwards made experiments to collect these invisible calorific rays, and cast them to act independently of the light, by which he concludes, that they are sufficient to account for all the effects produced by the solar rays in exciting heat; that they are capable of passing through glasses, and of being refracted and reflected, after they have been finally detached from the solar beam.

If we are to consider these invisible rays as being truly the same with artificial heat, emanated from terrestial bodies, under the temperature of 800° of Fahrenheit, some of the experiments of Dr. Herschel are strongly at variance with some of the experiments of Mr. Lefley, detailed in his work entitled "An Enquiry into the Nature of Heat," especially so far as relates to the transmission of heat through transparent bodies. It appears from the facts given by Mr. Lefley, that the heat of 212° of Fahrenheit is not transmitted by glasses in the radiant form, but is first absorbed by the glasses, and radiated again from its opposite surface. He was led to this conclusion by the fact, that more heat passed through white paper than the glasses. And what still more confirms this idea, he found equally as much heat passed through two plates of tin, one side of each being blacked, and the other polished. When the bright sides were placed together, and the black outwards, it transmitted as much as the glasses; but when the black sides were together, and the bright sides outward, there was no perceptible quantity passed through.

That culinary heat does not pass directly through glasses, may be tried by holding a pane of glass before a heated body, and alternately holding the hand on each side the glass. After some time, however, the glass gives heat to the hand, proving that the heat has been transmitted; but this will be found to result from a second radiation, and would have been more abundant, if a plate of metal, painted black, had been in the place of the glass.

The heat from the sun's rays is not so affected. It requires no perceptible time to pass through several thick prisms of glasses, and when we hold a convex lens in the sun's beams, we have instantaneous heat produced upon any opaque body in its focus.

We have not yet sufficient ground to establish the identity of light and heat; but if Dr. Herschel's experiments be correct, we must either conclude that the solar calorific rays are of a different nature from the invisiblerays, or that solar light is converted into calorie from heated bodies. The same philosopher, however, has made the same experiments with invisible culinary heat, and with similar results. How shall we reconcile the seeming contradictions? Dr. Herschel used two thermometers, one of which was his standard. Mr. Lefley used the differential thermometer, an elegant instrument, invented by himself. Dr. Herschel began his experiments with a red-hot cylinder, and continued them till it became invisibly cold. Mr. Lefley used a canister filled with boiling water. A more particular set of experiments is still wanting to clear up this mysterious subject.

Dr. Herschel has also given us some useful experimental facts on the relative quantities of light and heat transmitted by different substances. The following Table shews the quantity of light and heat, stopped by colourless and transparent solid substances.

</table>

The experiments in the first, second, and third tables, were made by letting the sun's rays act directly upon one thermometer, while the same light acted upon another after passing the different substanices. The numbers in the tables are the ratios of the differences of the degrees of each, after being acted upon for a given time. Table IV. was made in the same way, the red rays and the invisible rays being each separated by the prism, making two sets of experiments. In each of these, the red, or the invisible, acted on one thermometer, and on the other through each of the substanices.

Table V. is formed from three sets of experiments, made at different times, by causing, in the first, the rays of the flame of a candle to act upon one thermometer directly, and upon the other through the substanices. In the second set the rays of a common fire were used; and in the third, the invisible rays of an iron flame. See Phil. Trans. for 1806.

An abundance of useful knowledge is to be derived from these researches, which may be of the utmost importance to society, as well as in giving aid to different branches of science.

In delicate experiments of this kind, the thermometer seems to be the most important of the apparatus. The smallness of the scale, and the want of sensibility in those used by our ingenious experimenter, were certainly very objectionable, when compared with the differential thermometer of Leesley. A repetition of these experiments, under such
the advantage, is highly to be recommended. We have already pointed out some contradictions between these and Leffley's experiments.

By comparing the effect of the substances upon the solar invisible rays in Table IV, and upon the invisible rays from the iron flow in Table V, we are led to some very singular conclusions. It appears, for instance, that flint-glass stobs none of the invisible rays of the spectrum, although the same substance stobs 145,000 of the red rays, 91 of 1000 of direct solar heat, 34 of the direct light. Hence it would seem that carbonic acids mixed with the luminous, melt constitite the 9 of 1000, since all the invisible rays pass through.

We must from these data conclude, that either the rays of the solar spectrum produced heat, or that the carbonic acid in the coloured rays is a different nature from the invisible carbonic acids. If the latter be admitted, we have as much reason to consider the solar beam as consisting of different kinds of heat, as well as of light.

These anomalies are still increased, when we turn to Table V, where we find that the same flint-glass stobs out of 1000 rays 750 invisible rays from a flow, which would seem to establish that this carbonic acid is still different from both the visible and invisible carbonic of the sun; and in the experiments of Mr. Leffley, carbonic appears to possess still very different properties.

Here we see so much mystery and contradiction, that we must wait for more particular research. It is unlike the simplicity of nature; the fault must, therefore, rest with the philosophers.

Sir Isaac Newton, on finding so many different species of light, was unwilling to make so many fluids, but supposed they differed in the size of their particles; the largest being the least refrangible, and the smallest the most. The same thing would take place from the same particles moving with different velocities; the most refrangible moving with the least, and the least refrangible with the greatest velocity.

We have already stated, a fact discovered recently by Malus, that light acquires new properties by a peculiar reflection. Does it then appear impossible that it should not be changed in passing through diaphanous media? May not that which moves with the greatest velocity have a greater portion converted into heat; or, in other words, may not this conversion be as the velocity? This idea is strengthened, from the circumstance of carbonic rays being found throughout the spectrum. The greatest objections rising to this idea of light and heat being produced by the same rays moving with different velocities, are founded on the facts of combined light in phosphorescent bodies, and in the chemical effects which were thought to be peculiar to light. In our next subject, however, we shall shew that all the chemical effects producible by light can be produced by heat.

Besides the properties of the solar beams to produce heat and light, we find it to have other properties equally important to the animated world. This is most conspicuous in the economy of vegetables. It has been many times proved, that vegetables, growing without light, would not, in the first place, have more tendency to grow upwards than in any other direction. This arises from an evident attraction existing between light and living vegetables. This fact is familiar to those who have planted trees in windows. It is observable, that they always lean towards the light. The same effect would doubtless take place, if one side of a vegetable were shaded in the open air. The attraction of light is probably not the same for different vegetables; by which we may account for the different forms of trees. This is rendered plausible, when we contral the spreading branches of the oak with the towering branches of the poplar.

Experience has long ago established, that vegetables become detritus of smell and colour, and lose much of their combustibility, by growing in the dark. We find in Dr. Black's lectures, an account given by the celebrated Dr. Robinson, that when the vegetable plant is laid upon a very luxuriant soil, with large indented foliage, and perfectly white, he had not seen any thing like it, nor could any one inform him what it was. He had the plant with a rod brought into the open air in the light. In a little time the leaves withered, and from after new leaves began to spring up, of a green colour, and of a different shape from that of the old ones. On rubbing one of the leaves between his fingers, he found that it had the smell of common tansy, and ultimately proved to be that plant, which had been so changed by growing in the dark. Indeed it was recollected that some foil had been taken into the drain from a neighbouring garden, some time before it was found so altered.

This effect of light is not least conspicuous in the growth of celery. By covering it with earth, the light is shut out, which would very soon turn it green, and make its leaves strong as to render it unfit to be eaten, at the same time that it would render it more fibrous and tenacious.

From the circumstance of light giving odour and inflammability to vegetables, and since these properties are most common to bodies containing hydrogen, it would appear that light was essential to the production of hydrogen, perhaps by expelling oxygen; and hence it would also appear that hydrogen is necessary to the colour of vegetables. It has been affected by Humboldt, that he found vegetables growing in the dark mine, having their natural colour, but these plants were involved by hydrogen.

Light is found to produce various chemical changes upon bodies. When the oxyd of silver is precipitated from nitric acid by muriatic acid, the infodible muriat is at first white, and if kept in the dark at the common temperature, would doubtless remain so for an indefinite length of time. If, however, it be exposed to the light for a little time, it begins to assume a purple colour, and ultimately becomes black. This effect takes place more rapidly according to the intensity of the light. Hence it has been supposed to measure the intensity of light by the time of its changing. An instrument has been invented for this purpose by Mr. Leffley. See Photometer.

The general effect of light, as a chemical agent, appears to consist in digenerating the oxygen, or an acid from bodies which it effects, no doubt, by lowering the affinity of the base for oxygen, or the saline base for the acid. Hence, we find light is capable of decomposing those oxyds and salts, in which the oxygen or acid is held by a weak affinity. It therefore detaches oxygen from the oxyds of gold, platina, silver, and the peroxys of lead; also from nitric and liquid oxymuriatic acid. Dr. Herschel, in his experiments upon light, finding that the solar spectrum had different illuminating powers in different parts, conjectured that the power of the sun's light to effect chemical changes, might principally belong to some particular part of the spectrum, and it appears that this ingenious hint has been confirmed by experiments made by Dr. Woolston, and also by Ritter. It appears that the invisible rays have no action upon the muriat of silver, the red rays a little more, and so on, increasing to the utmost boundary of the violet; but the maximum of effect was found at some distance beyond the violet. It appears, therefore, from this curious fact,
Light.

Canton, the ingenious discoverer of this substanee, introduced equal quantities of it into two glass globes, and exposed them to the sun equally, to give them their greatest luminous power. They were then taken into a dark room, when they were equally luminous. One of them was now placed in boiling water, by which means it became much brighter, but it ceased to be luminous in ten minutes; while the other continued to shine for two hours after. After the latter, however, had ceased to shine, it became luminous by the application of heat. It appears, by the account of this author, when it had ceased to shine at one temperature, it always gave out light in a greater, even to the point of ignition; but never after the same, or a lower temperature, till it had been exposed anew to the sun's light.

These curious facts, on a first view, seem to prove that the light of this substance is derived from the sun's rays, which enters into combination with it, and is eliminated in the dark. This supposition, however, is rendered improbable by other facts. When it has ceased to shine, its property is restored by any of the coloured rays of the solar spectrum. It ought, therefore, to emit that particular light only to which it has been exposed, but contrary to this, under all circumstances, it gives out the same coloured light, which is generally white.

It seems more agreeable to the phenomena to suppose, that the influence of the light upon this substance consists in exciting some chemical action in the body, which cannot be produced by heat or, perhaps, the phenomena may be electrical, since we find that the electric spark, as well as light, is capable of giving it its luminous property.

A great variety of substances have the property of giving out light by different treatment, some by heat, others by rubbing, and by percussion. Most of the earthy salts have the property of shining in the dark, by being laid upon an iron plate, heated a short while of ignition. Flint of lime is by far the most brilliant by this treatment. The same is visible, though in a lees degree, in all the carbonates of lime, and in carbonates and sulphate of barytes, and also carbonate of fluoritum.

Several of the gems have the property of shining by rubbing. Quartz pebbles, rubbed briskly together, in the dark, give brilliant flashes, accompanied by a peculiar odour not unlike that produced by the wheels of a carriage grinding upon stones. The tourmaline also gives out light by rubbing. The shining property of this class of bodies is the same in vacuo, and any of the gases. The cause of these appearances is not even guessed at: they do not acquire these properties from the sun's light, like the phosphorous of Canton.

We are in possession of a number of curious facts relative to phosphenereence of animal and vegetable substanees. Canton has furnished a number of interesting experiments upon fish and the flesh of animals: and the subject has since been investigated and extended by Dr. Hulme. The flesh of animals, particularly seal, at a certain period after death, begins to be luminous, and continues so for some time. The light is extinguished when the meat has arrived at a certain state of putrefaction. This property, however, is more conspicuous in fish, and sea-fish more than that of fresh-water. A series of experiments is given by Dr. Hulme in the Philosophical Transactions for 1800, page 161.

He generally took about four drachms of the substance of different kinds of fish. This he put into a three-ounce phial, to which he introduced two drachms of sulphate of magnesia, dissolved in two portions of cold spring-water, but occasionally he used other salts.

Two
Two drachms of the flesh of the herring were put into the solution of sulphat of magnesia. On the second evening he perceived a ring of light round the top of the liquid, but it was dark below. On shaking the phial, the whole became beautifully luminous, and remained in that state. On the third night the light had again rifen to the top; but the ring was not so bright as on the preceding night, nor was it so bright after shaking as on the first occasion. In another experiment, the light disappeared entirely on the third night. The same experiment was made with sea-water. On the second night the liquid was dark; on the third lucid; on the fourth very luminous; on the fifth it began to decline; on the sixth it became clear; and on the seventh quite gone. At this period, neither the fish nor the liquid had any smell of putrefaction. The same took place in a second experiment. In another experiment, he used four drachms of the roe of the herring, two drachms of sulphat of magnesia, and two ounces of water, as before. On the second night, on shaking the phial, the liquid was luminous; it remained so on the third and fourth; and on the fifth it was extinct. In the same experiment, with sulphat of soda, the effect was less, but it was greater with sea-water. Similar appearances took place by a similar treatment of the mackerel.

He next suspended in a room the herring and the mackerel. On the second night the fishy side became luminous; on the third night both sides of the whole were exceedingly luminous. Dr. Hulme observes, that the soft roe of both these fishes afforded the molten light. At the time these fishes became very luminous, Dr. Hulme scraped off some of the luminous matter, which he named herring's light, or mackerel light. This substance he introduced to different solutions of salts.

The solutions used were sulphats of magnesia and soda; muriat and phosphi of soda; nitrat of potash; Rochelle salt; tartrat of soda; and sea-water. He also used solutions of honey and sugar; the quantity of water in each was two ounces; the quantity of each substance dissolved in the same was two drachms. With the exception of the nitre, and muriat of soda, the former being half a drachm, and the latter a drachm.

The herring or mackerel light being introduced to the solution of sulphat of magnesia, rendered the whole mass of liquid very luminous, and continued for 24 hours. All the above solutions became luminous by adding the same lucid matter. The phosphi and muriat of soda appear to have been better than the rest. The light with sea-water was more permanent, being luminous for several days. After the above luminous matter had ceased to shine, the light was in some degree revived by motion. What is very remarkable in these experiments, is the circumstance, that when the solutions were made stronger to a certain extent, the light became suddenly extingished, but was always restored by dilution with water.

The light is also extinguished by water, lime-water, water impregnated with carbolic acid, or with sulphured hydrogen, alcohol, alkalies, and acids.

In all the above experiments the light is not attended with the least elevation of temperature.

By expounding this luminous matter to a certain degree of cold the light is extinguished; but is restored with the return of temperature. A moderate heat causes it to be more brilliant; but the heat of boiling water entirely extinguishes it, and destroys the property. According to another set of experiments by Dr. Hulme, in the Phil. Trans. for 1801, page 453, it appears that these substances do not shine brighter in oxygen than atmospheric air. In nitrogen gas they do not begin to shine; although, after the shining has commenced, they continue to shine in this gas for a limited time; the presence of oxygen appears to be essential in first producing this property. Dr. Hulme found, that when two herrings were exposed, with their sides touching, the unexposed parts remained dark: he found the effect produced by covering any part with strong brown paper. In hydrogen gas the fresh fish begins to shine; and, if begun, it is very soon extinguished; it recovers its property, however, by re-expoision to the air of the atmosphere. By repeated and alternate exposure to these gases, the light is lost and regained a number of times. This light is also extinguished by nitrous, carbolic acid, and sulphured hydrogen gases. This phosphorescence is extinguished in vacuo; but is restored by letting in the air. The glow-worm and rotten wood were found to possess similar properties: they were similarly acted upon by the different gases, by cold, and by moderate heat. The light of the shining matter from the fish was extinguished by a heat from 96 to 100° Fahrenheit; the temperature of 110° impaired, but did not extinguish the rotten wood: the temperature of 114° increased the brilliancy of the glow-worm; but the temperature of 212° extinguished both.

It appears that rotten wood, like the fish, does not give out light till it has been exposed for some time to the air: it retains its luminous property immersed in spring-water, or distilled-water, and also in linseed oil; it is, however, extinguished by acids, by alcohol, and, perhaps, by alkalies. The luminous matter of the glow-worm is a kind of secreted and retained in the lower part of the abdomen. If the fluid be squeezed out, it still retains its shining property, and may be spread upon the palm of the hand; but it soon in this state disappears.

This property is observed in some other insects, particularly the lantern-fly of the West Indies.

The light of a great number of these artificial and natural pyrophoroi does not appear to depend in the least upon the presence of oxygen. Of this kind are phosphores of Canton, the different earthy salts which shine by the application of heat, and some of the minerals which shine by friction and pressure.

Those of which we have last treated require the presence of oxygen, at least to acquire the property of shining. This circumstance renders the suppocation of Dr. Hulme rather improbable, namely, that the light is a component part of the body from which it is illuminated. The only thing which the facts above given can be allowed to have established, is that, during a certain state of the animal substance, between death and actual putrefaction, some process is carried on in the presence of oxygen, by which light is evolved; and that during the time the substance is in vacuo, or in some gas which is delitute of oxygen, this process is suspended, and by the presence of other substances totally stopped. The fact of its continuing to shine in nitrogen, might arise from the preference of a small portion of oxygen. It appears, from the circumstance of its shining in atmospheric air, as much as in oxygen, that very little oxygen is necessary. Further affects that the glow-worm shines brighter in oxygen, but the oxygen does not appear perceptibly impaired. This shows, that although oxygen is necessary, the quantity required is very small.

It has been too common for chemists to draw the following conclusion, that when light, or light and heat together, are evolved, that it must either have arisen from combustion, or that the light is a component part of the body from which it is discharged. As, for instance, because Canton's phosphorescent shine without the presence of oxygen, the
the light is called light of combination; and Dr. Halme has, with less foundation, drawn the same conclusion. Instead of saying that light and heat are products of combination, from the union of oxygen with inflammable matter, we should say that it is the result of rapid chemical combination, when the bodies have great affinity for each other.

We have several facts which confirm this idea. When strong mineral acids combine with pure potash, lime, or magnesia, much heat and some light are emitted. The same thing is also observed in flacking of lime. In an experiment, made by a society of chemists, it appears, that when a mixture of sulphur and copper filings is exposed to a red heat, in a glass tube, the oxygen being excluded, the two sublimates suddenly combine, attended with the disengagement of light. In those chemical changes where heat and light are disengaged, the following law will obtain. The change of temperature will be as the difference between the specific heat of the compound body, and half the sum of the specific heat of the bodies before combination; while the intensity of the light and heat will be inversely as the time in which this change has been taking place.

We shall here leave the subject of phosphorescent light, to give some account of that produced by combustion; in treating which, we shall find our progress much facilitated, by considering combustion as dependent on the above law, rather than upon the laws of combustion, as laid down by Lavoisier, who was of opinion, that the light and heat furnished by combustion were entirely derived from the oxygen. If, as we have supposed, the quantity of heat be greater, as the specific heat of the resulting compound is less than the mean of the bodies before combination, we ought to have heat evolved whenever such change can be proved; and by ascertaining, before hand, the specific heat of the compound, and of the elements, the quantity of heat may be known. Experience has already given great strength to this notion. The intensity of the light and heat, however, during these changes, will not depend upon the absolute quantity evolved, but upon the rapidity of the evolution; and, if we are not greatly deceived, the quantity of light will always be as the rapidity of combustion. In the flow combustion of hydrogen gas, the light is not great, but the whole heat is greater than that afforded by any other combustible body. On the other hand, the absolute quantity of heat afforded by the combustion of phosphorus, is much less than that evolved by burning an equal weight of hydrogen; but the quantity of light given by the former, much exceeds that of the latter. The intensity of light, however, will also be inversely as the space which it occupies, and hence it will be as the specific gravity of the combustible body. We may therefore conclude, that the quantity of light afforded by combustion will be as the rapidity of combustion, which will be as the affinity of the body for oxygen, as the density of the burning body, and inversely as the cohesion of the body. The difference of cohesion between charcoal and the diamond accounts for the relative combustibility of these two bodies. For this reason, soft iron wire ought to afford more vivid combustion in oxygen than steel wire.

In order to obtain a relative idea of the value of different combustible bodies, used for procuring artificial light, we shall detail some ingenious experiments made by Dr. Henry, and published in Nicholson's Journal, vol. xi. p. 65.

Dr. Henry, with a view to ascertain the relative value of the combustible gases, made some trials with hydrogen, carburetted hydrogen, and carbonic oxyd. These he found did but afford a very inferior light, compared with the splendid light given by the gas afforded by the destructive distillation of pit-coal, which is equal to the light given by the finest spermacent oil. The following table points out the result of his experiments, and clearly shows the cause of the superior property of coal gas to produce light.

The first column contains the different gases, 100 measures of each being used in each experiment. The second, the measures of oxygen which were consumed, while each of the 100 measures were burning. The third, the quantity in measures of carbonic acid, which resulted from the combustion. It is a fact, already ascertained, that every measure of carbonic acid gas has resulted from a measure of oxygen; consequently, the quantity of oxygen consumed in its formation is equal to measure to the numbers in the third column; the excess of oxygen, therefore, appearing in the second. By subtracting the number in the third from that in the second, it will give the quantity of oxygen which has combined with the hydrogen in each of the gases. This excess of oxygen, in the second column, will combine with two measures of hydrogen, to form water. In order to form some idea of the relative value of these combustible gases, we will compare the first, which is pure hydrogen, and the last, or the pure olefiant gas, which has the greatest efficacy in producing light. The 50 measures of oxygen in the first combine with 100 of hydrogen, and since no carbonic acid is produced, this is the whole effect. In the last experiment, 179 of carbonic acid is formed at the expense of 179 measures of oxygen, and about 56ths its weight of carbon, which would alone have furnished considerable light. Since, however, 284 measures of oxygen are expended, we have 284 - 179 = 105 measures of oxygen, which would require 200 measures of hydrogen. If, therefore, hydrogen and carbon were equally efficacious as combustible bodies in producing light, the quantity of light in one, to that in the other, would be as 210 : 5 x 179 : 100, or as 2.5 to 1 nearly. The ratio of the specific gravities of these gases is as 90 to 8 nearly; therefore, multiplying these ratios, we get 270 to 8, or 34 to 1 nearly, for the relative intensity of the light of each.

These different gases are here supposed by Dr. Henry to be mixtures of several gases, the composition of which is known, and all consisting of different proportions of hydrogen and carbon, with the exception of the carbonic oxyd, which
which contains oxygen. Now, setting aside the latter gas, which being partly saturated, the rest will be in their effect to produce light, as the quantity of carbon they contain; not that carbon is more effective than hydrogen, but because the specific gravity of the gas is increased by the carbon. Since, therefore, the olefiant gas contains the most, and is of the greatest specific gravity in consequence, those gases which contain the greatest quantity of olefiant gas, must be the best for producing light by combustion. Now, it may be seen in the table, that the gases obtained from lamp oil and wax are the next to the olefiant gas in their effect of giving light; and hence we may conclude that those gases contain a large proportion of olefiant gas, and of course seem well fitted for producing artificial light. If we may judge by analogy, we may expect that the spermaceti fat will stand as high as the oil, and the beef tallow may, perhaps, be the next in order. During the burning of these substanices, the vapour which, when kindled, constitutes the flame, may consist of a great proportion of the olefiant gas. In the burning of all fatty substanices, however, there is a great redundancy of carbon, which flies off with the gaseous products in the form of smoke, and which is burnt in the Argand lamp. The above facts will furnish an elegant and simple method of appreciating the relative value of the different combustible bodies to produce light. See Gas-Lights, Lamp, and Combustion.

The light which is furnished by combustion, and commonly called artificial light, is considered by most philosophers as being a component part of the bodies employed in the combustion. Even in the simple process of heating a body red-hot, it is said that the body at that temperature begins to give out light. It is rather curious, that all bodies should give out light at the same temperature, which is said to be about 800° Fahr. It would appear, from a fact given by the late Mr. Wedgewood, that the emanating medium is heat or light, according to the density of the body from which it is emanated. The heated air is hot, so as to make a thin film of gold appear red-hot, although the aerial medium did not become luminous. Terrestrial light, as it appears to poise most of the properties of solar light, like it, can be transmitted and refracted by transparent bodies, and it strictly resembles it in being reflected by the same bodies. It is said, however, to contain a different proportion of the coloured rays from that of solar light, being defective in the blue, and redundant in the red rays.

Doctor Hufchel has made a number of experiments upon terrestrial heat, in order to compare it with the heat furnished by the sun; but he seems to have taken it for granted, that the solar light and the artificial do not differ, although his experiments prove, that terrestrial heat and solar heat differ essentially. Artificial heat does not pass through glass, while the solar calorific rays pass easily through the substance of a prism, and afterwards through a convex lens.

It has been found that artificial light has some chemical properties. The Abbé Teller found that the green colour of vegetables is produced by the light of a lamp. This fact has been confirmed by Decandolle.

**Light from Diamonds and other Bodies.** See Light, fupra, DIAMOND, ELECTRICITY, and PHOSPHORUS. VOL. XX.

**Light; Exhibition of, by living Animals.** This singular property belongs only to creatures of a simple structure. It appears to reside only in certain species of the four last classes as established by modern naturalists, viz. mollusca, insects, worms, and zoophytes.

The mollusca and worms contain each but a single species, which has been ascertained to give light; for the account of certain species of lepas, murex, and charus yielding light, does not seem to rest upon any good authority, and the stories told by Bruguiere and by Plancergues of earth-worms being luminous, are improbable in themselves, even if they were not contrary to common observation. See Journal d'Histoire Naturelle, tom. ii., and Journal de Physique, tom. xvi.

The examples of luminous species are more numerous amongst insects than in any other class. They are to be found in the following genera: elater, lampyris, fulgora, pau- fus, oedipoda, cancri, lycerus, and limulus.

There are also many luminous zoophytes, particularly in the genus Medusa, and in the new genus Berce.

Some writers have attributed the property of shining while alive to certain fishes; but, as it would appear, upon very questionable grounds. In a voyage from France to Cayenne, Mr. Bajon saw in the sea a number of luminous points which shone when struck, and another appearance of pale flames, about three feet below the surface of the water. He likewise observed in the migration of the dorado and other fishes, that their bodies were filled with similar luminous points. Upon examination he discovered those to be minute spheres which adhered to the surface of the fish. These were most probably the small species of luminous medusa. We shall hereafter notice that Bajon's observations therefore shewed no property of shining in the fish themselves.

Godeheu de Riville states in a paper he sent to the Academy of Sciences, that he found in the Scouber pelamis, on opening it alive, an oil which was extremely luminous. It should be observed, that Riville was prepossessed with the opinion of all the luminous appearances of the sea being occasioned by a peculiar oily fluid; other parts of his Memoir shewed inaccuracy of information; and it may be added, that if the oil of fishes were usually luminous, as supposèd by Riville, it would be a fact very generally known.

We shall now proceed to consider the luminous property in those animals which have been ascertained to possess it. Afterwards we shall describe the peculiar organs from which the light is known in certain species to emanate; and lastly, we shall examine the opinions that have been entertained respecting the nature and origin of animal light.

The species of Pliou, described by Pliny under the name of Dasylus, has long been known to possess remarkable powers of evolving light. It is recorded by Pliny, that every part of this animal's fabulence is charged with a fluid, which, like liquid phosphorus, renders any object luminous with which it comes into contact.

Reaumur has confirmed the observations of Pliny; he found also that the water contained in the shell of the das- tylius, and other fluids in which the animal might be immered, acquired the property of shining, and after touching the creature, the hands communicated to common water a milky or pale phosphoriac appearance. Reaumur observed that the light was most vivid when the dasylus was fresh; it afterwards gradually declined until it became extinct. He dried the entire animal, which deprived it of all power of shining, but this was restored in a weaker degree even after four or five days, by moistening it either with fresh or salt water. So far from the process of dissolation being at
L I G H T.

The glow-worms most frequently assemble in numbers upon dry banks, or under hedges on the sides of unfrequent'd roads; they are rarely seen on public roads, or in fields. They do not display their light upon all nights like; scarcely one of them will be seen for several nights together, and then, as it were by common consent, they appear with great splendour for a few nights, after which they again retire. Their disappearance probably depends upon their meeting with the male insect, for we have not observed that the state of the weather has any influence upon them. They commonly begin to shine before it is quite dark, and extinguish their light some time before the approach of day. It is remarkable with what regularity their instinct guides them in this particular; we have kept them the whole day in darkens, without their having any desire to move or expose their light, yet in the evening, although purposely placed near burning candles, they crawled about and shone with brilliancy.

The light of the glow-worm is always most vivid when the creature is in motion; it may also be excited or encreased by turning the insect on its back, or otherwise teasing it. But the luminous appearance is interrupted at all times by short and irregular periods of either diminished light or total darkens; usually, however, there are two small spots on the last ring of the abdomen, which retain their light whilst the other luminous rings cease to shine. The lamprypis italicita has been observed, like the noctilucus, to have the power of modifying its light; it is, however, rendered more brilliant at each motion of its wings. Mem. de l'Acad. des Sc. 1766.

The pyralis minor of Brown exhibits a vacillating light; sometimes stronger, sometimes weaker, and at times dying wholly away. The light is always renewed in a few seconds, the obscure intervals being of shorter continuance than the moments of illumination, which the creature seems able to command at pleasure. Every part of the abdomen appears to yield light in this insect, which is stronger and more confiant than what is emitted by the elater noctilucus. Brown's History of Jamaica.

It has been ascertained, that the larva and chrysalis of the lampyrides are luminous. Degeer mentions, that the larva of the lamprypis italicita has been mitaken by Limneus for the perfect female insect.

M. Gueneau de Montbiillard not only states the larva and chrysalis of the glow-worm to be phosphorecent, but that the eggs also for two, three, or more days after they are expelled from the female, emit light without intermission or decrease, and that for an equal time their light declines until it becomes extinct. He observes, that it is not necessary for the eggs to be fecundated, but those which have longest produced the larvæ. In one instance he did not find the eggs to be luminous; on another occasion, some eggs, which were laid on the 12th of June, shewed a degree of brilliany, even on the 28th of July. Memoire fur la Lampyre. Acad. de Dijon.

We have very frequently had great numbers of the eggs of the glow-worm in our possession, but we never saw them in a luminous state, except upon one occasion, when they shone unremittently for several days together, as described by Montbiillard; the fact is, therefore, the more remarkable, on account of the rarity of its occurrence.

Besides the species of fulgura, in which the luminous faculty has been noticed, there are probably several others, if we may judge by analogy of structure, that also possess it. The individuals most distinguished for this property are the lanternaria, candilaria, and pyrophilus.

The fulgura lanternaria displays a very brilliant sparkling light,
light, which is only seen during the night when the insect is in motion. Madam Merian having once collected a number of this species, she enclosed them in a box, without being aware of their luminous property. Being one night attracted by the noise that proceeded from the box, she opened it, and, to her great surprise, found every insect in motion, and yielding a strong light. Merian Suri.

Cuvier seems to entertain some doubts of the luminous property of the lanternaria. He says, in his Tableau Élémantaire de l'histoire naturelle, some voyagers have asserted, that the projection from the head of the insect emits a vivid light, but it appears, at least, that this does not exist at all times.

The fulgora candibraria has been observed to throw out flashes of light, which are succeeded by moments of obscurity.

The fulgora pyrophorus has been reported to shed a radiant light.

With respect to the luminous property of the other fulgors, we are not in possession of any particulars.

The pappus sphororus has been discovered to yield light by Dr. Azelius. On going to look at his specimen one evening, he says, he happened to stand between the light and the box in which it was contained, so that his shadow fell upon the insect; he observed, to his great astonishment, the globes of the antennae, like two lanterns, spreading a dim phosphoric light. He examined the insect several times during that night, when the same appearance still presented itself; he was, however, disappointed in not having the opportunity of making further observations upon the animal, as it was so much exhausted it died before morning, and he was not able to procure another specimen. Linnean Transactions, vol. iv.

The solpindra electra is an insect frequently found in this country, but is not observed to be luminous at all times. Duyer said he never saw it emit light, which was probably owing to the animal being only luminous under particular circumstances. It would appear that this species is incapable of shining unless after exposure to solar light. In several experiments that were made upon the solpindra electra, it was found, that the creature could not be excited to shine after it had remained all day in a dark situation, but a short exposure to the light appeared to be sufficient to restore the luminous property.

The light produced by the solpindra electra has a dull phosphoric appearance; it is a momentary emanation, which only takes place when the creature is disturbed or pressed.

The solpindra phophoria is but imperfectly known; in the edition of the Systema Naturae, published in 1757, Linnaeus states, that this insect is an inhabitant of Asia; that it yields, during the night, a light resembling that of the glow-worm, and that it is caught by falling from the sky on ships in the Indian and Æthiopian seas, 100 miles from the continent. Linnaeus quotes as his authority, Car. Geel. Ekeberg, who, he says, saw, described, and delineated the animal.

Ekeberg was a Swede, and the captain of an East Indian man-of-war. He made fourteen voyages, but, as far as we can learn, never published his discovery of the solpindra phosphoria, and as we have no subsequent accounts of this insect by other voyagers, its real characters, and perhaps existence, must remain doubtful.

The cancer fulgens was discovered by Sir Joseph Banks, during his first voyage with Captain Cook, in the pabbage from Madeira to Rio de Janeiro. He observed, that its whole body was illuminated, and produced very vivid flashes of light. Phil. Trans. 1810, part ii.

Habilitz relates, that a cable being on one occasion drawn up from the sea, it was found to exhibit light, and, upon closer inspection, it was perceived to be covered with the cancer pulux. Habilitz ap. Pall. a. nord. Beytr. 4. p. 356.

Thules and Bernard, of the academy of Verinias, also reported, that they met with the cancer pulux entirely luminous.

In different systems of natural history, the property of shining is attributed to this species of cancer, probably only on the above authorities. The accuracy of the assertion might perhaps be still called in question, as the cancer pulux being frequently under our eyes, its luminous property, if it existed, could hardly escape more general observation.

In 1754, Godouche de Riville discovered a luminous tellacous insect on the coast of Malabar, which appears to belong to that division of the Linnean genus, monocus, called by Muller lynceus.

Riville, perceiving the sea around his ship to emit a very brilliant light, procured some of the water and strained it; after which it ceased to shine, but the cloth was covered with luminous specks, that resembled in form and magnitude the ova of fish; on being examined in the light, with a magnifying glass, they were discovered to have an internal motion; some that were set at liberty in the water were seen to swim with great rapidity like water fleas. Riville seized one of these with a pair of forceps, which caust of it shed a luminous liquor of a blue colour, that illuminated the water to the distance of two or three lines. Some of these animals were put into fresh water, which they survived only a few seconds, and devoured, astringing, to the bottom of the vessel; many of them rendered much luminous fluid while dying.

Riville describes this creature as being enclosed in a shell resembling an almond, split along the side, and noteke at the upper end, which is so transparent that all the internal parts are seen through it. The insect has four jointed antennae, furnished at their extremities with long fets. There are two feet armed with hooks; and below these, a thick foot terminating in several claws. The viscera are contained in a round sac; and at the lower part of the shell there is found a number of azure-coloured globules, which Riville considered as reservoirs of the luminous fluid, because they became of a dull yellow colour when the animal was about to die: but they are more probably the ova, which are also visible in this situation in other tellacous insects.

The luminous liquor shed by the animal does not, Riville says, mix with water, but floats on the surface like globules of oil. By straining some water from which the animals had been removed, similar globules were left in a distinct form upon the cloth. From these circumstances, he was disposed to believe that the globules he saw were really of an oily nature: which opinion he was in a great measure induced to adopt, from a preconceived theory, that all the luminous appearances of animals depend upon the occasional presence of an oily fluid. Memoire fur la Mer lumineuse. Mem. Etrang. de l'Acad. des Scien. tom. iii.

A few years ago, captain Horburg prefented Sir Joseph Banks with some notes on the luminous appearance of the sea, and a drawing of a phofphorecent marine insect, which have been published in a paper of Mr. Macartney's communicated to the Royal Society in 1810.

Captain Horburg remarks, that the luminous state of the sea between the tropics is generally accompanied with the appearance of a great number of marine animals, of various kinds, upon the surface of the water; to many of which he does not, however, attribute the property of shining.
LIGHT.

Grifelini further mentions the shining of another marine insect, which appears to be the _monodon_ discovered by Ribville. Observations de Francois Grifelini in sua Scolopendria marine Infamte, Venise 1750.

The same animal has likewise been described and figured by Adler, under the name of the _neris phosphorans_. His description coincides with that of Grifelini. He states that this species is found in the African and Indian oceans, yet that it is rarely met with in the Northern seas. "Observations Academicae Carol. Linee.

The _neris noetiluca_ was seen by the abbé, Nollet, M. Rigaud, and Fougeroux de Bondaroy. The latter, however, describes it to be the *fire of the head* of a small pin. He says it increases, diminishes, or extinguishes its light at pleasure, which commonly issues from the posterior part of the body; but when fully illuminated, the head is only opaque. The *colour of the light is blueish*. When squeezed, it sheds a train of luminous fluid; which appearance is also seen, in a degree, when it is agitated in the water. He mentions having observed two sizes of the animal, but cannot determine whether these are different ages, sexes, or species. Mem. de l'Acad. des Sciæ. 1767.

The abbe Diecquemare states, that he saw the luminous animals discovered by Vianelli; that he exhibited them to his pupils during his lectures, and delineated them at the same time. These drawings he sent to Rigaud, who returned for answer, that the designs were precisely the same of those he had himself executed. Journal de Physique, tom. vi.

Spallanzani also asserted that he had seen the _neris noetiluca_.

After such a striking concurrence of testimony, we cannot preface to doubt the existence of this species of luminous animal: but we are led to think that it never visits the coasts of our country; as in numerous examinations we have made of sea-water in a luminous flat, we have not met with it. Judging from our own experience, and comparing it with the observations of others, we are led to conclude that the _neris noetiluca_ is, generally speaking, a rare species, and that the light of the sea is most frequently occasioned by _medusa_.

The largest and most splendid of the luminous _medusa_ is the _pellucens_, which was discovered by Mr Joseph Banks, in the first voyage of captain Cook. It was taken up from the sea, at the same time with the _cancer fulgens_ already mentioned, in the passage from Madeira to Rio Janeiro. This species measures six inches across the crown or umbrella, which is marked by a number of opaque lines that pass off from the centre to the circumference. The edge of the umbrella is divided into a number of lobules, which succeed each other, one large and two small ones alternately. From within the margin of the umbrella there is suspended a number of long cord-shaped tentacles. The central part of the animal is opaque, and furnish four thick irregularly shaped processes, which hang down in the midst of the tentacles.

The _medusa pellucens_ throws out flashes of light during its contractions, which are so vivid as to affect the sight of the beholders. When the water in which these animals, and some of the _cancer fulgens_, were contained, was emptied out of a bucket, it appeared like a stream of fire, or fueled gold. Phil. Transf. 1810, part ii.

The _medusa noetiluca_ is described by Forficai, as measuring about three inches in diameter, and about one and a half inch in depth. Its surface is convex, of a reddish glass colour, with brown spots. The margin is notched into 16 lobules. The
LIGHT.

The central part, containing the vilca, hangs down for some way, and is surrounded by eight somewhat broad tentacula. Forskal, Descriptiones Animalium.

This species is reported to be extremely luminous, particularly round the margin.

Forskal has described also a species of luminous animal under the name of medusa densa. It appears to be a beroe, and corresponds most nearly with the medusa pileus of Gmelin.

A luminous species of medusa was discovered by Spallanzani in the Strait of Messina. Its form is convex, with a faintly brindled margin. There are four thick tentacula, and eight which are long and slender. These are each hollow. In the concavity of the umbrella there are four small groups of long thin bodies, entwined together like intellines, and adhering to an entangled mass of small tubes of a silver colour, that are extremely transparent and elastic. At the internal edge of the cavity of the umbrella there is a thin mucilaginous lamina. The purle communicates with four lateral orifices, and has an aperture before. Spallanzani represents this species as being exceedingly luminous. He says it shone like a torch, and was visible 35 feet below the surface of the water. The water is variable; sometimes it continues for a quarter or half an hour, or longer; at others it becomes suddenly extinct, and re-appears after a considerable interval. He supposes that the effusion of the light depends upon the animal being at perfect rest. Memoria lopra le medufe folforiche. Mem. della Sci. Ital. tomo vii. and Spallanzani's Travels in the Two Sicilies.

Spallanzani further states, that he discovered in that part of the sea next the eastern coast of Genoa, in addition to the nereis nostitella, five other species of sea-glow-worms, as he calls them, two of which he met with again in returning from Messina to Lipari. He proposed to give a description of these animals in his voyage to Constantinople, which, as far as we can learn, was never published. We must, however, confess, that Spallanzani's known fondness for the wonderful, would lead us to receive these discoveries with some degree of distrust, particularly as they have not been confirmed by the observations of others.

One of the most brilliant of the whole tribe of luminous creatures has been lately discovered by Mr. Peron in the Atlantic ocean. Most naturalists would, from the general appearance and structure of the animal, consider it as a species of beroe, but Peron has created a new genus, of which this is the only species yet discovered, and which he calls the Pyrosoma altitum. The animal has an elongated and nearly cylindrical figure, truncated at one extremity, and rather conical at the other. The body is hollow, and does not contain any organ, except a very delicate net-work of vessels, which is spread over the internal surface of the cavity. The circular aperture, or mouth, is surrounded internally by a number of tubercules. The external surface is fluid with some thick elongated tubercules, and others of a smaller size. They are the principal seat of the light, and shine like polished diamonds. The interior of the substance of the body contains a number of small elongated glands, which are also more luminous than the transparent part.

The colour of this animal when at rest, or after death, is an opalescent yellow mixed with an inadaptable green; but during the contractions of its body, the creature appears, as it were, to kindle, and becomes instantly of the red colour of fused iron; it afterwards pales through different tints, as aurora, orange, green, and azure blue, according to the strength of its illumination.

The Pyrosoma, when at the same depth in the sea, gives the appearance of a red-hot bullet, but when floating on the surface of the waves, resembles a cylinder of incandescent iron. It was observed to perform regular and alternate motions of contraction and dilatation. The light is evolved during the contractile motions, and there may be excited irregularly, by touching the animal, or merely by agitating the water in which it is contained. The Pyrosoma, like all the other luminous marine animals, exhibits no light after death.

Mr. Peron only met with this species in a certain latitude, and observes that the mollusca and zoophytes, which are found at great depths in the sea, or at great distances from any shore, always inhabit particular regions of the ocean, out of which they are very rarely met with. Annales du Muséum d'Histoire Naturelle. Mem. par Peron. 24 Cahlier.

The pennatula phosphorea is well known to exhibit light; which, Dr. Shaw states in his History of Algiers, is so strong, that it directs the fishermen in their occupation.

The luminous effect is confined to the plumule of the pennatula, or that part which is inhabited by the polyps. Spallanzani, in a letter to Bonnet, states that the light is only emitted when the sea-pin is in motion, and that there is an ammus luminous-sub stance furnished by the polyps, which is soluble in water, and becomes mixed with the sea-water, that is admitted into the pin by means of a hole situated at the extremity of its flanks. (Mem. Soc. Ital. tomo ii.) Other species of pennatula are said to be luminous, particularly the grifitis, argenta, and grandis. The light exhibited by the last is reported to be an ash colour.

In a paper upon luminous animals communicated by Mr. Macartney to the Royal Society in 1816, he gives an account of three species he discovered on our own coasts. One is a beroe not described by authors. Another agrees most nearly with the medula bermasternia, that he conceives it to be the same, or at least a variety of it. The third is a minute species of medula, which he believes to be the luminous animal so often seen by navigators, although it has never been distinctly examined or described.

Mr. Macartney first met with these animals in the month of October 1814, at Herne bay, a small watering place upon the northern coast of Kent. Having observed the sea to be extremely luminous for several nights, he had a considerable quantity of the water taken up. When perfectly at rest, no light was emitted, but on the slightest agitation of the vessel in which the water was contained, a brilliant effulgence was perceived, particularly towards the surface; and when the vessel was suddenly struck, a flash of light illuminated from the top of the water, in consequence of so many points shining at the same moment. When any of these sparkling points were removed from the water, they no longer yielded any light. They were so transparent, that in the air they appeared like globules of water. They were more minute than the head of the smallest pin. Upon the slightest touch, they broke and vanished from the sight. Having strained a quantity of the luminous water, a great number of these transparent corpuscles were obtained upon the cloth, and the water which had been strained, did not afterwards exhibit the least light. He then put some sea-water that had been rendered particularly clear, by repeated filtrations, into a large glass, and having floated in it a fine cloth, on which he had previously collected a number of luminous points, several of them were liberated, and became distinctly visible in their natural element, by placing the glass before a piece of dark coloured paper. They were observed to have a tendency to come to the surface of the water, and after the glass was set by for some time, they were found congregated together, and when thus collected in a body, they had a dusky

Ian.
A raw colour, although individually they were so transparent, as to be perfectly invisible, except under particular circumstances. Their substance was indeed so extremely tender and delicate, that they did not become opaque in diffused vinegar or alcohol, until immerged in these liquors for a considerable time.

On examining these minute globules with the microscope, he found that they were not quite perfect spheres, but had an irregular depression on one side, which formed one of an opaque substance, that projected a little way inwards, producing such an appearance as would arise from the neck of a round bag, and turning it into the body.

The motions of these creatures in the water were slow and graceful, and not accompanied by any visible contraction of their bodies. After death they always subsided to the bottom of the vessel.

From the sparkling light afforded by this species, he has given it the name of *melusia* fenitills.

The night following that on which he discovered the preceding animal, he caught the two other luminous species. One of these he has called *beroe fulgens*.

This most elegant creature is of a colour changing between purple, violet, and pale blue; the body is truncated before, and pointed behind; but the form is difficult to allude, as it is varied by partial contractions, at the animal’s pleasure. He has represented the two extremes of form that this creature assumes: the first is somewhat that of a cucumber, which, as being the one it takes when at rest, should perhaps be considered as its proper shape: the other resembles a pear, and is the figure it has in the most contracted state. The body is hollow, or forms internally an infundibular cavity, which has a wide opening before, and appears also to have a small aperture, posteriorly through which it discharges its excrement. The posterior two-thirds of the body are ornamented with eight longitudinal ciliated ribs, the prococesses of which are kept in such a rapid rotary motion, while the animal is swimming, that they appear like the continual fage of a fluid along the ribs. The ciliated ribs have been described by Professor Mitchell, as arteries, in a luminous beroe, which probably was no other than the species we are now speaking of.

When the beroe fulgens swam gently near the surface of the water, its whole body became occasionally illuminated in a slight degree; during its contractions, a stronger light issued from the ribs, and when a sudden shock was communicated to the water, in which several of these animals were placed, a vivid flash was thrown out. When the body was broken, the fragments continued luminous for some seconds, and being rubbed on the hand, left a light like that of phosphorus; this however, as well as every other mode of emitting light, ceased after the death of the animal.

The bemiplieral species of *melusia* had a very faint purple colour. The largest individuals measured about three quarters of an inch in diameter. The margin of the umbrella was undivided, and surrounded internally by a row of pale brown spots, and numerous small twisted tentacles: four opaque lines crossed in an arched manner from the circumference, towards the centre of the animal; an opaque irregular-shaped processes hung down from the middle of the umbrella; when this part was examined with a lens of high powers, it was discovered to be inclosed in a sheath in which it moved, and that the extremity of the processes was divided into four tentacles, covered with little cups or suckers, like those on the tentacular of the cuttle fish.

This species of *melusia* bears a striking resemblance to the figures of the *melusia bemipliera*, published by Gronovius and Muller; indeed it differs as little from these figures, as they do from each other. Its luminous property, however, was not observed by these naturalists, which is the more extraordinary, as Muller examined it at night, and says it is so transparent, that it can only be seen with the light of a lamp. If it should be fully confirmed as a distinct species, or as a variety of the *bemipliera*, Mr. Macartney proposes to call it the *melusia lucida*.

In this species, the central part and the spot round the margin, are commonly seen to shine on lifting the animal out of the water into the air, presenting the appearance of an illuminated wheel, and when it is exposed to the usual percussion of the water, the transparent parts of its body are alone luminous.

In the month of September 1805, Mr. Macartney had again frequent opportunities of witnessing the luminous appearance of the sea at Herne bay, and of making observations upon the animals which occasioned it. He found that they always retreated from the surface of the water, as soon as the moon rose, and that exposure to the day light took away their property of shining, which was revived by placing them for some time in a dark situation.

In that season he had two opportunities of seeing an extended illumination of the sea, produced by the above animals. The first night he saw this singular phenomenon was extremely dark, many of the *melusia* fenitills, and *melusia bemipliera* had been observed at low water, but on the return of the tide the tides they had suddenly disappeared. On looking towards the sea, he was astonished to perceive a flash of light, about six yards broad, extend from the shore, for apparently the distance of a mile and a half along the surface of the water. The second time that he saw this fort of light proceed from the sea, it did not take the same form, but was diffused over the surface of the waves next the shore, and was so strong, that he could for the moment distinctly see his servant, who floated at a little distance from him; who also perceived it, and called out to him at the instant. On both these occasions the flash was visible for about four or five seconds, and although he watched for a considerable time, it was not repeated.

A diffused luminous appearance of the sea, in some respects different from this, has been described by several navigators.

Godeheu de Rivile saw the sea assume the appearance of a plain of snow on the coast of Malabar. Mem. Etrang. de l’Acad. des Sc. tom. iii.

Captain Newland, in a paper published in the Journal de Phylique, states that he has seen the sea appear like milk for a few nights. Cook and Peroune also observed it to be a straw colour.

Father Bourzes, in his voyage to India in 1754, saw what he called luminous vortices in the sea, which he said appeared and disappeared suddenly at certain periods, like flashes of lightning.

Captain Herburg, in the notes he gave to Sir Joseph Banks, says there is a peculiar phenomenon sometimes seen within a few degrees distance of the coast of Malabar, during the rainy monsoon, which he had an opportunity of observing. At midnight the weather was cloudy, and the sea was particularly dark, when suddenly it changed to a white flaming colour all around. This bore no resemblance to the sparkling or glowing appearance he had observed on other occasions in seas near the equator, but was a regular white colour, like milk, and did not continue more than ten minutes. A similar phenomenon, he says, is frequently seen in the Banda sea, and is very alarming to those who have never perceived or heard of such an appearance before.
L I G H T.

This singular phenomenon appears to be explained by some observations communicated to Mr. Macartney by Mr. Langlaff. In going from New Holland to China, about half an hour after sunset, every peroon on board was astonished by a milky appearance of the sea: the ship seemed to be surrounded by ice covered with snow. Some of the company supposed they were in foundings, and that a coral bottom gave this curious reflection, but on fouonding with 70 fathoms of line no bottom was met with. A bucket of water being hauled up, Mr. Langlaff examined it in the dark, and discovered a great number of globular bodies, each about the size of a pin's head, linked together. The chains thus formed did not exceed three inches in length, and emitted a pale phosphoric light. By introducing his hand into the water, Mr. Langlaff raised upon it several chains of the luminous globules, which were separated by opening the fingers, but readily reunited on being brought again into contact, like globules of quicksilver. The globules were so transparent, that they could not be perceived when the hand was taken into the light.

This extraordinary appearance of the sea was visible for two nights. As soon as the moon exerted her influence, the sea changed to its natural dark colour, and exhibited distinct glittering points, as at other times.

This account of Mr. Langlaff is very important, as it proves that the diffused light of the sea is produced by an effusion of minute medusae on the surface of the water.

In June 1806, at Margate, Mr. Macartney collected a great number of the small luminous medusae. A bucket of the water being fct by for some time, the animals fough the surface, and kept up a continual sparkling, which was occasioned by the motions of individuals, as the water was perfectly at rest. A small quantity of the luminous water was put into a glafs jar, and on fanding fome time, the medusae collected at the top of the jar, and formed a gelatinous mass, one inch and a half thick, and of a reddifh or mud colour, leaving the water underneath perfectly clear.

In order to ascertain if these animals would materially alter their fize, or assume the figure of any other known species of medusae, Mr. Macartney kept them alive for 25 days, by carefully chaffng the water in which they were placed; during which time, although they appeared as vigorous as when firit taken, their form was not in the slightest degree altered, and their fize but little increafed. This experiment confirmed his opinion of their being a diftinct species, as the young animalcs and medusae exhibit the form of the parent in a much fhorter period than the above.

In September 1806, he took at Sandgate also a number of the beroe fulgens: they were of various dimensions, from the full fize down to that of the medusae: they could, however, be clearly diftinguifhed from the latter species by their figure.

In April 1809, Mr. Macartney caught a number of the beroe fulgens in the sea at Haftefts; they were of various fizes, from about the half of an inch in length, to the bulk of the head of a large pin. Many of them adhered together in the sea; some of the larger forts were covered with small ones, which fell off when the animals were handled, and by a perfon unaccustomed to observe these creatures, would have been taken for a phosphoric fubftance. On putting a number of them into a glafs, containing clear sea-water, they still fhewed a disposition to congregate upon the surface. It was observed that when they adhered together, they fhewed no contractile motion in any part of their body, which explains the caufe of the pale or white colour of the diffused light of the ocean. The flaihs of light which Mr. Macartney faw come from the sea at Herne bay, were probably produced by a fudden and general effort of the medusae to separate from each other, and defend in the water.

The medusae feintillans almost constantly exist in the different branches of Milford haven that are called pilis. Mr. Macartney sometimes found these animals collected in fuch vast numbers in those situations, that they bore a confiderable proportion to the volume of the water in which they were contained; thus, from a gallon of sea-water in a luminous flate, he ftrained above a pint of thefe medusae. The sea under fuch circumstances yields more support in swimming, and the water takes more diffufed light than usual; probably the difference of density, that has been remarked at different times in the water of the sea, may be referred to this caufe.

Mr. Macartney concludes that the medusae feintillans is the usual caufe of the luminous appearance of the sea, not only around this country, but in other latitudes. Before the places already mentioned, he has found this species on different parts of the coasts of Suffolk, at Tenby, and in the bays of Dublin and Calfingford in Ireland. Many writers, he obferves, have mitaken this species of medusae for the nerit seolitus, and fome navigators have actually defcribed the medusae feintillans, without being aware of its nature. Mr. Bajon, during his voyage from France to Cayenne, collected many luminous points in the sea, which he fays, when examined by a lens, were found to be minute ifpheres. They defappeared in the air. Dr. Le Roy, in falling from Naples to France, obferved the sparkling appearance of the sea which is ufually produced by the medusae feintillans. By filtering the water, he feparated luminous particles from it, which he preferved in fpirits of wine: they were, he fays, like the head of a pin, and did not at all resembfe the nerit seolitut, defcribed by Vinnelli; their colour approached a yellow-brown, and their fubftance was extremely tender and fragile. Notwithstanding this fliking refeemblance to the medusae feintillans, Le Roy, in confequence of a preconceived theory, did not defcribe what he faw, were animals, but particles of an oily or bituminous nature. Obfcrv. fur un lumiere produite par l'Eau de la Mer. Mem. Etran. des Sc.

The minute globules seen by Mr. Langlaff in the Indian ocean, in all probability, were the feintillating species of medusae; on feeing fome of these animals that had been preferved in fpirits, he entertained the fame opinion.

Professor Mitchell, of New York, found the luminous appearance on the coast of America, to be occasioned by minute animals, that, from his defcription, plainly belonged to this species of medusae, notwithstanding which, he fuppofed them to be a number of the nerit seolitut. Phil. Mag. vol. x. p. 20.

The luminous animalcule, discovered by Forster off the Cape of Good Hope, in his voyage round the world, bears ftrong refeemblance to the medusae feintillans, that there is every reafon for believing them the fame. He defcribes his animalcule as being a little gelatinous globule, fels than the head of a pin; transparent, but a little brownifh in its colour; and of fo fift texture, that it was defroyed by the lighted touch. On being highly magnified, he perceived on one fide a defpiffion, in which there was a tube that paffed into the body, and communicates with four or five internal faces.

Many writers have alcuflated the light of the sea to other caufes than luminous animals. Martin fuppofes it to be occasioned by putrefction; Silberfchlag believed it to be phosphoric;
phosphoric: professor J. Mayer conjectured, that the surface of the sea imbibed light, which it afterwards discharged. Bajon and Gentil thought the light of the sea was electric, because it was excited by friction. Fother conceived that it was sometimes electric, sometimes caused from putrefaction, and at others by the presence of living animals. Fongerous de Bondaroy believed that it came sometimes from electric fires, but more frequently from the putrefaction of marine animals and plants.

It is unnecessary to enter into a diffusion of the above opinions: their authors have not attempted to support them by any argument or experiments; they merely gave them as speculations. It is sufficient to state, that they are contradicted by all the best observations upon the subject.

The only animals which are known to possess distinct organs for the production of light are, the luminous species of lampyris, elater, fulgora, and pafias. Of these Mr. Macartney has given the following description.

The light of the lampyris is known to proceed from some of the last rings of the abdomen, which, when not illuminated, are of a pale yellow colour. Upon the internal surface of these rings, there is spread a layer of a peculiar soft yellow substance, which has been compared to paste, but by examination with a lens, I found it to be organized like the common interstitial substan ce of the insect's body, except that it is of a closer texture, and a paler yellow colour. This substan ce does not entirely cover the inner surface of the rings, being more or less deficient along their edges, where it presents an irregular waving outline. I have observed in the glow-worm, that it is absorbed, and its place supplied by common interstitial substan ce, after the fason for giving light is past.

The segments of the abdomen, behind which this peculiar substan ce is situated, are thin and transparent, in order to expose the internal illumination.

The number of luminous rings varies in different species of lampyris, and, as it would seem, at different periods in the same individual.

Besides the luminous substan ce above described, I have discovered in the common glow-worm, on the inner side of the last abdominal ring, two bodies, which to the naked eye appear more minute than the head of the smallest pin. They are lodged in two flight depressions, formed in the shell of the ring, which is at these points particularly transparent. On examining these bodies under the microscope, I found that they were facets containing a soft yellow substan ce, of a more close and homogeneous texture, than that which lines the inner surface of the rings. The membrane forming the facets appeared to be of two layers, each of which is composed by a transparent silvery fibre, in the same manner as the internal membrane of the respiratory tubes of insects, except that, in this case, the fibre passes in a spiral, instead of a circular direction. This membrane, although so delicately constructed, is so elastic as to preserve its form after the fac is ruptured, and the contents discharged.

The light that proceeds from these facets is less under the control of the insect, than that of the luminous substan ce spread on the rings: it is rarely ever entirely extinguished in the season that the glow-worm gives light, even during the day; and when all the other rings are dark, these facets often shine brightly.

The circumference of there being points, which give a more permanent light than the other parts of the luminous rings of the abdomen, has been noticed before by the Comte de Razoumouflé. He states the number of these luminous points to vary from two to five. Mem de la Soc. de Languedoc, tom. ii.

I must however remark, that I never saw more than two of these luminous points, which were always upon the last ring of the body, and that the figures which accompany the memoir of the Comte de Razoumouflé, bear scarcely any resemblance to the insect they are intended to represent, from which we may fairly suspect him of inaccuracy in other particulars.

As far as my observation has extended, the small faces of luminous substan ces are not found in any species of lampyris, except the glow-worm of this country. Thurnburg mentions that the lampyris japonica has two vehicles on the tail, which afford light.

The organs for the production of light in the genus elater are situated in the corcelet; these likewise consist of a peculiar yellow substan ce, placed behind transparent parts of the shell, which suffer the natural colour of this substan ce to be seen through them in the day, and when illuminated, give passage to the light.

On dissecting the organs of light in the elater notilicus, I found that there is a felt yellow substan ce, of an oval figure, lodged in the concavity of the yellow spots of the corcelet, which parts are particularly thin and transparent in this species. This substan ce is so remarkably close in its structure, that at first view it appears like an inorganic mass, but with a lens it is readily perceived to be composed of a great number of very minute parts or lelules closely pressed together. Around these oval mafles, the interstitial substan ce of the corcelet is arranged in a radiated manner, and the portion of the shell that immediately covers the irradiated substan ce is in a certain degree transparent, but lies so than that which lies over the oval mafles; it is therefore probable, that the interstitial substan ce in this situation may be endowed with the power of shining. A fusciculus of the mafles of the corcelet arises in the interior of the oval mafles of the luminous substan ce, but not apparently with any design, as it contributes, with the adjacent fusciculi, to move the anterior feet.

In the elater ignitus, the mafles of luminous substan ce are extremely irregular in their figure; they are situated nearly at the posterior angles of the corcelet, and are more bose in their texture than the oval mafles of the notilicus, resembling rather, in composition, the interstitial substan ce which furrounds these mafles in that species. The shell of the corcelet is somewhat thinner, and more transparent along both sides of the margin, than at other places, but it is not, as in the notilicus, elevated, and peculiarly clear and thin immediately, over the tract of the luminous organ; consequently, the light emitted by the elater ignitus cannot be very brilliant.

I have not been able to procure any specimen of the elater phosboreus, but from the accounts of naturalists, it appears to resemble in every respect the elater notilicus.

I have had an opportunity of examining, preferred in a moit way, two species of fulgora, the candularia and lanter- naria. The light in this genus has been observed to issue from the remarkable pores on the fore part of the head. This part has always been described by authors as hollow or empty, which I have found to be perfectly correct; and what is more extraordinary, that the cavity communicates freely with the external air, by means of a chink or narrow aperture, placed on each side of the root of the proboscis. This projection is covered internally by a membrane, between which and the horny part or shell, there appears to be interposed a pale redish coloured soft substan ce, that is arranged in the candularia in broad lines or stripes; but it is so thin, that I could not distinctly examine its structure, or abso- lutely determine, whether it should be considered as a sub-
The phenomenon of animal light has been attempted to be explained in different ways. By many persons it was formerly ascribed to a putrefactive process, but since the modern theories of combustion became known, it has been generally believed to depend upon an actual inflammation of the luminous substance, similar to the slow combustion of phosphorus. Others have accounted for the luminous effect, by supposing the matter of light to be accumulated, and rendered latent under particular circumstances, and afterwards evolved in a sensible form.

The opinion of the light of living animals being the consequence of putrefaction, is evidently absurd, and contradictory to all observation on the subject. It has been proved by the experiments of Dr. Hume and others, that even the luminous appearances of dead animals are exhibited only during the first stages of the dissolution of the body, and that no light is emitted after putrefaction has really commenced.

Spallanzani, who was the most strenuous advocate for the phosphorescent nature of animal light, stated that glow-worms shine more brilliantly when put into oxygen gas; that their light gradually disappeared in hydrogen or in azotic gas, and was instantly extinguished in fixed air; that it was also lost by cold, and revived by the application of a warm temperature. He conjectured that the luminous matter of these insects was composed of hydrogen and carbured hydrogen gas.

Forier relates, in the Lichtenberg Magazine for 1784, that on putting a lampris splendida into oxygen gas, it gave as much light as four of the same species in common air.

Carradori has made some experiments upon the lucioli, (lampris illica) which led him to deny its phosphorescence. He found that the luminous portion of the belly of the insect shone in vacuum, air, in water, and different liquids, and under different circumstances, where it was excluded from all communication with oxygen gas. He accounts for the result of Forier's experiment, by supposing, that the worm shone more vivibly, because it was more animated in oxygen gas than in common air.

Carradori adopts on this subject, the doctrine of Brugnatelli, and ascribes the luminous appearances of animals to the condensation and extrication of light in particular organs, which had previously existed in combination with the substance of their bodies. He supposes the light to be originally derived from the food, or the atmospheric air taken into the body; in short, that certain animals have the peculiar property of gradually imbising light from foreign bodies, and of afterwards secreting it in a sensible form. Annal di Chimica. tom. xii. 1797.

The following experiments, which were lately made upon this subject by Mr. Macartney, would lead to different conclusions than those of the preceding authors.

**Experiment 1.**—A glow-worm was put into a glass of water, in which it lived nearly two hours, and continued to emit light as usual, until it died, when the luminous appearance entirely ceased.
L I G H T.

Experiment 2.—The luminous substance was extracted from the before-mentioned glow-worm, and from others killed in different ways, but it afforded no light.

Experiment 3.—The face containing the luminous matter was cut from the bellies of living glow-worms, and those uninterruptedly for several hours in the atmosphere, and after their light became extinct, it was revived by being moistened with water; some of these were put into water in the first instance, in which they continued to shine unremittingly for forty-eight hours.

Experiment 4.—The luminous substance of a glow-worm was exposed to a degree of heat which would have been sufficient to inflame phosphorus, without increasing the brilliancy of its light; and farther, it could not be made to burn by being applied to a red-hot iron, or to the flame of a candle.

Experiment 5.—A delicate thermometer was introduced amongst some living glow-worms, during the time they gave out much light: the temperature of the room being 69°, the instrument rose to 75°, 76°, and 77°, according to circumstances, as the warmth was reflected from the hand, or diffused by the worm crawling over cold substances. The luminous portion of the tail, when very brilliant, appeared to raise the thermometer more quickly than the other parts of the body; but it was not invariably the case. When shining strongly, the luminous rings appeared to communicate the sensation of warmth to the hand; but this was probably a deception, as the actual degree of heat was not sufficient for such an effect. It should however be mentioned, that in Templar's observations on the glow-worm, he said his feelings deceived him, if he did not experience some heat from the shining of the insect. Phil. Trans. N.° 72.

Experiment 6.—To ascertain how far the evolution of heat, during the shining of glow-worms, depended upon the life of the animals, the luminous portion of the tail was cut off from several living worms: if the thermometer was applied to them immediately, it was raised by them one or two degrees; but after these parts were dead, although they continued to emit light, they produced no effect whatever upon the instrument.

Experiment 7.—Some hemispherical medusae were put into a spoon, containing a small quantity of sea-water, and held over a burning candle. As soon as the water became heated, the medusae appeared like illuminated wheels; the spots at the margin and centre alone emitting light; in which manner they shone vividly and permanently for about twenty seconds, when they shrunk and died, after which they were no longer luminous.

Experiment 8.—Some of the same species were put into spirits: a strong and unremitting light was instantly given out, which issued from the central and marginal parts, as in the preceding experiment, and continued until they died.

Experiment 9.—Some of the scintillating and hemispherical species of medusa, contained in a small glass jar, were introduced into the receiver of an air-pump, and the air being exhausted, they shone as usual when shaken: if any difference could be perceived, the light was more easily excited, and continued longer in vacuum.

Experiment 10.—A medusa hemispherica was placed in a small glass dish, containing a quantity of water, merely sufficient to allow the animal to preserve its figure: being inflated, it was electrified, and sparks drawn from it, which had the slightest effect. The experiment was repeated several times with different individuals, but without exciting the animals to throw out light.

Experiment 11.—Some hemispherical medusae were placed in contact with the two ends of an interrupted chain, and flight electric shocks passed through them. During the very moment of their receiving the shock, no light was visible; but immediately afterwards the medusa shone like illuminated wheels, which appearance remained for some seconds. Upon the closest inspection with a magnifying glass, no contractile motion could be perceived to accompany the exhibition of the light. The application of electricity, in this instance, seems to have acted merely as a strong mechanical shock.

It seems proved by the foregoing experiments, that so far from the luminous substance being of a phosphorecent nature, it sometimes shews the strongest and most constant light, when excluded from oxygen gas; that is, in no circumstances, undergoes any process like combustion, but is actually incapable of being inflamed, that the increase of heat, during the shining of glow-worms, is an accompaniment, and not an effect of the phenomenon, and depends upon the excited state of the insect; and, lastly, that heat and electricity increase the exhibition of light, merely by operating like other stimuli upon the vital properties of the animal. Phil. Trans. 1810, part ii.

In addition to these opinions, we may mention that Professor Davy has found that the light of the glow-worm is not rendered more brilliant in oxygen, or in oxygenated muriatic gas, than in common air; and that it is not sufficiently diminished in hydrogen gas.

We may further add, that Spallanzani's experiments of diffusing the luminous liquor of the medusa in water, milk, and other fluids, are in direct contradiction of his own theory, as is also the extinction of the light of these mixtures by the application of a high degree of heat.

If the light emitted by animals were derived from their food, or the air they respire, as supposed by Carrodori, the phenomenon should be increased or diminished, according to the quantity of food or air that the creatures consume. But we do not find this to be the case; for in those situations where they are sometimes found to be most luminous, they are deprived, in a great measure, of these affirmed sources of their light.

In fact, the luminous exhibitions of living animals are not only independent of all foreign light, but are frequently destroyed by the latter. The shining of the medusa was always found by Mr. Macartney to cease upon the rising of the moon, or at the approach of day; and when out of the sea, he never could excite them to throw out light until they had been kept for some time in the dark; all the luminous insects likewise secrete themselves as much as possible during the day-time, and go abroad only at night. It is true that the scolopendra electrica will not shine, unless it has been previously exposed to polar light; but it is to be observed that it shines as brilliantly and as frequently, after being kept a short time in a light situation, as when left uncovered the whole day. The circumstance of the scolopendra requiring exposure previous to its giving out light, is very unaccountable, as the insect, when left to itself, always seeks as much as possible concealment during the day: indeed it is the opinion of some naturalists, that it is killed by the light of the sun.

We shall terminate this article with the following conclusions, drawn by Mr. Macartney from his own observations, and from a careful review of all that had been written on the subject.

The property of emitting light is confined to animals of the simplest organization, the greater number of which are inhabitants of the sea. The luminous property is not constant, but in general exists only at certain periods, and in particular states of the animal's body. The power of shoewing
ing light resides in a peculiar subsistence or fluid, which is sometimes situated in a particular organ, and at others diffused throughout the animal's body. The light is differently regulated, when the luminous matter exists in the living body, and when it is abstracted from it. In the first case, it is intermitting, or alternated with periods of darkness; it is commonly produced or increased by a muscular effort; and it sometimes absolutely dependent upon the will of the animal. In the second case, the luminous appearance is usually permanent until it becomes extinct, after which it may be restored directly by friction, concussion, and the application of warmth; which latter causes operate upon the luminous matter (while in the living body) only indirectly, by exciting the animal. The luminous matter, in all situations, so far from possessing phosphenic properties, is incombustible, and loses the quality of emitting light, by being dried, or much heated. The exhibition of light, however long it may be continued, causes no diminution of the bulk of the luminous matter. It does not require the presence of pure air, and is not extinguished by other gases.

The luminous appearance of living animals is not exhausted by long continuance, or frequent repetitions, nor accumulated by exposure to natural light: it is, therefore, not dependent upon any foreign source, but inheres as a property, in a peculiarly organized animal substance or fluid, and is regulated by the same laws which govern all the other functions of living beings.

The light of the sea is always produced by living animals, and most frequently by the preference of the _mollusca_ and _luminous animal one_. and _three-masted_. When great numbers of this species approach the surface, they sometimes coalesce together, and caudal that spongy or milky appearance of the sea, which is so alarming to navigators. These animals, when congregated on the surface of the water, can produce a flash of light, somewhat like an electric coruscation. When the luminous _mollusca_ are very numerous, as frequently happens in confined bays, they form a considerable portion of the masts of the sea, at which times they render the water heavier, and more noisome to the sailors: it is therefore advisable to always strain sea-water before it is drank.

The luminous property does not appear to have any connection with the economy of the animals possessing it, except in the flying insects, which by that means discover each other at night, for the purposes of sexual congress.

In the plates for illustrating the present subject in this dictionary, the reader will only find figures of those luminous animals which are not generally contained in books on natural history, or which are necessary for the explanation of lately discovered facts.

Fig. 1. is the _nervis noctiluca_, discovered by Vianelli, of the natural size.

Fig. 2. shows the same animal greatly magnified: _a_ is the head, furnished with two short antennae and a horn-like process; _b, b_ the two eyes; _c, c_, some of the lateral twisted processes proceeding from the segments of the body; _d, d, d_, some of the other lateral processes that contain the tufts.

Fig. 3. is the _ery photicus_ insect, discovered by Riville: _a_ is the transparent shell, through which the internal parts of the animal are visible; _b_, the face containing the intellises; _c_, one of the four-jointed faceteus antennae; _d_, the two feet armed with hooks; _e_, the foot which terminates in claws; _f_, the ovum, which Riville marks for globules containing a luminous oily fluid.

Fig. 4. exhibits the _cancer fulgens_, discovered by sir Joseph Banks. It is given of the natural size.

Fig. 5. represents the _limulus noctiluca_, discovered by captain Horstburg, greatly magnified.

Fig. 6. is the _mollusca phellos_, discovered by sir Joseph Banks, shown less than the natural size.

Fig. 7. is the _pyrausta atlantica_, lately discovered and described by Peron.

Fig. 8. shows the _mollusca lucida_, described by Mr. Macartney, of the largest size he met with.

Fig. 9. is the _heros fulgens_, discovered by Mr. Macartney.

It is represented of the usual size, and in the elongated form the creature assumes when it is at rest. On the posterior part are seen the ciliated ribs, which constitute its instruments of locomotion.

Fig. 10. shows the _mollusca ficientillans_, discovered by Mr. Macartney, as it appears to the naked eye.

Fig. 11. is the same highly magnified, by which the opaque parts upon the face and in the centre of the animal are made apparent.

Fig. 12. is the animalcula, discovered by Mr. Forsdyke, of the size it appears to the naked eye.

Fig. 13. exhibits a microscopic view of the same animalcula.

Fig. 14. is an enlarged view of the inferior surface of the abdomen in the _lumiferous lucida_, after the integuments had been removed, as delineated by Mr. Macartney: _a, a, a_, represent the three masts of luminous subsistence, which are applied to the three lateral rings of the abdomen; _b, b, b_, the arrangement of the cellular or interstitial subsistence on the other abdominal rings, which gives the pale colour to the whole belly of this insect.

Fig. 15. represents the common _glow-worm_, with the lower portion of the back cut away, to expose the face of luminous matter in situ on the lateral ring of the belly: _a_ indicates the face of one side; the intestine is seen to lie between them.

Fig. 16. is one of the light faces of the _glow-worm_, taken out and prodigiously magnified, in order to shew its structure, as described by Mr. Macartney: _a_, the external part of the face, which is composed of the interweaving of a spiral fibre; _b_, the luminous subsistence seen at one end, when the face has been ruptured to expose its contents.

Fig. 17. is the _cancer noctiluca_, with the shell of the corset removed on one side, by which the organ of light, described by Mr. Macartney, is uncovered; _a_, the yellow transparent spot of the corset; _b_, the oval masts of luminous subsistence surrounded by an irradiation of the interstitial subsistence; _c_, the ends of the muscles which are on the inside of the corset.

Fig. 18. shows the luminous apparatus of the _cancer noctiluca_, considerably magnified: _a_, the radiated appearance of the interstitial subsistence around the oval masts of luminous subsistence: this mast is seen to contain a number of smaller parts; _b_ shews the arrangement of the interstitial subsistence, when it passes down between the muscles; _c_, the ends of the muscles of the back; _d_, the shell of the corset.

Fig. 19. is the _cancer ignitus_; _a_ indicates the yellow part of the corset; _b_ shews the small masts of luminous subsistence in this species, the shell being removed.

Light is also used to signify the disposition of objects with regard to the receiving of light.

Thus we say, a painting is seen in its proper light, when its situation, with regard to the light, is the same with that for which it was painted.

Light, in _Agriculture and Gardening_. Experience has given its infinite service to the growth of vegetables, contributing exceedingly to facilitate their vegetation, and in-
create their perfection and duration; as it is obvious most plants are considerably more prosperous, and attain their perfection in a free exposure, fully open to the light and air, than in shady places; the same is observed of fruits. Those growing in a situation full to the light of the sun, are in general more large and fair, ripening sooner, and more perfectly, as to beauty and richness of flavour, than such as grow in the shade; these reasons should therefore determine us to cultivate most of the principal plants and fruits in situations open as much as possible to the full light and influence of the sun; though upon particular occasions, and in the heat of summer, shady places may be necessary for some sorts of plants, though not where shaded and darkened by spreading trees, &c., but a border open above to the full light, and only shaded from the immediate rays of the sun. For the general crops, a perfectly open, sunny, light situation, free from the shade of spreading trees, is always the most proper.

And its utility is very evident, from plants growing in garden-frames, green-houses, &c. in winter; when, in times of severe weather, covers or shutters have been continued long over the glases, so as to exclude the rays of light, they become sickly, grow pale, and assume an unhealthy appearance for a long time; the leaves often decaying or dropping off; and frequently, when the covers are continued very long without the admission of light, the whole plant in many sorts gradually dwindles and perishes. Great attention is of course requisite in this case, when, from the severity of the weather, the use of other covers besides the glases is necessary, to take every opportunity of a favourable day, or even an hour or two of a day, to admit the light as fully as possible. The fame is also the case with plants in early hot-beds, such as cucumbers, tobacco, &c. which, early in the year, require a covering of mats over the glases every night; as when these additional covers are applied too soon in the afternoon, and continued late in the morning, so as to keep the plants long in darkness, it is highly disadvantageous to their growth, causing them to grow weak, pale, and sickly.

As light is, therefore, so beneficial to plants in general, it should be increased as much as possible to those in frames, green-houses, flores, &c. In these situations it may be useful to paint the inside of all such departments white, to reflect the rays of light as much as possible, and particularly in the nights, and in the day time, when the severity of the weather requires covers or shutters to be placed over the glases or other conveniences where plants are kept.

The author of Phytologia remarks, that the contest for light, as well as for air, which is so visible in the growth of vegetables, thaws the former to be of great consequence to their existence, as well as the latter. Thus many flowers follow the sun during the course of the day, by the nutation of the stalks, not by the rotation of them, as observed in the sun-flower by Dr. Hales; and the leaves of all plants endeavour to turn their upper surface to the light, which is their respiratory organ, or lungs. The great use of all plants turning the upper surfaces of their leaves to the light is thus, he thinks, intelligible; the water periphrised from those surfaces is, he conceives, hyper-oxygenated; and, as it escapes from the sharp edges of the mouths of the periphrising vessels, when acted upon by the sun's light, gives out oxygen, which oxygen, thus liberated from the periphrised water, and added to that of the common atmosphere, prelents to the respiratory terminations of the pulmonary arteries on the upper surfaces of leaves an atmosphere more replete with vital air. This necessity of light to the respiration of vegetables is so great, that there is reason to believe that many plants do not respire during the night, but exist in a torpid state, like the winter sleepers insects. Thus the mimosa, sensitive-plant, and many others, close the upper surfaces of their opposite leaves together during the night, and thus preclude them both from the air and light; and the internal surfaces of innumerable flowers, which are their respiratory organs, are closed during the night, and thus unpaved both to light and air. It is, however, observed, that the fungi, which are termed vegetables, because they are fixed to the earth, or to the stones, trees, or timber, where they are found, can exist without light or much air; as appears in the truffle, which never appears above ground, and by other fungi, which grow in dark cellars; and in esculent mushrums, which are cultivated beneath beds of straw. The etiolation, or blanching of vegetables, depends upon the keeping of the light from them.

It is further noticed that the element of light, as well as that of heat, is necessary to vegetation. In this climate they both seem, in general, to be injurious only by their defect, and seldom by their excess. But as light acts as an stimulus on the more irritative or sensitive parts of plants, which appears by the expansion of many flowers, and some leaves, when the sun shines on them; and by the mutation of the whole flower, as of the sun-flower (helianthus), and by the bending of the summits of all plants confined in houses towards the light; there may be differences owing to the excess of this stimulus, which have not been attended to; to prevent which the flowers of tropogon salsas, and of other plants, close about noon. Other unobserved differences may be owing to a defect of the stimulus of light; as a mimosa, sensitive plant, which has been confined in a dark room, did not open its foliage, though late in the day; till many minutes after it was exposed to the light. The excess of light has not, however, been observed to be attended by vegetable diseases in the more northern latitudes so much as in others.

Light, in the Manege. A horse is said to be light, in French un cheval léger, that is, a swift, nimble runner. We likewise call a horse light that is well made, though he is neither swift nor active; for in this last expression we consider only the shape and make of a horse, without regard to his qualities.

Light upon the hand; a horse is said to be such, that has a good tractable quality, and does not resist too heavy upon the bit.

A coach-horse is said to be light, when he flies nimblly, and dreads the whip; or when he has a light trot.

Light-bellied. A horse is thus called that commonly has flat, narrow, contracted sides, which make the flank turn up like that of a grey-hound.

Light-hind. See Hand.

Light, in Painting, refers only to those effects which light (properly so called) produces upon the surfaces of natural objects; as exhibited by its reflection from them to the eye of an observer.

With regard to that art, light may be considered in two distinct points of view; viz., as to the natural and the artificial effects arising from it. The former is simply the effect produced upon the objects in a picture, by the direction in which it is introduced; which being once chosen, becomes a positive rule; and from which no variation can be allowed. The latter is ideal, and requires only to be probable or possible. It relates to the quantity of light employed to illustrate the character of a subject, and depends entirely upon the taste of the artist; who, by the use of ideal shadows and fictitious lights, may effect a diminution or augmentation to...
any proportion he pleases. These, together with light and dark colours, form the basis of chiaro-scuro; one of the
grand fundamental principles of painting, of which we have
already treated under the article Clarity-obscure.

As light, when acting upon substantial forms, is always
accompanied by shadow, and as they are necessary adjuncts
to each other, we shall here unite them, and treat of them
together. It is by the contrariety of each to the other, that
the effect of either is produced by colours; and however
paradoxical it may appear, it is nevertheless true, that light
in the art of painting is not more necessary to produce
shadow, than shade is for the production of light. The col-
ours which give the appearance of the former, obtain that
effect only when surrounded with darker ones, which consti-
tute shade; without the latter, they would appear nothing
more than an uninteresting mass of one plane tone, without
any degree of the quality which is termed luminous; but
contrasted by their opposites in tone, they become brilliant;
and when form is superadded, obtain the character of light.
The same, though in the contrary degree, is the effect of dark hues, which, without the contrariety of lighter ones,
produce only a heavy, dull, unmeaning mass, that merits not
the appellation of shade, till opposed by other tones,
and rounded into form by the assistance of light.

The management of light and shade is the most impor-
tant of the practical parts of the art; since, without the true
arrangement of them, vain must be every effort of the
painter to produce a just resemblance of those things which
nature offers to our view, and which are the immediate ob-
jects of his study. Outline is but as the friction of a
body; and colour, a simple, unvaried colour added to it,
would fill in no wise increase its value as the representative
of a substance; but let light and shade be superadded, and
duly disposed, and what was a flat surface becomes ap-
parently a rounded one, is relieved from its ground, and ap-
ppears to start from the canvas.

The sources of light are in fact but two; viz. the sun
and fire; but to the painter a variety of modifications of these
two take place, and become equally separate sources, with
distant qualities, both as to power and colour. Such, for
instance, are the moon's reflecting power; that of the at-
mosphere when the sun is hid; and likewise the illumination
proceeding from a window into a room. The effects pro-
duced by each of these differ so widely from those of the
two former, that we may fairly say there are five general
sources of light, at least, applicable to the purposes of
painting. Of that proceeding direct from the sun in full
blaze, it can only be observed, that, except for landscape,
its use is confined in the art; being too powerful, and pro-
ducing shadows too harsh, for the more interesting and
agreeable subjects of fancy or history. The softer illumina-
tion reflected from those parts of the atmosphere opposed
to the sun, is usually and reasonably preferred; or that which
the heavens yield when the source of its light is hid in clouds,
though not when it is too much lost in the gloom of tempete;
for then the lights and shadows become too indistinct
and confused. The open light of the air has another char-
acter distinct from the two just mentioned: which is, when
the sun is but faintly obscured by thick clouds, through
which its rays penetrate with diminished luster, but still in
direct lines. In this case the light, though direct and cauf-
ing shadows the same in form as when its source is un obscured,
is yet but weak, and soft; and the shadows it produces
being effected by the general light of the atmosphere, are
tender in their outline and tone. When the reflected light
proceeding from the northern parts of the atmosphere is ad-
mitted through a window into a room, it assumes a midway
character. For while the light is weaker, and consequently
softer than that from the sun; the shadows, owing to the smallness
of the aperture, become distinct but not harsh; and their
distinctions is heightened by the room wherein is the window,
which may be considered as an original source, receiving
only a partial quantity of light, and consequently little or
no reflection takes place, except from surrounding and con-
tinuous objects upon each other: whereas, when a figure is
so placed in open air as to receive the light reflected from the
sky, it partakes of it in every direction, and therefore has
little or no shadow; for there will be few parts where some
rays of light will not, under such circumstances, find ad-
nuion.

When the light proceeds direct from the sun, it is usual,
though not strictly correct, to consider its rays as parallel,
and consequently no enlargement or diminution takes place
in lengthened shadows. But, in reality, its distance, which
diminishes its size apparently, added to the effect of perspec-
tive, produces a real variation in shadows of objects whose
magnitude is at all consider.-able. This is always the case
when the source of light is larger or smaller than the illu-
minated body. In the former case, the shadow of a suspend-
ed ball would diminish to a point; as that of the earth does
from the light of the sun: and in the latter it would dilate as
it was extended, and project a shadow at a certain distance,
large in proportion to the comparative smallness of the lu-
inous body; as of the flame of a candle, for instance,
compared to a tennis-ball.

Shadows by day-light seldom become totally obscure: an
object must be placed in a situation where it could receive
very little indeed of that peculiar illumination, without hav-
ing some reflections falling into its shades, and consequently
yielding some visible effect of the forms on which they fell.
But by fire and candle-light, owing to the confined illu-
ence of their rays, forms hid in the shadows they project are often
totally lost; nevertheless, these shadows are not blackness,
but darkness, of a colour whose hue depends upon that of
the larger mass of surrounding bodies. Under many cir-
cumstances they receive reflections, and have a consider-
dable degree of colour in the bodies that lie within their range.

There are two causes which operate to weaken and even
destroy the force of reflected light. The one is the diatance
at which the reflecting object is situated from the luminary;
the other, the distance of the same from the observer. When
these two circumstances combine, the effect of light and
shade is very weak.

To comprehend the principle upon which the illumina-
tion and consequent shadows of objects are produced, and
to imitate them the most effectually, the painter must recol-
lect, that light, whenever it is necessary from its source to its
surface which intercepts it; and is reflected in the same way, at an equal angle with the plane
of that surface, but in an inverse direction. In the language
of optics, the angle of reflection is equal to the angle of inci-
dence. This is the simple but general rule, which is instali-
ably to guide the artist through all the difficulties of light
and shade in painting; whether arising from direct or
reflected illumination, this one principle holds equally good in
all; but the lines which it forms in the shadows, are sub-
ject to the variations produced by perspective on all solid bod-
ies whereon light can act.

The most important application of this rule the artist will
find to be, in fixing upon the precise point where he should
dispose of its most brilliant hues; or what are technically
termed his high lights; which are, in reality, those parts of
L I G H T.

his objects, where, if the surface be a polished one, the
image of the luminary is reflected; and is of course that
one, which, to the eye of an observer, is most illuminated.
These reflections will always be found to take place only
on that point, from whence a line drawn to the luminary,
and another to the eye of the artist, form angles equal to each
other with the plane of the surface of the illuminated object.
For though it may not in reality be the precise spot where
the greatest number of rays of light are intercepted by that
body, yet it is effectively so to him whose eye can only re-
ceive those which are thrown off in reflection towards him.
It may be observed as a consequence of this rule, that the
extreme edge of a round body can scarce ever be its
brightest part; it will, as it reedes from the observer, lose
to him its lustre, and melt into the ground or object behind
it; or, if relieved by a flat object equally white with itself,
a dark line will be seen to mark its boundary, in whatever
situation the source of light may be, within a right angle
with a line drawn from the object to an observer; or some-
what beyond that, to nearly 135 degrees.

It is fearfully necessary here to speak of the refraction
of light from its original course, when passing through various
substances, as glafs or water; except to deprecate paying
any attention to it in a picture where any essentlal form is
broken in upon by it; or choosing such subjects, where de-
formation from general rules serve rather to confound than to
satisfy the common understanding of mankind. Thence co-
yring the positive truth would create confusion, it is molt
just, at least most useful, to vary it: as in painting the portrait
of a man with spectacles on. What artist in his lenes,
and who had a true perception of the real object of
art, would think of painting exactly that which presents
itself to his view, a positive deformity, eyes misplaced,
and of monilous form; for such they are when seen through
the glaflies. Such procedure would totally defeat the ob-
ject of portraiture; for it would be hardly possible to make
a likeness of the person, with such a variation from the po-
tive form of his face.

The direction in which the light falls upon the objects
introduced into a picture, and which we propounded at the
beginning of this article as one of the points of view in
which to consider the subjecl, is of very great importance on
many accounts, and calls for the most attentive considera-
tion of the artist before he begins to colour his picture, and even
in the composition of his forms. If, without previous atten-
tion to this, he proceeds to execute his composition, and
complete the development of his ideas, he would be fortu-
ate if he did not find in his progress, that the necessity he
was under of making shadows to bring out his forms, very
frequently destroyed his general shapes, which previously ap-
peared well when in lines only. A due attention to this, in
the first instance, would frequently suggest ideas of forms,
and assist him in filling his canvas agreeably. It is, in o, pre-
paring the character of his subjects appropriately. It is, how-
ever, utterly impossible to give precise rules upon this subject
in historical paintings, as it depends to entirely upon the na-
ture of the subjects, and the local situations of the acts-
tors introduced. One general rule only may be given, viz. that
the disposition of the figures should be fixed, with regard to
the source of light, as to produce ample mafles of light and
shadow: either of the one or the other predominant, ac-
cordingly as the subject is grave or gay. If the subject be
of one single figure, then it is requisite (and more easily
to be managed) that care be taken that the light falls upon it
in such a manner as accords with the action, and produces
no unpleasant shapes. For great grace may be added to
figures by light and shade when agreeably disposed; and on
the contrary, an unfortunate disposal of them may diminish
the effect, if not totally destroy the most beautifully drawn
figure imaginable.

In portraiture, something more precise may be laid upon
this subject. Its object is to convey a resemblance of a
person in the most agreeable manner, generally speaking;
yet therein much must remain which the rules cannot attain
to, particularly where the object is to convey character
strongly, and not merely to render the picture agreeable.
In the latter case, if a person be so placed with regard to the
window or luminary, that the light falls upon him at an
angle of about 45 deg., and the greater part of the face be
exposed to it, the purpose will be answered. A still more
acute angle will give greater relief, but the effect will not
be so pleasing. Whether the face should be turned directly
facing the light, or so as to receive it partially, must entirely
depend upon the character of the features. If large, they
will bear a full light; if of a smaller and more delicate
nature, a little inclination from the light will give more force
and variety. But where the object is to convey character
strongly, to the disregard of positive beauty, there the chara-
ceter only is the guide, and every angle of illumina-
tion, with any turn towards or from it, may effect the ob-
ject, according to the flame which nature has laid upon the
face to be painted.

The angle of 45 deg. or thereabouts, is also the best for
the general illumination of a picture while the artist is
employed upon it, with such an inclination from the fource of
light, that no reflection of it is presented to his eye. He
will, in this situation of his work to the light, beleast in
his own way, and fee the whole of it together most effectually;
but this is an object of lesser moment; a good artist need not
wait to have his picture precisely in the very best situation,
to enable him to perform his task with pleasure or effect.
Indeed he cannot always have it so, particularly when en-
gaged in adorning walls and ceilings, &c.

With regard to the second division of our subject, or the
quantity of light proper to be introduced into a picture,
which is a matter that lies entirely at the discretion of the
artist, we must principally refer our readers to what has
been said under the articles CLAIR-OBSCUR, and EFFECT,
in Painting; more particularly the latter, where we have
shown that various masters have adopted as various quantities,
and shaded them all agreeable. The subject, the place,
and the time, must govern this point, and the taste of the artist
must lead him to decide the matter for himself; his only
guide is, the most natural, and at the same time the most
effective, illustration of his subject.

Another point for consideration, is the tone of colour
which should be given to the light. Of this, also, we have
treated under the words EFFECT, in Painting, and HARMONY
in the same art, and need only state here, that whatever hue
is adopted, the shade should range through the whole picture,
except when two kmds of light are introduced, as day-light
and candle-light. In that case the former will be of a cold
colour; and in situations where shadows from the candle fall
over parts illuminated by the day, those parts, if the object be
white, will appear of a light blue, as may be seen when
candles are lighted and placed on a table-cloth, where rays
of twilight can reach. The warm colour thrown off by the
flame of the candle, imparts its nature to whatever it illu-
mines, and as it is nearly yellow, it renders white and yellow
very nearly alike in hue, and makes green appear blue, and
purple nearly so. This renders it a difficult matter to paint
by candle-light for a day-light exhibition. The artist must
rely

L I G H T.

rely very much upon his judgment and previous knowledge of his colours who attempts it, or all the delicate admixture of teints and hues will escape him. Rubens has very frequently succeeded in the admixture of lights, and in one picture particularly, his beautiful work of "St. Roch interceding for the unhappy Sufferers from the Plague." And Titian has rendered most beautifully the effect of three lights, viz. those of the day, of fire, and of candle, in his grand work of "The Martyrdom of St. Lawrence;" and has contrived to produce one harmonious tone over the whole, while each part is characteristically maintained.

Light, in \textit{Sea Language}, is used in contradistinction to Laden. A ship is accordingly called light, either when she has no cargo, or when she is not sufficiently ballasted.

Light is also used for the luminous body that emits it. There are various kinds of lights; \textit{general} lights, as the air; \textit{particular} lights, as a fire, a candle, and even the sun.

Lights, in \textit{Architecture}, denote doors, windows, and other places, through which the air and light have a passage.

In the Pantheon, all the light comes from on high; it has no lights but in the dome.

Lights, in \textit{Gardening}, a term applied to the moveable glazed sashes which cover garden and other frames; and which, according to the number of lights, or separate moveable glasses, are denominated one-light, two-light, and three-light frames; the first being the most general different sizes of this sort of frame. \textit{See Frame and Garden-Frame.}

Lights, \textit{Fenst. of. See Dedication.}

Lights, \textit{Stopping, of a house}, is a nuisance; but stopping a prospect is not, being only matter of delight, not of necessity. If a man has a vacant piece of ground, and builds thereupon a house, with good lights, which he sells or lets to another; and afterwards builds upon ground contiguous, or lets the same to another person, who builds thereupon to the nuisance of the lights of the first house; the lessee of the first house may have an action of the ease against such builder, &c. And though formerly they were to be lights of an ancient messuage, that is now altered.

Light-horse, an ancient term in our English customs, signifying an ordinary cavalier, or horsemn lightly armed, and so as to enter a corps or regiment; in opposition to the men at arms, who were heavily accoutred, and armed at all points. \textit{See Cavalry and Horse.}

\textbf{END OF VOL. XX.}
