And to the great articles of breeding filk-worms, though a recommendation from the crown could not bring about the planting these trees in sufficient number for it in James the First's time, yet the trees have been found to flourish very well with us when properly planted, and the worms feed very kindly and work very well with us. When this manufacture was first attempted, the people of many parts of England, nay, and in some parts of the dappled places in Ireland, tried it, and always with success. The only thing that stopped the progress of so valuable a thing at that time, was the want of a sufficient quantity of mulberry-trees, and the scheme has been neglected ever since. Phil. Tranf. N° 133.

The tree was always esteemed by the ancients for its delicious fruit, before the use of its leaves was ever found out. The Romans, in the height of their luxury, preferred it before all the foreign fruits; and Columella and the other ancients are very explicit in the methods of propagating it.

The fullick-wood, which grows plentifully at Campeachy, and is exported from Jamaica, is a species of the mulberry; as also is the China and Japan mulberry-tree, of the bark of which the inhabitants make paper; and in some of the islands of the south sea a kind of cloth is made of it.

MULBERRY-Bltte. See BLITUM.

MULBERRY-Cyder, a name given by the people of Devonshire, and some other parts of England, to a sort of cyder rendered very palatable by an admixture of mulberry-juice in the making: they choose for this purpose the ripe and blackest mulberries, and preffing out their juice and mixing it with a full-bodied cyder at the time of the grinding and preffing, give it so much of it as adds a perceptible flavour. It is very worthy the attention of people who live in other countries, where strong and good cyder is made, that this renders it a sort of wine much more agreeable than any other English liquor, and might be brought into general use, to the great advantage of the dealer. The colour of this liquor resembles that of the bright red wine, and the flavour of the mulberry never goes off. Phil. Tranf. N° 133.

MULBERRY-Shell, a species of doolin.

MULBERRY-Island, in Geography, a small island in James river, Virginia. N. lat. 37° 6'. W. long. 76° 32'.

MULCH, in Gardening, a term made use of to signify such strawy dung as is somewhat moist but not rotted. It is found useful for protecting the roots of new-planted choice trees or shrubs from severe frost in winter, and from being dried by the fierce sun or drying winds in spring and summer, before they are well rooted; in which caches it is spread evenly on the surface of the ground round the stems of the trees, as far as the roots extend, about three or four inches thick, but which should be augmented in winter, when the severity of the frost renders it necessary. It may also be employed for many other purposes of a similar nature.

MULCOM, in Geography, a town of Sweden, in Warmeland; 13 miles N.E. of Carlshft.

MULCT, MULCTA, a penalty, or fine of money, imposed for a fault or misdemeanor.

MULDA, in Geography, a town of Saxony, in the circle of Erzgebirg; 8 miles S.S.E. of Freyberg.

MULDORF, a river which rises near the mountains between Bohemia and Bavaria, S.W. of Prachatic, passes by Budweis, Teyn, Prague, and joins the Elbe a little above Melnik.

MULDENHAMMER, a town of Saxony, in the circle of Erzgebirg; 6 miles W. of Schwarzenberg.

MULDONICK, or DeER ISLAND, one of the small western islands of Scotland. N. lat. 56° 51'. W. long. 7° 29'.

MULDORF, a town of the archbishopric of Salzburg, on the inn, ceded to the elector of Bavaria in 1802; 36 miles N.W. of Salzburg. N. lat. 48° 12'. E. long. 12° 25'.

MULDSCHEN, a town of Prussian Lithuania; 16 miles S.W. of Inertberg.

MULE, in Zoology, the Equus Aferus Mulus γ of Linneus, the O; of Ariofolte, the Mulus or Mula of Phyn, Geffer, Aldrovandus, Jonston, Sloane, and others. The Aferus Biformis of Klein, and the Grand Mulet of Buffon, is the hybrid produce of a jack-as with a mare: having a large clumy head, long erect ears, a short mane, and a thin tail. The Equus Aferus Hanii, called Hardou by Buffon, is the hybrid produce between the the-aas and a rallion: the head is long and thin, the ears are like those of a horse, the mane is short, and the tail is well filled with hair. This is the Ox of Ariofolte, the Illiniss of Phyn, Geffer, Aldrovandus, Jonston, Ray, &c. and the Petit Mulet of Buffon.

The former, or the Mule commonly so called, is much valued for the saddle and for drawing carriages in Spain, Portugal, Italy, and the East, and in the warmer parts of America. In these countries, where great attention is paid to the breed, it is as tall as the horse, exceedingly well limbed, but not so handsome, especially about the head and tail; Q q thf
MULE.

these animals are most fertile; some indeed have thought that they are altogether incapable of producing their kind: but some few instances have occurred, in which female mules have had foals, and in which even the male has impregnated females both of the as and horse species, though such instances are exceedingly rare. The mule called the Bardeau, is much smaller, and less useful, as well as less common, than the mule, and of a more reddish colour: its ears and tail have a similar resemblance to those of the horse, but the mane is short like that of the mule: it is, however, little known, being seldom cultivated designedly, because it is less hardy and less fitted for the various purposes of life, than the horse, the ass, or the mule.

Mules have been reckoned a breed of confidence, and it has been generally thought that they do not propagate their breed. And yet the ancients mention a sort of mules, that were prolific in Phrygia, Syria, Cappadocia, and Africa.

Steno, examining the teat-folds of a mule, found one therein, with a sort of placenta about them; which persuaded him, that mules might engender without any miracle. But the observation has been thought fanciful, and the conclusion seemed unworthy of able a naturalist.

This is a subject that has engaged the particular attention of the ingenious naturalist Buffon. With a view of distinguishing the relative influence of males and females in the production of generation, he has investigated the differences which subserve between the two animals above briefly characterised: The Bardeau, he says, is much smaller than the mule, and seems to preserve the dimensions of its mother, the ass; and the mule retains the dimensions of the mare. Hence, he concludes, that the limits of the species are fixed; and that the size of the body depends more on the mother than on the father. These two animals also differ in figure. The neck of the Bardeau is thinner, the back sharper, and the crupper more pointed: while the forehead of the mule is better shaped, the neck more beautiful, the sides rounder, and the crupper more plump. Hence both these animals retain more of the mother than of the father, not only in magnitude, but in figure of body. But this remark does not apply to the head, limbs, and tail. The head of the Bardeau is longer, and not so thick in proportion as that of the ass; and the head of the mule is shorter, and thinner than that of the horse: so that in the figure and dimensions of the head, they have a greater resemblance to the father than to the mother. The tail of the Bardeau is paralled with hair nearly in the same manner: that of the horse; and the tail of the mule is almost naked, like that of the ass. In this extreme part of the body, therefore, the similarity to the father predominates. The ears of the mule are larger than those of the horse; and the ears of the Bardeau are shorter than those of the ass; and the head of the horse is rounder, and limber, like those of the horse; and the limbs of the Bardeau are more flexible. Hence it appears, that these two animals, in the form of the head, limbs, and other extremities of the body, have a greater resemblance to the father than to the mother. From various experiments on the he-goat and ewe, the dog and the wolf, and the goldfinch and canary bird, our author infers, as a certain fact, that the number of males, which is always greater than that of females in pure species, is still greater in mixed species: and hence he concludes, that the male, in general, has a greater influence in the produce of generation than the female, because he transmits his sex to the greatest number, and because the number of males is augmented, in proportion to the remoteness of the species which intermix. He also observes, that in crossing the remotest of different races, we shall procure not only the most beautiful productions, but the greatest number of males; and he adds, that crossing the breed, both in man and in other animals, is the only mode of ennobling and preserving the perfection of the species. To these facts and experiments he subjoins the testimony of the ancients in reference to this subject. Aristotle (whom we have already cited) says, that the mule engenders with the mare, and that the junction produces an animal which the Greeks call "hinnus," or "guinis." He also remarks, that the mule easily conceive, but seldom brings the fetus to perfection. On the other facts, says M. Buffon, the second is more rare than the first; and both barren only in warm climates. In such climates, however, facts justify the assertion, that the female is not only capable of conception, but of bringing the fetus to full maturity. Such cases occur in Spain and Italy, but much more frequently in the West Indies. Upon the whole it must be admitted, as an established fact, that the he-mule can generate, and the she-mule produce. Like other animals, they have a females liquor, and all the organs necessary to generation. But mongrel animals are always less fertile, and more hardy than those of a pure species. Besides, mules have never produced in cold climates, seldom in warm regions, and still more seldom in temperate countries. Hence their barrenness, without being absolute, may be regarded as positive; since their productions are so rare, that few examples only can be collected. The facts, nevertheless, are sufficiently numerous to expose the error of accepting false names, and applying them, without sufficient discrimination, to all animals of a mixed species. Thus the word mule, in its original acceptation, included all kinds of barreens produced from the ass and mares, and hence the idea of barreens has been conveyed to all beings who have the denomination of mules, that is, to quadrupeds, birds, fishes, and plants.

BUFFON'S NAT. Hist. by Smellie, vol. viii. 8vo.

Mules have been much employed both in ancient and modern times. The Roman ladies had equipes drawn by mules, as appears from the medals of Julia and Agrippina. And at this day, in Spain, the coaches of the nobility, and even of princes, are usually drawn by no other than mules.

We are assured, that M. de Thou, first president of the parliament, had the fourth coach in France, in 1585, till which time every body rode to court, parliament, &c, on mules.

These animals are very hardy. Savoy produces very large ones, but the finest are bred in Spain.

Mules are chiefly used in countries where there are rocky and stony ways, as about the Alps and Pyrenees, &c. Great numbers of them are kept in these places; they are of a dark black, and are strong, well-bred, and large, being mostly bred out of fine Spanish mares.

The mules are sometimes fifteen or sixteen hands high, and the blem of them are worth forty or fifty pounds a-piece. No creatures are so proper for large burdens, and more so for footed. They are much stronger for draught than our horses, and are often as thick as our day-horses, and will travel several months together, with six or eight hundred weight upon their backs. It is a wonder that these creatures are not more propagated in England, as they are so much harder and stronger than horses, and are left subject to duties, and will live and work to twice the age of a horse.

Those that are bred in cold countries are more hardy and fit for labour than those bred in hot; and those which are light
light made are fitter for riding than horses, as to the walk and trot; but they are apt to gallop rough, though these do it much less than the short-made ones.

They take so much after the mare from which they are bred, that they may be procured of any kind, light or strong, as the owner pleases. The general complaint we make against them is, that they kick, and are stubborn; but this is only owing to our neglect in the breeding of them, for they are as gentle as our horses in countries where they are bred with more care.

Mules generated between the horse and a he-asf are the least valuable. They are commonly very dull, and take after the afs, and are not large; the other breed between an afs and a mare is, therefore, what is propagated chiefly in all countries where mules are used. The he-asfs must be procured for this breed; and in Spain, where mules are greatly esteemed, they will give fifty or sixty pounds for a fine he-asf, only to be kept as a stallion. They breed with this creature out of the finest and largest mares they have, giving the afs an advantage of height of ground, and putting the mare into a narrow pit, railed on each side.

If the afs designed to be bred on is fuddled by a mare, or the mare fuddled by an afs, it makes them much more familiar than they would otherwise be; and this may always be done, by taking away the colt that belongs to the dam, and putting the other in its place, keeping them in the dark ten days or a fortnight. However, the success in breeding of these, as well as most other animals, depends in a great degree upon the manner of keeping them while young.

In respect to the he-asfs, they should be well fed, and be kept in good order, both before they drop their foals, and afterwards while they fuckle. And the foals, when wanted, should be carefully fed, and defended from the cold in the winter season; sufficient exercise in the open air being allowed every day, when the weather is fine.

It is well known, that in the West Indies much of the labour on the plantations is performed by these animals. And Mr. Carpenter remarks, that mules used in agriculture on light soils, and particularly in some situations, are very serviceable, though not very common in these parts. He knows but of two teams in which mules do all the work on the farms: the one belongs to Samuel Skey, esq. of Spring Grove; the other Mr. Teverel’s, near Worcester, consisting of seven handsome mules, and bred by the former gentleman, who breeds and keeps a considerable number, many of them fifteen or sixteen hands in height, and some of a milk-white colour. The most beautiful of the white mules Mr. Skey reserves for drawing his carriages, for which he has been offered a very high price. They are bred from grey or white mares, and a white and spotted foreign afs, which curious animal he has had possession of many years. Mr. Carpenter has very lately seen Mr. Teverel’s mules at work, and afterwards in the stable, where they are fed with good straw; and he was assured that straw was their only food, it being then winter. Their hardiness is certainly a valuable property, as these mules, though kept to hard work, looked remarkably sleek and well. Their longevity is also a very considerable advantage. Mr. Skey remarked, that two working mules in Shropshire had arrived to the age of seventy years each; and he has been informed, by a person who has taken much notice of this breed, that though they will perform a deal of work when only two or three years of age, they do not arrive to perfection till about thirty.

But when three years old, mules are proper for use, or being employed as stallions.

And in the breeding of these animals, mares that are of a very large breed and well made should be employed. They should be young, full of life, large barrelled, but small limbed, with a moderate fixed head, and a good forehead. It is found of advantage to have the foals, from the time of their being dropped, often handled, to make them gentle; it prevents their hurting themselves by skittishness and sudden frights; and they are much easier broken at the proper age, and become docile and harmless, having nothing of that viciousness which is so commonly complained of in these animals. They may be broken at three years old, but should never be permitted to do much hard work till four: as they are thus freshened from being hurt by hard labour, till they have acquired strength enough to bear it without injury.

It was found by an expert breeder of these animals, that by feeding them too well while young, though it made them very fat, it was far from being any advantage to them; as it was not only incurring a much larger expense than was any ways necessary, but also made them wonderfully nice and delicate in their appetites ever after, and also, by increasing their weight of flesh, rendered them more subject to strains and hurts in their morning gambols. He therefore contented himself with giving them food enough to prevent their losing flesh, and to keep up their growth, without palling their appetites with delicacies, or making them over fat. He also took care to defend them from the injuries of the weather, by allowing them stallable room, and good litter to sleep on, besides causing them every day to be well rubbed down with a hard whip of straw by an active groom. This was fearfully ever omitted, particularly in cold, raw, wet weather, when they were most inclined to exercise themselves in a proper manner.

Mule, in the Manufactures. See Cloth, and Cotton Manufacture.

Mule’s Fern. See Hesinnidis.

Mules, among Gardiners, denote a sort of vegetable monsters, produced by putting the farina succaddans of one species of plant into the pituit, or utricle, of another.

The carnation and sweet-william being somewhat alike in their parts, particularly their flowers; the farina of the one will impregnate the other; and the seed so enlivened will produce a plant differing from either. An instance of this we first had in Mr. Fairchild’s garden at Hoxton; where a plant was seen neither sweet-william nor carnation, but resembling both equally: this was raised from the seed of a carnation that had been impregnated by the farina of the sweet-william. These convulsions being not unlike those of the mare with the afs, which produce the mule, the same name is given them: and they are, like the others, incapable of multiplying their species.

This gives us a hint for altering the property and taste of any fruit, by impregnating one tree with the farina of another of the same clas; e.g., a codlin with a pear-man, which will occasion the codlin so impregnated to lat a longer time than usual, and to be of a sharper taste. Or, if the winter fruits be succadated with the dust of the summer kinds, they will ripen before their usual time. And from this accidental coupling of the farina of one with another, it may possibly be, that in an orchard where there is a variety of apples, even the fruit gathered from the same tree differ in their flavour, and in the season of maturity.
It is also from the same accidental coupling that the numberless varieties of fruits and flowers raised every day from seed proceed.

MULELACHA, in Ancient Geography, a town of Africa, in Mauritanis Tingitana, on a promontory which extended into the Atlantic, according to Pliny.

MULETA, in Geography, a town of Naples, in Calabria Citra; 16 miles E.S.E. of Scalea.

MULETS, in Commerce, fines laid on ships or goods, and applied to the maintenance of confuls, garrisons, &c.

MULEVO, in Geography, a town of Ruffia, in the government of Viatka, on the Kama; 16 miles S. of Sarapul.

MULFINGEN, a town of the duchy of Wurzburg; 31 miles E. of Wurzburg.

MULGOM, a town of Hindooftan, in Bagdana; 47 miles S.E. of Saler-Mouler.

MULGRANOC, in Ichthyology, an English name for a small sea-fish, caught on the Cornith and other shores, the alauda non erifata of Rondeletius, the ellenius pholis of Linnaus, and the palmetto of other authors.

MULHÄRGUNE, in Geography, a town of Hindooftan, in the circus of Gohud; 11 miles S. of Lahaar.

MULHAUSEN, See MULHAUSEN.

MULHEIM am Ruhr, a town of the duchy of Berg, on the Ruhr; 14 miles N. of Duffeldorp.

MULIER, in Laze, signifies lawful issue born in wedlock, but begot before.

If a man have a son by a woman before marriage, which is a bastard and illegitimate; and he afterwards marries the mother of the bastard, while with child of another, and they have another son; this second son is called mulier, and is lawful, and shall be heir to his father. Thefe we sometimes also find with the additions bastard etnig, and mulier paifine.

Some derive the word from the Latin mulier, or French mifler, better; in regard the condition of a born born thus is better than that of an elder brother born before wedlock.

Though, according to Glanvil, the lawful issue is rather called mulier than mulier, because begotten on mulieres and not on concubine; for he calls such issue filius mulieratus; opposing them to bastarles. Agreeable to which, Briton has frere mulieres, i.e., the brother begotten of the wife; in opposition to frere bastard.

The like seems to obtain in Scotland, where, according to Skene, mulricatus filius is a lawful born, begot of a lawful wife.

Mulier was also ancienly used as an addition for a wife; sometimes also for a widow. According to Coke, virgin is also included under the name mulier.

MULLERTY, the being or condition of a mulier, or lawful issue. Co. Litt. 372.

MULLAZZO, in Geography, a town of Sicily, on the S. coast, at the mouth of the river St. Croce; 18 miles W. of Modica.

MULGEN, Gross, a town of Germany, in the duchy of Anhalt Zerlaff; 14 miles W. of Zerlaff.

MULGEN, Klein, a town of the duchy of Anhalt Zerlaff; 12 miles W. of Zerlaff.

MULVADDY, one of the principal rivers in Ceylon, takes its rise at a small distance from that of Malavagonga, at the foot of Adam's Peak, a high mountain in the S.W. of Candy, and runs towards the W. coast.

MULKAPOUR, a town of Hindooftan, in Golconda; 16 miles S.E. of Hydrabad.

MULKEE, a town of Hindooftan, in Camara; 16 miles N.N.W. of Mangalore; ceded, in 1799, to Great Britain.

MULL, a large island situated on the western coast of Scotland, and included within the county of Argyle, from the main land of which it is separated on the north-east by a narrow channel, called the Sound of Mull; and on the south-east by the large bay opening from the south into the Linnhe-loch. On the western parts, and on the south, it is washed by numerous bays formed by the Atlantic ocean, and every where interfaced with small islands, of which the celebrated Icolm-kil is the most remarkable. This island measures from east to west about twenty-four miles, and from north to south nearly the same extent, and comprehends three parochial districts; Killinichen, Kilimben, and Torsay. Its superficial contents, however, are by no means equal to its fields, and many indentations of the sea, particularly on its western side. The coast here is, for the most part, bold and rocky; and the face of the country generally exhibits a series of mountains, some of them rising to a considerable height. The most elevated are the "Bien-Mor," or the "Great Mountain;" and "Baintalindh," or "Prospect Mountain;" both of which command very extensive sea-views.

In this peculiarity of country, as may be supposed, agriculture is little attended to, and indeed almost the only parts of the island under cultivation, are some detached frpips of land near the shore. Some of the mountains form excellent sheep-walks, and to this purpose they are accordingly applied. All the other portions of the island, not covered with wood or swampy morasses, are devoted to the feeding of cattle, of which great numbers are annually reared and exported. These cattle are chiefly, if not entirely, of the black native species; and the sale of them contributes the principal mode whereby the tenants are enabled to procure money for the payment of their rents. Such of them as are unable to effect that object in any other way are generally compelled to leave their homes, after they have fenced their little arable spots, to seek work in the more southern districts, whence they return before harvest, with a trifling pittance saved from their hard-earned wages. As there are few inclusions in the island, either to separate the grazing farms from each other, or to protect the arable fields from the depredations of the cattle, a number of persons are necessarily employed in the capacity of herds, who lead a life of great toil and inactivity. They are, nevertheless, a hardy and vigorous race, much attached to their native soil, and furnish many excellent soldiers for the royal service. The only kinds of corn grown here are oats and barley; the former affording very indifferent crops, and the latter much more luxuriant ones than is usual in the western islands. The oats are generally made into meal; but the greatest part of the barley is distilled into whiskey, in spite of the constant efforts of the excise to prevent its manufacture. Sea-ware and shell-fands are much used as manure, and are carried to the fields on the backs of horses in baskets and iron vats. All the implements of husbandry are extremely rude, and probably the fame that have been employed during several centuries past; for as there are no regular ploughs or harrow-makers in the island, each farmer constructs his own, after the manner of his forefathers.

Of the villages in Mull, the only one worthy of notice is Tober-Moray, which stands close to the shore, near the northern extremity of the Sound. This village was built by the British Society for the Encouragement of the Fisheries, in 1788, and might soon be improved into one of the chief sea-ports on the western coast of Scotland, as it polishes a fine
MULL

fine bay completely sheltered from the ocean by the small island of Calve; and lies directly in the track of the numerous vessels which pass from the more southern ports to the northern countries of Europe. At present, however, it does not contain above thirty houses built of stone and lime; besides, perhaps, nearly double that number of small thatched huts. The inhabitants principally either hold situations in the post-office or cultom-house, or are employed in some capacity connected with, or dependent on, the herring fisheries.

Of the landed property in Mull, the greater proportion belongs to the representative of the ancient family of the M'Leans, but a considerable part of it is likewise in the possession of the Duke of Argyll. Torloigh, the residence of Mr. M'Lean, is the only mansion of note in the whole island. Castle-Duart, the seat of his powerful ancestors, which stands on a bold head-land projecting into the sea, is now wholly in ruins; as is also Castle-Aros, or Aras, said to have been long the residence of the M'Donalds, lords of the isles.

But what chiefly demands attention in an account of this island, is its mineralogy. The substratum, throughout a great extent, is a mass of whin-robine, only different from basaltes, which also frequently occurs, in the greater coarseness of its grain. Some of the basaltes assume a regular columnar form. Near Aros are some rocks of white lava, and apparently of the same kind with that described by M. Dolomieu, in his "Memoires fur l'isle de Ponces." Lime-robine is extremely abundant, and in some places is of so fine a quality as to re semble marble, and to be capable of a fine polish. Coal has been discovered in considerable quantity, but so situated as to render it impracticable to be worked with any prospect of advantage. Hence the investigation of the strata of the island is more an object of curiosity to the mineralogist, than of utility to the practical miner. In one spot a stratum of coal is discovered immediately under basaltes; and in another basaltes incumbent on that mineral; perhaps the only instance of the kind in the world." The mountain called Ben-Enoch contains a very uncommon mineral substance, a zeolite, or compound silicious spar impregnated with petroleum. Sand-robine, and granite of an excellent grain, are very plentiful, and the shore abounds with pebbles of great variety and beauty. At Balphstrath is the celebrated "Ringing Stone," which measures seven feet long, by fix broad; and is four and a half feet in thickness. This stone is of a dark grey colour, spotted with inars of black mica, and totally different from the surrounding rocks. It is so hard, that any attempt to break off the smallest fragment by the most vigorous strokes of a common hammer would be entirely vain; and when so struck it yields a sound like braus, or cast iron. The mineral properties of this curious stone, we believe, have not yet been ascertained. The other mineralogical curiosities in Mull are its caverns, which, though some have questioned the opinion, are, doubtless, natural excavations. Of these, two in the district of Airdmeanach are particularly deserving of notice. One, called "Ladder-Cave," is capable of containing about eighty men, and has a breast-work built at its entrance, to which a passage leads up the rock, where two men only can walk abreast. In this cave, tradition says, that the inhabitants anciently took shelter in times of danger. The other, called "M'Kinnes's Cave," is much more capacious than Ladder-Cave, and is commonly supposed to have taken its designation from a gentleman named M'Kinne, who went to explore it, and was never afterwards heard of. At that time it was generally thought to reach quite across the country; but this idea has been long since found to be erroneous, every part of it having been examined, and its dimensions determined by succeeding adventurers. If, therefore, there is any truth in the story of M'Kinnen, he must either have perished from some accidental cause, or have been murdered by persons who had taken shelter in the cave, and considered him as a dangerous spy or intruder.

The common language of Mull is the Gaelic, or Erse, but a number of persons also speak English, and, no doubt, if proper encouragement was given to the parish schools, the latter would soon become almost universal. Unluckily, however, it happens here, as in many other highland districts, that the stipend of a schoolmaster is scarcely equal to the wages of the meanest labourer; and hence it may be conjectured, that few persons of any ability will devote their time and acquisitions to such unprofitable employment, as taking the charge of education in a country, where their utmost efforts are inadequate to afford the most ordinary sufficiency of life.

The ferry boats to this island are two in number; one to Morven, and the other from Auchnarrow to Kernen, and from thence to the mainland near Oban.

Mull has, no doubt, been the scene of some severe conflicts in ancient times, which, however, for the most part, were of too little general importance to find a place in the page of Scototh or English history. Bloody-bay, according to tradition, is so called from a sea-fight between a M'Donald of the isles, and his son. The father was supported in this contest by the brave Hector Obhan M'Lean, who afterwards died so gloriously in the field of Flioden, covering his monarch, James IV., from the arrows of the English archers. In 1583, the Florida, one of Philip's incincible Armada, was blown up in "Tober-More" bay, after the dispersion of the fleet, as some avert, by the desperate resolution of a Scotchman; and in the same bay did the unfortunate earl of Argyll effect his first landing, attended by a few friends, when he invaded Scotland, with the view of supporting the cause of the duke of Monmouth.

MULL OF GALWAY. See GALLOWAY.

MULL SOUND, a narrow sea between the island of Mull and the continent of Scotland.

MULL OF KINLOCH, the S. extremity of the island of Isay. N. lat. 55° 43'. W. long. 6° 9'.

MULLA, a town of Sweden, in the government of Abo; 56 miles S.E. of Birnoberg.—Alfo, a town of Hindooflan, in Lahore; 24 miles N.W. of Rotas.

MULLAGHICARN, a mountain of Ireland, in the county of Tyrone, a few miles north of Omagh, the county-town.

MULLANA, mountains of Ireland, in the county of Leitrim, W. of lough Macnean, and on the border of the county of Fermanagh.

MULLAOW, a town of Hindooflan, in Guzerat; ten miles N. of Champaneer.

MULLARGUR, a town of Hindooflan, in the circuit of Chandore; 15 miles N.W. of Kinlaffa.

MULLAVELLY, a town of Hindooflan, in Myfor; taken by the British under the marquis of Cornwallis.

MULLAWAR, a town of Hindooflan, in the circuit of Biflah; 25 miles N.W. of Biflah.

MULLEIN, in Botany and the Materia Medica. See VIBRASCUM.

MULLEN, the common name provincially applied to a biennial plant, which perishes soon after it has perfected its seed. The leaves spread on the ground are nine or ten inches long, and six broad, very woolly, of a yellowish-white colour,
MUL

jour, and very little footstalk. The stem rises four or five feet high, and the upper part of it is garnished with yellow flowers, which fit very close, and form a thick spike. These flowers have an agreeable colour, appear in July, and the seeds ripen in autumn. It commonly grows on the sides of roads, and on banks; but when it once gets into the fields in a warm exposure, and is suffered to feed there, it soon over-runs the whole ground. It may be easily destroyed by cutting off the stem, when it is in a flowering state.

MULLEN'S BAY, in Geography, a bay on the coast of Yucatan. N. lat. 18° 15'. W. long. 89° 17'.

MULLEN'S ISLAND, a small island in the gulf of Mexico, near the coast of East Florida. N. lat. 28° 1'. W. long. 53° 55'.

MULLER, Andrew, in Biography, a celebrated German writer, a native of Pomerania, was born in 1650. At the age of sixteen he was sent to the university of Rostock, and became in a short time distinguished for his compositions in the Hebrew, Greek, and Latin poetry. After this he studied at Konigberg and Wittemberg, and became to completely master the Oriental languages; thus, he was invited to England by Walton, to assist him in his famous Polyglott Bible, which, and on Cæcilius' Lexicon, he laboured with incredible diligence for the space of ten years. After his return to Germany, he became inspector at Bénaun, and provost at Berlin. He found the duties of these offices incompatible with his oriental studies, resigned them in a short time, and devoted himself wholly to his favourite pursuits. At Stettin, whither he retired, he published, with observations, specimens of the Lord's Prayer, in sixty-six alphabets. He was intimately acquainted with the Chinefe, and promised to draw up a Clavis Sinica, which he thought would enable a person of ordinary capacity to read Chinese and Japanese books in the course of a few months. This work never appeared, and it is believed he burnt the MSs, with many others, during a fit of sickness attended with delirium. He died in 1694, and by his last will bequeathed his Chinese printing materials to the library at Berlin. He was author of many very learned works; of these the titles of the following may be noted: "Abadal Beidavi História Siningus Perferen Libri Sex in Latin," "Monumentum Sinicum cum Commentariis quatuor," "Hebraea, Exoticae, et Sinicarum," "Aciesomna Bibliothecæ Sinicæ," "Synta-pha Syriaca, cum dusibus Dissertationibus." Some of his works were collected together and published in 1695, with the title of "Mulleri Opuscula nonnulla Orientalia." It is recorded of him that he was so attached to his books, that he would not leave them for a moment to witness the great cavalcade, on the entry of Charles II. into London, that passed by his window. We have heard of a similar instance in two philosophers, who refused to cross the room to behold a much more splendid, and to Englishmen interesting spectacle, viz. the funeral of the immortal Newton. Gen.-Bâg.

MULLER, Gerhard-Frederic, a celebrated German, known as well for his travels as for his writings, was born in 1705, in Herford, in Westphalia, where he received the early part of his education under his father; at the age of seventeen he was sent to the university of Rinteln, where he resided a year, and then removed to Leipzig. Here he so distinguished himself, that he was recommended by professor Meckel as an adjunct in the historico-clas of the academy founded at Petersburg by Peter the Great. He accordingly set out for that city, and was soon employed in teaching the higher classes in the Latin language, geography, and history; he was then appointed assistant secretary to the institution; in 1728 he was made under librarian to the imperial library, and in 1730 he was chosen professor of history. He now applied for leave of absence, in order to gratify his wish of seeing foreign countries. In the year 1731 he visited London, and was elected a fellow of the Royal Society, and on his return to Peterburgh, he read lectures privately, till he was appointed to accompany Gmelin and de Fille de la Croyere on their travels through Siberia. The business assigned to Muller in this expedition was to collect every fact new and curious relating to the geography and antiquities of the country, as well as the history of the different tribes by which it is inhabited. On his return, he wrote an accurate account of his journey; traced out their various routes; wrote geographical, historical, and political descriptions of all the towns; examined their records, and took extracts from them, which formed go vols. folio. Helikewas acted as secretary to the expedition, and affiliated Gmelin in collecting objects of natural history. They set out on their travels in August 1732, and did not return till February 1743, during which time they had travelled 44,000 German miles, or more than three times that number of English miles. An account of their travels was published by Gmelin and Muller (see his article, vol. 12, p. 840). After this, Muller, who was not rewarded in any degree equal to the labours and sufferings which he had undergone, remained in Russia, struggling with poverty and other evils necessarily attached to untoward circumstances. He undertook, at the desire of prince Jufupof, "A dissertation on the trade of Siberia," which, though written, or at least begun, in 1744, was not published till 1750, and then only the first part. In 1747, he was appointed historiographer of the Russian empire, and in 1754 he was nominated by the president to be the secretary of the Academy of Sciences, and was employed in superintending the publication of their transactions, and in other literary undertakings. In 1758, he was appointed director of the school for confectioners, established by Catharine at Moscow, and in 1766, he was appointed keeper of the archives in that city, now (1813) alas! no more, with an additional salary of 1000 roubles. From this period till his death, which took place in 1783, he devoted himself entirely to the pursuits of literature, having been previously raised to the rank of counsellor of state, and received the order of Wladimir. Mr. Muller traveled much, and, in speaking of Muller, who was then living, says, "He collected during his travels the most ample materials for the history and geography of this extensive empire, which was scarcely known to the Russians themselves before his valuable researches were given to the world in various publications. His principal work is 'A collection of Russian Histories,' in nine volumes octavo, printed at different intervals at the press of the Imperial Academy of Sciences. The first part came out in 1732, and the last in 1764. This storehouse of information and literature in regard to the antiquities, history, geography, and commerce of Russia, and many of the neighbouring countries, conveys the most indisputable proofs of the author's learning, diligence, and fidelity. To this work the accurate and indefatigable author has successively added many other valuable performances upon similar subjects, both in the German and Russian languages, which elucidate various parts in the history of this empire.

Mr. Muller speaks and writes the German, Russian, French and Latin tongues with surprising fluency; and reads the English, Dutch, Swedish, Danish, and Greek with great facility. His memory is still surprizing; and his accurate acquaintance with the minutest incidents of the Russian annals almost surpasses belief. His collection of state papers and manuscripts is invaluable: they are all arranged in the exact order, and clasped into several volumes, distilling by
by the names of those illustrious personages to whom they principally relate; such as Peter I., Catharine I., Menzi- kof, Hellman, &c. Muller, John, commonly known by the name of Regiomontanus, from Mons Regius, or Königsberg, a town in Prussia, where he was born in 1436. Having acquired a good classical education in his own country, he was admitted very young into the academy of Leipsic, where he formed a strong attachment to the mathematics, and those other branches of knowledge connected with them. At this early period he felt that the affinities he obtained at Leipsic were not equal to his expectations, and he removed at the age of fifteen to Vienna, to study under the famous Purbach. A strong attachment was formed between these two, and Muller made such a rapid progress in the sciences, that he was soon able to affix his master, and become the companion of his labours. They spent ten years together in elucidating observatories, observing the motions of the heavenly bodies, and comparing and correcting the tables of them. While they were thus employed, cardinal Bessarion applied to Purbach to translate the Almagest of Ptolemy into the Latin language, which with the affinities of Muller he began: before, however, they had proceeded far in their labours, Purbach died, and the whole fell upon his pupil, companion, and associate, which he completed at Rome, whether he accompanied the cardinal. While in the metropolis of the ancient world he applied himself with great diligence to the study of the Greek language, and examined the rich stores of learning in the public libraries. He did not, however, neglect his mathematical pursuits, and continued with great eagerness his astronomical observations. In 1453 he went to Padua, became a member of the university there, and delivered a course of lectures to a very numerous auditory. In the following year he removed to Venice, and wrote his "Treatise of Triangles," and a refutation of the quadrature of the circle, which cardinal Cusan thought he had demonstrated. The same year he returned with Bessarion to Rome, where he copied several books which, from their high cost or great rarity, he could not pur chase, meaning hereafter to translate and publish some of them in Germany. Having finished what he intended to do in this way he returned to Vienna, and performed for some time the duties of his professorship. After this he went, at the invitation of Matthias, king of Hungary, to Buda, and from thence to Nuremberg, where he fixed his residence, and set up a printing-house, in order to print and publish his own works, in which he was assisted by the celebrated Bernard Walther. Here he published the "New Theories" of Purbach; the "Altronomicon" of Manilius; his own "Calendar." "Ephemerides," &c. He likewise prepared a new version of Ptolemy's Cofnography; and published Commentaries on the Almagest, which cardinal Bessarion said was worth a whole province. Having had good opportunities for making observations on two comets in 1471 and 1472, he published a treatise, entitled "Concerning the true Place and Magnitude of Comets." In 1474 pope Sixtus IV. conceived a design of reforming the calendar, and sent for Regiomontanus to Rome, as the most able person to accomplish his purpose. The philosopher was exceedingly unwilling to leave his own pursuits, but having received the most magnificent promises from his holiness, who also nominated him bishop of Ratibon, he set out, and arrived at Rome in 1475, but died the following year, at the age of forty. He was buried in the Pantheon, and his memory was celebrated by the best poets of the time. It may be observed that Purbach was the first mathematician who reduced the trigonometrical tables of sines to the decimal scale. This project was perfected by Regiomontanus, who not only extended the sines 10 every minute, the radius being 600,000, as designed by Purbach, but afterwards computed them to the radius of 1,000,000 for every minute of the quadrant. He also introduced the tangents into trigonometry, and enriched this part of science with many theorems and precepts. His "Treatise on plane and spherical Trigonometry" consists of five books; in the fifth are various problems concerning rectilineal triangles, some of which are resolved by means of algebra. Regiomontanus was author of other works besides those already mentioned: and of his mechanical projects are are told by Peter Ramaus, that in his workshop at Nuremberg there was an automaton in perpetual motion; that he made an artificial fly, which taking its flight from his hand, would fly round the room, and at last return to his master's hand; that he fabricated an eagle, which, on the emperor's approach to the city, he sent out, high in the air, a considerable distance to meet him, and that it kept him company to the very gates of the city. "Let us no more wonder," adds Ramaus, "at the doves of Archytas, since Nuremberg can fly a fly and an eagle armed with geometrical wings." 

MULLER, Henry, a learned German Lutheran divine and professor, was born at Lubeck in 1561. He began the study of Oriental literature and philosophy at Rostock, and in 1547 he was sent to the university of Grypswalde in Pomerania, where he continued three years. In 1561 he was admitted to the degree of master of philosophy, after which he spent about two years in augmenting his floc of knowledge at the universities of Leipsic and Wittensberg. In 1563 he came to Rostock, and was promoted by the senate to the dignity of archdeacon. Six years after this he was appointed Greek professor in the university, and in 1560 he received the degree of doctor of divinity at Helmfaht. In 1562 he was chosen paltor of St. Mary's Hamburch, and nominated professor of divinity in that city, an office which he held with great repute about eight years. At Rostock he thrice filled the post of rector of the university. He died at the age of forty-five, in the year 1675. His principal works are, "Harmonia Veteris et Novi Testamenti," "Theologia Scholastica," "Orator Ecclesiasticus." Besides these he published several others, controversial, practical, and devotional. Moreri.

MULLER, or Mullar, denotes a stone flat and even at bottom, but round at top; used for grinding of matters on a marble.

The apothecaries use mullers to prepare many of their tellaceous powders; and painters for their colours, either dry or in oil.

MULLER is an instrument used by the glas-grinders: being a piece of wood, to one end of which is cements the glas to be ground, whether convex, in a basin; or concave, in a sphere or bowl.

The muller is ordinarily about six inches long, turned round: the cement they use is compounded of ashes and pitch. See GLASSWORK.

MULLER, in Ichthyology, a name used by some for the fish called in Latin the euphractus, and in English the mulled fish, or pike.

MUL

Gen. Ch. Cal. Perianth inferior, of one leaf, bell-shaped, compressed, truncated, and flat at the base, with three teeth; the uppermost obliterated, rarely cloven; the two lateral ones more dilute, acute; the lower more produced and more awl-shaped. Cor. papilionaceous; standard reflexed, heart-shaped, ovate, entire, obtuse, flat, with a flattish claw scarcely longer than the calyx, remote from the wings and keel; wings oblong, clove, gibbous at the base, unguiculated; keel shorter than the wings, composed of two, distinct, clove, unguiculated petals, forming an oblong, compressed, bright sheath. Stam. Filaments ten, united into a compressed sheath, broader at the base; anthers ovate. Pfl. Gernon superior, linear, compressed; style short; stigma acute. Peric. Legume head-shaped, composed of three, four, or five globules, which form a sort of chain, and are firm, single-feeded. of one cell and one valve, the lowermost gradually larger. Seeds solitary, compressed, kidney-shaped, smooth.

Eff. Ch. Calyx four-toothed. Legumes elongated, of several, single-feeded, fleshy, globose cells, connected by thread-shaped portions.

Merian. Surinam. t. 35. (Cobwallia frutescens; Aubl. Guian. t. 356.)—Native of Surinam and Cayenne, in moist situations, where it is in flower and fruit nearly throughout the year. The trunk of this tree rises to the height of five or six feet, with rudly-coloured, somewhat warty branches. Leaves alternate, pinate, composed of two pairs of leaflets with an odd one; leaflets opposite, on flaks, ovate-oblong, like those of Privet, entire, acute, flat, smooth above, thick beneath, flat, veiny. Flowers in axillary and terminal, simple clusters, nodding, pink-coloured, the size of Laburnum blossoms.

The fruit of this plant, which the younger Linnaeus has described as very wonderful, is nearly allied to some plants that have been confused under Sophora, particularly the Edwardsia of Mr. Salisbury; see that article.

MULLET, in Geography, a peninsula of Ireland, in the county of Mayo, on the western coast. It is about nine miles long from Urish Head to Blackford Point, and in general about two wide, though in some parts it is not a quarter of a mile across. Dr. Beauport says that it is reported to be fertile, pleasant, and well inhabited; but no good account of it has been yet published.

MULLET, in Echymology, a name given in England, indeterminately, to several kinds of fish, of different genera; but the proper sense of the words is the same with that of the mugil, or cephalus, of the generality of authors; the cephalus of Arbottle and the Greeks; and the celatus or celare of Oppian and others. See MUGIL. Mullets are found in great plenty on several of the sandy coasts of our island, and haunt in particular those small bays that have influx of fresh water. They come in great shoals, and keep rooting like hogs in the sand or mud, leaving their traces in form of large round holes. They are very cunning; and when surrounded with a net, the who'e fish frequently escapes by leaping over it; for when one takes the lead, the others are sure to follow. This fish was sometimes made the instrument of a horrid punishment: for unfortunate gallants; and was in use both at Athens and Rome. "Legibus Atheniensem aduturi m. 150. decempana pena but pecunia. Raptum loco ut cantare nonmoxque magnum nimi- "pice, interdum scorpionem." Cauflon. Animad. in Athen.-num. lib. i. Juvenal Satire x. v. 316. and Horace Satire ii. lib. i. v. 132. refer to this punishment. Pennant.

MULLET, Black, mugil nigra, a name given by authors to a fish of the mullet kind, but all over black, more usually known by the name of the porus piges.

MULLET, Winged, mugil albus, a name given by some authors to the pirinda piges, or swallow-fish, as, excepting its wing-fins, it very much resembles the mullet in shape. See FLYING-SEABIRDS.

MULLET, in Ornithology, a name by which the people in some counties of England called the anas articola Linn. See DUCK.

MULLET, or Mullet, in Heraldry, a bearing in form of a flat, or rather of the rowel of a spur, which it originally represented.

The mullet has but five points; when there are six, it is called a far. Though others make this difference, that the mullet is, or ought to be, always pierced, which a far is not.

The mullet is usually the difference, or distinguishing mark for the fourth son, or third brother, or house.

Though it is often also borne alone, as coat-armour: thus, ruby on a chief pearl, two mullets diamond, was the coat of the famous lord Verulam, first sir Francis Bacon.

MULLICKPOUR, in Geography, a town of Bengal, 16 miles E. of Hooghly.—Also, a town of Bengal, 25 miles N.E. of Calcutta. MULLICO HILL, a town of America, in Gloucester county, New Jersey; 163 miles from Washington.

MULLICUS RIVER, a small river of America, in New Jersey, upon which are many mulls and iron-works, emptying itself into Little Egg harbour bay, four miles E. of the town of Leeds, and navigable 20 miles for vessels of 60 tons.

MULLIEBANG, a town of Bengal, on the left bank of the Ganges, opposite to Hooghly.

MULLINCOTT, a town of Hindoostan, in the Carnatic; 15 miles S.E. of Tinavelly.

MULLINGAR, a poilt-town of Ireland, in the county of Westmeath, of which it is the shire town. It is a large well-built town, situated on a river issuing out of lough Hoyle. There is a wool fair held here, but it is not as much frequented as formerly, in consequence of that held at Ballinaule. It formerly returned two members to parliament, but this privilege ceased at the union. Mullingar is 38 miles W. by N. from Dublin. N. lat. 53° 31'. W. long. 7° 18'.

MULLIONS, in Painted Architecture, are all those parts of windows which divide the light into compartments, and are either curved or straight. See GOTHIC ARCHITECTURE.

Vertical mullions are called munions; and those which run horizontally are called transoms. The whole of the mullions of a window above the springing of the arch is called the headwork.

MULLOCK, in Agriculture, a provincial term applied to dirt or rubbish of any kind.

MULLOIAH, MULLUVIA, anciently Malva, Molo- chath, or Moluchia, in Geography, a river of Africa (see MAURITANIA), which rises at the foot of the Atlas, between Morocco and Saguinuffe, and runs into the Mediterranean. N. lat. 34° 55'. W. long. 2° 6'. It separates Morocco from the province of Teneriffe, and in its whole course runs from S. to N. about 200 miles, and is navigable only for small vessels.

MULLUNG, a town of Bengal; eight miles S. of Rung- pour.

MULUS,
MULLUS, the Surmullet, in Ichthyology, a genus of fishes of the order Thracetid, of which the generic character is, head compressed, flapping, scaly; eyes oblong, approximate, vertical, furnished with a nictitating membrane; nostrils double, minute; jaws and palate armed with small teeth; tongue short, narrow, smooth, fixed; gill-membrane threerayed; the covers of three pieces, very lumpy flate; body round, long, red, covered with large scales, easily dropping off. Gmelin mentions six species only, but Dr. Shaw describes thirteen; we shall first notice those given by the former, and then briefly speak of the others.

Species.

*Barbatus,* called also Mullus Ruber, or the red surmullet, has its lower jaw with two cirri; its body is red; it is principally found in the Mediterranean and Northern seas, where it comes to the length of 12 or 15 inches. Its colour is an elegant rose red, tinged with olive colour on the back, and a silver cast towards the abdomen; the scales are thin, and easily separated, and when rubbed off, the skin is still of a brighter red than it was before. It is strong and active, and feeds chiefly on the smaller fishes, worms, and sea-urchins. It is said nothing can exhibit a more beautiful sight, than the colours of this fish when it is in the act of dying, and its flesh is esteemed very delicious; the Romans held it in such high repute that prodigious sums of money were given for them.

*Multaret*; Striped Surmullet. This species has likewise two cirri, and the body is marked with four longitudinal lines. It inhabits the European, American, and Mediterranean seas; it is found of all sizes, from four inches to a foot long; the scales are silvery, streaked with tawny; it feeds on other fishes, telesauscous animals, crabs, and dead carasses, is gregarious, and approaches the shore in the spring, for the purpose of spawning: as an article of food it is equally esteemed with the other.

*Japonicus*; Japanese Surmullet. Yellow without stripes; the tail is forked, and it has two cirri. It is, as its name imports, found in the seas about the island of Japan, is about six inches long, and can scarcely be distinguished from the M. barbarus. The jaws are without teeth.

*Auriflamma*; Oriflamma Surmullet. Two cirri, white; each side has a tawny stripe; tail is yellow. It inhabits the Red sea; the scales are membraneaceous at the edge. It is about ten inches long; the colour is a gilded brown, paler beneath, with a longitudinal stripe on each side; the body of an oriflamma is a tawny tint, situated above the lateral line, and accompanied by a dusky spot near the base of the tail, which, together with the dorsal fin, is yellow; the other fins are whitish.

*Vittatus*; Banded Surmullet. Two cirri; body with two brown and three yellow stripes on each side; the tail is obliquely brown. It inhabits the Red sea; the body is lanceolate white; scales finely toothed, with obsolete elevated rivules. The jaws are crowded with teeth at the edges.

*Indicus*; Beardless Surmullet. Lower jaw without cirri; a native of the Mediterranean, particularly near the island of Malta. The mouth is wide; it differs from the rest of the genus in wanting the cirri beneath the lower lip.

*Indian*; Indian Surmullet. The body above purple, whitish below, and marked on each side by two spots. Its size and habit are the same as those of the red surmullet; in the living fish the colour is extremely beautiful, but it fades very quickly after death; the upper part of the head, and back, dark changable purple, growing faint on the sides, which are marked by a few longitudinal azure and golden lines, and by two oblong spots on each side. It is a native of the Indian seas, was observed by Dr. Ruffell near Vizagapatam; as food it is much inferior to the M. barbarus.

*Bandi*; Whitish, with two longitudinal yellow bands on each side; it is about four inches long; the body is white, with two yellow fillets on each side from the gills to the tail; break and belly greenish-white; dorsal and caudal fin streaked obliquely with yellow and dusky lines; ventral and anal greenish-white; inhabits the river near Vizagapatam.

*Bifasciatus.* With three transverse brown bands on each side. It is a native of the Indian seas, and possesses of habits similar to those of the rest of the genus.

*Biocutatus.* With two transverse brown bands on each side. Body marked by two deep or dusky transverse bands, each terminating in a point towards the abdomen; its beards are rather short; inhabits the Indian seas.

*Macelatus*; Spotted Surmullet. Body marked on each side by three round black spots; shape, rather more in length than in the rest of the genus; colour of the fish bright red, with three large round black spots along each side. It is a native of the Brazilian seas.

*Radialis.* The orbits radiated with yellow, and a deep yellow spot towards the end of the back; the second dorsal and anal fins are marked with oblique yellow streaks; it is a native of the Indian seas.

*Argenteus.* Gold-striped Surmullet. The body brownish-blue above, whitish beneath, and marked on each side by a longitudinal gold-coloured line; the tail and tips of the dorsal fins are yellow; it is a native of the Indian seas.

*Mullus*; in Geography, a town of Hindoostan, in Oude: 42 miles W.N.W. of Lucknow. N. lat. 27° 10'. E. long. 80° 31'.

*Mulna Shady,* a town of Cundahar; 35 miles E.N.E. of Suffa.

*Mullapour,* a town of Bengal; 25 miles S.E. of Purneah.—Alfo, a town of Hindoostan, in Oude; 15 miles S.W. of Goorackpour. N. lat. 26° 58'. E. long. 83° 28'.

*Mullnitz,* a town of Cariticia; 10 miles N. of Bibas.

*Mulyasliiskih,* a town of Ruffia, in the government of Irikutik, on the Angara; 36 miles N. of Balsansko.

*Mulrea,* mountains of the county of Mayo, Ireland, north of the Killeries, and about 23 miles S.W. from Callieb-post.

*Mullrose,* a town of Brandenburg, in the Middle Mark, seated on a canal made from the Spree to the Oder; nine miles S.W. of Francfort. N. lat. 52° 17'. E. long. 14° 72'.

*Mulroy Bay,* a bay on the north coast of Ireland, in the county of Donegal. It has water sufficiently deep in the anchorage for the largest ships, and is well sheltered from all winds; but a part of the channel that leads to it is narrow and difficult, and therefore not fit for large ships that cannot be easily managed. Lough Swilly, which is very near it, is so much superior as a harbour, that Mulroy is not much used.

*Mullsum,* Mullas, a liquor made of wine and honey, or even of honey and water. See Hydromel.

*Multa,* Multura, ephippia, a fine of final satisfaction, anciently given by the king by the bishops, that they might have power to make their Lat wills; and that they might have the probate of other men's, and the granting of administrations.

*Multangular,* in Geometry, a figure or body, which has many angles.
MULTENEN, in Geography, a town of Prussia, in the province of Natangen; 40 miles S.E. of Königsberg.

MULTIFERNA, or Multiffarum, a village of the county of Wiltmarch, Ireland, on the river Gaine, and near lough Derravaragh, where there was a celebrated monastery. Some ruins of the abbey still remain. It is seven miles N. from Mullingar, and 45 W.N.W. from Dublin.

MULTIFIDUS Spine, in Anatomy, a muscle of the vertebral column, the transverse-fibres of Whishow, transverse-fibres of Dumas.

It is a muscle of an elongated figure, placed at the side of the spinous processes, in immediate contact with the vertebrae, and contributes to fill up the channel left on each side of the spine at its posterior aspect. It consists of a series of muscular fasciculi of unequal length, placed one above the other, extending obliquely from the transverse to the spinous processes, from the sacrum to the second vertebra of the neck, and differing in volume in the different regions of the spine. The length of its fibres is not at all equal to the length of the muscle; as the former passes from the transverse to the spinous processes of the neighbouring vertebrae; but they are continuous throughout the whole length, so as to compose one muscle.

In the sacral and lumbar regions it arises, in the first, from the inequalities of the posterior surface of the sacrum by short aponeuroses, and from the common aponeurosis, which gives origin to the sacrolumbaris and longissimus dorsi; in the second, from the articular processes by long and distinct aponeurotic laminae. The flabby fibres are directed upwards and inwards, and are inserted, those of the first origin, in the spinous processes of the last lumbar vertebrae, those of the second, in the same processes of the upper lumbar and lower dorsal vertebrae, by a mixture of aponeurotic and flabby fibres. The superficial fasciculi go from a transverse process to the points of the spinous processes of the third or fourth vertebrae above it; the more deeply seated, which become shorter and shorter, pass from one vertebra to that immediately above it, towards the base of the spinous process or the place at its root.

The muscle is flatter in the back, and consists of long superficial fasciculi, which ascend from the eight or nine last dorsal transverse processes, to the points of the eight or nine upper spinous processes of the same region; and of shorter deep-seated fibres, which are extended from the roots of the transverse to the bases and laminae of the spinous processes. They arise and are inserted by aponeurotic fibres. In the cervical region we meet, first, with a very long, distinct, and often almost isolated superficial fasciculus, composed of others, which arise from the superior dorsal transverse processes, and inserted into the fixed last spinous processes, and end in a point at the vertebra dentata. Under this are shorter fasciculi, passing from the bases of the transverse processes of the upper dorsal, and from the articular processes of the five lower cervical vertebrae, to the bases and laminae of the cervical spinous processes. Distinct aponeuroses are observed at the origin and insertion of each fasciculus.

This muscle is in contact with the spinous processes, and moreover with the interspinales muscles in the neck, the interosseous ligaments in the back and loins, on the inside; in front with the laminae of the spinous processes, with the yellow ligaments uniting there, with the articular and transverse processes, which are points of attachment for it; behind, with the complexus and transversals collis in the neck, the longissimus and spinialis dorsi in the back and loins.

In the description are included, with the multifidus spine, properly so called, the semispinales collis and semispinales dorso; the distinctions between these three muscles cannot be established without cutting very freely through the fibres. The former includes the longer superficial structure, which we have mentioned in the neck; and the latter the corresponding part in the back.

The action of the multifidus spine is that of extending the vertebral column, and moving it laterally. The former effect is produced, when the right and left muscles act together; the latter, when they are exerted separately. As all the fibres are oblique, they draw the spine, when they contract, towards their own side; now, as the force drawing to the right is equal to that which pulls to the left, these balance and mutually destroy each other, and that motion only is produced, in which both the muscles concur; viz. extension, or motion backwards. When the spine has been inclined forwards, either in its whole length, or in any particular region, this muscle assists in restoring the trunk to the erect attitude; and it is constantly exerted in maintaining the body in this attitude. The lumbar and sacral portions fix the lumbar vertebra on the pelvis; this region of the spine, being rendered steady, affords a fixed point for the action of the multifidus spine in the lower part of the back, which fixes that part of the back on the loins; and the same observation holds good of the higher portions successively to the top of the spine. Thus the series of small muscles, which form the multifidus, having its first fixed point in the pelvis, which is immovable, acts successively in such a manner, that each vertebra is the point in which the contractions of an inferior fasciculus end, and from which those of a superior one begin. The superficial fibres must have more power than the deep-seated ones, as they are longer, and farther removed from the centre of motion.

If the muscle of one side acts separately, it will incline the spine laterally, by drawing the fibrous towards the transverse processes. The whole will produce this lateral inclination in the entire vertebral column; but any part may act separately on its own region of the spine.

MULTIFORME Ols, the os cuboides, one of the bones of the tarso. See Extremities.

MULTIPOWER, in Geometry, is applied to those figures which have more than four sides or angles, more usual called polygons.

MULTINOMIAL, or Multinomial Roots, in Algebra, are such as are composed of many names, parts, or members; as, $a + b + c + d$, &c.

For raising an infinite multinomial to any given power, or extracting any given root out of such a power, see a method of M. de Moivre, in Phil. Trans. N. 230.

MULTIPLE, Multiplex, in Arithmetie, a number which comprehends some other several times.

Thus 6 is a multiple of 2, or, which is the same, 2 is a quota part of 6; 2 being contained in 6 three times. And thus 12 is a multiple of 6, 4, 3; and comprehends the fourth twice, the third thrice, the second four times, &c.

Multiple Ratio, or Proportion, is that which is between multiple numbers.

If the lesser term of a ratio be an aliquot part of the greater, the ratio of the greater to the les is called multiple; and that of the les to the greater, sub-multiple.

A sub-multiple number is that contained in the multiple.

Thus, the numbers 1, 2, and 3, are sub-multiples of 6 and 9.

Duple, triple, &c. ratios; as also sub-duples, sub-triples, &c. are so many species of multiple, and sub-multiple ratios.

Multiple Superparticular Proportion, is when one number of
or quantity contains another more than once, and a certain aliquot part; as 33 to one.

**Multiplication** Superpartitive Proportion, is when one number or quantity contains another diverse times, and some parts besides; as $43$ to $1$.

**Multiple Etho.** See Echo.

**Multipli&*;and** in Arithmetic, is one of the factors in the rule of multiplication, being that number which is given to be multiplied by another called the multiplicator, or multiplier.

**Multiplication,** the act of multiplying, or increasing the number of anything.

Accurately speaking, in every multiplication, the multiplicator must always be considered as a number; and it is easy to conceive a quantity of any kind multiplied by a number. But to talk of a pound multiplied by a pound, a debt by a debt, and a line by a line, &c. is unintelligible. However, by analogy, in the application of algebra to geometry, we meet with such expressions, and nothing is more common than to find $AB \times BC$, to denote the rectangle $ABCD$, the length of which is $A$, and the breadth $BC$. But this is only to be understood by analogy; because, if the number expressing the measure of the side $AB$ was multiplied by $A$, the number expressing the measure of $BC$, the product would express the measure of $ABCD$.

The sign of multiplication most commonly used among algebraists, is $\times$. But the Germans, after Leibnitz, only make use of a point placed between the quantities multiplying each other, thus: $a \times b$ is the same as $ab$ and $A \times B$, the same as $AB \times BC$, or the rectangle of $AB$ into $BC$, that is, the rectangle $ABCD$.

When the quantities to be multiplied are complex, they place them between a parenthesis instead of drawing a line over them, as we commonly do.

Thus they write $(a + b) \cdot (c + d)$ instead of $a + b \cdot c + d$, for the product of $a + b$ into $c + d$. Sometimes the point is omitted, thus: $(a + b)(c + d) = a + b \cdot c + d$.

An old statute says, it is ordained and established, that none from henceforth shall use to multiply gold or silver, nor use the craft of multiplication; and if any they do, he shall incur the pain of felony. Stat. 5 Hen. IV. cap. 4.

The statute was made on presumption that some perfons, skillful in chemistry, could multiply or augment those metals by elixirs, or other ingredients; and change other metals into very gold and silver. Under Henry VI. letters patent were granted to certain perfons (who undertook to perform the same, and to find the philospher's stone), to free them from the penalty in the said statute. But the statute has been since repealed. 3 Will. & Mar. cap. 50.

**Multiplication,** in Arithmetic, the act or art of multiplying one number in order to find the product.

Multiplication, which is the third rule in arithmetic, contains finding some third number, out of two others given; in which one of the given numbers is contained as often as unity is contained in the other.

Or, multiplication is the finding what will be the sum of any number added to itself, or repeated, as often as there are units in another. So that the multiplication of numbers is a compendious kind of addition.

Thus, the multiplication of $4$ by $5$ makes $20$, i.e. four times five amounts to twenty; which algebraists express thus, $4 \times 5 = 20$.

In multiplication, the first factor, i.e. the number to be multiplied, or the multiplicand, is placed over that by which it is to be multiplied; and the factum or product under both.

An example or two will make the process of multiplication easy. Suppose I would know the product of $269$ multiplied by $8$, or $8$ times $269$.

<table>
<thead>
<tr>
<th>Multipli&amp;*;and</th>
<th>-</th>
<th>269</th>
</tr>
</thead>
<tbody>
<tr>
<td>Multiplier</td>
<td>-</td>
<td>8</td>
</tr>
<tr>
<td>Factum, or product</td>
<td>-</td>
<td>2152</td>
</tr>
</tbody>
</table>

The factors being thus disposed, and a line drawn underneath (as in the example), I begin with the multiplicator thus: $8 \times 9$ makes $72$, I put down $72$, and carry $7$ tens, as in addition: then $8 \times 6$ make $48$, and I carried $55$; let down $5$, and carry $5$; lastly, $8 \times 2$ make $16$, and, with $5$ I carried, $21$, which I put down: so that coming to number the several figures placed in order, $2, 1, 5, 2$, I find the product to be $2152$.

Now suppose the factors to express things of different speci&*;es, viz. the multiplicand, or yards, and the multiplier pounds; the product will be of the same speci&*;es with the multiplicator. Thus the product of $269$ men or yards, multiplied by $8$ pounds or pence, is $2152$ pounds or pence; for many of thefe going to the $269$, at the rate of $8$ a-piece. Hence the great use of multiplication in commerce, &c.

If the multiplicator consists of more than one figure, the whole multiplicand is to be added to itself, first, as often as the right-hand figure of the multiplicator shews, then, as often as the next figure of the multiplicator shews, and so on. Thus $421 \times 23$ is equal to $421 \times 3$, and also $421 \times 20$. The product arising from each figure of the multiplicator, multiplied into the whole multiplicand, is to be placed by itself in such a manner, that the first or right-figure thereof, may stand under that figure of the multiplicator from which the said product arises. For instance:

<table>
<thead>
<tr>
<th>Multipli&amp;*;and</th>
<th>-</th>
<th>421</th>
</tr>
</thead>
<tbody>
<tr>
<td>Multiplier</td>
<td>-</td>
<td>23</td>
</tr>
<tr>
<td>Particular product of $421 \times 3$</td>
<td>-</td>
<td>1263</td>
</tr>
<tr>
<td>Particular product of $421 \times 20$</td>
<td>-</td>
<td>842</td>
</tr>
<tr>
<td>The total product</td>
<td>-</td>
<td>9683</td>
</tr>
</tbody>
</table>

This disposition of the right-hand figure of each product, follows from the first general rule: the right-hand figure of each product being always of the same denomination with that figure of the multiplicator from which it arises.

Thus, in the example, the figure $2$ in the product $842$ is of the denomination of tens, as well as the figure $2$ in the multiplicator. For $1 \times 20$ (that is, the $2$ of $23$) $= 20$, or $2$ put in the place of tens, or second place.

Hence, if either of the factors have one or more cyphers on the right-hand, the multiplication may be performed without regarding the cyphers, till the product of the other figures be found; to which they are to be then affixed on the right. And if the multiplicator have cyphers intermixed, they need not be regarded at all. Instances of each follow:

| 12 | 358 | 10 | 24 00 | 8013 |
| 10 | 6,000 | 10 | 3 | 5060 |
| 12 | 0 | 2148 000 | 10 | 72 000 | 48758 |
| 40065 |
| 40113078 |

Thus
MULTIPLICATION.

Thus much for an idea of multiplication, where the multiplicator consists wholly of integers; in the praxis of which, it is supposed, the learner is apprised of the product of any of the nine digits multiplied by one another, easily learnt from the common table, or otherwise. Its table is here annexed.

<table>

</tr>
</tbody>
</table>

There are also some abbreviations of this art. Thus, to multiply a number by 5, you need only add a cypher to it, and then halve it. To multiply by 15 do the same, then add both together. The sum is the product.

Expedients for the more easy and expeditious multiplying large sums are Sliding Rules, and Nper's Bones. (See these articles.) The want of which may be supplied by tabulating the multiplicand.

Where the multiplicator is not composed wholly of integers, as it frequently happens in buisines, where pounds are accompanied with shillings and pence; yards with feet and inches; the method of procedure, if you multiply by a single digit, is the same as in simple numbers, only carry from one denomination to another, as the nature of each species requires. E. gr. to multiply 1231. 14s. 6d. 3s. by 5; say, 5 × 39 = 195. that is, 5d. 39. write down the 39, and proceed, saying 5 × 9 = 45d, that is, 5d. 45, to which add 5d. 50, and proceed the same manner through the rest.

If you multiply by two or more digits, the methods of procedure are as follow: suppose I have bought 37 ells of cloth at 13l. 16s. 6d. per ell, and would know the amount of the whole. I first multiply 37 ells by 13l. in the common method of multiplication by integers, leaving the two products without adding them; then multiply the same 37 ells by 16s, leaving, in the like manner, the two products without adding them. Lastly, I multiply the same 37 by the 6d. the product of which is 222d, which, divided by 12 (see Division), gives 18d. 6d., and this added to the products of the 16s., the sum will be 615d. 6d., the amount of 37 ells at 13l. 16s. 6d. the ell. Lastly, the 615d. 6d. are reduced into pounds by dividing them by 20 (see Reduction); upon adding the whole, the amount of 37 ells at 13l. 16s. 6d. will be found as is the following:

<table>
<thead>
<tr>
<th>37 ells</th>
<th>37 ells</th>
<th>37 ells</th>
</tr>
</thead>
<tbody>
<tr>
<td>At 13 pounds.</td>
<td>At 16 shillings.</td>
<td>At 6 pence.</td>
</tr>
<tr>
<td>111</td>
<td>222</td>
<td>222</td>
</tr>
<tr>
<td>37</td>
<td>37</td>
<td></td>
</tr>
<tr>
<td>390 10</td>
<td>18 6</td>
<td></td>
</tr>
</tbody>
</table>

Product | 511 10 6 |
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>610 6</td>
</tr>
</tbody>
</table>

Or thus: suppose the same question; reduce the 13l. 16s. into shillings, the amount will be 276s. reduce 276s. into pence, adding 6, the amount will be 3318d. Multiply the 37 ells by 3318, the amount will be 122760d., which divided by 12, and the quotient 102200d. reduced into pounds, by cutting off the left figure on the right, and taking half of those on the left, yields 5111. 10s. 6d. the price of the 37 ells, before.

Though by these two methods any multiplication of this kind may be effected, yet the operations being long, we shall add a third much shorter. Suppose the same question; multiply the price by the factors of the multiplicator, if resolvable into factors: if not, by those that come nearest it: adding the price for the odd one, or multiplying it by what the factors want of the multiplier. So the work will stand thus: 37 ells at 13l. 16s. 6d. × 6 × 5 = 36 + 1 = 37.

Therefore

<table>
<thead>
<tr>

<td>511 10 6</td>
</tr>
</tbody>
</table>

The price of 37 ells.

Big the most commodious is the fourth method, which is performed by aliquot and aliquant parts; where you are to observe by the way, that aliquot parts of any thing are those contained several times in it, and which divide without any remainder; and that aliquant parts are other parts of the same thing composed of several aliquot parts.

To multiply by aliquot parts, is, in effect, only to divide a number by 2, 3, 4, 5, &c. which is done by taking a 3d, 4th, 5th, &c. from the number to be multiplied. Example: To multiply, a. gr. by 6s. 8d. Suppose I have 347 ells of ribbon at 6s. 8d. per ell.

<table>
<thead>
<tr>
<th>Multiplyer</th>
<th>-</th>
<th>347 ells.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Multipli(1)</td>
<td>-</td>
<td>6s. 8d.</td>
</tr>
<tr>
<td>Product</td>
<td>115l. 13s. 4d.</td>
<td></td>
</tr>
</tbody>
</table>

The question being stated, take the multiplicator, which, according to the table of aliquot parts, is the third; and say the third of 3 is 1, let down 1; the third of 4 is 1, let down 1, remains 1, that is 1 ten, which added to 7 makes 17; the third of 17 is 5, remain 2 units, i.e. two-thirds, or 13s. 4d., which place after the pounds. Upon numbering the figures 1, 1, and 5, integers, and 13s. 4d. the aliquot part remaining, I find the sum 115l. 13s. 4d.

For Multiplication by aliquant Parts. Suppose I would multiply by the aliquant part 19. I first take for 10s. half the multiplicand; then for 5, which is the fourth, and half for 4, which is the fifth. The products of the three aliquant parts that compose the aliquant part, being added together, the sum will be the total product of the multiplication, as in the following example; which may serve as a model for multiplication by any aliquant part that may occur.
MULTIPLICATION, for the Proof of. The operation is right, when the product, divided by the multiplier, quotes the multiplicand; or divided by the multiplicand, quotes the multiplier. A reader way, though not absolutely to be depended on (see Addition), is thus: add up the figures of the factors, cutting out the nines; and letting down the remainder of each; these multiplied together, out of the factors cast away the nines, and let down the remainder: if this remainder agree with the remainder of the factors of the sum, after the nines are cast out, the work is right.

MULTIPLICATION, Crof, otherwise called Duodecimal Arithmetic, is an expidilion method of multiplying things of feveral fpecies, or denominations, by others likewise of different fpecies, &c. or, gr. hillings and pence by hillings and pence; feet and inches by feet and inches. This is much used in measuring, &c. The method is thus: Suppofe 5 feet 3 inches to be multiplied by 2 feet 4 inches: fay, 2 times 5 is 10 feet, and 2 times 3 is 6 inches; again, 4 times 5 is 20 inches, or 1 foot 8 inches; and, 4 times 3 is 12 parts, or 1 inch; the whole fum makes 12 feet 3 inches. In the fame manner you may manage hillings and pence, &c.

MULTIPLICATION, in Algebra. To multiply algebraic quantities, we mufl attend not only to the quantities themselves, but alfio to their figns.

The general rule for the figns is, that when the figns of the factors are like, (i.e. both + or both -), the fign of the product is +; but when the figns of the factors are unlike, the fign of the product is -.

Then, if the quantities to be multiplied be fimple quantities, find the fign of the product by the laft rule; after it place the product of the coefficients, and then fet down all the letters after one another, as in one word.

If the factors be compounded quantities, multiply every part of the multiplicand by all the parts of the multiplier taken one after another, and then collect all the products into one fum; which will be the product required. See Maclaurin's Algebra, part i. chap. 4, Saunderson's Algebra, vol. i. p. 57. and Barrow's Eucl. Schol. Prop. i. Elem. 2.

Example.

See Exponent.

MULTIPLICATION, in Geometry, or in lines, is efpeoted by fuppofing a line ab (Plate X. Geometry, fig. 6.), called the describer, moving perpendicularly along another be, called the dirigent.

For, by this means, the describer forms the rectangle abed; and if it be divided, together with the dirigent, into any number of equal parts, it will, by its motion, describe as many little rectangles as the units in the describer and dirigent will produce, when multiplied into one another, viz. 21. For when the line ab hath moved over one part of a, it will, by its three parts, have defcribed the three little rectangles in the firt column; when it comes to two, it will have defcribed three more: and this is the rea/on why multiplication, in the Latin tongue, is ually efpeoted by the word duxata, drawn: and from hence also comes produce, as if ab were multiplied by be, they lay ab duxata in be; because the describer is led, as it were, or carried along.
along in an exact posture upon the dirigent, and by that means describes the rectangle; so that the rectangle and product are the same in geometry.

Now, as in all multiplication unity is to one factor as the other to the product; multiplication in lines may be performed thus. Let \( ab \) (fig. 7) be to be multiplied by \( a \).

Make any angle at pleasure; on one of the legs let off \( a = \) to unity; and on the same leg let fall \( u \), the multiplicator \( \times \); then let the multiplicand \( ab \) (2) from \( a \) on the other leg of the angle; draw \( ab \) and parallel to it, through \( d \), draw \( de \) (6), I say, \( de \), or 6, is the product; for \( a = a \times b = ab \).

MULTIPLICATION of Plants, in Botany. See Fecundity and Plants.

MULTIPLICATIVES. See Numerals.

MULTIPLICATOR, a number multiplying another called the multiplicand.

The largest number is ordinarily made the multiplicand, and placed above the smaller, or multiplicator; but the result is the same, which fewer of the numbers be made multiplicand or multiplicator; 4 times 5, and 5 times 4, making the same sum.

MULTIPLIER, in Arithmetic, the number multiplying, or multiplicator.

MULTIPLYING, in the Ancient Economy, the producing of one's like.

Mankind multiplied at a prodigious rate before the flood. Rabbits, flies, and most insects multiply incredibly; the single milt of a cod, examined with M. Leewenhoek's microscope, was found to contain more ova than there are animals on the face of the earth. See Fecundity of Fish.

M. Dodart has several discourses on the multiplication of plants, in the Memoirs of the Royal Academy of Sciences. He has examined the beeche-tree, particularly, with this view, and found its increase to far surpass all imagination.

MULTIPLYING, in Arithmetic, is the finding a number which contains the multiplicand as often as there are units in the multiplier.

The rule of three consists in multiplying the third term by the second, and dividing the product by the first. See Rule of Three.

MULTIPLYING-Glases, a lens or glase, in which objects appear increased in number.

A multiplying-glase, called also a polyhedron, is a glase formed or ground into several planes, or faces, making angles with one another; through which the rays of light, issuing from the same point, undergo different refractions, so as to enter the eye from every surface in a different direction; as if they came from several points.

And thus the same point is seen in several imaginary foci; and therefore appears multiplied. For the phenomena and laws of multiplying-glasses, see POLYHEDRON.

MULTISILIQUÆ, in Botany, the twenty-sixth among the Natural Orders of Linnaeus, to termed because the fruit consists of several aggregate feed-veilus, which have the appearance of pods. It is divided into four sections, the first consisting of Pennia, Aquilegia, Aconitum, Delphinium, to which Linnaeus afterwards added Cimicifuga and Achta: the second composed of Distans, Ruta, and Peganum: the third of Nigella, Garidella, Ispidynum, Trollius, Helbescus, Calhia, Romoncula, Myrsinus, Adonis; and the last of Anemone, Arranc, Clematis, Thalictrum, and originally of Aicra. The second section contains the very distinct order of Rutaceæ, of which Linnaeus, and even Jullien, had very slight and imperfect knowledge as a natural affembly. These require to be removed from hence. The remainder agree in their acid qualities, and are kept together by Jullien, under the title of Rhamnaliaæ.

MULTITUDE, MULTITUDE, an affembly, or collection, of a great number of things, or persons. Multitude is properly the abstract whereby things are said to be many.

In which feme, multitude may be considered as number; and flands opposed to unity.

In law, some will have multitude to imply at least ten persons; but Sir Edward Coke says, he could never find it restrained, by the common law, to any certain number, but always left to the discretion of the judges.

MULTIVALVES, in Natural History, the name of a general class of shell-fish, distinguished from the univalves, which consist of only one shell, and the bivalves, which consist of two, by their confining of three or more shells. See Conchology.

MULTO, in Geography, a town of Hindooftan, in the circuit of Bickaneer; 16 miles W. of Bickaneer.

A Multo Portius, or minore ad majus, is a way of argumentation often used by Lyttleton; whose force is thus: if it be so in a feoment passing a new right; much more is it for the refutation of an ancient right.

MULTONES AURIS, in our Ancient Writers, an old coin of gold, having an Agmus Dei, sheep or lamb, on the one side, and from that impression called multones. This coin was most common in France, and sometimes current in England. Patent 33 Edw. I., cited by the learned Spelman.

MULTUM, in Arithmetic. If A be one, B one, C one, D one, &c. and B, C, and D, be not the fame with A; A, B, C, and D are mutua, or plural, many. Wolius.

MULTURA EPISCOPI. See Multa.

MULCHA, in Geography. See Mulloiaah.

MULUD, in the Materia Medica, a word used by Avicenna and Scarpion to express a sort of litharge, called by the Greeks molybdites, as seeming to partake of the nature of lead alone, not of gold or silver, or any other metal, as they thought the argentymes and chrysesites. This mulud, or molybdites, was the leafe in edem of all the kinds of litharge, and was of a dusky greyish-white colour. It seems to be the fame that Dioscorides means by pelia and polia, and sometimes by lithargyrus Silexas, from the place whence it was brought.

MULÜPGUNGE, in Geography, a town of Bengal; 23 miles S.E. of Dacca.

MULWAGGLE, a fort of Hindooftan, in Mysore; 22 miles E. of Colar.

MULYGUNGE, a fort of Hindooftan, in Bahar; 60 miles S.S.E. of Durbungah. N. lat. 25° 53'. E. long. 87° 13'.—Alfo, a town of Bengal; 20 miles N.N.W. of Purnaah.

MUM, a wholesome kind of malt liquor chiefly prepared in Germany. The process of making mum, as recorded in the house of Brunfick, the place of most note for this liquor, is as follows:

Take sixty-three gallons of water that has been boiled to the convovation of a third part; brew it with seven bushels of wheat malt, one bushel of oat malt, and one bushel of ground beans: when it is tanned, let not the hogshead be too full at first; and as soon as it begins to work, put into it of the inner rind of fir three pounds, tops of fir and birch each one pound, cardamum beans three handfuls, flowers of rose one handful or two: burnet, betony, marjoram, aven, pennyroyal, wild thyme, of each a handful and a half; of elder-flowers two hand-
fals, or more; seeds of cardamom bruised thirty ounces, barberries bruised one ounce: put the herbs and seeds into the vessel when the liquor has worked a while; and, after they are added, let the liquor work over the vessel as little as may be; then fill it up. Lastly, when it is flopped, put into the hoghead ten new-laid eggs unbroken or cracked, flop it up close, and drink it at two years end.

Our English brewers use cardamom, ginger, and sassafras, instead of the inner rind of sir; and add also walnut-rinds, madder, red faders, and elecampane.

**MUMBA CUM**, in Geography, a town of Hindoostan, in the Carnatic; 15 miles S. of Arcot.

**MUMBLE PO NK**, a rock in the Bristol channel, at the entrance into Swansea bay. N. lat. 51° 37'. W. long. 4° 5'.

**MUMBOLLE**, a town of Hindoostan, in the Carnatic; 20 miles S.W. of Nore.

**MUMBOS**, a country of Africa, N.W. of Mocaranga. The inhabitants of this country are a race of cannibals, who have been accustomed to devour their captives and slaves, and who, with the Zimbies and Jagas, have defecated a great part of southern Africa. The Jagas, of whose savage conduct we have given an account under that article, seem to have been the Tartars of central Africa, confilting chiefly of wandering tribes who range from the south of Abyssinia to the confines of Congo W. and of Mocaranga E.

**MUMMERS**, from Mummerie, Fr. or from the Teutonic, mummen, to mimic; or rather it is a corruption of mimers, from pantomime, antic diversions in the Chriftmas holidays, to get money or good cheer.

**MUMMY, Mumia**, a carcase, or body, embalmed or dried in the manner of the ancient Egyptians.

Menage, after Bochart, derives the word mummy from the Arabic mumia; of mum, wax; Salmius from anonym, a kind of perfume; though others hold, that, in the Arabic tongue, the word mumia signifies a body embalmed, or aromaticized.

Properly speaking, mummy is not the flesh of the deceased, but the composition with which it is embalmed; but, in common acceptance, mummy is also used for the body.

The preparation of mummy is of so old a standing, that it was in use in Egypt before the time of Moses. The coffin in which the mummy is contained was to be of sycamore wood, which is found to keep found for the space of 3000 years; but the tree, properly thus called, was very different from our sycamore.

Mummy is said to have been first brought into use in medicine by a Jewish physician, who wrote, that flesh thus embalmed was good for the cure of divers diseases, and particularly for bruises, to prevent the blood gathering and coagulating. The Turks prevent the exportation of mummy into Europe as much as possibile.

There are two kinds of bodies denominated mummies. The first are only carcases, dried by the heat of the sun, and by that means kept from putrefaction; these are frequently found in the dry sands of Lybia. Some say, they are the bodies of deceased people buried there on purpose, to keep them entire without embalming; others, that they are the carcases of travellers, &c. who have been overwhelmed with clouds of sand raised by the hurricanes frequent in those deserts. Be that as it will, these mummies are of no use in medicine, and are only preferred as curiosities.

Mummies of the second kind are bodies taken out of the pits or catacombs near Cairo, in which the Egyptians deposited their dead after embalming. These constitute the mummy once so much valued, and to which such extraordinary virtues are ascribed. See Embalming.

It is said, that all the mummy sold in the shops, whether brought from Venice or Lyons, or even directly from the Levant by Alexandria, is fictitious, and the work of certain Jews, who knowing the value the Europeans set on the Egyptian mummy, counterfeit it by drying carcases in ovens, after having prepared them with powder of myrrh, caralline aloes, Jews' pitch, black pitch, and other coarse or unwholesome drugs.

The French charlatans, it seems, had likewise got the art of preparing mummies. Their method was simple enough: out of the carcase of a person hanged, they take the brain and entrails, and dry the rest in an oven, steeping it in pitch and other drugs; and this they sell for right Egyptian mummy.

There have been found in Poland a kind of natural mummies, or human bodies, preferred without the alliance of art. These lie in considerable numbers in some of the vault caverns in that country. They are dried, with the flesh and skin shrunk up almost close to the bones, and are of a blackish colour. In the wars which several ages ago laid waste that country, it was common for parties of the weaker side to retire into these caves, where their enemies, if they found it out, suffocated them by burning flame, &c. at the mouth of the cavern, and then left the bodies; which, being out of the way of injuries from common accidents, have lain there ever since.

Paraus has a very curious treatise of mummies, in which he shews the abuses of them; and makes it appear, that they can never be of any real medicinal use.

Matthiolus is of the same opinion, after Serapion. Both these authors state the Egyptian mummies to be no more than bodies embalmed with pitch and asphaltum.

**Mummy, Mumia**, is more particularly used for the liquor or juice oozing from human bodies aromatized and embalmed, gathered in the sepultures. This is the mummy chiefly spoken of among the ancient writers.

**Mummy, Mumia, also denotes a medicinal drug, or a vicarious composition, partaking of bitumen and pitch, found in the mountains and forests of Arabia, and other hot countries in the East; much used in embalming of dead bodies.

Dioecides speaks of mummy found on the sea-coast near Epidaurus, brought thither by the torrents from the Ceraunian mountains, and thence dried by the sun into huge masses.

It smells like bitumen mixed with pitch. The people thereabouts call it mineral wax. In Latin, or rather Greek, it is called pitch asphaltum.

This substance is found in Khorasan, and in the deserts of Kerman, in Persia, and derives its name from the Persian word mum, signifying wax, gum, or ointment. It was formerly supposed to proceed from the human body; but, according to Chardin, it is a singular gum which dittles from rocks; and the mine of the precious mastic, as he calls it, are carefully sealed for the royal use. It is probably a kind of asphaltum; but seems to be a variety which has escaped the notice of mineralogists.

**Mummy, Mumia**, is also used, by some physicians, for a suppos'd implanted spirit, found chiefly in carcases, when the infus'd spirit is fled.

The infus'd spirit is sometimes also called mummy in living subjests, and both the one and the other are suppos'd to serve in transplantaion.

A plant,
MUN

A plant, for instance, bringing this mummia from one subject to another, the mummia joins and unites itself immediately with the mummia or spirit of the new subject; and from this union arises a natural and common inclination between the two subjects. And on this principle they account for sympathetic or magnetic cures. But this whole doctrine is now deferedly ridiculed and exploded.

MUMMIA is also used, among Gardeners, for a sort of wax used in the planting and grafting of trees. Agricola directs the preparation of it as follows: take one pound of common black pitch, and a quarter of a pound of common turpentine; put them together in an earthen pot, and let them on fire in the open air, having a cover ready to quench the mixture in time; the matter is to be thus alternately lighted and quenched, till all the nitrous and volatile parts be evaporated. To this a little common wax is to be added; and the composition is then to be set by for ufe.

To apply it in the dressing of roots of trees, melt it, and dip in the two ends of the pieces of root, one after another; then put them in water, and plant them in the earth, the small end downward, so that the larger may appear a little way out of the earth, and so may have the benefit of the air; then press the earth hard down upon them, that they may not receive too much wet. Miller.

MUMPS, in Medicine, the popular appellation of that form of quiny, which is accompanied with inflammation and swelling of the parotid glands. In Scotland the disease is called the braeks. See Cynanche parotica.

MUMRAH, in Geography, a town of Bengal; 38 miles N.N.W. of Midnapour.

MUNARI, Pellegrino da, in Biography, a painter who had the happiness to be scholar and assistant to Raphael, in executing the works for the chambers of the Vatican. His real name was Pellegrino Munari, but being born at Modena, he most literally bore the name of his native city. He possessed considerable talents, and, according to M. Fattori, resembled his master more than any of his contemporaries in the air of his head, and the graces of attitude; but he lived too short a time to have much to testify the truth of this assertion, dying at the early age of 35, in the year 1523.

MUNCA, in Geography, a town of Bengal; six miles S. of Cossimbazar.

MUNCER, Thomas, in Biography, a famous fanatic, was born at Zwickeaw, a town of Mittau, in Germany, probably towards the close of the fifteenth century. He was educated to the church, and became a disciple of Luther, whose tenets he propagated some time with great zeal and success in Thuringia. He connected himself with Nicholas Storck, a leader among the Baptists, who pretended to have communications with the Almighty, and to hold greater purity of doctrine than the rest of the party. Muncer was a convert to his notions, and became ardent in making pros-lytes. He maintained that for men to avoid vise, they must practice perpetual mortification. They must put on a grave countenance, speak but little, wear a plain garb, and be fermous in their whole deportment. Such as prepared their hearts in this manner, might expect that the Supreme Being would direct all their steps, and by visible signs disclose his will to them; if that he would be at any time with them, he says we may expostulate with the Almighty, and remind him of his promises. This expostulation will be acceptable to God, and will at last prevail on him to guide us with the same unerring hand which conducted the patriarchs of old. He also maintained, that all men were equal in the sight of God, and that, therefore, they ought to have all things in common, and should on no account exhibit any marks of subordination or pre-eminence. These notions, so flattering to the feelings of the masts of the people, spread rapidly among the peasants of Thuringia, and produced the most serious tumults and commotions in that and some other parts of Germany, which in the end brought on their own destruction, and that of their leader. This occurred about the year 1526. Moret. Robertson's Hist. of Charles V.

MUNCHENBERG, in Geography, a town of Germany; in the principality of Culmbach; six miles S. of Hof.

MUNCHENBERG, in Geography, a town of Brandenburg, in the Middle Mark; 19 miles W. of Cuderm. N. lat. 52° 30'. E. long. 14° 15'.

MUNCHHAUSEN, a town of Bavaria; 12 miles W. of Vilshoven.

MUNCK, John, in Biography, a celebrated Danish navigator, who flourished in the early part of the seventeenth century; on account of the discoveries of Hudson in 1610, Munck was ordered by his sovereign to pursue the same route, to determine if it were possible to proceed to India by a north-west passage. Two ships were equipped for this expedition, and in May 1610, Munck set sail from the Sound. He passed through Hudson's Strait, and discovered an island in latitude 60°. 26' north, to which, on account of the reindeer found on it, he gave the name of Deer Island. He also gave the name of Mare Novum to the sea that washes the coast of Labrador, and the appellation of Mare Christianum, or Christian's Sea, to the part adjacent to Greenland. In the latitude where he was, he met with so much ice, as rendered it impracticable for him to advance farther north; he therefore directed his course to Churchill's river, where he landed, and where he found the ice to be more than one hundred yards thick. Here he and his crew were attacked most severely with the scurvy, which was followed by a dysentery, and when he was a little recovered, he found only two men of his ships companies alive, though the crews of the two ships had amounted to sixty-four. Thse two, it may be easily imagined, were overjoyed to see their commander, and the three afforded to each other every affittance in their power. As soon as the ice dissolved, and their health was pretty well restored, they left the two vessels in the river, giving it the name of Munck's harbour, and set out in a small boat to return. Misfortune, however, seemed to follow them, they broke their rudder, and for a time lost their boat; but in ten days they recovered it, and after encountering a violent storm, which flattened their mast and carried away their sails, they reached a harbour in Norway, and in a few days after arrived at Copenhagen. After this, Munck was employed by his sovereign in the North seas, and in the Elbe, in the years 1623, 1625, and 1627. He died in the month of June 1628. Gen. Biog.

MUNDA, Munda, in Ancient Geography, a town of Spain, in the S.W. part of Britain, famous for a battle fought in its vicinity, between Caesar and the sons of Pomp.
pay, in the year of Rome 708, in which the former was victorious, and the latter lost 3000 men.

MUNDANAGOODY, in Geography, a town of Hindoo- 
lan, in Coloconda; six miles N. of Rachore.

MUNDANDIS Viro et Verellis. See Viro.

MUNDAPUM, in Geography, a town of Hindoo- 
lan, in Marawar; 16 miles E. of Ramanadapurum.

MUNDATORY, the cloth or napkin used in wiping 
the facerdal chalice.

MUNDE, in Geography, a town of Pomerelia, on the 
Frith Nerung; five miles N. of Dantzie.

MUNDELLA, a town of Hindoo- 
lan, in the country of Gurry Mundella; 40 miles S.E. of Gurrah. N. lat. 23 
45'. E. long. 75'.

MUNDELSVILLE, a town of America, in Shenan- 
dough county, Virginia; 114 miles from Washington.

MUNDEN, or GEMUNDEN, a town of Weftphalia, in 
the principality of Calenberg, at the confluence of the Wa- 
ra and the Fulda, containing two Lutheran churches, an 
elegant building for the worship of the Calvinits, an 
hospital, and barracks for a double garrison. The goods brought 
thither by land and water are sent down the Wefer, and other 
goods in return are brought thither by the same mode 
of conveyance. No foreigner or non-freeman of Munden 
is allowed to trade here, but is required to confine his goods to 
a factor of the town; 13 miles S.W. of Gottingen. N. lat. 
51° 20'. E. long. 9° 35'.

MUNDER, a town of Westphalia, in the principality 
of Calenberg, on the Hammel, near which is a salt-work. 
N. lat. 52° 11'. E. long. 9° 24'.

MUNDERAK, a province of Cadahar, in the northern 
part of Egypt.

MUNDERLINGEN, a town of Wirtemberg, ceded to 
it in 1805 by Austria, situated on the Danube; nine miles 
N. of Bachi. N. lat. 48° 14'. E. long. 9° 40'.

MUNDI ANIMA. See ANIMA.

MUNDIBURDUS. See ADVOCATE.

MUNDIC, a name for marcellate; a kind of mineral 
glebe, found in the tin-mines, and elsewhere; sometimes 
white, yellow, or green; and sometimes of a dark brown 
colour. It is of an arfenchil nature. See Geoffroy, in 
Mem. Acad. Scienc. 1738, p. 107. edit. Par. It is 
frequently called marx.

The mundic ore is easily distinguished by its glittering, 
and sometimes by its discolouring the fingers. Some say, 
it feeds the tin; and yet they allow, that where there is much 
mundic there is little or no tin.

What is called mundic in Cornwall, frequently contains 
a large portion of copper.

The flans of the mundic are very troublesome to the 
miners; yet it is found a good slue, and the miners 
use no other remedy for wounds, but washing them in water 
that runs from the mundic ore. See MARCELLATE.

MUNDIFICATIVES, or MUNDIFIERS, in Medicine, 
denote cleansers, purifiers, or detergents.

Mundificative plasters, or unguments, are such as deterge 
and dry, and thus cleanse ulcers of two kinds of matter, 
viz. pus and sanies.

The chief ingredients in mundificative unguments are, gen- 
tian, arillochosa, enula, campana, and the vulnerary herbs.

MUNDINUS, in Geography. See MUNDINO.

MUNDU, in Geography, a town of Hindoo- 
lan, in the country of Malwa, formerly its capital; 32 miles S.W. of 
Indore. N. lat. 22° 45'. E. long. 75° 40'.

MUNDUS PATENS, among the Romans, a solemnity per- 
fomed in a little temple of a round form; and dedicated 
to Dis, and the infernal gods.

Vol. XXIV.

It was opened only three times, in a year, viz. on the day 
after the Vernalia, the fourth of October, and the seventh 
of the ides of November, during which days the Roman 
believed that hell was open; and therefore they never offered 
battle on those days, killed no soldiers, never put to sea, no 
mixed.

MUNDY, JOHN, in Biography, in 1594, gentleman, ba- 
chelor of matricke, and one of the organists of his majesty’s 
free chapel of Windor, published Sange et libellum 
compendio a trio, four, and five parte, for the use and delight 
of all such as either love or frame Scholastic. There are 
dedicated to the unfortunate Earl of Essex, with all the 
quitting, publishing, and efforts at wit, which the table of the times 
courteous, and indeed incoherent.

MUNERARIUS. See DESIGNATOR.

MUNGALOVA, in Geography, a town of Ruffia, 
in the government of Irkutsk; at the union of the rivers Ona 
and Uda.

MUNGAN, a town of Hindoo- 
lan, in the circle of Bopal; 20 miles S.E. of Bopalto.

MUNGARVA, a town of Africa, in Nigeria. N. lat. 
11° 42'. E. long. 23° 45'.

MUNGAL, a town of Hindoo- 
lan, in Bahr; 33 miles S.W. of Patua.

MUNGALPET, a town of Hindoo- 
lan, in Myfore; five miles N. of Dalmachery.

MUNGLOGRE, a town of Cardahar; 25 miles W. of 
Cachemire. N. lat. 34° 15'. E. long. 71° 15'.

MUNGO, in Zoology, the name of an American animal, 
of the ferret kind, called by authors viverra indica griege- 
rufefens, or the reddish-grey Indian ferret. Some call it 
also mungathia. See VIVERRA.

MUNGRAR, in Geography, a town of Bengal; 12 
miles S.S.W. of Curruckpore.

MUNGULHAUT, a large manufacturing town of 
Hindoo- 
lan; 12 miles from Calamattiy, situated on the S. 
side of the river Durlah, which divides the district of Cooch 
Bihar from that of Rungpore. The inhabitants of this 
town pay a greater attention to the comfort and commodi- 
ficants of living, than those of any other town which 
captain Turner visited in India. Their houses, compos- 
ed of mats inserted between frames of bamboo, are neatly 
thatched, and each had a portion of land encircled with 
a bamboo palisade. The streets are spacious; and hosts of 
large burthen upon the river, added to the neatness and regu- 
larity of the town, give it an air of industry and traffic. 
The staple commodity consists of cotton cloths, which fur-
nish the most considerable part of the large returning cargo, 
which is carried by the Bootan caravan annually from Rung- 

MUNILAY, a county of Africa, dependent on Moca-
ranga.

MUNI, in Hindoo Mythological History, is a name applied 
on a variety of occasions, and with seeming confusion and 
contradiction. Mr. Colebrooke, the worthy successor of Sir 
William Jones in the chair of the Asiatic Society of Bengal, 
on the authority of the Purana, seems to identify the 
Rishi and Muni. He calls them "the virtuous sages, who 
delight in protecting the people; the mighty sages." Ay. 
Ref. vol. ix. p. 35°. (See RISHI.) Some authorities emu-
rate twenty of these personages, who are sometimes 
called "inspired writers." Sometimes they appear as an-
chors or declastics. "In the midst of a wild and dreary 
forest, flourishing with trees of sweet-scented flowers, and 
abounding in fruits and roots, infested with lions and tigers, 
delicate of human society, and frequented by the Munis, 
reigned Buddha, the author of happiness, and a portion of 
S. F. Narayana."
MUNI

Narayana.” This passage is from an inscription on a stone found in Bengal, translated by Dr. Wilkins. (A.F. Ref. vol. i.)  The appellation is sometimes given to Budha or Boodh, (see Boord,) who is called Budhi Muni. Both words seem to mean wisdom, more especially divine wisdom, or theology: and Muni may perhaps be traced to the fame root with Menu, to men or man, the mind. See Menu.

In that curious work of Anquetil du Perron, which he titles Upnepakht, (see Uppnished,) the following passage occurs, translated from one of the Puranas: “Brahm said, Rife up, O Rudra (or Siva), and form men to govern the world. Rudra immediately obeyed: he began the work; but the men he made were fiercer than tigers, having nothing but the destructive quality in their composition; and they soon destroyed one another; for anger was their only passion. Brahna, Vijnan, and Rudra, then joined their different powers and created ten men, whose names were Nareda, Dakha, Vajfhtta, Bright, Kritu, Pulaha, Pala, Angira, Attri, and Marichi; (that is, Reafon, Ingenuity, Emulation, Humility, Piety, Pride, Patience, Charity, Deceit, Morality;) the general name of whom is the Munis. Brahna then produced Dharma, or Julice, from his breath; Adherma, Injustice, from his back; Labha, Appetite or Paffion, from his lips; and Karma, Love or Deire, from his heart. The last was a beautiful female, and Brahna looked upon her with amorous emotions; but the Munis telling him that he was his own daughter, he thrunk back, and Lady, Shame, a blushing virgin (see Lady,) sprung from him. Brahna, deeming his body defiled by its emotions towards Kama, purified himfelf by partially changing it into ten females, who were respectively expelled by the Munis.” Farther notice of those personages whose names in the above quotation are distinguished by italics, will be found under those articles.

In the Gita (see Mahabarat), Rithra, amplifying himself by comparison with many pre-eminent perfons and things, or rather identifying himself therewith, says, “J am Muni Kapila among the Saints.” (See Capula.) It is said, however, that the philosopher just referred to is not the Kapila of the Gita. The Hindu books abound with stories of the potency of these devotees, under the names of Rithra, or Munis. On one occasion, Kapila having been rudely disturbed while at his devotion, “filled with excefsive anger, uttered from his nostrils a loud sound, and inantly by him, of immeasurable power, were all the sons of Sagara (60,000 in number) reduced to ashes.” This is from a long and extravgant, but poetical, story related in the first book of the Ramayana. On another occasion, as related in the Sanferit book, entitled Maha-kala-fanthis, Mahadvra, or Siva, who was rambling over the earth naked, chanced to pas near the spot where several Munis were performing their devotions: Mahadvra laughed at them, and insulted them in very provoking and indecent terms, enforcing his abuse by significat signs and galeries. The offended Munis cursed him; and the Linga or Phalits fell to the ground. (See Linga.) Mahadvra, in this state of mutation, travelled over the world bewailing his misfortune; his comfort, too, gave herself up to grief, and followed him in a state of distraction, flinging mournful songs. In this legend, Mr. Wilford (A.F. Ref. vol. iii. and iv.) finds the Greek story of the wanderings of Bacchus, and the lamentations of Demetur. It may be here noticed, that the names of Bacchus and Demetur, (or Dieter, having two mothers) may be recognized in Baghefa and Devimati, names of Siva and his reputed, many-mothered, for Karttika. (See Karttika.) In the article just referred to, it is noticed how the rejected son of Baghefa, or Siva, claims also a fiery parentage, through the instrumentality of Agni. (See Payaka.) Hence he is also called Agni-bhuva, and Agniya, born from fire: Pyrigenes is a Greek name of Bacchus, of a like derivation. These analogies are not confined to names, but extend to actions and attributes, in reference as well to the defiled personages immediately under discussion, as to many others common to Grecian, Egyptian, and Indian mythology. See Mythology of the Hindus.

MUNI NEN, in Geography, a town of Prussia, in the circle of Natangen; 36 miles S. of Königberg.

MUNIC, BERNARD CHRISTOPHER, Count, in Biography, a celebrated general, was born of a noble family in the county of Oldenburgh, in the year 1683. He was well educated, and so advantageously did he improve his time and his talents. that at the age of sixteen he had made such a progress in the sciences, and in the languages, that he was deemed qualified to undertake a tour in France, where he made great advances in many branches of learning, and applied himself particularly to engineering and fortification. By Lewis XIV. he was appointed an engineer in the French army, an office in which he did not long continue, on account of his unwillingness to serve against the empire; he accordingly returned to Germany, was made a captain, and, with his troops, was present at the siege of Landsau. After this he entered into the service of the prince of Hesse-Coffeld, and had an opportunity of improving himself in the art of war under the duke of Marlborough and prince Eugene. On account of his great bravery at the battle of Malplaquet, he was raised to the rank of lieutenant-colonel. At the battle of Denain, in 1712, he was dangerously wounded, and taken prisoner by the French, but being liberated the following year he was promoted to the command of a regiment. After this he was employed in high civil and military posts by Augustus II. king of Poland, and by the Russian Peter the Great. In 1723 he was entrusted with the construction of the famous canal of Ladaga, (see Canal;) which he completed with so much skill and alacrity, that the czar, as a mark of his satisfaction, admitted him a member of his council. The empress Catharine conferred on him the order of Alexander Newkit; in the year 1727 Peter II. made him commander-in-chief, and in 1728 raised him to the rank of count. Under the empress Anne, he, in the course of a few years, became president of the college of war, general field marshal, chief of the new corps of noble land cadets, and knight of the order of St. Andrew. He was appointed commander of the Russian troops in Poland, and reduced Dantzie: in 1735 he defeated the Tartars of the Crimea, and made himself master of some very strong towns, but with the heavy loss of 30,000 men: for this, though his enemies did all in their power to undermine his reputation, the emperors rewarded him with the grant of a considerable estate in the Ukraine. In the year 1737 he took Oczaczow by storm, and, after an almost uninterrupted series of victories, reduced Choczeim in 1739, and subjected the greater part of Moldavia to the Russian dominion. After the death of the empress Anne, his great ambition was to be appointed generalissimo of the naval and land forces, and being disappoited, he resiged his various employments. On the accession of Elizabeth he was arraigned, under the pretence that he had perfuaded the empress Anne to nominate Ivan as her successor, but the real cause of this step was, that by order of that empress he had taken into custody one of Elizabeth’s favourites, whose turn it now was to take revenge.

Munic was brought before a committee appointed to examine state prisoners, or rather appointed to execute the
MUNICH, in Geography, a city of Bavaria, seated on the Iler, the capital of the kingdom and royal residence. This place, on account of its straight and broad streets, and fine buildings, is reckoned one of the handsomest cities not only in Germany, but in Europe; and the number of its inhabitants is said to be 40,000. Its palace, erected by the emperor Maximilian I., is an elegant and spacious edifice; and the city abounds with a variety of curious antiquities. Munich has manufactures of velvet, silk, wool, and tapestry. It was taken by the French in 1796, who, according to their usual practice, levied upon the elector a considerable contribution; and in 1809 it was taken by them again; 29 miles S.E. of Augsburg. N. lat. 48°0'. E. long. 11°12'.

MUNICH, a town of South America, in the audience of Quito; 60 miles S. of St. Jago de la Laguna.

MUNICIPAL, Municipal, or Municipia, compounded of munus, office, and capio, I take, or hold, an appellation given to the inhabitants of the municipia, or municipal cities.

In the Roman law, municipal denotes a person vested with the rights and privileges of a Roman citizen.

This title the Romans frequently bestowed on foreign cities and people; and, in effect, it was little more than a title.

Municipal Cities, municipia, were those whose inhabitants were capable of civil offices in the city of Rome.

Thee, however, according to Mariana, came somewhat short of the privileges of the colonies. They were towns or cities, which had the citizenship of Rome bestowed upon them, and yet still lived according to their own laws and constitutions; whereas the colonies were governed by the Roman laws.

They had no suffrages, or votes, at Rome, but were left to be governed by their own laws and magistrates. It is true, some few municipal cities, by particular merit, &c., obtained the liberty of votes; which occasioned that received distinction of municipium sine suffragio, &c.

They were so called, because numeris his honorariis participes; but by munus honorarium was meant no more than the bare appellation of a Roman, whereby they were privileged to fight in a legion, as denizens; and not in auxiliary bands, as associates. The first who had this honour were the Curiites.

Municipal, among us, is now applied to the customary laws that obtain in any particular city or province, and which have no authority in the neighbouring places. See Law.

Municipal Officers, are those elected to defend the interests of cities, their rights and privileges, and to maintain order and good policy: as mayors, sheriffs, consuls, bailiffs, &c.

In Spain, the municipal offices are bought; in England, they are obtained by election.

MUNIE, in Geography, a town of Hindooftan, in the circau of Hifar; 15 miles N. of Hifar.

MUNILLA, a town of Spain, in Old Castile; 8 miles S. of Calahorra.

MUNIMENTS, or Miniments, the evidences, or writings, whereby a man is enabled to defend the title of his estate.

Wragford says, the word muniment includes all manner of evidence, deeds, charters, &c.
MONUMENT-House, a little strong apartment in cathedral and collegiate churches, castles, colleges, or the like, defined for keeping the seal, evidences, charters, &c. of such church, colleges, &c. called muniments, or minims.

MUNDINIANA, formed of the Latin munio. I defend or strengthen, the grants or charters of kings and princes to churches: so called, because cum sit munimentum against all those who would deprive them of those privileges.

MUNIONS, in Architecture. See MUNITIONS.

MUNITIONS, or Munitions, the pieces that divide the stern and quarter galleries in a ship.

MUNITION, or Ammunition, the provisions with which any place is furnished, in order for defence, or with which a vessel is flocked for a voyage: or those that follow a camp for its subsistence. See AMMUNITION.

MUNITION-Bread is the proportion of bread distributed every day to the soldiers of a garrison, or army. Each officer is allowed so many rations of munition-bread.

MUNITION-Ships, in the Navy, those which have stores on board, to supply the necessaries to a fleet of men of war at sea.

In the time of an engagement, all the munition-ships and victuallers attending the fleet are to take their places and proper stations in the rear of all the rest, and not engage in the fight, but attend such directions as shall be sent unto them, at all times, by the admiral.

MUNKATZKOE, in Geography, a town of Russia, in the government of Kolivan, on the Torn; 180 miles E. of Kolivan. N. lat. 54° 52'. E. long. 86° 50'.

MUNKHOLM, a town of Norway, in the province of Drontheim; 3 miles N. of Drontheim.

MUNKOES, a town of Hungary, the castle of which, located on a steep rock, and artificially fortified, is deemed impregnable. The town is situated on the river Latoritz, and it is the residence of a Greek bishop, united with the Roman church, and a convent of the Order of St. Basil; 52 miles E.S.E. of Cakau. N. lat. 43° 29'. E. long. 20° 14'.

MUNKROP, a town of Sweden, in Westermalm; 7 miles W. of Stocmsfholm.

MUNKY, a town of Hindooftan, in Canara; 7 miles from Uney.

MUNNERSTADT, a town of the duchy of Wurtzburg, on the Loew; 9 miles N. of Schweinfurt. N. lat. 50° 18'. E. long. 10° 24'.

MUNNY-SHELIER, in Natural History, a name given by the natives of the East Indies to a species of red ornament, which they have plentifully there. It is of a glowing colour, and has a great many shining spangles in it. They give this in fevers, after it has been calcined; it first melts in the fire, and then emits copious white fumes, smelling like thole of arsine. These are supposed to contain the poisonous parts of it, and it then becomes a safe internal medicine, and is given with great success.

MUNNYPOUR, or Munnypoora, in Geography, a town of Asia, capital of City; 264 miles N.N.E. of Arcan. N. lat. 24° 46'. E. long. 95°.

MUNNOCORY, a town of Hindooftan, in the Carnatic; 7 miles S.W. of Amnc.

MUNOZ, Jerome, in Biography, a Spanish mathematician, and oratorical scholar, was born at Valencia, but at what period we cannot tell. He flourished in the sixteenth century, and so fierce into fame in Italy, as a teacher of the Hebrew language at Aracna, where he was highly applauded on account of his intimate knowledge of the sacred tongue; nor was he less esteemed for his profound skill in the Greek language, polite literature, and the mathematical sciences. He was next invited to undertake the professorship of Hebrew and the mathematics, at the university of Salamanca, where he spent the remainder of his days: he was author of several works, of which the following are the principal: "Institutiones Arithmeticae ad perpensisam Alphatogam et Mathematicas Facultates necessarias;" "Alphabetum Hebrewicum cum ratione legendi cum punctis;" "Lectura Geographica." Moreri.

MUNRY, or Munree, in Geography, a river of Ireland, in the northern part of the county of Mayo, which runs into Tullagh bay, on the north of Achill island.

MUNSALU, a town of Sweden, in the government of Vasa; 15 miles S. of Jacobstad.

MUNSTOPETTA, a town of Hindooftan, in the Carnatic; 5 miles N. of Trichinopoly.

MUNSE, a town of Hindooftan, in the country of Vifapour; 27 miles N. of Poonah.

MUNCHOLM, a small island of Denmark, in the Great Belt; 10 miles N.N.W. of Corficer. N. lat. 55° 29'. E. long. 11° 6'.

MUNSSINGEN, a town of Wurtemberg; 26 miles S.S.E. of Stuttgart. N. lat. 48° 25'. E. long. 9° 33'.

MUNSTER, Sebastian, in Biography, a distinguished mathematician and linguist, was born at Ingelheim, in the Palatinate, in 1489, and after fulfilling some time the character of a Franciscan monk, quitted that order, and embraced the reformed religion. He became professor of the Hebrew language and theology at Heidelberg, whence he afterwards removed to Bafle to hold the like offices, where he died of the plague in 1552. He was one of the first among the German literati who attempted to improve the science of geography, and composed a book entitled Cofmographia Universa, which was printed in 1550, and translated into the Italian and other languages. A French edition was published at Paris in 1555, in two vols. folio, with corrections and additions. He was so celebrated as a geographer, and also for his knowledge in theology, that he was voted the Strabo and Edfors of Germany. He constructed a map of the territory of Bafle, and another of Germany, which was corrected and enlarged by Tilenam Stilla in 1567. Munder was likewise great as a mathematician and astronomer. Monteuca speaks of a treatise of geometry written by him, entitled "Rudimenta Mathematica," and he composed another on gnomonics, which the same author says is the foundation of the modern art of dialling. It was printed at Bafle, under the title of "Compositio Horologiorum." In addition to these works, another is mentioned, viz. "Organon Uranicum," in which the author gives a theory of the planets, with their various motions, for more than 100 years. As a linguist, the following works are mentioned: "A Latin Translation of the Hebrew Bible:" "Grammatica Hebrewica:" "Deb Hebrewica Chaldaica-Latinum:" "Calendarium Hebrewum:" "Grammatica Chaldaica:" "Tabule nove ad Geog. Ptolomaei," &c. Gen. Bing.

Munster, in Geography, a bithopric of Germany, bounded on the N. by Fredland and Oldenburgh, on the E. by the bishopric of Osnabruck, and counties of Dipholz, Tecklenburg, Lingen, and Ravenberg, on the S. by Welfphalia, the counties of Mark and Recklinghausen, and duchy of Cleves; and on the W. by Holland, and the county of Beacham. The country is level, having only a few eminences, but no mountains. Its climate, which are extensive, serve for the breeding of cattle. It has fruitful plains, fine woods and turf, with good quarries of stone. Its rivers are abounding...
bound with linen. Of these the most remarkable are the Emb's, the Liffe, the Vecht, and the Berkel. Between the biphoric and the county of Delfzole lies the "Dun-
water" lakes, one German mile long, and half a league broad. At the commencement of the reformation, the Lutheran doctrine was received by many persons in this biphoric; but it was afterwards suppressed. In 1582, the biphoric was secularized, and given to the king of Prussia, but at the peace of Tilsit it was ceded to the kingdom of Westphalia.

Munster, the capital of the above-mentioned biphoric, is situated in a fruitful and agreeable spot, on the river As, not far from the Emb's. It was in the eleventh century that it obtained the name of Munster, from the collegiate church founded by Charlemagne. It is environed by double ditches and ramparts, and contains a citadel, called the "Brille." Among other churches is that of St. Lambert, on the tower of which were suspended, in iron baskets, John of Leyden, leader or king of the Anabaptists, and also both his princes. This city, which has undergone, in a succession of years, various calamities, is famous for a treaty of general peace, settled in the year 1658; and sometimes called the treaty of Munster, and also the treaty of Westphalia, beca-

Obf. Gartner says that the berry has frequently more than five cells.

Eff. Ch. Corolla of five petals. Calyx deeply five-cleft. Berry with five or more cells, each containing many seeds.

1. M. Calabura. Villoff. Muntingia. Linn. Sp. P. 728. Plum. Ic. t. 205. Jacq. Amer. t. 107. (Calabura alba; Plunk. Phyt. t. 152. f. 4).-Loti arbrosis folio angulior, rubi flore, fructu polyspermo umbilicato; Sloane Jans. v. 2. 82. t. 194.—Swartz says that it is a native of calcareous hills in Jamaica, flowering in the spring. According to Jacquin, however, who reports that it is common in the damp woods of St. Domingo, it flowers in the autumn. This tree generally rises to the height of ten or fifteen feet, and, according to Sloane, even to thirty. The trunk is much branched, and covered with a smooth, dark purple bark. Branches irregular, spreading, long, hairy. Leaves alternate, on short hairy stalks, ovato-lanceolate, pointed, rather unequally serrated, flat, spreading, green and hairy above, hoary and vilte beneath. Four or five inches long, unequal at the base. Stipulas solitary, thread-shaped, furnished with glandular hairs like the leaves. Stalks two to four, clustered, single-flowered. Jacquin remarks that they successively turn the flower, when it is about to expand, to the face of the leaf, which before was reflexed to the back. Flowers without scent, but handsome, resembling those of the bramble. Berry rose-coloured, with a tinge of yellow; when cut in a transverse section, it seems to be one-celled, but if the pulp and seeds be gently pressed out in water, it appears very clearly to be five-celled. Seeds white, or pale straw-coloured. Sloane says the fruit is as big as a cherry, and Miller, that it is as large as that of the cockspur Hawthorn; of a dark purple colour when ripe.

Linnæus, in his Syll. Veg. ed. 14. 490, has very unaccountably quoted Mallum tullum, Rech. Hort. Mak. v. 4. t. 49, as a synonym of M. Calabura, with which indeed it has nothing in common, except a slight resemblance in the leaves.

MUNTISSUR, in Geography, a town of Bengal; 20 miles N.E. of Burdwan.

MUNYCHIA, Monegguna, in Antiquity, an annversary feast.

MUNYCHON, Monegguna, in Chronology, the tenth month of the Athenian year. It contained twenty-nine days, and answered to the latter part of our March and beginning of April. See Month.

It had its name from the festival Munychia, kept in it.

MUNZENBERG, in Geography, a town of Germany, in the county of Hanau Munzenberg; 19 miles S.E. of Wetzlar.

MUODGUR, a town of Hindoostan, in the cirque of Ciescole: 18 miles N.N.W. of Ganjam.

MUONIO, a river which rises in the mountains of Nor.-way, and passing southerly through Swedish Lapland, joins the Torney in N. lat. 67° 12′.

MUPHTI, Mufti, or Shaki-islam, the chief or patron of the Mahometan religion, residing at Constantinople.

The mufti is the sovereign interpreter of the Alcoran, and decides all questions of the law; his decisions are called "fatess." The sultan has recourse to him in all difficult and intricate cases, and he pronounces no law, no makes no declaration of war, nor establishes any impost, without having obtained a fette.

He takes place of the baihaws; and his authority is often terrible to the grand signior himself. It is he who girds on the sword to the grand signior's side on his accession to the throne, which ceremony answers to the coronation of our kings; reminding him at the same time of the obligation of defending the religion of the prophet, and of propagating his creed.

This eminent place might serve, without doubt, as a counterpoise to the almost absolute and unlimited authority of the sovereign: it might even frequently paralyse it, if the sultan had not the power of appointing the mufti, of deposing him, of banishing him, and even of putting him to death after having deposed him; and, indeed, it seldom happens that a mufti opposes the will of the sultan and his ministers. His fettas are forced from him by the will of preferring his place, and by the fear of death; nevertheless, more than once, religious zeal and probity have induced some to prefer themselves to the sultan, and to make to him observations and remonstrances; some even, more fanatic and more courageous, braving every danger, have refused to condescend to his wishes. History affords various examples of sultans and vizirs killed or depose'd through the great influence of the muftis on public opinion: but it likewise presents more muftis who have been victims of their zeal for religion, and of their attachment to the interests of the people. The mufti is much respected by the sultan, and also by the people, who submit blindly to his fettas.

According to the established order the mufti must be chosen from among the kadiilekers of Romania, and those who have occupied that employment; and he remains in place as long as it pleases the sultan to keep him there. In public ceremonies the mufti and the grand vizir are in the same line; the grand vizir on the right, and the mufti on the left. When the latter is disgraced, he is not permitted to remain in the capital. The sultan fears the influence of a man whom the people are accustomed to regard as the oracle of religion. He is banished to some island of the Archipelago, or to some house situated on the Bosphorus, with a prohibition not to stir out of it, to receive any of the principal officers of the empire, or to correspond with them. For an account of the kadiilekers, or cadiilechers, see CAIDELECHER, and of the flambol-effendi, see STAMBOLEFFENDI.

MUK, in Geography, a town of France, in the department of the Northern Coasts, and chief place of a canton, in the district of Loundac; 9 miles W. of it. The place contains 2096, and the canton 528 inhabitants, on a territory of 130 kilometres, in 5 communes.

MUR-de-Barres, a town of France, in the department of the Aveyron, and chief place of a canton, in the district of Espalion; 30 miles N.E. of Rhodes. The place contains 951, and the canton 7421 inhabitants, on a territory of 187½ kilometres, in 19 communes. N. lat. 44° 54′; E. long. 2° 44′. 8
MUR

MURA, a river of Russia, which runs into the Tunguska, nearly opposite to Mureka.

Mura, a town of Sicily, in the valley of Noto; 15 miles S. of Modica.

MURABA, in Biography, a Brahman of the city of Poona, the capital of the Maharatta empire, in whose person and descendants is exhibited an extraordinaryinstance of priestcraft and superlition. He was the sect of Guffain, or more correctly Golfwami; and is reported to have been so pious that the god Ganea rewarded him by incarnating himself in his person, and covenanting that the divinity should descend to his children to the seventh generation: empowering the incumbent to work miracles, and, in a limited degree, to look into futurity. With this divine panunity is inherited the guardianship of a sacred stone, a type of the Deity. In the year 1800, the venerated incumbent was visited by lord George Beresford, field-marshal Beresford, and Mr. Moor, the author of the Hindu Pantheon. The latter furnished a detailed account of this person, family, and visit, to the Asiatic Society, which is published, art. xiv. in the 7th volume of their Transactions, under the title of "Account of an hereditary living deity, to whom devotion is paid by the Brahmanas of Poona, and its neighbourhood." The incarnation is represented to have taken place about the year 1426, and at the period of the above visit five generations had paffed away. Gabaji Deva, that is, the Lord, or Divine Gabaji, was the then incumbent. He has since died, and it is agreed by the Brahmanas, that the avatar, or manifestation (see Maya), will end with the life of the next inspired portion of carntinity, unless perpetuated or renewed by a farther miraculous intervention of the divine will. Great respect, indeed adoration, is paid by the Pethwa, (see Passiwa,) and of course all other Brahmanas of Poona, to this fancified inheritor of the gift of prophecy, as related at length, with many other particulars of grofs superstition, in the article above referred to.

Lord Valmilia has more recently visited this venerated personage, who refides in the abode of his ancestors at the town of Bhichunur, about a dozen miles from Poona; and has given the particulars of his visit in the second volume of his Travels, p. 156; together with some respecting the family and person of the Deo (or Lord,) differing from the information received by the preceding author.

The Hindoo deity Ganea, thus incarnated, is the god of prudence and policy: he is otherwise called Pollear, under which article some notice of him will be found.

MURACH, in Geography, a town with a castle of Bavaria, in the Upper Palatinate; 7 miles E. of Nabant. MURÈNA, the Eel, in Ichthyology, a genus of fishes of the order Apodes, of which the generic character is; head smooth; nostrils tubular; gill-membrane with ten rays; eyes covered with a common skin; body round, smooth, mucous; caudal, dorsal, and anal fins united; spiral behind the head or pectoral fins.

This genus seems to make a very near approach to the reptile class; for in the eel, as in reptiles, the body is long, slender, and flexible; and excepting the small pair of pectoral fins, it may be said to be without fins, inasmuch as the dorsal, anal, and tail fins are united in one web, which surrounds a large portion of the body. The apertures of the gills are small, and placed behind the pectoral fins. The eel differs from almost all other fish of that order in the mode of generation, and flaps at the top of it in almost all classifications. It is viviparous, and is impregnated in the same manner as obtains among the cartilaginous tribes. The ancients entertained very extravagant ideas respecting the generation of these animals: some of them affirmed that in the eel tribe there were neither male nor female, hence it was inferred that they sprang from the mud, or that the incrustation scraped from their bodies received animation. This opinion was rashly adopted from having observed that they were generated in pools, from which all the mud and water had been some time drawn off. This was a phenomenon, for which they could not account otherwise than by admitting the spontaneous generation of eels; but later and more accurate observations have shown, that ponds are frequently supplied with these fish, in the same manner that vegetation is spread, by transporting the seeds of plants. It has been thought that the heron and other water fowl may drop the eel, when carrying it to its young, or if swallowed by them alive and uninjured, the digestive faculties having no power over them, may be ejected from its stomarch, as the seeds of plants are voided by land animals, without being in the least degree affected by the process. In their habituation, the fishes of this genus are still more singular, than in the mode of propagating their young. They can refuse either in fat water or in fresh, and what is still more surprising, they are, in some measure, independent of either; for they have been known not unfrequently to leave their native element, and wander, during the night, along the moist meadows, not only for an exchange of habitation, but, it is believed, in quest of prey. Of these nightly excursions, the snail and the slug are the victims, being devoured by eels as they pass along. In the water no animal is more vivacious than the eel, and even when taken from its natural element it clings to life most tenaciously: it will survive blows that would deprive animals ten times its size of life in an instant: after it is skinned, and even cut to pieces, it exhibits signs of life some time. It is, however, easily affected, and destroyed by cold, of which it is so well aware, that to avoid its effects, it beds itself deep in the mud, and continues in a torpid state during the winter. Though fond of hiding themselves in the mud to answer their own purposes, they are said to be incapable of living long in thick turbid water; and hence, when a river is disturbed by land floods, they are frequently suffocated by the impurity of the stream. This genus includes nine species according to Gmelin, but Dr. Shaw describes eleven, of which the following is an account.

Species.

HELENA, or Romana; the Roman Eel. No pectoral fins; the body is variegated; there is a variety spotted with black and green. This fish, the celebrated favourite of the ancient Romans, is found in great plenty about the coasts of the Mediterranean. Its colour is a dusky greenish-brown, thickly variegated on all sides with dull yellow marks or patches; the head is rather small; the mouth moderately wide, and the teeth flat; the dorsal and caudal fins, which are hollowed, and covered by the common skin, are united, in the same manner as in the eel, and are of a dusky colour with whitish spots. The ancients, who kept it in referrers appropriated for the purpose, are said to have tamed it to such a degree, as to come at a call to receive its food. It inhabits other European seas besides the Mediterranean, and some American seas; it is exceedingly voracious, and bites dangerously. See Gymnotorhax.

COLEBRINA; Snake Eel. No pectoral fins; body alternately annulate, with yellow and black bands; a variety of this species is distinguished by brown irides with black spots. This is a native of the Indian seas, particularly about the coast of Ambon: it is about two feet long; the colour is pale or yellowish-white; marked throughout by
by numerous equidistant width bands of black or brown, passing through the fins; the body, when examined with magnifiers, is found to be covered with very small scales; the snout is sharp-pointed, and the eyes are very small.

*Muraena; Specled Eel.* Body blackish, thickly spotted with white: it is about two feet long, of a deep brown colour, thickly b-fret on all parts with almost innumerable small white round spots, which are less regular, or more confluent on the head and breast than elsewhere. The eyes of this species are small; the mouth is wide; and the teeth sharp and numerous. It is a native of the southern ocean.

*Ophius; Spotted Sea-Serpent.* Body flesser, spotted; tail round, fpear-shaped. naked. This species grows to the length of between three and four feet; it is found in European seas; the body is small in proportion to its length; the mouth is large; teeth pointing inwards; back spotted with white; belly and fins white.

*Serpens; Serpent Eel.* Tail naked, pointed; body round. It inhabits the southern European seas; the pectoral fins with about twenty-six rays.

*Anguilla; Common Eel.* In this species the lower jaw is the longer; and the body is of one colour. In muddy waters it is black, beneath yellowish; in gravelly, clear waters, it is green or brownish; beneath silvery, sometimes variegated with brown lines; the head is small, and narrowed on the fore-part; the mouth is large; beneath the eye is a small orifice, and at the end of the nose two others, small and tubular; the teeth are small, sharp, and numerous; the eyes are small, near the end of the nose; aperture of the gills seminlar; body a little compressed; lateral line straight, dotted with white; skin covered with soft oblong scales; the pectoral fins are small, round, paler, with about nineteen rays, dorsal, caudal, and anal fins united, frequently edged with white. It is found almost everywhere in fresh waters, grows sometimes to the length of fix feet, and has been known to weigh as much as twenty pounds: in appearance and habits it resembles the serpent tribe; during the night it wanders into meadows in search of minnows and worms, buries itself deep in the mud in winter, and continues in a state of repose: it is impatient of cold, and tenacious of life: the flesh of those that live in running streams is very good: it is viviparous, producing the young during the decline of summer, which at that time exudes are very small. In some parts of Europe the eel-herb is of surprising magnitude. Dr. Bloch says, that in some places near the mouths of the Baltic, so great a quantity is taken, that they are salted for exportation, and conveyed by waggonloads into Saxony, Silesia, &c. Two thousand have been taken in Finland at a single sweep of the net: and in the Garonne 60,000 are said to have been taken in a day by a single net.

*Mylus; Flat-tailed Sea-Serpent.* Fin surrounding the lower part of the body white, edged with black; a variety of this species is entirely cieausous. It is found in European seas; the head is narrowed on the for-part; two short tentacula on the upper lip; back dark olive spotted with white; body compressed. The second variety has been suspected of being poisonous.

*Conger; Conger Eel.* Lower-jaw rather shorter than the upper; nose with two tentacula; lateral line whitish, with a row of spots. It is found in European seas and rivers; is extremely voracious, feeding on other fish, crabs in their soft state, and particularly on eel-cases, grows as long as from four to ten feet; some specimens, we are assured, have been found to weigh a hundred pounds. A fishery of congers, at Mount's-bay in Cornwall, forms a considerable article of commerce. They are annually exported, in a dried state, to Spain and Portugal, whereas being reduced to powder, they are used for enriching soups.

*Gutta; Spotted Muraena.* Glauceous speckled with black, with a larger spot each side near the head. It is found in the Arabian seas; it has a callus between the eyes, gold-coloured irides; the upper lip is shorter than the lower, and the dorsal and anal fins are united at the tail.

Such are the species described by Gmelin in the *Muraena* genus; some later naturalists have given a distinct genus, called the *Anguilla*, including with the common eel, the conger, the ophius, the serpents, and the mytus. These perons give in the *Muraena* genus the following species, viz. the catena; reticularia; africana; zebra; and echinidae, which have been deferred under the word Gymnotheria.

*Muraena* is used by Albertus for the common small lamp, the *lampetra parva fluviatilis* of authors. This is one of the petromyzata of Ascidia, and is distinguished by the having only one row of very small teeth in the verge of the mouth, besides the larger lower ones.

*Murage, Muraglem, in our Cyloma, a reasonable toll to be taken of every cart or horse coming taken into a city or town, for the building or repairing the walls thereof.*

*Muraajama, in Geography, a town of Japan, on the W. coast of Niphon; 60 miles S. of Achita.*

*Murakwa, a town of Poland, in the palatinate of Prussia; 28 miles W. of Brelaw.*

*Mural, something belonging to a wall; which the Latins call muros.*

*Mural Crown, among the ancient Romans, see Crowns. Mural Arch is a wall, or walled arch, placed exactly in the plane of the meridian, i.e. upon the meridian line, for the fixing of a large quadrant, sextant, or other instrument, to observe the meridian altitudes, &c. of the heavenly bodies.*

Tycho Brahe was the first who used a mural arch in his observations; after him Hevelius, Mr. Flamsteed, De la Hire, &c. used the same means. See a description of the mural arch at Greenwich, constructed by Mr. Graham, in Smith's Opticks, book iii. c. 7: with the improvements of Mr. Bird, in the Method of constructing Mural Quadrants, published by the commissioners of longitude, 1768: and for that of Mr. Troughton, see Quadrant.

*Murallt, John, in Biography, an intelligent and industrious physician, was a native of Zurich, and defended from an ancient family in that city. He commenced his studies at Montpellier, and afterwards went to Leyden and to Paris, in which capital he attended chiefly to midwifery and anatomy, under the tuition of Mauriceau and Guyanet. On his return to Zurich, he practised all the branches of the healing art; and also gave lectures in natural philosophy, anatomy, and surgery. He was instrumental in establishing an anatomical theatre in this city, and frequently gave demonstrations, by dissection, both in human and comparative anatomy. He acquired a general reputation and esteem among his fellow citizens, and died much regretted in 1750. He was author of a considerable number of papers, printed in the Acta Academica Naturae Curiosorium, of which several he was admitted a member, under the name of Artetus. These memoirs relate principally to comparative anatomy. He likewise published the following works, "Vade mecum Anatomicum, five, Clevel Medicinis," Tit. 1677; which was reprinted in Amsterdam, in 1688, under the title of "Exerci-
MURATORI, Lodovico Antonio, in Biography, a learned Italian writer, was born at Vignola, in the duchy of Modena, in the year 1671. He was observed, even in his infancy, to have a passion for reading, which was inbred from perusing the romances of Madame Scudery, which by accident, at that early period, fell in his way. At the age of 13 he was sent to the Jesuits' school at Modena, where he daily stole from his sleep several hours to allot to his studies, and from this time to his death he refrained himself to seven hours sleep out of the 24. At his own desire he was devoted to the service of the church, and received the tonsure from the bishop of Modena in his 16th year. Having completed his course at school, he entered upon the studies of the university, and cultivated with great eagerness polite literature and poetry; and in a short time afterwards made great proficiency in the study of the Greek. In 1695 he was appointed one of the preceptors of the Ambrosian library at Milan, having previously received the degree of doctor of laws at Modena. He was soon after ordained priest, and, in a manner, flint himself up amidst the treasures of that celebrated repository. His researches enabled him to make those collections of curious literature, which he afterwards gave the world under the titles of "Anecdota Latina," and "Anecdota Graeca." At this time he began to make a collection of inedited inscriptions, and other remains of antiquity; and for the purpose of promoting philosophy and letters, he procured the institution of an academy in the Borromean palace. While thus employed, he was called by the duke of Modena to return thither, and take the office of keeper of the archives of the house of Este, to which, at his own desire, was added the office of ducal librarian. He returned in the year 1700, and in two years his labours were interrupted by the wars in Italy, and it was thought necessary to remove the archives to a safer place on the approach of the French, who soon made themselves masters of Modena. They treated Muratori with respect, and offered him the office of royal librarian, which he refused. In 1714, 15, and 16, he took several journeys into Italy for the purpose of collecting new materials for memoirs of the house of Este, and that of Brunswick, which derives its origin from it. In this business he was engaged as well by king George I. of Great Britain, who furnished him with letters of recommendation, as by the dukes of Modena. On his return he received the benediction of the church of St. Maria Pompofa, in Modena, and in the discharge of the duties attached to this office, he conducted himself so as to afford a model for parochial priests, in acts of kindness and charity to all those who were the objects of them. He instituted a society for the protection of the widow, the orphan, and the delinquent, and at his death bequeathed a large sum for its support. So benevolent was he on every occasion which he thought demanded pecuniary aid, that it was found after his death he had given away to the poor, and expended upon his churches much more than he had received from all his benefices conjointly. These offices of duty and kindness naturally attached him to the place of his residence, and no offers, however splendid, of which he had many, could tempt him to quit Modena, where he lived in high esteem. Of his labours in the cause of literature we have the testimony of Gibbon, who acknowledges Muratori to have been "his guide and master in the history of Italy."—"Its country, and not the public," says the historian, "are indebted to him for the following works on that subject: 1. Rerum Italicarum Scriptores (A. D. 500-1500) quorum textus pars uniprimum in hacce prorsis, &c. 28 vols. in folio, Milan, 1723-1751. A volume of chronos optical and alphabetical tables is still wanting as a key to this great work, which is yet in a disorderly and defective state. 2. Antiquitates Italiae medii Aevi, 6 vols. in folio, Milan, 1738-1743, in 75 curious disquisitions on the manners, government, religion, &c. of the Italians of the darker ages, with a supplement of charters, chronicles, &c. 3. Differtationes sopra le Antiquita Italiane, 3 vols. in 4to. Milano, 1751, a free version by the author, which may be quoted with the same confidence as the Latin text of the Antiquities. 4. Annali d'Italia, 18 vols. in octavo, Milan, 1753-1756, a dry, though accurate and useful abridgment of the history of Italy, from the birth of Chiril to the middle of the eighteenth century. 5. Dell' Antichita Ensefica et Italiane, 2 vols. in folio, Modena, 1717-1740. In the history of this illustrious race, the parent of our Brunswick kings, the critic is not seduced by the loyalty or gratitude of the falsified. In all his works, Muratori approves himself a diligent and laborious writer, who aspires above the prejudices of a Catholic priest." It was an early idea of our author to inculcate a literary republic in Italy, which should affect all the men of letters into one body; for this purpose, he wrote various addresses to the public, under the fictitious name of Lamindo Pritianio, in which he proposed his plan, and pointed out the advantages that would probably result from such an institution. The subject was amply discussed, but the idea was never realized. In 1706 he published a work, entitled "Della perfetta Poesia Italiana," in two volumes, which gave rise to a considerable controversy, as might be expected, in a country in which different poets of high
high celebrity had formed different schools of admirers, pupils, and imitators. In 1725 Muratori wrote a treatise on "Moral Philosoply," which was several times reprinted. It was followed by a treatise on the powers of the human mind, intended as an answer to Huett's tract on the weaknesses of the human mind. He carried his enquiries into medical subjects, and on the appearance of a pestilential disorder in Germany in 1713, he published a work, entitled "Governo della Peste," in which he treated on the office of the magistrates, the physician, and the divine, during the awful visitation of the plague. To a new edition of this work in 1721 was added a relation of the plague of Marfinelles. In 1742 he published a curious work, "Dei Difetti della Giurisprudenza," which was conciliated with his pursuits in history and antiquities, and there were the objects of his favourite studies. As a theologian he raised a formidable storm against himself in controversial divinity, the ground of which was the immaculate conception of the Virgin Mary. He endeavoured to moderate the zeal of the combatants, and in so doing he acquired the reputation of a heretic, and found it necessary to write an epitite in his own vindication to Benedicf XIV. Muratori was author of another celebrated but obnoxious work, entitled "Della Regolata Divozione dei Chirillani," printed in 1747, under the signed name of Lamando Pritamini. In this he went as far as he durst in avowing himself hostile to vulgar superstition, and on that account made himself many enemies. Muratori was author of many other works besides those that have been mentioned above, particularly of lives of eminent persons, as of Petrarca, Paolo Segneri, &c. and of various dissertations on antiquarian subjects. His reputation as a writer extended throughout Europe, and he was, by means of a good constitution and excellent health, enabled to continue his various labours till a very advanced period of life. He died in January 1750, in the seventh eight year of his age, and various tributes of high respect were paid to his memory, by persons of all parts of different countries. Gibbon.

Gen. Biao.

MURAWA, in Geography, a town of Hindoostan, in Babar; 36 miles S.W. of 42 rah.

MURCA de Fuxova, a town of Portugal, in the province of Tras los Montes; 12 miles S.S.W. of Mirandela.

MURCH, a town of Hindoostan, in Bundelcund; 45 miles N. of Callinger.

MURCHA, a town of Bengal; eleven miles N.E. of Morshedabad.

MURCHAPOUR, a town of Hindoostan, in the circuit of Elichpaur; 20 miles N.E. of Akowla.

MURCIA, in Botany, (or Murcia, for it is printed both ways within two pages of each other,) a name proposed by Linnaeus, for several species of Myrtus, in his Flora Zeylanica, p. 81-83, which he suspected might constitute an intermediate genus between Myrtus and Caryophyllus; but he has indicated no sufficient character to distinguish it, nor has he, or any one subsequently established this proposed genus. See Myrrh.

Murcia, in Geography, one of the smallest provinces of Spain, though called a kingdom, is about 36 leagues from the N.W. to the S.E., and 20 from the S.W. to the N.E., and is bounded by the kingdom of Valencia on the E., La Mancha and New Cadiz on the N. and W., the kingdom of Segovia on the W., that of Granada on the W. and S., and the Mediterranean Sea on the E. and S.E. It is a dry, hilly country, almost covered with mountains of various elevations, which are separated in some parts by dry parched up valleys, and elsewhere by others of more than common beauty and fertility. It contains a bishopric, a cathedral chapter, a collegiate chapter, six commanderies of military orders, ninety-one convents, twelve hospitals, two asylums, three colleges for the education of youth, two military government, one of the three grand departments of the royal navy, an intendancy of the province, an intendancy of the navy, six cities, sixty-four towns, seven villages, and some hamlets. It has two ports in the Mediterranean, the smallest being that of Las Aguilas, and the other the largest and most important in the whole of Spain, which is Cartagena. Its principal towns, besides Murcia, the capital and episcopal see, are Cartagena, a fortified town and formerly an episcopal see, Lorca, Chinchilla, Albacete, Villena, and Calasparra. This province is watered by two streams, the Benamor and the Guardavasar, and by two rivers, the Segura and the Guadalentia. The most remarkable of its mountains, which are branches of the Montes-Orospedani, are the Sierra de Pinao, Pinoa, Loftsillas to the W., that of Chinchilla to the N.W., those of Montes Agudo, Covatellas, and Orihuela to the E., the Sierra of Almanza to the N., that of El Cane to the S., of Esfena to the S.W., and of Caraceo to the S.E.

The kingdom of Murcia was the first part of Spain that was occupied by the Carthaginians, who formed in it their first colony, and built a town, the foundation of which is ascribed to Arodrubal, A. U. C. 592; and it is now called Cartagena; which see. This country was afterwards wrested from the Carthaginians by the Romans, of whose possession there remains the evidence of a military road, called by the people of the country the road of Hercules. Being afterwards taken from the Romans by the Goths, this country formed a part of the monarchy which the latter established in Spain; but it was laid waste by the Vandals, and afterwards completely destroyed Cartagena, which was afterwards rebuilt on account of its harbour. By the revolution which happened in 552, the maritime part of the kingdom of Murcia fell under the empire of the Greeks, who retained possession of it until the year 624, when it reverted to the Goths. The Arabs in their turn fezied this province, and became masters of it by a treaty of peace signed in 715. In 1144 Murcia was annexed to the kingdom established by the Moors, the capital of which was Granada; but in 1221, it became subject to the kings of Cordova, and formed a separate state. In process of time, Alphonso X. refforled it to the king of Castile, having dispossessed Aben Hudel, to whose sovereignty it was subjected by the dissolution of the kingdom of Cordova in 1236. Alphonso transferred the title and honour of king to Malomed, the Moors, who was the last who held that appellation in Murcia. Since that time this country has belonged to the crown of Castile, and has been under the same government and laws with the other provinces of this crown. This province has never been thoroughly re-peopled since the expulsion of the Moors. According to the enumeration in 1577 and 1578, the population composed of 355,686 inhabitants, a number very inadequate to the extent of the province, which is about 1100 square leagues. The land is divided into Campos, meaning dry land, Huerta or watered land, both of which are plains, and a third portion which comprehends mountains and valleys. The Huerta is uncommonly fertile, and well cultivated; the Campos have as good soil, but want irrigation. The chief production of Murcia is corn, consisting of wheat and rye. Calis is an object of some importance; there are also vineyards, which yield a considerable quantity of wine. Sparr is also cultivated, chiefly in the country about Cartagena, and furnishes an article of exportation. Saffron is also an object of some importance. Olive and mulberry trees are common. The hemp
hemp is of a superior quality; but it is not much cultivated. This province possesses the raw materials of several manufactures, as of linen and flax; but the manufactures are in a low state. Other articles, such as soap, earthen-ware, cutlery, and brandies, are too inconsiderable to deserve particular mention. The commodities of Murcia are too few and insignificant to support a foreign commerce of any great extent. There are three great fairs every year in this province, viz., at Albacete, Lorca, and Murcia, which last several days. Murcia presents an extensive field for natural history. Of lead, copper and silver mines there are various traces. The province affords sulphur, nitre, alum, bok, rock-crystal, marble, and various mineral waters. The climate of this province is much commended; the atmosphere is seldom cloudy, storms are unknown, and rain is very rare. The arts and sciences are little encouraged in this province.

Murcia, the capital of the kingdom or province of the same name. This town is of late origin, as it does not appear in history till the beginning of the eighth century, from which time it frequently changed its masters, until the year 1267, when Alphonso X., king of Castile, having taken possession of it, fortified it, and peopled it with Catalonians, Aragonese, and principally with French. Two circumstances give it some degree of celebrity. When it was besieged in 1234 by Abdelaziz, a Moorish general, it was in want of men to defend it. On this occasion, the women, habited like men, were placed by the governor upon the ramparts, and obtained an honourable capitulation. In 1766, this town held out for Philip V.; but it was open and defenceless; but its bishop assembled, and routed the people of the neighbourhood, placed himself at their head, and prepared to defend it; but still dreading the force of a large army, he opened the referrers, cut the canals, turned the river Segura; and thus inundated the whole surrounding country. Having thus secured Murcia, the bishop with his army marched against Cartaghesa, and compelled it to surrender. For this exploit, he was created a cardinal.

Murcia is situated in a large and beautiful valley, watered by the river Segura; its population is computed at 60,000 persons, including those who inhabit the Huerta, or neighbouring country dependent upon it, who are suppos'd to amount to a third part of the whole. It is the seat of a bishop suffragan to the archbishop of Toledo, which see was removed hither from Cartaghesa in 1291. Its diocese includes almost the whole present kingdom of Murcia; and the revenue of the bishop is equal to 22,916 l. 13s. 4d. sterling. The town has 11 parishes, 10 convents of monks, nine convents of nuns, three colleges for the secular clergy, two hospitals, and an asylum or penitentiary house. It has generally a garrison of two squadrons of cavalry, and is the chief place of an intendant of the whole kingdom of Murcia. Its public establishments are a custom-house, a board of public economy, two public libraries, a curia-house for falc-petres, gunpowder mills, some silk manufactories, and a considerable establishment for spinning and twisting silk. It was formerly fortified, but is no longer walled. Its suburbs are pleasant, communicating with the town by two bridges. The houses, being badly built, exhibit an indifferant appearance; many of them are ancient, loaded with ornaments of architecture and sculpture in bad taste. Its squares are numerous, it has many churches, and its cathedral is magnificent. The promenades of Murcia are four; viz., the Arfeial, the botanical garden, the Alameda, and the Malecon; but they are of little use, as the Murcians seldom walk, but stay at home, smoking cigars, and sleeping. In Murcia there are three colleges for education, and two public libraries. Its manufactures are such as have been mentioned in the preceding article; and it merely shares in the commerce of the province. Ignorance and sloth, says M. de Laborde, render the manners of this town disagreeable; prejudices run high, and the inhabitants are extremely litigious. The Murcian women, however, are mild and affable, and would be fond of society, if their liberty were not restrained by the authority and dispositions of their husbands. For want of lamps, it is dangerous to perambulate the streets at night. In summer the heat is extreme, Fahrenheit's therm. being often at 99; and in winter it is hardly ever necessary to have recourse for warmth to the fire. The complexion of the Murcian, indolent, as we have already said, in his habits, is often livid; he is fat, gloomy, choleric, hypochondriacal, and subject to diseases of the liver. At Murcia there are no mons; the want of which is a serious inconvenience on the road from Madrid to Cartaghesa, and on that from Catalonia and the kingdom of Valencia, into Andalusia; 96 miles S.S.W. of Valencia. N. lat. 37° 57'. W. long. 1° 30'.

Murcia, in Mythology, the goddes of Sloth, who disposed her votaries to indolence. Her temple, according to Fellus, was upon the Aventine mount.

Murcia, in Geography, two small Philippine islands, near the N. coast of Mindanao. N. lat. 9° 13'. E. long. 122° 28'.

Murder. See Murder.

Murderer's Bay, in Geography, a bay on the W. coast of New Zealand; so called by Taiman in commemoration of some of his crew being murdered there by the natives, in December 1642; between Cape Farewell and Rocky Point. S. lat. 40° 46'.

Murdering Battery. See Battery.

Murdochery, in Geography, a town of Hindoostan, in the province of Ciccule; 18 miles N.N.W. of Gazjam.

Murdocherry, a town of Hindoostan, in Myloire; 20 miles E.S.E. of Sirpy.

Mur, Eau. A term applied to the cakes of apples, grapes, &c. left in the press, after extracting the juices.

Mure, in Rural Economy, a term applied to the cokes of apples, grapes, &c. left in the press, after extracting the juices.

Mure, Counter. See Counter-mure.

Mureka, in Geography, a town of Russia, in the government of Tobolik, on the Tuungulla; 192 miles E. of Eniseik. N. lat. 58° 50'. E. long. 95° 14'.

Murengers, two officers of great antiquity in the city of Cheller; being two of the principal aldermen chosen yearly to see the walls kept in good repair, and to receive a certain toll and custom for the maintenance thereof.

Murenzkoil, in Geography, an offshoot of Russia, in the government of Irkutsk, on the Lena. N. lat. 58° 31'. E. long. 114° 50'.

Mures, a town of Spain, in Asturias; 17 miles N.N.W. of Oviedo.

Muret, Mark-Anthony, or Murtus, in Biography, an eminent classical scholar, was born in 1526, at a town of the same name as that by which he is known, near Limoges. With but little affluence, in the way of a preceptor, he acquired the Greek and Latin languages at an early age, and in his eighteenth year he went to Auch to read lectures on Cicero and the archbishop's library. He visited the famous Julius Caesar Scaliger at Agen, by whom he
he was recommended to the magistrates at Bourdeaux, where he taught the belles lettres in 1547. He left that city
for the capital, where he was made one of the professors in the
college of St. Barbe, and acquired so much reputation
by his lectures, that the king and queen came to hear him.
From Paris he went to Touloufe, where he studied the civil
law, and explained its elements. He had been driven from
the metropolis by the imputation of a crime, which in very
few countries meets with any quarter; the charge followed
him to Touloufe, and obliged him hastily to remove to
Venice. That the accusations were unfounded, has been
inferrred from the favourable reception which he met with
in Italy, even from popes and cardinals; and also from the
regularity of his life in that country, which was his
principal refuge from the year 1554. At Venice he taught
publicly, at a very considerable salary, and from thence he
was sent to Padua, to inculcate the Venetian youth in classical
literature, and there he contracted an intimacy with Bembo,
Manuzio, and other eminent Italian scholars. In 1560, he
was invited to Rome by cardinal Hippolito d'Este, whom
he accompanied in his legation to Paris. Here he printed
his edition of Cicero's Philippius, and on his return to the
capital he continued to reside with the cardinal, who
engaged him, in 1563, to write commentaries upon Aritotle's
works, which he performed during four years, with great
applause before a very numerous audience. He afterwards
gave lectures on the civil law; and at the desire of pope
Gregory XIII, explained several of the principal classical
authors. In 1576, though at the age of fifty, he took holy
orders, after which, Stephen Batteri, king of Poland, in-
vited him to his kingdom upon very advantageous terms, but
Gregory, at the earnest request of the conservators of the
Roman people, having doubled his appointments, the liter-
ature and society of Rome turned the scale, and he declined
accepting the offer. He died at Rome in 1585, and was
buried with extraordinary funeral honours. Moret was one
of the most elegant Latin writers of his time; he was like-
wise a man of general erudition, and well verified in that sort
of knowledge which is requisite for a critic on the writings
of antiquity. It is to his disgrace, that he wrote in praise
of the horrible massacre of St. Bartholomew, published in
his panegyric of the hateful Charles IX. His works were
published collectively at Verona in 1727—39, in five volumes
octavo. They consist of notes on various authors, orations,
letters, poems, disquisitions, &c. His place is rather
among men of letters, than men of genius.

MUCUS, in Geography, a town of France, and prin-
cipal place of a district, in the department of the Upper
Garonne, seated on the Garonne; nine miles S. of Touloufe.
The place contains 3,141, and the canton 12,562 inhabitants,
on a territory of 2,275 square kilometres, in 10 communes. N. 43° 27'. E. long. 1° 25'.

MUREX, in Natural History, a genus of the clas-
ves, and order Tellacan. The generic character is;
animal à filax; shell univalve, spiral rough, with mem-
branaceous future; aperture oval, ending in an entirely
straight or slightly ascending canal. This genus is separated
into six distinct divisions, containing in the whole more than
180 species, scattered through the different seas of the
world; of these, seven or eight only are common to our own
coasts.

A. Spinus, with a produced Beak.

Species.

1. ANTIPIEUM. Shell ovate tuberculate, with a long
subulate margined beak. There is also a variety of this
species. It is found in Asia, America, and in the Red seas;
it varies much in the colour and length of its tubercles on
the beak the aperture is rounded, generally rosy, the
mouth is sometimes white, sometimes blueish.

Tribulus; Thorny Woodcock. Shell ovate, with a
triple row of fætaceous spines, the beak elongated subulate,
with similar spines. Of this species there are two varieties:
1. With spines shorter than the beak. 2. With spines as
long or longer than the beak. It inhabits the same seas
as the last, but is more abundant. The shell is white or
reddish, transversely striate.

Conusurus. Shell roundish, and surrounded with subu-
late oblique spines, the beak long subulate, with a few
short spines. It is found on the southern coasts of Africa,
but is not frequently met with. The shell is eight inches
long, transversely striate, white, yellow, or pale chevron,
within it is rosé; spines are two inches long, the whorls
rounded and inflated.

Brandaria. Shell sub-ovate, surrounded with straight
spines; beak moderately long, subulate straight, and ob-
liguey surrounded with spines. It inhabits the Mediterra-
nean and Adriatic seas; the shell is white, cinerous, or
brownish, with a triple row of small spines, the third row
shorter, rarely a single row with the beak unarmed.

Trunculus. Shell ovate, knotty, and surrounded with
spines on the fore-part; beak short, perforate, and tran-
crate. Found in the Mediterranean, and in Jamaica; the
shell is variable in colours, sometimes barred and transversely
striate; beak sometimes straight, sometimes bent to the
left.

Pomum. Shell ovate, knotty, with protuberances from
three to seven; the beak is broad. It inhabits the eastern
shores of Africa; its cover is pious and puckers.

Decussatus. Shell ovate, transversely grooved, with
convex ribs, rounded by perpendicular knots; beak imper-
forate. Found on the eastern coasts of Africa. The mar-
gin of the lip of this species is membranaceous; the spire
has seven distinct whorls.

Triacanthus. Shell turgid, knotty, transversely
striate, with a triple row of spines. Found in a foliolic
state; shell shaped like a fig, with five or six horizontal
spines crossing the type; beak above an inch long; the
three outmost whorls knotty, and a little prominent.

Melanomathus. Shell transversely striate, with eight
rows of hollow black spines; spire a little knotty and
prickly; beak subulate. The place of its habitat is not
known.

Radix. Shell white, with numerous rows of frounso-
hed black subulate spines; this is extremely rare, and its habi-
tation not ascertained.

Candida. Shell white, with rows of spines, and very
short beak. The shell is about two inches long, and some
of the spines are black.

Fasciatus. The shell of this species is inflated, with
rows of spines, white barred with brown; the spire has
four distinct turgid whorls.

B. Suture extending into crisped foliations; the beak is
ob-
truncate.—Purpurea; that in this species of this division con-
sist of the tripe of purple; that properly so called.

Species.

Ramus. Shell with a triple row of foliations and con-
tiguous spines; beak truncate. The shell is transversely
striate, varying very much in shape, colour, and appearance
of the foliations.

Foliatus. Shell with a triple row of foliations; apere-
ture
MUREX.

Lateral. Shell with protuberances crossed by smooth belts; aperture oval. It is found in George's bay.

LAMAS. Shell rough, with opposite impressed protuberances, and a muticate belt or two; aperture commonly toothed and oval. Found on the Asiatic shores; the shell is white, grey, or brown, with elevated transverse flange, which are sometimes granulate.

GYRINUS. Shell with opposite continued protuberances, and barred with tuberculate dots; aperture orbicular. Found in the Mediterranean and Atlantic; also on the shores of America and India. The shell is small, white or brown, with alternately fleshy bands of elevated dots.

APIS. Shell turgescent, with opposite continued protuberances; spire pointed; the whorls surmounted by a crown of tubercles, the most glabrous. First whorl of the spire with a triple or quadruple crown of round tubercles.

LAMAS. The shell of this species has nearly opposite protuberances, gibbous, the protuberances longitudinally tuberculate. It inhabits India, and is from 4 to 14 inches long. The shell is of a red or chestnut colour, and rough with minute tubercles; aperture oval, toothed on each side, with white flesh-colour, with an orange oval coloured border within.

OLEARIUM. Shell with alternate protuberances, and numerous tubercles; back unarmed and friarite; the aperture is toothed. It inhabits the Mediterranean and African seas.

FENORAE. Shell with decussate protuberances, triangular, wrinkled, and knotty on the fore-part; aperture ovate, toothed. Inhabits Afn, Guinea, and America; it is from five to seven inches long. The shell is brown, with transversal ribs which are white towards the aperture, with intermediate grooves transversely flared; back turned inwards.

CUTACEUS. Shell with a single protuberance, angular, and a little wrinkled with knots; aperture toothed; back perforated. It inhabits Barbary, Guinea, and South America; is three inches long; shell brownish, with a tinge of bloom or white, with perpendicular undulate lines.

LOTORIUM. Shell with decussate protuberances, angular, with longitudinal tuberculous knots; back flexuous; aperture toothed. It inhabits the Mediterranean.

PILEARE. Shell with decussate protuberances, and a little wrinkled with knots; aperture toothed; back sub-ascending. Found in the Mediterranean.

BIRONA. Shell with fixed opposite, continued, vaulted protuberances and knotty belts; back oblique.

PYRAMUS. Shell varico, ovate, transversely grooved, and knotty, with a long flexuous tubular beak. It inhabits the Indian ocean, in numerous varieties; the shell is white, sometimes varied with brown, or chestnut, or yellow-brown; angular, longitudinally flared, and transversely grooved; aperture oval, toothed; pillar sometimes toothed, sometimes toothless.

CAUDATUS. Shell thin, transversely flared, brown varied with white; back tubular; spire a little prominent, and tufted brown, the whorls grooved, the first gibbous.

RUBICEA. Shell with decussate protuberances, obtuse with knotty wrinkles; belly equal; aperture toothed. Inhabits Africa, India, and South America; it is very rare. The shell is red or yellow, and barred.

SCROPHULUS. Shell with nearly opposite, burred protuberances; smooth; aperture toothed. It inhabits the Mediterranean.

RETIULARIS. Shell with nearly opposite protuberances, reticulate, with tuberculate spots; pillar almost toothed, back ascending. Inhabits the Mediterranean and America; is six inches long. Shell transversely ribbed, and longitudinally flared, with party-coloured knots in the angles of the fission; aperture with a red border; lip toothed.

LAMELLOUS. Shell with membraneous protuberances continued through the spire, and terminated with a spine. It inhabits the Falkland Islands.

NORATUS. Whorls knotty; back straight; aperture violet; lip toothed. It inhabits New Holland.

AXIS. Shell with dilated membraneous protuberances and lips, gibbous and reticulate, with tubercles; aperture fimbrious; the beak is erect. Inhabits the Mediterranean and Afn; is three inches long, and the shell is generally brown, with white bands and sub-angular aperture.

MILLARIS. Shell varico, with tuberculate belts; aperture a little toothed; back elongated; whorls ventricose; the shell is of a cinnereous greenish colour; the tubercles sometimes black, rarely russet.

SPECIES.
SENEGALENSIS. Shell transverse fritate, with spinous protuberances, the spines decreasing towards the head. This species inhabits Senegal; is about 2½ inches long; the shell with nine tubercles, alternately lefts; each of them armed with eight spines; the spire with eight whorls.

*CAMNATUS. Shell ventricose, with five or six whorls forming angular ridges; aperture semi-circular; beak a little reflected. It inhabits Europe.

D. More or less spinous, and without manifest beak.

Species.

RICINUS. Shell obvolute, with subulate spines; aperture and lip toothed. Inhabits the Atlantic ocean, is about 1½ inch long. The spines are disposed in rows; the spire prominent; mouth violet colour.

Nodos. Shell obvolate with conic spines; lip toothed; pillar smooth and coloured; shell is less than that of the Ricasus; the aperture is of a flesh colour.

NERITOIDUS. Shell with numerous rows of knots; lip with pointed angles; pillar flat-topped. It inhabits India, and resembles a Nerita. The shell is sometimes white with black tubercles and violet mouth, or yellowish-brown with brown tubercles and yellow aperture; first whorl with four rows of tubercles on the back; lip armed with three or four spines; pillar with from two to four teeth.

Fucus. Shell coarse ventricose, fritate transversely, with four rows of knots; pillar imprefsed, and with the outmost whorls flat-topped. This is a rare shell; the pillar is marked with two or three black dots.

Loco. Shell obvolate and knotty on the fore-part; aperture toothed and sub-ornicular. It inhabits the Chineese shores; shell four or five inches long; the inhabitant is eaten by the native, and contains a purple juice in the vehicle on the neck.

Hystrix. Shell sub-ovate, with acute spines; aperture toothed, expanded. The shell is sometimes of a bay colour, varied with white or yellowish-brown, with or without spots; the spines are in four rows; the aperture wide.

Mancineria. Shell ovate, with obsolete spines; aperture toothed; pillar transversely frigate.

 Hippocastus. Shell ovate frigate, with from three to five rows of obtuse spines or tubercles, aperture transversely frigate. Inhabits Guinea, India, and the islands of the Indian ocean. The shell is transversely frigate on the back, and armed with rows of obtuse spines or tubercles varying in numbers; whorls of the spire distant.

Senticosus. Shell a little tapering, longitudinally ribbed, and transversely cancellate; aperture frigate. Found in the Indian ocean; about two inches long; the shell is yellowish, with a brown band on each of the whorls, the ribs prickly; aperture oblong; pillar with a fiddle plait; spire pointed with distant whorls.

Melinjera. Shell obvolute glaucous, with a sub-filous whorl rather prominent spire, and smooth aperture. Found in India and America in great varieties; the specimens are generally about 5½ inches long. The shell is generally brown, barred with white; aperture oval, large; spire with knotty whorls, rarely smooth; the first very large and turgid, and mostly surrounded with spines.

Conch. Shell thick, ventricose, white, transversely grooved and knotty; aperture smooth; ovate; lip sinuous, plaited inwardly, and denticulate. It inhabits India.

Lima. Shell brown, sub-ovate, and slightly beaked, with crowded nodulous paler belts. Found in George's bay.

E. With a long straight subulate closed beak, and unarmed with spines.

Species.

CRUSTACEUS. Shell without beak, slightly plaited, ovate, pointed; tip curiosus. Found in the aqueduct at Seville, front of a bean; the shell is oblong, pointed cinereous, sub-diaphanous, longitudinally grooved, and emarginate at the base.

BABYLONUS. Shell tapering, with acute spotted, and straight tail; upper lip eleft. It inhabits India and the American islands; is about four inches long, and the shell is surrounded with white belts, and marked with square brown or black spots.

JAVANUS. Shell tapering, with immaculate knotty bands; the lip has a separate fissure. It inhabits India; resembles the Babylonus, but is white, immaculate, and sometimes varied with yellowish-brown rays; beak longer or shorter; whorls carinate or tuberculate, and sub-frigate.

Sinensis. Shell ventricose; pointed, with a cancellate reflected beak; aperture oval; whorls with transverse granulate frigate; base crowned with spines. It inhabits Senegal; the shell is spotted, and has a single plait on the pillar.

Stramineus. Spire with elevated wings, the interstices filled with short flake-like projections; all the whorls crowned with tubercles at the base; aperture violet; lip undulate, and with the pillar snowy. Inhabits the southern ocean. Shell flesh-colour; it is three inches long.

Australian. Shell ovate; longitudinally frigate; lip undulate; whorls caniculate; the firf turgid and four plaited; the next three-plaited. It is found in the South seas, and is 2½ inches long. The shell is of a flesh-colour, with a yellow pillar and snowy lip.

Uncinatus. Spire pointed, and transversely frigate; the four fir fwhorls with a callus, armed with hooks in the middle, the fith and sixth ribbed; the red glabrous. The shell is not above an inch long; the aperture is oval; lip toothed; spire with nine whorls.

Terris. Shell tapering, the whorls crowded with tubercles, and surrounded with a granulate belt, the first very finely frigate transversely. The shell is white, with a red-dish band; this also bears a strong resemblance to the Babylonus, but the lip is entire.

Costatus. Beak a little reflected, and obliquely frigate; the three first whorls of the spire ribbed; the other four cancellate, the fifth oblong; the pillar has a fiddle plait. It is found in a fiddle leaf in Campania; the ribs of the firth whorls terminating in spines above.

Asper. The shell of this is longitudinally plaited, and transversely ribbed; the spire is a little prominent; the aperture ovate; lip crenulat.

Colis. Shell tapering, frigate, knotty, carinate, with a long straight beak; lip crenulat. Found in the Indian ocean. The shell is white, transversely frigate, round, or angular; whorls separated by a groove, and crowned with knots; the upper ones brown; the beak is nearly three inches long, and beneath it is brownish.

Moho. Beak dilated; shell black, with a white band; whorls a little knotty; pillar wrinkled. Found in divers parts of Africa, and is about six inches long; the shell is brown or cinereous, and transversely frigate.

Conchifera. Beak dilated; whorls of the spire flat above. It inhabits the Indian ocean.

Spirillus. Shell with a long beak; spire mucronate; the whorls convex above. Inhabits Tranquebar; resembles the Cunectanus, (below,) but the whorls are not separated by a groove; shell ventricose beneath; convex above; spire with a prominent obsolete knob in the centre, the whorls surrounded with an acute margin above; the beak is sub-cylindrical.
MUREX.

cylindrical, and not dilated towards the aperture of the belly; pillar with a transverse wrinkle.

**Cancellatus.** Beak dilated; whorls of the spire separated by a small canal. It inhabits Canada and the Frozen sea; the shell is brown, sometimes larger and uniform, sometimes less and radiate, smooth or transversely striate; margin of the back knotty.

**Ficus.** Beak dilated; shell spireate, the whorls separated by a small canal; the outer ones brown, the first crowned with knobs at the base.

**Carica.** Beak dilated; shell transversely spireate; a little prominent; the whorls crowned with spines at the base. It is about eight inches long; the pillar is plaited.

**Rapa.** The shell of this species is solid umbilicate, with a triple row of knots, and transversely striate; the aperture large and striate. It inhabits India, and resembles the Bella rapa.

**Niveus.** Beak dilated; shell snowly diaphanous; whorls of the spire separated by a small groove; the first with transverse carinate ribs. It inhabits the seas about Brazil.

**Granum.** Shell hemispherical, glabrous, diaphanous, with a spreading straight beak, crown capillary. Found in North America. The whorls are convex, and growing gradually less towards the tip.

**Arcanus.** Beak dilated, spire crowned with spines. It inhabits New Guinea; shell coarse ponderous, black or blueish, surrounded with rings; aperture angular; beak rather long; spire mucronate.

**Perseus.** Beak dilated and repand; spire turned the contrary way, and sharply crowned. It inhabits the American ocean; this species is exceedingly rare; the spines are somewhat pointed, sometimes more obtuse.

**Antiquus.** Beak dilated; shell oblong, with eight round whorls; the first ventricose. It inhabits the European and Frozen seas, and is from four to six inches long. The shell is dark and of a dirty yellow, very finely striate, transversely or longitudinally plaited; whorls of the spire separated by a groove, the middle one sometimes crowned with tubercles, rarely turned contrary.

**Dorrites.** Beak dilated; shell oblong striate, and somewhat rugged; it has eight whorls, with two elevated lines. It inhabits the European seas, and is about five inches long. The shell is coarse white, with a glossy orange-yellow aperture; the animal is sometimes eaten, but is more frequently used as a bait for cod and ray-fish.

**Fornicatus.** Beak dilated; shell ovate oblong; the whorls ventricose, longitudinally striate, and a little angular. It inhabits the Greenland seas. The shell is more than three inches long, sub-diaphanous, smoothish and yellow, within white glabrous; there are seven whorls; with wide transverse lirae.

**Incassatus.** Shell oblong, transversely wrinkled, and longitudinally striate; lip denticulate within, and thickened without. *Aulacostoma.*

**Truncatus.** Shell oblong, longitudinally ribbed; beak a little retracted, emarginate, truncate. This is the Murex colatus of Pennant. It inhabits European coasts, is very abundant, with six whorls.

**Acuminatus.** Shell narrow, oblong, ribbed, with a pointed spire. It inhabits England.

**Argus.** Shell globular, with transversely tuberculate ribs; brown, with darker bands, within white; aperture ovate. It is found in India, and in the Friendly and Society islands.

**Maculatus.** Shell cancellate, yellow, with alternate white bands and chestnut patches; spire with eleven round whorls.

**Magellanicus.** Shell ventricose, umbilicate, transversely striate, cinereous within violet; whorls of the spire with parallel ribs, the first very large.

**Cancellatus.** Shell ovate, solid, opac, cinereous; whorls of the spire cancellate, and separated by a groove.

**Scolopacites.** Shell brown; whorls surrounded with grooves, and with tubercles above; tip of the tubercles and aperture white. There is a variety which is more elongated, and of a dirty yellow; with an obsolete band on the whorls, the tubercles more globular.

**Littoratus.** Shell ventricose, tapering, spotted with black; pillar with a single plait; shell short; shell snowy, with a wide aperture; spire with eight pricky whorls.

**Tritonius.** Shell sub-triangular, cancellate; spire with inflated contiguous whorls, the first with a large distinct tubercle. It is found in Senegal. The shell is two inches long; spire with fewer whorls.

**Semilunaris.** Shell longitudinally ribbed, and very finely striate transversely; spire with flattish plaited whorls, with rows of tubercles; aperture semituberculate. This is found in Senegal; the shell is about an inch long, the whorls with a single row of tubercles, the second with a double or triple row; the first with six or seven rows.

**Costatus.** Shell with annular flutes, and inflated round whorls, each of them with nine rounded, parallel, spiny ribs. Inhabits Senegal. The shell is about 1/2 inches long.

**Sulcatus.** Shell rounded, with annular grooves; aperture oval; first whorl of the spire turgid. Found in Senegal; shell 1 1/4 inch long, with nine contiguous whorls, which are sometimes inflated, sometimes flattish.

**Eciformis.** Shell elongated, with numerous rows of very minute crowded tubercules. This also inhabits Senegal; the shell is six lines long, with about eight whorls; the first with from twelve to fifteen rows of tubercles, the second with five.

**Tritonis.** Shell ventricose, oblong, smooth, with rounded whorls to the aperture, and short beak. Inhabits India and the South seas; there is a variety found in the Mediterranean; the shell is full sixteen inches long, white, and appearing as if covered with brown, yellow and black scales; the pillar is white, with transversely black lirae; whorls of the spire separated by a nodulous furrow, the first marked with striate grooves. This species is used by the natives of New Zealand as a musical shell, and by the Africans, and many nations of the East, as a military horn.

**Tulipa.** Shell ventricose, oblong, smooth; whorls round-ee, with a double furrow; pillar with two plait; beak dilated, striate. It inhabits South America; the shell generally spotted and clouded, within transversely striate; whorls with rarely a single furrow.

**Clathratus.** Shell oblong, beaked and grooved, with longitudinal sub-membranaceous plait. This species is found in Iceland: it resembles very much the Turbo clathratus, to be described hereafter, but it has a short beak, and numerous erect compressed plait.

**Nasso.** Shell solid, brown, or pale brown, with a white sub-diaphanous band; whorls knotty; pillar a little plaited. This is thought to be a species between the Veluta and Murex.

**Plicatus.** Whorls of the spire plaited and knotty. It is found, though rarely, in India.

**Scala.** Shell umbilicate, with dilated wedged, ribbed, and transversely striate whorls; aperture heart-shaped; the shell is reddish-white, sometimes yellow, with pale brown bands.

**Piscellum.**
FISCELLUM. Shell angular, longitudinally plaited, and transversely striated; lip toothed; mouth violet; beak straight, short. Inhabits China.

CORONLA. Shell fusiform, with brown and yellowish bands; whorls above flattened, with waved imbricate scales; beak straight, entire. It inhabits Mexico.

DOLARIAU. Beak dilated, shell ovate, with a few elevated obtuse belts on the whorls. This, which is about the thirteenth inch of a nutshell, inhabits the ocean; shell horn; tapering both ways, surrounded with numerous obtuses, and very much ruffled, two on the whorl; pillar perforated; aperture ovate, a little transverse forwards, excavated at the outer margin, and tapering behind into a hardly manifest and slightly emarginate canal.

CORNEUS. Shell oblong, slender, white, the margins of the whorls complicated, the tip tuberculate; aperture toothless; beak a little ascending. It inhabits the British and North seas; three inches long. The shell is white, covered with a brown skin, transversely striated; spire with eight round whorls.

LIGNARIAU. Shell oblong, coarse, with obtuse knotty whorls; aperture toothless; beak short, straightish. Found in divers parts of the ocean; about three or four inches long. Shell smooth, coarse, with a single row of knots on the whorls.

TRAPANUM. Shell oblong, obtusely angular, with slightly knotty whorls; aperture toothed; beak short and straight. It inhabits the Indian ocean; it is frequently seen above fix inches long.

VESPERTILIOU. Shell solid, ventricose, smooth, with an oblong oval aperture; beak and crowded spire striated; the outer whorls are sinuate. It is found in the Indian ocean, and is full four inches long. The shell on the outside is of a cheetah colour, but within it is of a flesh colour.

SCOLYIUS. Shell thin, diaphanous, ventricose, and transversely striated, the middle of the back smooth; spire with obtuse undulate knots; pillar three-plaited; the shell is white, with nine or ten whorls on the spire; the tubercles are hollow within, and the beak is annulate.

HARPUS. Shell ventricose, longitudinally ribbed, the ribs transversely striated; spire a little prominent, the whorls dilatant.

TUBA. Shell fusiform, transversely striated, white, with a brown tip to the spire; whorls dilatant, and crowned at the base with knots. It is found in China, and is nearly fix inches long. Beak is rather long; the spire has eight whorls.

SYRACUSANUS. Shell oblong, with striate plaited whorls, covered with tuberculated ridges; aperture toothless; beak short. It inhabits the Mediterranean, but is extremely rare. The whorls are terebrate, with white divisions; beak moderately long, obliquely striated outwardly.

CANTICUS. Shell oblong, with rounded, plaited, and transversely striated whorls; aperture toothed, beak short. It inhabits the Mediterranean. Shell white, slightly plaited longitudinally, with elevated ferruginous angles; whorls with elevated fringes; aperture striate within.

SCYPHUS. Shell nearly without beak, fusiform, smooth, pale, with longitudinal brown fringes; lip toothed. It inhabits the Mediterranean, and is not much larger than a grain of barley. The shell is oblong, with tuberculated flexuous fringes.

TERRATANUS. Shell transversely striated, with dilatant, undulate tuberculate whorls; aperture oblong; beak straight, longish. It inhabits the Ternate island; is yellow, and about four inches long.

INSUNDINUM. Shell umbilicate, undulately noddy, with elevated brown fringes; perforation funnel-shaped; pillar two-plaited. This is a very rare shell, about four inches long, with nine whorls.

POLYGONUS. Shell a little ventricose, undulate, with tubercles; striate, grooved, and obtusely angled; black, with an oval aperture and short beak. It inhabits the Indian ocean; shell is sometimes umbilicate, sometimes not; pillar with or without plates.

ISLANDICUS. Shell transversely striated, snowy, covered with a brown skin; spire papillous at the tip, with round whorls, the first very large and ventricose. It is found in Iceland. The shell is about five inches long, with from six to nine whorls; the aperture is oblong; the beak short, lip acute; pillar smooth.

LEVIGATUS. Shell fusiform; spire transversely striated, with dilatant flatish whorls, the first round and smooth; the beak rather long. It has been found in the foible state in Campania, and is 3½ inches long. The aperture is oval, and the beak sometimes a little bent.

FOSSILS. To call on account of its being found in Campania, only in the foible state; shell fusiform; thin, cancellate, with a long beak. It is an inch and a quarter long; the whorls are more or less dilatant; pillar plaited or smooth.

CANDIDUS. Shell snow, transversely striated; spire with dilatant whorls, carinate in the middle, and crowned with tubercles; aperture oval; lip grooved within, and dentriculate at the margin. The shell is between nine and ten inches long.

ANSATUS. Shell brown, transversely striated; spire mucronate, the whorls dilatant, convex and knotty at the base; beak long.

UNDATUS. Shell solid, ventricose, with waved angles, and very finely striate transversely; spire mucronate, the whorls knotty at the base; lip denticulate. It inhabits India; is eight inches and a half long, and ponderous; shell white, with fourteen whorls, and a slightly curved beak.

LONGISIMUS. Shell thin, striate, with an obtuse knotty spire and long straight beak. It inhabits India; is nine inches long; shell white with ten whorls.

LANCEUS. Shell narrowed; whorls of the spire transversely ribbed and longitudinally carinate; aperture ovate, ribbed with white within, and toothed at the margin; the pillar is two-plaited. It inhabits Ambona; shell exceedingly thin and narrow, the younger ones reddish, the adult ones white, interlaced of the ribs and aperture violet; the spire has eleven or twelve whorls.

ANGUSTUS. Shell narrowed; first whorl of the spire longitudinally plaited and transversely ribbed, the others smooth and round; beak transversely ribbed.

VERISICOLOR. Shell subcylindrical with an obtuse spire, the whorls round and striate, the lower ones mostly glabrous. It inhabits India; shell brown variegated, with nine whorls.

VERIECIVOCUS. Shell umbilicate, and surrounded with belts, the middle ones more raised; whorls crowned with tubercles which are spotted with brown; beak inflected. Inhabits the Red sea.

SYRIACUSUS. Shell thin, transversely striated; spire mucronate; the whorls round; beak long; aperture ovate; lip crenulate. This shell is about four inches long, covered with a brown skin.

PARDALUS. Shell rounded, white with violet spots, longitudinally ribbed and transversely striate; spire obtuse; beak long.

GIGAS.
MUREX.

GIGAS. In this species the whorls of the spire are tur- 
gid, gibbous, nodulous, and annulate; beak reflected; lip 
denticulate beneath. This shell is twenty-one inches long.

LIGNOSUS. Shell white; spire obtuse, the whorls 
slightly crowned with unequal tubercles; beak transversely 
spirated. It is about one inch and a half in length.

GIBBULUS. Shell tapering, orange; spire obtuse, the 
whorls dilated, with longitudinal ribs and flexuous transverse 
spiras; the beak is short.

GRANULARIS. Shell tapering, spire with contiguous 
whorls separated by a flexuous line, the first ventricose.

Found in the Adriatic.

VENEXILUM. Shell tapering, transversely ribbed; whorls 
cylindrical; aperture oval; lip inflated; white; beak short. The 
shell is of an orange colour with brown belts.

VOLUMINUS. Shell oblong, ventricose; the whorls with a 
spiral margin; aperture glabrous; beak short and bent out- 
wards. The shell of this species is middle-sized, tawny, with 
eight whorls.

APER. Shell ovate, transversely spirated; spire with flat-
tish whorls crowned with a row of tubercles. The shell is 
one inch and a half long, fulvous or white variegated; 
it has nine whorls.

CAMPANICUS. Shell ventricose; spire obtuse, cancellate, 
with cartilaginous whorls, the first ventricose and smooth; beak 
long and smooth. It is found officle in Campania, and is three 
incches long.

ARENOSUS. Whorls of the spire with decussate ribs; 
the first very large, the third outmost smooth; beak acute; 
aperture oval; lip toothed outwardly. It inhabits the sandy 
shores of India; very small.

MARCENSIS. Shell narrow, brownish, transversely spirated; 
spire mucronate, with dilatant, contrary, round, longitudinally 
ribbed whorls; beak prominent; aperture oval.

LINEATUS. Shell oblong, whitish with transverse spiras; 
beak short, straight. Found on the shores of New Zea- 
land.

PERRON. Shell a little tapering; the whorls cartilag- 
ous, margined and flattened; beak long, straight. It in- 
habits the Southern ocean.

LARVA. Shell cylindrical; spire with a crenate callous 
belts, the upper whorls with plaited knots; lower ones flat-
tish; beak striate, short, emarginate.

NERITOIDES. Shell solid, thick, coarse; spire exerted; 
the whorls transversely spirated; aperture semicircular, and 
spirated; beak straight and short.

PRISMATICUS. Shell ovate angular, iridescent, longitudi- 
nally grooved and plaited; beak short; lip denticulate. It 
habitats India and the South seas.

COLUMBARIUM. Shell with longitudinal plaited ribs, and 
transversely grooved, angular, spinous, cartilage, alternately 
varied with white and brown; whorls leflying suddenly; 
beak short, straight; mouth violet. It inhabits Pulo 
 Condore.

ASPERINUS. Shell ribbed, varied with brown, yellow, 
and white; whorls oblique, with a tuberculated margin, and 
brown band in the middle, and another white one; beak 
dilated, acorning; shell nearly two inches long.

UNDULATUS. Shell white, undulate with bay, with 
grooves marked with raised spiras; the whorls, at the mar-
gin, nodulous; beak striate. Found in the Red Sea, and 
is about four inches long.

F. Taperings, undulate, with a very short beak.

VERTAGUS. Whorls of the spire plaited above; beak 
acorning; pillar plaited within; it inhabits India, is about 
three inches long, with fifteen or more round whorls sep-a- 
rated by a groove; the lower ones smooth on one part 
beak very short.

ALUCO. Whorls of the spire tuberculate with a spiri-
tuous streak in the middle; pillar with a single plait, beak 
ascending. It is found in the Southern seas, in the Atlantic, 
also in the Red sea; and is about four inches long; whorls 
generally whitish, sprinkled with blue, or brownish dots; 
whorls transversely spirated; beak smooth.

ANNULARIS. Whorls surronded with longitudinally 
spirated helices, the first whorl transversely spirated; beak 
ascending.

FLICATULUS. Shell ventricose, with a transversely spirated 
spire, the whorls with longitudinally knotty plates; apertu-
re oval. The shell is yellowish, with white plates; spire 
with eight whorls; pillar with a single plait.

SORIDUS. Shell ventricose, transversely spirated, and 
crowned with black knots; lip dilated. The shell is gen-
erally blueish, with a very trifling prominent beak; this is 
thought by some to be a variety of the Strombus tuber-
culus.

CINGULATUS. Spire transversely spirated and grooved; 
the whorls surronded with three rows of granulations, the 
first a little knotty. It is found in Tranquebar.

FUSCUS. The shell of this species is rounded; first whorl 
of the spire is gibbous; the following ones variegated; the last 
with numerous spines.

FASCIATUS. Shell transversely spirated; the spire crowned. 
This is found in the rivers of America.

FLUVIATILIS. Shell brown; first whorls of the spire 
crowned with spines, the other with knots; aperture re-
pand.

ALATUS. Shell reticulate; spire mucronate, the first 
whorl grooved and transversely spirated; lip winged; spire 
annulate, with nine whorls bordered with a spirated band.

NOBULUS. Shell transversely spirated, and alternately 
barred with brown and white; spire mucronate, the 
whorls dilated and undulate knots. Shell with a slightly promi-
nent lip.

TEREBELLA. Shell with a triple moniliform belt on each 
side the whorls; aperture oval, with curved spiras within. 
The shell is from an inch to two inches and a half long; in 
colour it is a sort of chemift brown; sometimes uniform, or 
chemift with white belts, or white with chemift suburb 
belts; aperture often variegated.

FUSCUS. Spire with crenulate whorls, the upper spiras 
denticulated. It inhabits the Mediterranean; the shell is co- 
vered with a brown skin, the base obtuse; whorls with a 
knotty belt in the middle, and a band on each side, one of 
them granulate, the other crenulate.

TORULUS. Whorls of the spire with a slightly knotty 
zone above; beak short. In colour it is white, smooth, or 
marked with oblique longitudinal spiras; the tip plaited; 
zone of the whorls elevated, gibbous, obtuse.

REDULA. Whorls of the spire tuberculate, with a dou-
ble row of punctured spiras. It inhabits Africa; shell red-
dish or brown; tubercles often tipt with white; the apertu-
re is oval.

ASPER. Whorls of the spire grooved, transversely spirated 
and mucrate; beak ascending; it inhabits Guinea; the 
shell is of a milk-white, with rows of brown dots; solid, 
with from twelve to fourteen longitudinal grooves; aperture 
sub-oval; pillar with a single plait.

GRANULATUS. Shell rough with decussate tubercles; 
beak acute, ascending; it is found in India; the shell is 
about two inches long, white; the whorls are longitudinally 
ribbed and transversely spirated; aperture oval; pillar with a 
single plait.

U u

DECOL.
MUR

**Decollatus.** Whorls of the spire with longitudinal plaited grooves, the tip appearing as if the point of it were broken off. It inhabits the European seas; resembles the Helix decollata, but is emarginate at the base; aperture obovate; upper margin of the whorls tapering with longitudinal slires and imbricate plates; the grooves are opaque black.

**Moluccatus.** Shell friate; whorls of the spire transversely grooved with undulate longitudinal plates; lip dilate crenulate, beak tubular. It is found among the marines of the Molucca islands.

**Minimus.** Shell with transverse undulate slires, crossed by longitudinal lines; aperture orbicular. Found in Jamaica.

**Strigilatus.** Shell longitudinally friate; whorls unindented, with a lowly belt at the future spotted with rufous.

**Tuberculatus.** Shell transversely friate and surrounded with glabrous knots; lip thickened. The shell of this species is solid, a little gibbous, obtuse; the knob black tipped with white.

**Gibbosus.** Whorls of the spire margined; belly gibbos; lip cleft denticate; beak short. Spire with nine slires, and longitudinally plaited; beak straight and short; shell with reddish spots.

**Attras.** Shell black, the whorls transversely friate and tuberculate; pillar with a single plait; beak straight. The spire has ten whorls; lip crenulate.

**Contrarius.** Shell with four contrary whorls marked with double slires, beak dilated. It inhabits the European and North seas.

**Eurynus.** Shell contrary, hyaline, with six very fine crenulate whorls.

**Constrictus.** Shell tapering, very rough, with granulations; lip doubled, emarginate each side, and toothed within; aperture oval, friate.

**Clava.** Shell transversely friate and spotted; whorls with plaited knots; beak ascending; lip doubled, dilated, pilarly replicated and glabrous. It inhabits Pulo Condore.

**Hexagonus.** Shell yellowish, hexagonal, with transverse granulate frie; first whorl tuberculate; aperture roundish; lip dilated. It is found in the South sea, and specimens of it are frequently seen foible.

**Minutissimus.** Shell with five spirally friate whorls and remote ribs; beak closed. It inhabits the Welsh coasts; the shell agreeing with its name is exceedingly minute, elegant, and pollicid.

**Murex Mutans**, in Conchology, a name given by some authors to the genus of shells, known at this time under the name of porcelains and concha venere. See Porcelain-field.

**Murex**, among the ancient Romans, a caltrap, or iron instrument, with sharp points every way, used as a defence against the enemy's horse.

**Murga, in Geography, a town of Hindooftan, in Bunderland; 15 miles E. of Callanger.**

**Murfersborough**, a part-town of America, in North Carolina, and capital of Gates' county; situated on Melvern river, and containing a few houses, a courthouse, jail, and tobacco warehouse, and carrying on a small trade with Edenton, and the other sea-port towns; three miles from Princetown.

**Murg, a river of Germany, which rises about two miles S.S.E. of Oppenwe, runs S.S.E. about six miles to lake Epf, near which it is joined by the Lorhech, when it runs northward to Gerispach; and having paused this town it runs N.W. by Kapperhein, Ralladt, &c. into the Rhine.**

**Murga, a river on the coast of Chili, in South America, S. of the south point of Quintero bay, and not far from the entrance into Chili river.**

**Murga, a town of Hindooftan, in Gerry Mundella; 25 miles E. of Mundella.**

**Murgaw, a town of Hindooftan, in the circuit of Goor; 10 miles S. of Calpy.**

**Murgenthal, a town of Switzerland, in the canton of Berne; 15 miles E. of Sooleure.**

**Mugian, a town of Persia, in the province of Comis; 50 miles E. of Damegan.** Also, a town of Persia, in the province of Kerman; 50 miles N. of Sirgian.

**Murook, a town of Hindooftan, in Colonda; 25 miles S.S.E. of Combamet.**

**Murdhard, a town of Wurtemberg, on the Muhr; 22 miles N.E. of Stuttgart.**

**Muralto, a town of France, in the department of the Stura, on the Bormida; five miles E. of Ceva.**

**Muriate of Iron, in Agriculture, a salt which seldom occurs in nature. It has been supposed highly injurious to vegetation. It is decomposed by fixed alkalies, lime, and magnesia, forming digestive salt, sea-fall, muriate of lime, and muriate of magnesia.**

**Muriate of Lime, an earthy fall which consists of the muriatic acid and lime. It is found native in the sea-water, and in the mother-water of culinary salt. It is likewise obtained either by direct combination, or by the decomposition of lal ammoniac by quick lime. Lord Dundonald says, that it is very soluble, and, when mixed with dung, its effects in promoting vegetation will probably be found similar to those of the muriate of magnesia. It is decomposed by fixed alkalies, forming therewith muriate of potash, or digestive salt of Sylvius, and muriate of soda.**

**Muriate of Magnesia, an earthy salt which consists of the muriatic acid and pure magnesia. It is found in the mother-earth of nitre manufacturers, and may be produced artificially both by direct and indirect combination. According to Lord Dundonald, it is found in great abundance in sea-water, constituting upwards of one-fourth of the saline matter it contains. It may be procured in great quantities from the bitter refuse liquor which at present runs to waste at the salt-works. It is a salt very delicate, and of difficult crystallization; its acid is capable, in a great measure, of being expelled by heat, and very considerable benefit has been experienced from its use in promoting vegetation, when mixed with dung or compost dung-hills. It seems to possess, when applied in moderate quantities, the septic powers of sea-fall, and thus to promote the complete putrefaction of dung. It is decomposed by fixed alkalies and lime, forming therewith digestive salt of Sylvius, sea-fall, and muriate of lime. With ammoniac, or volatile alkali, it forms a triplicate salt of easy crystallization.**

**Muriate of Soda, a neutral saline suffulment, consisting of a muriatic acid and soda, or the fixed mineral alkali. It has received various denominations, according to the state in which it is found in nature, as rock-fall, which is dug cut of the earth in solid masses, bay-fall, formed by the evaporation of sea-water, and river-fall obtained from fall-pumps. But none of these falls is pure, they are always mixed with some heterogeneous parts; thus rock-fall contains exploin, bay-fall, a great deal of muriate of magnesia, and river-fall, frequently both. Sometimes they contain by accident biter fall,
MURIATIC ACID.

It may probably be useful as a manure. See Sea-Salt.

MURIATIC ACID, in Chemistry, a substance which, although it has not as yet been decomposed, is presumed to be a compound of some inflammable body with oxygen, and, in consequence, has been classed with the other acridous oxides. Our ignorance of its constituents does not admit of its procuration by synthesis. It is, however, found in great abundance in nature, being a component part of muriate of soda (common salt), and some others. It is obtained by the following process:

Let equal parts, by weight, of sulphuric acid and muriate of soda, be put into a glass retort, or common gas bottle. Let the beak of the retort be placed in a mercurial trough, below the surface, under a jar filled with mercury. An elastic fluid will be diffused, which will ascend into the jar, displacing as much of the mercury. If a small lamp be now applied to the retort, the gas will be rapidly set free, and will soon fill the jar with a gas having all the appearance of common air, but, as we shall soon notice, is possessed of very different properties. This product is called muriatic acid gas, and has till lately been generally held to be the muriatic acid in a state of purity. It has a disagreeable smell, and is exceedingly suffocating. It is almost instantly fatal to animals, when taken into the lungs.

The specific gravity of muriatic acid gas is that of hydrogen as 15.3 to 1, and 100 cubic inches of it weigh 59.5 grams.

This gas is rapidly absorbed by water, producing much heat. Under the average pressure and temperature, water absorbs more than four hundred times its bulk. This constitutes the liquid muriatic acid, formerly called spirit of salt. The following is a table of the per cent of acid, in the liquid acid, of different specific gravities.

</table>

From the preceding table it will appear, that the specific gravity of liquid muriatic acid is in the direct ratio of the combined gas, so long as it retains the liquid form. Whether it is combined with water in its gaseous form, is a matter not yet decided. On this point we shall make some observations in the course of this article. The condensation of the two bodies, with the evolution of heat during combination, are proofs of their great attraction for each other. No liquid acid appears to be capable of existing when the proportion of gas is much more than four or five hundred times the volume of the water. At this strength it appears to contain about 48 per cent. of the acid gas. Its specific gravity is 1.5, and its boiling point 60°. Mr. Dalton is of opinion that it consists of 3 x 8 + 22, or 3 atoms of water, and 1 of acid.

Its boiling point gradually lowers with a less proportion of gas, as may be seen in the table, till it gets to the proportion of 12 per cent. of gas, under which it boils at 23.5°.

Mr. Dalton very justly observes, that when the acid gas is in greater proportion, the gas escapes to bring it to that standard. When, however, it is in a less proportion, the water evaporates till it arrives at the same strength.

The methods of ascertaining the strength of a given acid are various. Let a given measure, or weight, of the acid be saturated with crystallized carbonate of lime in powder, and let the carbonate of acid be carefully collected. For every 194.4 by weight of carbonate of acid, allow 22 of real muriatic acid.

To a given weight of the liquid acid, let nitrate of silver be added till no more precipitation takes place. Collect the muriate of silver and dry it. For every 100 grams of this muriate allow 17 of muriatic acid.

The process for obtaining liquid muriatic acid consists of the most convenient means of precipitating the gas to water intended to absorb it. The common salt is put into a retort of glafs in the finall, and of iron in the large way. The gas is then received into a set of Woulfe's bottles. (See Laboratory.) This gas is to be supplied till no more is absorbed.

This liquid is generally of a yellow colour, which is said to be owing to a small portion of iron, since the pure acid is without colour.

The presence of muriatic acid, in the gaseous form, is easily ascertained by ammonia. The two gases combine, forming dense white fumes, which, when condensed, form muriate of ammonia.

The acid in any liquid is detected with great sensibility by sulphate of silver: the acid forms with it a heavy white precipitate, which turns purple by exposure to light. This is the muriate of silver.

Muriatic acid, which has been considered a compound of some inflammable body with oxygen, combines with an additional portion of oxygen, forming the compound called oxy-muriatic acid. This substance was discovered by Scheele, and is obtained by adding oxvd of manganese to liquid muriatic acid: by applying heat a gas comes over exceedingly acid and pungent to the smell, having at the same time a disagreeable effect upon the lungs. When it is collected in a glass jar, it appears of a greenish colour. Its specific gravity is greater than that of muriatic acid gas, being to that of hydrogen as 30.75 to 1:100 cubic inches weigh 70 grams.

It is much less absorbable by water than muriatic acid gas, the water taking up not more than double its volume.

It supports combustion with most of the inflammable bodies. Several of the metals, as zinc, bismuth, copper, arsenic, and antimony, take fire when introduced to this gas in the flake of thin foil or fine powder. This gas, when accompanied with moisture, destroys the colours of vegetable substancess, and hence is employed for bleaching linen and cotton.

Chemists are at present divided respecting the nature of this substance, as well as the muriatic acid. In all probability.
MURIATIC ACID.

bility the disputed point may be settled in a short time, so that we may be able to give a more satisfactory account of it under Oxymuriatic Acid. We shall here give a brief detail of the facts and reasonings which have led to some new conclusions, but which we shall not venture to adopt, till we are in possession of an experimentum crux which shall leave but one opinion on the subject.

Since the celebrated discovery of potassium by Sir Humphry Davy, the French chemists, Gay Lussac and Thenard, have made some experiments upon muriatic acid gas, with a view to ascertain the component parts of the acid. In all these experiments, they were obliged to adopt one of the following conclusions, namely, that muriatic acid gas is either a compound of real acid combined with about one-fourth of water, or that the acid is a compound of hydrogen with oxymuriatic acid, the latter being regarded as a simple body of a nature similar to oxygen.

The following are the experiments which led to these conclusions. By passing muriatic acid gas over litharge, muriate of lead was formed, and a quantity of water produced. The same took place when oxyd of silver was similarly employed. The water was equal to about one-fourth the weight of the gas. Conceiving, from these facts, that muriatic acid gas was a compound of three-fourths of the real acid with one-fourth of water, they next made some experiments with a view to obtain the acid free from water. For this purpose, they applied the dry vitreous superfusephate of lime, and afterwards the vitreous boracic acid, to the dry muriates; but although they exposed them to a high temperature, no muriatic acid could be difengaged. If, however, a few drops of water were added, the muriatic acid instantly separated in the form of gas. Hence they found, that muriatic acid could not be separated from its compounds without the presence of water.

Their next object was to attempt to separate the oxygen from the oxymuriatic acid, and by that means get the muriatic acid free from water, as they had reason to believe that the former did not contain water. This object, however, they found of no less difficulty than the last. Metallic sublunacies were inefficient for this purpose, in consequence of their combination with the acid they wished to obtain. When they employed sulphur, they obtained a peculiar compound with the acid, and the sulphur which had before been discovered by Dr. Thomson, under the name of the sulphurred muriatic acid. Phosphorus also combined with the acid, forming a peculiar substance. Their next experiment was to pass oxymuriatic acid gas over red-hot carbon: at first some muriatic acid was formed, but ultimately they found that carbon had no effect upon oxymuriatic acid when no moisture was present. They further found, that when the oxymuriatic acid was brought in contact with sulphurous acid gas, with nitric oxyd, or with carbonic oxyd, no decomposition took place, except with the presence of water or hydrogen. In the whole of these experiments, the two hypotheses above-mentioned were equally applicable to explain the phenomena. The above chemists, however, were more inclined to give preference to the idea that muriatic acid gas is a compound of real acid with water, than that oxymuriatic acid is a simple body, which, when combined with hydrogen, constitutes muriatic acid.

Sir Humphry Davy, who has made some experiments, has explained the facts by the latter hypothesis, and appears so confident of its truth, that although few chemists of eminence are as yet decided on the subject, he has adopted it in his new work, with a new nomenclature relative to oxymuriatic acid and its compounds. The substance which is supposed to unite with hydrogen to form muriatic acid, is the same with oxymuriatic acid, and is called by Sir Humphry Davy chlorina. He represents it as a substance possessing many of the qualities of oxygen, particularly in its attraction for inflammable bodies. All those bodies which are deemed compounds of muriatic acid with the different saline bases, and free from water; or, in other words, all the dry muriates, are deemed by the above chemists compounds of chlorine with the inflammable bases. When muriatic acid gas is heated with a metallic oxyd, he concludes, that the oxygen of the oxyd unites with the hydrogen of the acid, forming water, while the chlorine thus liberated combines with the metal.

The compounds of chlorine with different inflammable bodies, have been named by Sir Humphry Davy agreeably to the names of the different bodies combining with chlorine. Its compound with sulphur he has called sulphurane; the same termination "ane" being applied to the name of the base in the other compounds of chlorine. The compounds which contain the second proportion of chlorine are named by the termination "ana" to the base, as "phospho- rana," the second compound of chlorine with phosphorus.

It would be worse than useless to give a further view of this theory. Its rejection or final adoption will, in all probability, take place before we come to the article Oxymuriatic Acid. Before, however, we quit the subject, we will make a few observations upon the relative grounds on which the two theories stand. This we will do by explaining several prominent facts on both principles. Sir Humphry Davy burnt eight grains of potassium in 22 cubic inches 8.69 grains of muriatic acid gas, which produced eight cubic inches (3 grains) of hydrogen. Now the .2 grains of hydrogen were, according to the new hypothesis, let free from the 8.69 grains of muriatic acid, hence the proportions in which they united are 43.1 by weight. Sir Humphry has since stated that this compound consists of equal volumes, or, according to the specific gravity of the gases given by this chemist, 33.1 by weight. But, according to the authority of Dalton, it would be 30 of oxymuriatic acid, and 1 of hydrogen.

In the above experiment, if we consider the .2 grains of hydrogen, produced by burning eight grains of potassium in muriatic acid gas, as refuting from water, it will follow that the oxygen which had been taken from the water by the potassium, was 14 grains. This would give 1.6 of water. If we consider potash as the protoxyn of potassium, then an atom of potash will be 35 + 7 = 42, and we shall have \( \frac{42}{1.6} = 8 \) atoms of oxygen, so that there is a difference of .2 grains of oxygen between the calculation and the experiment. Sir Humphry does not appear to have been correct in the experiment above given. The muriatic acid is in too great proportion for the exact formation of muriate of potash. Since, however, the same quantity of hydrogen would result from this or any greater proportion of acid, the quantity of hydrogen to the metal is nearly correct.

If muriatic acid gas be a compound of the real acid with water, the proportions cannot be less than 1 atom of acid to 1 of water, or 22 + 8 = 30. In order, therefore, that the potassium may be in such proportion to the acid gas that every may be saturated, the atom of potassium, which is 35, should be added to an atom of acid gas, 22 + 8 = 30. The oxygen of the water 7 will unite with 25 of potassium, forming 42 of potash. This unites with 22 of acid, forming 42 of muriate of potash, while 1 of hydrogen will be set free from the atom of water. If the above numbers be considered
ordered grains, the volume of the hydrogen will be equal to 40 cubic inches. Comparing this with the above experiment, we shall have \( \frac{35}{40} = \frac{8}{9.1} \), so that by calculation, on the idea that the acid gas contains an atom of water, 8 grains of potassium would afford 9.1 cubic inches of hydrogen, which is more by 1.1 cubic inches than in the experiment. Agreeably to this calculation, the quantity of muriatic acid gas to have been taken up exactly by 8 grains of potassium, would be about 17.4 cubic inches, or 6.86 grains. This would consist of 5.031 of acid, and 1.829 of water; 1.6004 of oxygen from the latter would combine with eight grains of potassium, forming 9.604 of potash, while 2.286 of 9.144 cubic inches of hydrogen will be evoked. The 9.604 of potash will combine with 5.031 of real acid, forming 14.6114 of muriate of potash. This added to 2.286 of hydrogen gives 14.86 grains, the original weight.

The above will very nearly agree with Sir Humphry Davy's account of the proportions of hydrogen and chlorine to form muriatic acid. In the last statement the acid is 6.86, conflating 5.031 of real acid, and 1.829 of water. When the hydrogen, which is 2.286, is separated, the 5.031 of real acid will combine with 1.6004 of oxygen, forming 6.0035 of oxymuriatic acid; the volume of which is 8.77. The volume of hydrogen in the same is 9.144 cubic inches. Sir Humphry states them to equal volumes, which is not far from the above numbers.

From these statements it will appear that both opinions agree in the fact, that an atom of oxymuriatic acid, and an atom of hydrogen, form an atom of muriatic acid gas. It is from this circumstance that the two explanations so exactly agree in all the experiments hitherto made.

The only thing in dispute as to real fact is, whether water is or is not a component part of muriatic acid gas. If the latter is not the case, the oxymuriatic acid is a simple body, and the view taken of it by Sir Humphry Davy must be adopted. If, on the contrary, the acid gas be a compound of an atom of water with an atom of real acid, then the oxymuriatic acid will as usual be considered as an atom of real muriatic acid with an atom of oxygen; or an atom of the acid gas with an atom of hydrogen, abstracted from the atom of water which it contains. When muriatic acid combines with any saline base, both parties would agree that a quantity of water would be the result, and the same quantity would be admitted by each. Those of the new opinion would say that the water resulted from the hydrogen of the muriatic acid, and the oxygen of the saline base. Those of the old opinion would account for the water from the acid gas giving its water when the real acid combined the oxy.

In all attempts to extract oxygen from the muriatic acid, the muriatic acid itself either disappears, or the oxymuriatic acid remains unaltered. Sir Humphry explains this fact by not allowing the existence of oxygen in oxymuriatic acid. Those who hold oxymuriatic acid to be a compound, would say that the muriatic acid would not give up its atom of oxygen, excepting an atom of water were present, to which the acid owes its gaseous form.

The only experiment in which the result can be unequivocal is, in uniting muriatic acid to ammonia, since the latter is the only false base which does not combine with oxygen. If the gases do not contain free moisture, the muriatic acid ought to combine with the ammonia, while the water of the acid gas is liberated. This experiment was made by Mr. Murray, in which he affirms that water is separated. The experiment has been repeated by Sir Humphry Davy, without producing any water, when the salt was not exposed to the air before examination. Mr. Murray has since made a second trial, with the caution of baking the salt before the gases from the atmosphere. Mr. Murray still insists that water is obtained from the salt by distillation. We hope by the time we have occasion to resume this subject, the experiment will have been made upon a larger scale, which will settle the point in dispute.

Dr. Henry has, on several occasions, tried the effect of electricity upon muriatic acid. Traces of hydrogen gas have been frequently found to be the result. This ingenious experimenter, from some recent experiments, has concluded, that when the gas is completely free from hygroscopic moisture, no hydrogen gas is produced. If, therefore, the muriatic acid contains water of combination, it is not within the influence of electricity.

MURIATTAH, in Geography, a river of Bengal, which runs into the bay of Bengal, N. lat. 21° 43'. E. long. 89° 38'.

MURIC, a town of Japan, in the island of Niphon; 75 miles S.W. of Meaco.

MURICHOM, a town of Bootan; 48 miles N. of Bhavar.

Gen. Ch. Male, Cal. the outermost large, inflated, obtuse, simple-flowered sheath. Perianth in five deep, awl-shaped, irized, coloured, spreading, equal segments. Cor. bell-shaped, of five ovato-lanceolate, ribbed, spreading petals. Stam. Filaments three, short, thick, triangular, dilated and connexed at the base; anthers three, or rather five, those on two of the filaments being double, with two divaricated lobes, arcuited at the base, the third simple, all distinct, with a pollen-bearing line at the outside.

Female, on the same plant, scattered. Cal. and Cor. as in the male. Fig. Germen between the sheath and perianth, oblong-ovate, villos; style round, thick, as long as the flamines, slightly three-echl at the top; stigmas three, horizontal, arrow-shaped. Peric. Berry large, ovate, muricated, of one cell. Seeds numerous, large, orbicular, reticulated, tuberculated at the edge.

1. M. cochinchinensis. Native of China and Cochinchina. A large climbing shrub, with a thick, woody, branched stem. Tendrils solitary. Leaves leaved, alternate, five-lobed, smooth, veinly, finely toothed; the three upper lobes pointed, the lower (or lateral) ones blunt and short. Flowers lateral, solitary, pale yellow, on long flanks. Berries of a reddish purple both within and without, rather fleshy, with brown seeds, imbedded in the pulp. Persimmon. Sheath green. The fruit has an impis fat, and no smell. It is used to colour wafers, cakes, or other eatables, of a fine purple. The seeds and leaves are reported by Loureir to have an opening and cleansing quality, removing obstructions in the liver and spleen, &c.

MURILLIO, Don Bartolome Esteban, in Biography, one of the most pleasing painters Spain ever produced. He was born at Plas, near Seville, in 1613, and having exhibited very early an inclination for the art, became a disciple of Juan del Cañillo, whose favourite subjects were fairs and markets;
markets; of which Murillo painted many pictures before he left him to go to Madrid. There he became known to, and favoured by, Velasquez, who enabled him to see the works of Titian, Rubens, and Vandyke, which were in the royal palaces, and the houses of the nobility. Of these he copied many, under the auspices of his friend, and having very much advanced himself in the knowledge and practice of his art, he returned to adorn the city of Seville with his performances.

This justly esteemed artist never went to Italy for his improvement, and the Spanish authors boast of this, forgetting that if Murillo did not visit that feat of the arts, at least he derived much of the excellence he polished from the works of its professors; he does not appear to have had to high a stamp of genius as to have advanced so far as he did without their assistance.

He was employed upon his return to Seville to paint for most of the principal churches there, and the pictures he produced, which were of subjects collected from holy writ, and the legends of the Romish calendar, were remaining in their original stations when the French so basely took possession of Spain. They, at least many of them, are most probably too good to have escaped transportation to Paris, that grand depot of plunder, where they cannot fail to receive their just portion of applause.

The style of Murillo is his own. He copied his objects from nature, but combined them ideally; that is, his backgrounds are generally confused and indistinct, and the parts very much blended together, with a loose pencil and indeterminate execution; but most of them have a very pleasing effect, and perhaps the principal objects acquire a degree of finish and beauty from this very circumstance. An instance may be recollected in his very pleasing picture of the good Shepherd, an excellent copy of which is at the markus of Stafford's gallery.

It was in small pictures of familiar life that this artist most completely succeeded, although the pictures above-mentioned in the churches of Seville are exceedingly large, 16 or 18 feet high some of them, and containing an immense number of figures, as is required in such subjects, as Christ feeding the Multitude, St. John preaching, St. Thomas giving alms to the Poor, &c. &c. In these pictures, skilfully wrought as they are, he does not appear to have penetrated the areana of grandeur or style; even his expressions are often of a mean character in the most dignified personages; but in the amiable and tender sentiments, which are expressed by the silent actions of the human features, he was eminently successful. His pictures capture very much by the gentleness and fineness of their colour, and the softness of the execution.

It was not only at Seville that Murillo's talents were called into action, Granada, Cadiz, and Cordova, each contained altar-pieces of his painting, and his smaller works were widely dispersed through the country. He enjoyed his renown to the advanced age of 72, when he died, universally lamented by those who felt any interest in the arts.

MURUO, in Geography, a town of Naples, in the province of Otranto; six miles N.E. of Alellana.—Also, a town of Naples, in Basilicata, the fee of a bishop, suffragan of Conza; 11 miles S.E. of Conza. N. lat. 40° 47', E. long. 15° 30'—Also, a town of Matera, containing a convent, a good hospital, and several chapels; abounding in all sorts of grain, fruits, vegetables, and a number of cattle.—Also, a mountain of Portugal, which forms a western boundary to the province of Trás los Montes.

MUROR, a town of Hindoostan, in the circuit of Mah; 38 miles N. of Neermul.

MURORUM DOMESTICUS. See DOMESTICUS.

MUROS, or Muroz, in Geography, a small sea-port town of Spain, in the province of Galicia, situated between Bayona and Corunna, upon the N. bank of a small gulf, formed by the mouth of the Tamba; on the other side is "Nya" and its fertile plain, where is one of the beautiful dock-yards of Galicia for the construction of ships.

MURPHY, Arthur, in Biography, a considerable dramatic writer, was born, according to his own account, which he extracted from his mother's prayer-book, at Clonquin, in the county of Roscommon, in Ireland, on the 27th of December, 1727. His father, Richard Murphy, who was a merchant, sailed, in 1729, in one of his own trading-vessels for Philadelphia, but the voyage was truly disastrous; the ship was lost, probably in a violent storm, and neither maller nor one of the ship's company were ever afterwards heard of. From this time the care of the subject of the present article devolved upon his mother. In 1733 she removed, with her children, to London. Arthur did not remain long in the metropolis, he was sent for to Boulogne by his aunt, Mrs. Blunkett, his mother's sister. At ten years of age he was placed in the English College at St. Omer's, where he remained five years; and was in 1744 dif-
milled to London, being then seventeen years old. In speaking of his college exercises, he says from the middle of the second year he obtained the first place, and, excepting three times, maintained his ground through five successive years. In the middle of the year in poetry, the young scholar found a public examination of the Arislaed by heart. The Jesuits were arranged in order; the rector of the college examined his pupil, and never once found him at fault: at the end of half an hour, the rector took a pen to write Murphy's eulogium. The scholars all went by assumed names, Murphy changed his to Arthur French; in reference to this, the words of the rector were, "Gallus nomine, Gallus es, qui simul ac alas expandis, creatores supervolantias". "This," says Mr. Murphy, towards the close of his life, "at the time filled me with exultation, and even now is remembered by me with a degree of pleasure. I often look back with delight to my six years' residence in the college of St. Omer, during that time I knew no object of attention but Greek and Latin, and I have thought, and still think it, the happiest period of my life." On his return to England, he refixed with his mother till August 1747, when he was sent to Cork, to an uncle, in whose counting-houfe he was employed till April 1749. After this his uncle, Jeffery French, would have sent him to Jamaica to overlook a large estate which he possessed in that island, but having very little taste for that sort of business he returned to his mother in London. This was in the year 1751. He soon became acquainted with the wits of the day, and in October 1752, he published the first number of "The Grey's Inn Journal," a weekly paper, which he continued for two years. On the death of his uncle, Jeffery French, he was much disappointed in not finding his name mentioned in his will, and the more so as he had contracted debts, in faith of a good legacy, to the amount of 100l. In this embarrassed state, at the advice of the celebrated Foote, he went on the stage, and appeared for the first time in the character of Othello. In one leafl, by the help of ill fortune, he paid off his debts, and had at the end of the year 100l in his pocket. With this sum he determined to quit the dramatic line.

In 1757, he offered himself as a student in the Middle Temple, but was refused admission, on the ground that he had been on the stage. He was at this time engaged in a weekly paper, called "The Tolf," undertaken chiefly in favour of Mr. Fox, afterwards lord Holland, which ceased on the overthrow of the administration to which his lordship was attached. Mr. Fox interested himself very much in the favour of Murphy, spoke in his behalf to lord Mansfield, and he was admitted, through his means, as a student in the Society of Lincoln's Inn. This was in the year 1757; he now attended the law in conjunction with other subjects more adapted to his taste, and which proved more profitable to him. In the beginning of 1758, he produced the farce of "The Upholterer," which was very successful, and which he modestly fays owed its prodigious success to the acting of Garrick, Yates, Woodward, and Mrs. Clive. Before the end of the same year he finished "The Orphan of China," which is founded on a dramatic piece, translated from the Chinese language, in Du Halde's "History of China." The representation of this play gave Mrs. Yates the first opportunity of displaying her theatrical powers, and confirmed her reputation as one of the most excellent actresses who have trod the English stage. His "Defeat Island," a dramatic poem, and his "Way to keep Him," a comedy of three acts, afterwards enlarged to five acts, the most popular of all his dramatic compositions, appeared in the year 1760. After Mr. Murphy had been called to the bar, he occasionally went the circuit, but not making the profession the object of his life, he never obtained much practice. A variety of other dramatic pieces, consisting of tragedy, comedy, and farce, successively proceeded from his fertile pen. For the ground-work of these he was generally obliged to a foreign original, but he never spared pains to fit them for the English theatre. To this sort of business he refers in his prologue to his "Zenobia."

"Not to translate one hard his pen both dips; They take a play, as Britons take a ship; They have her down; with many a lurdy stroke Repair her well, and build with heart of oak; To every breeze let Britain's Dreamers free, New maw her, and away again to sea."

"This," says one of Mr. Murphy's biographers, "is an ingenious illustration of the business of dramatic alteration, but cannot elevate it to the rank of original composition. Mr. Murphy's plays generally acted well, and had temporary success, but they made little addition to the true theatrical stock of the country." His farces still are acted, so also are his "Way to keep Him," and the "Grecian Daughter." At one period of his life, as we have seen, he engaged in the field of political warfare; he published several occasional poems, and gave Latin versions of some popular English poems; by the latter he obtained great credit as an elegant scholar. In 1786, he published his works collectively, in seven volumes, octavo. In 1792, he appeared as one of the biographers of Dr. Johnson, in "An Essay on his Life and Genius;" and in the following year he published a translation of Tacitus, in four volumes, quarto, dedicated to the late Edmund Burke. To this work, which is done in a respectable and even matterly manner, he has added "An Essay on the Life and Genius of Tacitus;" also, historical supplements and frequent annotations and comments. Mr. Murphy continued to write to an advanced age, and in 1798 he published his "Arminius," intended to excite the nation to measures of war, which he thought, to use the cant of politicians, "to be just and necessary." Through his interest with lord Longbrough, he obtained the office of one of the commissioners of bankrupts, to which, during the last three years of his life, was added a pension of 200l. a-year. Mr. Foote has given an interesting account of the close of Mr. Murphy's life, from which it appears he had perfectly reconciled his mind to the stroke of death: when he had made his will, and given plain and accurate directions respecting his funeral, he said, "I have been preparing for my journey to another region, and now do not care how soon I take my departure." On the day of his death, which was on the 18th of June, 1805, he frequently repeated the lines of Pope:

"Taught, half by reason, half by mere decay, To welcome death and calmly pass away."

Besides the works already mentioned and alluded to, Mr. Murphy was author of the Life of Garrick; and a translation of Sallust, from his pen has appeared as a polished work. He was a man of great urbanity of manners, and much regarded by his friends, whom, to the last, he used to entertain with anecdotes of the literary acquaintance of his younger years, related with humour and vivacity. Foote's Life of Murphy. Gent. Mag. Monthly Mag. MURR Islands, in Geography, a cluster of small islands, near the S. coast of Labrador. N. lat. 50° 33'. W. long. 59° 8'.

MURRA, a town of Arabia, in the province of Yemen; 10 miles N.W. of Zebid.

MURRA,
MURRAY, among the Ancients, a volatile substance, found in Parthia and Carmania, of a fine smell, and beautiful variety of colours.

It was thought to be some humour condensed in the earth by the heat of the sun. See Murrahine.

MURRA was likewise a dry perfume, made of the murra reduced to powder.

MURRAIN, GARGLE, a mortality, or contagious disea se among cattle.

Murrains are occasioned various ways, but principally by a hot, dry season; or rather by a general putrefaction of the air, which begets an inflammation in the blood, and a swelling in the throat, with other symptoms: the disea se soon proves mortal, and is communicated from one to another.

The symptoms are, generally, a hanging down, or swelling, of the head, rattle in the throat, short breath, palpitation of the heart, staggering, abundance of gum in the eyes, &c. breath hot, and tongue shining.

The most remarkable murrain we hear of, is that mentioned in the Philosophical Transactions; which spread itself through Switzerland and Germany, into Poland, &c. See Mist.

MURRAY, William, earl of Mansfield, in Biography, a distinguished lawyer and judge, the younger son of David, viscount Stormont, a peer of Scotland, was born at Perth, on the second of March, 1704—5; and at the age of three years was removed to London, where he received his early education. He was admitted a king's scholar at Westminster in the year 1719, and in a very short time distinguished himself by the excellence of his declamations, which were regarded as prognostics of that eloquence for which he was afterwards so much celebrated at the bar, and in both houses of parliament. He was admitted a student of Christchurch, Oxford, on the 18th of June, and in about four years he took his first degree, and in 1730 his degree of M.A., at which period he left the university. He had supported his classical reputation at college by a copy of Latin verses on the death of George I, and an elegant Latin oration in praise of Demoiselles. From Oxford he went to the continent, and spent some time in a tour through France and Italy, after which he entered himself at Lincoln's Inn, and engaged seriously in the study of the law. From the moment that he was called to the bar, he seems to have formed the idea of rising by the flow drudgery of common practice. He cultivated the talent and graces of fine elocution. In consequence of a display of his abilities in an appeal cause before the house of lords, he rose rapidly into fame and biffects. So sudden was the change, that he has been heard to say, he scarcely knew an interval between the want of employment and the receipt of 3000l. per annum. Mr. Murray at a very early period engaged the friendship of Pope, who left behind him several testimonials of his singular affection for this rising lawyer: he addressed to him an imitation of the first ode of the fourth book of Horace, in which he paints his friend as

"Noble and young, who strikes the heart
With every sprightly, every decent part."

The natural and acquired advantages which characterized the eloquence of Mr. Murray were so conspicuous, even on the spur of an occasion, and his perception so quick, as to enable him to fince upon any emergency; a circumstance of this kind occurred in 1737, when he was junior counsel in a considerable cause: his leader was suddenly seized in court with a fit; the duty of course fell to the lot of the junior, who wished to decline it for want of time to make himself master of the cause. The court adjourned for an hour, and with this short preparation Mr. Murray made so able and eloquent a defence, as not only to reduce the damages to a mere trifle, but to gain the reputation of a most prompt, perspicuous, and eloquent pleader. In 1738, there were fifteen or sixteen appeals heard and determined in the house of lords, in eleven of which Mr. Murray was engaged. Among the several interlocuting causes in which he was employed, one of great importance was that in the case of the provost and corporation of Edinburgh, for the punishment of whom, on account of misconduct in the case of captain Porteous, an act of parliament was framed. Mr. Murray, their counsel, opposed it in all its stages, and in both houses, and for his exertions he was presented with the freedom of the city of Edinburgh in a gold box. The chancery-bar was that to which he had hitherto confined his practice; but in 1742, his being raised to the office of solicitor-general, gave a wider scope to his professional talents. In this same year he took his seat in the house of commons as representative for Boroughbridge, and from this time he became the strenuous defender of the duke of Newcastle's ministry, and was frequently the speaker opposed to Mr. Pitt, who then began to distinguish himself in parliament. In 1746, he was called upon to take an active part against the rebel lords, and exerted all his talents on the occasion, particularly in the impeachment of lord Lovat, whose guilt he proved, but in so candid a manner, that he received the acknowledgments of the culprit himself. In 1754, Mr. Murray was promoted to the office of attorney-general; and in 1756, on the death of sir Dudley Ryder, he was raised to the high dignity of lord-chief justice of the court of king's bench, and at the same time was advanced to the peerage by the title and title of baron Mansfield of the county of Nottingham. From this period lord Mansfield may be considered as at the head of the judicature in this kingdom; "and although," says his biographer, "his conduct and principles have undergone severer censure in the violent party contents which have agitated the nation during the greater part of the present reign, yet his character seems permanently established, as one of the most able, the most eloquent, the most enlightened, and, in his legal capacity, separated from his political, the most upright judges who have ever occupied the bench. His behaviour towards the gentlemen of the bench, the finding of the counsel, was always courteous, obliging, and dignified, and no man was more attentive to the public accommodation in his dispatch of business. His quickness of apprehension, denoted by an eye of fire, enabled him at once to discover where the force of a case lay. This he stated with wonderful clearness, and placed in so striking a point of view, that he seldom failed to dispose the minds of the hearers to follow that impulsion which he wished to give them." It is much to the praise of lord Mansfield that he was uniformly a friend to religious toleration, and would probably, in the present day, have gone much farther than the ideas of mere toleration will carry a man; he would probably have concurred to blot out from the statute-books all laws that inflict punishment, or disability, on account of religious opinions. On various occasions he fet himself against vexatious prosecutions founded upon intolerant laws, and in the terrors' cause, as it is denominated, in 1767, he greatly distinguished himself by his sound and forcible reasoning in favour of the Protestant dissenters, whom the paltry politics of the corporation of London had habitually subjected to the fines for refusing to serve the office of sheriff, while they lay under the severe penalties of the telf and corporation acts should they have served without qualifying, by taking the incantation of the Lord's
Lord's supper in the church of England, with which they could not comply. His exposure of the tyrannical injustice of such a dilemma carried with it a conviction that put an end to the practice. In speaking of the reovation of the edict of Nantes, as introductory to perfections in France, his lordship said there was no occasion for that measure, "the suits needed only to have advised a plan similar to what is contended for in the present case; make a law to render them incapable of office; make another to punish them for not serving. If they accept, punish them (for it is admitted on all hands, that the defendant, in the cause before your lordships, is procutable for taking the office upon him): if they accept, punish them; if they refuse, punish them; if they say yes, punish them; if they say no, punish them. My lord, this is a most exquisite dilemma, from which there is no escaping; it is a trap a man cannot get out of; it is as bad a persection as that of Procrustes: if they are too short, stretch them, if they are too long, lop them."

It must be, however, be concealed, that lord Mansfield was, in politics, a favourite of high maxims in government, and directly hostile to those popular principles which were the subject of so much contentious in the early part of this reign. He maintained that the jury, in all cases of libel, were only judges of the fact of publication, and had nothing to do with the law as to libel or not; and in all the great causes concerning the liberty of the press, he ever attached himself to the court, so that, as it has been well said, "his conduct as a politician will probably not be dwelt upon by an encomiast, as that part of his public life which does him most honour."

In 1776, he was advanced to the dignity of an earldom, with the remainder to the Stermont family, as he had no issue of his own. At this period the popular disputes were subsiding, and he probably expected to wear his well-earned honours in peace, but the disgraceful riots in 1783 brought upon him a storm for which he was totally unprepared. Although the part he had taken in the liberal bill for the relief of the Roman Catholics was by no means conspicuous, yet, as the head of the executive justice of the kingdom, he was marked out for the attacks of a mob, who had, unquestionably, no other object than the subversion of all law and order. According to Murphy, whom we have lately noticed, his lordship made his escape, in disguise, before the flames blazed out. His house in Bloomsbury-square was, with all its furniture, pictures, books, manuscripts, and other valuables, entirely consumed by fire. He bore his calamity with great equanimity, and refused to take any steps for procuring a compensation for his losses. He once, in the house of lords, made a very pathetic allusion to it, when, having given his opinion upon a legal matter, he said, "I speak this not from books, for books I have none." No man was, in all respects, better qualified to enjoy the "odium cum dignitate" than lord Mansfield, yet he was not in haste to withdraw himself from scenes of buffoonery, and he continued on the bench till 1788, when he resigned his seat, having filled it with distinguished reputation for thirty-two years. A respectful and affectionate address from the bar, signed by all the counsel who had practised in the court of king's bench during the time he was on the bench, was transmitted to him by Mr. Erkine: in this address they say, "we desire, in this manner, affectionately to assure your lordship, that we regret, with a just sensibility, the loss of a magistrate, whose conspicuous and exalted talents conferred dignity upon the profession; whose enlightened and regular administration of justice made its duties less difficult and laborious, and whose manners rendered them pleasant and respectable."

Vol. XXIV.

The faculties of earl Mansfield still continued clear, though their vigour was abated, and he retained his recollection till within a few days of his decease, which took place without a groan, on the 20th of March, 1793, in the 89th year of his age. His remains were deposited in Westminster Abbey. The private virtues of lord Mansfield were universally acknowledged, and the singular amanity of his manners, in which vivacity and gaiety were tempered with elegance and decorum, rendered him the delight of all the social circles which he frequented. In his early years, he had undoubtedly been friendly to Jacobitical principles, but from his first entrance into public life, he suffered no symptoms of his original attachments to appear, excepting, perhaps, a certain bias always discernible through all the variations and vicissitudes of his political career, in favour of prerogative. His person was graceful, the tones of his voice exquisitely melodious, and his style of oratory clear, dignified, calm, and persuasive. Haliday's Life of Earl Mansfield, New Ann. Register, 1797. Purtzeaux's Letters to Mr. Justice Blackstone.

Murray, John-Andrew, a distinguished physician, was born at Stockton in the year 1745, in which city his father was preacher to the German congregation. His ancestors were a Scotch family, who had fled from their country during the usurpation of Cromwell, and settled in Poland and Prussia. He was carefully instructed in his early years by his father, and till the age of fourteen attended the German lyceum, where he studied the languages, history, philosophy, and the mathematics. He was afterwards put under the care of a private tutor, and in 1756 he removed to Upsal, and had the benefit of the instructions of Linnaeus, for whom he conceived the highest veneration and esteem, which continued through life; and with whom he subsequehtly maintained an uninterrupted literary correspondence.

In 1759 he took a journey through the southern provinces of Sweden, and thence to Copenhagen, with a view to extend his acquaintance with natural history; and in 1760 he proceeded to Gottingen, where his brother, John Philip, was professor of philosophy. Here he returned his studies with great industry, and devoted some time to the English, French, and Italian languages. In 1763, he took the degree of M.D., and by a special licence from the Hanoverian government, gave lectures in botany: and, in the following year, he was appointed extraordinary professor of medicine in that university. From this time his reputation rapidly extended: he was elected a member of the Academy of Sciences at Stockholm in 1768, and of the Royal Society of Gottingen in 1770; and, in the course of a few years afterwards, of most of the learned societies in Europe. In 1769 he was appointed to the actual professorship of medicine, and made doctor of the botanic garden. Linnaeus had already honoured him by giving the name of Califda Murrayi to an insect which he had discovered; and in 1771 he gave the name of Murraya exotica to an East Indian tree. Professor Murray was full farther honoured by receiving the title of the order of Vafa from the king of Sweden in 1780; and by being raised to the rank of privy-councilor by his Britannic majesty in 1782. In the beginning of 1791 he was attacked with a purulent perineum, from the effects of which the lungs never recovered, and which ultimately proved fatal, on the 23d of May in that year, when he had attained the age of fifty-one.

Murray was a man of sound judgment, great activity and industry, and extensive information. He constantly roved early, and laboured till a late hour in his closet, unless prevented by his avocations in the botanic garden. Hence he was enabled to compose a number of tracts, on various subjects, in botany.
botany, natural history, medicine, pharmacy, and medical literature. His principal work, however, was on the subject of the materia medica, and had occupied a large portion of his time and attention. It was published at different times, and entitled "Apparatus Medicinum, tam simplicium quam preparatorum et compositorum, in Praxedis adiumentum consideratur," and consists of six volumes, octavo.

This work was the object of his anxiety and attention, until the day before his death, when he corrected part of the tenth sheet of the sixth volume, and confounded the completion of it to his friend and physician Dr. Altorf. Among his other productions, are, "Opera in quibus Commentationes variarum, tam medicarum quam ad Rem naturalem spectantes, restructavit, emendavit, auxit." vol. i. Gott. 1785; ii. 1786.

"Commentatis de Hepaticis, maxime Indis Orientalis," ibid. 1788.

"Spina bifida mala officium conformatiae initia," ibid. 1785.

"Retriu Prime Lineae Pharmaciae," translated from the Swedish, 1771.

"Rosenlein's family dictionary," translated from the same, Leipzig, 1781. In the Transactions of the Royal Society of Gottingen, are inserted many valuable papers of professor Murray's, chiefly relating to the most remarkable plants cultivated in the botanical garden; and his descriptions are deemed models of elegance and accuracy. Gen. Biog.

MURRAY Frith, in Geography, a large bay of the German sea, on the E. coast of Scotland, and S. of the county of Murray, whence its name: anciently "Ritinarium Varivars."

MURRAY Harbour, a harbour on the E. coast of the island of St. John, in the gulf of St. Laurence. N. lat. 46° W. long. 62° 20'.'

MURRAY's Islands, several small islands on the S.W. coast of the island of Kirkcudbright, at the mouth of Fleet-bay; 11 or 12 miles N.N.E. of Burrow Head.

MURRAY Townshend, a township of Upper Canada, in the county of Cumberland, lying northward of the illusmus which joins the county and peninsula of Prince Edward to the Main. It is washed by the waters of Lake Ontario and the river Trent, as well as those of the bay of Quinte.

MURRAYA, in Botany, originally written MURR critique, was named by Koenig in honour of John Andrew Murray, an illustrious Swede, knight of the order of Vafa, and professor of botany at Gottingen, born in 1742, and who died in 1791. (See Murray.) He was the author of several tracts on natural history, and enjoyed so much of the confidence of his great preceptor Linnaeus, as to be entrust with him by the editing of the 13th edition of the Systema Vegetabilium. He likewise published the 14th edition of the same work, after his author's death, in 1784. It is to be regretted that in the execution of his task, he did not follow the original principles of Linnaeus, in introducing the new genera from the Supplementum and other sources. These are disposed by Murray according to their technical characters, and not their natural affinities. Although this was subsequently found to be the same plant as the Linnaean Chalcas, the latter name has been universally allowed to give way to that of Murraya. —Linn. Mant. 554. Schreb. 284. Wild. 1. M. exotica. Ash-leaved Murraya. Linn. Mant. 563. Murray in Comm. Gotting. v. 9. 186. t. 1. (Mariae bursula; Sonnerat. Ind. Or. v. 2. t. 139).—A native of the East Indies, and introduced at Kew in 1771, where it flowers in August and September. This is a shrub or small tree, about six feet in height, whose trunk is branched, and covered with a greyish bark. Leaves alternately pinnate, composed of three pairs of leaves, with an odd one; leaves alternate, on short stalks, ovate, blunter, rigid, smooth, resembling those of the common Buxus, whence its French appellation Buis de Chine. Flowers corymbose, white, somewhat like an orange-flower, but about half the size; their scent is said to be somewhat like that of Jasmine, but by no means powerful. Berries globular, pointed, tubercled, red. Seed large, whitish or pale draw-coloured. This plant is extremely well figured in Rumph. Amboyn. v. 29. t. 18. f. 2, under the name of Communium japonicum. Loureiro also, in his Flora Cochinchinensis, 271, describes it as Chalcas japonica. We are unable to discover what is meant by the name author's Chalcas paniculata.

MURRAYSHIRE, or ELGIN, in Geography. See Morayshire.

MURRE, in Ornithology, a name given in some parts of England to the razor-bill. See AUKA.

MURRECOW, in Geography, a town of Hindooftan, in Benares; 14 miles S. of Jionpour.

MURREY, in Heraldry, a kind of purple colour, called azo jargon.

MURRTHINA, in Antiquity, a kind of sweet medicated wine.

MURRINE, MURRINUS, MURRINEN, an appellation given to a delicate sort of ware, brought from the East, of which cups and vases were made, which added not a little to the splendour of the Roman banquet.

Critics are divided concerning the matter of the pecula, or Sib murrhina, murrina, or murrea. Some will have them to have been the same with our porcelain, or china-ware.

The generality hold them to have been made of some precious kind of stone; which was found chiefly, as Pliny tells us, in Parthia, but more especially in Carmania. Arrian tells us, that there was a great quantity of them made at Diospolis in Egypt. This he calls another sort of murrina work; and it is evident, from all accounts, that the murrina of Diospolis was a sort of glas-ware, made in imitation of the porcelain or murrha of India. There is some difference in the account given by Pliny and Martial of the murrina vafa. The first author says, that they would not bear hot liquors, but that only cold ones were drank out of them. The latter, on the other hand, tells us, that they bore hot liquors very well. If we credit Pliny's account, their porcelain was much inferior to our's in this particular. Some conjecture them to have been of agate, others onyx, others of coral. Barony, doublets, was farthest out of the way, when he took them to be made of myrrh, concealed and hardened. Some have supposed these vessels to be made of crystal, but this is contrary to the account of all the ancients.

The Greeks had the words μυρρίνα for myrrh, very common among them, and therefore
if thee vessels had been made of either of these substances, they would in some places have called them simyra or cryyllina. On the contrary, the most correct among them call them murrhina, or murrhea. The cups made of cryylla, which were also in use at those times, were called cryyllina, and these murrhina or murrhea, by way of keeping up the distinction; and Martial tells us that the flower they were made of was spotted and variegated, calling them PASCO maculojes murra. And Statius mentions the cryyllline and murrhine cups in the same sentence, but as different things, not the same. Arrian mentions also the aulos meijis, which his interpreters conferee as an error of the copies, and would alter into myrrha, the name of the gum myrrh.

Pompey is recorded as the first who brought these murrhine vessels out of the East, which he exhibited in his triumph, and dedicated to Jupiter Capitolinus. But private persons were not long without them. So fond, in effect, did the Roman gentility grow of them, that a cup which held three sextaries was sold for seventy talents. T. Petronius, before his death, to spite Nero (or as Pliny expresseth it, ut nefam ejs exsperedaret, to dishonour his table), broke a baton, trulla murrhina, valued at three hundred talents, on which that emperor had set his heart.

MURROBATHRARI, among the Romans, a kind of perfumers. See Murra.

MURTEZABAD, in Geography, a town of Asiatic Turkey, in Natalia; 12 miles N. of Angura.

MURTHER, or Murder, the act of killing another with violence and injustice.

The word is derived from the Saxon "murth, death;" which some will have to signify a violent death; whence the barbarous Latina murdurn, and mordrum.

Among the number of popular errors, is the notion which has obtained, that the dead body would bleed in the presence, or upon the touch of the murderer.

The crime of murder is punished with death in almost all nations.

MURTH, or Murder, in our Law, is that species of criminal homicide, which denotes a wilful and felonious killing another upon premeditated malice, whether secretly or openly, and whether Englishman or foreigner living under the king's protection.

In order to constitute the crime of murder, it must be committed by a perfon of sound memory and discretion: for a lunatic and infant are incapable of committing any crime. Besides, the unlawfulness of this crime arises from the killing without warrant or excuse; and there must be also an actual killing to constitute murder; and this may be by poisoning, striking, striking, drowning, and a thousand other forms of death; the most detestable of which is poison, because it is the least capable of being prevented either by mankind or forethought. There was also, by the ancient common law, one species of killing held to be murder, which is hardly so at this day, nor has there been any instance in which it has been held to be murder for many ages past. i.e. by bearing false witnesses against another, with an express premeditated design to take away life, so that the innocent person be condemned and executed. The Gothic laws punished in this case the judge, the witnies, and the prosector; and, among the Romans, the lex Cereaia, de Siniarios, punished the false witnes with death, as being guilty of a species of afflication. If a man does such an act, of which the probable consequence may be, and eventually is, death; such killing may be murder, although no stroke be inflicted by himself. In order to make the killing murder, it is requisite that the party die within a year and a day after the stroke received, or cause of death admitted; in the computation of which, the whole day upon which the hurt was done shall be reckoned the first. Further, the person killed must be a reasonable creature in being, and under the king's peace, at the time of the killing; and, therefore, to kill an alien, a Jew, or an outlaw, who are all under the king's peace or protection, as much murder as to kill the most regular born Englishman, except he be an alien-enemy, in time of war. To kill a child in its mother's womb, is now no murder, but a great misfortune; but if the child be born alive, and death be the reason of the poison or bruises it received in the womb, it is murder in such as administered or gave them. But as there is one case where it is difficult to prove the child's being born alive, namely, in the case of the murder of baillard children by the unnatural mother, it is enacted by 21 Jac. I. c. 27, that if a woman be unlawfully and wilfully, or in any such unlawful manner, which, if born alive, should by law be a baillard, and endeavours privately to conceal its death, by burying the child, or the like, the mother, or offending shall suffer death, as in the case of murder, unless she can prove, by one witnesses at least, that the child was actually born dead. But it has been usual, upon trials for this offence, to require some sort of presumptive evidence, that the child was born alive, before the other constrained presumption, that the child, whose death is concealed, was therefore killed by its parent, is admitted to convict the prisoner. Moreover, the killing must be committed with malice aforethought, to make it the crime of murder; and this malice premeditated may be either express or implied in law. Express malice is, when one, with a sedate, deliberate mind, and formed design, doth kill another; which formed design is evidenced by external circumstances discovereth that inward intention; as lying in wait, antecedent menaces, former grudges, and concerted schemes, to do him some bodily harm. This takes in the case of deliberate dwelling. Also, if upon a sudden provocation, in an angry, enmity manner, so that he doth, though he did not intend his death, yet he is guilty of murder by express malice. Such is also a person going deliberately with a harne used to strike, or discharging a gun, among a multitude of people. So if a man resoloves to kill the next man he meets, and does kill him, it is murder, although he knew him not; for this is universal malice. And if two or more come together to do an unlawful act against the king's peace, of which the probable consequence might be bloodshed; as to beat a man, commit a riot, or to rob a park, and one of them kills a man, it is murder in them all, because of the unlawful act, the motuus praegetitum, or evil intended beforehand. Further, the law will imply malice in many cases where none is expressed; as, where a man wilfully poisoneth another, though no particular enmity can be proved; and in the case of a man's killing another suddenly, without any, or without a considerable provocation. Thus also, if one kills an officer of justice, in the execution of his duty, or any of his assistants, knowing his authority, and the intention with which he interposes, the law will imply malice, and the killer shall be guilty of murder. And if one intends to do another felony, and unawaresly kills a man, this is also murder. In a word, we may take it for a general rule, that all homicide is malicious, and amounts to murder, unless where justified by the command or provocation of the law; excepted on a principle of accident or self-preservation; or alleviated into manslaughter, by being either the involuntary consequence of some act, not strictly lawful, or (if voluntary) occasioned by some sudden and sufficiently violent provocation.

Formerly, murder was restrained to a clandestine and treacherous killing. Thus, *Murdatus homo antiquitus N. X 2* dicetur.
dicebatur, cujus interfecto neciebatur ubicunque, vel
quomodocunque effet inventus. Nunc adjunctum eff, licet
seiatur quis murdrum fecerit, homocidium per pridieonem.”
Leges Hen. 1. “Arthurum nepotem propriis manibus per
pridieonem interfect, pellimo mortis genero, quod Angli

The punishment of murder, and that of manslaughter,
were formerly one and the same, both having the benefit
of clergy; to that none but unlearned persons, who left knew
the guilt of it, were put to death for this enormous crime.
But now, by 23 Hen. VII. c. 1, and 1 Edw. VI. c. 12,
the benefit of clergy is taken away from murder through
book iv.

MURTHEW, Appeal of. See Appeal.
MURTHEW, Self, is otherwife called suicide. See Felo
de fe.

MURTHERS, or MURThRINO-Pieces, are small
pieces of ordnance, either of brass or iron, having chambers
put in at their breeches.

They are mostly used at sea, at the bulk heads of the
fore-castle, half-deck, &c. in order to clear the decks,
when an enemy boards the ship.

MURTY, or MURT, a word, among Hindoos meta-
physicians, meaning a form, an appariion, image, or idol.
It denotes any show or appearance assumed by a celestial
being. According to the Vedanta theory (see Vedanta)
our vital souls are murti, or images merely of the Supreme
Spirit. Homer describes the idol of Hercules in Elyfium,
with other deceased heroes, though the god himself was at
the fame time enjoying bliss in the heavenly mansions.
The Hindoos theory, in like manner, would describe such a murti,
as not susceptible of affecting with any lufation, either
pleasing or painful, the being from which it emanated; though
it may give pleasure or pain to collateral emanations from
the same source. Hence they offer no sacrifices to the
Supreme Essence, of which our souls are images or murtis,
but adore him with silent meditation. (See Yaj.) Oblia-
tions are made to fire, and acts of worship performed to
the sun, the stars, the earth, and the powers of nature, which
are confidered as murtis or images, the fame in kind as our
selves, but transcendently higher in degree. This difficulf
subject is discussed by Mr. Wharton, in vol. iii. of the Asiatic
Researches. The Hindoo triad is called Trimurti, (see
that article,) literally tri form.

[From the latter part of the article JEFURY, reference is
made to Murty; but it is a mistake. Murl is the word
and article intended.]

MURU, in Geography, a sea-port town of Japan, in the
island of Nipon: it has a narrow but safe harbour, fenced
by a mountain; 75 miles S.W. of Meaco.

MURUA, a town of Hindoollan, in Oude; 33 miles
N. of Kairabad.

MURUCUIA, in Botany, according to Maregrave,
book 2, chapter 11, is the Brazilian name for ivy, and is
therefore borrowed by him and others for certain climbing
plants, better known under the denomination of Passiflora,
or Passion-flower. From theo however Tournefort, Inft.
241. t. 125, and Jutt. 398, separate one species, on ac-
count of the inner crown of the nectary being tubular and
undivided. This is Passiflora Muruncia of Linnæus. See
Passiflora.

MURVIEDRO, in Geography. See Morvidro.

MURVILLE, a town of France, in the department of the
Herault, and chief place of a canton, in the district of
Beziers; 6 miles N.N.W. of it. The place contains 1550,
and the canton 6427 inhabitants, on a territory of 1874
kilometres, in 11 communes.

MURZAROLT, in Falconry. See Falcon
MURZINEI, in Geography, a town of Russia, in the
government of Tobolfs, on the 1rufch; 40 miles N.N.W.
of Tara.

MUS, a town of the island of Sardinia; 5 miles W. of
Cagliari.

Mus, in Zoology, a genus of quadrupeds of the class
Mammalia, and order Gires. The generic character is
fore-teeth upper wedged; grinders three, rarely two, on
each fide the jaw; clawies perfect. The whole genus is
characterized as living in holes, or any concaved chinks,
climbing and running twifly; some of them swim. They
seek their food by night, which is chiefly vegetable, and
which they convey to the mouth by the fore-paws. The
females have molely eight teeth, breed several times in
the year, and bring forth numerous litters. Some of them
migrate; their ears are short and rounded; the fore-feet are
usually four-toed, with a warty excrefcence instead of a fifth.
There are forty-six species, divided into five families, &c.
A, having the tail compressed at the end; B, tail round,
naked; C, tail round, hairy; D, cheeks pouched; and E,
earles, eyes small, tail short, or none, subterraneous. This
numerous tribe constitutes a formidable phalanx, against
which mankind find it necessary to employ various artifices
of exftirpation, in order to leffen the ravages occasionally
suffered by its depredations. In our own island, the black
and brown rats, the ffield and domefic mice, are the prin-
cipal destroyers; but in other parts of Europe, as well as
in the hotter regions of Asia, Africa, and America, many
other species, still more formidable, are found.

A. Tail compressed at the End.
Species.

COYPUS; Beaver Rat. Tail middle length, sub-com-
pressed. hairy; hind-feet palmate. It inhabits the waters of
Chili. In appearance and colour it resembles the
otter, but in its teeth it agrees with the rat tribe; it is
easily tamed. The female produces five or fix young at a
birth.

ZIBETHICUS; Musk Rat. The tail of this species is
long, comprifed, lanceolate; feet eleft. It is found in the
flow streams of North America, on the banks of which it
builds, but more timely than the beaver. It feeds on
shellfish, in summer on fruits and herbs, in winter on roots,
particularly on flags and water-lilies. The female has fix
tears, and brings from three to fix young at a time, and
three or four times in a year. It swims and dives de-
terously, walks unfeadily, and is a foot long. About the
anus of this rat are glands that fecrete a mofty oily fluid:
hence it derives its trivial name.

B. Tail round, naked
Species.

PILORIDES; Musk Cavy. Tail long, scaly, truncate;
body white. A variety of this species has its body tawny,
behind white. The firft inhabits India; the fecd is
found in the Weft India islands. It burrows, infeds houfes,
smells of muflk, is the fize of a rabbit, and the tail is four
inches long.

CARACO. Tail long, scaly, bluntpif; body grey; hind-
feet firmly palmate. It is found in the waters of Eastern
Siccris and China; burrows on the banks, swim well, fre-
quenfs houfes, and is about fix inches long. The head of
this
MUS.

This species is long and narrow; the eyes are nearer the ears than the nose; toes of the hind-feet connected by a fold of skin, the back is brown, mixed with grey; the tail about four inches and a half long.

Decumanus; Norway Rat. Tail very long, scaly, brilliantly grey above, white beneath. This species inhabits India, Persia, and has been of late years imported into Europe. It burrows in the banks, swims well, migrates in vall armies, and does infinite mischief; frequents houses, stables, gutters, gardens, granaries; feeds on vegetables, and likewise on animal substances, and even on its own tribe. It is hunted by the dog, cat, and ferrets. The female breeds thrice in the year, and brings from twelve to eighteen young at a time. In the East Indies they burrow under the foundations of houses, and cause much to fall.

Rattus; Black Rat. This species is supposed to have come originally from the East. Its tail is very long, scaly; its body is black, and beneath hoary. Its general length, from nose to tail, is about seven inches, and of the tail eight inches. The colour of the head and whole upper part of the body is a dark iron, or blackish-grey; the belly is of a dull ash colour; the legs are dusky, and very lightly covered with hair; the tail is nearly naked, coated with a scaly skin, and marked into numerous divisions or rings. Like the decumanus, it breeds frequently, and brings forth about seven or eight young at a time. Sometimes they increase so fast, as to overlook the place of their abode; and in this case they fight and devour each other; on this account, these animals, after having been very troublesome, sometimes suddenly disappear. Various have been the methods adopted for the expulsion of rats from the places which they frequent; among these we shall notice that mentioned by Genier, who says, if a rat be caught, and a bell be tied round its neck, and then set at liberty, it will drive away the evil. Its greatest natural enemy is the weasel, which pursues it into all its recesses, and destroys it. There is a variety much smaller, scarcely weighing an ounce. This is found about the deferts in the lower part of the Wolga.

Americanus; American Rat. Tail long, scaly; head long; nose pointed; upper jaw much longer; ears large and naked. It is found in North America, among stones and clefts remote from habitations; sometimes larger than the rattus. The body is of a deep brown; the belly paler; the hair coarse.

Musculus; Mouse. This species has a long tail, which is rather naked; fore-feet four-toed, hind-feet five-toed; thumb without a claw. It inhabits houses and granaries in Europe, Asia, and America; follows mankind; eats all kinds of provisions, drinks little; is gentle, timid, quick, and very prolific. It is devoured by rats, cats, weasels, owls, and hedge-hogs; is destroyed by elder and hellebore; is about three inches and a half long; varies much in colour, and is said to possess some trifling electrical properties, white alive.

Silvatius; Field Mouse. Tail long, scaly; body yellowish-brown, beneath white; breast yellow. A variety is entirely white; eyes are red. Inhabits Europe, in woods, fields, gardens, shrubberies, and in housetops in the winter; feeds on corn and seeds, which it collects in large repositories; it gnaws through the hardest planks; is devoured in its turn by hawks, foxes, and weasels.

Messonianus; Harvest Mouse. Tail long, scaly; body rufous-brown, belly white, a straight line dividing the colours. This is found in many parts of England, chiefly in Hamp-shire; is something smaller than the silvaticus; never enters houses, but is found in numerous fields during harvest, hence its trivial name; burrows deep in the ground, forms a bed of dry grass, is carried with the sheaves of corn into barns; the tail is a little hairy.

Agrarius; Rusty Mouse. Tail long, hairy; body yellowish; dorsal stripe black. This is found in Russia and Sileia, rarely in Germany; it is gregarious, and wanders about in large troops, doing great injury to the corn. There is a variety that has a dorsal stripe, mixed dusky, and ferruginous; cheeks, between the ears, and sides orange; the under parts, legs, and feet pure white. It is found in New York.

Minutus; Minute Mouse. Tail long, scaly; body above ferruginous, beneath white. It inhabits Russia, and lives in corn-fields and in barns. It is not above half the size of the common mouse; the female is still smaller, less elegant; the face is dusky; mouth at the corners whitish. A variety, found in Siberia, is very beautiful; above elegantly yellow, beneath snowy.

Soricinus; Shrew-like Mouse. The tail is of about the middle length, a little hairy; snout lengthened; ears round, hairy; above yellowish-grey, belly whitish. It is a native of Strauburg, where it was first discovered by professeur Hermann. It has seven rows of whiskers; its claws are very short; tail yellowish, mixed with cinereous, more hairy beneath.

Vagus; Wandering Mouse. Tail very long, naked; body cinereous; dorsal stripe black; ears plain. It was first discovered by Dr. Pallas. It is found throughout the whole of the Tartarean desert, but particularly inhabits the rivers Ob and Ural; lives in the cellars of rocks, among stones, in hollow trees; feeds on seeds, and leffer animals; wanders in flocks, and leaps in winter.

Betulius; Beech Mouse. Tail very long, naked; body tawny; dorsal stripe black; ears plain. This, as its specific and trivial names import, inhabits beech woods, in the deferts of Ithim and Baraba, and near the Oby; lives solitary in the hollows of old trees; climbs easily, is very delicate, and soon growing torpid. In ascending the branches of trees, it coils round the twig with its tail, in the manner of an opossum. Dr. Pallas informs us, that he has often observed it ascending the trunks of some strong gracles, which were scarcely bent by its weight. He also kept several of them a considerable time, which grew tame, and delighted in being held in the hand.

Pumilio; Dwarf Mouse. Tail middle length, and rather naked; body of a dark ash colour; forehead naked, black; four dorsal-lines black. It inhabits the forests east of the Cape of Good Hope. This is one of the least of the genus, being little more than two inches long from nose to tail. It was first described by Sperman.

Striatus; Oriental Mouse. Tail longish and nakedish; the body has twelve rows of parallel white spots. It inhabits India, and is only half the size of the common mouse. The body is dusky, but whitish beneath; tail is of the same length as the body; the ears are short, round, naked.

Barbarus; Barbary Mouse. Tail middle length; body brown, with ten pale stripes; three toes before, and four behind. It is a native of Barbary; is less than the common mouse; the tail is naked, annulate, the length of the body.

Mexico; Mexican Mouse. A large reddish spot on each side the belly. It inhabits, as its name denotes, Mexico; and its colour is whitish, mixed with red.

C. Tail
C. Tail round, hairy.

**Species**

**VIRGINIANUS;** Virginian Mouse. Tail entirely hairy, thick at the base, long, tapering. Inhabits North America, and lives in corn-fields and pastures. The body is white; nose black pointed; ears sharp; limbs slender.

**SAXATILIS;** Rock Mouse. Tail longish; ears longer than the fur; fore-feet three-toed, with the appearance of a fourth. It is found in Siberia, in the clefts of rocks, and feeds chiefly on the seeds of the alpine grass.

**CYANUS;** Blue Mouse. Tail of the middle length, rather hairy; the fore-feet have four toes, and the hind-feet five; the body is blue, but the under part is white. It inhabits Chili. In size and appearance it resembles the field mouse; very timid, forms large burrows divided into many chambers, collects vast stores of bulbous roots, which the natives search carefully after.

**AMPHIBIUS;** Water Rat. Tail middle length; ears held above the fur; the feet are three-toed, with the appearance of a fourth. There are four other varieties: 1. Tail a little hairy; fore-feet three-toed, with the appearance of a fourth; hind-feet five-toed; ears shorter than fur. 2. Black; in structure resembles the last. 3. Uniformly blackish. 4. Back with a large white spot; on the breast a white line. Inhabits Europe, Northern Asia, and Northern America. It frequents rivers and stagnant waters, and forms its burrows in the banks. It is of a thicker and shorter form than many others of this genus, and has somewhat of the shape of a beaver. The water rat is about seven inches long, and its tail about five. Its colour varies much with the climate in which it is situated, being sometimes nearly black, and sometimes paler than usual. It also varies in size, and the varieties above described have been mistakenly confused as distinct species. It never frequents houses, but confines its haunts to the banks of rivers, and is supposed to live on fish, frogs, &c. and probably on various roots, and other vegetable substances. The flesh of this species has sometimes been eaten. The female is smaller and of a lighter colour than the male; she has eight teats, four pectoral and four abdominal, and brings eight young at a time.

**ALLIARIUS;** Garlic Mouse. Tail short; ears large, and a little hairy; body cinereous, beneath whitish. It inhabits Siberia; feeds on the roots of garlic, which it hoards up in large quantities.

**RUTILUS;** Red Mouse. Tail short; ears longer than the fur; fore-feet three-toed, with the rudiments of a fourth; body above reddish, beneath whitish. It also inhabits Siberia; lives in holes and hollow trees, in winter in the cavities of corn, in granaries, and in houses. It feeds on grain, flesh, and roots; runs all the winter among snow, and is about three inches and a half long. The feet are hairy, white; tail above yellowish, with a brown stripe, beneath white; scarce an inch in length; its face is bristly.

**GREGALES;** Gregarious Mouse. Tail short; ears longer than the fur; fore-feet three-toed, with the rudiments of a fourth; the body greyish. It inhabits the eastern parts of Siberia; burrows in dry fields, with many holes leading to chambers, where are deposited stores of roots, chiefly of the garlic and the lily.

**OECONOMUS;** Economic Mouse. Tail short; ears shorter than the fur; fore-feet three-toed, with the rudiments of a fourth; the body is brown. It inhabits Siberia, especially the eastern parts, and Kamtschatka, in vast numbers. It is said to have been found in the arctic circle. This species was named **economic mice,** from their very curious mode of living. They inhabit damp soils, and forage, finding many chambers and entrances. In these chambers they lay up stores of provisions, collected with great pains in summer, from various plants, which they bring out of their holes in hot sunny weather, that they may the more effectually dry and preserve them. In certain years, they make considerable migrations out of Kamtschatka; they collect in the spring, and go off in incredible multitudes. They proceed in a direct course, and suffer nothing to impede their course, not even rivers and the arms of the sea. Many of them, in their pailage across the water, fall a prey to the fish, but on land they are safe; for the inhabitants of Kamtschatka have a superstitious veneration for them, and are so far from hurting them, that if they find any of them lying in the road, exhausted through fatigue and hunger, they afford them every assistance in their power. On their return from their migration, express letters are sent to all quarters of the country with the joyful tidings, because their arrival is considered as a fore-prognostic of a successful chase and fishery; and they are said to lament their departure, which is usually succeeded by tempestuous and rainy weather.

**LAINERG;** Woolly Mouse. Tail of the middle length; fore-feet four-toed, hind five-toed, body cinereous, woolly. Inhabits the northern parts of Chili; it burrows, is cleanly, docile, tame; feeds on bulbous roots, chiefly onions; female bears young twice in the year, and five or six at a time. The ears are small, acute; snout long; the hair is long and soft, and was formerly used by the Peruvians instead of the finest wool.

**ARVALIS;** Meadow Mouse. This species has a large head; a blunt nose; short ears hidden in its fur; prominent eyes and a short tail; the head and body are ferruginous, mixed with black; the belly is of a deep sih-colour; feet dicky; it is six inches long. It is an European mouse, and is found in great abundance in Newfoundland, where it does much mischief in the gardens. In this country it makes its nest in moist meadows; brings forth several young at a time, and several times in the year. It refires under ground, and lives on nuts, seeds, and corn.

**SICALIS;** Social Mouse. Tail short, ears round, and very short; fore-feet three-toed, with the rudiments of the fourth; body pale, beneath it is white; inhabits the sandy deserts between the Wolga and the Ural rivers, in families of male and female with their offspring; feeds much on tulip and other bulbous roots; is the prey of crows, otters, and weasels, and is a little more than three inches long.

**LAGERUS;** Hare-tailed Mouse. Tail shorter even than the fur; the fore-feet three-toed, with the rudiments of a fourth; body cinereous, with a longitudinal black line. This species is found in the sandy and muddy deserts on the Ural and Irtych, each mouse in a round burrow; it migrates in great swarms; feeds chiefly on the dwarf iris, and on the smaller species of mice; it is flow in its motions, sleeps much when it rolls itself up, but it is not torpid in the winter; brings forth several times in the year, and five or six at a time. It is a very fierce animal.

**TORCATUS;** Collared Mouse. Tail short; ears shorter than the fur; fore-feet five-toed, body rufus, variegated; round the neck a whitish collar; a dark line along the back. It inhabits the Uralian mountains, and reaches the frozen sea; feeds on lichens and bulbous roots, which it hears in its burrows; it migrates in troops, and is three inches long.

**LEMUS;** Lemming. Tail short; ears shorter than the
fur; fore-feet five-toed; body tawny varied with black, beneath white; whiskers long, six hairs on each side longer than the rest, upper lip divided; ears small, round, reflected, belly white, tinged with yellow; there is a variety smaller, and more uniformly tawny. It inhabits Siberia; burrows in the ground; lays up stores of provisions for the winter: this variety does not migrate; but the migrations of the other variety have long rendered it celebrated in the annals of natural history. The lemming differs in size and colour according to the regions which it inhabits, those which are found in Norway being almost as large as water rats, while those of Lapland and Siberia are not much larger than the field mouse. The colour of the Norwegian kind is an elegant variegation of black and tawny on the upper parts, disposed in patches and clouded markings; the sides of the head and under parts of the body being white; the legs and tail greyish. In the Lapland kind the colour is chiefly a tawny-brown above, with indistinct dusky variegations, and beneath of a dull white, the claws are smaller than those of the Norwegian animal. The natural residence of the lemming is in the mountainous parts of Lapland and Norway, from which it is frequently absent. It is also a frequent visitor in the Faeroes, inhabited by a small species of this genus. In their usual mode of life they are not observed to be of a social disposition, but to reside in a scattered manner, in holes beneath the surface, without laying up any regular provision, like some other animals of this genus. They are said to breed several times in the year, and to produce five or six at a time.

Hudsonius; Hudson's Mouse. Tail short; no ears; hind-feet five-toed; dorso-stripe brownish-yellow; breast and belly yellow. It inhabits Labrador, and is about five inches long. The body is chiefly cinereous, a pale tawny stripe along the sides; tail terminated with long stiff dirty-white hairs; the feet are short.

Lena; Lena Mouse. Tail short, covered with coarse hair; toes four before and five behind, the body is white. Inhabits the banks of the river Lena, whence it derives its name, and is about three inches long.

D. Cheeks pouched. Species.

Acredula; Siberian Hamster. Ears plaited; body grey, beneath whitish. It is found in Siberia, near the river Ural. It is about four inches long; lives in burrows, seeks food by night. Snout thick, upper lip deep-divided; the upper fore-teeth are yellow, convex, truncate; the lower are sharp; the tail is short, round; brown above, white beneath; it is only an inch long, and its legs are white.

Cricetus; German Hamster. Body beneath deep black; the sides have each three white spots. A variety of this is entirely black, except the tip of the nose, edges of the ears, and feet, which are white. Of the pouched rats, this is the most remarkable, and the only European species provided with those peculiar receptacles, which are situated on each side the mouth, and when empty, so far contracted as not to appear, but when filled resemble a pair of tumid bladders, having a smooth veiny surface, concealed, however, under the fur or skin of the cheeks, which bulge out extremely in this state. The hamster inhabits Siberia, and the south of Ruffia; it is also found in Poland, as well as in many parts of Germany. They are very destructive in some districts, devoured great quantities of grain, which they carry off in their pouches, and deposit in their holes, in order to devour during the autumn. Their habits, which they dig to the depth of three or four feet, confit of more or fewer apartments, according to the age of the animal; a young hamster makes them fearedly a foot deep, and the old sinks them to the depth of four or five feet, and the whole diameter of the residence, taking in all its habitations, is sometimes eight or ten feet. The principal chamber is lined with dried grass, and serves for a lodging; the others are defiled for the preservation of provisions, of which the animal amasses a large quantity in the autumn. Each hole has two apertures, the one defending obliquely, the other ascending in a perpendicular direction, and it is through the latter that the animal goes in and out. The hamster feeds on all kinds of grain, herbs, and roots, and when driven to it, on smaller animals. In harvest time, we are told, it makes excursions for provisions, and carries every article it can find into its granary. To facilitate the transportation of his food, nature has provided him, as we have seen, with pouches on the outside: these are membranous, smooth, and shining, and in the inside are many glands, which continually secrete a fluid, that preserves their flexibility, and enables them to refill or to keep the grain dry. It is the growth of these glands which is called sharpness of the grain, which might occasion the approach of winter, the hamster retires into his subterraneous abode, the entry of which he shelters with great care, and that remaining in a state of tranquillity, feeds on his collected provision, till the frost becomes severe, at which period he falls into a profound slumber, that grows into a complete torpitude, so that the animal continues rolled up with all its limbs inextensible; its body is perfectly cold, and without the least appearance of life. Anatomists have examined it in this state; have opened it, and found the heart alternately contracting and dilating, but with a motion so exceedingly slow, as to be scarcely perceptible; though in the waking state of the animal it beats 150 pulsations in the same time. In this state the fat of the animal has the appearance of being coagulated, its interines cannot be excited by the application of the frongell stimulants; and the electric shock may be passed through it without effect. The waking of the hamster is a gradual operation; he first loses the rigidity of his limbs, then makes profound inspirations, at long intervals; after this he begins to move his limbs, and utters a sort of unpleasing rattling sound. After continuing these operations some time, he at length opens his eyes, and endeavours to rise, but reverts about some time, as if in a state of intoxication, till at length, after roaring a small space, he perfectly recovers his usual powers. There seems to be no sort of society excited among the hamsters. They are naturally fierce, and make a desperate defence when attacked; they also pursue and destroy every animal which they are capable of conquering, not excepting even the weaker individuals of their own species. It is recorded by M. Sulzer, that they abound to such a degree in Gothia, that in a single year, more than 80,000 of their skins were delivered in the Hotel de Ville of that capital, upon which a premium was paid, on account of the enormous devastations which these animals commit among the corn.

Arenarius; Sand Rat. Body above cinereous, beneath on the sides and limbs snowy. It inhabits Barbary; is characterized as fierce and untameable; it burrows, and feeds, by night, on leguminous plants and seeds. The head of this animal is large; the snout long; whiskers longer than the head; the fore-feet are four-toed; the hair soft; and the creature about 3½ inches long.

Phurus; Zaryan Rat. Body and tail dark cinereous; beneath white. It inhabits the deserts of Siberia, and the mountains of Persia; it devours fields of rice, does not become
come torpid, and is about 3½ inches long: This, by Shaw and other naturalists, is denominated the Asian mole, on account of its abode, Zaryzn, which is near Afracan; it is occasionally taken in the winter season about stables and other out-houses. It is also found about the Persian villages in the Hyrcanian mountains, and was first distinctly described by Dr. Pallasi.

Songari; Songar Rat. Back cinerous, with a longitudinal black line, sides variegated white and brown; belly white. It inhabits the sandy deserts of Siberia, burrows and forms repositories for grain, is easily tamed, and is three inches long. The tail is thick, blunt, and hairy; the whiskers shorter than the head, ears longer; the feet are white.

Furunculus; Barbara Rat. Body grey above; dorsal stripe black; beneath whitish. It inhabits the deserts of Barbara, near the rivers Ob and Dauria; is three inches long. It is of a yellowish-grey colour above, and white beneath. It feeds on farinaceous seeds.

E. No Ears; the Eyes very small; Tail short, or perhaps none; Subterraneous.

Species.

Talpinus; Talpine Mole-rat. The body of this species is brown, tail short; fore-teeth wedged; no ears; fore-feet five-toed, formed for digging. There is a variety entirely black. It inhabits the turfy plains of Russia; forms chambers under the fod, in which it deposits various bulbous roots; is not torpid in winter; fights weak in the day; brings three or four young at a time, and is about 3½ inches long. The nose is truncate; the eyes hidden in the fur; chin white; belly and limbs whitish. In the winter it sometimes makes its nest beneath a hay-rick, at a considerable distance below the ground.

Capensis; Cape Mole-rat. Tail very short; fore-feet wedged; no ears; fore-feet five-toed, mouth white. The head is rounded; hair longish, brown, tip with yellow; orbits and nape of the neck white; ears with a longitudinal white spot; inner toe short, the two next long, fourth shorter, outer very short; five inches and a half long. This, as its name imports, is an inhabitant of the Cape of Good Hope; it is exceedingly destructive to gardens, flinging up hillocks, and eating various kinds of roots.

Martinius; African Mole-rat. The tail of this species of rat is short; upper fore-teeth furrowed; it has no ears; the feet are five-toed; body above whitish, mixed with yellowish, sides and belly grey-white. The head is large, the nose is black, flattened, and wrinkled at the end; lower fore-teeth long, and it has the power of separating these at pleasure, after the manner of a kangaroo. This large species is a native of the Cape of Good Hope, and is there known by the name of the land mole, being chiefly found in the neighbourhood of the shores, and never in the interior parts of the country. It makes the ground, in the places it inhabits, so hollow, by flinging up the earth, in forming its burrows, as to be highly inconvenient to travellers; breaking every six or eight minutes under the horse's feet, and letting them up to their shoulders. It feeds on bulbous roots, runs very slowly, digs its chambers with great rapidity, bites extremely hard, is very good eating, and is about a foot long.

Aspalax; Daurian Mole-rat. Tail short; fore-teeth wedged; no ears; claws of the fore-feet long. This species, in form and manner of life, agrees with the M. typhlus, which will be next noticed, but is in general smaller, and of a yellowish shade; the head is flat and broad, the body short and somewhat depressed, the limbs very strong, especially the fore-legs; the feet of which are large, naked, and well adapted for burrowing in the ground. It is a native of the Altaic mountains, and of the country beyond lake Baikal; it differs considerably in size in different regions; those of the Altaic mountains sometimes measuring nearly nine inches in length.

Typhlus; The Blind Rat. This species has no tail; fore-feet five-toed; fore-teeth broad; and without eyes or external ears. This is one of the largest and most remarkable of the whole tribe, being, as we have observed, entirely destitute of eyes and tail; the defect of the former is thought to be a very singular circumstance, and the animal perhaps affords the only instance of a truly blind or eyeless quadruped. In the mole, the eyes are small and deeply seated, they are nevertheless perfect in their kind, though not at all calculated for acute vision; but they are enough to enable the animal to avoid the danger of exposure; but in the blind rat, there is merely a pair of sub-cutaneous rudiments of eyes, smaller than poppy-seeds, and covered with a real skin. It inhabits southern Russia; each animal forming a long burrow under the turf; it feeds on bulbous roots; when irritated, it gashes its teeth and bites very hard; in lieu of eyes, the feathers of the tail, touch, and hearing are very acute.

Mus Alpinus, a name given by many authors to the mountain-rat, more commonly known by the name of the marmotte.

Mus Arabicus. See Shrew.

Mus Marinus. See Anthodon.

Mus Norvegicus, in Zoology, the name given by authors to the Norway rat, commonly called the lemming. See Sable Mouse, and Mus.

Mus Pharaonis, Pharaoh's rat, a name given by the people of Egypt to the ichneumon, a creature of the weefel kind, which they are very fond of for its destroying ferrets, and kept tame about their houses, as we do cats.

Mus Terreæ, in Botany, a name given by some authors to the roots of the bulbocastanum, or earth-nut; it was probably at first turris terreæ radix, the earth-mouse's root, and so called from the earth-mice or field-mice being very fond of them; but the word radix being left out, it stands only terreæ.

Mus Tagi, in Geography, a mountain of Tartary, which, in Strahlenberg's map, runs parallel to the Belur on the E. See Belur.

Gen. Ch. Col. a number of partial sheaths, on a simple common stalk, each ovate-oblong, rather concave, large, alternate, containing many flowers. Perianth none. Cor. superior, unequal, ringent, the petal constituting the upper lip; the nectary the lower. Petal cret, bilugate, abrupt, five-toothed, its two sides meeting at the base. Nectaries of one leaf, heart-shaped, boat-like, compressed, pointed, shorter than the petal, and infected with its nectar, spreading outwards. Stam. Filaments fix, awl-shaped, five of
MUSA.

of them within the petal, erect, the sixth within the nectary, reclining; anthers linear, longitudinally attached from the middle of the filament to its summit, some of them, in one flower or another, imperfect. 

Fili. Germen inferior, very large, bluntly triangular; style cylindrical, erect, the length of the petal; stigma capitellate, roundish, with five or six toothed, often frothy. Berry pulpy, with a coriaceous coat, with three or six flat angles, gibbous at one side, of one cell, spongy or hollow in the centre. Seeds numerous, imbedded in the pulp, roundish, roughish, excavated at the base.

Obf. The flowers about the lower part of the common stalk or receptacle, have usually five of the anthers abortive, or altogether wanting, that of the sixth flamen only, which accompanies the nectary, being perfect; while in most of the upper flowers the reverse is the case, five of their flaments being perfect, and the sixth incomplete; their pili also is smaller in all its parts, and abortive. These therefore are, in effect, a fort of male flowers, and the former female. Such being the case, this genus has fearely the proper characters of the class Polygonia, but rather thoef of Monocotyledons. Considering the partial and variable imperfection of the organs, all as they are both present in all the flowers, Myrt ought rather perhaps to be referred to 

Heliconia. In natural affinity it is nearer the Scitamineae than any other order, the chief difference being, as Juffieu observes, in their flaments.

Eff. Ch. Calyx a many-flowered sheath, of one leaf. Petal one, ligulate, five-toothed. Nectary of one leaf, opposite to the petal. Berry inferior, with many seeds. Most of the flaments abortive in some flowers, pili in the others.

1. M. paradisiaca. Plantain Tree. Linn. Sp. Pl. 1477; (M. caudicis viridis, fructu longiore facetate angulofo; Trew. Ehret. 3. t. 18. 19. 20. Muza; Rumph. Amb. v. 5. book 8. t. 125. t. 60. Ger. em. 1515. Bala; Rheedem Malab. v. 1. 17. t. 12, 13, 14.)—Flower-stalk drooping. Male flowers permanent. Fruit oblong. Native of the East Indies. Cultivated every where within the tropics, for the sake of its fruit, which makes a principal part of the vegetable food of the inhabitants, and is almost infinitely variable in quality, like our apples. Notwithstanding its size, which is that of a moderate tree, this can be considered only as an herbaceous plant. The root is perennial. Stems erect, unbranched, 12 feet or more in height, 10 or 12 inches in diameter, round, smooth, spongy, and succulent, flowering but once, which, in hot countries, usually happens the second year, after which it dies down to the root. In our flowers it will often remain many years without flowering, but after that event, the fern always dies. Leaves numerous, about the top of the stem, oblong, entire, several feet long and one broad, with a strong midrib, and innumerable transverse parallel veins; they are quite smooth, easily torn, rather glaucous and opaque. Flower-stalk terminal, solitary, bent almost perpendicularly downward, several feet long, bearing numerous alternate tufts of flowers, each accompanied by a fine purple deciduous flower. The petal is often striped with red. Fruit eight or nine inches long, 1½ thick, green, with a sweet, mealy, pale-orange pulp. Such at least Ehret describes, and such we have seen ripened at Sion house, under the care of Mr. Hoy. No seeds are found in the cultivated plant.

2. M. sapientum. Banana Tree. Linn. Sp. Pl. 1477; (M. caudicis maculato, fructu recto rotundo brevirostro odorato; Trew. Ehret. 4. t. 21, 22, 23.)—Flower-stalk drooping. Male flowers deciduous. Fruit ovate. This is now usually considered as a variety of the former, the characters on which its supposed specific difference was founded, being to all appearance accidental. The fern is spotted.

The fruit of this, as well as of the former, roasted before it is quite ripe, is used as bread.

3. M. tropidolytarum. Wild Plantain Tree. Linn. Sp. Pl. 1746. (M. uranocephalus; Rumph. Amb. v. 5. book 8. t. 61. f. 20.)—Flower-stalk erect. Native of the Molucca islands. This seems to be the true wild flate of one or both the former. Rumphius says, the fruit can be eaten when roasted only, being rather acrid when raw, and that it contains abundance of seeds. We apprehend some mistake in Gartner respecting this being a Heliconia; see his v. 1. 30.

4. M. occinea. Scarlet Plantain Tree. Andr. Repof. t. 37. Redout. Liliac. t. 307, 308.—Flowers capitate, erect. Sheaths ovate, permanent. Stamens five. Native of China. Said to have been at first introduced into the British flowers by T. Evans, eqq. of Stepney, about the year 1792. This is of much more humble growth than any of the foregoing, and remarkable for the rich scarlet colour of its flowers, which are imbricated and permanent, forming a cone-like head. The lowermost of them often ends in a leaf. Redouto very justly observes, that these scales ought to be called bracteas, and not to be considered as a calyx. This author, as well as Mr. Andrews, describes five flaments only in each flower, all alike perfect in some, abortive in others.

For MUSA BIAHAI of Linneas, see HELICONIA.

MUSA, in Gardening, comprehends plants of the perennial kind for the hot-houfe, of which the species cultivated are; the plantain tree (M. paradisiaca); and the banana tree (M. sapientum).

Of the second fort a very excellent drink is made from the juice of the ripe fruit fermented, resembling the bell Southam cyder.

Each of these species has several varieties.

And it is observed by Brown, that "these two fruits are among the greatest blessings bestowed by Providence upon the inhabitans of hot climates." As "three dozen plantains are sufficient to serve one man for a week instead of bread, and will support him much better." Method of Culture. — These plants may be increased by planting the young suckers of the roots of such plants as have fruited, taken off carefully with root-fibres, in large pots filled with light rich earth, and plunged in the tan-bed of the flove, in the summer season. They afterwards require to have water given pretty plentifully in the hot summer months, but more sparingly in the winter, and in less proportions at a time. They succeed best in about the same degrees of heat as the pine apple. The pots should be increased in size as they advance in growth.

But the best way to have them fruit well in this climate is to shake them out of the pots, after they have become fully established, with the balls of earth about their roots, and plant them in the tan-bed in the flove, old tan being laid round their root-fibres to strike into. When new tan is added, care should be taken not to disturb their roots, and always to leave plenty of old tan about them, to guard against too much heat. They should have water twice a week in winter, about two quarts each plant at a time, and in summer twice as much at a time, and every other day. The signs of perfecting their fruit, are their pushing out their flower-items in the spring. The flowers should be sufficiently high for this purpose, as twenty feet or more.

In their native country, these trees thrive best where the soil is rich, cool and moist. Their fruiting in the South
Sea islands is said to be promoted by the use of lime and wood-ashes.

These plants are mostly cultivated here by way of curiosity and for variety.

Musa, in Geography, a town of Arabia, in Yemen, which is a kind of market for fruit and fowls to Mocha. The town is populous, and surrounded with walls; 18 miles E. of Mocha.

Musa, a river of Saxonv, which runs into the Elbe, near Mefflen.

MUSACCHIA, a town of European Turkey, in Albania; 26 miles S.S.E. of Albasano.

Musa, in Botany, the first natural order of the fourth class in Jussieu's system. The character of that class is to have the feed monocotyledonous, and the flamenes inserted upon the germen. The latter are definite in number. Germen (of course) inferior; styles either solitary, or wanting, rarely numerous; stigma simple or divided. Fruit of one cell or many, pulpy or capular.

The Musa are thus defined. Calyx (corolla of Linnaeus) superior, deeply divided into two parts, which are either simple or lobed. Stamens six, standing on the germen; some of them occasionally barren or abortive. Germen inferior; style; stigma simple or divided. Fruit of three cells, with one or many seeds in each. Circulam in the cavity of the farinaceous albumen.

Stem herbaceous or arborecent, often clothed with the theathing bafes of the footstalks. Leaves alternate, theathing, convolute when young, furnished with a simple longitudinal rib, which sends off innumerable transverse, or obliquely parallel veins. Flowers accompanied by stigmas, and disposed in alternate tufts, along a stalk originating from the centre among the leaves.

This order conficts of Musa, from which its name is taken; Heliconia; Strelitza; and Ravana of Adanson, which is Urania of Schreber. It differs from the Scitamineae, (Jussieu's Canne), chiefly in having six flamenes, instead of one flamen with the nutlings of two others, which are pointed out by Mr. Brown, Prodr. Nov. Holl. v. 1. 305. See Scitamineae.

MUSEUS, in Geography, is more celebrated by ancient writers as a philosopher, astronomer, epic poet, and priest of Ceres, than as a musician; however, he lived in to remote a period, and has so far survied his contemporaries, that he is one of the few melancholy remains of his age, of which poerty has cherifhed the memory; he therefore cannot, without injustice, be omitted: for whoever looks into the ingenious and well-digested biographical chart of Dr. Priefley, will find Linus, Orpheus, and Museus, placed in such barren regions of history, that, like the once beautiful cities of Palmyra and Balbec, they now stand in a defert; but great and exalted characters are buoyed up by time, and reit the stream of oblivion, which soon sweeps away all such as have not eminently dilignified themselves.

Museus, according to Plato and Diodorus Siculus, was an Athenian, the son of Orpheus, and chief of the Eleusinian mysteries, instituted at Athens in honour of Ceres; or, according to others, he was only the disciple of Orpheus; but from the great resemblance which there was between his character and talents, and those of his master, by giving a sligter outline to the figure, he was called his son, as those were ityled the children of Apollo, who cultivated the arts, of which he was the titular god.

Museus is allowed to have been one of the first poets, who verified the oracles. He is placed in the Arundelian marchers, Epoch 15, 1426. B.C. at which time his hymns are there said to have been received in the celebration of the Eleusinian mysteries. Laecritius tells us, that Museus not only composed a theogony, but formed a sphere for the use of his companions; yet, as this honour is generally given to Chiron, it is more natural to suppose, with Dr. Isaac Newton, that he enlarged it with the addition of several constellations after the conquest of the Golden Fleece. The sphere itself shews that it was delineated after the Argonautic expedition, which is described in the afterins, together with several other more ancient histories of the Greeks, and without any thing later: for the ship Argo was the first long vessel which they had built: hitherto they had used round ships of burthen, and kept within the shore; but now, by the dictates of the oracle, and consent of the princes of Greece, the flower of that country sail rapidly through the deep, and guide their ship by the stars.

Museus is celebrated by Virgil in the character of Hicrhopant, or priest of Ceres, among the most illustrious mortals who have merited a place in Elysium. Here he is made the conductor of Anes to the reeds, where he meets the shade of his father, Anchises.

A hill near the site of Athens was called Museum, according to Paufanias, from Museus, who used to retire there to meditate, and compose his religious hymns, and at which place he was afterwards buried. The works, which went under his name, like those of Orpheus, were by many attributed to Onomacritus. Nothing remains of this poet now, nor were any of his writings extant in the time of Paufanias, except a hymn to Ceres, which he made for the Lycomedes. And as these hymns were likewise set to music, and sung in the mysteries by Museus himself, in the character of a priest, he thence perhaps acquired from future times the title of musician, as well as of poet, the performance of sacred music being, probably, at first confined to the priesthood in these celebrations, as it had been before in Egypt, whence they originated. However, he is not enumerated among ancient musicians by Plutarch; nor does it appear that he merited the title of fon and successor to Orpheus for his musical abilities, so much as for his poetry, piety, and profound knowledge in religious mysteries. But notwithstanding the numberless testimonies come down to us from the belt and molt ancient writers of Greece and Rome, concerning Linus, Orpheus, Musaeus, Volfinus, in the name of system and invention, of an etymologist, as well as from an ambition of being thought deeply versed in the Eastern languages, particularly the Phcenicin, pretends to resolve those names, which have been known and revered by all antiquity, into words signifying things, not persons: as Linos, a song; Mofa, art, discipline; Orpheus, scientific. But if this fancy were generally practised upon ancient authors, there would be little chance of one among them cepung annihilation.

Museus, another of the same name, called the Grammarian, author of a Greek poem on "The Loves of Hero and Leander," is supposed to have lived as late as the fourteenth century, since he is not referred to by any of the older scholars, and none of his verses appear borrowed from the Dionysiacs of Nonnus. Nothing is known of him personally, yet his work is in a pure and elegant style, with much delicacy of sentiment. It has been frequently reprinted, both in collections and separately.

MUSACATTA, in Geography, a town of Portugal, in the province of Beira; nine miles S.S.W. of Toere de Moncorvo.

MUSAGETES, in Mythology, the appellation of Apollo,
MUS

Apollo, as the conductor of the Muses. The same name was also given to Hercules.

MUSALI, in Hindoo Mythology, a name of one of the Ramas. (See RAMA.) The word musali is derived from the large wooden pestle used for separating rice from the hulk. This pestle is called wenjih, and in images and sculptures is seen in the hand of Bala Rama, indicating that, as well as a warrior, he was also a benefactor to mankind. In his hand a plough is also sometimes seen, and one of his names, Halayuddha, or plough-armed, is thence derived; also Haladhara, or the plough-bearer: more correctly, perhaps, Haladhar; like Gauadharra, or Murlidhara, as mentioned in the article MURL.

MUSANO, in Geography, a town of Italy, in the Trevisan; five miles W.N.W. of Treviso.

MUSART, or MASEURT, a snowly ridge of mountains, which passes south in Aficatia Russla from Bogdo Alim, and is supposed to join the mountains of Thibet. This may possibly be the Alak, (Alak Ul, or Alak Tag,) which joins the Belur Tag. It is said to give rife to the rivers Sir or Sihon, and the Talas.

MUSAY, a town of Hungary; 10 miles from Munkacz.

MUSCA, the Fly, in Entomology, a genus of insects of the order Diptera, of which the generic character is as follows: mouth with a soft exserted fleshy proboscis, and two equal lips; sucker furnished with bristles; feelers two, but very short, and sometimes none at all, antennae generally short. About 550 species are described by Gmelin: these are divided into two families, viz. A, with two short feelers; and B, without any feelers. The latter, however, includes only eleven species of the vast number already mentioned. These grand seotions are again separated into still smaller divisions. Thus the family A is divided into six seotions, and that of B into two.

The vast extent of this genus, according to Dr. Shaw, makes it necessary to divide the whole into different affections, in order to the more ready investigation of the properties of the species. These divisions, (which answer to Gmelin's subdivisions,) are intituled from the form of the antennae, which are either fimple, without any lateral hair or plume; or armed, that is, furnished with a lateral hair or plume. The subdivisions, or seotions, are still farther divided, as we shall see in the enumeration of the species, into others, according to the more or less downy or hairy appearance of the insects.

Although the number of known species in this genus is so very large, yet it is probable it bears no sort of proportion to the number that is still unknown, or that, at present, has not been arranged under specific characters. Mr. Harris, in his English Entomology, has described a greater number of species than Linnaeus enumerated as existing in the world; but England is not the country that is likely to be most productive of this insect. The southern countries of Europe afford a much greater variety of species than those that are more northern; in hot climates, in general, they are always numerous, and, in a multitude of instances, they multiply to a degree that is almost intolerable. The different species are extremely diversified in their external form, structure, their organization, their metamorphosis, their manner of propagating their young, and in providing for their holiness. A full explanation of these different parts of their economy would require a large volume, which is incompatible with the limits prescribed to our work.

Some of these insects have trunks instead of a mouth; others have that organ armed with teeth; and many have a mouth and a trunk. The proboscis of flies is a machine contrived for extracting the blood from the vesseis of large animals, and the nectar from the petals of flowers; and the use of hydraulics has not enabled men to construct machines more exactly arranged, or better adapted to these purposes. Some of these pollefs considerable firmness and solidity, those especially that are destined to pierce the skins of cattle. In order to tie them at work, expose a syrup to attract them, and then take a lens for the inspection.

Each eye of the fly contains in it an assemblage of a vast number of small ones, which has, perhaps, the effect of multiplying the surrounding objects, and creating representations of them, which the experience of the insect corrects. From the eye, if we pass on and survey the body, we find it provided with the organs of respiration. Four flagmata, for this purpose, are found upon the thorax, and a greater number distributed over the annuli of the abdomen. The coverings of the different parts of the abdomen are scaly, and do not consist of one piece, but admit of the contraction and dilatation of that part, according to the circumstances of the animal. Each of the feet terminates in a small bunch of hairs resembling a brush.

The interior organization of this genus, when examined with a proper apparatus, presents two pulmonary faces of a white colour, arranged longitudinally along the body. The action of the heart may also be discerned, as well as the liquor it contains, continually driven along the great artery leading to it, and returning by the same course. During their larval state, flies go through a greater variety of metamorphoses than even the filk or butterfly-worms: in their progress from the vermicular to the chrysalis state, they pass through a change unexperienced by other insects. From the floritum of their lives, all these vicissitudes must rapidly succeed each other: this circumstance does not prevent many species from containing a cocoon for their last metamorphosis, of a curious fabric. The greater part of these cocoons are of silk, with a mixture of other materials; those most common with us satisfy themselves with their own skin, which becomes an incrusted covering to protect them during their dormant state.

When the different members have acquired sufficient firmness, the fly is ready to burst from its shell in its winged form. The covering of the chrysalis, especially of those that are metamorphosed in their own skin, would seem by its hardness an effectual bar to that event. About the time, however, of its change, the head of the fly is capable of being swollen and dilated in an unusual manner; and it is by means of this dilatation that the fly bursts its covering, and opens a passage for its escape.

The food of flies is, as we shall see, as various as their different kinds; some being supported wholly by vegetable substanccs, while others are carnivorous; and among the latter there are some that only devour flies in a state of purification.

The female flies are all fecundated by copulation; an act in which the most inattentive observer must have frequently seen them engaged. The far greater part of insects are oviparous; some, however, belonging to this genus bring forth living young. Many of the viviparous flies possess a degree of fecundity that must appear altogether incredible to those who have not been conversant in the study of insects. Some of them have been found to contain in their body no less than twenty thousand living animals at one time. We now proceed to a description of the species enumerated by Gmelin.

Yy 2  A. With
MUSCA.

A. With two short Feelers.

§ a. Sucker with a single bristle, without sheath; antenna short, clavate, furnished with a lateral hair.

† Hair of the Antennae feathered.

Species.

**JEJUNA.** The colour of this fly is cinereous; abdomen pubescent, with three black belts; the legs are pale. It inhabits Tranquebar. Thorax and femur dusky, with a paler margin; antenna subferruginous; legs pale, with black tarsi.

*Meridiana.* This is an European insect, found in our own country. It has been described and figured by Harris in the work already referred to. It is hairy and black; front golden; wings ferrugineous at the base. There is a variety that has a faint rufous spot at the base on each side of the abdomen.

*CARNARIA.* This is hairy, black; thorax with paler lines; abdomen shining, and tesselate. It is found in almost all parts of Europe, in putrid carcases and meat.

The Musca carnaria, or the common large blow-fly, as every one knows, deposits its eggs on animal flesh, either fresh or putrid. The larve, or maggots, hatch in a few hours, and, when full grown, which happens in eight or ten days, are of a white, or yellowish-white colour, with a flight tinged of pale-red, and of a lengthened shape, with a sharpened front, in which the mouth is situated, and from this the body gradually enlarges in size to the last segment, which is of a very broad and flattened form, surrounded by several slightly prominent tips, and furnished with a pair of specks resembling eyes; so that an inaccurate spectator might easily mistake this part for the head, and the proper head for the tail. When the animal changes to a chrysalis, the skin dries round it, and the whole assumes an oval form, and a reddish colour, soon changing into a reddish-brown. In ten days more the fly itself emerges, which is too well known to require particular description.

**CARNIVORA.** Dusky; abdomen blue, subferruginous; the segments edged with black. This is found very common in Germany, in putrid meat. The head is black, mouth ferruginous; thorax and femel hairy, blackish, without lines, legs black.

**LARDARIA.** Black; thorax and abdomen tesselate. This also is found in Germany: it is less than the M. carnaria; the abdomen is subglobular, obtuse, and the legs are black.

**RUFICORNIS.** This is hairy and cinereous; thorax with black lines; abdomen tesselate; the antenna are rufous. Found in the East Indies. The head is cinereous, with a black line on the crown; the thorax has three black lines, the middle one reaching down the feutel.

**RUTILANS.** Thorax cinereous, with black lines; abdomen tesselate, the tail rufous. This species is found in South America; it is larger than the M. domestica, to be shortly noticed. The mouth is whitish; the antenna are black; the thorax and abdomen are hairy.

**MACULATA.** About the size of the last; thorax and abdomen with numerous black spots. It inhabits divers parts of Europe. The head is cinereous, with a black proboscis; antenna black; abdomen with two black lines in the middle beneath; wing whitish, immaculate; legs black.

**RUDIS.** This is found in Germany, likewise larger than the M. domestica: hairy; thorax grey; abdomen tesselate; the mouth is cinereous; the antenna are black; the scale of the poifers whitish; the legs black.

**OBScura.** Hairy, dull black; wings and scales of the poifers cinereous. Found in Germany.

*DOMESTICA.* Hairy, black; thorax with five pale lines; abdomen tesselate; beneath pale at the base. Inhabits many parts of Europe, on horse-dung. It seldom makes its appearance till July.

**OCCIDUA.** Thorax with black lines; the abdomen is banded. It inhabits South America, and is smaller than the last.

**STRIATA.** Cinereous; thorax with black lines; abdomen tesselate. It is about the size of the Domesticia, and inhabits Germany. The head is cinereous, with a black line in the middle; wings white; tail a little roundish; legs are black.

**AMERICANA.** Black; sides of the thorax grey, dotted with black. It is found in several of the West India islands, and resembles the *Cettrus.* The head is smooth and black; thorax glabrous, with an impressed line in the middle, the sides are downy, with three black dots; scutellum large, rounded, subtriate, black; the wings are also black, and the scale of the poifers prominent and vaulted.

**RETUSA.** Hairy, grey bronzed; abdomen with a gold glos; tail retuse. This species inhabits New Holland. A specimen is preferred in the museum of Sir Joseph Banks. The head of the insects of this species is whitish, with a black frontal line; thorax hairy; segments of the abdomen shining gold, the edges black; wings white, with a brown spot at the base.

**PATAREA.** Hairy, shining bronze; abdomen globular; legs black. It inhabits the American islands, and is about the size of the next species, the Cetar. Its wings are white.

**CÆSAR.** Hairy, shining green, with black legs. It inhabits Europe, and feeds on putrid meat and carcasses; there is a variety not more than a third part as large.

**MEGAcephala.** Shining bronze; segments of the abdomen edged with black. It inhabits Guinea; is the same size as the Cetar; the head is cinereous, with a brown front; wings whitish; legs black.

**FELINA.** Shining bronze; abdomen tesselate, with a bronzed tail. It inhabits New Spain. Mouth cinereous; downy; eyes chestnut, dotted with black; thorax hairy; abdomen diaphanous; legs black bronzed, with tesselate flanks.

**CORNEXS.** Thorax polished coppery; abdomen green bronze; legs black. This is found in various parts of Italy; and very much resembles the M. cæsar; the sides of the lip have a silvery glos.

*CADAVERINA.* Body polished, thorax blue; abdomen green. This is found in several parts of Europe, and in our own country.

**STYGA.** This is a hairy insect; the thorax is blueish; abdomen bronze; legs ferrugineous. Inhabits America. The head is brown, and the mouth ferruginous.

*MOPTURO.** Thorax black; abdomen green bronze; legs black. It is found in many parts of Europe, in carcasses, and is rather a large fly.

**LAVINIA.** Dark brassy, dotted with white; abdomen blue, with a white dot on the second segment, and two on the tail. It inhabits New Holland, and a specimen is preferred in Sir Joseph Banks's museum.

**VOMITORIA.** Thorax black; abdomen shining blue; front fulvous. This is an European insect.

**VISPILLO.** Hairy, blackish; abdomen black bronze; the
the legs are black, is not above half the size of the last, and is found at Kiel.

Cyanka. Thorax and abdomen of a bright blue; legs black. Inhabits Africa. A specimen is in the museum of Sir Joseph Banks: scale of the poifiers milk-white; fore-thighs blue.

Macellaria. Thorax coppery, with black lines; abdomen bronzed; legs black. Inhabits the American islands: its is of the size of the M. caspar; the thorax of this species has three black lines; the wings are white.

Vulpina. Thorax black, with four grey lines; abdomen subferruginous, spotted with black. Found in different parts of Europe.

Nicipes. Hairy, black; sides of the abdomen telfaceous, tessellate with white. Inhabits Germany. The head is black; the mouth silverly; antennae black; wings whitish; scale of the poifers clear white.

Corvina. Black; the abdomen is telfaceous, with a black 4d line. It is found in Germany, and is the size of the Vulpina.

Testacea. Cinereous; scutel, abdomen, and legs telfaceous. It inhabits Germany. The wings are white; the antennae are black.

Pallida. Pale telfaceous, with black tail and ends of the legs. It inhabits Germany, and is the size of the M. telfacea. The body of this insect is covered with black hairs; the last segment of the abdomen is brown; the legs are pale, tipped with black.

Dickon. Thorax dull brassy; abdomen pale; the edges of the segments and tail are bronzed.

Nebulo. Cinereous; thorax with black lines; abdomen telfaceous, with a black line down the back. Found in the East Indies. The head is cinereous, with a black frontal line; wings white, immaculate; abdomen slightly tessellate with white; the legs are black.

Mactans. Telfaceous; wings with two black dots; the posterior one transverse. It inhabits Cayenne.

Augur. Cinereous; abdomen bluish, the sides telfaceous, pellicid. It inhabits New Holland; and is in the museum of Sir J. Banks.

* Canina. Grey; thorax with four black dots; segments of the abdomen edged with black. It is found in this country, and also in several parts of Germany. The thorax is very hairy; the legs telfaceous.

Strigosa. Hairy, cinereous; thorax with five black lines, the middle ones punctured; abdomen with black streaks and line down the middle. It is found frequently in Kiel. The mouth of this insect is snowy; the antennae are black, and the wings white.

Plebeia. Black, with rufous legs. This is an inhabitant of Germany. Head black, with a changeable grey gloss; the thorax is hairy, with a cinereous line in the middle at the base; the scutel telfaceous; the ends of the legs are black.

Rustica. Grey, with rufous thighs. This is a large insect, and found in Germany.

* Tiphina. Hairy, cinereous; tips of the tibiae and flanks ferruginous. It inhabits England, and is of the size of the M. domestica. Its wings are white, and the tail terminated by a flake.

Meditabunda. Hairy, dusky; abdomen cinereous, with four brown dots. It inhabits Italy. Its mouth is whitish, and the tarsi rather red.

Elata. Pale telfaceous; wings with a brown rib and two dots. It inhabits Europe. The mouth is veicular white; antennae rufous, with a black feathered bristle; wings whitish, with two spots, the hinder one transverse; the rib black.

Lupulina. Blackish, with telfaceous abdomen and hindlegs. It inhabits Zealand, and is small. The antennae are telfaceous; the thorax black with a grey gloss; wings pale telfaceous.

Lupina. Black; thorax with faint white lines; abdomen ovate, telfaceous; the first segment and line down the middle black. Inhabits Kiel; is the size of the M. domestica. Head black, mouth silverly; wings whitish.

Longipennis. Black; wings yellowish and longer than the body. It inhabits Germany.

Funereus. Ruddy-brown; abdomen black, the edges of the segments pale. It is found in Germany, and is a very small insect. The head is dusky; white silverly; wings large hyaline; legs telfaceous.

Substantiosa. Downy; thorax slightly bronzed; abdomen black, with three bands something interrupted and tint with yellow. It is found in Europe.

Claviventris. Brown; abdomen clavate; thanks yellow. It inhabits Europe.

Lutea. Yellow; thorax brown, with an oblong yellow spot on each side beneath. It is found in divers parts of Europe.

Elysius. Thorax brown; abdomen yellowish-grey; legs yellow; the ends brown. Found in Europe.

Altitallis. Black; abdomen changeable grey. Inhabits Europe.

Varia. Black; abdomen varied with yellow, grey, and black. Inhabits Europe.

Melanura. Cinereous, with a black tail; four hindlegs at the tip and thanks ferruginous. It is found in Germany.

Strigosa. Telfaceous; crown with a ferruginous dot on each side; wings with numerous transverse telfaceous streaks. It inhabits Europe.

Argentata. Cinereous; thorax with four black lines; abdomen changeable grey; the front on each side is silverly. Inhabits Europe.

Abilabrona. Black, with a white front. Inhabits Europe.

Furta. Black; wings deflected, brown with a white lateral margin. It inhabits Upfal, under the leaves of herbs; very small; antennae telfaceous, concealed within the head; legs white.

Tugurionum. Cinereous; antennae, feelers, scutel, and legs ferruginous. Inhabits Austria.

Taa. Black; abdomen pale ferruginous, with a black base, and line down the middle. It inhabits Austria.

Deceptilia. Cinereous, with rufous legs; abdomen grey ferruginous, with a black dorsal line. This is also found in Austria.

* Melanopyrrha. Downy, black; abdomen with a rufous tip. It inhabits England and Germany. The front of this insect is pale; its eyes are black; scutel olive; wings with fulvous nerves at the base, and a large brown spot in the middle.

Olea. Brown; thorax downy, blue, with three protuberances; tip of the scutel and thighs yellow. Found in the southern parts of Europe, particularly in the south of France and Italy.

1-Maculata. Thorax black; breast with two fulvous spots on each side; abdomen purplish violet. It inhabits New Zealand.

Bimaculata. Blue; breast with a whitish spot on each side; abdomen green with a blue base. Found in New Holland.

†† Hair
**VARIA.** Grey; abdomen rufous, varied with white and black. It inhabits the East Indies, and is about the same size as the M. radicum. The mouth of this species is white; antenna incumbent, rufous tip with black; tail with long black bristles; wings dusky; legs black.

*BRASSICAE.* Thorax greenish; abdomen cylindrical and black; the second and third segments rufous. It inhabits Europe, and is found at the roots of cabbages. The head is rufous; the wings brownish hyaline.

*SEMARGENTEA.* Thorax silvery-green; abdomen silvery-grey with a yellow band at the base. This is found in England. The antennae and head are brown; wings hyaline; legs pale.

*NAPOLEONZ.* Hairy, grey; with longitudinal black lines down the back and sides. This is found in different parts of Sweden, and is extremely destructive to the roots of turnips, especially to those growing in sandy loams; its larva is white, and without legs; the head is pointed and tibet with black; undergoes its transformation about the month of September; the pupa is brown, oblong, annulate with segments, and becomes a perfect fly in the following May.

*LABRONZ.* Thorax hairy, with pale black lines; abdomen ferruginous, the tip tesselate with black and grey. It inhabits the American Islands, and is very large; the head is silvery; the crown dusky; antenna long, incumbent, black; festellate ferruginous; wings dusky; scale of the poikers white, legs black.

*ERINACE.* Hairy; lip cinereous; wings white with a black rib. Inhabits Germany; the antennae are oblong and black; thorax and abdomen very hairy; black, immaculate; scale of the poikers arched, snowy; legs black.

**ESTIVATION.** Hairy; legs with transverse white dots. It inhabits Europe.

*VOLYRA.* Black; abdomen cylindrical, with two whitish bands in the middle. It inhabits Italy, and is about the size of the Comprella already described. Head whitish, with a black line on the crown; thorax blackish and slightly festellate; abdomen very hairy.

*LATERALIS.* Black; abdomen red with a black tip, and irate down the middle. It inhabits Europe, and is the size of the Domestica. The mouth of this species is white.

*ALBIFRONZ.* Hairy; black; abdomen festellate, the base ferruginous each side. It inhabits Denmark. Abdomen subcylindrical.

*CAPULARIS.* Blackish; second segments of the abdomen and sides of the third diaphanous. It inhabits Europe, in swarms under the shade of trees; it is only half the size of the M. domestica.

*PLEURALIS.* Cinereous; thorax with five black spots; abdomen with obsolete spots. It inhabits Europe, and appears in vast swarms before rain.

*SUFFIXANS.* This is entirely black with hyaline wings; hind thighs formed for skipping. It inhabits Europe; is very small, and flies by a sort of skipping motion.

*CHORRA.* Black, with white wings. Found in Germany, and very like the Parasites, described below.

*LABRATA.* Hairy, blackish, with a shining silver tip; wings white, immaculate. Found in Germany, and in its skipping motion resembles the M. subfunicans just noticed. The legs are black; the scale of the poikers arched and snowy.
VIRGATA. Cinerous; abdomen with two streaks of black dots. This is found in France; the body is small, hairy; wings white, immaculate; thanks teellaceous.

* RORALIS. This insect is of a deep black; wings whitish at the tip. It inhabits Europe, and is small; the antennæ are very short, incumcent; abdomen hairy, the poifiers black.

FENESTRATA. Glabrous, black; abdomen rugged above, with white streaks, wings brown; legs black, and the hind ones long.

RUGOSA. Glabrous, black; abdomen rugged and immaculate above; wings brown. Inhabits Kiel, larger than the last; the legs are black, with ferruginous tarsi.

SENSILIS. Glabrous, black; abdomen rugged and immaculate above; wings white; legs teellaceous. It inhabits Germany; the head and thorax naked.

SERATA. Cinerous; rib of the wings ferrate, with short hairs; abdomen and legs ferruginous. Found in divers parts of Europe.

NIGROCINEREA. Cinerous; segments of the abdomen tipp with black. Inhabits the East Indies, is the size of the Domestica; head snowy; mouth fringed; thorax with many black lines; feutel brown, with a cinereous margin; wings white, hyaline; legs black.

CENERA. Hailey, cinereous; antennæ and legs blackish. It inhabits India, and is about the same size as the last. In this species the proboscis is tipped with black; scales of the poifiers snowy; wings white, legs dull, and with black tars.

SCALARIS. Black; abdomen cinereous, with five black bands connected by a line down the middle. It inhabits Germany, and is a little larger than the M. roralis. The orbits of this fly are slivery; the wings white, and the legs black.

MACULATA. Hailey, black; tip of the abdomen with four grey dots. This is found at Kiel, and is larger than the last, the Celleria, which is well known here.

* CELLARIS. Black; abdomen paler; eyes ferruginous; found chiefly in wine vaults; hence its specific name.

CYLINDRICINEREA. Antennæ long and cylindrical; body hailey, black, with yellowish wings. It inhabits France, and is less than the M. cellaris. The last joint of the antennæ is cylindrical, nearly as long as the thorax, with a long whitish hair; tarsi yellowish.

CELLATA. Hailey, black; segments of the abdomen blueish at the base. It inhabits some parts of the European continent, and is about the size of the M. metonica. The head is black; sides of the mouth slivery, with a black line; wings cinereous, hyaline; scales of the poifiers fringed with white.

* MACRORICA. Black; abdomen pale grey; wings yellowish at the base. This is found in our own country, and, like the Pluvialis, comes in swarms before showers of rain.

ATRATA. Naked, shining black; wings hyaline; joints of the legs teellaceous. It inhabits Germany, and is small; the head is subglobular and black; the eyes teellaceous; wings hyaline.

* FRIT. Black; poifiers, end of the hind legs, and abdomen of a pale green. It inhabits Europe, and is not larger than a flea. The larva is found in the ears of barley and other grain, to which it is so exceedingly destructive, that in one year corn to a vast amount has been destroyed by its ravages: in Sweden it is said one-tenth of the corn is annually destroyed by this insect.

PUMILIONS. Black, beneath yellow; head and two lines on the thorax yellow; poifiers white; legs cinereous, tip with black. The larva of this fly has a sharp head, black at the extremity; the body is white, and composed of ten segments; it is changed into the pupa form about the end of May. The pupa is yellow, shining, and composed of segments; the perfect insect appears about the month of June; but it does not appear at what time it deposits its eggs. The larvæ are perceived early in the spring, in the centre of the flalks of wheat and rye, very near the root. It has been thought that the eggs are deposited in September or October, because the earliest sown grain is most affected by them. White wheat is more liable to the depredations of this insect than the red. The flalks in which the larva is lodged do not advance in growth, but continue in a very dwarf state, hence the insect itself has obtained its specific name. The flalks become yellow early in the summer, and soon after die away; but others usually spring up on the same root, and supply their place. This insect first attracted notice in our own country in 1791, when it excited a considerable degree of alarm, lest it should prove as mischievous as the Helian fly, that has done so much injury in America. An account of this insect has been given by Mr. Markwick in the Linnæan Transactions; but the first description of the Pumilions, and of the mischievous caused by it, was given in the Transactions of the Royal Academy of Sciences at Stockholm for the year 1778, by M. Bjerkander, who discovered it on the young shoots of rye early in the spring, and in such quantities, that in some fields he found three or four flalks affected in a square foot.

LEPRAZ. Shining black; antennæ and legs white; eyes reddish gold. It inhabits America. It breeds in the legs of the natives who are afflicted with the elephantiasis, and is smaller than a louse.

PUTRIS. Black; wings white, with a black rib. It inhabits Europe. The larva of this fly are the maggots found in decayed cheese, bacon, &c. well known in common language by the name of hoppers.

ATERRIMA. This is filky black; wings white, with a double black rib half-way down; legs long, compressed. Inhabits France, and is of the size of the M. putris.

MANICATA. Black; abdomen with pale marginal spots; fore-thighs thickened. Inhabits France, and is larger than the M. cellaris. The head is brown, mouth grey, and wings hyaline.

STRIGULA. Thorax with two pale lines; abdomen black, the segments with snowy edges. It is found in France.

CUPRARIA. Body glaucous bronze; thorax green; abdomen coppery, hence its specific name; poifiers naked. This is an European insect. The legs are black, and very rarely yellow.

* AURATA. Thorax polished, brassy or greenish; abdomen polished, obtuse, brownish-gold. Inhabits Europe. The head is black; segments of the abdomen blackish; wings dull; abdomen sometimes blue.

ANEAE. Shining green bronze; head and legs teellaceous. Found in the East Indies.

* POLITA. Polished; thorax blue; abdomen brassy; poifiers naked. An inhabitant of Europe. Poifiers and legs yellow.

* VIDULATA. Black bronze; abdomen brassy; scales of the poifiers fringed. It inhabits Europe, chiefly found in gardens.

PURERA. Black; left segments of the abdomen incurved, with reflected down on each side. It inhabits Europe.

FASCIATA. This species is teellaceous, with a black abdomen; wings brown at the tip, with a white band; legs long.
long; it is found in the American islands; the body is very narrow; there is a variety of this species, that has its head and thorax black.

* Petronella. Livid; front red; legs long, teftaceous, with black joints. Found on the surface of waters in Europe.

Cylindrica. Glossy black; head globular, with teftaceous eyes; legs long and yellowish; it is found chiefly in Germany. The antennae of this species are small, teftaceous, with a black hair; thorax naked and thin; abdomen ovate, with teftaceous spots beneath, at the base; wings white.

Filiformis. Body filiform, black; head ovate with red eyes; legs very long and teftaceous. Found in Germany. In shape it is very long and narrow.

Tipularia. Body long and black; head and legs teftaceous; wings tift with brown. Found on the African continent, particularly in Barbary. The head is pale and teftaceous, with a scarlet crown.

Petiolata. Hairy and black; abdomen compressed; wings black. It is found in Cayenne, and is the size of the Comprella. The head of this insect is black, with a white mouth, and reddish eyes; poifers snowy, abdomen long and black; the segments a little whitish at the edges; the legs are black.

Ephippium. Body long and black; thorax rufous; legs teftaceous. It inhabits France.

Elongata. Teftaceous; legs long, hind shanks black, the ends whitish. It inhabits Sierra Leono. In this species the eyes are large and brown; and the wings hyaline.

Longipes. This is black; wings are brown, with a white band at the base, and dots; the legs are long and teftaceous. This is found in Cayenne.

Annelata. Black; wings hyaline, with a brown band; legs long, black, hind thighs with two white rings. Found also in Cayenne.

Cristata. Hairy, cinereous; abdomen and legs pale; front ferruginous, clavate, and projecting beyond the antennae. Inhabits Barbary.

Corrigiata. Black, with long yellow legs; thighs with a black ring. Is found in the flagrant ditches in various parts of Denmark.

* Curvistans. Black, with long pale legs; wings incumbent, white. It is found in many parts of this country, on trees and walls, resembles a Cimex, and runs with great velocity.

Cimicoides. Black; wings incumbent, white, with two black bands. It inhabits Denmark, is found about trees, and, like the lafi, is very like a Cimex. The last fourteen species are distinguished from the rest by a globular head, with prominent rounded eyes, and a linear body with long legs.

Pallipes. Shining bronze; abdomen with two yellowish dots at the base; the legs are yellowish. It inhabits Germany, and is very small.

* Ungulata. Brassy green; tail hooked; the legs are long and liquid. It is found in many parts of Europe, about waters.

* Nobiletata. Brassy green; tail hooked; wings with a black spot tift with white. Found in Europe, in gardens.

Equestris. Brassy green; abdomen with five black bands; the tail is hooked; the wings are white, with a brown spot. This is found in Brazil; Sir Joseph Banks has a specimen of it in his museum.

* Notata. Hairy; thorax brown, with four greenish lines; abdomen bronzed; wings clouded with brown, with a black dot. It inhabits England.

Glabrata. Shining black bronze; head black; antennae teftaceous. This species is found in France, and is the size of the Ungulata just noticed.

Nigripes. Shining brassy; antennae and legs black; wings white and immaculate. It inhabits France, and is very small; the thorax and abdomen are hairy, and the legs black.

Arroges. Hairy, black; wings brown, with three white bands; an inhabitant of Europe.

Longicornis. Antenna long; body hairy; shining bronze; abdomen darker. It inhabits the American islands.

Rostrata. Body bronzed; abdomen with black bands; mouth hairy, prominent, black. Inhabits Germany; it is the size of the M. ungulata.

Fasciata. Pale, with four black bands on the abdomen; wings white. It inhabits Germany, and is a little less than the last.

Ferruginea. This, as its name imports, is ferruginous; the wings white, with a ferruginous rib and streak. It inhabits the East Indies.

Histrionica. Cinereous, with a ferruginous head; abdomen cylindrical, and black with a whitish base; wings with a black spot at the tip. It inhabits the East Indies.

Sulla. This is teftaceous; the segments of the abdomen are edged with black; the wings are marked with two black dots. It is found in various parts of Germany.

Flaveola. This species is hairy and teftaceous; abdomen downy, tift with brown, and is found also in Germany. The head is teftaceous; the antennae are brown, and the wings white.

Fuscata. Hairy, dusky; feutul projecting, and forked. It inhabits France.

Oratoria. Teftaceous; abdomen pale, the segments are edged with black; the wings are marked with three or four brown dots. This inhabits the Barbary coasts; the head and thorax are hairy, of a pale colour, and teftaceous.

Merdaria. Hairy, cinereous with rufous shanks; wings white with a brown dot. It inhabits Kiel. The mouth is whitish; the crown is generally black, with a reddish spot; antennae black; abdomen flat and hairy.

Lutaria. Grey; abdomen, tail, and legs ferruginous. It inhabits Kiel. The mouth is whitish; the antennae are rufous; the abdomen beneath and at the sides brownish; wings yellow with a small brown vein in the middle, and a larger one towards the tip.

Livens. This, as its name signifies, is of a livid hue, with a ferruginous spot on the front; joints of the legs ferruginous. It is found in Denmark. The mouth is white, front yellowish, with a red spot behind the antennae; thorax and abdomen naked.

* Cucularia. Thorax grey; abdomen ferruginous; wings yellowish, with a darker dot. It is found in many parts of Europe. The antennae have a few spots on each.

* Scutaria. Hairy; dull ferruginous; wings yellowish, with a dark dot; legs rufous.

Marginalia. This is of a dull lead colour; wings reticulate, with a black rib. Inhabits Saxony, and is the size of the lafi. The mouth is vesicular white; the antennae are brown, with a long white hair; wings reticulate, with white dots, the rib black.

* Finnetaria. Antennae slightly feathered; body glistening, ferruginous; wings immaculate. It is found about dung-heaps in various parts of Europe.

Nigrifemur. Thorax cinereous; abdomen, wings, and legs black. It inhabits France, and is the size of the lafi. The mouth is ferruginous, and the head has a ferruginous spot.
It

**Vibrans.** Wings hyaline, t ipt with black; the head is red. It inhabits Europe, and is continually agitating its wings.

**Punctum.** Wings with a black lateral dot at the tip; abdomen bronzed. It inhabits France, in moist shady places.

---

**Cynipsea.** Wings with a lateral black dot at the tip; abdomen cylindrical. It inhabits Europe, and yields a fragrant smell.

**Graminum.** Front im prested, fulvous; wings clouded, with two dots, the hinder one linear and tranverse. This species inhabits France, and is the size of the Latin. Mouth vellucular white; antennae rufous, with a black margin all round, and projecting white hairs; wings whitish with black dots, and the legs are rufous.

**Cincta.** This species is cinereous; head and legs teltaceous; wings clouded with a black rib. It inhabits Denmark.

**Reticulata.** Hair, cinereous; wings faintly reticulate; the rib is dotted with black and white; found in divers parts of Italy; the head and antennae are rufous; the mouth from.

**Contigua.** This species is teltaceous; wings white with three black dots united to the rib, and a single distinct one. This is a Brazilian insect. The mouth is whitish; the thorax hairy; the legs teltaceous.

**Punctata.** Cinerous with rufous legs; wings white with rows of black dots between the nerves. It is found in Kiel, and is known by its whitish mouth and greyish body.

**Umbellulata.** Brown; thorax with faint ferruginous lines; breast and legs teltaceous. It inhabits France, and is a small fly.

**Penneas.** Hair, abdomen rufous; wings black, with a ferruginous spot and white hind margin. It inhabits North America.

**Legum.** Thorax with yellow lines; abdomen blue; wings black, with two white bands, which are biffed at the outside. It inhabits Sierra Leon.

**Moeras.** Hair, black; thorax with white lines; wings long, black, with a white line at the base, and three bands, the first of which is biffed. It inhabits Guinea.

**Ofle.** Thorax yellowish; abdomen conic, ferruginous, the sides spotted with black. It inhabits Italy; the larva is found in the fruit of the olive. The head is yellow, with two black dots above the mouth; thorax with faint black lines; abdomen with three black dots on each side; wings hyaline; legs yellow.

**Clavata.** Teltaceous; abdomen brown, the segments are teltaceous at the base, and terminated by a clavate style. The antennae and thorax are hairy; the wings are large and whitish.

**Parietina.** Cinerous; wings brown spotted, and dotted with white, front teltaceous. It inhabits Europe.

**Discorpa.** Black; wings with white dots and marginal lines; head and legs teltaceous. It inhabits Denmark, and is a large insect. The eyes, thorax, and abdomen of this fly are black and immaculate.

**Connea.** Abdomen cylindrical and black; wings whitish with three black bands, the third connected with a spot at the tip. It inhabits France, and is large.

**Umbraea.** This species is cinereous; the abdomen is marked with black bands; wings brown spotted with white. It inhabits many parts of Europe, and is found among flowers.

**Vibrans.** Wings hyaline, t ipt with black; the head is red. It inhabits Europe, and is continually agitating its wings.

**Punctum.** Wings with a black lateral dot at the tip; abdomen bronzed. It inhabits France, in moist shady places.

Vol. XXIV.
a black dot at the tip. It inhabits Europe, and varies very much in its size.

*Punctata.* Yellow, with four black dots on the abdomen. It inhabits Europe. The dots on the abdomen are remote.

*Estuans.* Wings hooked, white, with a blackish central dot. It inhabits Europe, on flowers.

*Linetata.* Black, with yellow lines on the thorax; scutel and body yellow beneath. Inhabits many parts of Europe, in ears of barley, which it renders sterile. The head is yellow, with a black crown; wings immaculate.

*Rosae.* Head russet; head russet; legs tectaceous. It inhabits Kiel, on flowers, and is very small; wings hyaline.

*Serratula.* Wings white; thorax greenish; abdomen cinereous, with four black lines of dots. It is found on thistles in many parts of Europe.

*Urtica.* Black; wings white with a terminal brown dot, and three distinct bands. It is found in England and other parts on the nettles, as its specific name imports.

*Crassipes.* Cinereous; abdomen with black bands; wings milky-white, with four abbreviated black bands. It inhabits Germany.

*Coronata.* Antennæ projecting, spinous, and one-toothed; body grey; wings white, with four brown bands. It is found in Germany.

*Dace.* Wings white, with four distinct black bands; scutel and legs tectaceous. It inhabits Sweden, and is less than the M. urtica; the abdomen is black, with a long style.

*Cerasi.* Wings white, with unequal brown bands; the lower ones connected outwardly. It inhabits this country, and is found in the kernels of cherries. Body black; front tectaceous.

*Annone.* Blue; wings white, with four black bands; the lower ones connected outwardly. It inhabits the American islands, and is small. The front fulvous; crown blue; legs black.

*Cras.* Cinereous; wings white, with three unequal black bands; legs tectaceous. It inhabits the East Indies, and is the size of the M. urtica. The abdomen is varied with cinereous and black, and ending in a long style; the wings have three bands at the base.

*Cardui.* Black; wings white with a flexuous brown band. It inhabits Europe, in the flowers of the thistle.

*Synsegnes.* Black; wings white with three abbreviated black bands and spot at the tip; it is a small fly, and inhabits Germany.

*Tufflaginis.* Yellow; wings white with four brown bands. It inhabits Denmark, on flowers; abdomen cinereous, with ferrugineous style tinged with black.

*Fungata.* Cinereous, with a tectaceous tail; wings brown, dotted with white. It inhabits the American islands; the eyes of this insect, which is small, are green.

*Solestitialis.* Wings white with four connected black bands; feutel yellow. It is an inhabitant of this country, and has been described and figured by Mr. Donovan. The head is pale; body bluish-black; abdomen ending in a long style; wings with a brown outer margin connecting the four bands; legs yellow, thighs black.

*Costalis.* Blue; wings white with two black coflal spots. It inhabits the South American islands, and is small.

*Lycinæus.* Black with yellow head and legs; wings black, the border streaked with white. It inhabits Kiel.

*Omphæin.* Ferrugineous, with a yellowish feutel; wings with brown marks and tip. It inhabits Europe, and is described in Donovan’s Eng. Inf., head and legs pale.

*Centauræ.* Black; head and legs yellow; wings with brown marks and tip. Inhabits Kiel, and resembles the last.

*Scabiosi.* Yellow; disk of the wings cinnamon, brown and dotted with white. It inhabits France, and is large.

*Halicæ.* Wings brown, varied with white, on the thicker margin three black spots, with a white pupil. It inhabits England, and is found among flowers; the body is grey with a few brown dots; thorax grey with two brown dots on the shoulders, four in the middle and two behind; the abdomen is grey with four black bands, the two first interrupted; legs yellow.

*Mina.* Yellow; thorax black on the back; abdomen with two black streaks and two dots behind. It inhabits Kiel, and is characterised as very small.

*Aequostricæ.* This species is glabrous, black; tectaceous; eyes chestnut-brown, legs long. It inhabits South America; the body is long and narrow.

*Cibaria.* Smooth, with ruffled stigmata; the abdomen is cinereous, hooked; the legs are long. It is found very much in kitchens in divers parts of Europe.

*Terrestris.* Brown; thorax with a brown dot without the lines; abdomen ariate beneath. It inhabits Sweden, and feeds on the ground.

*Saltuum.* Wings white with a brown rib and terminal dot; body yellow; head blackish behind. This is an European insect.

*Arnica.* Wings hooked, grey spotted with black. It inhabits Europe, on the disk of radiate flowers; particularly the Arnica montana.

*Sonoil.* Wings hyaline, with a black marginal spot; the eyes are green. It inhabits Europe, on the receptacles of the Sonchus arvensis.

*Subcutanea.* Wings white with flexuous brown bands; eyes green. It inhabits Europe, under the leaves of the hieracium.

*Rufivenalis.* Thorax cinereous; abdomen rufous, with a black spot at the base, with two brown spots and brown hind margin.

*Setosa.* Black; abdomen bristly, with a pale spot on each side of the base. This and the next thirty-seven species are described generally as inhabiting Europe.

*Versipellis.* Black; the three first segments of the abdomen on each side are changeable reddish-grey.

*Polla.* Black; abdomen glabrous, greenish-black. It inhabits Europe.

*Brunnea.* This is entirely of a chestnut colour.

*Nigerpis.* Cinereous, with black bristles; legs tectaceous, black at the ends.

*Nigripes.* Cinereous; wings yellowish at the base; legs black.

*Trimalis.* Cinereous; front tip of the thighs and tarsus tectaceous.

*Vercolor.* Black, with a changeable grey gloss.

*Picea.* Picceus, glabrous; legs black.

*Crassipes.* Black, rough; thighs thick.

*Lepisticta.* Black; wings with numerous white dots.

*Rupicellæ.* Cinereous, with a rustous crown and tectaceous thighs.

*Ochroptera.* Black; front white; wings yellowish; tarsus ferruginous.

*Subulata.* Picceus; abdomen fuscatic; wings with a ferrugineous spot; tarsus pale.

*Conica.* Cinereous; abdomen conic; legs brown tectaceous.

*Abrupta.* Cinereous; wings with three abrupt tectaceous bands.
**MUSCA.**

**CHRYSOCEPHALA.** Crown ferruginous; back of the thorax and linear abdomen black; wings white, with two brown bands, the tip brown with a white spot.

**FLAVESCENS.** Yellowish-grey with a ferruginous crown; head and legs yellow; wings white with four yellow bands.

**LACINIOIDES.** Blackish, with a white face; tip of the scutellum subfuscous; abdomen changeable grey.

**CILYNDRICA.** Blackish; abdomen cylindrical, changeable grey.

**TERES.** Piceous, glabrous, cylindrical; legs yellow.

**SETICORNIS.** Reddish-brown with brown eyes and wings.

**ORDINATA.** Black; wings brownish, with hyaline thinner margins.

**TRICOLOR.** Cinerous; wings brown; legs black.

**DRYPES.** Brown with ferruginous legs; abdomen deprefed.

**QUADRICOLOR.** Polished; thorax blue; abdomen green; thighs black, the tip and thanks yellow.

**SQUALIDA.** Blackish; abdomen cylindrical, cinereous, with a black dorsal line.

**LATIPES.** Yellow; abdomen clavate; hind-thighs yellow; thanks with a white ring.

**DISPERSA.** Telfaceous with a cinereous back; segments of the abdomen brown at the base.

**LITURATA.** Grey; wings with a ferruginous spot; legs pale.

**TRIPODICA.** Blackish; crown with three black dots each side; thorax pale, cinereous.

**LEUCOPTERA.** Piceous, glabrous; legs ferruginous; wings white.

**GLAUCOPTERA.** Piceous, glabrous; wings glaucescent.

**9-PUNCTATA.** Thorax black; abdomen pale grey, with nine black dots.

**PICATA.** Thorax black; abdomen piceous, glabrous; ends of the hind-legs thick.

**9-MACULATA.** Yellow; wings with five blackish spots, and three at the tip.

**RUBRIPES.** Black, with ferruginous legs.

**MELANOCHRYSA.** Yellow, with a black dot on the crown; thorax with three longitudinal black stripes.

**GRANDIS.** Glabrous; thorax black-brown; abdomen ferruginous, tippd with black. It inhabits England.

**APIS.** Hairy, black; base of the thorax yellow; abdomen with a yellow belt; the tail whitish. It inhabits Auloria.

**ARGYROLOMA.** Hairy, black, with a silvery front; abdomen with silvery bands. It inhabits Vienna.

**FULVIVENTRIS.** Blackish; abdomen with yellow down beneath; wings dotted with white. It inhabits Vienna.

**CLAVERGUS.** Yellow, naked; eyes green; hind-thighs clavate. Inhabits Auloria.

**5-PUNCTATA.** Cinerous; wings with a dot at the tip, one at the inner margin, and three at the outer. Inhabits Auloria.

**STICTICA.** Yellow; thorax and abdomen with four lines of black dots; wings white, with a yellow margin and three bands. It inhabits Vienna.

**POCCHOPTERA.** Wings reddish-brown, variegated with white. Inhabits Auloria.

**LINeen.** Black; front red, the margin with two anastomosing brown spots. It inhabits France.

**NASUTA.** Yellow; thorax with five black lines; abdomen with four black bands. It inhabits France.

**LAMEN.** Wings hyaline; the outer margin varied with brown, the inner margin marked with a brown fuscous lamed. It inhabits Auloria.

**Miliaria.** Yellow, with black eyes; wings yellow, with a triple brown spot and numerous dots. It inhabits Europe.

**CINNOMONOPHTHALMIA.** Hair; eyes violet, with six purple bands; legs with a white ring. It inhabits Auloria.

**METICULOSA.** Glossy-black; thanks rufous, with a black hand, the hind ones curved. It inhabits Auloria.

**MERULINA.** Glossy-black, with red eyes; wings hyaline, immaculate. It inhabits Auloria.

**RENEELLE.** Black; scale of the poisons ferruginous; abdomen with two thin white belts.

**CORNUTA.** Yellowish, with two horns sending out three branches from the upper side; wings hyaline, spotted with brown. It inhabits Carniola.

**TIBIDATA.** Thorax splendid green; abdomen lucid lanceolate, violet-brown. It inhabits Carniola.

**CASCADINA.** Thorax bronzed; abdomen pellucid yellow, with alternately narrower black bands. It inhabits Carniola.

**LUCINA.** Thorax cinereous, with four interrupted black lines; abdomen subfuscous, the halves diaphanous. It inhabits New Zealand.

**TESTACEA.** Scutel two-toothed; body telfaceous; first segment of the abdomen brownish. It inhabits South America.

**ERRANS.** Scutel two-toothed, black; abdomen black, the second and third segments with white sides. It is less than the last.

**CHAMHELEON.** Scutel two-toothed, yellow; abdomen black, with three triangular yellow spots on each side, and one at the end. It inhabits Europe. This is one of the most remarkable species: it is a large black fly, with a broad, flatish abdomen, having the sides of each segment yellow, forming to many abrupt semi-bands across that part. It proceeds from an aquatic larva, of very considerable size, measuring two inches and a half in length, of a somewhat flattened shape, and of a brown colour, with a narrow or flayer front; the body widening by degrees towards the middle, and from thence gradually tapering to the extremity or tail, which is terminated by a circle of radiating or diverging hairs. This larva is common in flagmant waters, during the summer months, and paves into its chrysalis flate without casting its skin, which dries over it, so as to preserve the former appearance of the animal in a more contracted form.

**SPLENDENS.** Scutel two-toothed; body covered with rich gold down; abdomen with black bands. It inhabits Spain.

**PURCATA.** Scutel two-toothed, black, edged with yellow; abdomen black, the sides spotted with yellow. It inhabits Germany.

**EPHEMVM.** Scutel two-toothed; thorax rufous and spinous on each side. It inhabits Europe.

**CRUCIS.** Scutel two-toothed, black; abdomen black, with two lateral yellow spots and tip. It inhabits the South American islands.

**FLAVSSIMA.** Scutel two-toothed; body black; abdomen rufous, with a longitudinal black line. It inhabits Italy.

**MICROLEON.** Scutel two-toothed; abdomen black, with lateral white streaks. It inhabits Europe.

**STISTRACA.** Scutel two-toothed; abdomen black, with white streaks beneath. It inhabits Italy.

**CAYRNA.** Scutel two-toothed; body blue; head verticaly white. It inhabits Cayenne.

**PALLIPES.** Scutel two-toothed; abdomen above black, Z Z 2 th.
the edges of the segments whitish each side. It inhabits North America.

**Mutabilis.** Scutell two-toothed; body grey, downy; abdomen black at the base; rib of the wings ferruginous. It inhabits Cayenne.

**Fasciata.** Scutell two-toothed; body black; abdomen with two white streaks above, beneath filvery. It inhabits Cayenne.

**Argentata.** Scutell slightly two-toothed; body black; abdomen covered with filvery down and yellow lateral spots. It inhabits Saxony.

**Tigrina.** Scutell two-toothed; body black; abdomen rufous beneath. It inhabits the waters of Denmark.

**Hydroleon.** Scutell two-toothed; body black; abdomen green, with a black line down the middle. It inhabits about flagrant waters of Europe.

**Virdula.** Scutell two-toothed; abdomen green, with a black back. It inhabits Germany.

**Tyrrhineata.** Scutell two-toothed; abdomen greenish-yellow; thorax with three black stripes; abdomen with black marks. It inhabits Europe.

**Hyppoloea.** Scutell two-toothed, yellow; thorax black edged with yellow; abdomen black, with five yellow spots. Inhabits Europe.

**Muscaria.** Scutell two-toothed, yellow; body black; margin of the abdomen spotted with yellow. It inhabits Italy.

**Minuitor.** Scutell two-toothed; body black; segments of the abdomen edged with white. It inhabits Tranquebar.

**Melangops.** Scutell two-toothed; body teflaceous, with black eyes; second and third segments of the abdomen with a yellow spot on each side behind. It inhabits Europe.

**Nigricans.** Scutell two-toothed; black with yellow teeth; abdomen black; the hinder margins of the segments whitish beneath. This is an European insect.

**4-Lineata.** Scutell four-toothed; body black; abdomen with four white lines. This is found in Sierra Leoa.

**Clavipes.** Scutell fix-toothed; body black; abdomen ferruginous. Inhabits Sweden; wings brown; legs rufous.

**6-Dentata.** Scutell fix-toothed; thorax bronzed; abdomen ferruginous. It is an inhabitant of this country; a specimen is found in the museum of Sir Joseph Banks. The thorax is shining bronze; scutell with fix black teeth; abdomen long, flat above, and pubescent; wings whitish, with a black marginal spot; legs yellow, the hind ones long.

**Chalyrea.** Scutell fix-toothed; thorax fleck blue; abdomen black. This is an English fly; the wings and poaters are black; legs teflaceous, the ends black and elate.

**Similis.** Scutell fix-toothed, shining green-blue; abdomen fleck-blue. It inhabits England; wings ferruginous, with a brown dot; legs black; poaters white.

**Valvata.** Scutell fix-toothed; abdomen and thighs yellow. It is found in England. Wings subferruginous, flt, incumbrant, with a brown dot in the middle of the rib; poaters yellow; shanks near the tip and tarso brown.

c. Sucker with a single bristle and univalve sheath; antenna seated on a common peritome; in this sub-section there is but a single

### Species

**Univalvis.** Black; front yellow; thorax spotted with yellow; abdomen with three yellow streaks. It inhabits Kiel and Barbary.

**Sucker with three bristles, without sheath; feelers placed at the base of the sucker.**

### Species

**Scolopacea.** Cinereous; abdomen yellowish, with three rows of black dots; wings clouded. This is found in other parts of Europe as well as in this country.

**Tringaria.** Cinereous; abdomen yellowish, with three rows of black dots; wings immaculate, thorax of one colour. It is found in the woods of Europe.

**Vanella.** Cinereous; thorax lineate; abdomen teflaceous, immaculate; wings sub-teflaceous. It inhabits Denmark, and resembles the last.

**Ardea.** Black; margin of the abdomen spotted with grey; wings immaculate, shanks teflaceous. It inhabits Italy.

**Vermileo.** Cinereous; abdomen with three rows of black dots; wings immaculate; thorax spotted.

The Mufca vermeleo is a middle-sized fly, of a somewhat lengthened form, with a distant resemblance to a Tipula; it is of a dull yellow colour, with transparent wings; the thorax marked above by two black lines, and the abdomen by triple rows of black spots. The larva mafeories three-quarters of an inch in length, and is of a pale yellowish-grey colour, slender or sharpened in front, and growing gradually broader towards the tail. It is found in the southern parts of Europe, and is not uncommon in some districts of France; it is remarkable for preftituting a method exactly similar to that of the Hemerobius fornicaculo, in order to obtain its prey; cxcavating a circular pit or cavity in the dry sand; concealing itself, waiting the arrival of any small insect which may happen to fall into it, and after absorbing its juices, throwing out the exhausted remains to a considerable distance from the cavity. This larva seems to have been first observed and described by Reaumur, in the Memoirs of the French Academy for the year 1752. It affumes the state of a chrysalis by caking its skin, which of itself rolls to the hinder part of the body; the chrysalis is of a dull reddish colour, and is rounded or clubbed at the upper part, suddenly tapering from thence to the extremity, and after lying nine or ten days, it gives birth to the perfect insect.

**Lineata.** Lineate; abdomen black; wings hyaline, with a brown spot and tip. This is an English fly; the antennae are cylindrical, incurved, longer than in others; the fore-legs are long and black.

**Fuscata.** Thorax cinereous, with black lines; abdomen brown; wings with a black marginal spot, in which is a cinereous dot. This is found in Sweden.

**Nigricana.** Teflaceous; abdomen with five black bands; wings hyaline, with a brown spot at the tip. Inhabits Norway. Thorax gibbous; abdomen cylindrical; legs long and brown; thighs pale.

**Tipuliformis.** Brown; wings white, tipt with black. It inhabits Germany.

**Chrysopous.** Thorax ferruginous; abdomen black, with yellow spots on the sides. It inhabits Germany, and is a small fly.

**Bicolor.** Teflaceous; back of the thorax and tip of the abdomen black; wings with a brown spot. It inhabits Italy.

**Dipsera.** Abdomen black, the segments edged with white; wings brown hyaline, with brown spots. This species inhabits Germany.

**Bilineata.** Blackish; thorax cinereous, with two black lines; wings hyaline, with black marginal spots. It inhabits Kiel.

**Macroceras.** This species is teflaceous, with lateral black.
black spots on the abdomen; antennae very long. It is found in Germany.

Succineta. Telfaceous, with black bands on the abdomen; wings hyaline, with black spots.

Tomentosa. Black; abdomen covered with gold down; wings white, with a black marginal spot. It inhabits Denmark.

Lineola. Cinereous; abdomen telfaceous, with a black tail, and spots on the back; wings hyaline, with a black marginal spot. This also is an inhabitant of Denmark.

Maura. Deep black, with blackish wings. It inhabits Germany, and is of the middle size.

Nigrita. Black; segments of the abdomen edged with a cinereous down, wings white with a marginal black spot; the legs are black. This species inhabits Italy.

Diadema. Cinereous; wings white, with a marginal brown spot; legs yellowish. It is common at Leipic.

Aetha. Black, immaculate; wings hyaline, with a black marginal spot. Inhabits Italy.

Colombuscens. Black, with white incises of the abdomen, tints, and tarsi. This species is found in many parts of Russia and Siberia, particularly in the spring and autumn. It is extremely troublesome, and often fatal to the cattle which are attacked by it. It infesteth itself into the nober parts, and destroys the creatures thus affected in the course of four or five hours.

Papataci. Antennae, body, and wings hairy. It inhabits Italy; it is very small, and very troublesome in the night during the whole summer; the eyes are black, and dotted white; the abdomen is red.

Acuminata. This is black; abdomen thin, long, and subulate at the end; wings spotted; thighs yellowish-rufous; hands brownish.

c. Sucker with three bristles, and a single valved sheath; antennae united at the base, and pointed at the tip.

Species.

Aenea. Black, downy; abdomen bronzed. Inhabits Germany.

Plebeia. Cinereous, hairy; segments of the abdomen edged with white. This is found in our own country, and other parts of Europe. The hind tarses are ferrugineous.

Octopous. Hair, cinereous; segments of the abdomen edged with yellow; legs telfaceous. It inhabits Germany.

Marginata. Black; abdomen conic, the segments edged with white; wings spotted with black. This is found in Italy.

Nobilis. Ferrugineous and hairy; abdomen conic, fulvous, with a black tail. This species is found in the woods of Denmark.

Lugubris. This species is hairy and black; mouth cinereous; tarses telfaceous. It inhabits Kiel. The wings are white; and the legs black.

Strigata. Hairy and black, with two white streaks on the abdomen. This resembles the half, and is found in Germany.

Florescens. Black; feelers and fore-legs telfaceous. It inhabits Germany.

Anis. Villous, whitish-grey, with hyaline wings. Found in several parts of Europe.

Pantherina. Black; back of the abdomen with three white spots, united to as many at the sides. It inhabits Sweden, and is naked.

Dexippus. Hairy and black; thorax with a white line on each side; wings varied with black.

Melanoptera. Black; feutel ferrugineous; abdomen beneath, and angles of the segments, ferrugineous. This is found not to be known in Europe.

Fuscus. Hairy, yellowish; wings and abdomen brown; the segments with a ferrugineous spot on each side.

Polyzonias. Abdomen ferrugineous, with a longitudinal black stripe; wings hyaline, and banded.

† Antennae feathered.

Species.

Manis. Thorax subtelfaceous; abdomen with two black belts.

Micans. Thorax black on the back; abdomen pelucid, with three black belts. It inhabits Italy.

* Pellucens. Black; first segment of the abdomen white, pelucid. This is described and figured in Harris's English Insects.

* Bombylans. Downy and black; abdomen rufous at the end. This also is described and figured by Harris.

* Mystaceae. Downy and black; thorax and tip of the abdomen yellow. This species inhabits Europe, and has been given in Harris's Insects.

Mesusitas. Downy; thorax fulvous; abdomen greenish. Inhabits Kiel.

Lapponeum. Downy, black; scutel ferrugineus; abdomen with three whitish interrupted belts. This is found in Lapland.

Insflata. Head and scutel yellow; first segment of the abdomen pelucid and yellow. It inhabits Italy.

Aphria. Downy; thorax yellow before; abdomen tipt with white; wings ferrugineous at the base. This is an inhabitant of Italy, and resembles the M. mylaceus.

Esuriens. Body naked; abdomen ferrugineus, pelucid. It inhabits the American islands.

Intrigata. Downy, yellowish; abdomen black; the tip and joints of the legs are white.

Crassa. Naked, black; hind thighs rufous, and one-toothed. It is an inhabitant of Tranquebar.

Bombilyformis. Downy, yellowish; hands white at the base. It inhabits Germany.

Vacua. Naked; thorax with yellow lines; abdomen pelucid, yellow, with black belts. It inhabits the American islands, and is a small fly.

Obera. This species is likewise naked; wings with two brown spots; body bronze. It inhabits America.

Plumo. Black; abdomen rufous behind; thorax hairy, black. This is suspected to be a mere variety of the M. bombylans.

†† Antennae naked.

Species.

Pinguus. Body naked; thorax black, spotted with white; abdomen telfaceous, with a white band. It inhabits America.

Pendula. Downy; thorax black, with four yellow lines; abdomen yellow with transverse black lines, connected by a longitudinal stripe.

The Mufca pendula is a moderately large, and very beautiful insect. Its colour is black, with four bright yellow stripes down the thorax, and three broad interrupted bars across the abdomen. Its larva, which is an inhabitant of stagnant water, is of a remarkable appearance; it is furnished with a tail of great length, composed of a double tube, the interior of which is very slender, extensible at the pleasure of the animal to a vast length, and terminated by a very small
small spiracle. The length of this tube is, therefore, varied in proportion to the greater or smaller depth at which the insect chooses to continue; the tip reaching to the surface, in order to supply the requisite quantity of air. Sometimes great numbers of these maggots are found coiled or twisted together by their tails in such a manner, that it is not easy to separate any one from the rest. The chrysalis resembles that of the M. tenax, the remains of the tail being visible in a dried and contracted state. The complete insect is frequently seen on flowers during the autumnal season.

**Natans.** Downy; thorax with four lines; first segment of the abdomen ferruginous, with an abbreviated white streak. It is found in various parts of Italy.

**Versicolorata.** Downy; thorax with two faint whitish dorsal lines; abdomen rufous, the back is black, but varied with cincereous. It inhabits Germany, and is very like the M. pendula.

*Florea.** Downy; thorax with black bands; abdomen yellow, with a black dorfar line; the segments are edged with black.

**Subcoleoptera.** This species is downy; thorax black; wings thicker, cincereous, with two brown flexuous fillets. This is found in Sweden, and is larger than the M. hemiptera, the next in the order of description.

*Hemiptera.** Downy; thorax with a ferruginous border; wings thicker, cincereous, varied with yellowish-brown.

**Crassipennis.** Downy; thorax yellowish; wings thicker, the disk white with a dilated black dot. This is found at Paris, and resembles the last.

**Affinis.** Thorax fulvous at the sides; abdomen black. It inhabits France.

**Nemorum.** Downy; abdomen black, with three white belts, the first segment is yellow at the sides; the legs are black, with white joints.

**Cryptarum.** Downy; abdomen brown, with three white belts; the first segments are yellow at the sides; feutel and legs telleaceous. It inhabits Germany.

**Acroorum.** This is downy and black; feutel and sides of the abdomen are ferruginous.

**Arvorum.** Downy; thorax yellowish, with four black lines; abdomen black, with three yellow dots. This inhabits China, and is said to resemble the M. nemorum.

**Hortorum.** Downy; thorax brown, with two pale bands; abdomen with three white bands; hind legs thick and ferruginous. It inhabits the American islands.

**Arbustorum.** Downy; abdomen black, the first segment, and sides of the second, ferruginous.

**Pratorum.** Downy; black; thorax with two yellow bands, and two dots; abdomen with three yellow spots on each side. It inhabits the American islands.

**Saltuum.** Naked, black; thorax spotted with yellow; segments of the abdomen edged with yellow; hind thighs toothed. It inhabits Italy.

* Frutetorum.** Downy, with two yellow lines on the thorax; abdomen ferruginous, with an interrupted black dorfar line. Inhabits England; a little less than the M. pendula. The antennae of this species are ferruginous, with a brown hair; thorax black with ferruginous down, and two yellowish lines on the back; abdomen ovate, with a black cincereant at the base and tip, connected by a black line: the second segment black with yellow sides, and three ferruginous dots on the back.

**Enetorum.** Slightly downy; thorax bronzed with yellow sides; abdomen ferruginous with three black streaks. This is found in Africa; and a specimen is in the museum of Sir Joseph Banks.

**Murorum.** Downy; abdomen black; the segments edged with white; hind thighs clavate. Found in Barbary.

* Texan.** Downy; thorax grey; abdomen brown; hind flanks compressed and gibbous.

The M. tenax is about the size of a drone, and of a brown colour, with transparent wings, and the first segment of the abdomen is yellowish on each side. It proceeds from a larva of singular appearance, being a long-tailed brown maggot of rather slow motion, measuring about three quarters of an inch in length, without the tail, which is extensible, and consists of a double tube, the exterior annulated into numerous segments, and the interior terminated by a circle of hairs, surrounding a spiracular or air-hole. This maggot is seen in muddy stagnant waters, drains, and other places of the like description, and withstanding its unpleasing appearance, exhibits, when accurately examined, many particulars well worthy of admiration. The feet, which are few in number on each side, are wonderfully calculated for enabling the animal to ascend walls or other perpendicular places, to seek some proper situation in which it may undergo its change into a chrysalis, being very broad, and befitting their under surface with numerous small hooked claws; thus giving it the power of clinging with security during its alent.

Of the larva a particularity is stated, on the authority of Linnaeus, which, if true, may indeed well be numbered among the marvels infectorum; viz., that being a frequent inhabitant of the turbid pulp used in the operation of paper making, it is often expelled to the action of the wooden mallets used in the process, as well as squeezed in the strongfell presses; and yet survives uninjured by these feemingly destructive operations.

This larva commonly changes to a chrysalis about the end of August; the skin contracting, and drying round the body, and the tail continuing in a thrivalled state. After thus remaining about the space of a fortnight, it gives birth to the complete insect, which has so much the general appearance of a drone, that it is very frequently mistaken for fuel. It is very common during the month of September.

**Setosa.** Downy; black; hair of the antennae long and clavate. It inhabits Barbary.

**Sectetum.** Downy, paler cincereous; abdomen black, with two yellowish spots at the base. This is likewise found in Barbary, and is of the same size as the M. tenax.

**Tirlineata.** Downy; thorax pale, with black lines; abdomen black, with an interrupted ferruginous band at the base. This is a New Holland fly, but a specimen is preserved in Sir J. Banks's museum.

4. **Lineata.** Thorax yellowish, with four bronzed lines; abdomen ferruginous, the tip black, with a white streak. It inhabits Tranquebar.

5. **Striata.** Thorax bronzed, with five white lines; abdomen ferruginous; the tip black, with a white streak. This is an inhabitant of the East Indies.

5. **Lineata.** Downy; thorax with five alternately white and black lines; abdomen black, the segments white at the base. This species is found in Africa; Sir Joseph Banks has a specimen of it.

6. **Fusiformis.** Downy, thorax yellow, with a black band; abdomen black, with yellow base and fulvous tip. This is found in France, and is the size of M. mylaisae, already deflected.

7. **Obstrata.** Black, with a whitish fectel; abdomen yellowish at the tip.
**Asiliformis.** Thorax downy, yellowish; abdomen black; the two first segments yellowish. It inhabits Germany.

* Lucorum. Downy; thorax grey; abdomen black; the first segment entirely white. It is found in this country and in other European states, chiefly in the fields and gardens.

**Fallax.** Downy, brown with a yellow front; tip of the abdomen covered with a fulvous down; scale of the poikers white. It inhabits Europe, on flowers.

**Sylvarum.** Downy; black; last segment of the abdomen covered with yellow down. It inhabits Europe on flowers.

**Nigrana.** This species is characterized as naked, black, and having blue wings. It is a large fly, and is found in Jamaica.

**Clavipes.** Downy, cinereous; thorax with a black band; tip of the abdomen fulvous; hind thighs curved.

**Equestris.** Downy, cinereous; thorax with a black band; abdomen fulvous; hind thighs and franks toothed at the tip. It inhabits Italy, and resembles the last.

**Flavicans.** Downy, yellowish, immaculate, with black legs. It inhabits Italy, and is less than the M. equistris.

**Cineara.** Downy, cinereous, with a black tail; thorax with a black band. It inhabits Italy.

**Bigincta.** Black, with two yellow belts on the abdomen; sides of the thorax dotted with yellow. An European fly.

* Arcutata.** Black, with four curved belts on the abdomen; thorax spotted with yellow at the sides. This species is found in our own country.

**Cinculata.** Downy; abdomen black, the first segment white at the base, the red with white dots. It inhabits New Zealand. To be seen in the museum of Sir Joseph Banks.

**Zonelis.** Downy, black, with cinereous tail, front and fore-part of the thorax; first segment of the abdomen whithish. This species is found in China.

**Errans.** Downy; thorax cinereous with a black band and scutel; abdomen black, the sides yellow at the base. It inhabits China.

**Mutabilis.** Downy; thorax immaculate; abdomen black with a changeable grey gloss. It inhabits the meadows of different parts of Europe.

* Devia.** Downy, with a blueish thorax; abdomen dull violet.

**Segnis.** Naked; thorax bronzed; abdomen ferruginous, tupt with black; franks white. This as well the last inhabits our own country, and other parts of Europe, on flowers.

**Volvula.** Downy, black; abdomen cylindrical, blue; antennae and legs rufous; hind thighs thick. This is found in France, and is of the same size as the M. fregius.

**Picha.** This is nearly naked and black; abdomen ferruginous with a black tail; hind thighs clavate. It inhabits Germany.

**Lunata.** Downy; thorax cinereous; abdomen with white crecentis; the base rufous, and tip black; hind thighs thick. Found in Barbary.

* Femorata.** Downy; thorax slightly bronzed; hind thighs clavate. It inhabits the flowers of this and other countries of Europe.

**Spinipes.** Downy; abdomen black with white lines, the first segments rufous; hind thighs toothed. It inhabits France.

**Annulata.** Downy; abdomen black, the segments edged with white; hind thighs clavate and toothed. Found in France.

**Dentipes.** Naked; thorax black, with four white lines; abdomen clavate; hind thighs thickened and toothed. This species inhabits Cayenne.

* Conopea.** Naked, black, with lateral lines on the thorax, abdomen with three yellow bands. This is found in England and other parts of Europe. The wings are white, with a black thicker margin.

* Ichneumonea.** Cylindrical, black; front, hind part of the thorax, and legs ferruginous. It is found on flowers in this country and other parts.

**Bicolor.** Black; abdomen rufous with a black base and tip. It is found in Barbary, and very much resembles the last species.

* Spiriegia.** Black with rufous legs. It inhabits England; a specimen is preserved in the museum of Sir J. Banks.

**Clavata.** Naked and black; abdomen clavate, with three yellow spots on each side. Found in the West India islands.

**Cylindrica.** Naked, black; wings blackish, the thinner margin spotted with white. Inhabits, like the last, the West Indies.

**Vesicolosa.** Naked; abdomen clavate, the tip testaceous and vesicular. It inhabits Italy.

**Elongata.** Naked; thorax bronzed; abdomen clavate, black, with two yellow bands. It inhabits Denmark, on flowers.

**Podagrica.** Naked; thorax bronzed; abdomen with two yellow bands; hind thighs clavate. It is found in Denmark.

**Chabroniformis.** Downy; thorax variegated; abdomen yellow, the two first segments tint with brown. This is an inhabitant of Madeira, and a specimen of the species is in the museum of Sir J. Banks.

**Dioptalama.** Naked; thorax spotted; abdomen with six yellow belts; hind thighs toothed. It inhabits Europe.

**Apiformis.** Downy; thorax black with white dots and lines; abdomen yellow with black belts. It inhabits Germany.

* Vespiiformis.** Naked; thorax black, spotted with yellow; abdomen with yellow belts uniting at the sides. This is found in our own country, and other parts of Europe. And independently of the specific character just given, its thorax is marked with a lateral interrupted yellow line; scutel black, edged with yellow bands on the abdomen uniting in pairs.

* Festiva.** Naked; thorax black with yellow lateral lines; abdomen with four interrupted yellow belts. Is found chiefly in gardens, here and elsewhere in Europe.

**Laeta.** Naked; thorax black, with yellow lateral lines; abdomen with four yellow belts, the first interrupted. It inhabits Kiel.

**Rupicollinae.** Downy; thorax brown with grey lines; abdomen bronzed, wings with two brown spots. It is found on flowers in different parts of Denmark.

**Semirupa.** Black; abdomen ovate, with a broad ferruginous tip. Found in Germany.

**Calarata.** Downy; thorax brown; abdomen black with whitish lateral spots; hind thighs toothed.

**Flavicoris.** Downy; obscure bronze; antennae and franks yellowish. It inhabits Germany.

**Neonea.** Downy; black-bronze; joints of the legs white. It inhabits Germany.

**Fenesta.** Thorax downy; obscure bronze; abdomen black with three pale cinereous bands. It inhabits Italy.

**Melanochilica.** Thorax bronzed with white lines; abdomen black, with cinereous lines. It inhabits Italy.
SEFULCHRALIS. Downy, blackish; abdomen shining-black. Found in Sweden.

TRIISTIS. This species is nearly naked; thorax black, with five paler lines; the abdomen is bronzed. Found in Germany.

LUGUBRIS. Black, immaculate; wings white with a brown spot. It inhabits Denmark.

CEREMETERIORUM. Black-bronze; abdomen depressed, shining-black; wings blackish.

METALLINA. Shining black-bronze; antennae black. Found in Germany.

SUBSULTAN. Glossy-black; wings white and immaculate. This is found in Germany.

GLACIA. Slightly downy, black; abdomen with a pellucid base, and two whitish interrupted belts. Found in Europe.

NOCTILUCA. Slightly downy, black; abdomen with two pellucid spots on the first segment. This inhabits Europe, chiefly in gardens.

* GLOBOSA. Slightly downy; thorax ferruginous on the fore-part; abdomen sub-globular, pale, tinted with black. It inhabits this and other European countries. The mouth is white; front ferruginous, with a black line; thorax ferruginous before, and black behind; legs black; wings white.

* RIBESI. Nearly naked; thorax immaculate; abdomen with four yellow belts, the first interrupted. Found usually among the Aphides ribis.

BIFASCIATA. Downy; thorax bronzed; abdomen black, with two yellow belts, the first interrupted.

PYRASTRI. Nearly naked, black; thorax immaculate; abdomen with three pair of white recurved lunules. Found among the Aphides pyri.

THYMASTRI. Downy; thorax slightly bronzed; abdomen black, with three whitish bands; the second is interrupted. It inhabits Germany, on flowers.

TRANSFUGA. Downy; abdomen black, with three pair of whitish lunules.

SALVIE. Naked, yellow; back of the thorax and edges of the abdominal segments black. Found in Sierra Leon.

COROLLE. Dowdy; thorax bronzed, with a yellow lateral line and feutel; abdomen depressed, black, with four yellow spots and tip.

UNSELATARIUM. Nearly naked; thorax blueish; abdomen black, with three white spots at the sides, and two streaks. It is found in Germany.

ABDOMINALIS. Black; abdomen rufous, with a black tail; antennae long; with a snowy hair. It inhabits France.

ROSAIUM. Naked; thorax black-bronze; abdomen black, with two yellow spots. It is found among flowers in Germany.

* MELLANA. Naked; thorax slightly bronzed, immaculate; abdomen with eight yellowish spots. It inhabits Europe, and is found among various species of Aphid.

* MENTHRASII. Naked, black; thorax spotted; abdomen with four yellow belts; feutel yellow. Thus, like the last, is found among various kinds of Aphid.

SCALARIS. Nearly naked, shining-bronze; abdomen with fine fulvous spots.

* SCRIPTA. Naked; thorax with yellow lines; abdomen linear, with yellow bands. It inhabits Europe.

OCYMI. Shining black-bronze; abdomen rufous, with a bronzed base and tip. It inhabits Germany.

DIPAR. Naked; thorax black, with a yellow lateral line; abdomen variegated with yellow and black. It inhabits South America on the Parthenium hysterophorum.

NECTAREA. Downy; abdomen yellow, the margins of the segments black, with a yellow band.

* ALBIMANUS. Downy; thorax bronzed; abdomen elongated, black, with white dots. It inhabits England. A specimen is in the museum of Sir J. Bankes.

DIMIDIA. Naked, deep black; wings black at the base. Inhabits the South American islands. This is a small fly.

PIPIENS. Naked; abdomen spotted with white at the sides; hind thighs clavate and toothed.

GIBBA. Variegated with black and yellow; head minute and orbicular. Found in Barbary.

GIBOSA. Dowdy, brown; abdomen sub-globular, black, with four white belts; scales of the poifiers inflated. This inhabits Europe.

ORBICULA. Naked, black; abdomen tinted with white.

ERRATICA. Nearly naked; thorax immaculate; feutel ferruginous; abdomen with three whitish bands.

CROSSIPES. Glabrous, black, with pale eyes; legs piceous, the hind ones large. It inhabits Europe, and is very small.

SALTATRIX. Naked, yellow; abdomen brown above; thorax with three brown lines. This is an European insect, and it skids like a Cicada.

OCHROLEUCUS. The front of this fly is white; crown and thorax yellow; the abdomen of ochre-yellow; legs black; hind thighs thick; wings white, with a brown band. It inhabits Europe.

FULVA. Thorax fulvous; abdomen black, with fulvous down, beneath ferruginous on each side; thighs black; shanks yellow, the hind ones black towards the tip; wings white, with a black band.

RUGINOSA. Black; feutel yellow; wings with white veins; the first two segments of the abdomen have a ferruginous band at the base; thighs ferruginous, the hind one thick and black towards the tip; shanks brown, the hind ones curved.

LEUCOCEPHALUS. Head white, according to its name; eyes coppery, dotted with brown; thorax cincereous, with four black bands; abdomen blue-black.

VULGA. Oblong and black, with rufous legs; hind thighs long and thick, with black curved shanks.

MELANOCHRYSUS. Black; second and third segments of the abdomen fulvous.

EUNEA. Thorax slightly bronzed; abdomen black with two cincereous bands; legs yellow, thighs black at the base.

INTERRUPTA. Thorax slightly bronzed; abdomen black, with a yellow band on the first two segments; the frill of which is interrupted; the legs are yellow; the ends of the hind ones brown.

NEVIA. Black; thorax spotted; abdomen with four interrupted bands; wings with a brown marginal spot.

HYROZONIUS. Thorax slightly bronzed with two oblique bands; feutel pale; abdomen with four interrupted bands and tip.

LUTPOLA. Black; second segment of the abdomen yellow on each side.

LINKOLATA. Black-bronze; crown with imprecised transverse lines on each side; abdomen depressed.

PHARIS. Thorax black; abdomen greenish-black, a little downy and depressed.

USHILA. This is a minute species, black with a downy
MUS

downy front; abdomen depressed, wings white; legs rufly-brown.

**Atraspis.** Slightly downy; thorax whitish, with three black spots; abdomen black, with interrupted yellow bands and margins of the segments. This is found chiefly in Austria.

**Alternata.** Thorax green-black; scutel yellow; abdomen black, with yellow bands alternately larger, the first interrupted. This also is an Austrian fly, as are the five that follow it.

**Muina.** Grey; thorax with three black lines; wings spotted with brown.

**Elephantopus.** Black; abdomen ferruginous at the base; hind thighs thick.

**Opuncata.** Black; base of the shanks and antennae fulvous-brown.

**Dizionius.** Naked; abdomen with two yellow belts; the fore-legs yellow.

**Larvata.** Silvery tefaceous; head inflected, snowy; legs annulate with black; wings brown hyaline spots.

**Monoculus.** Eyes large, very approximate; thorax brown; abdomen pale-gold. This is found in South America.

**Depressa.** Abdomen roundish, and depressed with three yellow bands; the first and third interrupted.

**Americana.** Thorax pale, with a black band; abdomen reddish on the back, and tipt with black; the body of this fly is very large, and covered with down.

B. The Flies in this Division are without Feelers.

A Specimen with a single recurved bristle without a sheath; the antennae are inserted at the base of the proboscis.

Species.

**Ulioziina.** Black; abdomen snowy, tipt with black. It is found in Germany and in this country. The proboscis is cylindrical, grooved on the back for the reception of the bristle; there is a white dot in the front; the poifers are white, and legs pale.

**Marginata.** Black; margin of the abdomen and shanks yellowish. This species is common in France and England; and is decribed as having, independently of its specific character, a black head. The antennae united at the base; thorax black-bronze; abdomen depressed, with a few faint whitish spots on the back; the thighs are black, and the wings are white.

**Villosa.** Black, with cinereous hairs; segments of the abdomen with a lateral whitish margin. Found in Hungary.

**Punctata.** Black, with three lines of yellowish dots on the abdomen. This species inhabits Barbary.

**Minor.** Black; abdomen snowy, with a black spot at the base. It inhabits Tranquarius.

**Tarda.** Smooth and black; thorax lightly bronzed; legs tefaceous.

**Formosa.** Thorax green; abdomen blue and dilated.

b. Sucker with a single bristle, without a sheath; antennae approximate, with an ovate compressed club.

**Filata.** Black; second segment of the abdomen pellicid at the sides; hind thighs ferrate. It is found in South America.

**Leucopis.** Abdomen black, the edges of the segments pellicid; sides of the legs white. It inhabits South America, and is about the size of a wasp.

**Bilignata.** Black, with two white lines on the thorax; shanks ferruginous at the base. It inhabits New Zealand. A specimen is in the museum of Sir J. Banks.

Vol. XXIV.

**Nectarivora.** Black; antennae cylindrical, perfoliate; wings white. This, wherever it is met with, is found on the flowers of fruit-trees; where it remains the whole day extrating their nectar. It has a small and oblong body.

**Musca, Grabronformis and Rapax, names sometimes used for the hornet-fly.** See Asilus.

**Musca Flissimemis, the wasp-fly.** See Asilus.

**Musca in Atriarum.** See Apis.

**Musca, in Antiquity, a designation given to parasites, buffalo, &c. who intruded themselves into the company of those that depilified them, or found means to be admitted to entertainments where they were not welcome.

**MusCADINE, a rich wine, of the growth of Provence, Languedoc, Cividad, &c.

The word, as well as the liquor, is French: some fetch its original from mufe, the wine being supposed to have a little of the smell of that perfume; others from musca, a fly, because the flies are extremely fond of its grapes; as the Latins had their vinum apinum, so called apidius, from the bees which fed on the grapes it was made of.

The way of making muscadine at Frontignac is as follows: they let the muscadine grapes grow half dry on the vine, and, as soon as they are gathered, they tread and press them immediately, and turn up the liquor, without letting it stand and work in the vat; the lees occupying its goodness. Phil. Trans. abr. vol. ii. p. 657.

**MuscAe** is used for officers of the popish inquisition, who feign themselves of the sect of the prilerrons, in order to detect, and confound their opinion from them, and thereby betray them; there being perions placed to overhear their conversation. See Musca.

**Musca: Volitantes, in Opiniæ, dark irregular veins and spots, seeming to fly before the eyes of many people, especially on looking at bright objects, such as white paper, the fly-light, the candle, &c. These have only the appearance of cobwebs, sometimes that of smoke, dust, &c. The resemblance of many of these spots to flies has given them the name of musca volitantes, q. d. flies flying about.

It is not easy to account for this phenomenon. Some will have its cause to lie in the aequous humour; others in the retina. Mons. de la Hire's account of them is this: they are of two sorts; some permanent, which, in fixing the eye upon a point of an object, appear always fixed in the same situation to that point; others seem to fly about, and to change their situation, though the eye be fixed. The shapes of both sorts are changeable; those of the first sort are commonly like a dark spot upon a white ground; those of the second sort appear like the knots of a dial board, some parts of them being very clear, and surrounded with dark threads; they are also attended with long illites of irregular shapes, which are bright in the middle, and terminated on each side by parallel black threads. On fixing the eye upon an object, they appear to descend gradually, especially after shaking the head suddenly.

The spots that appear fixed in respect to the axis of the eye, meir, for that reason, be caused by some disorder in a corresponding part of the retina, or in some part of the vitreous humour lying very close to the retina. For an opacity of the coats or humours in any part remoter from the retina, by intercepting some part of the rays of every pencil, could only cause an uniform obscurity or faintness of light in every place of the retina, and not a total defect of it in any particular place. Hence M. de la Hire attributes the cause of these permanent spots to small drops of extravafated blood upon the retina.

But he finds it more difficult to account for the moving spots. When the rays of the sun are tranfmitted through

3 A 3 piece
or insensibility in some parts of the retina, by which the im-
pulse received from the rays is made less sensible.

But, besides these defects in the retina, there is another
cause which may give occasion to these spots, both in the
myopia and myope's eye; and that is, certain small opaque
marks in the cornea itself, or any where within the eye,
which, by intercepting some of the rays, must occasion a de-
fect in the picture, from which defect a kind of dark spot will
be seen in the object. Thus, in the eye of a myop, if there
be any opacity in the cornea, or within the eye, which inter-
cepts the rays B b c d, and V L a, (Plate XV. Optics,
fig. 18,) there will be a defect in the picture at e, d, and a;
from whence also the external appearance will be deficient
at the corresponding points E, D, and A; where, by con-
sequence, dark spots will be seen. For it is to be observed,
that there is not one point in the picture which is formed by
a plurality of rays which meet at the point, but every ray
goes to a different point of the picture, both in myopic
and prebytchal eyes; and therefore, when any of the rays
are intercepted, that part of the picture to which such rays
belong will not be illuminated, which must occasion a cor-
responding defect in the appearance of the object. But in
the perfect light, where the rays which come from the se-
veral points of the object, are all refracted as to meet again
at the same point, and the corresponding points in the retina,
every point of the picture is formed by a cone of rays, whose base
is the pupil; and therefore, though some of those rays be in-
tercepted, yet no part of the picture will be darkened, and
consequently no defect will be seen in the object from any
such opacity in the cornea, or humours of the eye; unless
this opacity be in the back part of the vitreous humour,
where the pupil is narrow, and intercepts the whole pencil.
This may be proved from the camera obscura, by flicking
some small patches on the glas. These will not be per-
ceived if the paper is placed at the due focal distance;
but if the distance be greater or smaller, the spots will
appear.

The doctor also observes, that these spots are not all of
the same kind. He thinks that those which change not their
place with respect to the axis of vision, proceed from some de-
fect either in the retina or cornea, or in the vitreous and crys-
talline humours. As for those which are in constant motion,
he supposes them to arise from some corpuses floating in
the vitreous humour.

Besides these dark spots, there is another kind often met
with, which are more bright and luminous than the object itself
before which they appear. These spots appear first by looking
at distant bright objects, and are always of the same colour
with the object. In the middle their colour is clear and
strong, surrounded by a dark shady border. They are com-
monly accompanied with certain irregular veins, which pro-
cceed from each spot, and these, as well as the spots them-
selves, change their order and disposition. These veins are
also of the same colour with the object, and being bright and
luminous in the middle, are like-wise terminated by a
dark and obscure edge. These spots change their position
with respect to the axis of vision, according as the eye is dif-
ferently moved, being sometimes in the axis of vision itself,
and at other times to the right or left of this same axis; but
when the eye is kept fixed in the same direction, they, as well
as the dark kind of spots first mentioned, commonly defend
gradually.

As to the cause of these brighter spots and veins, it seems
that, first, they must proceed from some corpuses within
the eye, which are at liberty to change their place, and
which therefore must be supposed to float in the aqueous
humour. Secondly, seeing these spots always defend when
the
the eye is kept fixed, the corpuscles from which they arise must ascend; and are consequently lighter than the aqueous humour in which they swim. Thirdly, these spots being more bright and luminous than the object, they cannot be occasioned by any opaque corpuscles, which, by intercepting the rays, would cast a shade upon the retina. What therefore bids fairest for producing these brighter spots and veins, is some small, oily, diaphanous particles and filaments, which swim in the aqueous humour before the crystalline; for such, by their lightness, will ascend, when left to themselves; and, by their greater refractive power, produce these luminous spots terminated by dark lines. That oily and sulphurous substantiae, though less dense than water, have a stronger refractive power, is evident from the observations of Sir Isaac Newton. From which it follows, that the rays of light, which pass through these oily particles, will meet sooner behind the crystalline than the other rays; whence in a physiological eye, the rays of light which come from the several points of the object will not converge to so many other points in the retina, but behind it, by which the picture in the retina will be rendered more dark and obscure; but the rays which pass through these oily grains, by having their refraction increased, will meet nearly at the retina, where they will form small luminous spots, surrounded with dark borders.

But we must here observe, that the same appearances happen to myopes; and this seems difficult to account for from this theory of the learned doctor.

Many medical authors have looked on the mufcae volitantes for forerunners of a cataract, or gutta serena. And we suppose it cannot be denied, that many who have fallen into those terrible disorders have had those appearances before their eyes; and hence they might have been taken for prognostics. But as it is no less certain, that many thousands have the same appearances, and yet preserve their sight very well to the last, there seems to be no great reason to be alarmed about them; and far less should people be running to quacks, and injuring their stomachs and constitutions by ill-judged physic on such occasions. St. Yves denies these appearances to be at all dangerous, and he thinks them owing to the separation of some parts of the retina from the choroid. However, as the disorder is troublesome and alarming to the patient, be advises purgatives from time to time, and millepedes. We can say, from experience, that neither mercurials, nor sea-water, nor other purgatives, nor mille pedes, nor again Tunbridge or other chalybeate waters, have had any effect towards removing or diminishing these disorders. A greater dose of wine than usual has been known to increase it for a little time; and Pleni pus has made the like observation. We shall only add, that several of these flying appearances resemble little globules joined by threads, thus: and these globules appear in different numbers, and at different distances.

All authors agree, that these appearances change their figure, as is true, in some measure; but from our own observation we can say, that though they seem, on a sudden looking to the sky, or other bright object, to vary in their figures; yet when they begin to descend, they return in one constant figure before we lose sight of them. On the whole, it seems this phenomenon is not yet fully accounted for. The vaeular form of most of these appearances, and their resemblance to small veins or arteries, make it difficult to conceive them floating in the humours of the eye; and, on the other hand, their seeming contortions, and change of figure, on suddenly looking up, or shaking the head, make it no less difficult to conceive them fixed and obstructed capillaries, as many authors suppose.

MUSCI, in Botany, Mofci, a most distinct and natural order of plants, of the Linnean class Cryptogamia. The word occurs in the best Latin writers, but its origin is unknown. Ambrobinus deduces it, in his Phytologia 113, from mycor, a young calf or lamb, as well as the young foetus or tendril of a plant, which is not an improbable etymology, and is adopted by Ray. The elder botanists have found still more difficulty in defining the nature of a Mofc, than in the derivation of its name. Ray says, "Mofces are bell distinguis hed by their minutenees; their lefs succulent, or even arid, substance; their power of reviving quickly, by immer sion in water, after they have been dried; their dry or objection situations, expofed either to extreme cold or to searching heat, upon trees, timber, or flones, where no other plants could exist or endure; finally, their mode of producing fruit, which is unlike that of other vegetables." Dillenius, who takes the idea of a Mofc in its widest sense, and who has illustrated the whole order, as he understood it, in a most careful and learned manner, has scarcely improved upon the definition of Ray. He speaks of Mofci as "an inferior tribe of plants, the most imperfect kinds of which confit, either of simple and uniform parts, delatuate of flower and seed; or of parts differing among themselves, accompanied with something in the place of flowers and fruits, which is analogoues to those organs. The more perfect kinds are composed of parts not so much differing in figure, but are besides furnished with organs containing a pulpy matter, that becomes dry in ripening, and when arrived at maturity flies off, in the form of an extremely subtil powder, serving for the propagation of the plant." Of these "more perfect" kinds, or Mofci properly so called, we are now to treat. It is therefore needless to detail more of the definitions of Dillenius, which apply to the vail tribe of Lichenes (see that article); as also to Byssus, Confervos, Tremello, &c. all now excluded from Mofci; nor shall we, except incidentally, speak of the Hepatice, which the eminent writer last mentioned includes under Mofci, and which indeed compose the next link in nature's chain. See Hepatice.

Linnaeus first circumferbed the natural order of Mofci within its just limits. It makes the second order of his Cryptogamia, and except the genus Lycepodium, which does not so properly belong to this order as to the Filice, and Portellis, which is a mistake, he includes nothing but what answers to the most correct and most recent ideas on the subject.

Mofci, according to the Linnean idea of the order, as well as the latest discoveries, are defined as follows.

Herb leafy. Corolla like a hood, bearing the style, and covering the capitule, which is clozed with a lid. Thee plants agree with the Hepatice in the very extraordinary nature of their corolla, which is formed like a conical hood, and tipped with the style. It is termed the calyptra, or veil. But Mofcis differ from the order just mentioned
tioned in having the capsule closed with a lid, usually deciduous. Their herbage also confits of a item with distinct leaves; in the Hepaticae the herbage is frondose. (See Hepaticae.) Hence the appellation by which the great Hedwig designates the tribe in question, "mutefi frondosi," seems incorrect. Such would have well expressed the Hepaticae; while the Moles might have been called "mutefi foliati."

It muft however be confessed, that there is in Moles, as well as in the leafy Jungermannia, a frictive union between the item and leaf; that the latter scarcely ever separates from the former by a solution of continuity, as in other clafes of vegetables. The old leaves of many moles indeed break off, but always in an irregular manner, from brittlefefs caused by decay, and not by the separation of a dying or difeased part from a vigorous living one, as in the leaves of trees and shrubs. Moles more agree in this particular with some herbaceous plants, especially of those termed monocotyledonous, which also reemble in their highly vafcular or cellular texture, and in the rapidity of their adsorption and perifpiration. Some of them are no fooner gathered than they begin to wither, as Polytrichum undulatum, Engl. Bot. t. 1220, and Bryum biglutatum, t. 1449. But though ever fo long dried, even for fifty years, or probably as long as their texture endures, they retain their original form, with the greatest facility and exactnefs, by immersion in water. Some of their minutest parts are the moft perfect of hygrometers. See Fringe of Moles.

The reticulated structure of their diminutive vegetables, like that of the Jungermannia, is rather known to us by its beautiful appearance under a microscope, than by any precise notion of its construction or economy. We know scarcely anything of the form or action of the vessels of their leaves, except that the strong mid-rib, usual in Moles, though almost universally wanting in Jungermannia, is a cluster of parallel tubes, much the fame indeed as in the foliage of other plants. But this rib fends off no visible branches, or tranfverfe veins, into the apparently uniform cellular fubftance of the reft of the leaf, nor is any thing known of the mode of the propagation of fluids, however rapid, through that fubftance.

The roots of Moles, which are fibrous and branched, absorb with equal facility. There are not confined to the bafe of the plant, where it is fixed to the soil, but are often abundantly protruded, in fine, minutely joined, branched tufts, from various parts of the item, which double its imbibite nourifhment, as they readily do any portion of humidity.

The item of these plants, always more or lefs prezent, is often fimple, though frequently branched; either in the usual manner; or by protrusion, or innovation as it is termed, through or beyond their fructification, much the fame as in the Bromelia Ananas, or Pine-apple, the genus Pinus, and fome-others. The leaves of Moles however are invariably fimple and undivided, their margin only being often ferrated, and in one or two inftances toothed. (See Trichophorum kaingiophorum; Engl. Bot. t. 1248.) Their fructification is in some lateral, and in that cafe always perhaps axillary, but it is more generally terminal.

The Fructification of Moles is one of the moft curious fubjefts of vegetable phyfiology. As we detail its history, we fhall declare the organs concerned. There are of two kinds, and constitute the flowers of Moles, though they are neither fo determinate in number, circumfcribed in situation, nor fanced with appropriate and distinct integuments, as in flowers or blossoms commonly so called. The male, or barren, flowers of the plants in question, confist of an indefinite number of flaments, confifting of erect parallel anthers, supported by very short filaments, and difpofed on an horizontal receptacle. Each anther is membranous, of one cell, opening at the summit, for the molt part with a lid, and difcharging an extremely fine elastic powder, or pollen, after which the anther becomes flaccid, and withers. Intermixed with the anthers, we find a number of slender, club-shaped, jointed, pellucid, juicy flaments, about whole nature there has been much difpute, but which feem moft probably abortive slaments, capable, according to circumfances, of being perfected, but generally inefficient and superfluous. Abundant fimilar indications to this, occur throughout the vegetable kingdom. Such is the usual structure of the flaments of Moles; but the genus Sphagnum differs somewhat from the reft. Its anthers are elliptical, supported by taller flaments, and each is encompassed with the fembleance at leat of a vertical jointed ring. They likewise indeed burft at the top, though not with a lid. Their structure approaches nearly to the anthers of Jungermannia, fo copiously illustrated, and now placed beyond the reach of doubt, by Mr. Hooker, in his valuable monograph on that genus. It may be worth observing that the habit of Sphagnum approaches Jungermannia, in its pallid hue, highly cellular texture, and want of a midrib in the leaves. The male flowers of moles are often accompanied by an extraordinary change in the neighbouring leaves, which affume an enlarged, coloured, fcarlet-like aspect. Thofe parts were all noticed, in the Bartramia fontana, by Linnaeus, as he travelled through Lapland, in the fummer of 1732, and the juft ideas which he conceived of their nature may be seen in his "Tour in Lapland," v. 1. 193, which remained latent in his manucript journal till very lately. It does not appear that he had then obtained any knowledge of the fimilar obfervations of Micheli, published in 1729 at Florence. That author, in his 59th plate, describes, with great fidelity, the anthers, accompanied by their barren flaments, in feveral moles; but mistakes the former for female organs, the latter for male, comparing their situation, with refpeft to each other, to the florets of compound flowers.

The female or fertile flowers, or pillifs, of Moles, were at first defcribed by Schmelz, in his Icones Plantarum, p. 16, where he mentions having obferved them in Mnium pellucidum, now called Tetraphis pellucida. At the fame time we think he clearly indicates their nature; though Hedwig gives this honour to Schreber, who certainly in his celebrated difcuffion upon Phoefum, p. 19, more decidedly explains the matter. To Hedwig himself however belongs the merit of having amply defcribed and delineated the pillifs of numerous Moles, in his various publications. Thofe are ufually, but not invariably, in a separake flower from the flaments, and confift, in their earliet flate, of feveral erect, parallel, tubular bodies; highly enlarged, and moist, at their bafe; membranous, dilated, and apparently pervious, at their summit. It is feldom indeed that thofe organs have been inveftigated in their earliet and unimpregnated flate; for one, if not more, of them is commonly found more vigorous than the reft, which wither at its bafe. It feems that, as soon as impregnation has taken place, the tubular part, which confists of both stylo and stigma, is greatly and speedily elevated, in conformance of an enlargement of the infant german; and still more, by the produc tion, or elongation, of a peculiar organ, termed the fruit-flask, on which the german stands, and by whose sudden growth the young vei, or calyptra, is torn from its bafe, and carried up along with the german or young fruit. There it remains entire, crowned with the brown withered stigma, till the swelling fruit oblige it to sipe, turn afide, or fall off. The elevation of the calyptra is one conflant point
point of difference between the Musci and Hepaticae; for in
the latter it bursts to let the capsule pass. Nor can we re-
frain from mentioning another coincidence between that
order and the genus Sphagnum. The base of the calyptra
is permanent in the latter, as well as in Andreaea, the upper half
only of that membrane being torn off by its swelling cap-
sule, which capsule is remarkable for remaining entire, hav-
ing no fruit-flask, in which circumstance we trace a further
resemblance to some genera among the Hepaticae. We mean
not, by pointing out these analogies, to hint at any real am-
biguity in the nature of the genus Sphagnum, which is truly
and properly a MoS, as well as Andreaea.

The fruit of this order is invariably a capsule, of one
cell, opening by a transverse dehiscing lid, and distillate of
valves, except in Andreaea, which has four valves, and a
more permanent lid. There is another leaning objection,
in the genus Phafcum, the most diminutive of Musci, whose
lid, though indicated, as usual, by a beak, and by some dif-
difference of colour, is not really deciduous, the capsule split-
ting at one side only, in an irregular manner. This is one
of those curious exceptions, which occur in every depart-
ment of natural history, like the solitary inflorescence of three
stamens, instead of five, in one fynageneous plant, a species
of Siegesbeckia, and the diffusion of the anthers in a very few
more of that most natural clafs. The lid of the capsule of
Mollus is rarely without a conspicuous point at the summit,
which is often elongated into a conical or taper beak. To
this the inner side of the veil is, in an early state, attached,
their union being disjoined sooner in some species than in
others. The central part of the lid itself is united to a
central column, most conspicuous in Gymnoleaen, and, ac-
gording to Hedwig, present in all Mollus. Whether impreg-
nation be communicated to the seeds through this col-
umn, or by any other channel, has not been explained.
By Hedwig's figures of some unripe seed-vessels, the young
seeds seem to occupy but a small cavity, in the midft of a
highly cellular or vascular mass, through which it must be
presumed the action of the pollen may be communicated.

The base of the capsule or the top of the fruit-flask, is some-
times accompanied by a tumour, or succulent append-
dage, often coloured, highly remarkable in the beautiful
genus Sphagnum, of which it forms one of the most striking
characters, being in some species far more obvious than any
other part, in the form of a broad circular disk or cap, of a
vivid red, or bright yellow. Yet its use is totally unknown.
Its colour indicates some connection between this part and
the action of light; which may perhaps operate through it
upon the fructification, as is supposed to be the cafe with
the petals of other plants.

The base of the lid, or the orifice of the capsule, is in
everal mollus surrounled by an elastic band, termed the
anulus, or ring, whose infde is lined with two, three, or
four rows of succulent pellucid procefses. The precise use
of this part is not determined, except that, being an ex-
quifite hygrometer, it may by its spring serve to throw off
the lid. Hedwig has detected it in many species of Hypnum,
but recommends the common Dicranum pulvinatum, or rather
Grimmia pulvlnata, Engl. Bot. t. 1728, as a fit subjed for
examination on this account.

The Fringe of the capsules of Molles has already been
explained in a separafe article. (See Fringe.) We shall
advert to it again presently. It is hardly worth mentioning
that Meefe, as well as our Sir John Hill, fancied the fringe
to be the flaments of Mollus.

The seeds of these plants are extremely abundant and
minute, appearing to the naked eye like an impalpable
powder, of a green or brown colour, protruded from the
capsule on the removal of its lid, either spontaneoufly, or
by the slightest comprefion of that part. That this fine
powder is really feed, has first been proved by Meefe, who,
in the year 1767, raised plants of Polytrichum from thence.
(See Meenfa.) But the far more accurate and lucid ex-
periments and remarks of Hedwig, now leave no doubt on
this subjed. That acute observer detected differences in
the shapes and surfaces of the feeds in different Mollus, in
some measure analogous to the various configuration of the
same part in other natural orders. He has also repeatedly
observed their germination, and delineated their cotyledons,
that if such they may be called, which are perhaps the most
curious and extraordinary part belonging to these plants.
When the feed of a Mollus lends forth its radicle downward,
it protrudes upward an oblong, obtuse, succulent, pellucid,
jointed shoot, either simple or branched, solitary or accom-
ppanied by several others like itself, which should seem to be
analogous to the cotyledons of other plants; and yet in
their appearance, and frequently multiplied and undeter-
mine configuration, are very unlike the generality of those
organisms. The diftinction between them, and the infant germ
or herbage is as strongly marked as possible, in which refept
the germination of Mollus differs a little from that of Ferns.
Otherwise the latter might be expected to throw much light
uppon the former. The detection of these parts in Mollus,
overthrows the classification of them among the monocotyled-
ones, or acotyledones; which indeed, though generally
adopted, has always been hypothetical. The ingenious
Mr. Brown, well aware of the danger which hence arises
to the main hinges of the natural fyflems at present esta-
blifhed, hints, at the end of the preface to his Prodomus
of New Holland plants, that the fuppofed cotyledons, both
of Ferns and Mollus, are entirely the produce of germina-
tion. We ought not, perhaps, to throw this opinion from
us at present, to be ced, and shall be very glad to get rid of
the difficulty, which fems to have been all befioned by con-
dering the parts in question as of a new and unheard of
nature, unless we on that account decidedly separate the
two natural orders from all other plants, as clafs by themselves,
which their anomalous nature in many respects would abund-
antly authorize.

Having given the above view, which appears to us the
true one, of the fructification of Mollus, it is proper to
mention some different hypotheses, which have been
advanced, by botanists of great eminence, upon the fame
curious subjed. We shall first difmiss the decision of
Necker, who declares that "whatever has been advanced,
or may in future be said, of the sexual propagation of
Mollus, will always be to him a fiction and a dream;" that
he is "certainly persuaded no perfection in any age will be
able to demonstrate such, in any of the Mollus at prefept
known;" and he undertakes to prove that "Mollus have
neither any distinct male and female organs, nor any real
feed." This challenge he never made good, and he is re-
futed by the experiments of Hedwig. Necker, like Adan-
on, believed that Mollus were propagated by birds or
buds, the latter says even by feeds, without any fecunda-
tion. No doubt they are so increased, like the bulb-bearing
Lillium, Dentaria, and Saxifraga; but this does not pre-
clude sexual generation, in the one cafe more than in the
other. Haller was nearly of the fame opinion with Necker,
but rather from reading than experiment, as many others
have been. Another sect of philosophers have made a
comprehensive the sexual fyflem, by presuming that the dust
of the capsules, now proved to be feed, might partake so
far of the nature of pollen as to give vigour and increase to
the buds of the plant by falling upon them. What they
under
underfoot by these buds, were in some cases really so, but
most frequently the male blossoms, after the production of
which they observed the branches of some mosses, as the
Polytrichum, to make a sudden float, and this was the only
circumstance that favoured their hypothesis. Of this opinion
was Dillenius, the great investigator of the species of Mosses,
but of less authority as a physiologist. We have already
mentioned his influence over the better judgment of Lin-
neas, whom he misled on the point before us. (See Dille-
nius.) Hence, throughout the works of the great Swedish
botanist, what is really the capside is called the author, for
such he, as well as Dillenius, believed it to be; though the
latter negligently termed it capside, meaning by that word
simply a little box, not a feed-veiffel. Hedwig, who rightly
understood the nature of this part, not content with its pro-
per name, denominated it Sprotangium, which is merely a
translation of feed-veiffel into Greek; for by the term fopkre
he meant precisely fiefs, the produce of sexual impregnation,
so as all his experiments tended to prove. This mistake
cannot be too often imputed on the Cryptogamic student.
We have already twice adverted to it. (See Grama and
Hedwig.) Nor can we too often depurate the admission of
new terms into the sciences of natural history or philosophy,
when they communicate no new information, and either mark
a distinction without a difference, or, as in the present cafe,
lead only to error.

The Hedwigian theory of the impregnation and femal
propagation of Mosses being, as it appears to us and to most
practical muscologists, to lately established, it was little to
be expected that a new hypothesis would, in our days, be
advanced. Yet such a phenomenon has appeared, from the
able pen of no inexperienced theoretical adventurer, but a
practical and philosophical botanist, M. Palhgot Beafoois,
whose ideas on the subject, which we shall briefly state, may
be seen at length in Sins and Konig’s Annals of Botany,
v. 2, 218.

This writer considers what we term the capside, as a
flower, containing within itself the male as well as female
organs of impregnation. It is composed of five parts,
which are always present, and indispensable; and occasion-
ally of one or more of five others, which are accessory or
adventitious. All these we shall detail.

1. The veil, which is, as we have described, of a hood-
like shape, either smooth, or frutated, naked or hairy, single
or double. This part is considered by the author as a sort
of external corolla, at least with regard to its functions. It
envelopes every part of the young budding flower, except
the peristetum, or sheath, where such is present.

2. The lid, an organ almost peculiar to this family, as
above described. This, as M. P. Beavous thinks, falls off
at the time the flower is ripe for impregnation. The Hed-
wigian botanists believe it to remain till the feeds are ready
to be dispersed.

3. The urn, which is not other than our capside, or at
least its external coats, with which the outer fringe, when
present, is connected. This urn the author compares to a
real corolla, or second integument of the flower.

4. The pollen, or fecundating dust. An assemblage of
minute round rough grains, contained in a peculiar mem-
brane, covered by the urn. This membrane is open in some
mosses, and furnished at its orifice with fine teeth, the inner
fringe of Hedwig; in others it is closed, buried when ripe,
without any teeth or marginal fringe. Its shape is conform-
able to that of the urn. In mosses furnished with a fringe,
this dust explodes with one or two puffs. This supposed
pollen is what those of the Hedwigian school believe to be
the feed, because they have seen it germinate and produce
plants, which is surely enough to confute the system of our
author.

5. The pilif or capside; the central column, or columnella,
of Hedwig and his followers. “An organ of various forms,
occupying the centre of the urn, inclosed within the anther-
erous sac, and surrounded by the pollen.” No style is to
be discovered, except perhaps in Splachnum. The stigma
is capitata, four or five-leaf; pointed and conical in some
species of Hypnum. Germs oval or oblong, smooth or
villos. “It is generally supported on a fillet, that takes
its rise from the sheath, traverses the tube (or fruit-falk),
and penetrates as far as the urn, where it sometimes divides
into several branches, that unite again at the base of the
germs. At other times it traverses a green feiffly fab-
liance, that occupies the bottom of the urn, and on which
the capside appears to rest.”

The five following parts are of only partial occurrence.

6. The teeth (or outer fringe). These form a border
to the outer covering of the urn, and are generally lanceolate,
pointed, variable in number from eight to thirty-four (the author
considers the four teeth of Tetraphis as constituting the lid. not
the fringe, a great error, copied from Schmidel), single or
in pairs, or each split into two, rarely short and obtuse.
“They when present contribute essentially to fecundation,
by means of a regular movement of irritability, by which
they alternately recede from and approach each other.” In
Polytrichum the teeth are immovable, and accompanied by
an horizontal membrane. In some genera they are attended
by an inner fringe, in others not. Several mosses are de-
finite of these teeth altogether.

7. The eliks (or inner fringe). These form, at the orifice
of the urn, a border to the inner membrane, of which they
appear to be nearly a continuation. They are slender, of a
shy aspect, straight or spiral, generally eight, eighteen,
or thirty-two, distinct or united into one or several bundles,
and as like the teeth, separately or conjointly with them,
in the fecundation of the seeds. Their irritability is less,
and consequently their movement not very evident. The
author considers the twifled teeth of the genus Tortula
as of the nature of an inner fringe, unaccompanied by an outer
one, in which he appears to be very correct.

8. The horizontal membrane. This is peculiar to the mosses
included by Hedwig under Polytrichum, of which M. P.
Beavous makes three genera, and what is commonly taken
for their inner fringe. It is very thin, perforated like a
veil, and supported by the teeth.

9. The fheaths, which is nearly universal, is a small cylin-
drical tube, at the base of the fillet or tube of the urn,
and may be considered as an inner calyx, in which the urn,
and all its parts above described, are enveloped at their first
formation.

10. The peristetum, or fcallie fheath, this is effected by
the author as a real calyx, in which we concur. It con-
stitutes of several leaves, generally membranous, constandy dif-
ferent from the fheath, and more or less imbricated. This
part is exemplified in Hypnum and some other genera. We
have not before mentioned it, or the foregoing.

M. P. Beavous observes that as soon as the fringe, or
fringes, are no longer retained by the lid, “they begin to
move one among another, separating and approaching each
other alternately, as long as the urn contains pollen and
feeds.” He conceives, therefore, that in all mosses fur-
nished with any fringe, the pollen and feeds are discharged
with an explosion, the inflant the lid falls off; and that the
teeth serve to retain both for a while, and to promote their
coming in contact with each other; for his opinion is, that
fecundation
The objections of Gärtner to the Hedwigian doctrine of the flowers of Moffes, though laboured, are entirely hypothetical, and in that respect unworthy of so great a practical inquirer. They are, if, the diocious nature of most Moffes. "Why," says he, "should Nature, in this numerous tribe, have chosen the most uncertain and difficult of all modes of fecundation, unless it be said that she has purposely aimed at defeating her own ends?" On this point we humble leave Nature to answer for herself, and we believe that a satisfactory reply will not be withheld from any unprejudiced inquirer. 2dly. Gärtner says the impregnation of these plants is supposed to take place at a period when nothing like the rudiments of seeds can be seen in the corolla or germin, the contents of which are then a pulpy chaos. We would ask, in answer to this, what could be discernible, at the same period, in the germs of many of the largest and most perfect flowers, if reduced to the same exquisite minuteness? How are the pulvini coats of seeds scarcely visible when ripe, and umbilical vessels hitherto unseen at any period, though Gärtner himself would certainly not doubt their existence; how are these to be detected so early? As to the word chaos, as applicable to what is incertible to the human eye, would Gärtner apply that term to the yolk of an egg even before impregnation? 3dly. This writer affords that many of these supposed anthers never discharge any thing, but fall off entirely. Here he appears to have taken buds for anthers. He adds, that if some of them do "belch forth" (we use his literal expression) some granular matter, that explosion is allowed by Hedwig himself to be chiefly caused by moisture, "whereas nothing is more certainly fatal than moisture to real pollen, nor does any thing more hinder its explosion." This last passage is truly curious. Did not Gärtner know that pollen in general explodes by moisture alone, that the liquor of the stigma is destined to make it explode, and that the accession of wet is injurious, only by causing it to explode prematurely? If we give him credit for being ignorant of the nature of the pollen in the Orchideae and Convolutae, had he not seen enough of other plants to understand that there may be different kinds of pollen, whose structure and whole mode of operation may be in some measure as various, as those admirable seeds and seed-vessels with which he was so conversant? Could he not conceive that the pollen of vegetables destined to blossom in moisture, like Myrti and Hepatic, might, by something refinens in its composition, be protected against atmospheric humidity, and be soluble, or active, only through the operation of a substance appropriated to that purpose, which Hedwig seems actually to have detected in the stigma of Bryum pinnatum; see his Fund. 4. t. 10. p. 67.—45thly. He objects to the probability of the supposed anthers being fuch, and fill more to their being, instead of anthers, themselves naked pollen (as Hedwig at one time thought), because of their prodigious size compared to the seeds. As to their being anthers, as we believe, or naked grains of pollen, it is of no importance to the argument. Does not this very circumstance, of the great bulk of these parts, tend to invalidate Gärtner's first objection, as it would appear that in their, as well as in the larger diocious or monocious plants, there is a superabundance of pollen to compensate for the hazard which attends its conveyance?

Veuve has been favourable to Gärtner's opinion, in his Tableau du Regne Vegetal. v. 2. 44—49. chiefly because he says many Moffes are totally deprived of the supposed male flowers. He ought rather to have said "they have not been observed in all," at which those who have ever so little practical knowledge of the subject will not wonder. Moffes
Moffes are generally most noticed and collected when their capsules are fully formed, or ripe. The more they are examined earlier, the more of their male flowers are, from time to time, observed. The same writer remarks that there are Moffes which fruixly under water, where they pass all their lives. He asks, "If the organs are not both in the same cover, how can they reach the female organ, without being spoiled by the water?" This is indeed a difficulty respecting the history of mosses, as well as of some other plants. To remove it, we ought to investigate the very few Moffes so circumstanced, and to observe carefully whether they do not rise above the water at the flowering season, like the numerous tribes of other aquatic plants; or if otherwise, whether their pollen be not of a peculiar nature, accommodated to its situation, like that of the Chama. We think the former would most likely prove to be the truth.

The Systematical Arrangement of Musci comes next under our consideration.

On this subject nothing can justly be said to have been attempted previous to the labours of Dillenius and Linnaeus. They most laudably depended upon the parts of fructification only, as far as they knew, or thought they understood, those parts, for the accomplishment of their purpose. They aimed at establishing genera upon this bare basis, while they paid at the same time a due regard to habit in their conceptions of the genera. On this last point, the great men stand unrivalled by any of their successors, few of whom appear ever to have kept any such object in view. The deep-seated philologists of the German school, seem unaccountably ignorant and incurious respecting this part of the study. Dazzled with the discoveries of their great Hedwig, and with the beautiful preface of his technical marks of discrimination, they take those marks for absolute guides, without advertizing to natural differences or affinities.

Some of Hedwig's successors especially, carry this artificial principle to excess, and take its extreme refinements as a standard of excellence. "Such different talents are observation and judgment!"

Dillenius considered a transverse decussate lid to the capsule as the distinguishing mark of his "more perfect mosses," our Mufci properly so termed. This character also belongs to his Mniun, though he places that genus by itself, on account of its bearing "two kinds of powdery heads," one of which indeed is the male flower, the other the capsule. Dillenius in his ideas reversed them, taking the one for the other, as we have already explained; nor is his primary definition, in which he includes Mniun with the tenth, strictly correct, according to his own theory, "fructification conscienz in powdery heads," for he telescoped those heads to be anthers, consequently only a part insufficient to fructification. It is however more literally true, if we take the heads for real fruits, or capsules of seed, as they now are proved to be.

We shall therefore continue to use this appellation for the part in question, as we explain the arrangements of Dillenius and Linnaeus, though the former only called them so, believing them to be anthers, and the latter used the latter word, because he judged it to be correct. To recur to this confusion of ideas and terms, would perplex us in our progress, and the reader of Linnaeus has only to substitute everywhere the word capsule for anther in his characters of these plants.

The next subdivision of Dillenius, into Moffes with a calyptra (veil), or without, is erroneous. The latter consists of Sphagnum alone, which is known to have a veil.

His next section is into Moffes with fertile capsules, enclosed in a sheath or calyx," of which Fontinalis is the only example, though its capsule is by no means really fertile; and Moffes whose capsules have no such calyx (or rather are not included therein), but stand on longish fruit-talks, termed by him bristles.

The latter are distinguished into those whose fruit-talks are axillary, and produced along the branches, being encompassed at the base with a scaly involucrem, different from the leaves, which are the characters of Hypnum; and those whose fruit-talks proceed either from the ends of the stems or branches, or from the roots, or from annual shoots which, in the preceding year, were the termination of the stem. Such fruit-talks want the scaly involucre, but have a tubercle for their base. The veil of this last section is either smooth, which marks the genus Bryum, or hairy, which is the character of Polytrichum. These are all the Dillenian genera. Linnaeus has added to them Ptkum, Buxbaumia, and Splatbtum; but his characters of the two first are erroneous, though the genera are distinct. We have already mentioned that Linnaeus includes Lycopodium among the Mufci, as indeed does Dillenius, but the latter places it (subdivided into four genera) in a separate section, distinguished by having no lid to the capsule. As to the Porell (or Porania as Dillenius at first called it) of these authors, it is proved by Mr. Dickson, in Tr. of the Linn. Soc. v. 3. 236, to be a Jurrgermania which had met with some injury.

Botanists have often met with difficulties in the application of the above principles, which did not escape those who first advanced them. Some Moffes referred by Dillenius and Linnaeus to Bryum, have really a false involucrem; as the Aspiarium and its allies, Dill. i. 46. In others there is great difficulty in ascertaining the fruit-talk to have been originally terminal, so much is the stem or branch elongated beyond its origin or inflorescence, of which some of those, formerly supposed Bryum, now referred to the new genera of Diasiunum, Trichophorum, and Tortula, afford instances. All such difficulties are removed by the modern improvements, of which we are now to speak. Hedwig, by taking the Fringe and its various forms into consideration, has opened a new and most successful road to the clear definition of the genera of this natural order, as we have already explained. (See FRINGE.) We have in that article exhibited the characters of the part in question, in all the genera which appear to us well distinguished thereby. But it is necessary here to give a full exposition of Hedwig's system, including all his genera; that the student may see to what extent this original principle of the author is there employed, as well as what use he has made of the principles of his predecessors. Thence, as well as his own, he has carried to their greatest extent, introducing the lateral or terminal situations of the male as well as female flowers into his generic characters. This is his chief error; splitting the subject into obscure, uncertain, and unnatural refinements; losing sight of the great Linnean rule, that "the genus ought to give the character, not the character the genus," and, in short, rendering the whole system as artificial and as difficult as it could be made. We shall correct a few incidental mistakes as we proceed. It would be too tedious to trace the progress of Hedwig's arrangement, through the changes which have taken place in his different publications; especially as there are not material; and we shall take his latest view of the subject, from the Species Muscorum, published in 1801, after his death. The hard Greek names which encumber, rather than diftinguish, his sections, and his new terms for well-known things, may be dispensed with. His merits far outweigh such blemishes.

Sys.
System of Hedwig.

The capsule of Metz is either deilettate of a regular orifice, as in
or constricted with one, as in all the following.

Mouth naked, or deilettate of a fringe.

1. Male flower club-shaped - Spagnum.
2. Do. in a terminal lead - Gymnogonium.
3. Do. auxiliary - Anidium.

For remarks on these three, see Gymnostomum.

Fringe of a single row of undivided teeth.

Teeth four, unconnected at either end; flowers polygamous - Tetraphis.

[Mr. Hooker has shown, Tr. of Linn. Soc. v. 10. 382 - 387, that this latter has a capsule of four valves, which botanists in general, like Hedwig, have taken for the fringethe, but which in fact afford the peculiar character of Andrea. bearing the lid on their points, and flaring at the base of the middle part, only to let the seeds past. Ehrlhart originally described this capsule rightly; but his ideas, buried in pedantic novelty of phraseology, have been overlooked.]

Teeth eight, capsule without an apophysis - Oolithothamn. Splachnum.

Teeth sixteen, capillary or linear, straight and equidistant;

male flower axillary, female terminal on the same plant - Encalypta.

male and female flowers axillary on separate plants - Pterigynandrum.

(Pterigynium of other writers.)

male as well as female flower terminal - Gymnotidum.

male as well as female flower axillary - Didymodon.

male flower axillary, female terminal - Tortula.

male and female flowers terminal - Barbula.

Teeth sixteen, pyramidal;

male flower axillary - Grimmia.

male flower terminal - Weijsia.

Teeth more than thirty, cohering by a membrane;

male and female flowers terminal - Polytichium.

Fringe of a single row of elongated teeth;

Teeth thread-shaped and straight, narrow at the base; male flower axillary - Trichomium.

Teeth broad, deeply elongated;

male flower axillary - Fissidens.

male flower terminal - Dicranum.

Fringe double.

Inner Fringe membranous, with pointed teeth;
flower united, terminal - Weblera.

Inner Fringe membranous, with abrupt teeth;

male flower terminal - Buskiaenia.

Inner Fringe membranous, furrowed, contracted into a cove, finely laciniated at the orifice;

flower united - Bartramia.

Vol. XXIV.

Inner Fringe with reticulated teeth;

male as well as female flower axillary - Fontinalis.

male as well as female flower terminal - Mesea.

Inner Fringe with ciliary teeth;

unconnected and equidistant - Neckera.

unconnected, approaching each other in pairs - Orithorichum.

Inner Fringe with ciliary teeth; cohering by a membranous base;
tooth uniform; male flower axillary - Timmia.

female terminal - Pohlia.

male and female flower axillary - Lefkea.

tooth of various shapes; female flower terminal; male flower terminal, divided - Mnium.

male flower terminal, in a round head - Bryum.

male and female flower axillary - Hymnum.

Inner Fringe with ciliary teeth; cohering by their points;

male and female flower terminal - Funaria.

The author of the Flora Britannica first presumed to abolish Gymnotidum and Didymodon, uniting them to Trichomium, from which they differ in having their teeth, though approximated in pairs, quite unconnected at the base. But the membranous web in Trichomium is often so very flat and narrow, as to be hardly discernible, though in other cases more obvious; and these mosses are all by nature evidently of one genus. The lateral or terminal situation of the flowers, whether male or female, in mosses with a single fringe, will appear, to those who consider them under that point of view, to lead to no natural disentanglement whatever. The character is also peculiarly difficult in these to ascertain, and we question much whether Didymodon will really be found to have axillary female flowers, if examined at the time of their first formation. For the same reasons Barbula of Hedwig is sunk in Tortula, and Weijsia in Grimmia, by all British botanists.

As to Fissidens, the genuine species of that genus, whose leaves are two-ranked and compressed, form so natural and distinct an assemblage, that it is much to be wished they could be separated from Dicranum. In consideration of their very peculiar habit, perhaps the Hedwigian character of the axillary male flowers might here be allowed to mark the genus; more especially as the female flowers are in some cases lateral. (See Dicranum, sect. 8.) It must also be observed, that none of Hedwig's species of Fissidens appear to be no less improperly considered as such by their character than their habit. In the latter they agree with Dicranum, and it is difficult to understand, by Hedwig's own excellent plates, how he could consider their male flowers as otherwise than terminal. The species to which we allude are F. polycarpus and stems, Hedw. Crypt. v. 2. p. 31. 32.

In the generic arrangement of Mosses with a double fringe, we find the union of the stamens and pistils in one flower, by which alone Webera and Pohlia are separated from their natural congeners, a character of no consequence whatever, and not less artificial than obscure.

On the uncertainty and obscurity of generic characters founded on differences of the inner fringe, we need not repeat what may be found under the articles Fringe of Mosses, Hymnum, Leskea, Meesia, and Mesium. The last mentioned, like Bartramia, is best marked by the six-
een strong furrows of its capscale, though many of Hedwig's species are thereby discarded. If Meja be retained as a genus, it must be on account of the short blunt teeth of the outer fringe, rather than any thing in the structure of the inner.

The genus most difficult to characterize by the Hedwigian characters is Orthotrichum, though no genus can be more natural. Its species, one only excepted, all seem, as Mr. Turner remarks, scarcely more than varieties, so closely and naturally are they allied. Yet they differ widely in their fringe, the inner one being in some composed of sixteen, in others of but eight teeth, and in others totally wanting. Their outer teeth, naturally sixteen, each marked with a longitudinal furrow, are in some species combined into eight, each with two furrows. But here another part of the fructification offers itself to our aid. The strongly angular or deeply furrowed veil, to say nothing of its ascending hairs, which are not confluent, it seems this genus decidedly. A valuable paper on this subject, by the late Mr. Mohr, may be seen in Sims and Conolly's Annals, v. 253. We hesitate to adopt a new genus of the author's, named Ulota, though it differs from Orthotrichum in the curving of its leaves when dry, of which O. criptum, the species above alluded to as unlike the rest, is an example. Mr. Mohr characterizes Orthotrichum as having eight keeled ribs to its veil, with deep furrows between, whereas in Ulota, intermediate furrows take place of those ribs. His remarks however are well worth attention, as well as what concerns the veil in Neckeria and some others. He hints at the practicability of making this part subfertile to generic discrimination, where the Hedwigian characters have been objected to, as in Anidantium and Gymnojloium, Grimmia and Weigela. We fear his distinctions are too nice for common use, especially as it is often so difficult to obtain specimens with the veil in a good state for examination. But a more weighty objection is, that it does not appear to us to lead to the determination of much more natural genera. The acute and learned author however is of a different opinion, and he has candidly put the decision of the question into one's power, having enumerated, under each genus, the species of each, as he would, on this new principle, wish to dispose them. He subcribes to Anidantium, Grimmia, and Trichophorum, "a veil shaped like a mitre," (we should rather say an exquising, ) "somewhat halved," that is, partly split up on one side, "unequally torn at the base, and falling off obliquely." To Gymnojloium, Weigela, and Dis- cranum, he gives "a hooded or halved veil, nearly entire at the base, falling off obliquely."

There are several distinguished writers on Musci, besides those whose systems and remarks we have detailed, especially Bridel, the author of a large and elaborate Muscologia in Latin, making two quarto volumes, published in 1792 and 1798, and composed on the principles of Hedwig. Dr. Swartz, who wrote the Methodus Muscorum, published in 1781, under the presidency of the younger Linnaeus, printed in 1769 a neat little volume on Swedish Mosses, with several coloured plates; and Mr. Dawson Turner, in 1804, gave a more detailed account of those which are natives of Ireland. The writer of the present article has, in his Flora Britannica, vol. iii, first distributed the Mosses of Britain and Ireland according to the system of Hedwig, with some alterations, and with original descriptions; and has in the English Botany published figures, with English descriptions, of nearly the whole of them. Heffmann and Roth have described the Mosses of Germany in their Flora; but the latter is less original in this department than in most of his excellent writings. Many of this tribe are figured in the Flora Da-
nica, but not happily: a very few in Curtis's Flora Londin-
ense, and the works of Jacquin. We must repeat that Hedwig is unrivalled in his figures and descriptions, if not in his technical definitions, of this his favourite family. The accurate and ingenious Schrader, wherever he has touched upon the same subject, has contributed to elucidate it, but appears to have paid less attention to Musci than to other Cryptogamic subjects. A few New Holland Musci have been described by Labillardiere; but a much more complete account of the novel productions of that country, in this as well as other botanical departments, is to be expected from Mr. Brown; one of whose new genera may be found described under the article Lepismum. We have also, in Tr. of the Linn. Soc. v. 10. 56, along with Lepismum, described and figured another new genus, called Davonia, in honour of Mr. Dawson Turner, the very curious and singular character of which is as follows.

Frute tufted, of innumerable capillary straight equal hairs, originating from the capscale and central column! Capscale flat on one side, convex on the other. Outer Veil of entangled hairs; inner rough at the point.

D. polytrichoides, ibid. t. 23. f. 1. is the only known species, found about the sandy banks of rivers, at the foot of the mountains, near Port Jackson, New South Wales. Its habit is precisely that of the larger species of Polytrichum, while its capscale and central column nearly agree with Bux-
baumia; but the fringe is totally unlike every thing before observed.

S. MUSCICAPA, the Fly-catcher, in Entomology, bill nearly triangular, notched on each side, bent in at the tip, and beft with bristles at the root; the toes are mostly divided to their origin. Gmelin has enumerated ninety-six species, which are scattered over the warmer tracts of the globe, two only are common to our own country; the greater number are inhabitants of Australasia and Polynesia. Among ourseftes the fly-catcher is a bird of paflage, that breeds in the island, but retires as early as the month of Augtul. It builds its nest upon the fides of trees, or of old walls, and feeds upon insects. When the young are led out, they generally take their station upon the higher boughs of trees, whence they are taught to drop perpendicularly upon the flies below, and to rise again in the same manner. Sub-
ordinate to the rapacious birds, and in the next class, nature has placed this tribe of hunters, more numerous than that of its superiors, became more useful. The largest of this genus is of the size of the butcher-bird, while the smallest is not larger than the nightingale. All the intermediate degrees are occupied by various kinds, differing in magni-
tude, but marked by the same generic characters.

We shall now give an account of the

Species.

PARADISEI; the Paradise Fly-catcher. Crested, head black; body white; tail wedged, the two middle feathers very long. There are three varieties: 1. Head greenish-black; body chestnut, beneath white; lower part of the neck and breast grey. 2. Chestnut, beneath white; breast blueish. 3. Body paler, wing coverts golden. It inhabits Africa and Asia, and is about eight inches and a quarter long; head, neck, and chin greenish-black; back, rump, throat, and body beneath white; wing-coverts and quill-
feathers black, edged with white; two middle tail-feathers fifteen inches long; legs lead colour.

MUTATA; Mutabile Fly-catcher. Head crested; tail wedged; two middle tail-feathers very long; eye-brows blue. There are two varieties: 1. The body and tail of the one is of a cinnamon colour. 2. The other is a chestnut-colour;
MUSCICAPA.

colour; two middle tail-feathers varied with black and white. It inhabits Madagascar, and is nearly a foot long.

Bill and legs black; head, neck, and back greenish-black, the latter varied with white; body beneath white; wings blackish, longitudinally white in the middle; the two middle tail-feathers are more than four inches longer than the others, white, with a black spot near the tip, the rump is white on the inner, and black on the outer webs.

STRIATA; the Martinicinio Fly-catcher. Head crested; body brown, beneath cinereous; outer edge of the quill-feathers whitish. This, as its trivial name imports, is found in Martinicinio, and is six inches long; the feathers of the crown at the base, and quill-feathers at the edge, whitish; legs cinereous.

FUSCA; Black-headed Fly-catcher. Brown, beneath yellowish-white; bill, crown, and legs black. It inhabits Carolina, and is six inches and a quarter long; the tail is a little forked; the crown of the female is blackish.

TYRANNUS. Tail is very long, forked; body is black, beneath white. It inhabits Canada and Surinam.

FORRICATA; Swallow-tail Fly-catcher. Pale grey, beneath white; tail forked; quill and tail-feathers black, edged with grey, the outmost of the latter half white on the outer webs. This is about ten inches long, and inhabits New Spain.

SURINAM; Surinam Fly-catcher. Tail rounded, tip with white; body black, and beneath it white.

FULIGINOSA; Brown Fly-catcher. This species is of a black-brown colour, the feathers edged with yellowish-brown, beneath whitish; quill and equal tail-feathers edged with whitish. It inhabits Cayenne, and is hardly four inches long. The bill and legs are black; the breast is mixed with brownish.

AURANTIA; Orange-breasted Fly-catcher. The colour of this species is greenish-rufous, beneath white; breast orange; head and neck above greenish-brown; quill-feathers black, edged with rufous. It inhabits the woods of Guiana.

The bill is black and legs pale.

CORONATA; Round-crested Fly-catcher. It inhabits near the Amazon, and is five inches and a half long; quill-feathers edged with grey, the legs are reddish.

MALACHURA; Soft-tailed Fly-catcher. Brown, beneath ferruginous; throat (of the male) blue; tail long, wedged, with loose-webbed feathers. It inhabits the marshy places of New South Wales, lives among the long grass and rushes, in which it hides itself very dexterously.

RUFESCENS; Rufous Fly-catcher. Glossy pale rufous, beneath white; quill-feathers black; crown with a brown band. It inhabits Cayenne. Bill and legs black.

CINERA; Rufous-bellied Fly-catcher. Cinereous; rump, tail, and body beneath rufous. It inhabits Cayenne, and is about eight inches and a half long.

PYGMAEA; Dwarf Fly-catcher. Beneath straw-colour; head and neck rufous, spotted with black; feathers of the back and wing-coverts cinereous, edged with greenish; quill-feathers black, edged with grey; tail black, short. It inhabits Cayenne, and is barely three inches long.

MINUTA; Petty Fly-catcher. Olive-grey; wings blackish, with a few yellowish streaks. It inhabits South America, and is less than the last.

BARBATA; Whitewinged Fly-catcher. Olive-brown; beneath greenish-yellow, crown orange; rump yellow. It inhabits Cayenne.

RUBRICOLLIS; Purple-throated Fly-catcher. Black; chin and throat with a large purple-red spot. The purple-throated fly-catcher is about the size of a blackbird; the whole plumage is black, except the chin, throat, and forepart of the neck, on which is a large bed of beautiful crimson, inclining to purple; the legs are black. These birds inhabit Cayenne, and other parts of South America; where they are found in flocks, and precede in general the toucans in their movements. They feed on fruits and insects; and are lively birds, always in action. They, for the most part, frequent the woods, like the toucans; and where the first are found, the others are seldom far off.

CHRISTA; Crested Fly-catcher. Crested, head and neck blueish, belly yellowish; back greenish; quill and tail-feathers rufous. It inhabits Carolina and Virginia, and is eight inches long.

FEROX; Tyrant Fly-catcher. Brown; chin, throat, and breast cinereous; belly yellowish; greater wing-coverts edged with olive. It inhabits Cayenne, is seven inches long, and the legs are blackish.

LUDOVICIANA; Louisiana Fly-catcher. Grey-brown; beneath yellowish; chin cinereous; quill and tail-feathers edged with rufous. It inhabits Louisiana, and is the size of the last.

AUDAX; Yellow-crowned Fly-catcher. Blackish waved with rufous, beneath yellowish; crown yellow; frontlet white; rump and tail rufous. It inhabits Cayenne, and is eight inches long.

ATRIBULILLA; Pied Fly-catcher. Black; parts, spot on the front, and shield on the wings white; lateral tail-feathers white without; bill and legs black; tail-coverts spotted with white. There are three varieties: 1. Above varied with grey; thighs varied with brown and white; the three outmost tail-feathers edged with white. 2. Collar white, outmost tail-feathers edged with white. 3. Brown; beneath, front, sides of the head, and longitudinal line from the shoulder to the back white. The first three inhabit Europe, but the other is an Indian bird. The pied fly-catcher is not to be found in great numbers in any part of this island, but is most frequently to be met with in Yorkshire, and the contiguous counties. A nest belonging to two birds of this species was taken in 1803, in Axwell park, with a great number of young, and allo the parent birds. The affluence of the latter, which were almost unremittently employed in taking flies for their numerous family, was highly interesting. The dexterity and attention of the male bird appeared most conspicuous. The third variety is found in the East Indies, and is four inches and a quarter long.

RUTICILLA; Yellow-tailed Fly-catcher. Black; breast, spot on the wings, and base of the quill and tail-feathers yellow. It inhabits America and Jamaica, and is the same size as the last.

VIRENS; Cinereous Fly-catcher. Greenish-brown, beneath pale yellow; eye-brows white. It inhabits during summer in Carolina, and is rather more than five inches long.

VIRIDIS; Chattering Fly-catcher. Green, beneath yellow; belly and vent whitish; eye-brows and spot under the eye whitish; tail brown. It inhabits unfrequented places of Carolina, and is seven inches long. It is a fly bird, and flies with its legs extended.

SIBERICA; Dun Fly-catcher. Brown; throat and vent spotted with white. It inhabits Siberia and Kamtschatka. The body of this species is inclining to cinereous.

ERYTHROPS; Red-faced Fly-catcher. This species is spotted, beneath it is white, and has a red front. It is a Siberian bird.

CAYANENSIS; Cayenne Fly-catcher. This is brown, but under the parts are of a pale yellow; the eye-brows white, the crown pale orange. It is found, as its species name imports,
ports, at Cayenne; also in Hispaniola, and is about seven inches and a half long.

**Canadensis**; Canada Fly-catcher. This is cinereous; beneath pale yellow; lores yellow; but the crown is spotted with black. It inhabits Canada, and is four inches and a half long.

**Cinnamomea**; Cinnamon Fly-catcher. Yellowish-cinnamon; bar on the wings and tips of the coverts yellow; quill-feathers black, edged with ferruginous. It inhabits Ceylon, is eight inches long, and has a black bill.

**Spadicia**; Yellow-rumped Fly-catcher. This is of a chefsuont colour; quill-feathers, and even tail, brown; wing-coverts with rufous; rump yellow; belly and vent yellowish. It inhabits Ceylon, and is seven inches long. The bill is brown.

**Olivacea**; Red-eyed Fly-catcher. Olive, beneath white; eye-brows white, eyes red. There is a variety that has olive-coloured eye-brows, and wings marked with a double pale band. This species inhabits Carolina in the summer, and Jamaica in the winter. It is about five inches and a half long.

**Senegalensis**; Senegal Fly-catcher. This is variegated; eye-brows white; outmost tail-feathers half white. There is a variety that has a black breast, and a body waved with black and white. It inhabits Senegal, and is four inches and a half long.

**Cristata**; Crested Senegal Fly-catcher. This species has a crested head, the throat is of a glossy black; the body above is bay, and beneath cinereous; the tail is wedge-shaped. It inhabits near Senegal, and is more than eight inches long.

**Borbonica**; Bourbon Fly-catcher. Beneath cinereous; head greenish-black, with a violet gloss; back and tail pale bay; rump grey; quill-feathers black, edged with bay. This bird is found, as its name signifies, in the island of Bourbon, and is rather less than six inches long.

**Melanoptera**; Collared Fly-catcher. Cinereous, beneath white; throat brownish-bay, with a transverse black bar beneath; bill, wings, and tail black. This species inhabits Senegal, and is little more than four inches long.

**Nigriperus**; Black-fronted Fly-catcher. Brown, beneath olive-brown; front and temples black; chin and throat yellow; tail-feathers olive-brown, the two middle ones brown. The name fizes as the last; the bill is blackish, and the legs are black.

**Leucura**; White-tailed Fly-catcher. Greyish-ash, beneath white; bill, legs, and middle tail-feathers black; the rest obliquely half white, the outmost nearly white. This inhabits the Cape of Good Hope, and is four inches and a half long.

**Pondiceriana**; Coromandel Fly-catcher. Grey-ash, beneath white; lateral tail-feathers half white; spot on the wing-coverts and eye-brows white. Inhabits, as its name imports, Coromandel, is less than a sparrow, and sings well; the bill and legs are black.

**Afras**; Spotted Yellow Fly-catcher. Dirty-yellowish, spotted with black; crown rufous, streaked with black; tail and wings rufous, the latter edged with brown. It inhabits the Cape, and is eight inches long; the sides of the neck are marked with two or three stripes, and there is one from the mouth.

**Casa**; Ash-coloured Fly-catcher. Cinereous; head, cape, and chin blackish; vent white; quill-feathers black, edged with cinereous; bill and tail black; lateral tail-feathers cinereous at the tips; middle ones cinereous, blackish at the tips. This species inhabits Madagascar, and is eight inches and a half long.

**Madagascariensis**; Madagascarien Fly-catcher. Olive; chin yellow; throat and breast yellowish. This also is found in the island of Madagascar, and is seven inches and a half long.

**Undulata**; Undulated Fly-catcher. Waved with white and brown; head blackish; wings rufous brown. It inhabits the Isle of France.

**Teuctec**; Indian Fly-catcher. Brown, varied with small rufous spots, beneath pale rufous; throat whitish; tail and quill-feathers at the edges tinct with rufous. It inhabits the island of Bourbon. The tail and legs are brown; the female is white where the male is rufous.

**Rufiventris**; Rufous-vented Fly-catcher. Black; vent and lower tail-coverts rufous; legs whitish. Inhabits Bourbon, and is four inches and a quarter long.

**Comata**; Black; beneath, rump, and tips of the middle tail-feathers white; vent yellow; head crested. It inhabits Ceylon. Its legs are bluish.

**Hamorrhousa**; Red-vented Fly-catcher. Waved with brown, beneath white; vent red; subterminal head and tail black. There is a variety that has a yellow vent; tail black, with a white bar towards the tip. The first is found at Ceylon, and the second at Java. It is about four inches and a half long.

**Psed**; Guava Fly-catcher. Brown, beneath white; vent yellowish; crown, lores, and legs black; eye-brows white. It inhabits Mauritius.

**Melanisthæ**; Yellow-breasted Fly-catcher. Head and cheeks black; back and wing-coverts grey-brown, varied with yellow; breast rufous; quill and tail-feathers black, edged with yellow. It is found in Ceylon; and the second first at Java. It is about four inches and a half long.

**Nittens**; Green Fly-catcher. Green-gold; wings black; throat and breast rufous; rump and belly yellow; tail-feathers long, green on the outer, and black on the inner webs. It inhabits India.

**Sinensis**; Wreathed Fly-catcher. Greenish-grey; head, bill, and legs black; chin white; throat and breast grey; belly and vent yellowish; quill-feathers yellowish-green.

**Grisea**; Grey-necked Fly-catcher. Black, beneath reddish; throat grey; wings-coverts with a white band; tail a little wedge. It inhabits China; its legs are yellowish.

**Flavicollis**; Yellow-necked Fly-catcher. The upper part of this species is green; the crown and orbits yellowish; face black; throat and edges of the quill and tail-feathers yellow; the belly is greenish, with three yellow spots. It inhabits China, and is about six inches and a half long.

**Planamæa**; Flammeous Fly-catcher. Black; back, tail wing-coverts, breast, vent, edges of the secondary quill-feathers, and tips of the tail-feathers, orange. There is a variety, which is hoary, beneath scarlet; chin black; the first four quill-feathers are red at the base. It inhabits India, and is six inches long.

**Fusciscens**; Orange-vented Fly-catcher. Brownish, beneath white; head subterminal; rump and vent orange. It inhabits China, and is six inches long.

**Lucionis**; Black Fly-catcher. Black glit-fly-violet, beneath grey; wings with a white stripe in the middle. It is found in the Philippine islands, and in Madagascar, and is very small.

**Philippensis**; Philippine Fly-catcher. Grey-brown, beneath whitish; eye-brows white. This is found in the Philippine islands, and is the size of a nightingale.

**Capitella**; Azure Fly-catcher. Blue; hind-head and breast with a black spot; belly and vent blueish-white; quill
and tail-feathers dusky-blue. It inhabits the Philippine islands, and is five inches long.

**Cyanoccephala**: Blue-headed Fly-catcher. Red, beneath brownish; head blue; tail-feathers tip with black. It inhabits Manilla, and is the size of a limnet.

**Manillensis**: Yellow-throated Fly-catcher. Hind-head and back grey; rest of the head and nape black; middle of the back bay; chin yellow; middle tail-feathers black, lateral ones white. It inhabits Manilla.

**Flagellifera**: Fan-tailed Fly-catcher. The upper part of this bird is olive, beneath ferruginous; eye-brow, chin, throat, sides of the neck, and lateral tail-feathers white; middle tail-feathers, head, and collar black. This species inhabits the southern isles of New Zealand, where it is seen constantly hunting after insects and flies, always with its tail in the shape of a fan. It is easily tamed, and will then fly on any person's shoulder, and pick off the flies.

**Superilios**: Superbous Fly-catcher. This species is cinereous, beneath reddish-white; eye-brows black; tail wedged, the middle feathers black, the rest white. It is about four inches and a half long.

**Caledonica**: Olive Fly-catcher. Olive, beneath yellow; chin and vent yellow; quill-feathers ferruginous. It is found in New South Wales; is about six inches long, and its legs are black.

**Lutea**: Lusitaneous Fly-catcher. Whitish-yellow; wing-coverts and quill-spots dotted black; tail dusky towards the tip. It is found in Oathette, and is about five inches and a half long.

**Ochrocephala**: Yellow-headed Fly-catcher. Head, neck, and breast golden; body above yellowish-green, beneath white. It inhabits New Zealand, and is less than the latter.

**Flavifrons**: Yellow-fronted Fly-catcher. Yellow-olive, beneath yellow; fore, eye, edges of the blackish quill-feathers, and brown tail-feathers, yellow; arch over the eyes white. It inhabits Tanna island, and is five inches and a half long.

**Nevia**: Black; middle of the back and shoulders spotted with white. It is found in New South Wales, and is more than eight inches long.

**Multicolor**: Red-bellied Fly-catcher. Black; front white; breast and belly red; vent reddish. It inhabits Norfolk island, and is about four inches and a half long.

**Sandwichensis**: Sandwich Fly-catcher. Brown, beneath eye-brows white; breast ferruginous; wing-coverts, quill, and lateral tail-feathers tip with white. It inhabits the Sandwich islands, and is five inches, and a half long.

**Obscura**: Dusky Fly-catcher. Brown, beneath paler; tail-feathers long, even, pointed; belly inclining to rufous. This also inhabits the Sandwich islands, and is five inches, and a half long.

**Maculata**: Spotted-winged Fly-catcher. This species is ferruginous, but beneath it is pale chestnut; quill-feathers black; wing-coverts with rufous-white spot near the tip; tail-feathers brown, the outermost tip with white. It inhabits the Sandwich islands.

**Turricuta**: Cape Fly-catcher. Black, beneath white; breast rufous; innermost quill-feathers tip with white. There is a variety that is brown, but beneath it is white; the breast is black; the wings with a rufous band; tail feathers tip with white. It is about four inches long, and inhabits the Cape of Good Hope.

**Bicolor**: Black and White Fly-catcher. Black; front, orbits, throat, rump, purplish wings, band on the greater wing-coverts, tips of the tail feathers, and body beneath white. A variety is generally white; the hind-head, neck wings, rump, and tail black. It inhabits Cayenne; is four inches and a half long. The female of the variety is wholly grey.

**Carolinensis**: Cat Fly-catcher. Brown, beneath cinereous; head black; vent red. This bird is somewhat bigger than a lark; length eight inches; bill black; the upper part of the body and wings are of a deep brown; the under ash-coloured; the crown of the head is black; the tail is blackish, and the legs are brown. It is found in Virginia in the summer season, where it frequents throns rather than tall trees, and feeds on insects. It is very resemblance of a cat, whence the English name given it by Catesby.

**Ochroleuca**: Golden-throated Fly-catcher. Dirty-olive, beneath whitish-yellow; chin and edge of the wings yellow; primary quill and tail-feathers olive. It inhabits New York.

**Nitida**: Nitid Fly-catcher. This species is of a pale green; wing coverts edged with white; quill and tail-feathers blackish, edged with yellow. This is a small species, and inhabits China.

**Atra**: Dark Fly-catcher. Olive-ash; breast cinereous; belly whitish-yellow; head, tail, and quill feathers black; the second oraries at the edge and outermost tail-feathers on the outer webs white. This species inhabits New York, and feeds on bees.

**Noveboracensis**: Hanging Fly-catcher. Greenish; middle of the belly and two bands on the wings white; chin cinereous; spot on each side the bill and flanks yellow; primary quill and tail-feathers bluish, edged with green. It is found in New York from May to August.

**Passerina**: Blackish, beneath white; the tail is black. It inhabits Tanna, in the Pacific ocean.

**Acadica**: Lesser crested Fly-catcher. Sub-crested, green-ash beneath, yellowish-white; wings with a double white band. It is found in Nova Scotia.

**Aedon**: This species is of a rufous-brown; but the under parts are yellowish-white; middle tail-feathers sub-equal, the outermost each side much shorter. It inhabits Dauria; and sings in the night very sweetly.

**Nov. Hollandiae**: Brown, beneath whitish; under the eyes, on each side, as far as the ears, there is a yellow streak. It inhabits New Holland, and is seven inches long.

**Ferruginea**: Rufous Fly-catcher. Brown-rufous, beneath whitish-yellow; chin white; wings black, edged with a rufous colour; tail-feathers edged and black, above black, edged with brown; the eye-ruff short and white. It inhabits Carolina, and is five inches and a half long.

**Nigra**: This is totally black; bill, head, and legs dusky-black. It inhabits the Society islands.

**Ochracea**: Neck and breast ferrugineous-ash; wings and tail black-ash. It is found at the Cape of Good Hope.

**Albifrons**: This species is black-brown above; but the throat and breast are whitish; the belly is pale ferruginous; front whitish; its bill and legs are black. It inhabits the Cape of Good Hope.

**Melanoleuca**: This is of a snowy colour; but the feathers at the base are brown; the breast is of a palish-yellow; the head and neck, as far as the middle wings, tips of the tail-feathers, bill, and legs are black. It inhabits Georgia, in the summer months only, and is about six inches long.

**Petechia**: This is brown; but beneath it is cinereous, spotted with rufous; throat and vent rufous. It inhabits the island of Martinois. It is five inches and a half long.

**Virgata**: Steaked Fly-catcher. Brown, beneath whitish-brown, with longitudinal brown streaks; crown

---

**Muscicapidae**
sub-crested, varied with cinereous and yellow; edge of the quill-feathers, and two bands on the covert, rufous. It inhabits Cayenne, and is four inches and a half long.

**Agilis;** Active Fly-catcher. Olive-brown, beneath whitish; quill and tail-feathers black, edged with olive-brown. It inhabits Cayenne. is the size of the *M. virgata*, and is continually hunting after insects, which it picks out from under the bark of trees.

**Grisola;** Spotted Fly-catcher. Brownish, whitish beneath; neck longitudinally spotted; vent pale-rufous; bill black, whitish at the base; indife of the mouth yellow; head large, brownish, and spotted with black; back mouche-coloured; wings and tail black; the former edges with white; chin spotted with red; legs black. About the size of the tit-lark; length five inches and a half. It inhabits this country, and others in Europe. This bird visits us in spring, and departs in September. It frequents orchards and groves, and will make its nest on the limb of some fruit-tree nailed against the wall, or in a hole, sometimes in out-buildings, on the end of a beam or rafter, and at other times against the body of a large tree, or on the stump of a decayed branch. The nest is formed of bents, moss, and such kind of materials, interwoven with spiders' webs, and lined with feathers. The female lays four or five eggs, not much unlike those of the red-bread, but rather lefs, and the ruf-st-coloured spots more distinct, and not so much confined to the larger end. Its food seems to be entirely winged insects, though it is said to be particularly fond of cherries, probably from the circumstance of its frequenting the cherry-tree for the sake of flies that are attracted by the fruit. As soon as the young birds leave the nest, they are led by the old ones to some neighbouring wood or grove where insects abound, and where they may be seen darting in every direction in purfuit of flies, and frequently returning to the same station. The note of this species is a simple weak chirp, not frequently used till after the young are fled; so that the bird, though common, is not readily discovered.

**Dichroa;** Two-coloured Fly-catcher. Above cinereous, beneath ochre; tail-feathers partly ochre, partly cinereous. It inhabits Africa.

**Deserti;** Defert Fly-catcher. Body ferruginous and footy; wings and tail blackish; bill yellowish. It inhabits the deserts of Arabia.

**Javanica;** Javan Fly-catcher. Tail very long, rounded; body varicolored with ferruginous, beneath white; throat black; eye-brown white. It inhabits Java.

**Camarisuis;** Cambay Fly-catcher. Glossy-black; back yellowish-green; beneath tawny-yellow; wings-coverts with a double white band. It inhabits Cambay.

**Muscicapa Madagascariensis**, &c. or Fork-tailed shrike.

See *Lanius Forficatus*.

**Muscicapa Tyrannus**, the Tyrant shrike of Latham, and Tyrant fly-catcher of Pennant. See *Lanius Tyrannus*.

**Muscicapa Emeria**, the Bengal shrike of Latham. See *Lanius Emeria*.

**Muscicapa Paradisi**, the Paradise fly-catcher of Latham. See *Todus Paradisae*.

**Muscicapa Rubra**, the Summer Tanager of Pennant and Latham. See *Tanagra Rubra*.

**Muscicapa caerulea**, Cinereous, Febe, Lutea, Varia, the Jamaica warbler of Latham. See *Motacilla Dominica*.

**Muscipeta**, the Stone-chat of Latham. See *Motacilla Rubicola*.

**Muscipula**, in Botany, is used in a different sense from the classical one, and deriv'd from *Muscia*, a fly. See *Silene* and *Dionea*, where it occurs as a specific name, synonymous with Catch-fly, or Fly-trap: in the former instance alluding to the gluttonous nature of the flies in several species of *Silene*; and in the latter to the peculiar structure and irritability of the leaves. *Muscipula* however always means, with the ancients, some sort of mouche-trap, from *Maus*, a mouse; and such may in general be the *muyci* or *muycy*, as well as the *muycy*, of the Greeks, but not, it seems, the *muycy*, of Dioscorides. See *Myagrum*.

**Musc, in Geography**, a town of Lusatia, on the river Neisse; the chief place of a lordship, about 30 miles in circumference; 52 miles N.E. of Dresden. N. lat. 51° 31'. E. long. 14° 46'.

**Muscule, in Anatomy and Physiology**, is that soft and fibrous structure, generally of a red colour, known in common language by the name of flesh, and possessing the property of contraction, by which it becomes the instrument of almost all the motions in the living body. It consists of threads or fibres joined together by cellular substance; these are rendered very constrictive in the meat, which has been boiled for a long time. They are arranged in different forms according to the purposes to which they are subordinated. Connected together in large masses, and united to tendons, which are fixed to the bones, they constitute the voluntary muscles. These compose nearly the whole bulk of the soft parts of the limbs, and a very considerable proportion of the trunk, and execute all the motions, which take place in obedience to the commands of the will. They fix the body, and determine the attitudes of its various parts in standing, sitting, and lying: they move it forwards in walking, running, jumping, dancing, swimming, climbing, &c.; and are the sole agents in seizing, holding, thrusting, throwing, &c. By alternately enlarging and contracting the chest, their aseilance is essential in respiration; and these motions, together with those which they cause in the larynx and mouth, produce the voice and speech. They direct the eyes towards surrounding objects, and elevate or depress the lids: they open or close the mouth and nose. They are the agents of sucking, chewing, and swallowing, and are essentially concerned in copulation and parturition, in expelling the urine and feces, &c.

Under another arrangement, in which they surround various hollow organs, they move the contents, whether solid or liquid, of such parts. In this way they drive the blood through the different cavities of the heart, and propel it in the arterial canals; they convey the food through the cavities of the stomach and intestines, and the urine along its passages.

Some motions are not executed by muscles: the elasticit of a cartilage, for instance, may restore it after it has been moved out of its natural state. It is still a controverted point whether the arteries are muscular (see Heart); and the veins certainly are not. Similar doubts exist concerning the iris (see Eye). We can detect no muscular fibres in the Fallopian tubes (see Generation), nor in the excretory canals of the glands (see Gland). The motions of exhalation, secretion, absorption, and nutrition, are for the most part imperceptible to us, and the minutest of the organs, in which they are performed, conceals them altogether from our reach; we have, therefore, no grounds for believing that they are executed by muscle.

According to the preceding view, we may state that the perceptible motions (excepting those of the iris and the large absorbing vesseis) are performed by that kind of structure which we call muscle; while the movements, which escape our observation, are executed in a manner, of which we may rather
The organization of the different organs enumerated above, which perform motion, yet are not manifestly fibrous, has afforded an opportunity for much unmerited controversy among anatomists, which might, perhaps, have been spared by a little attention to the meaning of the terms employed. If muscle be a tissue consisting of long, cylindrical, and parallel threads, possessing the power of contraction, muscularity must be denied to many parts of the body which perform motion: if the executing motion be a criterion of muscular structure, these parts must be ranked among muscular organs.

Hitherto we have considered the subject in a general point of view, regarding muscle as a structure capable of contraction, and thereby performing most of the animal motions: this power has generally been called irritability. A more close inspection will soon convince us that the muscular system must be divided into two great sections, differing from each other in their organization, vital properties, external form and functions. In one of these motion is produced in obedience to volition; in the other it is independent of the will: in a few instances the two characters are united. Hence the muscles have been divided into voluntary, involuntary, and mixed. Yet their structure and properties have generally been confederated together. Bichat has separated completely the voluntary and involuntary muscles: he makes of the former, the muscular system of the animal life, and of the latter, that of the organic life, according as they are concerned in the one or the other of the great divisions established by him in the animal functions. (See Life.)

This arrangement appears to us to be the most conformable to nature, and we shall accordingly adopt it in the present article. We shall, therefore, divide it into two parts; of which the first will include the account of the muscular system of the animal and the second of the organic life. The following order of subjects will be adopted in the first part: 1. The organization. 2. The properties of the animal muscular system. 3. The application of the muscular fibres to tendons, composing the muscles. 4. Division, names, forms, and arrangements of the muscles. 5. Tabular view of the muscles. 6. Explanation of the plates. 7. Phenomena of the muscular system in action. 8. A view of the powers, by which the more general motions of the body are effected. 9. Development of the animal muscular system. In the second part we shall consider successively, 1. The organization. 2. The properties. 3. The phenomena of action. 4. The development of the organic muscles.

1. Organization of the Muscular System of the Animal Life.—The distinguishing character of a muscle is the muscular fibres: it contains, besides, blood-vesseils, nerves, exhalants and absorhents, and cellular tissue, which are common parts; (we speak of those visible to the naked eye.)

The muscular fibres are slender, long, cylindrical, red, softish, of uniform size in the large and the small muscles; posseessing every where the same characters and appearances; sometimes disposed in distinct bundles separated from each other by considerable grooves, but more generally arranged in a plane surface; always joined to numerous others of the same nature, and easily distinguishable by the naked eye. If we proceed to examine minutely any particular muscle, we easily separate it into a number of bundles, or fasciculi; each of these is again separable into smaller bundles, and this division may be repeated until the parts become too minute for our observation: they are distinguished throughout by the same fibrous or thready appearance, and the whole muscle differs from its smallest portion only in the number of the threads. Indicated by the hope of discovering the mechanism of muscular motion, anatomists have examined the structure of the organs in every possible way, and have prosecuted inquiries into the organization and properties of the ultimate fibre by the aid of the microscope, when the unskilled eye had traced their divisions as far as possible. Boiling for a long time, and immersion in spirits of wine, render the fibres more perceptible; they become smaller, harder, more opaque, and easily separable: but we still find nothing in them but threads of an uniform appearance, reducible into smaller and smaller bundles, in which the elementary fibre cannot be traced. We believe that the long labours of the numerous microscopical enquirers have not hitherto advanced our knowledge any further; and if it be true, as Soemmerring informs us, that Muyrs spent eighteen years in investigating the subject, we can only collect from his investigations, as detailed in the Musculorum artificiosa Fabrice, 4to. Lugd. Bat. 1751, that the physiology of muscular motion is not likely to receive any important elucidation from this quarter.

Microscopical observation shows us, that the fibres pursue their course without bifurcation or any kind of division: they are placed in mutual opposition, and lie parallel to each other: hence much fewer fibres are divided by a perpendicular than by a transverse section. It is not determined whether the fibres run through the whole length of a long muscle or no. Prochaska affirms that they do: Haller says that they do not: a short course among the neighbouring ones, and are lost in the cellular substratum. In general they appear cylindrical; but sometimes they are more or less serpentine or undulated, particularly after boiling, or when observed soon after death: occasionally the line of the fibre is quite zigzag, or it has a knotted appearance. The connections by means of cellular substratum, and the course of vessels and nerves, seem to be the causes of this appearance. The fibres are too small, that Muyrs estimates they would not tranmit the 46th part of a red globule of the blood if they were hollow, and that they are forty times smaller than the thinnest hair. On these points, however, a great variety of statements will be found in the reports of the most observant. "Hae omnia," says Haller, "mutilum habent ex arbitrlo, et ex cafu nata, cum aliis ultimus, ali penultimus ordinem decrescente, ut fibrarum vidisse potuerint. Sed necesse au mou modo probable videatur, nos ultima elementa, et proxima organa motus animalis, ut epiloqal perpercire; aut oculo ejusmodi continuos, veris limitibus distinctos, ordines effe, in quo filia flororum revolvantur." Eelm. Phyfioi. t. iv. p. 416.

A great diversity of opinion has exsisted about the figure and appearance of the ultimate fibre, of the last threads, into which the muscular structure can be resolved. It has been a matter of dispute whether it be solid or hollow, cylindrical or flattened. Some have represented it as composed of vessels or globules, some of a series of rhombs, others as cellular, &c. Lecuvenhoek and Muyrs, whose researches seem on the whole to have been the most numerous and accurate, represent them as cylindrical, and sometimes, but rarely, knotted. When we consider that this is a point determinable only by the microscope, and remember how many sources of error such observations are exposed to, we shall agree with Haller: "Iterum, si quatuor fuerit, et ultima fibrae fabrica, non solida, non membrana fibris interposita, &c. nam denique tota infar tabulis cava sit, timidius certe oportebit de re ultra omnem ocularum aciem polita pronunciare." P. 418.

That the muscular fibres are a continuation of the nerves, under a different form and arrangement, or that they are hollow and prolongations of blood-vessels, are doctrines which
which have been maintained by very eminent men, and very generally received. These strange notions rest on no direct observations: they are vague and confused fancies, contradicted by well-known physiological facts, and repugnant to all analogy. The objects in question are beyond the reach of our senses; consequently we can procure no data for an opinion concerning them. Our study of nature should begin where it falls within the sphere of our organs. All that we know about the nature of the muscular fibre is, that it constitutes a peculiar tissue, not identical to that of the nerves, blood-vessels, tendons, or cellular substance. Where the organisation is the same, the properties must be the same. Now the properties of all these systems differ essentially, and their structure cannot therefore be analogous.

The muscular tissue is remarkable for its softness, and in this respect differs from the fibrous: hence it is very easily torn in the dead body; the mere weight of the limbs will sometimes do this. During life it is no less remarkable for its powers of relinance: it seems to acquire, when contracted, an augmentation of strength, that renders it capable, not only of bearing great violence, but of supporting enormous weights, rupturing the tendons, breaking the bones, &c. Ruptures of the muscles during life are very rare, but not altogether unexampled: we have seen three or four instances of it in the recti abdominis.

The chemists have exerted themselves very busily in the examination of the muscular tissue, and we refer the reader to their works, and to the chemical articles of the Cyclopedia on this subject. (See FIBRE.) We shall consider the matter here in a physiological view.

When cut into thin slices, and exposed to the air, the muscular tissue assumes a dark brown colour, becomes thin, hard, and brittle. When put into water a few days after being thus dried, it recovers its original softness and form, and has a lighter colour. When the muscular flesh is exposed in large masses, or to mild air, it purifies very quickly, assuming a green or livid colour, and exhalings a pungent odour. A thick pulpy pulp, after a certain time, holds the place of the fibres: this gradually evaporates, and leaves a hard, blackish, brown refuse.

Cold water destroys the colour, and very rapidly if thin slices are placed in a current, or if they are frequently immersed and then squeezed; the surface only is whitened when a muscle is left in a jar of water. The fluid, which has been used in washing a muscle, is reddish; it contains the colouring matter with some gelatine, &c. No part of the animal structure loses its colour more readily than muscles. When kept in the same water, at a moderate temperature, its surface is reduced after a long time into a soft putrid matter. Sometimes, however, it is converted into a fibre resembling permaceti. This change is generally preceded by a reddish appearance in different spots on the surface of the muscle, which is the commencement of the decomposition. See Adipocire.

When repeated washings have removed the colouring matter of a muscle, there remains a white fibrous substance, from which we may extract by ebullition albumen, which refines in the form of froth, which grows firm on cooling, an extractive matter of a deep colour when concentrated, and some phosphoric salts. The residue is a greyish fibrous matter, insoluble in warm water, soluble in weak acids, yielding much acetate under the action of nitre acid, and precipitating all the characters of the fibre of the blood. This, as Foureroy has observed, is probably the peculiar nutritive substance of the muscle, which bestows the distinctive character on the organ, as the phosphat of lime does on the bone. Whether this be found in the blood, and conveyed into the muscle, or be formed by the processes of nutrition in the muscle, and thence carried into the blood, we have no means of determining. It seems to exist in various degrees; and, hence, probably, the varieties in the consistence of the muscular tissue. To this fibrous substance is owing the property, which a muscle possesses, of becoming corrugated under the action of heat, whether by exposing it to naked fire, or in boiling water. The quantity existing in the muscles is in proportion to that contained in the blood.

When muscles are boiled, connected with surrounding parts, an albuminous froth and some drops of fat arise, probably from the cellular tissue: a gelatinous matter is produced from the aperistaltic parts; and an extractive substance is very free, giving a colour and a peculiar taste to the fluid. The latter remains partly adherent to the fibres, and gives them a deep tint very different: from that of raw flesh: the colour becomes lighter as the part cools. Certain fats are dissolved in the boiling, and add to the flavour of the broth: these are particularised by the chemists.

As the water approaches the boiling point, the muscular tissue, which had not hitherto undergone any change, becomes corrugated and condensed, and acquires very great firmness. Its condition may be compared to that of its contraction during life, and it will now support weight that would have broken it easily before it was boiled. This condensation of the muscular tissue is very rapid, and is at its highest degree at the moment of ebullition; it continues for a certain time and then gradually diminishes, the fibres becoming again soft, and more easily lacerable than they were at first. The muscle, however, does not go back to its original state; it has lost the power of corrugation by heat, alcohol, or acids; its taste is different; it purifies less easily, and produces a different odour under that process.

Exposure to naked heat, as in roasting, changes the colour, consistence, and taste of the muscles, and destroys the power of corrugation by the agents already specified. The muscular system is acted on very remarkably by the fluids of the stomach, and performs a very important office as the principal nutriment of carnivorous animals and man. See DIGESTION.

There are differences in the properties of muscles connected with the differences of sexes: this is known from their employment as food. The flesh of the male, in the rutting season, has a very peculiar odour, and a strongly disagreeable taste. See GENERATION.

The cellular tissue is very abundant in the muscular system. (See Cellular Substance, and Membrane, Cellular.) It forms round each muscle a fibrous, which is generally loose, filled with fat, and easily digested with air in emphysema, or water in anasarca. In some instances it is more dense, and diffused in the form of a membrane; as for example, in the obliquus externus abdominis. Each fasciculus, and each fibre, down to the smallest perceptible divisions, has a covering, which becomes more delicate as the divisions are more minute. The quantity of the cellular tissue in the substance of a muscle varies greatly; it is generally the most abundant in the broad, and the large and long muscles. Those about the spine have but little. The general covering of the muscle fixes it to the neighbouring parts, while the pliancy of the cellular tissue enables it to yield readily to the motions in every direction. The coverings of the particular fasciculi and fibres attach them to each other, while the seruin and fat of the cells facilitate their reciprocal motions.
MUSCLE.

At the muscular fibres are all parallel to each other, the cellular threads uniting them pass at right angles to them, and have sometimes been taken for transverse fibres. We believe that all the fibres in the voluntary muscles are parallel to each other. Hence, if be cut according to their course, the power of motion remains; but it is entirely lost if the section is carried transversely.

The fat is sometimes accumulated in a muscle to such a degree, that the appearance of the muscular fibres is almost lost. In animals which are fattened for slaughter, we often observe a considerable quantity of fat mixed with the fibres, which is never seen in the muscles of wild animals which preserve their native powers of exertion.

The arteries of muscles are very numerous and apparent; they enter towards the middle, rather than at the ends of the muscle, run at first between the principal fasciculi, and proceed, as they divide, along the intervals of the smaller divisions, until they end in capillary ramifications. In proportion to their bulk, hardly any organs receive more blood than the muscles. It gives them their peculiar colour, not by circulating in their vessels, but being combined with their tisue. Hence these organs are not changed in their appearance in asphyxia; if a muscle be divided in an animal dying in that state, black blood is thrown out from the arteries, but the muscular fibres continue red. The veins correspond to the arteries, and every where accompany them: they receive, from the contraction of the muscles, a preasure, which accelerates the stream of blood, as may be seen when a perfon on whom phlebotomy is performed moves his forearm and fingers. No effect of this kind is produced on the arterial circulation. As the muscular contractions afflict in fo considerable a degree the progress of the venous blood, these veins probably have few or no valves: certainly they are very little subject to variestes.

Exhalants and abortents exist in the muscles; but they cannot be demonstrated.

The nerves of the voluntary muscles are almost all derived from the brain, or from the spinal marrow; when they receive any branches from the ganglia, as in the neck and pelvis, they have others from the cerebral or spinal nerves. The muscles receive larger nerves than any parts in the body, except the organs of the sexes; and in general the size of the nerves is in proportion to the bulk of the muscle; but this is not constant, the muscles of the eye, for example, receive very large ones. Small muscles have often only a single nervous branch, but the larger ones generally receive several. It has been remarked that the flexors have larger nerves than the extensors: the truth is, that the former muscles very greatly exceed the latter in size, and the great nervous as well as vascular trunks usually run along the limbs in the aspect of flexion, dispatching branches to the extensors. There is no reason for alleging that more nerve goes to an equal bulk of flexors than of extensors.

The nerves enter the muscles at various angles, and in all situations. They divide and run between the fasciculi, like the blood-veils, and may be traced in this manner until they have become very minute. Whether they grow fater as they become smaller; whether the ultimate filibril lay aside their external coat and assume a pulp form; and whether every fibre of the muscle receives a nerve, are points which cannot be ascertained. The fact that the whole muscle is thrown into action by irritating the nervous trunk that supplies it, favours the affirmative side of the latter question; but the whole muscle contracts equally if a few fibres only are stimulated.

The nerves generally enter the muscles in company with blood-veils, particularly arteries, and connected to them by loose cellular tisue. They are rendered more apparent in the muscle by maceration, as they refill putrefaction for a long time.

II. Properties of the Muscular System of Animal Life.—

There are no sytema in the animal structure, in which the vital properties, and those resulting from organisation, exist in a more marked degree than in the subject of our present consideration. The phycial properties, on the contrary, are weak; the tisue is soft, and offers very little resistance after death: the power, by which its functions are characterized, is derived from life.

1. Properties derived from Organisation.—Extenstibility is shown under various circumstances. When any part is moved, the muscles antagonising those that have moved it are stretched; all great flexions put in action the extensibility of the extensors, and vice versa. This phenomenon belongs to the muscular fibres only, and not at all to the tendons; hence the degree, in which it is poifled by any muscle, depends on the length of its flabby fibres. Tumours, dilatations of the abdomen in afeces, pregnancy, &c. occasion the exertion of the same property.

Contractility of tisue belongs to the muscles in a very considerable degree, and is constantly disposed to exertion when they have been extended beyond their natural length. It is independent of the nerves, and of the irritable nature of the muscles; influenced by life, but not necessarily connected with it; and depends effentially on the organisation. It acts in a slow and regular manner, and is diminished or increased only in proportion as the muscular tisue is strengthened or weakened. Hence the variations in its quickness can only be seen in different individuals, or in the same individual at different times; there are never such sudden changes in a short time as we see in the exertions of the vital properties; and this is a striking division between them. The contractility of tisue is seen in the recovery of the abdomen after paraentesis or parturition, in the return of parts to their original state after the evacuation of an abfoes or the removal of a tumour. This property causes the two ends of a divided muscle to become separated from each other; and Bichat ascribes to it the attitudes which the limbs present, when they are not influenced by any muscular action. He observes, that in the middle state of a limb, between the two extreme points to which it can be moved, the antagonist muscles balance each other by their contractility of tisue. The part can be moved in either direction from this middle state only by the exertion of the vital powers of the muscles, and can be maintained in its new position only by the continued action of such powers. In this case the opposite muscles are stretched in a degree proportioned to the motion which the limb has performed; and the contracted muscle not only acts on the bone, in which it is implanted, but also on its antagonist. Hence the muscles reciprocally act on each other; they are alternately active and passive, moving and moved organs. A muscle, when thus stretched, is disposed to contrate itself, and more, in proportion to the degree of extension: as soon as the vital powers cease to operate in the contracted muscles, the contractility of tisue of the antagonists carries back the limb to the middle state. Hence, says Bichat, whenever the muscles feel nothing of the cerebrul influence, and are not irritated by any stimuli, as in sleep, and in the fetus, the limbs are constantly found in a middle position between flexion and extension, abduction and adduction, &c. The horizontal extension of the trunk and limbs in fevers does not arise from any superiority in the extensor muscles, but from a deficient energy in the flexors, which cannot overbalance the weight of the limb.
Hence such an attitude is a clear sign of general and alarming weakness.

Besides the retraction of the two ends, there is another effect following the division of a muscle: the contractility of the fustus of the antagonist, being no longer opposed, draws the moveable part towards the opposite side to that on which the division has been made. Hence we find the mouth drawn towards the sound side in a case of paralysis; but the deviation is not so remarkable here, as when the muscle has been divided, because the contractility of fustus remains, and opposes the opposite muscles so long as the parts continue at rest. When the person endeavours to speak, and the muscles of the sound side are put in action, the deformity becomes more apparent. The contractility of fustus seems to be weakened in some instances of paralysis; but it is never entirely destroyed. Bichat divided the nerves of the leg in a dog; and cut off the leg some days after: the muscles retracted when divided.

The extent of the contractility of fustus is in a direct ratio to the length of fibres: hence the superficial muscles, which are the longest, always retract the soil in amputation; the phenomena arising from this power during sleep are most apparent in the limbs, where the muscles are the longest; hence, too, antagonist muscles correspond in length to each other.

This power is weakened, but not annihilated by death; putrefaction alone completely puts an end to it. Bichat states, however, that the power of retraction in the muscles is greater, so long as they retain vital warmth, than after the coldness of death has seized them.

This contractility of fustus appears very nearly the same with the vis mortis of Haller. He calls it by that name, because it is exerted after death. “Ceterum hac vis cum vita nihil commune habet. Eti enim in humeetca et flexili animali materie est manifestior, diu tamen a plena morte, inque excitat membris, in musculos, inque membranis integra supernel.” Elem. Phyiol. t. iv. p. 444. To the fame property he refers the phenomena arising from the action of fire, concentrated acids, alcohol. &c. on animal matter, which is corrugated and curled up by such applications.

“Ad hanc ipsum potentiam referre mortue irritabilitatis genus, quod venena chemica in omnibus partibus corporis humani demonstrat, potissimum etiam niti spiritus humani, unde oleum vitrioli, et butyrum antimonii, et aha id genus. Acerrimi enim hi latices cellulosae palpant, cetum, caque cellulosa tela compositas membranam, placentam uterinam, vitreum, arterias, venas, etiam lacteum, ductus excretorios, facculos urinæ et bilis, nervos, tendines, musculos ipsum, et cor, quando contigerunt, continuo cogunt in minorem longitudinem fe recipere. Tela quidem cellulosam, cum ipso adipe, exciditur et conficitur, reliquam firmam contrahuntur, fulco exarantur profundo, et arcantur, fuscui cava sunt receptacula, et in curvatam contracta; repunt quando longi et recti sunt funiculi.” The effect of heat is analogous; that is, it causes a cramping and curling of the animal texture. Bichat has designated these phenomena by the term racornimentum: and he points out several circumstancies, by which they are distinguished from those which he ascribes to the contractility of fustus. The latter property exists in a very slight degree in several organs, which enjoy the power of racornimentum, very considerably; e.g. the fibrous, fibro-cartilaginous, ferosus, &c.

It varies very much in different organs, from the muscles and skin, where it is the most sensible, to the cartilages, which hardly seem to possess it; while the latter is nearly uniform throughout the body. It is destroyed by drying, which does not affect the power of racornimentum, as we may see in leather and parchment; it receives an additional energy from life, particularly in the muscles, while the other is not modified by this cause. The contractility acts very gradually; the racornimentum very suddenly: to feel the influence of fire, and become curled, are almost simultaneous phenomena. The latter produces a remarkable density in the organs, which they never exhibit under the exertion of the contractility. The cessation of extension is the only condition necessary to the exertion of contractility: the contact of a foreign body is necessary to the crampation of the fustus.

2. Vital Properties.—Animal sensibility exists in a very obfure degree in the muscles, at least in their natural state. We are not conscious of their contraction. When they are divided in amputation, or in experiments on living animals, no very considerable pain is occasioned, unless when a nerve is included in the cut. The irritation of chemical stimulants does not render their sensibility more apparent. Yet they are the seat of a peculiar feeling, produced by repeated or powerful contractions, and termed fatigue. This is felt in the muscles, which are principally employed in the action that has produced fatigue, as in the lumbar muscles after standing, in the muscles of the calf and the extensors of the knee, after walking or running up a hill, &c. It may take place without any previous exertion, as in fivers, where the patient has the same kind of latitude, as would be produced by a long muscular exertion. When the muscular fustus is inflamed, the animal sensibility is exalted in a very remarkable degree; the weight of the bed clothes cannot be borne, and the slightest motion of the part produces the most lively pain.

Animal contractility, on which depend all the phenomena of locomotion and the voice, and which afflicts several of the internal and external functions, refides exclusively in the muscular system of the animal life, and forms its distinguishing character. It confinits in the power of moving under the influence of the brain, whether that be determined by the will, or by any other causes. In the exercise of this kind of contractility, and the corresponding species of sensibility, the action of the brain and the nerves is required, while the two kinds of organic contractility are centered in the organ that is moved. If we may be allowed such expressions, the brain may be called the source from which this property is derived, as it is the point to which all the sensations are conveyed: the cerebral nerves are the agents transmitting it, as they are in an opposite direction conductors of the sensitive phenomena. In order, therefore, to gain a clear notion of this property, we must examine it in the brain, the nerves, and the muscles.

All the phenomena of animal contractility evince the influence of the brain. Its energy is augmented when the brain is excited by the passions, as wrath, by opium, or by wine: terror, which diminishes the action of the heart, and causes a kind of atony in the brain, and the various narcotics taken in excess, which have an analogous effect, cau[e] a languor, or even a complete intermission, in the voluntary actions of the muscles. When the brain is concentered in its relations to the organs of sense, or in its intellectual functions—when we are looking or hearing very attentively, or employed in profound meditation or reflection, the voluntary powers all remain at rest.

In disease, all cau[es], which act powerfully on the brain, re-act suddenly on the animal muscular system, and produce paralysis or convulsions, of which the former indicates diminished, and the latter increased energy. The one is caused by compression of the brain, and by the consequences of apoplexy: it generally takes place at the com-
MUSCLE.

We have similar proofs of the influence of the nerves on the voluntary motions. Irritation of a nerve, as by prick- ing or cutting it, by chemical stimuli, but more certainly by the former, causes contraction of the muscles supplied by it: that particular motion, which is the office of the muscle, as flexion or extension of a limb, &c. is performed. When several muscles are supplied by one nerve, they are all convulsed. The muscles, which have no branches from the nerve, are not affected; nor those which receive branches from it above the irritated point, i.e. between the brain and the seat of the experiment. A continuance of the irritation exhausts the muscles, so that they at last remain motionless; but the convulsions are removed, if the irritation be applied lower down in the nerve. If a nerve be compressed, tied, or cut through, the muscles supplied from it no longer contract under the influence of the will: they are paralysed. Irritation of this nerve between the brain and the injured part produces no convulsions in the muscles situated beyond the injury: but irritation of the nerve below the injury causes contraction of the muscles for some short time; this effect, however, soon ceases. Remove the cause of compresion, take away the ligature, and the power of motion returns; unless, indeed, which sometimes happens, the ligature should have disorganized the nerve at the point of its application. If a divided nerve should be afterwards united, the power of motion returns. Irritation of the brain, or of the medulla spinalis, produces no contraction in the muscles placed below the section of the nerve; but it convulses all the others.

All the muscles of the animal life are not equally influenced by the different states of the brain. Those of the limbs are the most readily convulsed or paralyzed; the muscles of the abdomen, of the neck, and particularly of the chest, exhibit these phenomena only when the causes of excitation or debilitation are carried to a high degree, and are often seen in a perfectly natural state, while those of the face and limbs are violently convulsed. In hemiplegia, the mouth is often drawn aside, and the limbs motionless, while the motions of the chest and abdomen continue. The muscles of the larynx are more easily affected than the latter; and hence the alterations of the voice. If we arranged the parts of the body according to the susceptibility of the muscles for receiving the cerebral influence; or of the nerves for propagating it (for we do not know on which of these principles the phenomenon rests), we should place the limbs at the top of the scale, then the face, the larynx, the pelvis and abdomen, lastly the intercostal muscles and diaphragm. This scale bears a very important relation to the functions of the organs: injuries of the brain easily produce paralysis of the limbs, which merely deprives the animal of a mode of communication with exterior objects; if the muscles of respiration were affected in the same way, both the internal and external life would be suddenly interrupted.

The nervous influence is propagated only from the brain towards the muscles, and never in the inverse direction. Irritation of a nerve, or of the medulla spinalis, produces no contraction of the muscles placed between the brain and the point of irritation. The muscles, defined to receive the influence of the brain through the medium of the nerves, must be in a natural state, so far as regards their organization, in order to perform their part in the series of phenomena that constitute voluntary motion. If they are inflamed, bruised, distended excessively, as by a tumour, &c. they cannot contract. It has been affected, that a supply of blood is necessary to their performance of this function; so that affection...
MUSCLE.

may be true, but it is difficult to afford experimental proof of it.

Steno stated that paralysis of the lower limbs immediately followed tying the abdominal aorta above its division into the two iliac arteries, and Bichat corroborates this by his own experience. No doubt was entertained that this experiment completely cut off the supply of blood to the lower limbs. In a very interesting experiment of this kind performed by Mr. A. Cooper, and recorded in the Medico-Chirurgical Transact. vol. ii., paralysis did not take place; and as the limbs were fully nourished, and retained their natural warmth, we may conclude that the muscles received blood through the medium of the inoscilating branches. It appears, however, that red blood is necessary to the contraction of the muscles; and that they can no longer execute their functions when black blood is sent to them. (See Long.) When fluids different from blood are introduced into the vessels, the muscular action is not kept up: this is the case with water, oily and albuminous fluids, &c. and a fortiori with acid irritating matters, such as urine, solutions of acids, alkalies, &c. Bichat found that the injection of these into the crucial artery weakened and depressed the motions of the limb. The result of his experiments varied according to the fluid employed: the effects on the moving power were more or less marked, from debilitation to complete suspension; but the deviation from the natural condition was always striking. The fame physiological tried the effects of various gases, brought in contact with the muscles by artificial emphysema, on their contractions. The animals were not incommenced by these trials: oxygen did not excite or accelerate, hydrogen and carbonic acid did not diminish the contractions; and the gases themselves were gradually removed. Emphysema produced with nitrous gas is constantly mortal: its contact seems to strike the muscles with a sudden stony. Various fluids introduced into the cellular substance produce different effects on the muscles, according to their mild or acrid properties, &c.: none have a more sudden or considerable operation than opium. When applied in solution, it quickly paralyzes the muscles. It produces relaxation in a contracted muscle. Probably several causes, besides those enumerated above, are capable of affecting the muscles: for example, mercury, lead, and copper, impair the work of manufactories; cold and certain fevers greatly influence the muscular powers, &c. The tremulous motions observed in those cafes do not seem to have their cause in the brain, for there is no sign of affection of that organ: whether, however, they depend on the muscles or nerves, is not easily decided.

We have just seen that three things are necessary in the exertion of the animal contracility: 1. an action of the brain; 2. of the nerves; 3. of the muscles: the principle of motion resides in the brain, it is conveyed along the nerves, and received by the muscles. But the brain must receive some impulse to determine it to exert its influence. As the animal contracility is exercised only at intervals, whenever its action has intermitted, some new cause must be applied to call it again into exertion: in the natural rate this cause acts first on the brain.

These causes are the will, and the impressions made on the brain, independently of the influence of the mind. The production of motion in consequence of volition must be so familiar to every individual, that it needs no illustration. We may only observe that the motions are regular and precise when the intellectual functions are perfect, while the perception, the memory, and the imagination are exercised naturally, and the judgment directs with regularity the acts of the will: they have an opposite character when these functions are disturbed, as in the various kinds of mental derangements in dreams, delirium, &c.

When we speak of the production of motion by volition, of the power or energy of the will, &c. these expressions are not to be understood as conveying any other fact than the simple connection of two events. How they are connected is entirely unknown to us. The anatomist indeed is aware that the brain, nerves, and muscles are essential in this operation; but the volition, that act of the mind, of which we are conscious, is just the same in him as in the person who does not know that the body contains brain, nerves, and muscles. We will to bend the elbow: this is effected by a contraction of the biceps and brachialis internus muscles, to which our thoughts are not at all directed. In Mr. Hume's "Essay on the Idea of Necessity of Connection," this matter is explained with great clearness: we shall make a short extract from it. "A man suddenly struck with a palsy in the leg or arm, or who had newly lost those members, frequently endeavours, at first, to move them, and employ them in their usual offices. Here he is as much conscious of power to command such limbs, as a man in perfect health is conscious of power to actuate any member which remains in its natural condition. But consciousness never deceives. Consequently, neither in the one case, nor in the other, are we ever conscious of any power. We learn the influence of our will from experience alone. And experience only teaches us how one event constantly follows another; without inferring us in the secret connection, which binds them together, and renders them inseparable.

"We learn from anatomy, that the immediate object of power in voluntary motion, is not the member itself which is moved, but certain muscles and nerves, and animal spirits, and perhaps something still more minute and more unknown, through which the motion is successively propagated, ere it reach the member itself, whose motion is the immediate object of volition. Can there be a more certain proof, that the power, by which this whole operation is performed, is far from being directly and fully known by an inward sentiment or consciousness, is to the last degree mysterious and unintelligible? Here the mind wills a certain event: immediately another event, unknown to ourselves, and totally different from the one intended, is produced: this event produces another, equally unknown: till at last, through a long succession, the desired event is produced. But if the original power were felt, it must be known: were it known, its effect must also be known, since all power is relative to its effect. And, vice versa, if the effect be not known, the power cannot be known nor felt. How indeed can we be conscious of a power to move our limbs, when we have no such power; but only that to move certain animal spirits, which, though they produce at last the motion of our limbs, yet operate in such a manner as is wholly beyond our comprehension?"

In the other class of causes, motion takes place without the participation of the will, or even in opposition to its determinations. We see this in experiments, when the organ is irritated, in great determinations of blood to the head, in inflammation and injuries of the part, &c. The motions exhibited under these circumstances are involuntary, although they take place in parts habitually subject to the will; and they are produced by the direct application of a mechanical cause. But in other cases the brain is affected only by sympathy, a term which conveniently substitutes an appearance of knowledge in the place of our real ignorance of the relations existing between different organs. We may have delirium, convulsions, &c. without any discoverable mechanical action on the brain, and appearing merely as con-
concomitant symptoms of some other disease. Here the will has nothing to do with the muscular contractions; the patient cannot refrain the convulsive motion;—the sympathetic irritation of the brain is stronger than the influence of the will.

To a sympathetic influence exerted on the brain, by the interior organs, Bichat refers the effects of the passions in exciting or depressing the muscular powers. He conceives that they act in the first place on the parts about the epigastic region, as the heart, liver, stomatch, spleen, &c.; that these react on the brain, which excites the muscles, and gives to their exertions an impetuosity, which the will is often unable to control. This is exemplified in men actuated by jealousy, hatred, rage, &c. Other passions have the directly contrary effect of weakening all the muscular motions: we see this strongly in fear, it is also observable in the surprise accompanied by grief or by joy, &c.

Thus we see that the animal contractions either may or may not be subjected to the will; that the series of phenomena in the brain, nerves, and muscles is the same in both instances, and that the only difference is in the cause exciting the brain, which may be either the will, or an irritation directly applied to the organ, or a sympathetic irritation.

The animal contractions continue for some time after apparent death. The intellectual functions always cease first, however death may come on; and the notion of the departure of life is particularly attached in popular acception to their cessation: consequently muscular contraction in obedience to the will is as an end. Still convulsive contractions of the muscles may be produced by irritating the brain, spinal marrow, or nerves; and often this phenomenon is more apparent immediately after death than it was before. In the latter case the influence of the will upon the muscles may interfere with the result, which cannot be disturbed by any such cause in the former. Some birds, as ducks, geese, &c. will run and jump after decapitation; the limbs sometimes exhibit flight motions, and the muscles of the face contract under execution by the guillotine; and these phenomena may be rendered much more sensible by irritating the divided end of the medulla spinalis. The animal contractions cease after death first in the brain, then in the medulla spinalis, and lastly in the nerves; that is, we can excite contraction by irritating the two latter when we can no longer accomplish it by irritating the former; and a similar observation holds good of the medulla and the nerves. The diaphragm continues longer obedient to these irritations than any other muscle; whereas during life it is little affected by the state of the brain, and hardly ever paralyzed or convulsed. The effects of different irritants continue for a longer or shorter time: galvanism still acts forcibly, when mechanical or chemical agents produce no farther influence.

The effects of galvanism on the muscular system excited, when they were first noticed, considerable attention in the minds of physiologists, as they were supposed to offer a solution of the phenomenon of muscular motion. More extensive and accurate inquiry seems to justify us in referring the phenomena noticed by Galvani, and the more powerful exhibition of them in the voltaic apparatus, to electricity. (See Galvanism.) We regard them now only as examples of electrical irritation of the muscles, and acknowledge that they leave the problem of muscular motion in all its original obscurity. In order to exhibit them, it is necessary to place the muscles between the two ends of a galvanic apparatus. The most simple form of the experiment is to lay the hind leg of a frog, with the skin stripped off, on a piece of zinc, and another of silver, so that one extremity shall rest on the other, and the other on the latter metal, all the apparatus being moistened: when the two metals are brought into contact, or when they are united by a metallic arc, convulsions are produced. If the nerves be in contact with one metal, while the muscles rest on the other, the phenomena are also produced by their contact; but the intervention of the nerves is not necessary. When the nerves are made a part of the circle, the convulsions take place, although they should be tied or even divided, provided in the latter case the divided ends are in contact. The pile of Volta, and the subsequent improvements on it, afford the means of producing these phenomena with greater energy. If a wire from one end of the apparatus be placed in the mouth of an animal just killed, while that from the opposite end is placed in the rectum, the parts being moistened, the whole body is convulsed: or the medulla spinalis, and any of the muscles of the body, may be treated in the same way. In this mode of operating, the eyes and eyelids, lips, tongue, &c. may be made to move after decapitation; these phenomena at first excited great general curiosity; but the philosopher perceives in them nothing more than an example of the well-known operation of electricity. If the body is kept warm, these contractions may be produced for one, two, or three hours after death; but, as it cools, the power is lost. The susceptibility is weakened or entirely destroyed by alcohol or opium; when it is nearly exhausted, immersion in oxygenated muriatic acid refires it. Humboldt found it greatest in the spring in frogs, in young individuals, and in the front limbs of the male, by which it seizes and holds the female in their long copulation, while the hind legs of the female are the most susceptible. It is very great in animals killed by repeated discharges of an electrical battery. Apohystax by strangulation, by drowning in mercury, by pure and carbonated hydrogen, oxygenated muriatic acid, and sulphurous acid gases, and the air-pump, do not weaken it: drowning in water, death by breathing sulphurated hydrogen, azote, ammonical gas, and the vapours of charcoal, entirely annihilate it.

Phenomena similar to those produced by the metals may be witnessed sometimes without their being employed at all. Detach the lumbar nerves from their surrounding connections, and bring them in contact with the muscles of the thigh in the frog, and convulsions are produced.

3. Organic Properties.—Organic sensibility clearly belongs to the muscles of the animal life, and is called into constant exercise in them by nutrition, absorption, and exhalation. It is rendered still more apparent by exposing and irritating them; they feel that irritation, and the motion, of which we shall speak presently, is the result of such feeling, which is concentrated in the muscle, and not referred to the brain. Insensible organic contractions belong to the muscular as to all other systems.

The sensible organic contractions is very manifest in the present system. If a muscle be exposed in a living animal, and irritated, it is contracted, and agitation or thrown into a tremulous motion. The same phenomena are produced after apparent death, and that for a considerable time. They are produced also in a muscle, or in a part of one removed from the animal. Almost every thing acts as a stimulus on an exposed muscle: viz. air, water, neutral salts, acids, alkalis, earths, metals, animal and vegetable substances, electricity, whether of the common or voltaic kind, &c. Simple contact is sufficient to produce contraction; but, besides this, there is something depending on the nature of the stimuli, and causing a variation in the intensity of the contractions. Powdered wood, charcoal, or metal, produce but slight motions; a felt causes strong agitation, and various oscillations of the part. Every substance affects the muscles differently,
differently, according to its nature; and these organs are differently acted on according to the age and temperament of the individual, the climate, season, &c.

It is not necessary to irritate the whole muscle in order to produce its contraction; a single puncture, affecting a few fibres only, will throw the whole into action. Often, in performing these experiments on animals, the contraction is communicated from one muscle to another.

In a living animal the contraction is often not so vigorous, nor so strongly marked, as just after death: sometimes, indeed, during life, irritation produces no contraction. The nervous influence, the power of the will, interferes with and disturbs the contraction. By dividing the nerves of the part, this power is entirely got rid of; the permanence of the sensible organic contractility after such an experiment, as well as after apparent death, or paralysis, in which the influence of the brain is equally annihilated, marks the distinction between this property and the animal contractility, and shews that the former is inherent in the muscular tissure.

The contraction of the animal muscles from the application of stimuli is exhibited under two very different forms: it either affects the whole of the muscle, so as to approximate the two points of its infection, as when death has occurred recently; or it produces numerous oscillations of the fibres, and a general vibration or trembling, which does not draw together the points of attachment. The latter phenomenon occurs when the vital powers are nearly extinguished.

The sensible organic contractility is seldom exerted during the life of the animal; so that we are at a loss to account for its existing in this texture in so high a degree. All muscles do not possess it equally: the diaphragm and intercostals are the most irritable, and retain this property for the longest time after death.

On the subject of the vital powers, by which the muscles are enabled to execute their functions, physiology is greatly indebted to the experiments and writings of Haller. He distinguished the property, by which the muscles contract under the application of stimuli, from the vis mortua on the one side, or the contractility of tissue, and from the vis nervosa on the other, or the power of moving under the influence of the brain; and he gave to it the name of vis infa, or vis muscularorum propria. It had been called by Grifon irritability, tone by Stahl, vis vitalis, officiatio, &c. by others; but was generally confused with the other vital powers. The views, which were taken of the subject by Haller, will appear from the following quotations from the eleventh book of his Elementa Physiologic.

It will probably be expected that we should take some notice of the speculations of physiologists concerning the cause of muscular motion: we shall advert very shortly to this subject, on which the reader will find more copious details in the Elementa Physiologic of Haller, lib. ii. sect. 3, because we are of opinion that the time consumed in such investigations has hitherto been worse than lost: it has not only thrown no light on the subject of inquiry, but has drawn men away from the only path by which they could arrive with certainty at a knowledge of the muscular system, namely, observation of the phenomena. "Iterum," says Haller, "in hypothesibus invenies origines, non quod propria aliquam congejuram habeas, quam exores, fed quod ad inventendos fontes admirabilis illius potentiae vivorum carnium potius per speculaciones adhibe. quam per experimenta, fere scriptores physiologicorum paraerit." Our knowledge concerning muscular motions amounts to this, that certain physical changes are produced in the fibres under the action of certain causes: these we call contraction and relaxation. When we say that a muscle acts by virtue of its irritability, contractile power, or contractility, we merely denote this fact, and express these phenomena in a general word: we know no more of this irritability, what it is, or how it is brought into exercise, than we do of attraction, or the force by which the phenomena of dead matter are regulated. This view of the subject coincides nearly with the sentiments of Haller: "Cauam quidem neque mechanicam hujus potestatis quae, neque omnino phytica, qui prouedio, propria et innatae fibrae animali vin effe, cujus non aliam porro cauam quaeere oporteat, live nunc unice fortior fuerit contractionis mortue gradus, quin alia vis, ut ex co postis argueri, quod mortua vis omnibus animales et vegetabilis, hec certe in animato corpore fibrae musculari propria fit." Nothing appears more evident than this distinction between the two kinds of motions ordinarily designated by the epithets voluntary and involuntary: yet a very numerous fact in physiology, the followers of Stahl, deny the existence of any original difference in this instance, and refer all the motions in the human body to the mind or soul (anima): this produces all motion, and guides it by wife design to the production of certain ends. It governs the body, after forming it in the uterus of the mother, and is the agent of reparation after injuries. They hold that all motions, even those of the heart, were originally voluntary: and they cite the case of colonel Townshend, related in Cheyne's English Malady, p. 307, who is said to have been able after death to suspend and renew at pleasure the action of the heart. They ascribe the loss of voluntary power over the heart to habit, which has destroyed the influence of the will on the motions of the iris and palpebra, and other voluntary organs; and assert that repetition is attended with the loss of consciousness in these cases, so that the reflex operation of the mind is not perceived. They think that the mind would be able to move at its pleasure the inlines and heart, if it could see them. They cite the operation of the pallium on the heart. Fears and dilekts are the efforts of the mind (anima) against evils which threaten the body. They discern the operations of a designing intelligence (provided anima confilia) in crises, in the salutary augmentation of secretions, and laeity, in sleep, which they regard as a voluntary act granted by the mind to its body, lest perpetual exertion should wear out its powers.

The conficuousness of the heart's action is lost in confluence of its familiarity; as is the case in some obviously voluntary motions, when they have been very frequently repeated. Men immersed in thought walk, eat, and perform many other actions without being conscious of them.
The exertion of the will on the brain in playing on a violin is very obscure. They conceive that the mind regulates the internal organs "intellectu parvo, abaque reflexione et ratione," but that it performs our communications with external objects "cum aucto reflexo, cum confidente fixa sensationis & actionis." From these and such considerations the Stahlian school assert that irritability is the protectory power of the mind against stimuli that affect it unpleasantly, by which, with a more or less strongly marked feeling according to the amount of the cause, it produces a contraction of the fibres for the removal of that cause. Hence that no motion takes place without sensation, nor without the participation of the mind; and that not only those contractions which are caused by irritating a muscle, but all others, even such as occur from the mere recollection of an unpleasant object, as in vomiting, proceed from the mind.

It appears to us, that in these opinions objects which are the most unequivocally distinct, are confounded together; that the term mind, or anima, is employed in a very indefinite or obscure sense; and that the affections are most obviously repugnant to every man's experience, if this word, as the authors apparently mean, should be deemed synonymous with will.

That the mind, when intent on any thing that powerfully interests it, is not conscious of many flight impressions, is well known; and in such cases consciousnefs and voluntary action seem disjoined: but let this more important occupation cease, and the flughter impressions are immediately perceived. In playing a musical instrument too, as well as in many operations in the arts, the motions are so rapid, that we find it difficult to allow that there can be a distinct volition for each: neither are we conscious at any time of the particular muscles employed. But the motions cease, as soon as the will to move is discontinued, and begin again when that is renewed. Either of these cases is most obviously distinct from the action of the heart or intestines, in which the closest observation can discern no sensation, and the most resolute exertion of the will cannot modify the motion.

The supposition that the actions of the involuntary organs are at first voluntary, and are continued by habit without the exertion of the will, is inconsistent with what we see in respiration. That is a function necessary to life, yet performed by voluntary powers: we can accelerate, retard, or suppress it. This dominion of the will is never lost; the necessity of the function to life, or the invisible structure of the diaphragm, has here no effect. The heart, on the contrary, of which the office is so closely connected to that of the lung, and the motion of which is perceptible to the touch, has never been excited or retarded in its action by any individual: we know too little of the cafe of colonel Townshend to admit it as an exception to the otherwise invariable testimony of experience. It does not explain the matter to say that we do not see the heart; for we do not see the diaphragm in the preceding case; nor can we influence the motion of the penis which we do see, nor of the intestines when protruded from the abdomen in various ways.

It has been asserted that the passions of the mind influence the heart, and that as the mind influences thece, it must therefore operate on that organ. That wine, poison, or an affront, will accelerate the heart's motion is most true; but these are not voluntary affections: we cannot avoid being drunk, when we have taken wine, nor can we help being angry when we are irritated.

It is not true that habit confounds the clasps of voluntary and involuntary motions; the former are all equally subject to the will in the infant, boy, and adult. No voluntary muscle is ever removed from the dominion of the will, while life continues. Although we move the upper eyelid frequently without perceiving it, yet we perceive it as soon as we attend; we can moreover move it more or less frequently as we choose: by exercise we can hold it quiet when an object is brought suddenly before the eye. On this analogy, then, the habit of contraction ought not to make the heart an involuntary power, if it had been a voluntary one in the fetus. The perillatonic motion is interrupted for months in hybernating animals; the vis does not contract in a dark place, nor does the pens move in an individual who does not see or think of a woman: on the application of proper stimuli, all these parts move, yet they are as much out of the control of the mind or will as in animals where they are constantly exerted.

We may therefore most truly affirm, with Haller, "Æterna lege separatur voluntatis imperium ab irritabilitatis provincia. Nemo mortuum unquam, ullo exemplo, voluntate sua aut in cor, aut in intelliginn, aut in ventriculum, aut in arteriam, aut alid in vitale organum arbitration exercuit ullum, neque eos motus vel excitare didicit, vel retardare, vel accelerare, vel supprimere. Nemo mortuum in musculis voluntatis obsoxit, si fani fuerunt, dederavit obsequium quod præfenter voluntati. Eos omnes musculos et ad motum ciever nihilum omnes, et in motu incitare, et vicissim morari, ad quietem denique jubendo reducere." Lib. xi. sect. 3 and 8.

That fevers are excited by the command of the mind is affirmed without any proof; and the total want of power in the will over critical evacuations, &c. is too obvious to require mention. The accelerated action of the heart, the convulsions, &c. produced from injury or disease, are so far from being adapted to the purposes of remedy or restoration, that the physician endeavours to lefien them by every means in his power.

That any obscure sensation causes the motion of the heart is manifested contrary to the testimony of sense itself. When intently occupied, we either do not perceive or do not retain in our minds the flighter impressions: but we are immediately conscious, even of the most gentle impulse of the air, when we turn our attention to it exclusively: how then does it happen that no man ever felt the four ounces of blood rushing into his heart, nor could ever perceive any difference between the systole and diastole of that organ? Further, the heart when removed from the body still contracts, when all suppuration or sensation must surely be removed.

To the notion of the formative power, exercised by the mind in composing the new being, Haller has very justly replied, "Struærcem animam quis credat, qui imperitiitum animalium, incredibilis artificio corpus, perinde ut fapientissimum mortuum, frure videat; qui nullam diversitatem in rebus fabrica corporis infantis nuncquam fane mente ufu videat, et infantis in Newtonum convalitur? Frequentissimum hic mihi observerat animo exemplum futur generis hominum, quod vicina Valeria abuant: Idi omne vita humanæ officium inepti, vel in aprico folo humana dignitate manifesto minores fessitant, vel in lecithis cucurbitum fere immoti, tota vita sua decumbunt. Nihil unquam mihi vel a poeta vifum eit minus credibile dici, quam hanc animam, adeo sero, adeo modice sapientis, zulam divini creatoris potellatem: si enim plantas Dei fabricatur, digniora plantis animata corpora ipfa fructus fribi anima." Ibid. sect. 9.

The reader will find a more ample disquisition of this subject,
subject, and of other hypotheses concerning muscular motion, now nearly forgotten, in the eleventh book of the Elements of Physiology. Haller’s own idea, which has been very generally adopted, but which we confess appears as little instructive as any other, is that the unknown nervous fluid, of almost infinite subtilties and velocity, acts as a stimulus on the elements of the muscular fibres, as the electrical matter excites motion in these fibres, independently of the will. Not that both these fluids are the same, but that they agree in the velocity of their course, and in the power of penetrating all the elements of the bodies, in which they reside.

The inadequacy of all the attempts at solving this interesting problem is manifest from the confluent fabrication of new hypotheses. No sooner is any great discovery made in physics than an application of it to physiology is brought forwards. Thus oxygen and galvanism have been applied into the service on this occasion. A modern author on physiology represents it as the most ingenious and strongly supported of all the hypotheses, devised for the purpose of explaining the phenomena of muscular action, that which makes it depend on the combinations of the hydrogen, carbon, azote, and other combustible substances in the muscular fibres, with the oxygen brought by the blood of the arteries. To effect this combination, says he, it is necessary, not only that arterial blood should bathe the muscular flesh, and that oxygen should be brought into contact with the substances with which it is to unite, but also that a nervous current should traverse the tissue of the muscle and produce the decompositions, as the passage of the electrical spark through a mixture of oxygen and hydrogen produces water. (Richerand Elements de Physiologie, fect. 162.) If this be the best of the hypotheses, we may allow the rest to pursue their journey without obstruction to the tomb of all the Capulets.

Sympathies.—Convulsive motions of the animal muscular system attend various affections of our organs, particularly in children. Animal contractility is the predominant vital property in this system, and is therefore most frequently called into action in sympathies. Convulsions are particularly frequent in the affections of our organs accompanied with great pain; there are indeed very acute pains unattended with sympathetic convulsive motions, but convulsions are rarely observed, except in cases where the organ originally affected has its animal sensibility very strongly developed. From this view, which we have given, of the part which the brain performs in animal contractility, we must conclude that the sympathies, in which that property is called into action, take place through the medium of the brain. Next to the animal contractility, the sensibility of the same kind is the property most frequently called into action in sympathies. The latitude, the feeling of weight, the vague pains experienced at the attack of many diseases, are examples. The organic properties are seldom sympathetically exerted; or, if they are, the fact is not indicated to us by any sensible figure.

Tendons.—The muscular fibres, which are the moving powers, are not in general applied immediately to the bones, which are the parts moved. The skeleton would not afford a sufficient surface for this purpose: indeed, in most cases, a very small part only of the fibrous fibres could be directly implanted in the bone. Instead of this they are fixed to fibrous organs, which are implanted in the bones. Some muscles, which have no long attachments, as the face and pharynx, have no tendon in their structure: but where the muscle, as is the general case in this system, is fixed at both its ends to bones, a considerable portion and very frequently the whole of its attachments is tendinous. An example will show in what manner the advantage, connected with the tendons, of bringing an increased quantity of fibre to bear on a particular point of bone. The tibialis and cruralis, the principal extensors of the knee, cover by their origin, which is in great measure, nearly, nearly the whole body of the thigh-bone: had they been infefted by muscular fibres, they must have covered the whole tibia. The tendon, by which they are attached, is fixed to a surface of about three or four inches in breadth, and the rest of the bone remains for the origins of muscles moving the foot and its various parts.

The fibrous system, so far as it is connected with the muscles, is seen in two forms: either in hard and thick cords, called tendons; or in broad and thin plates, called aponeuroses.

The latter are often condensed into the former: that is, an aponeurosis of several inches in breadth, receiving muscular fibres in its whole surface, may be contracted into a tendon not broader than the finger. In this case, the fibrous texture, which is expanded in the one, is condensed in the other, and their only difference is in the form.

The organization of the tendons, and their properties, have been already explained in general, under the article Fibrous System.

The aponeurosis admit of being divided into three kinds.

1. Those which possess a broad surface, are very numerous: they are sometimes formed by the expansion of a tendon, as in the extensor extensor crus; sometimes, as in the malleus, they come immediately from the bone. They may receive muscular fibres on one side only, or both. In the latter case they form septa, placed between muscular fasciculi, which they separate from each other and yet unite into one organ. They always receive the infection of the muscular fibres in a very oblique direction.

2. The advantage, which we have mentioned as belonging to the tendons in general, of multiplying the points of infection for muscular fibres, is very obvious in these aponeuroses. The whole of the temporal fossa would not be sufficient for the attachment of the malleus, if it were effected by separate fibres: the aponeurotic septa in its substance receiving the fibres, and then fixed to the bone, concentrate the infection in the edge of the zygoma. All the very powerful muscles, which must consequently possess numerous fibres, are interfaced by similar aponeuroses.

The fibrous system is identical with the tendons; many are continuous with them, the fibres following the same general direction, but spreading out in the aponeuroses. Their fibres are in general not interwoven, as in the fasciae, but follow one direction.

By macerating a tendon for a short time, it is softened, and may be stretched laterally so as to assume a form exactly like that of an aponeurosis.

2. When a large vessel passes under a muscle, it is covered by an aponeurosis in an arched form, so that the origin of the muscular fibres is not interrupted: these however are not numerous. They may be seen in the diaphragm, over the course of the aorta, and in the muscles, at the passage of the posterior tibial artery. The muscular fibres are implanted in the convexity, and the passage of the vessel takes place under the concavity of the arch, the extremities of which are fixed to the bone. If the action of the muscle has any effect on these arches, it must rather enlarge than diminish the openings under them, as the fibres draw upon the convexity of the arch.

3. Aponeuroses formed of inelastic fibres. These consist of a vast number of small fibrous bodies, distinct from each other, separately attached to the peritoneum, and continued
MUSCLE.

continued into the fulness of the muscle. This is a mode of infection requiring broad bony surfaces.

The tendons are commonly situated at the extremities of the musculature; but sometimes they occupy the middle, as in the digastricus. They are generally placed at the most moveable end, the opposite extremity of the muscle, having its fibres implanted in aponeuroses, as we see particularly in the forearm and leg, where all the muscles, attached above by broad bony or aponeurotic surfaces, terminate below by comparatively tender tendons. From this arrangement, the ends of the limbs, which execute the most extensive motions, are left bulky, and consequently less heavy; and the whole effort is thus transferred to the limb and the tendon is concentrated upon a narrow point of bone.

The refilling powers which characterise the fibrous tissue in so remarkable a manner, render the tendons particularly fit for these situations, where they have to turn over, and consequently rub against, the ends of the bones; and the same property enables them to withstand the external efforts and violence to which these parts of the limbs are necessarily much exposed in executing their various functions.

The form of the tendons is generally round; that figure includes the greatest bulk under the smallest surface. But sometimes they are more or less flattened. They may be divided into two or more secondary portions, implanted into separate bones, or receiving muscular fibres. A loose cellular fulness connects them to each other, or to surrounding organs, and allows them a free power of motion. Sometimes, instead of this tissue, they are surrounded by synovial membranes, or partially covered by such membranes, which are expanded also on the surfaces of the parts over which the tendon moves. These arrangements are found in situations where the tendon is very extensive, or where friction between a tendon and a bone very considerate; they have been commonly called bursa musculi; the details concerning their structure will be found under the articles Membrane (division of synovial membranes), and Fibrous Sytem (division of fibrous sheaths).

The mode of connection of the muscular fibres to the tendons varies. The tendon sometimes has a few fibres joining it at acute angles on each side, so that it may be compared to the shaft, and the fibres to the barbs of a feather; such have been called penniform muscles. When the fibres run into the tendon on one side only, it is called a semipenniform muscle. Sometimes the tendon is contained in the fulness of the muscle, and can be exposed only by making a longitudinal section.

The connection of the muscular fibres to the tendons and to the aponeuroses is the same. If we follow carefully a particular bundle of fibres, we see it continued in the aponeurosis (for example in the diaphragm) under an alteration of bulk and characters. The muscular and fibrous parts are inseparably connected, and compose one organ. As the power produced by the contraction of the muscle is applied through the tendon to the bone, this firm connection is obviously essential to the functions of the part. Yet in no instance are we at any loss in marking the boundary between the fleshy and the fibrous structure; the differences in their organisation and sensible characters are as striking as between their vital properties and functions.

In the muscles of a robust and recently killed individual, an appearance of a rising line has been described at the conjuction of the muscular fibre and tendon, and the boundary between the two is hidden and clearly marked. Generally the fibres of the tendon are dilated in the muscle in a penicillus form.

We deem the opinion, which regards tendons as formed by indurated muscular fibres, no more worthy of discussion than the conceit of the latter being a continuation of the nerves.

Ebullition causes the tendon and fleshy fibres to separate gradually, and long maceration detaches them. The union is not so intimate in the young subject; scraping with a scalpel detaches the muscular fibres from the tendon at this age, and leaves the surface of the latter nearly smooth.

The opposite end of the tendon is fixed to the periosteum. In the young subject this membrane is easily detached, and carries with it all the tendinous infections. At a more advanced period, the tendon, periosteum, and bone are identified, and nothing but the hardest scraping will detach the former from the latter. The tendons are implanted in other fibrous membranes, as the falciform and corpus cavernosum penis; but in no other description of organs.

The fibrous tissue is extremely dense in the tendons; several of them appear homogeneous on the first view; but attentive examination soon enables us to discover fibres united by a very compact cellular tissue in very sparing quantity. Ebullition renders these fibres very perceptible; when a tendon has been cut transversely, and plunged into boiling water, it swells at the divided end, and appears rendered very apparent. When they expand to form an aponeurosis, or to be fixed to the periosteum, they are visible without any preparation. Continued maceration expands and softens these organs, and renders their fibres very distinct. They are parallel to each other, and seem straight; they may be separated into smaller and smaller bundles joined by cellular substance, and the end of this division is doubtful. They have been described as appearing wrinkled, or spiral under microscopic examination.

The vascular system of the tendons admits no red blood; but they become red under certain circumstances of inflammation.

Their vital properties are more obscure, and their mode of vitality in general is more feebly marked than in any other part of the fibrous tissue. No fluid escapes, no pain is felt when they are dissected in living animals; and their temperature (except inasmuch as it is influenced by that of surrounding parts) is low.

Division, Name, Arrangement, &c. of the Muscles.—When we speak of a muscle, we do not restrict the term to the proper muscular or fleshy tissue, but mean a particular mass of that tissue together with the tendons or aponeuroses connected to the muscular fibres. In this way we talk of the tendon or aponeurosis of a muscle. Hitherto no certain and regular method has been followed in establishing the separations and distinctions of the animal muscular system. Our general notion of a muscle is that of a mass of muscular fibres, which, with its tendons, is connected in every direction with the surrounding ones; the pronator quadratus, and the muscles of the eyeball are examples. Or there may be two or more distinct portions of muscle joined to a common tendon, as in the peclotus major and biceps flexor cubiti; or a common mass of muscle may have separate tendons, as the flexors and extensors of the toes and fingers. But, in some cases, anatomists have separated and described as distinct muscles those inserted into a common tendon, as the muscles of the calf, and the extensors of the knee; and they have even done this where the two parts are most closely connected, as in the sterno-mastoideus and cleido-mastoideus, the facro-lumbalis and longissimus dorfi, &c. They have also proceeded in a very arbitrary manner in dividing the muscles of the face, which are very closely connected together. Hence there are numerous exceptions to any general rule concerning the distinctions of the particular muscles.
MUSCLE.

As a voluntary muscle is an organ composed of fleehy and tendinous fibres, having the office of moving the parts of the body on each other, in which the motion produced by the contraction of the muscular fibres is brought to bear on the parts moved by means of the tendons, it must be fixed to at least two movable parts. The ends, which are generally tendinous, are comparatively small, while the middle, composed of fleshy fibres, swells out into a much larger bulk. The extremity fixed to the leaf movable part, or that which is nearest to the trunk of the body, is usually called the origin (caput or origo) of the muscle; the opposite end, its insertion (cauda, finis, infitio); and the middle, its belly (venter). Where a muscle is connected to two equally movable points, either end may be called the origin or insertion. The effect produced on any part by the contraction of the muscle is called its action.

Anatomists have drawn the names by which they distinguish the particular muscles, from various sources; 1, from the action, as extensor, flexor, pronator, supinator, adductors, &c.; 2, from the attachments of its extremities, as coraco-brachialis, stylo-hyoideus, geno-glossus, &c.; 3, from the attachment of one end only, as pterygoideus, palmaris; 4, from some remarkable circumstance, as septum transversum; 5, from the direction of its course, as circumflexus, rectus, obliquus; 6, from the figure, as deltoides, triangularis, rhomboideus; 7, from the number of origins, as biceps, triceps; 8, from the relative position, as radialis, ulnaris, &c.; 9, from size, as vastus, &c. &c. The belt names are those drawn from the second of these sources, as they indicate the attachments, and therefore are, in some measure, descriptive; the principle cannot be very well followed, when the connections are numerous, as the names become then immediately long, and burden the memory, as much as they offend the ear. Occipito-dorso-clavi-fus-acromi, the name given by Dumas to the trapezius, is a specimen of these.

The muscles in general are double, and correspond perfectly on the two sides of the body; a few are single, placed on the middle line of the body, and divisible into right and left corresponding halves; vis. axygos uvale, arytenoideus transversus, sphincter oris, sphincter ani, sphincter vaginae. The law of symmetry, therefore, which belongs to the parts concerned in the animal life, is applicable to these organs. The diaphragm partakes of the organic as well as animal life; and its structure is not symmetrical; the two halves do not correspond.

The male and female have each a small number of muscles connected with the organs of generation, peculiar to itself; all others are common to both sexes.

The muscles are very numerous; taken altogether, they compose a larger volume, and occupy a larger space than any other system in the body. Besides their other situations, they form a layer generally expanded under the skin, and partaking in some degree the functions of that organ; that is, they protect the subjacent parts, receive with impunity the action of external bodies, and may even be divided to a considerable extent without the general functions of life being sensibly impaired. Hence they are well calculated to defend the more deeply-feated organs, the injuries of which would, in many instances, be fatal. They may be divided, so far as regards their general form, into long, broad, and short.

The long muscles in general occupy the limbs, to the form of which their figure is accommodated. They are separated from the skin by the aponeuroses, from the bones by the peristome, and thus are lodged in a kind of fibrous tube, which confines them strongly. In this they are disposed in more or less numerous strata, of which the deeply-feated are bound down by the superficial, which in their turn are supported and confined by the aponeuroses. The latter are always the longest, and belong to the motions of three or four bones, as the flexors of the knee, the flexors and extensors of the wrist, fingers, ankle, toes, &c. In proportion as they are deeper, they are shorter, and concerned almost always in the motions of one joint only.

The different layers are separated by cellular strata, which are loose or close in their texture, according as the motions are free or limited, and thick where vesiels or nerves run between the muscles.

The long muscles have been distinguished into simple and compound. The former consist of a single mass of muscular and tendinous fibres; in the latter, there may be either two or more separate portions, arising distinctively, and joined into one mass, as in the serratus anterior, biceps cubiti, &c.; or a single muscle may be split into several insertions, as in the flexors and extensors of the fingers, &c.

They are generally inflated, but sometimes connected together by aponeuroses, which may join two, three, or more of the neighbouring muscles into one mass at their origins; this is the case with those that come from the condyles of the humerus.

The long muscles upon the spine do not resemble those of the limbs; the fibres do not run from one end to the other, but are arranged in numerous short fasciculi, placed in apposition to each other, and therefore forming one muscle.

The broad muscles in general cover the large cavities of the body, particularly the thorax and abdomen; they contribute to form the sides of these cavities, protect the internal organs, and facilitate their functions by the motions which they execute. The thickness of these muscles is inconvenient; they compose broad strata, sometimes arranged in fascicile layers, as in the abdomen, sometimes placed over the long muscles, as in the back; in the female they are more extensive in proportion as they are more superficial.

When a broad muscle arises and terminates on one of the great cavities, it is equally broad throughout, as there are extensive surfaces for all the attachments. But if it proceeds from the trunk to a long bone, its fibres converge; it becomes thicker and narrower, and ends in a comparatively small tendon fixed to the bone. The latissimus dorsi, pectoralis major, &c. exemplify this arrangement.

Cellular strata separate the broad muscles from each other, in the same way as the long; but they are very seldom covered by aponeuroses. They are simply subjacent to the integuments, and their form prevents those displacements, to which the long muscles would be subject, were they not confined by fascia. See FASCIA.

The short muscles, in which the three dimensions are nearly equal, are found in situations where the motions are not extensive, but require considerable force. The muscles of the jaw, those in the hand and foot, several about the hip and shoulder, and others in the spine, exemplify this arrangement. The number of their fibres gives the strength, while their shortness corresponds to the limited nature of the movement. These short muscles are often joined together, either at their origin or insertion; they are seldom covered by aponeuroses, and they vary in figure.

This division of the muscles into long, broad, and short, like the corresponding one of the bones, is subject to numerous modifications. Many have a mixed character, and might be classed with equal propriety in either of two divisions. Nature varies the conformation of the moving powers according to the functions of the organs, so that our anatomical
anatomical divisions, instead of being rigorous and precise, are to be regarded merely as approximations.

In describing the muscles, anatomists generally divide the body into certain regions, and consider together the muscles which are connected in point of situation. As this is an arbitrary method, the number of regions is different in different works. The arrangements of Albinus, Innes, and Dumas, as well as the synonyms of all writers previous to the first of these anatomists, and the new names proposed by the last, are contained in the first part of Dr. Barclay's book on the muscular motions of the human body. The particular muscles are described in this dictionary under their respective titles, with a few exceptions. Those of the eye, ear, and nose, are given under those articles: those of the lips, cheeks, tongue, os hyoides, palate, pharynx, and jaw, under DeGlutition. The muscles belonging to the organs of generation, are described in the article Generation; and those connected with the anus, in Intestine.

The synonyms most frequently met with are mentioned in the account of each muscle.

In order to present a general view of the muscles, we shall adopt the arrangement of Dr. Barclay, from whose work the following table is copied. It contains all the muscles connected with the skeleton by origin or insertion. In the middle column the bones are arranged in the usual order of demonstration; the series commencing with the bones of the cranium, and proceeding regularly through those of the face, neck, and trunk, to the extremities. Each bone is followed by the muscles attached to it, the names of which are either in Roman or Italic characters; the former expresses the muscles which are connected to the bones by infection, the latter those by origin. When any muscle has other origins, they are to be found in the first column in Italic characters; when other insertions, in the third column, in Roman characters.

Explanations of the Plates, in which the Anatomy of the Muscles is represented.—In each of the muscular figures, different strata of muscles are represented in the two sides of the body. Each is followed by a corresponding plate of outlines; in which, besides the principal figure, the smaller parts are drawn on a larger scale, to make the letters of reference more clear.

ANATOMY. Myology. Plates VIII. and IX.

On the left side, the first stratum of muscles, or those exposed on removing the skin, are seen: on the right, the second layer, or those brought into view when the preceding have been partially removed, are exhibited.

A. In the Head, Neck, and Trunk.

1. Frontal portion of the crurasius.
2. Union of the right and left portions.
3. Aponeuroses of the crurasius.
4. 5. Atollens or superior auris; 4, the tendinous; 5, the fleshy part.
6. Anterior auris.
7. 8. Orbicularis palpebrarum; 7, the interior; 8, the exterior portion.
10. Levator labii superiors alaeque nasii.
11. 12. Fibres from the orbicularis palp. to the upper lip.
14. Lower portion of the levator anguli oris.
15. Zygomaticus major.
16. Orbicularis oris.
17. Nasalis labii superioris.
18. Deprefor anguli oris.
19. Deprefor labii inferioris proprius.
20. Levatores menti.
22. Maffeter.
23. 24. Platynia myoides; 23, risorius of Santorini. The lower jaw, clavicle, and ferno-cleido-mastoideus are marked by dotted lines.
25. Biventer maxillae inferioris.
26. 27. 28. Serrato-cleido-mastoideus; 27, the fernal attachment; 28, the clavicular.
29. Trapezius.
30. Serrato-hyoidus; a little of the ferno-thyroideus is seen at its site.
31. Omo-hyoidus.
32. Levator scapulae.
33. Sclalenus medius.
34. Pectoralis major.
35—39. Pectoralis minor; 35, the fleshy part.
MUSCLE.

36—38. Attachments to the ribs; 39, to the coracoid process.
40—42. First and second bones of the sternum; and eni-
form cartilage.
43. Serratus magnus.
44. Intercostales externi.
45. ———— interni.
46. Latifilium dorsi.
47-51. The left obliquus externus abdominis; 47, the
fleshy portion; 48—51, the aponeurosis.
48. The obliquus internus seen through the aponeurosis.
49. The rectus; 50, the pyramidalis; 51, the tendinous in-
tersections of the rectus.
52. Umbilicus.
53. The abdominal rug.
54, 55. Obliquus internus abdominis of the right side. The
external lamina of the aponeurosis (55), by which the
rectus was covered, is removed.
56. 57. Rectus abdominis of the right side, exposed by the
removal of its sheath; 56, the fleshy part; 57, the ten-
dinous intersections.
58. Pyramidalis of the right side.
59. Cremaster.

B. In the Upper Limbs.
60. The clavicle.
61. The coracoid process of the scapula.
62. 63. The subclavius; 62, the fleshy, and 63, the tendi-
inous part.
64. Deltoides.
65. Subscapularis.
66. Teres major.
* Supraepipatellar.
67. 71. Biceps brachii; 67, the fleshy belly; 68, the short
head; 69, the long head; 70, the aponeurosis cut off;
71, the tendon inserted in the radius.
72. Coracobrachialis.
73—75. Triceps: the long, middle, and short heads.
76, 77. Brachialis internus; 77, infertion of the tendon in
the ulna.
78. Supinator longus of the left arm. It is removed on the
right side.
79. Extensor carpi radialis longior.
80. .— brevior.
81. Extensor primi internodi pollicis.
82. —— fp. dntrrnodi pollicis.
83. Pronator teres. It is removed on the right side.
84. Supinator brevis.
85. Flexor carpi radialis. In the right arm a portion of the
tendon only is left.
86. Left palmaris longus.
87. Left palmar fadoca.
88. Left palmaris brevis.
89. 90. Flexor digitorum sublimis; 89, the fleshy part; 90,
the four tendons divided to allow the passage of the ten-
dons of the flexor profundus.
91, 92. Flexor profundus; 91, a part of its tendinous ori-
gin; 92, its four tendons.
93—96. The four lumbricales.
97, 98. Flexor longus pollicis; 97, the fleshy; 98, the
tendinous part.
99. Pronator quadratus.
100. Flexor carpi ulnaris.
101. Left abductor pollicis.
102. Flexor brevis pollicis.
103. Right opponens pollicis. The abductor has been re-
moved.

104. Abductor digiti minimi.
105. Right flexor brevis digiti minimi.
106. Adductor pollicis.
107. Left abductor indicis.
108. Annular ligament of the wrist.

C. In the Lower Extremities.
110. Right gluteus minimus.
* Edge of the left gluteus maximus.
111. Left tenor vaginae femoris.
112, 113. Left fartorius; 112, the fleshy; 113, the ten-
dinous part.
114. Iliacus internus.
115. Plius magnus.
116. Plicicus.
117. Adductor longus femoris.
118, 119. Gracilis; 118, the fleshy portion; 119, the
tendon.
120. Tendon of the femitendineus.
121, 122. Rectus femoris; 121, the fleshy part; 122, the
tendon. It is cut away on the right side.
123. Ligament of the patella.
124. Vastus externus.
125. ——— internus.
126. Right cruralis.
127. Biceps femoris.
128. Inner head of the left gastrocnemius.
129. Soleus.
130. Left tendo Achilles.
131. Tendon of the left plantaris.
132, 133. Flexor longus digitorum pedis; 133, the
tendon.
134. Tendon of the tibialis posterior.
135. 136. Peroneus longus; 136, its tendon.
137. Peroneus brevis.
138, 139. Extensor longus digitorum; 138, the fleshy
part; 139, the tendon divided into four portions on the
back of the foot.
140. Peroneus tertius.
141, 142. Extensor longus pollicis; 142, its tendon.
Under this and the tendons of the extensor longus digi-
torum, those of the extensor brevis are partially seen.
143, 144. Tibialis anterior; 144, the tendon, which is cut
off in the right foot.
145. Left abductor pollicis.
146. Flexor brevis digitorum.
147. Annular ligament of the ankle.

Plates IX. and X.—A front view of the deeply-seated
muscles. Those of the first and second orders, expressed in
the former plates, have been removed; the right half
reprepents those of the third, and the left thofe of the fourth
layer.

A. In the Head, Neck, and Trunk.
1, 2. Orbicularis palpebrarum; 1, the exterior; 2, the
interior portion.
3. Corrugator supercilii.
4. Levator palpebrarum superius, et rectus oculi superior,
which are cut through near their infertion.
5. Rectus externus occlui cut through.
6. Obliquus inferior cut through.
7. Temporalis.
8, 9. Masseur; 8, the anterior; 9, the posterior portion.
10. Levator anguli oris.
11. Depressor anguli oris cut through near its apex.
12. Or-
MUSCLE.

12. Orbicularis oris.
15. Posterior belly of the digastricus.
17. Sclerus anterior.
18. Rectus capitis anticus major.
19. Longus coli.
22. Mylo-hyoideus.
23. Intercoftaies externi.
24. —— interni.
25. Trasversus abdominis.
26. Posterior layer of the aponeurosis of the obliquus externus abdominis.
* Spermatic cord cut through in front of the ring.
27. Peritoneum.
28—31. Diaphragm; 28, the convex; 29, the concave surface; 30, the tendon; 31, the crura.
32—33. Ploas minor; 32, the tendon.
34—35. Ploas major; 35, the tendon.
36. Iliacus internus.
37. Quadratus lumborum.

B. In the Upper Extremities.
38. 39. Subcuapusalis; 39, the tendon.
40. 41. Teres major; 41, the tendon.
42. Short head of the biceps cut off.
43. Coracobrachialis.
44. Place where the biceps has been cut.
45—46. Brachial internus; 46, the tendon.
47. 48. Inner head of the triceps; 48, the tendon.
49—50. Extenfor carpi radialis longior; 50, the tendon.
51. Extenfor carpi radialis brevis.
52. Remainder of the promotor teres, which has been partly cut away.
53. Supinator brevis.
54—55. Flexor profundus; 55, its four tendons.
56—58. Flexor longus pollicis; 56, the fleshy belly; 57, the tendon; 58, the accessory portion.
59. Promotor quadratus.
60—63. Lumbicales.
64—65. Flexor brevis pollicis; 65, the tendons inserted into the scaphoid bones.
66. Addutor pollicis.
67. Adductor metacarpi minimi digiti.
68—71. Interosseus interni.
72—74. —— externi.
75. Annular ligament of the wrist.
76. The penis cut off; the erectors and acceleratores urinae are imperfectly seen behind it.
77. Sphincter ani externus.
78. Transversus perinei.

C. In the Lower Extremities.
79. Gluteus minimus.
80. Obturator externus.
81. Adductor brevis femoris.
82. —— magnus femoris.
83. Semimembranosus.
84. 85. Gracilis; 85, its tendon.
86. Biceps femoris.
87. Peroneus longus.
88. —— brevis.
89—90. Tibalis pollicis; 90, the tendon.
91—92. Flexor longus digitortum; 92, the tendon.
93. Extenfor brevis.
Plates XII. and XIII. Back view of the muscles, the superficial fratum is represented on the right, and the second on the left side.

A. In the Head, Neck, and Trunk.
1. 2. Occipital portion of the epicranius; 1, the tendinous; 2, the fleshy part.
3. The frontal portion of the epicranius.
4. The aponeurosis of the epicranius.
5. The thin and membranous portion of the aponeurosis.
6. Part of the temporal fascia.
7. 8. Attollens auriculae; 7, the fleshy; 8, the tendinous part.
10. Anterior auris.
11. Retractantes auriculae.
12. Zygomatomicus major.
13. 14. Malfetor; 13, the anterior; 14, the posterior portion.
15. Pterygoideus internus.
17. Platymyoides.
18—19. Sterno-cleido-mastoideus; 18, the fleshy; 19, the tendinous part.
20. Biventer cervicis: its tendinous origin from the head is seen on the left side.
21. Splenius capitis: its origin is also seen on the left side.
22. Levator scapulae.
23—27. Trapezius; 23, the fleshy part; 24—27, the tendinous portion; 24, the attachments to the occiput; 25, the part contiguous to the opposite muscle; 26, the attachment to the spine of the scapula; 27, to the acromion.
28—31. Latissimus dorfi; 28, the fleshy; 29, the tendinous part; 30, attachment to the acromion; 31, to the ilium.
32. Right obliquus externus abdominis.
33. Serratus politicus superior.
34. 35. Rhomboides minor; 34, the fleshy; 35, the tendinous part.
36. 37. Rhomboides major; 36, the fleshy; 37, the tendinous part.
38—42. Serratus politicus inferior; 38, the tendinous origin; 39—42, attachments to the four last ribs.
43. Left obliquus internus abdominis.
44. Serratus magnus.
45. Sacrolumbalis.
46. Longissimus dorfi.
47. A portion of the longif. dorfi, transversalis cervicis, tracheo-mastoideus, and splenius colli, comes into view here.
48. Spinalis dorfi.
49—51. 9th, 10th, and 11th intercoftaies externi.
52. 11th intercoftaies internus.

B. In the Upper Extremities.
53. Supraspinatus.
54. Infraspinatus.
55. Teres minor.
56. Teres major.
57. Deltoides.
58. Biceps brachii.
59—61. Triceps cubiti.
62. Common tendon of the three heads of the triceps.
63. Anconeus.
64. Bra-
MUSCLE.

64. Brachialis internus.
65. Supinator longus.
66. 67. Extensor carpi radialis longior; 67, its tendon.
68, 69. Extensor carpi radialis brevis; 69, its tendon.
70. Extensor pruini internodi pollicis.
71. 72. Extensor secundi internodi pollicis.
73. 74. Extensor tertii internodi pollicis.
75. Extensor communis digitorum, with its tendons.
76. 77. Extensor carpi ulnaris, and its tendon.
78. 79. Flexor carpi ulnaris, and its tendon.
80. Palmaris longus.
81. Flexor digitorum sublimis.
82. ______________ profundus.
83, 84. Indicator, and its tendon.
85. Supinator brevis.
* Ligamentum carpi commune dorsale. The interossei are not marked with any numbers.

C. In the Lower Extremities.

86. Gluteus maximus.
87. 88. Gluteus medius, and its tendon.
89. Pyriformis.
90. Geminus superior.
91. ________ inferior.
92. Obturator internus.
93 ______________ externus.
94. Coccygeus.
95. Levator ani.
96. Sphincter ani externus.
97. Tranversus perinei.
98. Quadratus femoris.
99. Tensor vaginae femoris.
100. Vastus externus.
101—103. Biceps femoris; 101, long head; 103, short head; 102, tendon.
104. Semi-membranosus.
105. Semi-tendinosus.
106. Adductor magnus.
107. Gracilis.
108. Tendon of the factorius.
110. Inner head of the gastrocnemius.
111. Outer head of the gastrocnemius. In the left leg these are removed.
112. Tendo Achillis.
113. Soleus.
114, 115. Plantaris, and its tendon.
118, 119. ________ brevis, and its tendon.
120. Flexor longus pollicis.
121. Tendon of the tibialis pollicis.
122. Popliteus.
123. Adductor minimi digiti.
124. Flexor brevis digitorum.

Plates XIV. and XV. A back view of the more deeply-feated muscles: those of the first and second orders have been removed. The muscles of the third layer are represented on the right, and those of the fourth on the left side.

A. In the Head, Neck, and Trunk.

1—4. Biventer cervicis; 1, the first belly; 2, the middle tendon; 3, portion derived from the spinoen processes of the first dorsal vertebra; 4, the second belly attached by tendon to the occiput.
5. Complexus.
6. Tracheo-mastoideus.

7. Transversus cervicis.
8. Cervicalis descendens.
10. ________ pollicus.
11. Common origin of the sacroluminals and longissimii dorfi.
12. Division of the common origin.
13—15. Sacroluminals; 14, tendon inserted into the 11th rib; 15, tendon inserted into the 12th rib. The intermediate tendons are not numbered.
16. Longissimus dorfi.
17. Semispinales dorfi.
18. Quadratus dorfi.
19. Semispinales cervicis.
20. Intertransversarii cervicis. Two only are numbered; the others are easily distinguished.
21. Tranversus abdominis.
22. Common tendon of the obliquus internus abdominis and serratus pollicis inferior cut through.
23. Rectus capitis posterior major.
24. ______________ major.
25. Obliquus capitis superior.
26. ______________ inferior.
27. Left multidiis spine. Its upper part is covered by the semiispinales cervicis.
28. Intertransversarii lumborum; of which two only are numbered.
29. Levatores collaris breves.
30. ______________ longi.
31. Interossei externi.
32. ______________ interni. Those of the left side only are numbered.
33. Quadratus lumbarum.

B. In the Upper Extremities.

34. Subscapularis.
35. Teres major.
36. Biceps brachii.
37. Inner head of the triceps.
38. Outer head of the same cut through.
39. Remaining portion of the long head.
40. Common tendon of the three heads.
41. Brachialis internus.
42, 43. Extensor carpi radialis longior, and its tendon.
44, 45. ______________ brevior, and its tendon.
46. Sapiator brevis.
47. Flexor longus pollicis.
48. Pronator quadratus.
49. Flexor digitorum profundus.
50. Pronator teres.
51. Tendons of the extensor communis cut off.
52. Tendon of the abductor minimi digitii cut off.
53. Adductor offis metacarpis digitii minimi.
54. Flexor brevis pollicis.
55. Adductor pollicis.
56. ________ externi.
57. ________ interni.
58. Common tendons formed by the junction of those of the extensor communis, interossei, and lumbricales.

C. In the Lower Extremities.

57. Iliacus internus.
58. Pioas magnus.
59. Common tendon of the two preceding muscles.
60. Gluteus minimus.
63, 64. ________ externus, and its tendon.
MUSCLE.

65, 66. Semimembranosus, and its tendon.
67, 68. Gracilis, and its tendon.
69. Adductor magnus femoris. The tendon is marked with an * on the left side.
70—72. Biceps femoris; 70, the short head; 71, the
tendon; 72, cut edge of the long head.
73, 74. Divided heads of the gastrocnemii.
75. Plantaris cut off.
76, 77. Popliteus, and its tendon.
78, 79. Tibialis posterior, and its tendon.
80, 81. Flexor longus digitorum, and its tendon.
82, 83. —— pollicis, and its tendon.
84, 85. Peroneus longus, and its tendon.
86, 87. —— brevis, and its tendon.
88. Extensor brevis digitorum.
89. Flexor accessorius.

Plate XVI. Lateral view of the muscles.

A. In the Head, Neck, and Trunk.

1, 2. Occipital portion of the epicranius; 1, the tendinos
in origin; 2, the fleshy part.
3. Frontal portion.
4. The aponeurosis.
5. The middle thin part of the aponeurosis.
6. Part of the temporal fascia.
7. 8. Anteiors auricula; 7, the tendinous origin; 8, the
fleshy portion.
9. Retractores auricul. three in number.
10. Anterior auricular
11, 12. Orbicularis palpebrarum.
13. C. prefor nasi.
15. Zygomaticus major.
17. Buccinator.
18, 19. Malleolar; 18, the anterior; 19, the posterior
portion.
20. Pterygoideus internus. Between 20 and 24 the
hyo- and ifylo-glossus are partially seen.
21—23. Platysma myoides; 21, the lower part arising
from the chest; 22, accessory falciculi from the side of
the neck; 23, fissions of Santorini.
24, 25. Stermo-cleido-mastoideus; 24, the fleshy; 25, the
tendinous part.
27. Splenius capitis.
28. —— colli.
29. Scalenus medius.
30. Levator scapulae.
31—33. Trapezius; 31, the fleshy part; 32, tendinous at
tachment to the occiput; 33, to the spine of the scapula
and acromion.
34—36. Levatissimus dorsi; 35, tendinous attachment to the
deltoid; 36, 37, 38, attachment to the ribs.
39, 40. Pectoralis major; 40, its attachment to the aponeurosis of the obliquus externus abdominis.
41. Pectoralis minor.
42—48. Serratus magnus; 42, the origin from the 3d rib;
43—48, origin from the 4th to the 9th ribs.
49—51. Obliquus externus abdominis; 49, the fleshy por
tion; 50—52, the aponeurosis; 50, pr. portion of the
obliquus internus; 51, of the rectus; 52, tendinous in
terconnections of the rectus; 53, prominence of the pyra
midal

B. In the Upper Extremities.

56. Infraspinatus.
57. Teres minor.
58. —— major.
59. Deltoides.
60. Acromion.
63. Brachialis internus.
64—66. Triceps; 64, the long head; 65, the outer; * the
inner head; 66, the common tendon.
67. Olecranon.
68, 69. Supinator longus and its tendon.
70. Pronator teres.
71. Flexor carpi radialis.
72. Flexor sublimis.
73, 74. Flexor carpi ulnaris.
75. 76. —— brevis, and its tendon.
77—79. Extensor communis digitorum, with the extensor
proprius auricularis; 77, the extensor communis; 78,
extensor proprius; 79, their tendons.
80. Extensor carpi ulnaris.
81. Flexor carpi ulnaris.
82, 83. Extensor primi internodi pollicis; 83, its divided
tendon.
84, 85. Extensor secundii internodi, and its tendon.
86. Tendon of the extensor tertii internodi.
87. Common ligament of the back of the wrist.
88. Abductor pollicis.
89. Opponens pollicis.
90. Adductor pollicis.
91. Abductor indicis.
92. Prior interosseus indicis.
93—97. The thumb and fngers.

C. In the Lower Extremities.

98. Pectineus.
99. Adductor longus.
100—101. Sartorius and its tendons: 100, * fartorius of the
right thigh.
102. Tensor vaginae femoris, with its tendon cut from the
fascia.
103. Gluteus medius.
108—110. Biceps; 108, the long head; 109, the short
head; 110, tendinous insertion in the fmbula.
111, 112. Vastus externus, and its tendon.
113, 114. Rectus femoris, and its tendon.
115. Ligamentum patell. 
116, 117. Vastus internus, and its tendon. c, tendon of
the right vastus internus.
118. Tendon of the gracilis.
119. —— semimembranosus.
120. Outer head of the gastrocnemius.
121. Inner head of the gastrocnemius.
122. Soleus.
123. Tendo Achillis.
124. Tendon of the plantaris.
125, 126. Peroneus longus, and its tendon.
127. Peroneus brevis, and its tendon.
128—132. Extensor longus digitorum pedis; 120—132, its
tendons proceeding to the four smaller toes; the tendons
of the extensor brevis appear between them.
MUSCLE.

133. 144. Peroneus tertius, and its tendons.

135. Tendon of the extensor longus pollicis.

136. 137. Tibialis anticus, and its tendon.

138. 139. Abductor digiti minimi, and its tendon.

140. Tendon of the flexor brevis digiti minimi.

141. Anular ligament of the ankle.

142. 143. Flexor longus pollicis; 143, its tendon contained in a peculiar sheath.

144. 145. Flexor longus digitorum, and its tendon.

146. Tendon of the tibialis pollicis.

147. Ligamentum laciniatum malleoli interno.

148. Abductor pollicis.

149. Flexor brevis pollicis.

150. — — — — digitorum.

Phenomena of the Action of the Animal Muscular System. — We have spoken hitherto of the power of motion belonging to the muscles abstrackedly from the phenomena, which it presents when in exercise. The latter will engage our attention at present. They are referrible to contraction, as that is the essensially active state of a muscle, relaxation being merely a passive condition of the organ.

Contraction is by no means an uniform phenomenon. When a muscle is divided, or its antagonis is paralyzed, it takes place slowly and insensibly; the power which precedes over this we have called the contracility of tissue. The action of an irritatory body in the muscles of an animal recently killed, causes a quivering of the flesh, an oscillation affecting the fibres throughout, but not producing an any sensible effect on the whole mass, not bring the together its attachments. The fibres are drawn from the ends towards the centre, and then rephored; and these motions are repeated with great rapidity; the muscle is thrown into a tremulous state. This kind of motion is exemplified in the shaking caused by cold, by fear, on the accses of intermitent fevers, &c. The operation of the will, or irritation of a nerve, caues a sudden contraction of the whole muscle. A permanent state of contraction is called spasm; quickly repeated contractions are called convulsions.

When a muscle contracts, all its fibres are rendered shorter, and, consequently, the length of the whole organ is diminished: hence the points, to which its extremities are connected, are drawn towards each other, and move respetively, more or less, according to their relative firmness. The surface of the fibres is also observed to be wrinkled, or folded transversely. As its fibres are drawn from the extremities towards the middle, it becomes thicker, and appears to swell. Hence the presence of the superficial muscles, when the body is in a state of excetion. The statuary and the painter know that the character of the surface is very different in a man at rest, and one in any violent action; they are aware that the muscles, employed in any particular motion, swell and caufe prominences, which must be carefully displayed in their representations; to express these faithfully is one of the great difficulties of their art. The swelling is accompanied with a hard and rigid state of the muscle, which is more clearly characterized, in proportion as the exertion is greater. If we place the hand on the maffeter, and shut the mouth, these phenomena are immediately rendered apparent.

As the muscle is shortened and swells in its middle, do these two changes compenfate each other, so that the bulk remains the same? or is it rendered on the whole larger or smaller? All these opinions have been maintained. Borelli placed a man in equilibrio on a piece of wood, and then made him contract the muscles of the lower limbs; the balance was not destroyed, and he concluded that the muscles gained nothing in their contraction. The arm has been im-
continues long, although the stimulus be kept up. The same phenomena are produced whether galvanism, mechanical, or chemical agents are employed. The contraction or convolution is more forcible and rapid at first; it gradually languishes, and so on the muscle remains at rest. When, on the contrary, contraction is produced by the will, it can be maintained for a considerable time. The support of burdens, the act of standing, and the maintaining a limb in any attitude, &c. &c. prove this fact. Tetanus affords us a terrible example of the permanence of contraction under morbid irritation. This continued exertion, however, fatigue the muscle much more than alternate contraction and relaxation; hence, when we are standing a long time, we throw the weight of the body alternately on the two limbs, so as to rest the muscles of each successively. The law of intermission, to which the animal muscular system is particularly subject, prevents the muscles from continuing in a contracted state beyond a certain time: the sense of fatigue admonishes us of the necessity of relaxation, and very quickly becomes so urgent that it cannot be neglected; it soon rises to intolerable pain, which forces us to intermit the exertion. A person may soon convince himself of this by holding a weight in the hand with the arm and fore-arm horizontally extended; after a short time tremulous motions occur in the muscles, and the limb finks in spite of the most resolute exertion of the will.

Various circumstances influence the velocity of the contraction. When stimuli are directly applied to an exposed muscle, the contractions depend on the state of vitality of the muscle, and on the nature of the stimulus. They are performed, and succeed each other so quickly at the beginning of the experiment, that the eye can hardly follow them; they gradually become weaker, but may be excited by a more powerful stimulus, which also soon looses its effect. Irritation of the nerves produces a more rapid contraction than that of the muscle itself; and the velocity is very considerable when an active animal, and an active muscle, as galvanism, are both employed. The velocity or force of the contraction are not greater when all the nerves of a muscle are irritated, than when only one is acted on. The velocity of muscular contraction produced in obedience to the will is very variable, and is regulated by volition. There are great differences between individuals in this respect, and these differences are foreign to the general strength of the muscular system. We shall gain a general notion of the powers of muscles by reflecting on the motions of the racer, the greyhound, or a prattled runner; of the fingers in playing on musical instruments, as the violin, flute, piano-forte, in writing, &c.; of the lower limbs, in jumping, kicking, &c. The possible rapidity of muscular contraction depends much on exercise. What can be more awkward than the first attempts at writing, drawing, playing on a musical instrument, or performing any of the mechanical processes in the arts? and what can be a greater contrast to these efforts than the celebrity and precision which practice never fails to confer in any of these departments? In running, jumping, or any other motions of the body, one man can perform with ease, what another, with equal original powers, cannot possibly effect, merely because he has never made the attempt. In all such exertions there is a point beyond which we cannot go; and we soon arrive at this point.

By considering the motions employed in transporting the body in the examples of the fleetest horses, Haller concludes that the elevation of the leg must have been performed in $\frac{1}{4}$ of a second. He calculates that the rectus femoris is shortened three inches in $\frac{1}{4}$ of a second in the most rapid motions of a man. He says that the quickest motions are executed by the muscles concerned in articulation; in an experiment he pronounced 1500 letters in a minute. The relaxation of a muscle occupies as much time as its contraction; therefore the contraction of a muscle in pronouncing a letter must be executed in $\frac{1}{15}$ of a minute, and in much less time in some letters, which require repeated contractions of the same muscle. The time occuring in the pronunciation of this letter are ten, the hyphoglossi must contract in $\frac{1}{15}$ of a minute, or in $\frac{1}{3}$ of a third. According to some accounts of distances, which pigeons have performed, an agitation of the wing must have been executed in $\frac{1}{15}$ of a third, or within $\frac{1}{5}$ fourths. Element. Physiol. tom. iv. p. 483.

There is a great difference in the force of contraction of the animal muscles, according as it is excited by irritation or by the influence of the brain. By stimulating an exposed muscle we produce a rapid and abrupt, but, in general, feeble contraction, which is always far behind that energy which is communicated through the brain. The organic muscular system is principally set in motion by the immediate application of stimuli, and never exhibits exacerbations of power corresponding to those which the animal contracility presents under certain circumstances. We have already seen that the latter property may be brought into action by irritating the brain in experiments, or by its excitation through the will or by sympathy. In the first case the action is never very energetic, whether we irritate the brain or the nerves: a rapid convulsive motion is produced, analogous to that caused by exciting the muscles themselves. Galvanism is the most powerful means of exciting such contractions; the effect of which is best appropriated by irritating a single nerve; for, when the brain or spinal marrow is acted on, the whole system is thrown into convulsions, and the contractions of the antagonist muscles destroy each other.

Two causes, namely, the state of the muscles and of the brain, influence the force of muscular contraction during life. If the energy of the brain be equal, a strongly marked muscle, of which the outline can be traced through the skin, because its fibres are well nourished and strong, will contract much more powerfully than a thin and flat one, with soft and pale fibres. In statues, which represent strength, the muscular forms are always energetically developed. The influence of the brain has again a great effect in augmenting the energy of muscular contraction. In general, the will determines the degree of power developed in the voluntary motions, and adapts it exactly to the effect which we design to produce: if we simply elevate the arm, or raise by its elevation one pound or a hundred pounds, the force of the contraction is precisely adequate to the object. Various causes will give to the will of one individual a greater energy and steadiness than to that of another, and therefore enable him, with equal muscular powers, to produce much more considerable effects. Many excitations, which are foreign to the will, very greatly exalt the power of the brain, as we see in maniacs, in men transported by rage, in the delirium of some fevers, &c. The fleshy muscles of a woman in such states often surpasse in energy those of a powerful man in his ordinary condition.

Calculations of the force of muscles cannot arrive at much accuracy, because the data, on which they are founded, cannot be precisely ascertained. The vital forces vary infinitely: they are not the same in two individuals: the influence of the brain and the strength of the muscular organisation are constantly varying in their relative proportions in the same subject. VITAL PHENOMENA ELUDE CALCULATION, and present, like the forces from which they are deduced.
duced, a character of irregularity, which distinguishes them essentially from physical phenomena. We may, however, conclude, that a muscular effort, carried to its highest degree by excitation of the brain, is capable of producing atomizing effects; such are the rupture of strong tendons, of the patella, &c. and the reflexion often opposed to the violent extinctions employed for the reduction of dislocations.

We should also remark here the surprising correctness with which the contraction of the muscle is adapted to the extent of motion which we wish to produce in a bone. "Let us suppose," says Dr. Barclay, "the circumstance, in which a bone can be moved, to be twenty-four inches, that each of the inches is equally divided into twelve parts, and that the bone may be arched at each of the divisions, which we know to be possible; with what accuracy must the muscles contract towards the centres in order to regulate their extent of motion, with so much preciseness, towards the circumference! In producing the several muscular notes, by changes in the small aperture of the glottis, or in balancing the body on the tight or slack ropes, we know that the muscles must contract with such minuteness and accuracy, as frequently to regulate their extent of decoration by smaller measurements than the two hundred thousandth part of an inch." The Muscular Motions of the Human Body, p. 290.

Thus it appears that the power of muscular contraction is in a compound ratio of the strength of organization in the muscles, and of the excitation which they receive from the brain. When both these are small, the motions are feeble; when both are elevated to their highest pitch, we can hardly fix a limit to the effects which they may produce. If energetic nervous influence be combined with a weak muscular tissue, or vice versa, the phenomena of contraction hold a middle place; and this is the kind of arrangement which we generally observe in nature. Women and children, who have weak muscles, have a nervous facility easily excited; men, on the contrary, particularly athletic ones, have nerves less readily moved.

We cannot alscertain, with any degree of accuracy, the power of a given bulk of muscular fibres, as muscles do not act separately, and the mechanical disadvantages, under which they are placed in the living body, take off a great deal of their effect. Yet if we consider, that power is very great. The extensors of the knee and ankle break respectively the patella and tendo Achillis by their contraction. When a person, with a burthen on his back, stands on tip-toe on one foot, the whole weight of the body and of the burthen is sustained by the extensors of the foot. In jumping, these muscles project the body, either in length or breadth, with vast power. Three hundred pounds have been elevated by the muscles of the lower jaw; and Thomas Topham lifted in this way a table of six feet in length, with fifty pounds attached to its farther end. Haller informs us, that a man was drawn up six hundred feet, suspended by one finger. This author has collected in his Elementa Physiologicum, lib. xi. feot. 2, § 25, a great number of instances of muscular exertion, to which the reader is referred.

The preceding examples, however, will give us but an imperfect notion of the power polled by muscles. We have stated the facts as if the whole force of the muscle were effectually employed in elevating the weight, as in a balance the whole weight of one scale acts in raising the other. But the cafe is quite different in the human body, where we always have a great expanse of force for the production of a trifling effect. There are numerous causes tending to diminish the operation of these forces. In the first place, almost all the muscles are fixed to the bones near to the centre of motion; while the weight, which they have to move, is applied usually at the extremity of the lever. If we regard the bones as levers, the joints as the fulcra, and the muscles as the moving powers, it will follow, from the well known laws concerning this subject, that the nearer the muscle is inflected to the fulcrum, the less effect will it have in moving the part. Suppose we support a weight on the elbow by the action of the deltoid muscle; the fulcrum is here in the shoulder joint, and the inflection of the muscle is much nearer to that part than to the end of the bone on which the weight rests; let us state this proportion as one to three. Now if we raise 55 pounds in this way, and add five pounds for the weight of the limb, which, in order to simplify the matter, we conceive to operate entirely at the end of the bone, the power which the deltoid must exert in order to produce the effect, is not equal to 60 lbs., but to 60 x 3 = 180 lbs. A great number of the muscles have inflections much less favourable, much nearer to the lever than this. The biceps and brachialis internus, for example, are fixed to the fore-arm, at least eight or nine times nearer to the elbow than to the extremity of the lever at the wrist.

Secondly, muscles are fixed to the bones at unfavourable angles: if they were inflected at right angles, their whole force would be effectually applied in moving the joint, as a weight placed in a scale depresses the arm of the balance. If the muscle were parallel to the bone, the resistance would be infinite, and no effect could be produced. There are very few muscles of the former, and none of the latter kind in the animal body: almost all join the bones at angles much smaller than right angles. The deltoid is implanted in the humerus at an angle of about 10°. A power acting obliquely is to one acting perpendicularly as the sine of the angle of inclination is to the whole sine. In the present example, this proportion is as 7,735,482 to 10,000,000. Wherefore, if the muscle in the former case exerted a power equal to the elevation of 180 lbs., in elevating 55 lbs. it will, in the present view, exert a force equal to 105 lbs.

Again, the direction of the fibres, with respect to the tendon, has an important influence on the power of the muscle. The fleshy fibres have the same direction with those of the tendon, only in a few infinities; and they lose more of their power in proportion as the angle, at which they are fixed to the tendon, is greater. If we had a right angle, they would have very little effect. The force exerted is to the effective force (of the force which acts in moving the limb) as the whole sine is to the sine of the angle at which the fibres join the tendon. If the angle be of 30°, these proportions are as 100 to 87; if of 45°, as 100 to 70; if 60°, as 100 to 89, &c. The largest angle formed by the outer fibres of the deltoid is about equal to 30°; the smallest by the inner fibres about 8°. If this be taken into the account, with the two preceding circumstances, the force exerted by the deltoid in the elevation of 55 lbs. would lift 128 lbs., if no causes diminished its efficacy.

It is contended further, that the force of the muscle, as estimated in the preceding calculations, must be doubled, because it will have to exert as much force in refiting the bone, which affords a fixed point at one end, as in elevating the weight at its other extremity: the force of the deltoid, in raising the 55 lbs., must therefore be carried up to 256 lbs. This is stated by Borelli, and admitted and explained at length by Haller. See Element. Physiol. lib. xi. feot. 2, § 30.

Muscles, which go over two or more joints, cannot act upon the bone, in which they are inflected, without moving the
the intermediate articulations. These motions are resented by the antagonist muscles, yet they confine a certain portion of the force exerted in the contraction.

The advocates of final causes have prepared an answer to these objections, which a view of the foregoing circumstances in the muscular system might give rise to. "It may be inquired," says Haller, "why the all-wise Creator admitted in the animal frame a principle of structure, according to which so large a portion of the power produced is lost. The explanation is not difficult. All the contrivances of human skill end in this, that the moving power passes through a large space, while the resistance describes a small one. In the human body, on the contrary, the effect to be produced is that the resistance should describe a large, and the power a small arc of a circle. The foot in stepping, and the hand in seizing, move over a large space: in all cases, in short, the object is, that the weight should be carried over a large, while the power moves within a small extent. Hence the velocity is increased at the expense of the power; and the loss of the latter was not regarded by the Creator, in the construction of the frame, because it was rendered sufficient to the fulfillment of a more important object.

"The origins of the muscles must necessarily be derived from the trunk and adjoining parts; and they must be intersected, if the parts are to be moved, beyond the last articulation. Thus, as the wants of man required a limb composed of several moveable pieces, it necessarily followed that muscles must pass over some joints.

"The limbs are round, and of a conical figure, that they may be lighter towards their extremities. The joints could not therefore be made thick enough to elevate the muscles far from the centre of motion; and that part of the force, which is lost from the smallness of the perpendicular line drawn from the centre of motion to the direction of the muscle, was necessarily sacrificed.

"Again, as the muscles are carried over a limb constantly decreasing in size and weight, as it is necessary to unite many fibres in a small tendon, and to bring them together from different parts, so as to bear on one point, the radiated and penniform arrangements are necessary, although attended with loss of power." *Elem. Phyiol. lib. ii. sect. 2.*

There are, on the other hand, many circumstances which augment the mechanical power of the muscles, when it can be accomplished conveniently with the views just alluded to. The angles formed by the muscles at their insertions are generally increased in consequence of the articular ends of the bones being made thick; this increases the distance between the course of the tendon and the centre of motion. The projecting processes for muscular attachments; such as the trochanters, the protuberance of the os calcis, &c. and the bones placed in the course of tendons, as the patella and femur bones, have a similar but more powerful effect. The smoothness of the cartilaginous surfaces of the joints, and the unctuous fluid lubricating them, by diminishing the effect of friction, augments the power. The different contrivances of the pulley kind act only in changing the direction of the force without augmenting its amount.

The motions produced by the muscles are either simple or compound. We shall consider the former, as it occurs in straight muscles, in those which are reflected in their course, and in circular ones. In the first case, where the muscle has an elongated form, and is terminated by a tendon, each fibre by its contraction draws the tendon in its own direction; the whole will therefore bring it towards the centre of the muscle. The whole effect of the contraction, in a long muscle, is concentred in a single point, that is on the tendon. In most of the broad muscles, on the contrary, as the attachments at both ends are generally made to different points, all the fibres do not concur in one effect. The various parts of the same muscle may have different, and even opposite uses; and they are capable of contracting separately. The simplest method of determining the effect, which a straight muscle is capable of producing on the bones to which it is fixed, is, to examine the direction of the muscle from its fixed to its moveable part, and to take the inverse of that direction: the latter is always the direction of the motion. Where two bones are alternately moveable and fixed, they are moved in opposite directions. When the whole of a broad muscle is brought to bear on a single point, as in the deltoid, the middle line of direction of all the fibres must be taken for the purpose of establishing the action. Where a muscle is reflected, as the trochlearis, the peronei, &c. its action is in the line drawn from the point of reflexion to the infection; as a force acting upon a rope which passes over a pulley, acts in a straight line from the pulley to the weight. The circular muscles surrounding the mouth, eye, &c. have no fixed or moveable points: they contract the apertures, which they surround.

The influences are very few, in which muscular motion is of the simple kind just described, or confined to a single muscle. The muscles belonging to the same part combine their actions very variously. The four straight muscles of the eye correspond nearly to the four cardinal points of a sphere: where any two neighbouring ones are contracted together, the part is moved in a diagonal, of which the sides are the lines of direction of the two muscles contracted. According as the one or the other muscle is exerted most powerfully, the eye may be moved in any line between those of the two muscles. A similar combination occurs in all the joints, where motion is admitted in various directions. When it has a radiated form, a single muscle may execute oblique motions, the lateral fibres on one side of the middle line acting more strongly than the opposite ones: the deltoid is an example; it can elevate the arm towards the front or the back of the trunk.

Again, when a part moveable in various directions is arrived towards any point, it must be rendered steady, and prevented from deviating materially by the muscles on each side; and the extent of its motion must be limited by the antagonist muscle. Thus the head, neck, and vertebral column, may be moved forwards, backwards, to the right and left. Suppose that they are bent forwards; there must be muscles, not only to move them in that direction, but also to prevent inclination to the right or left, and to limit the motion forwards. Thus the different powers employed on this occasion may be classed under the heads of direct movers, directors, and moderators.

When we consider the effects, which may be produced by variously combining the actions of the muscles, and further, that the force, extent, duration, and order of succession of the contractions may be almost infinitely varied by the will, we shall be able to account most satisfactorily for the number of motions produced. If there are ten muscles, and each had only two degrees of contraction, the different effects produced by their combinations would be not less than $1,024$.

Another source of the combinations of muscular motions is in the necessity of rendering one of the attachments fixed. Excepting those, which go from a bone to some soft part, as the eye, tongue, or pharynx, the muscles seldom have one extremity perfectly immovable: and, in most cases, one end is firmer, the other looser; the former being towards the trunk, the latter towards the extremities. Even very distant muscles may
may be concerned in fixing the attachments of muscles, so that these powers are connected over almost the whole body, and may assist or impede each other's actions. If the deltoid acted alone, it would draw down the scapula and clavicle, as well as elevate the humerus; if, therefore, we wish to produce the latter effect, the former bones must be fixed by the levator scapulae, rhomboidi, trapessii, &c. But these muscles come from various vertebrae of the neck, which are themselves moveable; if these vertebrae were drawn downwards by the muscles just enumerated, the deltoid would still not have a fixed point to act from. The neck must therefore be fixed by its extensors; by the multifidi, faciolumbales, logisissimi, cervicales descendentes, and all the numerous muscles lying on the back of the spine. By the combined action of so many muscles, the deltoid will at last be enabled to produce its full effect, and to exert its whole force in elevating the humerus. Let us suppose a person lying on the ground, and endeavouring to raise himself by seizing any object above him. The hand, being retained by its flexors, is rendered as firm as the object which it holds. The deltoid will now elevate the scapula and clavicle; we confine our view to this muscle, to make the statement more short; for all the muscles passing between the humerus and the scapula and trunk will concur with it. The deltoid, then, elevates the scapula and clavicle, and through them the trunk of the body; all the muscles between the hand and the humerus are employed in fixing the latter for the action of the deltoid. If a person in the recumbent posture endeavour to bend the head forwards, the recti abdominis are immediately rendered tense: they are exerted for the purpose of fixing the sternum, and affording a firm point for the action of the sternocleido-mastoidei. If the trunk be bent forwards, the latter muscles fix the sternum for the action of the recti. These instances are sufficient to exemplify the mode in which the muscular motions are combined; the same principle extends throughout the whole body. The combinations are still more numerous and complicated in cases where the whole body is moved.

"As all the motions that vary the position of the head, neck, trunk and extremities, must likewise vary the centre of gravity, a number of muscles must be thrown into action, merely on purpose to preserve the equilibrium, if a person be sitting, or standing, or moving from one place to another: these muscles, if a name were necessary, might be called librators. In general, we are not conscious of their action, unless when a state of morbid sensibility happens to shew a connection between them and the muscles employed in changing the positions; or unless, when happening to perform a motion which we did not intend, we fall to the ground; or all on a sudden change the librators with a violent jerk of the whole body. It is from the general and prompt co-operation of the different muscles in harmonizing the flexions and extinctions, the fixations and librations throughout the several parts of the body, that the yielding yet steady flexibility of the joints, from the orbicular apposition of their surfaces, from the angles, the curves, and the varied directions of the bones united by articulation, and from the elastic substances interposed, that the body is enabled to resist so successfully the violent concussions to which it is exposed in running, leaping, hopping suddenly, or falling from a height. By these contrivances, under the direction of the vital principle, concentrated forces are so admirably and suddenly dispensed and diffused throughout every part, that even the functions of the most delicate are, in ordinary cases, seldom impeded. To these, therefore, more than to the strength of the bones and muscles, are we frequently indebted, in cases of concussion, for the safety of the viscera contained in the cranium, thorax and abdomen; for the safety of the blood-vessels, nerves and aborberts; and even for the safety of the bones and muscles. This must be obvious, from the violent shocks to which men are exposed, from the want of libration, when they are intoxicated; from the violent jerks we often receive in attempting suddenly to recover our balance; from the distortions of the joints and the bones in cases of rheumatism; from the great number of luxations and fractures arising from unequal action in the muscles, when not prepared to meet with the accident; and also from the practice of bending iron bars over the forearm when the muscles are every way prepared for the resistance."—Barclay on the Muscular Motions, p. 301.

The effect produced by the action of each particular muscle is considered in its description; we shall point out here the mode, in which the individual muscles cooperate, in some cases where a great number of them are employed, as in standing, walking, &c. The mechanism of these attitudes and motions, so far as the bones and joints are concerned, is explained in the article Extremities: our principal object at present is to point out the part which the muscles perform.

Standing is that condition of the body, in which an animal is supported by his legs extended and fixed. If a man in the erect posture suddenly dies, or differentiates from any cause those efforts which are necessary to maintain the erect attitude, the joints of the lower limbs would yield to the weight of the body, bend, and allow the trunk to come to the ground. Standing, therefore, is produced by the continued action of the extensor muscles of all the joints; and, for this reason, it is so much more fatiguing than walking, in which the muscles are alternately contracted and relaxed. If the trunk were held immovable in this attitude, the muscular exertion necessary for its continuance could be supported only for a very short time, as any person may convince himself by standing perfectly erect and motionless.

Generally, however, there is a series of oscillations, of very small alternate flexions and extensions, to which the numerous and easily moving joints of the body are excellently adapted, and by which the fatigue of a constant extension is avoided: we accomplish the same object, too, by throwing the weight of the trunk alternately on the opposite legs.

To bow on an animal the power of maintaining his body in a vertical position, all its parts should be so disposed, as to be easily held in a state of equilibrium; the muscles should have the power of correcting continually the movements of aberration; the line of gravity of the whole body should fall within the place covered by the feet, and lastly, the feet themselves should be so constructed as to seize, in a manner, the inequalities of the ground, and fix themselves to it. Man is the only animal, in which all these conditions are united in the necessary degree. See Extremities.

In the attitude of standing, the sole of the foot is firmly prehended against the ground by all the muscles which bend the toes (flexor longus and brevis digitorum pedis, and pedis pedis, lumbricales, interosseous, flexor brevis minimi digitii), and by those, which extend the foot (the gastrocnemius, soleus, plantaris, tibialis posterior, peroneus longus et brevis). The weight of the body would bend the leg on the foot; it is extended and maintained erect by the muscles of the calf. This motion in the direction backwards is limited by the flexors of the ankle (tibialis anticus, extensor digitorum et pollicis, peroneus tertius, which prevent the leg from being carried too far in that direction: on the sides
sides the leg is fixed by the tibialis, the peronei, and the opposite forces of the flexors of the great and the smaller toes, which correct any tendency to lateral deviations. These muscles, then, surrounding the leg in all directions, sustain it firmly on the foot, like so many cords passing from it to be fixed to the earth.

The powerful vasti and crurales extend the knee-joint, and preferve the femur in the same vertical line with the leg, preventing that flexion of the knee, which the inclination forwards of the thigh, and the position of the pelvis behind a straight line drawn from the knee, would tend to produce. These powers are balanced and limited by the flexors of the knee (the biceps, feminitenotinus, feminimembranofus, gracilis).

The pelvis is extended on the thighs by the glutei magni, moderated by the rectus cruris, psoas magnus et iliacus internus.

The trunk, taken altogether, would fall forwards if left to itself; the pelvis may be carried freely forwards on the heads of the thigh bones, and the chief may be bent on the pelvis; but these parts cannot be moved in the opposite direction. The weight of the head, the ordinary position of the upper limbs in front of the body, and the prominence of the abdominal vices, give to the trunk this inclination forwards. The glutei magni, the sacrolumbales, the longissimi dorsis, and all the extensors of the spine, correct this tendency. The psoas and iliacus, the rectus cruris, and the rectus abdominis in some degree, are the moderators of this extension.

The vertebral column gives the point of support for the head; which, as it is produced considerableness in front of its articulation with the atlas, and consequently always falls spontaneously forwards in a person dressing asleep, requires, for supporting it in equilibrium, numerous extensor muscles, as the recti pollici, obliqui superiores, trachelo-mastoidei, complexi, splenii capitis, trapzezi. These are balanced by few and weak muscles in front;—the recti antici and longi coli. Several muscles on the lateral aspects prevent either the head or neck from deviating towards the side.

We have not enumerated all the powers exerted in standing; since they are so numerous, and must be constantly contracted to maintain the body erect, we shall no longer wonder at the fatigue produced by that attitude, and the necessity for retiling the muscles alternately by varying the bearing on the lower limbs.

Walking.—All the motions, in which the body is transported from one place to another, require that an impulse should be made, in a certain direction, on its centre of gravity. To this end, a number of articulations more or less bent are extended; these are so placed, that their extension is free in the direction of the centre of gravity, and confined in the opposite one; so that the movement produced takes place in the first of these directions. The body may be compared to a spring composed of two branches, one of which rests on an immovable support. If these branches, after being approached by an external force, are set at liberty, they separate until they again form the angle which they formed before the compression; but, as the supported branch cannot force the obstacle, the motion takes place altogether in the opposite direction, and the centre of gravity of the spring is moved away from the obstacle with more or less velocity. In the progressive motions of the body the flexor muscles are the force which compresses the spring; the extensors are the elasticity which tends to separate its branches; and the resistance of the ground is the obstacle. In walking, the centre of gravity is alternately moved by one limb, and supported by the other, without the body being ever entirely detached from the ground; by the latter circumstance it is distinguished from leaping.

Suppose the person to be standing, and to leap forwards with the left foot, the ankle and hip of that limb are bent by their respective flexors; the sole of the foot is detached from the ground by the muscles of the calf and the other extensors. The hip is then bent to a more acute angle, the extensors of the knee adventuring the leg to a straight line with the thigh, and thus suspend the foot over the part on which it is to rest: they then are relaxed, and allow the foot to come to the ground. The body is now supported on both limbs; the left thigh is inclined forwards, the right backwards, on the pelvis; the former leg forms an obtuse, and the latter an acute angle with the foot. The extensors of the right foot now act; the end of this member cannot move the ground; the heel, the leg, and the thigh are consequently elevated, and the impulse thus given to the pelvis moves forward the trunk of the body, which describes a small circle round the fixed point afforded to it by the left leg. That leg is now carried forwards on the foot by the flexors of the ankle, the femur is advanced by the extensors of the knee, and the trunk by the flexors of the hip. The right leg, having given this impulse to the trunk, is advanced by the flexors of the hip, and extensors of the knee, in front of the other, and brought to the ground; when the extension of the left foot in its turn propels the trunk on the right limb. The motion of the body is assisted, by inclining the trunk forwards over the advanced limb; this is effected by a relaxation of the extensors, and the contraction of the flexors of the hip, the rectus and obliqui abdominis of the same side. This attitude of the trunk in progression, which we avoid as ungraceful, particularly facilitates the ascent of an inclined surface. In this case, the body must not only be thrown forwards at each step, but elevated against its own weight by the extensors of the advanced knee, and of the foot left behind: hence this mode of progression is very fatiguing.

In leaping, the whole body is elevated from the ground, and projected, as it were, into the air, where it remains without any support for a certain time, which is longer or shorter according to the force of projection. It is performed by a sudden extension of the lower limbs, which are previously bent to the greatest degree. The tibiae are carried forwards on the feet by the flexors of the ankle, so that the heels project in an acute angle; the knees are advanced, and the thighs inclined backwards; the pelvis and trunk are bent forwards on the thighs. By this bent state of the ankle, knee, and hip, the whole body is shortened; as much as possible. The leap is performed by a sudden extension of all these articulations, by the muscles of the calf, tibialis posterior, peronei, and flexors of the toes in the ankle, by the rectus, vasti, and crurales in the knee, by the gluteus magnus, biceps, feminitenotinus, feminitenotinus, gracilis in the hip. The impulse produced by this extension is communicated to the centre of gravity of the body, and urges it in a direction more or less opposed to its own weight: all the motion must take place in this direction, as the other end of the extremities rests on the immovable earth. The extent of the leap must depend on the proportionate length of the bones, and the power of the muscles. Its direction is influenced by the position of the centre of gravity in relation to the limb, from which the impulse is derived; consequently, the human subject can leap vertically, as its trunk is placed perpendicularly over the lower limbs; it can, moreover, throw the body forwards, by making
MUSCLE.

making the chief exertion in extending the thigh, or backwards, by employing chiefly the extension of the leg.

Running is a succession of low jumps performed alternately by each leg. It differs from walking in the circumstances of the body being projected at each step, and the hind foot being elevated before the advanced one is fixed. It is more rapid than the quickest walking, because the velocity is preferred and augmented at each step by the newly produced quantity; consequently, we cannot stop suddenly in running, as in walking. This velocity favours jumping forwards, as it adds to the force, which the jump itself produces in that direction; but it injures, or even entirely impedes, a vertical leap. The body and arms are inclined forwards, that the centre of gravity may be in the most favourable position for its propulsion by the hind leg; hence the latter must be quickly carried forwards to prevent falling. Even in walking, where the motions are performed slowly, and the trunk is nearly vertical, the centre of gravity is advanced at the time that the hind leg should be carried forwards, and a fall is produced by any obstacle which prevents the latter motion. In running, however, the smallest obstacle, which retards the advance of the foot in the flighted degree, brings the trunk instantly to the ground.

In climbing objects are seized by the extremities, which are thus rendered fixed points to which the trunk can be moved by means of the muscles, which pass between it and the limbs, as the pectorales, latissimus dorsii, &c. The existence of long and separate fingers, and of thumbs capable of being opposed to the fingers, favours the holding of any bodies, and consequently facilitates climbing. These conditions exist in a very favourable degree in the hands of man; but he is a bad climber because he has no prehensile power in the feet.

In swimming the body is moved forwards by a sudden extension of the previously bent limbs; but the motion imparted to the body is not equal to that produced in walking, &c. because the ends of the limbs, instead of resting on a solid surface, are opposed by the fluid, which is itself easily moved. The impulse, therefore, partly throws the water into motion, and partly propels the trunk. The lower limbs urge the body forwards, and the upper support the head and shoulders. The weight of the latter parts is so great in man, that more exertion of the arms is required in him than in any animal; and he is almost the only instance in which swimming cannot be performed naturally.

There are many other motions, the description of which would lead us into interlacing and intricate, but too long details: the preceding will serve as a specimen, and enable the reader to develop the powers employed on other occasions. We have only a few remarks to add on the subject.

The moving powers of the human frame are able to produce much more numerous and diversified effects than what are exhibited to our observation under ordinary circumstances. These dormant capabilities, when excited by necessity, altnonah and may instruct us. Persons born without hands are often able, with the flumps, by which their limbs are terminated, to execute the numerous offices, and even those requiring the greatest exactness and delicacy, which are ordinarily performed by the fingers. Others can do with their feet, what is commonly executed by the hands, such as writing, drawing, spinning, &c. &c. The feats of the rope-dance, the harlequin, the tumbler, and all the varied excursions derived from the lessons of that successful instructor Necessity (ingeni largior venter), do not flow from any properties peculiar to the individuals, but are the offspring of powers common to all, and are chiefly worthy of attention, as exhibiting to us what the body can perform. They shew us, in a very striking manner, the admirable mechanism by which the equilibrium of the body is maintained; by which so many separate pieces, with the greatest power and facility of relative motion, are constantly adjusted, amidst the most rapid changes, so as to maintain the necessary bearing by which the solidity of the whole is preserved.

In all the motions, whether gentle or violent, the actions of the muscles are so regulated, as to prevent any shock; we are unconscious of the exertion by which this is effected, but we are immediately rendered sensible of its importance by what happens when it is omitted. If our step is either shorter or longer than we had calculated upon, if we descend two steps of a stair instead of one, &c. we experience a jar in the whole frame which admonishes us of the wrong calculation.

The effect of education is very striking in this system, both in the force and duration, as well as in the kind of contraction. Practice will enable us to lift a much heavier weight, to bear a greater burthen, to project the body farther in leaping, or advance it more rapidly in running, than we could do on the first trials, and that to a very great extent. It is equally efficacious in enabling us to bear protracted exertion of any kind, as in running, walking, &c. Motions, to which the muscles have not been accustomed, are at first performed difficulty, merely from that cause; we can assign no other reason for the awkwardness of the first attempts at writing, drawing, playing on a musical instrument, or exercising the various mechanical processes of the arts; and in these cases nothing but very long practice will confer facility, although all the powers exist in the first instance.

Development of the Muscular System of the Animal Life.—In the first months of foetal existence, it is confounded, with the others, in a homogeneous mucus mass, in which we can hardly trace any line of demarcation. Muscles, aponerates, tendons, &c. have all the same appearance. The limits of these different systems are gradually established, and the muscular tissue is rendered evident at first by its assuming a deeper tint. The interior of the bones is redder than the muscles in the fetus, while the difference is just of the opposite kind in the adult. In connection with this circumstance we may remark the inactive state of the muscles before birth; although a few motions announce the presence of the fetus in the uterus in the latter months of pregnancy, these are inconsiderable in number and extent, when compared to what will take place afterwards. The bent state of the limbs and body, and the confined space in which they lie, particularly in the latter periods, when the waters of the amniotic are so much diminished, account for this want of motion.

The muscles of the chickens in the shell exhibit but slight marks of irritability, either under the action of the more common irritants, or of the galvanic influence. Bichat has ascertained the same irritability in experiments on guinea-pigs, both when he irritated the muscles directly, or through the medium of the nerves, spinal marrow, or brain: the nearer the animal is to the time of conception, the less effect is produced. During foetal existence also, the muscles lose their irritability very quickly after death: this property remains rather longer immediately before parturition, but its duration is still much less than after birth. In the adult, the nutrition, the bulk and redness of the muscles are in proportion to the motions which they execute; their light colour and slender size correspond very well to their inactivity in the fetus. Can the inactivity of the foetal muscles be at all connected with the black blood that circulates through them at this time?
MUSCLE.

The small size of the fetal muscles is as remarkable as their pale colour: the bulk of the limbs at this time depends chiefly on the subcutaneous stratum of fat. The cavities and processes of bones for muscular attachment are hardly visible.

Some have asserted that the flesh part is more developed in proportion than the tendinous; but this is not supported by observation. There is the same proportion between these parts as in the adult. The muscles, at the time of birth, undergo the same change as all other organs; red blood is sent to them instead of black. The brain too, which has been hitherto inactive, is excited, and acts on the organs of motion. All the muscles are exerted, and produce more or less marked agitations of the limbs and motions of the trunk and face, very soon after birth. The circulation of red blood does not, however, suddenly change the colour of these organs; they retain for some time after birth, the lividity which characterized them before, as their colour at all times depends, not on the blood which circulates in their vessels, but on that which is combined with their tissue. Their substance gradually acquires a red tint, and they grow more in proportion than the other parts; but this growth does not affect their thickness, they do not produce those prominences which are so remarkable in the adult.

Many facts prove to us that there is a considerable difference between the muscular development of young and old animals; although we do not know exactly what that difference is. The flesh of young animals produces a more gelatinous and insipid broth, and has hence been supposed to contain less fibrine. The cripitation on exposure to heat is less sensible, &c.

After the growth of the body in length is finished, it fills in thickness; and this circumstance is particularly observable in the muscles. To the slender figure and rounded outlines of the youth succeed the strong forms and muscular prominences of the man. These organs elevate the skin, and produce risings and depressions of the surface: they are now more strongly marked in the face of reft, than they were before in the greatest exertion of the body. The time at which the genital organs are developed, and the covering of hair is produced on some parts of the body, is that at which the muscles assume this prominence in the male; for no analogous phenomenon occurs in the female: there the outlines of the body preserve their roundness and softness. This increase in the muscles of the adult affects the muscular, and not the tendinous or aponeurotic part. The augmentation of thickness is attended with increased density. A sensible difference may be perceived by the hand, between a muscle of a child and of an adult in contraction; and the latter will support, in the dead subject, heavier weights than the former.

The red colour of the muscles begins to be less bright after the middle period of life. The tint is very variable in the adult. Slow difcises make it tawny or pale: in dropy, when long continued, this is clearly seen. In general, whatever gradually debilitates the vital powers, has the same effect. Acute difcises affect it but little; nor is it changed in fevers, however marked the proflration of strength may be, if they are quickly fatal. It is affected only by nutrition, the phenomena of which function take place very slowly.

In old age the muscles become hard and tough: they are not easily chewed. They contract slowly; the influence of the brain over them is diminished, and they are soon tired: yet they feel hooke and flaccid, when compared to those of the adult. There is a firmness in the latter, which makes them preferve their form, and gives them a refilience to the feel: this seems to arise from a cohesion of their particles connected with the vital influence, and retained for some time after death. The contractility of tissue is much less in the old than in the young man: in the latter the muscles are firm, and do not move under the skin; there is a flabbiness in the former, and a vacillation is observed in all the great motions.

The colour of the muscular substance, in the old subject, is often converted into a light yellow, so as to give it an appearance like fat: yet ebullition or combustion do not shew the existence of animal oil in such muscles. Those on the back of the spine undergo this change most frequently, which, however, only affects particular muscles, and never the whole system. A nearly analogous appearance is sometimes seen in walked limbs. In recent paralyzes, even to the date of three, four, or six months, there is very little change in the limbs, the colour and bulk of the muscles being preserved; but after a longer time, the absence of motion, and perhaps the want of nervous influence, affect nutrition; the muscles lose their colour, and are contracted in fize. But this change is not observed in all cases. Long continued external pressure will cause diminution and change of colour in muscles.

The state of the animal muscular system after death varies considerably. While the body retains its heat the muscles are soft, as in the state of relaxation during life, and allow the parts to be moved in any direction; they then become rigid, so as to fix the joints, and retain them firmly against any efforts at bending them. This rigidity does not take place invariably, and its absence has been noticed in particular kinds of death; for example, in persons or animals killed suddenly by electricity or lightning, or by a violent blow on the thorax, in malignant fevers, in animals hunted to death, in cases of a sudden and violent shock to the whole system, in apoplexy by deleterious gases, as the carbonic acid, and, according to Dr. Adams, (On Morbid Poisons, Prel. Remarks, p. 34.) in death by wounding the medulla spinals close to the brain. In these cases, too, the blood does not coagulate after death.

Where the muscles become stiff, they present this appearance in every variety of degree. Sometimes, if the subject be placed upright against a wall, the rigidity is so great that it retains its position, and a very great force is required to bend the thigh or leg. Some muscles may be stiff, while others continue soft. These which have become very rigid are easily torn by forcible flexions; while this rupture cannot be produced, where they remain relaxed, by any motion of the limbs.

The connection between different kinds of death, and their various appearances in the animal muscular system, and the circumstances which attend, produce, or modify the latter, afford an interesting subject of research. Hitherto we possess too few facts for any general conclusions.

Muscular tissue is never accidentally developed in organs, where it does not exist naturally, as the officous, cartilaginous, and even fibrous systems are. If it were produced, it must belong to the organic life, because cerebral nerves are necessary to the animal life.

The Muscular System of the organic Life.—This is not so generally distributed over the body as the preceding, and differs from it also remarkably in forming a much smaller share of the frame. It is concentrated in the chest, where the heart and esophagus belong to it; in the abdomen, where the alimentary canal is partly formed by it; and in the pelvis, where it composes part of the urinary bladder.

Whether the uterus possest any of this texture is rather a doubtful point. Thus it occupies the middle of the trunk,
is foreign to the limbs, and is removed from the action of external bodies; while the animal systen is placed superficially, forms almost the whole bulk of the limbs, and appears in the trunk as much designed to protect the other organs, as to execute the various motions of the animal. No part of the organic muscular systen is found in the head.

The muscules of the preceding systen have almost universally straight fibres; in this, on the contrary, they are curved, so as to form muscular cavities of various shapes. They are never attached to bones, and have no tendinous fibres: the white threads connected to the flabby columns of the ventricles of the heart differ from tendons in many respects. The organic is distinguished from the animal muscular systen by the circumstance of its fibres not arising from, nor terminating in, fibrous organs: those of the latter are always continuous either with tendons, aponuroles, or fibrous membranes; the organic come from cellular tissue, and end in that again, after finishing their course. Sometimes the fibres seem to encircle the organ completely; but generally they are interrupted, so as to be connected at the ends with a different tifue from themselves.

The forms of this systen can hardly be considered in a general manner: they depend entirely on that of the organs, in the formation of which it concurs. It is never collected into inflated fasciculi, as in the animal life; and, excepting the heart, does not form more than the third, fourth, or even still smaller share of a viscus. The arrangement is generally in thin flat membranous plates, constituting more or less broad flatra, and scarcely ever strongly marked fasciculi. The fibres are disposed side by side, and consequently not accumulated in any one spot: though the extent may be considerable, the volume is small. All the fibres of the stomach, intestines, and bladder, would not equal the bulk of the glutens magnus.

Organism. This is not so uniform as in the foregoing system: there the varieties affect the form, and not the texture of the organ; here, on the contrary, there are marked differences of texture.

The organic muscular fibres are in general much more slender than the animal, and not collected into such large fasciculi: red in the heart, and whitish in the gastric and urinary organs; the colour, however, varies very much. The direction is never uniform, as in the animal muscules; the fibres descantify in all ways, and the fasciculi intersect each other at every variety of angle, so as to constitute a true net-work of muscule. Hence arises their power of contracting the cavities to which they belong in every direction. They are always short: when, as in the case of the longitudinal fibres of the aëophagus and rectum, they extend through a long course, they are not continuous, but arise and terminate within short spaces, then arise and terminate again, always in the same fibre. They cannot be compared for length, in any instance, to those of the gracilis or fatumus.

We know their nature no more than we do that of the animal fibres; but they exhibit nearly the same phenomena, on the application of the different re-agents. The crispation (racorniffement), which occurs at the instant of erubescence, is the same whether the fibres were previously dilated or contracted. The refiunct of the fibres is proportionally greater than in the animal systen: the hollow organs are hardly ever ruptured during life by the greatest distention. This phenomenon is seen in the bladder only, and there very rarely.

The quantity of cellular tifue between the fibres is very small; they are connected in the heart, rather by juxta-

position, than by this kind of union. The quantity is rather more considerable in the gastric and urinary organs. The organic fibres are never the seat of anafarcous effusions; they never pass into the fatty flatte, which is sometimes seen in the animal muscules; nor do they ever exhibit the yellow colour.

The blood-vesseis are numerous: in these, as well as in the exhalants and absorbents, there is nothing peculiar to be observed. The nerves are derived both from the brain and the ganglia: the latter predominate every where, except in the stomach and lungs, where the par vagun is distributed; they are the most numerous in the heart, and exit alone in the intestines; they exceed the nerves derived from the spine at the end of the rectum and in the bladder. The cerebral nerves are interwoven with thse, as they enter the organic muscules. The nerves of the ganglia, which enter the organic muscules, are not exclusively distributed to them; they form a network closely surrounding and belonging to the arteries. It has even been concluded that the nerves of the heart are entirely loit upon the arteries, and cannot be traced to the muscular substance. (Behrens, Differ. Cor Nervis carea; in Ludwig's Scriptores Neurolog. minores.) The size of the nerves is, at all events, very much below that of those which are distributed to voluntary muscules.

Properties. Extensibility.—Numerous phenomena exemplify this property: in the alimentary canal, distention by the food, or the gales liberated from it; in the bladder, accumulations of urine, &c. It can be brought into exercise very rapidly, and carried to a very great extent. The stomach and intestines pass in a few moments from the contraction of complete emptiness to very great distention, and the urinary bladder can be extended to three or four times its natural size in a short time. The animal muscules are never distended with such rapidity: hence, when the abdomen is opened after death in tympanites, the intestines tet at liberty occupy a much larger space than when they were confined by the abdominal muscules. The degree of extensibility in the organic muscules may be estimated, by comparing the empty stomach, which is often not larger than an innertine, to the same organ containing five, six, or eight pints of fluid; the bladder retired behind the pubes, to its condition when it has reached the umbilicus, in consequence of distention, &c. The rapid extension in the organic, and the limited power of increaf in the animal muscules, bear an evident relation to the successeive order in which the gastric viscera become distended in executing their functions: the stomach is filled, when the intestines are empty; and the latter are distended by the matters discharged from the former, &c.

A different kind of extensibility is observed sometimes in the organic muscules, as in the heart, for example, in aneurism. The left side of the organ has twice or thrice its natural sise, and is at the same time proportionally increased in thickness: this is not distention, but preternatural growth. The enlargement of the uterus in pregnancy arises, in the same way, from a greater activity of nutritive powers.

The contracility is in proportion to the extensibility. By virtue of this property, the stomach, intestines, bladder, &c., when empty, contract upon themselves, and are reduced to a small volume. The extremes of distention and contraction are never separated so widely in the animal as in the organic muscules. This power, although not dependent on, is modified by the vital forces. An empty stomach, in a subject who has died suddenly, is very contracted; but this organ is much larger and flaccid, when death has been preceded by a lingering and debilitating disea.

Vol. XXIV.
MUSCLE.

The matters contained in the hollow muscles of the organic life are their antagonists: so long as they are detained by them, the contractility of tissue is not exerted; when this distention ceases, that property is immediately brought into action. The expulsion of these contents is effected by a very different property, viz. the organic contractility. The latter is sudden, and consists of a series of contractions and relaxations; the former, slow and gradual, goes on without any alternation of relaxation. When the organic contractility has emptied the hollow muscles, the contractility of tissue reduces their dimensions. This latter property is in proportion to the number of muscular fibres; hence the ventricles will be more contracted, when empty, than the auricles, &c.

Vital Properties. Animal Sensibility.—This exists only in a flight degree. In the instance mentioned by Harvey, where a caries of the sternum had exposed the heart, it could be irritated almost without the person being conscious. If the peritoneum be removed from the back of the bladder in a dog, and the muscular structure irritated, the animal shews very little symptoms of pain. It does not appear that these muscles are the seat of any feeling analogous to the sense of fatigue experienced in those of the animal life.

Animal contractility is foreign to the muscles of the organic life. In this property we require an influence in the brain and nerves to set the muscle in action, and an excitation of the brain, by the will, by stimuli, or by sympathy, none of which conditions exist in the present case. Every individual knows that the functions of the organic muscles are not in the slightest degree influenced by his will; that the motions of the heart, or bowels, cannot be suspended, accelerated, or retarded by volition, &c. Irritation and compression of the brain, instead of convulsing or paralyzing, have no effect upon these muscles. Circulation is carried on perfectly well in a cephalus after the brain has been cut off, and rendered his voluntary muscular system motionless, the heart is still agitated for some time, the bladder and rectum expel the urine and feces, and the stomach sometimes rejects the food. Opium, which deadens the animal life, because it acts particularly on the brain, which is its centre, which paralyzes all the voluntary muscles, does not stop the contractions of the others. The action of wine, and of other narcotics, exhibits analogous phenomena.

The inferences afforded by disease are the same. Depression of the cranial, extravasations on the brain, apoplexy, &c. excite, debilitate, or annihilate the action of the voluntary muscles: but the organic are unaffected. In a paroxysm of mania, or an attack of malignant fever, analogous phenomena may be noticed.

Affections of the head are sometimes attended with vomiting; and the action of the heart is accelerated in cerebral inflammations. These are merely sympathetic phenomena, which may be present or absent, and which are irregular in all respects; while the contraction of the animal muscles from affection of the brain is a constant and invariable occurrence.

On the other hand, affections of the organic muscles do not influence the brain; that organ is not deranged in vomiting, diarrhea, palpitation of the heart, &c. In syncope the brain is influenced, because the heart's action is entirely stopped: it no longer sends blood to the brain, nor excites it by the motion imparted to the brain.

Irritation or division of the branches, which the eighth pair leads to the heart, does not affect its motions. Division of both trunks is indeed fatal at the end of some days; every thing shews the existence of great disturbance in the pulmonary functions, so that the circulation seems to be affected indirectly.

The division of one nerve does not ordinarily interrupt the functions of the stomach; while the section of both causes very great disturbance. It produces vomiting, which continues for the two or three days during which the animal survives the experiment. This result affords a striking contrast to the sudden immobility of an animal muscle, consequent on dividing its nerve. Irritation of the par vagum causes contraction of the stomach.

The bladder and rectum approach more nearly to the voluntary muscles, in their relations to the brain, than the stomach and heart. Falls on the facrum, producing concussion of the lower part of the medulla spinalis, paralyse the bladder as well as the lower limbs, and thus cause retention of urine. Yet the bladder is so much afflilated by several voluntary muscles, that the phenomenon may arise partly from the effects of the accident on them. For irritation of the lower part of the medulla spinalis, which throws all the muscles of the lower limbs into convulsions, has no effect on the bladder; and the involuntary jets of urine produced by violent pain in animals, are caused by contraction of the abdominal muscles. If the bladder be ever so full when the abdomen is opened, the urine will not be expelled. Hence, although the bladder may be regarded as a voluntary muscle, so far as its nerves, derived from the sacral plexus, are concerned, it is brought under the action of the will chiefly through other organs, of which the action is accessory but essential to its functions.

In the rectum, while the contained matter is in small quantity, the firelible organic contractility is not sufficiently excited to expel it: the action of the surrounding voluntary muscles is required. When the faces are collected in larger quantity, they produce an irritation which ends at last in the voluntary evacuation of the gut.

Thus it appears, that the bladder and rectum, although they receive nerves from the brain, are less influenced by that organ than we should suppose on the first view. They cannot be deemed, as some have called them, mixed muscles; and there is reason to doubt, whether, if no accessory power acted on and composed them, we could ever produce voluntary contraction of them through the nerves derived from the pelvic plexus. Bichat says that he never saw an animal void his excreta after the abdomen had been laid open.

We may conclude that the cerebral nerves going to organic muscles, have over them an influence, which does not at all resemble that of such nerves distributed to the animal muscles. The nature of this influence seems at present to be unknown.

Cutting, tying, or irritating any of the nerves coming from ganglia to organic muscles, or the ganglia themselves, does not affect the contractions of the muscles. Bichat tried galvanism with this view, but found it as ineffectual as all other irritants.

The nature, therefore, of the cerebral and nervous influence on the organic muscles is unknown to us: it is quite different from the effects produced in the animal muscles.

The organic sensibility is very strongly marked in this system; and its exercise must precede that of the sensible organic contractility.

Inferrible organic contractility, or tonicity, exists in the muscular system, to the degree necessary for its nutrition; but there is nothing peculiar to be observed concerning it.

The leading property, however, on which almost all the functions rest, as those of the animal muscular system do upon the animal contractility, is the sensible organic contractility.
The property, for the illustration of which physiology is too much indebted to Haller, may be considered under three points of view: 1. in the exciting causes; 2. in the organs; and 3. in their mutual action.

I. The exciting causes are either natural or artificial.

The former act contiguously during life: the organic phenomena partly depend on them; they set in action the muscles, which would otherwise remain motionless. The others are applied for the most part only in experiments.

1. The natural stimuli are, the blood for the heart, urine for the bladder, aliment and excrement for the gastric organs. Some irritation is habitually in contact with every organic muscle, and keeps up its motions; as the animal muscles, connected with the brain, derive from it the principle of their movements. So long as these stimuli continue the same, they maintain their respective organs in the same attitude for motion. If the organs are in the same state, the pulse, the digestive periods, the intervals of the urinary excitations are uniform, while the blood, chyle, and urine are unchanged. But, as these stimuli vary almost infinitely, the motions of the organs undergo frequent changes. When the chyle enters the languorous system in digestion, the pulse is changed; analogous changes occur from absorption of pus, from injection of fluids into the veins, from the inflammatory affection of the blood, &c.

The only obvious way of explaining these phenomena is by an alteration of the mode of action of the heart, produced by the change of stimuli.

The influence of the degeneration of the fluids may have been exaggerated, and pathologists may have placed in this class of causes too frequent a source of morbid changes. Yet we cannot deny that fluids may impart a different excitation to the solids, according to the changes which they undergo. In the same individual, and with the same quantity of food, the duration of digestion varies according to the quality; some kinds pass quickly, others are retained. As the urine differs in its properties, the bladder holds it for a longer or shorter time. How variable are the effects of different emetics and evacuants on the intestinal tube. The quantity of fluid contained in an organic muscle has, too, a decided influence on its contractility. The heart's action is accelerated, when the mafs of blood is augmented by transfusion; or when it is returned quickly from the heart to all quarters, in consequence of strong muscular exertion and running. The quantity of urine and feces is an important circumstance in determining involuntary contraction of the bladder and rectum. A single glass of warm water will not excite vomiting, when three or four will have the effect with certainty.

2. In the class of artificial stimuli may be included all the substances in nature. That a muscle in contact with a body, to which it is not habituated, should immediately contract, belongs to the very essence of organic contractility. The contact of the surrounding organs has no influence of this kind; perhaps habit has deadened the feeling: but, if they are removed from the body and cooled, and then applied to the organic muscles, they cause contraction. Heat or cold, air, and all kinds of liquids, excite the organic muscles.

These artificial stimuli act in various ways: 1. by simple contact. In this view, fluids are more efficacious than solids, as they stimulate more points. Solids operate according to their shape and aspect, their hardness, the pressure they produce, &c. Nature almost always employs fluids as stimuli in the natural state. 2. Laceration is more effectual than mere contact. When a touch with the scalpel has no effect, puncturing with its point excites the organ forcibly. 3. Chemical excitation is in general the most powerful. But here we must distinguish between crispation and irritability. A strong or concentrated acid digorges the part entirely; a very diluted one causes alternate contraction and dilatation, leaving the texture unchanged: the former is a chemical, the latter a vital phenomenon. There is every intermediate degree of effect between these two extremes: but we cannot establish a rigorous limit between the racemification and the irritability.

II. The sensible organic contractility, considered in the organs, presents numerous varieties, according to the diversity of tisue, age, sex, temperament, &c.

The animal contractility is uniform in the voluntary muscles, because the organisation is uniform: in this system the varieties of structure determine corresponding varieties in the properties. There is a relation between each organic muscle and the fluid which commonly excites it. The blood alone maintains regularly the motions of the heart: foreign irritations introduced by the veins disturb the contractions. The urine, which excites naturally the motions of the bladder, would cause trouble in those of the heart; while the blood will produce convulsive motions of the bladder. Thence, and the number of other phenomena of the same description, are connected with the different fenitures of the mucous membranes (see Membrane); the nervous systems, and every muscle has a degree of organic contractility peculiar to itself, and excited into action in a natural way, exclusively by some particular fluid.

We arrive at the same result with respect to extraneous irritations: an emetic, which causes contraction of the stomach, may be introduced with impunity into the bladder: purgatives do not cause vomiting, &c. This relation of certain irritations to the sensible organic contractility of particular organs is apparent, both when they are directly applied to the corresponding mucous surfaces, or when conveyed by the circulation; as in the injection of different irritations into the veins. Although the emetic or purgative in the latter case is presented to all the organs, the stomach or intestines alone contract. They have the same effect when introduced into the body by cutaneous absorption.

Age modifies very remarkably the sensible organic contractility. It is easily excited in infancy. The urinary function retains its contents only for a short time; the heart contracts with a rapidity, of which the pulse affords a criterion; all the digestive phenomena are quickened, so that hunger returns more quickly. This susceptibility of the organic muscles is constantly diminished after the period of infancy, and this change is evinced by the pulse, the length of time occupied in digestion, and the retention of the urine. The action of the organic muscles is weakened in the old man: the bladder and rectum particularly prove this, and hence the retention of urine, and the accumulations of feces, so common at this age. The functions of the stomach, and of the rect of the intestinal canal, do not languish so soon. The heart holds out the longest: it is the ultimium moriens, as it was the first in exercise: its pulsations are the exact measure of the duration of the organic life.

Temperament is another source of considerable modifications in this property: the pulse and the digestive phenomena are quick in fome, slow in others, &c. The variations in the force of the organic do not coincide with those of the animal muscles; the one may be weak when the other is strong; the heart, however, more frequently bears a relation in point of strength to the external muscles, than the stomach, intestines, or bladder. A full and strong pulse generally coincides with an athletic constitution; and these are frequently joined to a weak gastric system; while, on the contrary...
MUSCLE.

Flegg, gastric organs are often joined to external weaknesses.

The variations of strength in this system are partial: one part predominates over the rest: the heart, the stomach, or the bladder may take the lead. Sometimes all the gastric visera are not at the same level of strength: the stomach may be weak while the intestines have their natural strength, and vice versa. In the animal system, the varieties are general: we may strengthen this or that region by exercise; but the natural differences of force affect the whole. This difference appears to arise from the circumstances that the contractility of the animal muscular system is derived from a common centre, the brain; while that of the organic has its principle inhaled in each organ.

Women approach to children in the characters of their sensible organic contractility: the movements are weaker and more rapidly executed in this sex.

These observations on the different degrees of irritability, are not applicable to the organic muscles exclusively; they apply also to those of the animal life, and to the animal contractility of that system, as well as to the sensible organic contractility. We may observe, in general, that the same stimulus, applied in the same manner and extent, will produce different effects on different muscular organs; that it will even affect them differently in the same individual at different times. They are more easily excited after a great prostration of strength, loss of blood, violent action of purgative remedies, &c. There seems to be a natural difference in the degree of these powers, so that of individuals of the same general appearance, some are much more irritable than others.

III. We have considered separately the stimulus and the organ stimulated: the exercise of the sensible organic contractility takes place when they are brought together. We no more know what happens on this occasion, than what takes place when a body attracts another, when an acid combines with an alkali, &c. In attraction, affinity, and irritability, we can only pursue the phenomena to the action of bodies on each other: this action is the term of our researches.

The action is in no case direct: an intermediate tissue, which receives the irritation, is always interposed between the stimulus and the organ acted on. This is a very fine membrane in the heart; a mucous surface in the gallic visera and the bladder. We even find that this intermediate organ is more susceptible of excitation than the muscles itself. More lively contractions of the heart are produced by irritating the internal surface of the cavities, than by stimulating the muscular substance, after exposing it by removing the mucous membranes. Irritation of the mucous surfaces also excites the organic muscles. An altered state of the medium changes the effects produced by stimuli, as diseases most abundantly evince. The action of a stimulus, too, extends to fibres, which cannot be affected even through the intermediate organ: by irritating a small spot of the intelleve, the canal will often be thrown into contraction for a considerable length.

The existence of this intermediate organ constitutes a striking difference between the sensible and indescribable organic contractilities. The same system in the latter receives the impression and reacts: in the former, one system is impressed or perceived, and another moves. The tatt is more analogous to the eafe of the animal life, where the organs of the senses and of motion, totally different, are also widely separated from each other.

This property continues much longer after death than the animal contractility. The internal organs may still be excited to contraction, when irritation of the medulla spinalis has no effect on the external muscles. This fact is so familiarly known, and the experiments in proof of it have been so multiplied, that it seems no longer necessary to enter into a detailed proof of what no person contends. To this permanence are owing the evacuation of the faces and urine after death, and the expulsion of the contents of the stomach, which are often driven into the mouth. In sudden deaths, produced either by violent injury of the brain, as in apoplexy, concussion, compulsion, or by an affection of the heart, as in syncope, the bursting of an aneurism, &c. or by cessation of the action of the lungs, as in asphyxia, the permanence of this contractility is very remarkable: general death occurs first, and the organs then die partially, each vital force being in a manner extinguished successively. In all flow deaths, particularly where a debilitating disease has preceded, each vital force is gradually weakened, and the partial death of every organ comes before the general death. When the latter happens, therefore, none of the particular organs retain their life. Bichat states, that in dogs, killed by hunger, the contractility was extinguished at the time of death, and that in several, who died of a debilitating epidemic complaint, the same circumstance was observed.

Sympathies.—No organs are more easily influenced by others, than the organic muscles: but all are not equally susceptible. The heart holds the first rank; then come the stomach, the intestines, and lastly, the bladder.

The action of the heart is suddenly changed by every affection, which is at all decided, in the animal economy: a very slight wound or pain is often sufficient to produce this effect. Sometimes the action is stopped for a moment, and hence remits. It is a common effect of sudden and violent pain. More frequently it is accelerated; and hence the febrile attacks common in all local affections: they are merely sympathetic, and cease when the local cause is removed. We cannot deny that this accelerated action may depend on a foreign substance mixed with the blood, and rendering it more irritating, or that it may arise from an affection of the substance of the organ, causing it to be more irritable: yet certainly it is often purely sympathetic, or derived from that unknown relation, which connects together all our organs, from that content (constitutum partium), which unites all their actions, and brings them into a state of reciprocal dependence.

Sympathetic affection of the stomach is not so common as that of the heart. Inflammations are often accompanied by vomiting; and several fevers have this symptom at their outset. It does not arise from bile being introduced into the stomach; for that fluid is naturally in the empty stomach; nor does it arise from unhealthy secretions of the mucous coat, for they frequently do not exist. If there are such secretions, or if bile be contained in the stomach, they are rejected by the act of vomiting. How, it will be asked, does the stomach come into action in consequence of the lung, the pleura, or the skin being affected? By sympathecity, it is the convenient word under which we shelter our real ignorance of the mutual relations of our organs. The vomiting is an effect analogous to the augmented action of the heart in fevers, or to the disturbance of the brain that causes delirium. These phenomena shew that other organs, somehow or other, feel the flate of that which is disturbed.

The bladder is the organic muscle least frequently affected by sympathy. In fevers there is sometimes a paralytic, lasting for a short time, and producing retention: uncontimance occurs least frequently.

The sensible contractility is very active in this system. Indeed, the organic muscles are constantly in action; and they
are very easily influenced by other organs. This is the vital property derived in such cases: the insensible contrac-
tility, which does not perform an essential part in the pheno-
mena of these organs, is seldom affected. Disease generally a-
ffects the prevailing vital power of any part; as the animal
countility, for instance, in the systen laid described. The in-
sensible contracility, or tonicity; existing only to the degree
necessary for nutrition, is very seldom influenced; that func-
tion is therefore uniform, and consequently alterations of the
mucular tissie are rare, and seem to be produced, when
they do occur, rather by communication from the mucous
surface, as in cancers. In systen where the insensible con-
cantly is constantly exerted, as in the cutaneous, ferous;
mucous, and glandular, where it prevails over the functions
of nutrition, exhalation, and secretion, that property is al-
tered in disease. Hence all the changes of tissue, which
are properly enough called organic diseases, are as common
in these systems, as they are rare in those where the insen-
sible contracility exists only in the degree necessary for
nutrition. The unfrequency of acute inflammation in the mu-
cular systen, and its very common occurrence in the cutaneous
ferous, mucous, and glandular, where it prevails, as explained
on the same principle. We hardly ever find the mucular tissie of the
heart inflamed. Inflammation of the ferous and mucous
membranes of the alimentary canal is very common; we
know nothing of this affection in the mucular fibres.

Organic mucular Sytem considered in Action.—The force of
the contraction is never raised to the pitch which that of the
animal muscles sometimes attains. Between the strongest
and the weakest pulse, or jet of urine, there is nothing even
approaching to the difference between the languour of the
voluntary muscles in some women, and their energy in a
maniac, or a man enraged. The heart and the deltoide are
nearly equal in volume. What would become of the circu-
lation, if the former should ever exert, in expelling the blood,
the force which the latter often displays in elevating the arm.
The organic muscles, on the contrary, are never exposed to
the proitations of strength so common in the voluntary;
they are not exposed to paralysis, because they are not un-
der the influence of the brain. The irregular agitations of the
heart, producing so many varieties of the pulse in acute
fevers, bear some resemblance to convulsions.

The force produced by the contraction of these muscles,
is not subject to the diminutions which affect that of the
voluntary muscles: it is all exerted in accomplishing the object,
and consequently does not admit of the distinction into ab-
solute and effective, which isessential in the other case.
According as the body to be expelled from a hollow muscle
is solid or fluid, a greater or less contractile energy is re-
quired. Hence the longitudinal mucular fibres are more
strongly pronounced in the large, than in the small intestine,
and in the rectum than in the colon. Hence the lightest ef-
fert is sufficient to expel the fluid matter of diarrhoea; while
the strongest exertion of the respiratory powers is necessary
in aid of the fibres of the rectum, to get rid of hardened
fumes.

The force of the organic muscles is much greater in the vital
phenomena than in our experiments: when the heart
is exposed, its motions become weak and irregular. There
is no comparison between the contraction, which throws a jet
of blood leven or eight feet from the chest, and that which
stimuli produce in the heart taken out of the body. In every
individual this force varies from a thousand cubic; exercise,
repose, a tranquil or disturbed state of the mind, sleep, &c.
modify it incessantly. Perhaps we hardly digest twice
in the same period; retain the urine for the same length of
time, or expel it with the same force. Hence all calculations
must be very uncertain.

The force of the organic muscles often remains at the same
pitch, or is even augmented, while a general debility affects
the animal mucular system. A strong pulse, vomiting,
diarrhoea, &c. frequently coincide with prolation of strength
in diseases.

The velocity of the contraction varies very much; it is
very great in experiments with strong stimuli, but much less
considerable in the natural state. We might almost say that
it is in an inverse ratio to the strength. The contractions
become much quicker in several diseases, and here this state
is not joined with strength. When the force of the heart is
increased, there is generally a little additional velocity; but
a diminution of strength often coincides with increased quick-
ness, or the latter is augmented, the former remaining the
same. The highest degrees of strength and quickness are
perhaps hardly ever united.

In each individual there is probably a certain natural and
peculiar rate of velocity. In two examples of the same fever,
with the same symptoms, and the same general degree of
disturbance, there will be considerable difference in the quick-
ness of the pulse.

Every organic muscle has its own peculiar velocity: the
heart, stomach, intestines, and bladder differ from each other
most widely in this respect.

The organic muscles are never permanently contracted like
the animal. We see a constant succession of contractions and
relaxations in the heart. The contracted state of the stomach
and intestines, when empty, arises from the contracility of
tissue. The alternation of contractions and relaxations char-
acterizes the sensible organic contracility, and distinguishes
it from animal contracility, or contracility of tissue.

The phenomena of contraction are the same in this systen
as in the animal muscles. Some differences, bearing a manifest
relation to the functions of the parts, are observable between
the heart and the abdominal organic muscles. In the former,
as in the voluntary muscles, there is a sudden contraction of
the whole, projecting the blood in the execution of the na-
tural functions, and producible by stimuli, while the animal
muscles of the body, and the organic muscles of the blood,
while in a state of rest, produce a contraction which
agitates all the fibres, but not producing any general movement,
not propelling the blood for instance. In the alimentary canal
and bladder there is merely a flow, and often obscure motion,
which is well enough calculated for propelling the contents
of those cavities, but would be altogether unfit for projecting
the blood. When this has ceased, no oscillation can be
produced by stimuli.

What is the relaxation of the organic muscles? What is
the nature of that state, which succeeds contraction, and
alternates with it? After the contraction of a voluntary muscle
has ceased, it is in a passive state, and is restored to its or-
iginal condition by the action of its antagonist on the bone to
which it is fixed. As there are no antagonists in the organic
muscular system, the phenomenon of dilatation must be pro-
duced in some other way. Physiologists have generally ad-
mitted, as the cause of dilatation, the introduction of a fresh
supply into the mucular cavities, to fill the place of what
has been expelled by the contraction. Thus a new quantity
of blood and of food, have been regarded as the means of
dilatation in the heart and alimentary canal, of which the
muscles were supposd to be completely passive in this busi-
nesses. There are some doubts of the correctness of this re-
prentation; we have mentioned them in the article Heart:
the observations are mostly applicable to the alimentary canal
as well as to the heart.
Development of the organic muscular System.—The progress of this system in its formation is exactly inverse to that of the preceding. The heart is the first point in which motion can be observed; it forms the punctum saliens of the embryo, when the rest of the frame is merely homogeneous jelly. The internal muscular parts of the abdomen are discerned later, but they appear before the muscular coverings of the cavity: they contribute, with the liver, to the considerable size of the abdomen at this time. The heart is firm in its tuffe, and red, while the fibers of the alimentary canal are soft and pale. The contractions of the heart are very rapid, but its contractility is not so easily excited after death, nor for so long a time in the fetus, as after birth. The latter observation is applicable also to the fibers of the alimentary canal. The urine remains in the bladder, and the meconium in the large intestines, without exciting any contraction of those organs.

At the time of birth the gastric and urinary organs display an active interior motion: the introduction of food into the stomas, the evacuation of the meconium and urine evince this. The organic muscles grow less in proportion than the others after birth. The predominance of the organic system is however less strongly marked in the fetus than that of the nervous; the brain has a much greater relative size than the heart.

We have stated that there are two distinct periods in the growth of the animal muscles: one terminating their increase in length, and the other in breadth. The former does not seem equally applicable to the organic muscles; the general stature is already fixed, where the gastric and urinary organs still grow considerably.

In the phenomenon of growth each system seems to have a different limit. The general stature is determined by the bony, animal muscular, fibrous, cartilaginous systems, &c. But this does not at all influence the length of the intestines, the capacity of the stomach, heart, bladder, &c. The glandular, mucous and serous fibers are equally independent of the general stature. Its varieties, therefore, affect the limbs much more than the abdomen and chest. The end of growth in height is the end of the increase of the muscles, bones, and their dependencies: the internal viscera still increase, as may be ascertained by comparing them in a man of eighteen and another of thirty or forty years.

The organic muscles are not subject to the irregularities of growth, which are observed in the others: the general stature is sometimes at a stand for several years, and then suddenly increases. We see nothing of this sort in the organic muscles; the regularity of the internal functions, in which these muscles are concerned, is inconsistent with such irregularities, which do not interfere with the functions of locomotion.

The organic muscles have acquired their full development about the twenty-sixth year; the chest and abdomen, which contain them, have then arrived at their perfect size. Their density is more considerable, and their colour deeper than in the youth. The color varies considerably in the heart; but is more uniform in the alimentary canal.

With the advance of age this system is weakened like all the others; yet its action is more durable than that of the animal muscles. When the old man can scarcely move, his pulse and digestion retain much of their vigour. This difference between the two systems is the more remarkable, as the time of activity of the organic is nearly twice as great as that of the animal system: sleep supplies the voluntary motions, leaving the involuntary unaffected. This phenomenon seems to be nearly the same on a large scale, as the latitude produced by any particular motion is on a small one; a convulsion of half an hour in length completely exhausts the animal muscles, and leaves the perfon incapable of moving, while the heart, after being long agitated in a fever, returns to its natural type of contraction. These phenomena of the two systems prove manifestly that that of the animal life is fatigued much the sooner; and hence arise the intermissions of its action. We cannot therefore be surprised at finding that this, although less frequently exercised than the other, should sooner exhaust the powers given to it by nature, and should be sooner extinguished. Life is a great exercise, which gradually consumes the organs of motion, and induces a necessity for their repose; this repose is death.

Every moving organ arrives at it sooner or later, according to the different degree of force which it has to expend, and its greater or less disposition to become tried by this exercise.

The organic muscles, however, are gradually weakened. The pulse becomes slower, and digestion languishes; the bladder and the rectum first cease to act; then the intestines are inactive; the stomach, and particularly the heart, die the last. For a long time before death the muscular cohesion is weakened in this, as in the preceding system; the tulle becomes flaccid; the sides of the heart, which support themselves in the young subject, collapse in the old, and analogous phenomena may be observed in the gastric and urinary organs.

The best works on the structure and physiology of muscles are Haller’s Elementa Physiologiae, t. iv.: his Opera Minora, t. 3. Myus, Mucostrarum Artificiosa Fabrica, 4to. Prochorus, de Carne Musculari, Vienna, 8vo. 1778. Bichat, Anatomie Generale, tome iii. Soemmerring, de Corporis Humani Fabrica, t. iii. In the last work there is a list of various publications concerning the application of electrical and galvanic agents to the muscles. On the description and actions of muscles, the most important sources of information are Albini, Fllores Muscularium, 4to. and his Tabulae fecelet et Muscularum Corporis Humani, folio. Haller’s Elementa Physiologiae, on many parts of the subject. Winlow’s Exposition Anatomique de la Structure du Corps Humain. D’Agoty Effay d’Anatomie in Tableaux, imprimes, qui representent au naturel tous les Muscles; fol. Paris, 1746. Sandifort Descriptio Muscularum Hominis, fol. L. B. 1781. Barclay on the Muscular Motions of the Human Body. The Anatomy Syllems of Soemmerring, Bloyer and Bichat. Barthez Nouvelle Mechanique de l’Homme. Particular parts of the subject have been illustrated by some writers; the muscles of the face and perineum in the Tabulæ Poltimum of Santorini, the latter also in Camper’s Demonstrations Anatomico-pathological, lib. ii.: thefle of the palate by Haase; and the diaphragm by Haller.

Muscle, in Ichthyology. See Mylius.

Muscle Bank, in Geography, a fishing bank on the E. coast of Newfoundland, at the entrance into Trinity bay or harbour.

Muscle Bay. See Monsel Bay.—Alfo, a bay in the ftrait of Magellan, half-way between Elizabeth’s bay and York road; in which is good anchorage with a westerly wind.—Afo, a bay called “Mellifons,” on the coast of Chili or Peru, in South America; five leagues S. by W. from Atacama. See Missions.

Muscle Shells, a name given to a part of Tenesine river in America, extending about 25 miles, distant about 250 miles from its mouth, and so called from the number of soft shell turtles and fresh water clams found there. Here the river spreads to the breadth of two or three miles, and forms a number
a number of islands, rendering the passage difficult. From this place to the Whirl or Suck, where the river branches through the Great Ridge, or Cumberland mountain, is 250 miles; the navigation of which is excellent. From these shoals to the navigable waters of the Conoco is a distance of 40 miles, and thence to Mobile bay 330.

Muscles, in Agriculture, a fort of shell-fish which abound on the rocky shores on the borders of the sea in many parts of the island, adhering to the rocks. Where they can be collected in large quantities they may be made use of as an excellent manure, either alone or in the state of compound with earthy subfubstances. They were formerly much employed on the sea coasts of Lancashire, but have lately been much on the decline.

Musco, in Geography, a town of South America, in the viceregency of New Granada; 30 miles N. of Santa Fe de Bogota. N. lat. 5° 10'. W. long. 73° 30'.

Muscoïdes, in Botany, a name derived from Musca, a mof, and form or affeét, which might seem to authorize the Greek etymology of the former, (see Musch) if botanists are always attentive to such propriety. Unfortunately they too often tag Latin, or even barbarous, names with this Greek termination, when they wish to compare a plant to any thing already known. Names so contructed are however not allowed at all at present, except for fpecies; by no means for genera. Micheli used the above, for a supposed genus of his own, confilting of fuch Jangemanni as have three, four, or five rows of leaves, including flippaceous fcales; like J. dilatata, tambusina and platypbilla; but nobody has followed his example, as to the genus or its name; except that the latter may be found occasionally employed by writers, to express the mossy habit of certain plants.

Musconeck, in Geography, a river of New Jersey in America, which empties into the Delaware, six miles below Elkton.

Musconis, or Mirconis, two small islands in the gulf of Adramytti, near the coast of Natalia; 5 miles S.W. of Adramytti. N. lat. 30° 30'. E. long. 26° 44'.

Muscoavado, in Commerce, sugar that has been cured in the West Indies, in the manner described under the article Molasses, and is the raw material from which the British sugar-bakers chiefly make their loaf, or refined lump. See Sugar.

Muscovite Bible. See Bible.

Muscovite Coinage. See Coinage.

Muscovite Glass. See Mica.

Muscovy. See Russia.

Muscular, or Muscular, something that relates to the muscles, or that partakes of the nature of them. See Muscle.

In which fene we hay, muscular fibre, muscular coat, muscular flesh, muscular veins, muscular arteries, &c.

Musculo Cutaneus, in Anatomy, a muscle belonging to the arn. See Nervc.

Muscus Flotis Late. See Membranous and Fascia Lata.

Muscus Latus. See Latus Musculi.

Muscus, the name by which some call the common fca muscle, more properly called myiasty.

Muscus, Wolfgang, in Biography, a celebrated German Lutheran divine, was born in 1479. His father, who was a cooper by trade, perceiving in his son, while very young, an inclination for learning, was desirous of gratifying his wishes, but, being in humble circumstances, he could afford little towards his maintenance at school, and left him to provide his own subsistence, by fencing from door to door, according to the custom of poor scholars at that time. With the aid of what he thus obtained, he was enabled to support himself at different seminaries till he was fifteen years of age. He now set out with the view of visiting his parents, and happening to enter a convent of Benedictines, at the time of evening service, he particularly struck the superior by the excellence of his singing, and the comeliness of his person. He accordingly offered the youth an admission into the convent free of all expense, and promised likewise that he would furnish him from his own purse with clothes and other necessaries. Musculus instantly, with the permission of his parents, accepted the offer, and having taken the monastic habit, spent thirty-three years of his life diligently employed in study, and a fluinc example to the community of regularity, temperance, and obedience to the duties of the cloister. His first object was the attainment of classical learning, in which, and in the other departments of the belles lettres, he made great progress. At the age of twenty he devoted himself most avidiuly to the study of theology, sacred criticism, and the scriptures. Thus furnished, he entered the pulpit, and obtained a high reputation as an eloquent preacher. About the year 1518, he became a convert to the Lutheran doctrines, and zealously advocated the opinions of the great reformer; hence he obtained the name of the "Lutheran Monk." On account of his zeal in the cause of the truth, he would have drawn upon him the heaviest punishments, had he not been protected by Richard a Rottenburg, governor of the castle of Lutzelstein, and the patron of the convent, who was a person of great weight and authority in the Palatinate. In 1527, he was elected prior of the convent, but he refused the honour, and soon after, to free himself from the danger to which he felt he was exposed, quitted the house in which he had lived so long, and went to Strasburg. He almost immediately married, and for his support bound himself to a weaver, in order to learn his business, but 5 bonds for disfrituation dissolved the connection between himself and the weaver, and he had now no other prospect left, but that of gaining his livelihood by joining the labourers who were employed in repairing the fortifications of Strasburg; upon this drudgery he had prepared to enter; but on the evening before he was to commence the labour, he received a message to meet Martin Bucer, who intimated to him that the magistrates of the city desired that he should preach every Sunday at the village of Dorlichem. He was delighted with the prospect before him, and became earnestly attached to the duties of his profession. At this period he was entertained in Bucer's house, who gave him his board as an equivalent for his assistance in transcribing his MSS. for the prel. After a residence here of a few months, he went to Dorlichem; where he continued twelve months, zealously employed in the duties of the gospel ministry, and continuing the rigours of extreme poverty with the most admirable charity. He had no household furniture, but a little bed brought by him from his convent, which was occupied by his wife during her confinement, while he himself was contented with a straw on the bare ground, and a few undeserved which the humanity of his companions supplied him with. To such great diitresses was he, at one time, reduced, that he must have perished for want, had not the magistrates of Strasburg ordered him small sums of money from their public treasury. At the end of the year he became deacon-minister of the principal church of Strasburg; and in 1531 he removed to Augsburg, where he was first officiated as miniller in the church of the Holy Cross, and afterwards in that of the Holy Virgin. He was for some years involved in continual disputes either with the Papists or Anabaptists,
MUS

He successfully refilled the cruel design of putting the latter to death, and was the instrument of reclaiming, by the forcible weapon of reason and argument, several of the deluded followers of Muncer. He retained his situation at Augsburg till the year 1547, and during this period he made himself master of the Greek and Hebrew languages, to which he had been before a stranger. He gave evidence of his skill in these languages by the publication of various well-executed translations, particularly of the commentaries of Chrysostom, on the epistles of St. Paul; some of the works of Basil, Athanasius, St. Cyril, Eusebius, Socrates, Theodoret, and others. In the years 1540 and 1541, he was deputed by the senate to attend the conferences held between the Protestant and Catholic divines during the diets of Worms and Ratibon; and in the conference during the latter diet, between Melanthon and Eckius, he was appointed one of the secretaries, and drew up the acts of it. When Charles V. came to Augsburg, in 1547, to hold a diet, after the defeat of the league of Smalkalde, Musculus was deprived of his church, but he still maintained the privilege of preaching the tenets of the reformed religion, though it was often at the hazard of his life. He afterwards preached decidedly against the Interim (which fee); but as the magistrates of Augsburg chose to submit to it, he thought it prudent to withdraw to Switzerland, and occasionally officiated as preacher at Constance, St. Gall, and Zurich. While he was at the last-named place, he was invited to England by archbishop Cranmer, but the ill health of his wife, and the largeness of his family, consoling of eight children, led him to declined the prelate's offer. In 1549, he became professor of divinity in the university of Berne, the duties of which office he discharged with great reputation for more than fourteen years. In 1552, when Augsburg had recovered its liberty, he was recalled, and about the same time he had invitations from Strauburg, the electors palatine Otho-Henry, and Frederic, and the landgrave of Hesse, to pofts of honour and emolument, but his gratitude to Berne was so great, for affording him an asylum in the hour of his distress, that he refused, without hesitation, the advantageous proposals made to him. He died in 1563, at the age of sixty-six. His works were chiefly theological, and they gave him a high character among the Protetants of his day. Moreri. Bayle.

MUSCUS, in Zoology, broad-nosed whale, a species of Balena; which fee. This has a double pipe on the forehead, and a very broad under jaw. It is the balena, with three fins, a round snout, and wrinkled belly of Ray. The musculus inhabits the Scottish seas: it is sometimes 78 feet long, and above 35 in circumference. The lower jaw is semicircularly turned at its extremity, and is much broader than the upper jaw, which ends in a sharp snout: the opening of the mouth is enormous, and contains a number of laminae of black whale-bone, but the longest do not exceed three feet: the sparscle, or blowing-pipe, is of a pyramidal form, divided into two orifices by a septum, or partition, and is situated on the forehead: the back is black, and is furnished with a soft ruffled fin; and the belly, which is white, has a number of folds of the skin. This whale is very destructive to the shoals of herrings which visit the Scottish coast, and which, with proper exertion, might prove an immense source of wealth and industry to Britain. From long experience the Norwegians are so thoroughly convinced of the benefits derived to their fisheries, by the whales' driving the fish into the creeks and estuaries on their coast, that they are protected by the law, under severe penalties.

MUSCUS, among the Romans, a military machine, under cover of which the soldiers approached and undermined the walls of places besieged, or filled the ditches.

MUSCUS, in Botany. See MUSC.

MUSCUS, in Natural History, a name given to several species of zoophytes. (See Millepora, Spongia, Flustra, Tubularia, Corallina, Sertularia.) Marigli has described several of these marine substances, under the erroneous denomination of sea-plants. See CORALLINE.

CUSDEREE, in Geography, a town of Hindooftan, in Bahar; 16 miles S.W. of Kotaigur.

MUSEAU, in Natural History, a term applied by M. de Reaumur to a fort of bladder, which the insects of the flay clafs are provided with, to make their way out of the shell, after their final transformation into the nymph flate.

The word is French, and literally signifies a snout or muzzle.

The flies to whom nature has given this instrument, have it only during that short stage of their lives which is between their being inclosed in the membrane which covers them in the nymph flate, and their first flying about liberty. At this time, in order to their getting out of their shell, nature gives them a power of inflating and swelling out their head to a great size, and throwing out this fort of bladder to its anterior part, by which means the cap of the cafe or shell is thrown off, and the end of it opened by the two longitudinal lines giving way. The creature, after this, as it has no use for this singular piece of mechanism, has no power to exert it during the remainder of its life. Reaumur, Hist. Inf. vol. iv. p. 340. See Transformation.

MUSEBYTER, in Ichthyology, a name given by some to the fish called by authors doblo, a German fish, found in several parts of Germany, much approaching to our common dace. See CYPRINUS Dobula.

MUSEIA, MUSIA, in Antiquity, festivals in honour of the Muses at several places of Greece, especially among the Theopians, where solemn games were celebrated every fifth year.

The Macedonians had also a festival in honour of Jupiter and the Muses, which was celebrated with flaggs-plays and games, and lasted nine days, according to the number of the Muses.

MUSES, MUSIA, in Mythology. Muses, fabulous divinities of the ancient heathens, who were supposed to preside over the arts and sciences.

The word, according to Phornutus, is derived from the Greek μουσα, which signifies the same with ζυλης, to instruct: others derive it from miusos, similar, or alike; all the sciences being bound and united together. Eusebius derives it from miusos, to initiate, to instruct; Plato and Scaliger from μαυσωλος, obsetricaries; because to them is attributed the invention of arts; and by them arts were produced. Diodorus derives the name from mijins, which signifies to teach things sublime. Huetius deduces it from Mofes. Lastly, Heinius and Voiffus derive it from the Hebrew מושל, miusiar, science, disciplina. The Muses are called by various names: Camænx, Heliconiates, Parnassides, Aenides, Citherides, Pierides, Pegasiades, Agrippiniades, Theopides, Libethridæ, and Caftandæ.

They were called Camænx from Cane, as their principal employment was to celebrate the actions of the gods and heroes: Heliconiates from Helicon, a mountain in Buxotia; Parnassides from mount Parnassus, in Buxotia, which they much frequented; Aenides from the Aonian mountain in Buxotia; Citherides from mount Citeron; Pierides, or Pieris, from mount Pierus, or the name of a city, or from that part of Macedonia called Pieria; Pegasiades and Hipperseis...
Muses, from the fountain which Pegæus caused to spring out of the earth with a blow of his foot; and from the same fountain they were called Aganipæides: Thebæides from a town in Boeotia, called Thebæa; and Libethrides from Libethra, the city where Orpheus was born. The ancients admitted nine Muses, and made them the daughters of Jupiter and Mnemone, or Memory. At first, indeed, their number was but three; viz. Mneme, Mnemosyne, and Aëdes; Greek words, signifying meditation, memory, and singing: but a certain sculptor of Scyros, according to Varro, having orders to make three statues of the three Muses for the temple of Apollo, and marring his instructions, made three several statues of each Muse: thence, however, were found so beautiful, that they were all set up in the temple; and from that time they began to reckon nine Muses; to whom Hesiod afterward gave names; viz. Calliope, Clio, Erato, Thalia, Melpomene, Terpsichore, Euterpe, Polyhymnia, and Urania.

Diodorus Siculus says (I. iv.) that these goddesses, so famous among the Greeks, were nine fingers whom Obris carried about with him in his conquests, and that he gave to two of his generals, Apollo and Hercules, the name of Muses, because they were the conductors of these fingers. According to M. Le Clerc they were the nine virgins who formed Jupiter's Royal Academy of Music in Crete. He adds, as a reason why that god passed for the father of the Muses, that he was the first among the Greeks who, in imitation of Jubal, had a regular concert; and that these singing virgins had Mnemone, or Memory, for their mother, because the furnishes the subjests of verses and poems.

Each of these was supposed to predominate over her respective art; Calliope over heroic poetry; Clio over history; Melpomene over tragedy; Thalia over comedy; Euterpe over wind-music; Urania over astronomy; Terpsichore over the harp; Erato, the lute; Polyhymnia, rhetoric. They were painted as young, handfome, and modest; agreeably dressed, and crowned with flowers. Their usual abodes were about Mount Helicon in Boeotia, and Mount Parnassus in Phocis. Their bursiness was to celebrate the victories of the gods, and to inspire and assist the poets; and hence the custom of invoking their aid at the beginning of a poem.

It must not, however, be imagined, that the deities, thus invoked, are considered, even by the ancient poets themselves, as divine persons, from whom they expect any real help. Under the name of Muses they pray for the genius of poetry, and all the talents and circumstances necessary for a happy execution of their undertaking.

Their addresses to the Muses are mere allegories, and manners of expressing themselves poetically: as when they make gods of sleep, of fame, of revenge, and other natural and moral things.

Accordingly, the Muses are of all ages, countries, and even of all religions: there are Christian as well as Heathen Muses; Latin, Greek, English, and French Muses. There are also new Muses, who appear every day in favour of those, who, disdaining things too trite and common, choose to strike out of the road.

When Virgil wrote his Eclogues, he invoked the Sicilian Muses, because he imitated Theocritus: and the Sicilian poet having succeeded, the Roman begged for a genius as happy as that of this islander.

The Muses of the poet Lucretius had never inspired any person before him. It is plain, from the doctrine of his book, what kind of divinity it was he invoked. He addresses himself to Venus; but, at the same time, tells us, that none of the deities trouble themselves with human affairs. His Muses, therefore, must of necessity be mere allegories.

MUSESTRE, in Geography, a town of Italy, in the Tréviani; 8 miles E.N.E. of Trésigus.

MUSET, Colin, in Biography, was a simple jongleur or minstrel, whose art advanced him to the rank of academician of Troyes and Provence. It is believed that the king of Navarre would not suffer him to stroll about the country as a ballad-finger or a piper, but took him into his service.

According to a very ancient tradition, Colin Mufet contributed to the expense of building the church of St. Julien des Menetriers, which still subsists in the street of St. Martin at Paris, and that one of the figures in front of that church represents him with a violin in his hand: but this instrument seems so much to resemble a modern violin, that it is suspected to have been added to the building long after.

MUSETTE, in Instrumental Music, a bagpipe. It was called by the Latins sibilla uerticularis. This instrument has two pipes on one side, two flutes or two pipes pierced with four or five holes, and on the other nine pipes, which appear fixed in one piece of wood. These pipes are disposed like reeds of the syrinx or Pan's pipe, always diminishing in length. All nations claim this instrument. The Greeks and Romans had it. The Scots and the Irish dispute the title to it; as they do of Offian's poems.

MUSEUM, MUSETTE, was originally used to signify a palace of Alexandria, which took up, at least, a fourth part of the city; so called, as being defined and let apart to the Muses and the sciences.

Here were lodged and entertained a great number of learned men, who were divided into companies or colleges, according to the sciences or parts of which they were professors. And to each house or college was allotted a handsome revenue. This establishment is attributed to Ptolemy Philadelpus, who here fixed his library.

MUSEUM has hence palled into a general denomination, and is now applied to any place let apart as a repository for things that have some immediate relation to the arts, or to the Muses. See Repository and Cabinet.

MUSEUM, Account of the progress of history of, in England.—The first person whom we read of having formed a cabinet of natural and artificial curiosities in England was Sir John Tradescant, who lived in the reign of Charles I. This gentleman poffessed large phyfic gardens in Lambeth, and travelled over a considerable portion of the globe with the delight of viewing himself in natural science, and procuring specimens of whatever appeared rare and curious. The fon having imbibed the spirit of his father followed his example, and by their joint exertions, a very valuable collection was framed, which afterwards became the property of Mr. Elias Ashmole, and was comprifed in his noble donation to the university of Oxford. Among the more remarkable of the venerable remains of this original cabinet, still preserved in the Ashmolean Mudefum, is the head of the bird called a Dodo, or Didus, (see Didus,) the only one in Europe, and most probably in the world, the species being suppos'd to be entirely extinct. (See Pennant's Account of London.) The next collection, after that of the Tradescants, appears to have been Dr. Woodward's, which subfequently came to be included in the superb and splendid one of Sir Hans Sloane, and, of course, now constitutes a part of the British Mudefum. About this time the Royal Society seem also to have begun their collection; and shortly afterwards, Mr. Leman, of the
MUSEUM.

Poultry-Compter, established the first museum of birds preserved in their present manner. About forty years ago Mr. Rackfrow made a fine collection, not only comprising many curious specimens of natural history, but likewise a great variety of anatomical preparations. A few years subsequent, Sir Alton Lever opened his most magnificent cabinet to the public, in Leicester-square, which had cost him upwards of thirty thousand pounds in collecting. This museum for some time was one of the most fashionable places of resort in London; and when dispofed of by lottery, became the property of Mr. Parkinson, who erected a building suitable for its reception on the Surrive side of the river Thames, near Blackfriars-bridge, London. The situation, however, was injudiciously chosen, being at too great a distance from the residence of those clafs of people most likely to afford support to such an institution; and in consequence, the proprietor not meeting with the encouragement he expected, was induced to dispofe of the whole by auction, in several thousand lots, in the spring of 1760. Mr. Bullock, of Liverpool, next removed to the metropolis about three years afterwards, and opened his inftrument museum of natural history and other curiosities in a large apartment in Piccadilly. That collection, from the very numerous, choice, and beautiful specimens it contained, as well as from the scientific and picturesque manner in which they were arranged, soon attracted universal attention, and excited a predilection for the study of natural history totally unknown in this country before. This success has lately induced Mr. Bullock to erect a magnificent edifice, in the Egyptian style of architecture, near the end of Bond-street in Piccadilly, to which the museum is now transferred, and where it continues to be exhibited with superior advantage, under the liberal and well-merited patronage of a discerning public. The expanse of the collection, and the building together, is estimated at 45,600; and the proprietor, we understand, is full ofIluvions in augmenting the number of his specimens; so that this museum promises to be a lasting source of gratification and rational instruction to the curious, as well as an ornament to the English metropolis.

Museum, British. The basis of this national repository was the collection of the celebrated Sir Hans Sloane. After the demise of this indefatigable collector in 1753, his museum was purchased by parliament, who, having, about the same time, obtained full possession of several libraries of MSS. and printed books, to be mentioned hereafter, vested the same, together with a considerable fund for the permanent support of the establishment, in an incorporate body of trustees; conferring on them ample powers to take such measures as should be deemed expedient for the disposition, preservation, and management of the institution, which it was now determined should bear the name of the British Museum. The first act of these trustees was to purchase, for the reception of the collections confided to their care, the noble mansion built, about the year 1680, by Ralph, first duke of Montague, who, being at that time ambassador at Paris, lent over the celebrated architect Peter Puget, and other French artists, for erecting and adorning the edifice he had in contemplation. The collection being removed thither, and properly arranged, the museum was opened for inspection in January 1759. Ever since that time, the treasures of this noble repository have been considerably increased, not only by various royal and parliamentary grants, to be mentioned hereafter, but by many additions made by the trust, and by private donations. Within the last ten years an addition building has been erected, for the reception of ancient sculptures, &c.

The following is a short account of the contents of the thirty-eight rooms, in which the various collections are arranged.

The ground-floor of the old building, consisting of twelve rooms, contains the library. The original library, at the time of the foundation of the museum, comprised the collection of books formed by Sir Hans Sloane, and that of major Arthur Edwards, which latter was obtained together with the Cottonian library of MSS. In 1757, king George II. made over to the British Museum the whole of the very choice and important library of printed books and MSS., which had been gradually collected by the sovereigns of these realms, from Henry VII. down to William III., and which also contains the library of archbishop Cranmer, and those of Henry Fitzalan, earl of Arundel, and his son-in-law Richard, lord Lumley, of Sir John Morris, and of Isaac Calfabon. This library also contains abundance of old and rare editions, many of them being presentation copies to the sovereigns from their respective authors; and among the MSS., the venerable Alexandrian codex of the Bible. His present majesty made a valuable addition to the library, by a numerous collection of pamphlets and periodical papers, published in the convulsive interval between the years 1640 and 1660. This collection consists of upwards of 30,000 tracts, most of which are now become uncommonly scarce, and many of them probably unique. This department of the museum has also obtained considerable accretions, in the select and valuable libraries bestowed upon it by Thomas Tyrwhit, esq., Sir William Muff, and especially by the Rev. Mr. Cracherode, who ranks among the most generous benefactors of the institution.

The upper story comprehends the saloon and twelve rooms. The first room contains objects of but little importance with regard to scientific information, except the curiosities from the islands of the South sea, the east and west coast of North America, &c., most of which were brought from those parts, and deposited in the museum, by celebrated British circumnavigator.

The second room is at present appropriated to the use of the readers. Persons, not wholly strangers, are freely admitted to this reading-room, and there supplied with whatever books or MSS. they may desire to consult.

With the third room the department of MSS. commences. In it is deposited the Landdown library of MSS., consisting of 1152 volumes, of which 114 contain the ample collection of lord Burleigh's latest papers; 46 volumes of sir Julius Caesar's papers relative to the time of Elizabeth and James I.; 108 volumes of historical collections of Dr. White Kennet, bishop of Peterborough, &c.

The fourth room contains the Sloanean and Dr. Birch's collections of MSS.; the former consisting of 4000 volumes, principally on physic and natural history; the latter, which was bequeathed to the museum by Dr. Birch, consists of 337 volumes, chiefly on history, biography, divinity, and literature. In this room are also placed sir Halhed's Oriental MSS., consisting of 93 volumes, written in the Sanscrit language, and the chiefly Persian, to which are added from other collections, relative to the same department of literature; such as that of colour John Hamilton, the collections which came with the trophies of our Egyptian expedition, &c.

The fifth and part of the sixth rooms contain the Harleian library of MSS. This library, which, together with the Cottonian collection of MSS., formed part of the original collections of the museum, consists of upwards of 47600 volumes.
The seventh room contains, in 33 pressos, the royal library of MSS., presented by King George II., together with the collection of printed books above mentioned. In the remaining 19 pressos of this room is deposited the Cottonian library of MSS., collected by Sir Robert Cotton, in the times of queen Elizabeth and James I., and increased by his son, Sir Thomas Cotton, in the subsequent reign. This collection chiefly abounds in authentic documents relating to the history, the antiquities, the laws, and constitution of these realms; and also in many ancient and splendid biblical and liturgical volumes, chronicles, and a variety of political tracts; the whole consisting of 801 volumes, of which 54 are so much damaged by fire, which happened in the year 1731, as to be almost unread. In this room are also deposited, as an addition to the Cottonian library, 54 volumes of extracts, &c., chiefly relating to the exchequer, collected by Thomas Maddox, Esq.; and on the table is the original of the Magna Charta, belonging to the Cottonian library. The original of the articles, preparatory to the signing of the great charter, perfect with the seal, is likewise deposited in this room.

Between the seventh and eighth rooms is the saloon, a magnificent apartment, which, before the erection of the new gallery, contained Sir William Hamilton's collection of Greek vases and other antiquities, but is now destined for the reception of the consolidated mineral collections of the museum. The original inconsiderable mineral collection of Sir Hans Sloane was, in 1795, incorporated with the more perfect one of Mr. Hatchet, which was purchased by the trustees at that period; and soon after, this part of the repository was farther increased by the very useful and elegant collection which formed part of the bequest of the Rev. Mr. Cracherode. These collections, together with some smaller ones, were, and are still partly preferred in the ninth room; but the very extensive and splendid collection of minerals which belonged to the late right honourable Charles Greville, having, in 1810, been purchased by parliament for the British Museum, the trustees pitched on the saloon for the future exhibition of these treasures, which, when the arrangements shall be completed, will, it is supposed, not be surpassed by any other public collection either in utility or splendour.

The ninth room, in which part of the old collection of minerals is still exhibited, will, as soon as the arrangement in the saloon is completed, be fitted up for the reception of rocks and geological specimens in general.

The ninth room contains an instructive collection of fossils, together with the Cracherodean and the old collection of shells: the latter, though left splendid, is more general and scientific than that bequeathed to the museum by the late Mr. Cracherode.

In the tenth room is deposited the Sloanean collection of insects, some of them rather injured by the tooth of time; and the same may be had of a collection of vegetable substances, preferred in this room. In a far better state of preservation are the molluscs and the numerous zooophytes, and the insects preferred in spirits. Along the bottom of the tables in this and the preceding room are deposited a great number of volumes, containing dried plants, among which there are several of considerable importance, such as Sir Hans Sloane's Jamaica plants, Kämpfer's herbarium, Buddle's British plants. &c. Very remarkable are also the fern trees placed over the chimney of this room.

The eleventh room contains the birds and a few mammals; the former difposed, so far as convenience would admit, according to the Linnaean mode of arrangement. On the tables are preferred the nests and eggs of various birds.

The twelfth room contains a general and extensive collection of fishes, serpents, tortoises, lizards, frogs, &c., as well as many specimens of quadrupeds preferred in spirits.

From this last room, on descending the back staircase, we proceed to the gallery of antiquities, an edifice lately erected, forming a wing on the west side of the main building. The basis of this excellent repository of antiquities was formed by the exquisite collection of Greek and Roman statues, busts, and other sculptured marbles which belonged to the late Charles Townley, Esq. and were purchased by parliament, in 1805, for the sum of 20,000/. To these were added the collection of Sir William Hamilton, and several others to be mentioned hereafter, which, together with those articles of antiquity which originally belonged to the museum, constituted an affluence too considerable and extensive not to demand the additional building, which is now open to the inspection of strangers, as well as for the improvement of artists; an advantage which the students in the fine arts have never before enjoyed in this country.

The first room of the gallery of antiquities contains the terracotts, most of them baffe-relie vos, symmetrically arranged along the walls; with some statues, among which is the muse Urania. One of the largest statues which have been found of terracotta.—The second room contains Greek and Roman sculptures: the attention of the spectator, on entering the gallery, is particularly arrested by a most exquisite statue of Venus naked to the waist, and covered with drapery from thence downwards; it was found in the maritime baths of Claudius at Oliva. Other striking features of this room are, a statue larger than life of a caryatid, being one of the caryatides which supported the portico of a temple dedicated to Bacchus; two colossal heads of Hercules, one of them in a very ancient style of Greek sculpture; and two colossal heads of Minerva, one of which is a fine specimen of very early Greek work. The Engravings of the contents of these two first rooms have lately been published.—Among the Greek and Roman sculptures of the third room are several valuable baffe-relievos in marble; of the many exquisite statues in this room we mention only the graceful recumbent Diana, and opposite to it the spirited statue of a youth holding with both hands a part of an arm, which he is biting; this statue belonged to a group, originally composed of two boys who had quarrelled at the game of talius, as appears by one of those bones called talii, remaining in the hand of the figure which is lost.—The fourth room, equally appropriated to Greek and Roman antiquities, contains only fifteen sculptures, the most striking of which are, a statue of Thalia, found at Oliva, in the maritime baths of Claudius, and a statue of Diana: both in a peculiar style with regard to the execution of the drapery; and a group of Bacchus and Ampelus.—The fifth room is fitted up after the manner of an ancient sepulchral apartment, or columbarium; it is deposited a considerable number of cinerary urns and olives, bearing monumental inscriptions, and baffe-relievos: some niches
MUSEUM.

In the walls exhibit earthen olize, placed in the manner of those which contained the ashes of the flaves, and the inferior orders of the Roman people. In the centre of the floor of this sepulchral room is a Mosaic pavement, lately discovered in digging the foundation for the new buildings at the bank of England.—Among the numerous Greek and Roman sculptures of the sixth room, consisting of bas-relievo, busts, statues, sarcophagi, and other sepulchral monuments, votive altars, &c. may be particularised, a bas-relievo, representing a female bacchante holding with one hand a knife, with the other the hind quarter of a kid belonging to Jupiter Serapis, in which the paint with which the face was anciently covered, is still discernible; a head of Apollo Mugagtes, resembling, in the disposition of the hair, and in the character of the face, the head of a muse; a statue of Libera, holding a thyrsus over her right shoulder, and a bunch of grapes in her left hand, with a panther at her feet; a fragment of a magnificent sarcophagus, representing an elderly man, with a manuscript roll in his hand, a muse standing before him; the front of the cover of another superb sarcophagus, representing a group of cattle, on one side of which is an old fab, and on the other a young fab, both recumbent; a sepulchral cippus richly ornamented on the four sides with festoons of fruit.—The seventh room contains a few Roman antiquities, among which are four pigs or prismatic maffes of lead; one, with the name of the emperor Domitian inscribed upon it, was discovered, under ground, on Haythwa moor, in the West Riding of Yorkshire; another inscribed with the name of L. Arconius Verecundus, found at Matlock bank, in Derbyshire; two others, each with the name of the emperor Hadrian inscribed upon it, the one found in the parish of Welbury, ten miles from Salop, the other in Cromford moor, in Derbyshire.—In the eighth room we find, among other highly interesting Egyptian antiquities, two mummies with their respective coffins, in excellent preservation; the one sent to England by Edward Wortley Montagu, esq., and presented to the museum by his majesty; the other found in one of the catacombs at Sakkar, and sent to England, in the year 1722, by Col. William Lethicullier: one of these mummies has been elaborately and beautifully ornamented with coloured beads, the greater part of which still remain; the face of the other mummy is girt, and the body ornamented with painting; the coffins are made of fycanmore wood, and covered with paintings and hieroglyphic figures. There are also deposited in this small room many canopufes, idols in bronze, basalt, marble, porcelain, and wood, faebrite, the skeleton of an ibis, &c.—The Egyptian antiquities contained in the ninth room are principally those which were collected by the French in different parts of Egypt, and came into the possession of the English army, in consequence of the capitulation of Alexandria, in the month of September 1801. They were brought to England in February 1802, under the care of Col. Turner, and were sent, by order of his majesty, to the British Museum.

Among the most remarkable of these articles are, the sarcophagus brought from the mosque of saint Athanasius, at Alexandria, being the largest and most valuable monument known to exist of the breccia, called breccia verde d’Egito; and another large sarcophagus of fenite (covered, like the preceding, with hieroglyphics, both within and without), which was brought from Grand Cairo, where it was used as a cistern called “the lover’s fountain;” various figures of Isis and other Egyptian deities; a colossal fig, executed in granite, of enormous dimensions; the celebrated Rosetta Stone, containing three inscriptions of the same import, one in hieroglyphics, another in the ancient vernacular language of Egypt, and another in the Greek language: these inscriptions record the services which Ptolemy V. had rendered his country, and were engraved by order of the high priests, when they were assembled at Memphis for the purpose of inviolating him with the royal prerogatives.—The tenth room contains Greek and Roman sculptures, and most of them of exquisite workmanship. The first which attracts our attention is the Discobolus, which is represented at that precise moment of time which immediately precedes the delivery of the discus; this fine statue is an ancient copy in marble from the celebrated bronze statue, executed by Myron. The group of a small Venus is one of the greatest ornaments of this room. Among the more remarkable busts is that of an unknown Grecian lady, in the character of Isis; it is gracefully terminated by the flower of the nymphæa lotus, on which it rests, and which having, by some antiquarians, been mistaken for a sun-flower, has given rise to the erroneous idea of a Clythia being represented by this bust. The terminal head of Homer, represented in an advanced age, is equally a masterpiece of Grecian art. Remarkable both on account of their form and their excellent preservation are, an oblong square basin of a fine granite, similar to such as were used in the temples for sacrificial purposes; and a cifer of greenish-black basalt, anciently used as a bath. The latter was formerly in the possession of Chrithna, queen of Sweden.

On ascending the stairs of the gallery we arrive at the anti-room, in the centre of which is placed the celebrated Barberini vase, which was, for more than two centuries, the principal ornament of the Barberini collection. This vase was purchased of Mr. Wm. Hamilton, nearly thirty years ago, by the duchess of Portland, since which period it has been more generally known by the name of the Portland vase. It was found, about the middle of the sixteenth century, two miles and a half from Rome, in the road leading to Frascati. At the time of its discovery, the vase was enclosed in a marvelous sarcophagus within a sepulchral chamber, under the mount called monte del Grano. The material of which the vase is formed is glafs; the figures which are executed in relief are of a beautiful opaque white, and the ground is of a dark transparent blue. This superb specimen of Greek art was deposited in the British Museum in 1810, by his grace the present duke of Portland.—The first room of this upper story (the eleventh of the gallery) contains the coins and medals, of which more will be said under the article NUMISMATOLOGY. (See also MEDALS.)—The antiquities in the twelfth room are principally those which belonged to the collection of Mr. William Hamilton, who, during a long residence at Naples, as his majesty’s envoy, had acquired a great number of articles of Greek and Roman antiquity, particularly the largest more then known of ancient vases, vulgarly called Etruscan, the whole of which was purchased, by parliament, for 840l. in order to be deposited in the British Museum. The contents of this twelfth room are a good collection of bronzes, among which there is a raven as large as life, and of most exquisite workmanship; also various specimens of ancient armour, veils, &c. &c. in bronze; curious specimens of ancient glafs, such as cinerary urns, lachrymatories, &c.; various necklaces, ear-rings, armillæ, &c. in gold; engraved gems; fragments in terracotta; a very rich collection of ciphers in terracotta; specimens of sculpture in ivory, crystal, agate, &c. and other articles too numerous to be specified, are deposited in the cases of this spacious apartment, which derives particular interest from the great collection of Greek vases above alluded to, the greatest number of which was found in sepulchres, in Magna Grecia.—The thirteenth room is appropriated to the reception of the extensive valuable collection of prints and drawings, the
most important part of which was bequeathed by the Rev.
C. M. Cracherode.

We now proceed to give a short account of two cele-
brated national museums in France, viz. the Musee Napo-
leon, and the Musee d'Histoire Naturelle.

The Musee Napoleon, in the Louvre, is a very splendid es-
establishment; it contains above 1000 paintings of the Ita-
lian, Flemish, and French schools; a collection of designs
of great masters; and above 300 statues and other articles
of antiquity. This last department of the museum is par-
icularly remarkable, on account of the many celebrated
works of Greek and Roman art which it contains, and
which are disposed in six distinct apartments of the gallery
of antiquities. The first room is called Sala des Saisons,
because the ceiling exhibits the seasons painted by Ronna-
elli, and in it are principally deposited the rural divinities,
&c. The following are among the more remarkable articles
of this room; a young faun with the flute, supposed to be an
antique copy of the celebrated faun by Praxiteles, in
bronze; the celebrated spinarius or tureen d'épinies, in
bronze; Venus rising from the bath, with the flsurous in-
scription BOUNTS; Pius, in Pentelic marble, formerly pre-
erved in the Museo Pio-Clementino; Amor and Psyche
embracing each other, from the Museo Capitolino, in Parian
marble; a statue of Ceres, and another of Flora, in Pen-
telic marble.—The second apartment is entitled Sala des
Hommes Illustres; it is ornamented with eight antique columns
of granitio, which formerly supported the ceiling of that
part of the church at Aix-la-Chapelle, where the tomb of
Charlemagne was situated. The principal statues in this
room are, that of Demosthenes sitting, formerly in the
Museo Pio-Clementino; a sitting figure of Trajan, in the
garb of a philosopher, holding a globe in his left hand, also
from the Museo Pio-Clementino; Menander and Moridip-
pus, both sitting statues, in Pentelic marble, from the fame
museum; a flanding statue of a Greek philosopher, gene-
 rally taken for Zeno, in Greek marble (grecchetto), for-
merly preferred in the museum of the Capitol.—The third
apartment is La Salle des Romains. The paintings of the
ceiling, by Romanelli, represent the rape of the Sabine
women, Mutius Scaevola, and other subjects of Roman
history. The articles in this room are all relating to Roman
history and manners; the most curious among them are the
following; a beautiful head in bronze of Publius Cornelius
Scipio the elder, with eyes of silver; a female statue in
Parian marble, generally supposéd to be Ceres, but which
is probably the muse Cio; the drapery of this statue, which
was formerly in the museum of the Vatican, is of superior
beauty; a Roman matron, with the pallia or cloak, is one of
the best preferred statues we are acquainted with, and
remarkable on account of the tafte which the artist has dis-
played in the management of the drapery; the wounded
warrior, commonly called the dying gladiator, from the
museum of the Capitol; the celebrated Antinous of the
Capitol, formerly in the possession of cardinal Alexander
Albani.—The fourth apartment bears the title of Sala de
Laocoon; it is decorated with four large columns of verde
antico, which formerly belonged to the mausoleum of the
famous Anne de Montmorency, in the church of
Montmorency. Besides the celebrated group from which
its name is derived, the more remarkable objects in this
room are, a Dicobolus in a reposeing attitude, formerly in the
Museo Pio-Clementino; a beautiful statue of an amazon,
from the same museum; a most characteristic head of a
youthful Bacchus, generally known under the name of
Ariadne of the Capitol; a graceful small statue of a priest of
the god Mithra, remarkable on account of the tafte dis-
played in the drapery, from the museum of the Vatican,
where it was known under the name of Paris; the Dicobolus
from the museum of the Vatican, a copy of the fame
statue in bronze, by Myro.—The fifth apartment is the
Salle de l'Apollon; it is ornamented with four columns of a
beautiful red granite, two of which were formerly in the
church at Aix-la-Chapelle, which contained the tomb of
Charlemagne; the floor is inlaid with beautiful and scarce
varieties of marble. Among the treasures of this apart-
ment are, the Apollo of Belvedere, and the Venus of Me-
dici (the two most perfect models of the human form ever
produced); the Mercury, called the Antinous of Belvedere,
and considered as a first rate production of art, worthy of a
place near the Apollo; Venus Capitolina; the Venus of
Arles, so called from Arles in Provence, where it was
found; a beautiful group representing Hercules and his son
Telephus, from the Belvedere of the Vatican; the Egyptian
Antinous, from the museum of the Capitol; the statue of a
Bacchus in a reposeing attitude, equally remarkable on ac-
count of the excellence of the workmanship, and its very
high state of preservation; a Bacchus, perfectly naked, carelessly
relying with his left arm on the trunk of a tree: this statue,
executed in the marble called Greco duro, is not surpassed
by any statue of Bacchus we are acquainted with.—

The sixth apartment, called Sala des Muses, contains,
besides the complete collection of Muses which belonged to
pope Pius VI., the bulbs of various philosophers and
poets, who were particularly favoured by these deifieds.
The statues of the Muses here preferred, are Clio, sitting, in
Pentelic marble; Calliope, sitting as meditating and pre-
paring to write; Melpomene, with her left foot resting on
a rock, against which she leans, holding in one hand the
dagger, and with the other the heroic mask of Hercules;
Polyhymnia, entirely wrapped up in a mantle, in excellent
preservation; Erato, in a theatrical garment, with a lyra
and her left arm; Terpichore, with the lyra of tortoise-shell;
Thalia, sitting. These seven statues were found in 1774,
at Tivoli, in the villa of Caius, called Pianella di Caius,
with the statue of Apollo Mugafetis; and pope
Pius VI. having purchased this beautiful collection for
the museum of the Vatican, caused a magnificent saloon to be
prepared for their reception. The statues of the two re-
maining Muses, Euterpe and Urania, which were not
among those found at Tivoli, were taken from the palazzo
Lancellotti, at Veletri. The Apollo Mugafetis, discovered
in the Pianella di Caius, is supposed to be an antique copy
of the statue of Apollo Citharæus, by Timarchides, which,
according to Pliny, was placed in the portico of Octavia,
at Rome, together with the nine Muses by Phidias,
of which those of the Musee Napoleon are perhaps antique
copies. Among the busts of illustrious men in this room
are those of Hippocrates, of Socrates, Homer, Virgil,
and some others, most of them executed in Pentelic marble.

Besides the antiquities and the great collection of paint-
ings and drawings above mentioned, there is still a con-
iderable number of articles not yet incorporated with that
part of the museum which is exhibited for public inspec-
tion. The collection has also lately been added to by the
exquisite articles of antiquity of the Villa-Borghese, among
which are the celebrated gladiator, the group of Cen-
tauras, &c.

Another museum at Paris, which is exclusively dedi-
cated to natural history, is the Museum d'Histoire Naturelle,
known also by the name of Jardin des Plantes, it having or-
iginally been intended for a botanical garden alone, which
was instituted in 1633, according to a plan laid down by
Guy la Brosse, physician to Louis XIII. After the death of
of La Broffe, the original professor of botany of this institution, a chemical laboratory, and an anatomical theatre, together with professorial chairs in these sciences, were added to it, and the foundation was laid for the several collections. The name of Jardin des Plantes was altered into that of Museum National d'Histoire Naturelle, by a decree of the National Assembly, in the year 1793, when the institution received its present organization. We shall confine ourselves to a short account of the collections, and refer the reader for a complete history of this interesting establishment to Filcher's National Museum der Natur-Gefährichte zu Paris, 1802, and Buffon's Notice historique, &c., in the Annales du Muséum d'Histoire Naturelle, vol. i. and ii.

The upper story of the building is set apart for zoology. Here we find not only the systematic and trivial names affixed to all the species, but also tickets descriptive of the families and orders into which the animals are distributed. Thus, for instance, on entering the apartment containing the mammals, the following inscription is seen above the glazed cases at the right hand side.

1 Division.
Point d'ailes membraneuses ni de nageoires
Quadridéps proprement dits.

1 Sousdivision.
Les quatre pieds en forme de main
Quadromanes.

1 Ordre.
Dents incisives lanaires et molaires.

1 Genre: Simia; Singe.
Quatre dents incisives à chaque mâchoire; angle facial de 65 degrés; point d'abajoues, ni de queue.

After which follow the species of the genus Simia.

The mammals are in glazed cases, on which the light is thrown from above, as is the case in all the rooms. Some species of considerable magnitude, such as the giraffe, brought by Vaillant from Africa, the rhinoceros, &c. are without covering, and placed in the middle of the apartment.

The great saloon, adjoining the mammalia room, contains the remaining animals, all of them systematically arranged and ticketed, in the same manner as the mammalia. The number of birds is very considerable. The amphibious animals are classed after Lacépéde's system, as are the fishes. The animals without vertebrae are disposed after Lamarck's classification: the mollusca which belong to this class are preserved in spirits, and to each shell is added the animal thus preserved, where it could be obtained. Between the mollusca and crustacea are placed the annelides, one of the classes of Lamarck's arrangement, comprising amphipholis, aphroditii, nereis, &c. The crustacea are preserved in spirits, and also in a dried state. The complete collection of spiders, separated by Lamarck from the insects which undergo a metamorphosis, are deposited in glazed cabinets. The collection of insects is particularly enriched by the many scarce and beautiful species formerly in the possession of Réaumur and Dombey. In a separate glass case are contained the most rare and beautiful caterpillars, both in spirits, infused with air, or modelled in wax. The intestinal worms are not numerous; but the collection of the rotuaires is remarkably complete. The polypii are deposited in four large glass cases, and comprehend many scarce species.

The first room on the ground floor is allotted to the vegetable productions, which are disposed in large glass cases. Among the more remarkable objects in this room are, the collection of specimens of wood in large square pieces; the collection of fruits in spirits, which are partly preferred, and in a dried state, partly modelled in wax; a collection of gums and resins; and, in an adjoining small room, the herbaria, which, among others, contain Tournefort's, Vaillant's, and Haller's plants, together with the treasures collected by Dombey, Commeron, Forster, &c.

In the two adjoining apartments are deposited the minerals, arranged after Hauy's fifth, in fifty upright glass cases: the first room contains, in thirty-one cases, the acidiferous substances, the earthy substancess, and those minerals whose nature and affinity are not yet sufficiently well understood; the twenty-nine cases of the second room contain the inflammable substancess, the metals, the various aggregated minerals or rocks, and the volcanic productions. This collection is particularly well calculated to make the student acquainted with the method of the celebrated Hauy.

The next room contains the collections of fossil bones and petrifications, the greater part of which were brought together by the exertion of M. Faujas St. Fond.

The library, on the same floor with the mineral and vegetable rooms, is very rich in works relative to natural history, chemistry, and anatomy. In it are also preferred Commeron's and Plumer's drawings and manuscripts, the Chinese drawings of fishes, and the véline, or that beautiful collection of drawings which was begun as early as the time of Vallot (one of the first directors of the Jardin des Plantes), and which, a few years ago, constituted sixty-four volumes, forty-nine of which contain drawings of plants. Among the artists who have contributed to them are, Robert, Aubriet, Abeille, Desfontaines, Joubert, Madelaine, Baffe forte, Van Spaendonck, Marchal, Redouté, Jen., and Jun., Oudinot, &c. The drawings have been always exhibited to the public in the library. In the saloon of the library we see an exquisite statue of Buffon, with the inscription, Magnæstì Natûræ Par Ingenium.

A most valuable part of this repository is the cabinet for comparative anatomy. In the first room of it, adjoining Cuvier's house, are deposited the anatomical preparations belonging to white-blooded animals, being a collection of the most delicate preparations, almost all of them by the hands of Cuvier. Each animal is exhibited both in its natural state, and displayed by dissection. In this first room is also preferred the superb collection of models in wax of the animals represented in the "Tétraque utrinaque Siciliae," by Poli, under whose superintendence they are executed; during the revolutionary wars this collection had found its way into Hermann's cabinet at Strasburg, from whence it was afterward obtained by the Museum for the moderate sum of 6000 livres. These preparations are exquisitely beautiful, and superior even to those of Fontana.

The second room contains the organs of red-blooded animals preferred in spirits, and classed, in some measure, according to their functions. Among the human brains is the cerebrum of La Belleunce.

In the third room are deposited the skeletons of birds, Pinson's preparations in wax, and various other objects of comparative anatomy.

The fourth room contains a considerable collection of skeletons of fishes and amphibious animals, executed by the indefatigable Rouxseau with unparalleled care; also a very instructive collection of crania and teeth of various animals.

The fifth room is appropriated to skeletons of the larger ruminating and other animals, among which is that of the giraffe, from the collection of the fladholdcr.

The sixth room contains skeletons of ruminating animals of the generi bosus, antilope, capra, and ovis; in the seventh, are deposited those of the fœr, didelphis, flying mammalia, species
species of myrmecophaga, armadillos, elephants, rhinoceros, and tapir. In the eighth room is deposited the rich collection of skeletons of animals, of glares, &c.; also the well-proportioned skeleton of Bebe, the dwarf; skeletons of mummies, &c.

In the ninth large room are preserved the large oxeous frames of whales, skeletons of dolphins, cranes of the narwhal, &c.

The menagerie of the National Museum is kept in a good state, and generally very rich in scarce and curious animals. The botanical garden of this institution is among the most celebrated in Europe. For a detailed account of it, we refer to the works above quoted.

MUSEUM at Oxford, called the Ashmolean Museum, is a noble pile, erected at the expense of the university, for the promoting and carrying on several parts of curious and useful learning. It was begun in 1679, and finished in 1683, at which time a valuable collection of curiosities was presented to the university by Elias Ashmole, esq. and the same day there repolished, and afterwards digested and put in a just order by Dr. Plot, who was constituted first keeper of the museum.

Divers considerable accessions have been since made to the museum; as of hieroglyphics and other Egyptian antiquities, by Dr. Huntington; and of an entire mummy, by Mr. Goodey; of a cabinet of natural curiosities, by Dr. Lister; also of divers Roman antiquities, altars, medals, lamps, &c.

Over the entrance of the museum is this inscription: MUSEUM ASHMOLEANUM, SCOLA NATURALIS HISTORIE, OFFICINA CHYNGICA.

MUSGRAVE, William, M. D. in Biography, a learned physician, was born at Charlton-Musgrave, in Somerfettshire, in 1657. He was educated at Winchester, and afterwards at Oxford, where he was made probationer fellow of New college in 1675. His first intentions were to study the law; but he afterwards adopted the profession of medicine, and was elected a fellow of the Royal Society, of which body he was appointed secretary in 1684. In this capacity he edited the Philosophical Transactions, from No. 167 to No. 178 inclusive: he likewise communicated several papers on anatomical and physiological subjects to the society. In 1689 he took the degree of doctor of physick, and became a fellow of the College of Physicians. Ultimately, however, he quitted London, and settled at Exeter, where he practiced his profession, with considerable reputation and success, for nearly thirty years, and died in 1721. Beyond the circle of his practice, he made himself known principally by his two treatises on gout: the one, "De Arthritis Symptomatica," Exon. 1703; the other, "De Arthritis Anomala sive Interna," ibid. 1707; both which were several times reprinted. They contain numerous cases of the disease, under all its forms and irregularities; but the author not infrequently ascribes to gout, symptoms which probably were not connected with that malady. Nevertheless, these are valuable practical works.

Dr. Musgrave was also a dilligent antiquary, and published several learned tracts upon the subject of his researches in this way; especially one, entitled "Belium Britannicum," 1716, octavo, which treats of the topography, history, and antiquities of Hampshire, Wilts, and Somerfettshire, which were anciently in the possession of a tribe of Belgae. He likewise published "Julii Viraliis Epitaphium cum Commentario," 1711; "De Legionibus Epitoliu," "De Aquilis Romanis Epitola," 1713; "Inscriptio Tarraconensis, cum Commentario," "Gesta Britannica," &c. 1715; and "Differtatio de Dea Salute," 1716. Gen. Biol.

MUSHAKEN, in Geography, a town of Peria, in the province of Irak; 35 miles N.N.W. of Ispahan.

MUSHIEDAU, a town of the kingdom of Candahar; 60 miles W. of Ghizni.

MUSHKROOM, in Botany. See FUNGI, PHALUS, and AGAMIC.

Matthiolus mentions mushrooms which weighed thirty pounds each, and were as yellow as gold; Fer. Imperator tells us, he saw some which weighed above a hundred pounds a-piece; and, to add no more, the Journal des Scavans furnishes us with an account of some growing on the frontiers of Hungary, which made a full cart-load.

The poison of mushrooms has been much talked of by several persons; but there seems to be no certain account of any body's ever having been injured by eating the common mushroom, unless by accident, as from the eating too many at once, and thereby over-loading the stomach; or by their being eaten by persons who had a particular dis- like to them, as some persons have to the most innocent aliments, particularly to cheese. If these mushrooms had any poisonous quality, it must have been often found out by the physicians in such a place as London, where there are annually such vast quantities of them consumed, yet nothing of this kind is observed; and there seems, upon the whole, to be nothing hurtful in this species; though there may be many others which, are truly poisonous. Nor is it more wonderful, that the different subjects of this clafs of vegetables should differ in their virtues, than that those of other kinds should. The roots of carrots and parsnips are daily found a very wholesome food, while those of other plants of the same clafs, such as the water-hemlock, the dropwort, and others of the umbelliferae, are known to be poisonous.

The ancients have taken great pains to distinguish the several kinds of mushrooms, that the world might know the hurtful from the safe. The boletus mentioned by Juvenal, on account of the death of the emperor Claudius, is sufficiently described by Pliny. Clusius, among the moderns, has described a vast number of different species, every where distinguishing the eculent and wholesome from the poisonous or pernicious kinds. The several authors who have treated of them since the time of Clusius, have all mentioned the effects of some of other of the poisonous kinds; and there are numerous instances of the mischief done by them at one time or other. Some have been willing to ascribe this mischief to animalculae inhabiting the plant; but this seems erroneous, and particularly from the following instance: we have one kind of mushroom growing in England, called the white acrid fungus. This is so extremely sharp, that it stimulates the tongue, as if it had been touched with spirit of niter; and Tournefort observes, that if rubbed on blue paper, it turns it red in the same manner as that liquor, or any other of the violent acid spirits would: this caustic quality remains in the plant even after drying; and it is very evident, that we need look no farther than this for the origin of the poisonous quality in this species. There is another kind which is observed to kill the very flies as they settle upon it. It is not probable that such plants as these should be inhabited by any kind of animalculae, nor is it necessary to have recourse to such caustics of the mischief which ensues from the eating them, when their own juices from so very able to have occasioned it. Philof. Trans. N. 473. P. 54.

Mr. Miller says, that the true eatable mushroom is disting-
The vast variety of known fungues, which are found regularly every season in their proper foils, are not all that the naturalist has to inquire into the nature of; there are others whose productions are much more surprising. There are such as are only seen once or twice in an age, and that in places where it is very difficult to account for the manner of their production. One of these we had some years ago, which appeared upon an old piece of wood in a blacksmith’s cellar in the Haymarket, and grew to twelve inches or more in height; and, when cut down, appeared again at the same time the next year, and so on for several succeeding years, as if, contrary to the nature of the generality of these plants, it had a perennial root, and grew regularly from the old flock. This appeared to us a singular production, and a wholly new species; but so long ago as in the year 1692, Mr. Tournefort found such a one growing on an old beam in the abbey at St. Germaines. His description of it is very accurate; and its resemblance with our’s as great as could be expected, in fo loose a growing plant as an irregular fungus. The beam on which this mushroom grew was very firm and found in all other places, but just where it was rooted there was a crack, out of which moisture oozed; and probably the beam was in that part rotten, or worm eaten within. The smell of the plant was like that of others of the same kind, and an infusion of a piece of it turned an infusion of turnip to a bright red; so that it manifestly abounded in acids.

It is not easy to account for the appearance of these plants which are seen so rarely, and that in places where no plant could be expected to grow; the only probable solution of the point seems to this, that as the seeds of the mushroom kind are all very minute, and generally in these species which have no lamellated heads, cover the whole surface of the leaves, the number of seeds produced by one such plant must be numerous beyond all account, and at the same time light enough to float about in the air. These must be at times thrown against a thousand different bodies where there is no proper nourishment for them, and must therefore perish; whereas, if any accidents are required to concur, to make a foil proper for it to grow in, wherever such soils happens to be produced, as the air has free access every where, it is not impossible but that, at one time or other, one of these small seeds may happen to be properly deposited. Mem. Acad. Par. 1692.

The Laplanders have a way of using fungues, or common toad-frogs, as we call them, as the Chinefe and Japanese do the moza, to cure pains. They collect the large fungues which they find on the bark of beech and other large trees, and dry them for use. Whenever they have pains in their limbs, they bruise some of this dried matter, and pulling it to pieces with their fingers, they lay a small heap of it on the part nearest to where the pain is situated, and let it on fire. In burning away, it blisters up the part, and the water discharged by this means generally carries off the pain. It is a coarse and rough method, but generally a very successful one, especially when the patient has prudence enough to apply it in time, and resolution enough to bear the burning to a necessary degree.

Mushroom, Pepper. See Pepper.

Mushroom Gall, in Natural History, a name given by authors to a small species of galls very common on the leaves of the oak in September and October, and resembling the common elegant mushroom. They are placed on the upper surface of the leaf, and are often in great numbers on it. The leaves which have considerable numbers upon them make a very beautiful figure, and appear as if ornamented by
by art with a number of elegant figures. These galls are usually about a sixteenth, though sometimes a tenth of an inch in the diameter; they are composed of an orbicular head, which adheres to the leaf by a very short pedicle, so that its edges which droop a little in the manner of those of the common mushroom, usually touch the surface of the leaf all round. These little galls are of various colours, according to their different degrees of maturity; they are of a greenish-white at first, after that they become of a yellowish tinge, from which they pass through all the shades of orange and flame-colour to a very beautiful red, which is always their colour when perfectly mature. When they are observed by the microscope, their surface appears hairy, and the several hairs all stand near one another at their bases, and diverge at their points, as is the natural confluence of their standing on a convex body. Reaumur, Hist. Insects, vol. vi. p. 194.

The use, as well as the figure, of this gall is very singular. Malpighi and M. Reaumur have both described it, and the former of these authors describes a cavity in the centre of the head; but this seems to have been done at random, and rather supposed from analogy, than found in fact; for the latter author, who is perhaps one of the most accurate observers that ever wrote, could never find any cavity in any one of the great numbers he dissected; but he observed what was an U, the same kind with that of the other galls, in this, though performed in a different manner; they are plainly all destined for the lodgment and security of small animals; not to be distinctly seen without the help of glases; but they are of the nature of those worms which turn into two-winged flies.

The flies into which these worms are finally transformed, have not yet been discovered; but this is no wonder, since the animals themselves are to minute as to require glases to view them. It is probable that they undergo their change in the chrysalis state in some other place, for they are never found in it under the galls; but this is common also to many other species.

**Mushroom Worms.** The various species of mushrooms are subject to be eaten and destroyed by a great variety of insects. There is, however, one species which is more frequent than all the rest, and which has therefore obtained, among authors, the name of the mushroom worm. This is a white worm, with a hard scaly black head; it has some fleshy tubercles, which it throws out at pleasure from the under part of its several rings, and which serve it as legs. This is found indifferently in almost all the species of mushrooms; but in none so frequently as in the great wood-fungus, which is porous and greenish underneath. It is found to change to a tipula or long-legs of no great beauty, being of a dulky brown colour, and middling lize.

The other species of funguses have also their worms; but there is one of a very singular nature which is found frequently on the agaric which grows on the stumps of oak trees especially near the roots. This is a long and slender worm, somewhat flattened, and resembling a small leech, but that it has a hard and scaly head of a blackish colour. The body is composed of many rings, in the manner of the earth-worm, and looks very bright and glossy, being always covered with a viscous liquor. This creature is easily found, for it never eats into the substance of the fungus, but only crawls about its surface; the traces, wherever it has been, are marked with a coat of a shining varnish, and resemble the places over which snails have crept.

This worm makes a very beautiful object for a microscope. When young it is as transparent as glafs, and the motion of its internal parts is very easily distinguished. When this creature is to pass into the chrysalis state, it does not remove from the fungus, but spins itself a web, and remains upon it. This web is composed of the same material with the covering or habitation under which it usually resides, but it is thicker, more opaque, and of a coarser structure.

The creature remains about a fortnight under this covering, and then comes forth in the form of a fly, which is evidently a species of tipula. It has very long legs, and a long and slender body; the body is brown, and the breast yellowish; the wings are long and slender, and the antennæ are of a very singular and remarkable figure; they are broad and flat, and yet terminate in a point. These are composed of several articulations, and make a very beautiful figure when examined by the microscope.

Besides these, this fly has, in the manner of the other tipula, a pair of beards placed on the anterior part of the head, which it at pleasure bends down over the face, and completely covers with them the longitudinal suture, which is the mouth, situated in this as in the other tipula: Reaumur, Hist. Inf. vol. ix. p. 23, seq.

** MUSIC, as well defined by Rousseau, is the art of combining tuneful sounds in a manner agreeable to the ear. This art becomes a profound science, when geometry is called in to find and to ascertain the principles of these combinations, and the ratios of those affections which they excite. Arifides Quintilianus defines music the art of finding the beautiful and decorous in musical tones, and in their measure. It is not surprizing, that with definitions so vague and general, the ancients have given a latitude so extensive to the art which is thus defined.**

It is generally supposed, that the word music comes from mu/a, because it was imagined that the art was invented by the Muses; but Kircher, from Diodorus Siculus, derives the title from an Egyptian word, pretending that it was in Egypt that music began to be cultivated after the deluge, and that the first found that was heard came from the reeds on the banks of the Nile, when blown into by the wind. Whatever etymology may be adopted, the origin of the art certainly came from something nearer man, and if speech has not begun by singing, it is certain at least, that whenever men speak, they sing.

Music naturally divides itself into theoretical or speculative, and practical. Speculative music may, perhaps, be called a knowledge of musical materials, that is, of the different ratios of grave and acute, of quick and slow, hard and sweet, loud and soft, of which sounds are susceptible; relations which comprehend all the combinations possible of sounds and of music, and seem also to include every cause of those impressions which their succession can make upon the ear and the soul.

Practical music is the art of applying and judicially making use of speculative principles, that is to say, of conducting and disposing sounds with respect to their confluence, duration, and succession, in such a manner, that the whole may impress upon the ear the effect proposed; it is this art which is called composition, which fee. With respect to the natural production of sounds by voices or instruments, which is called execution, it is merely a mechanic operation, which only supposes the faculty of producing just intervals, accurate duration of notes, and giving to each sound the degree preferred by the key, and the value required by the time; all which rigorously requires no other knowledge.
knowledge than that of musical characters, and the habit of expressing them.

Speculative music consists of two parts; knowledge of the ratio of sounds or their intervals, and of their relative duration, with respect to time or measure.

The first is what the ancients called harmonics. It teaches in what melody consists, and marks what is consonant, agreeable or displeasing in modulation. It treats, in short, of the different ways by which sounds affect the ear by their quality of tone, their force, and their intervals; all which is equally applicable to their accord and succession. The second has been called rhythmic, because it treats of sounds with respect to time and quantity. It contains the explication of rhythm, of time, of long and short measures, lively and slow, of times and their different proportions into which they are divided, in applying them to sounds in their succession.

Practical music, likewise, divides itself into two parts, which correspond with the two preceding.

That which answers to harmonic music, and which the ancients called melopoeia, contains the rules for combining and varying intervals, consonant and dissonant, in an agreeable and melodic manner. See Melopoeia.

The second division, which answers to rhythmical music, and which is called rythmapoeia, contains rules for the application of accents, feet, and measures, indeed for the practice of rhythm. See Rhythm.

Porphyry gives another division of music, confined to motion, whether violent or languid; and without distinguishing it into speculative and practical, he finds the six parts following:

Rhythmic, for dancing movements.
Metrical, for the cadence and numbers in verification.
Organic, for the practice of instruments.
Poetic, for the tones and accents of poetry.
Hypocrític, for the attitudes of pantomimes, and Harmonic for melody.

Music, at present, divides itself more simply into melody and harmony; for with rhythmical music we have no longer any concern, and very little with the metric, as our verse is in verse as it were in verse, and when it is of their own accord. By the melody, we direct the succession of sounds in such a manner as to produce agreeable airs. See Melody.

Air, and Modulation.

 Harmony consists in uniting to each of these sounds, in a regular succession, two or more other sounds, which striking the ear at the same time, mingle it by their concord. See Harmony.

We might, and we ought, perhaps, to divide music still further, into natural and imitative: the first, confined to the mere physical property of sounds, and acting only upon the sense, does not carry its impression to the heart, and can only give sensations more or less agreeable. Such is the music of songs, hymns, canticles, and all the airs which are only combinations of melodious sounds, and in general, all music which is only harmonious.

The second by lively inflexions or passions accented, and in a manner speaking, which expresses all the passions, paint all scenes, represent all objects, and at the same time excite the heart of man with sentiments which have the power to move it. This music, truly lyrical and dramatic, was that of the ancient poets. And it is that which is in general, in which we try to be the most in a song. It is only in this music, and not in mere harmony and agreeable combinations, that we should seek to account for the agreeable effects it produced formerly. As long as we seek for moral effects from physical causes of sound, we shall never find them, and only reason without knowing what we are talking about.

Ancient writers differ very much among themselves concerning the nature, object, extent, and departments of music. In general they gave to this word a sense much more extensive than that which it retains at present. They not only comprehend music; as we have elsewhere observed, dancing, gesture, and poetry, but even the aggregate of all the sciences.

Hence all that sublime music of which philosophers speak: music divine, human music, celestial music, terrestrial music, active music, contemplative music, music ensouling, intellectual, oratorical, &c.

It is under these vast ideas that we must understand many passages of the ancients concerning music, which would be unintelligible in the sense which we give this word at present.

It appears that music has been one of the earliest arts; we find it among the most ancient monuments of human kind. It is also very probable that vocal music was found before instrumental, if ever there was among the ancients any music purely instrumental, that is, composed purposely for instruments. Not only before any instrument was found, men must have observed a difference in the tone of human voices, as well as early learned, from the natural concerts of birds, to modify their voices in a melodious manner: after that, wind instruments might have been first invented; Diodorus and other authors aborning the invention to observations that were made of the whistling of the wind in reeds, and in the pipes of other plants. This was also the opinion of Lucretius.

"At liquidas avium voces initiarius ore
Ante huit multo, quam levia caríma cantu
Concelebrarum hominum pollint, amique juvare;
Et zephyri causa per calamorum fibula primum
Agreëtis docëre cavas indare citáus."

With respect to other instruments, sounding strings are so common, that men must have observed their different tones very early; and this of course must have given birth to stringed instruments. See String.

Instruments of percussion, such as tambors and drums of different kinds, must have originated from the sonorous ringing of hollow bodies, when struck.

It is difficult to divest ourselves of these general ideas, in order to have recourse to other means for the invention of music as an art. Without mounting higher in the history of the world than the deluge, many of the ancients attribute the invention of music itself to Mercury, as well as to the lyre. Others make the Greeks obliged to Cadmus, who, in flying from the court of the king of Phoenicia, brought Hermione, or Harmony, into Greece. Whence it follows, that the art was known in Phoenicia before the time of Cadmus. In one part of Plutarch's Dialogue on Music, Lucius says that it was invented by Amphion; in another place, Socrates says that it was Apollo; and in still a third place, he seems to give the honour to Olympus. They hardly ever agree on the subject, nor is it of much importance that they should.

To these first inventors succeeded Chiron, Democritus, Hermes, and Orpheus, who, according to some, invented the lyre. After these came Phœmus; then Terpander, contemporary with Lycurgus, who furnished rules for music. Some ascribe to him the invention of the first modes. At length
length Thales is added, and Thamyris, who is said to have been the inventor of instrumental music.

Most of these great musicians lived before Homer. Others more modern were Lalius of Hermione, Melanipides, Philoxenus, Timotheus. Phryniss, Epigenius, Lyfander, Simmicus, and Diodorus, who have all considerably contributed to the formation of music.

It is pretended that Lalius was the first writer on the art, in the time of Darius Hyllaspe; that Epigenius invented the instrument with four strings, which bore his name. Simmicus invented also an instrument of thirty strings, called Simmicium.

Diodorus perfected the flute, and increased the number of holes; and Timotheus the lyre, by adding a new string to it, for which he was fined by the Lacedaemonians.

As ancient authors explained themselves very obscurely concerning the inventors of musical instruments, they are also very unintelligible concerning the instruments themselves, of which we know little more than the names. See Instrument.

Music was in high estimation among many people of antiquity, but principally the Greeks; and this esteem was proportioned to the power and surprising effects which they ascribed to the art. Their authors thought they could not exalt it sufficiently, without lifting it up to heaven, and adorning us with it the principal amusements of the gods, and reward of the blessed.

Plato has the courage to say, that no change can be made in music, without affecting the constitution of the state; and pretends that there are sounds which excite menaces of foul, insolence, and their contrary virtues. Aristotle, who seems to have written his Politics only to oppose the sentiments of Plato, agrees with him; however, concerning the power which music has over morals. The judicious Polybius tells us, that music was necessary to soften the manners of the Arcadians, who inhabited a country where the air was cold and impure; that those of Cynethis, who neglected music, pursued all the Greeks in cruelty, and that there was no city in which so many crimes had been perpetrated. Athenæus affirms us, that formerly all laws divine and human, exhortations to virtue, knowledge of what concerned the gods and heroes, the lives and actions of illustrious men, were written in verse, and sung publicly in chorus to the sound of instruments. And we see by our revered books, that such were, from the earliest times, the usages among the Iraclites, as more efficacious had not been found, of engraving in the mind of man the principles of morality and love of virtue; or rather, this was not the effect of a premeditated plan, but of the grandeur of sentiments and elevated ideas, which fought by proportionate accents to form a language worthy of them. (2)

Music made a part of the study of the Pythagoreans; they used it to inspire the heart with laudable actions, and to inflame it with the love of virtue. According to these philosophers, our soul was in a manner comprised of harmony; and they believed that they could establish, by means of the harmony of sense, the intellectual harmony and primitive faculties of the soul; that is to say, that which, according to them, subsisted in its pre-existent state, before it animated our bodies, and when it inhabited the heavens.

Music is at present fallen from this degree of majesty and power, so low as to make us doubt of the truth of those wonders which it operated formerly, though attested by the most judicious historians and most grave philosophers of antiquity. However, we find in modern history some similar facts. If Timotheus excited the fury of Alexander by the Phrygian mode, and calmed it by the Lydian, a music more modern is said to have extended this power still farther, in exciting in Eric, king of Denmark, such a fury as to kill his best domestics. Doubtless these unfortunate domestics were less sensible to the charms of music than their prince, otherwise he might have run the risk of sharing half the dangers that D'Aubigny relates another story, quite similar to that of Timotheus. He says, that in the reign of Henry III. of France, the musician Claude le Jeune, playing at the nuptials of the duke de Joyenue in the Phrygian mode, animated, not the king, but a courtier, who forgot himself so far as to put his hand to his sword in the presence of his sovereign; but the musician, halting to calm him, had recourse to the Hypo-Phrygian mode. This is said with as much confidence, as if the musician Claudius knew exactly in what the Phrygian mode and the Hypo-Phrygian consisted!

If our music has but little power over the affections of the soul, it is at least capable of acting physically upon the body; witness the history of the tarantula, too well known to be mentioned here. (3) Witness, too, the Gacof knight, mentioned by Boyle, who, at the sound of a bag-pipe, could not retain his water; to which we must add, what the same author relates of those females, who burst into tears when they heard a certain tune, which had no uncommon effect on the refl of the audience. Rouelle adds, "and I knew at Paris a woman of condition, who could not bear any kind of music, without being filled with an involuntary and violent fit of laughter." We read, in the History of the Academy of Sciences, of a musician who was cured of a violent fever by a concert at his bedside. Sounds act even upon inanimate bodies, as is manifested by the vibrating and resonance of a Sonorous body, when another, with which it is perfectly in tune, is caused to sound. Morhoiff mentions a certain Dutchman, of the name of Petter, who broke a glass by the sound of his voice. Kircher speaks of a great flute, which vibrated at the sound of a certain organ-pipe. Pere Merienne also speaks of a certain flag-flute in the pavement of a church, which trembled at the sound of an organ, as much as if there had been an earthquake. Boyle adds, that the plates tremble often at the sound of the organ in a cathedral; that he has felt them tremble under his hand, at the sound of the organ or a voice; and he has been assured, that those which were firmly put together, vibrated at some determinate time. Every one has heard of a famous pillar in the church at Rheims, which trembles sensibly at the sound of a certain bell, while the other pillars remain motionless; but what becomes found of the marvellous in this case is, that this same pillar equally shakes, when the clapper is taken from the bell.

All these examples, the chief part of which belong more to found than music, and of which physics can give some explanation, render not the marvellous and almost divine effects, which the ancients attributed to their music, more intelligible or worthy of credence. Many authors have tormented themselves in trying to account for this. Wallis attributes it greatly to the novelty of the art, and the exaggeration of authors. Some bellow all the honour upon poetry; while others again suppose that the Greeks, having more sensibility than we, from the constitution of their climate or their manner of living, might be moved by things which we never feel. M. Buffet, even in adopting all these tales, is of opinion that they prove nothing as to the perfection of the music that has produced them; he sees nothing in their performance but what miserable village seraphs might have achieved, according to him, as well as the first musicians in the world.
MUSICAL

Most of these sentiments arise from our persuasion of the
c Excellency of modern music, and from the contempt which
we have for the ancient. But is this contempt as well
founded as we imagine? It is a subject that has often been
discussed, and which, from the obscurity of the matter, and
from the insufficiency of the judges, is still in need of better
discussion. Of all those who have written in this
conflict, Isaac Vossius, in his treatise "De Poematum
chantu, et de Viribus Rhythmico," seems best to have dis-
cussed the question, and approached the nearest to truth. (4).

The world has so long wished to see some fragments of the
music of the ancients, that father Kircher and M. Murette
have laboured to gratify the public on the subject. (5)
But who shall dare, says Rouffeau, to judge of ancient
music by such fragments? I suppose them faithful, but
should wish that those who examine them should sufficiently
know the genius and accent of the Greek language; that
they should recollect, that an Italian is an incompetent judge
of a French air, and that a Frenchman is utterly ignorant of
Italian melody: then let them compare times and places,
and pronounce, if they dare.

Thus far, in this important article, which furnishes a text
for almost all other articles in our musical department, we
have faithfully translated Rouffeau, preferring him to all
other musical lexicographers, for his eloquence, good taste,
and enlarged views on imitative or dramatic music. We
must however own, that he has some strong prejudices, per-
haps bordering on paradox, as in his other writings; and in
some few instances, there is a want of recent and accurate
information. Thlefe, however, we shall point out, to put
our readers on their guard against error as much as we are
able, particularly in writers of eminence.

Notes to Rouffeau's article Music.

(1). We think that Rouffeau's partiality here for imitative or
dramatic music, made him forget that there was any other.
To imitate the human speech and passions, it is doublesleft the
highest style of musical composition and performance; but
as there are three distinct styles of music, as musica di chiesa,
church music; musica teatrale, theatrical music; and musica
di camera, chamber music, we shall, therefore, plead the
cause of all. As we cannot always be in a theatre, is har-
monic music to banish the church and the chamber?
In the church its reverential and solemn simplicity render it
fittetl for the place and purpose of its performance. Imi-
tative music is not precluded the chamber in cantatas and
opera fecenes; but mere instrumental music brought to its
present degree of perfection in the trios, quartets, quintets,
and symphonies, such as those of Haydn, Mozart, and
Beethoven, can amuse, interest, and delight cultivated ears
even to rapture. Yet this sublime music is not properly im-
tative, there being no words to explain it, or fix its meaning.

(2). The numerous stories of the extenfive use and miracu-
ulous powers of ancient music have been lately so often told by
musical historians and others, that our lexicographer might
have spared himself the trouble of repeating them.

(3). Rouffeau had not heard that this medical and mira-
culous power of music, so long believed and asserted,
"has not the least truth in it." See Phil. Transf. vol. ix.
for the year 1770, letter from Dr. Currilo; and "Lezioni
fopra la Tarantula," Nap. 1770.

(4). This partiality for Isaac Vossius will be further con-
sidered under the biographical article of this credulous cham-
pion for the music of the ancients.

(5). But Vincento Galilei, and Dr. Fell, bishop of Ox-
ford, were the first editors of these fragments of ancient
Greek music.

The article Music of Rouffeau is in fact a compendium of
its history. After an elogie on Isaac Vossius, he mentions
the national tunes given on the plates of his dictionary.
The celebrated Swits tune, called the "Ran des Vaches,
" an air, he says, so dear to the Swifs, that it was forbidden
under the pain of death to play it to the troops, as it imme-
dately drew tears from them, and made those who heard it de-
Iert, or die of what is called la maladie du pain, so ardent a de-
fire did it excite to return to their country. It is in vain to
seek in this air for energetic accents capable of producing such
agonizing effects, for strangers are unable to account
from the music, which is in itself uncouth and wild. But it is
from habit, recollections, and a thousand circumstances re-
traced in this tune by those natives who hear it, and remind-
ing them of their country, former pleasures of their youth,
and all those ways of living, which occasion a bitter reflection
at having loft them. Music, then, does not affect them as
music, but as a reminiscence. This air, though always the
fame, no longer produces the fame effects at present
as it did upon the Swifs formerly; for having loft their
taste for their first simplicity, they no longer retreg its lofs
when reminded of it. So true it is, that we mull not seek
in physical causes the great effects of found upon the human
heart.

Rouffeau, wishing to have no important part of the
discourse or art of music unnoticed in his long article on
the subjeft, speaks of the Greek musical notation, upon
which, however, he has been able to throw no new light.
See the articles Musica Antiqua, Characters, Boe-
thus, Pape Gregory, Guido, Points, Staff, and
Gammut.

The invention of modern musical characters has been long
ascribed to John de Muris, but erroneously. See Time-
Table and De Muris, where he acknowledges himself,
that Franco was the inventor of the fift characters used for
time in counterpoint. See Franco.

Rouffeau, in the recapitulation of his elaborate article, gives
a lift of Greek, Roman, and modern writers on the subjeft
of music of the greattest eminence; but these will be found
detailed in their several alphabetic places. As all the writers
on music from Aristroxenus to the present time, that could
be found, have been procured and consulted, and for others,
which we were unable to appropriate, it may appear ollaentia-
tions to say, however true, that we have had recourse to most
of the great libraries in Europe, such as the Vatican, the An-
brohan library at Milan, the Imperial library at Vienna, the
Bibl. du Roi at Paris, the Bodleian, and principal college li-
ibraries of our universities, his majesty's library at the queen's
house, the Musem library, &c. &c. in which, besides MSS.
we have found almost all the printed books on music men-
tioned in the lists of Broffard, Padre Martini, Salamafius,
Fabricius, and others. In none of these scarce books,
however, nor in others in general circulation, has the deri-
vation of the word music, or the inventor of the art, been
settled to satisfaction. Some make the musical found that
was likely to have been first noticed by man, animal, and
some vegetable. The dried finews of the dead tortoise, ac-
cording to some, suggested the method of producing sounds
from the tension of strings; and zephyrs, it has been ima-
gined, breathing through broken reeds on the banks of the
Nile, were the first flutes or wind-instruments. But we shoul
d rather suppose, that in a state of nature, even before the in-
vention of language, mankind communicated their fenfations
of pain or pleasure to each other by the mere cries of na-
ture; in pain and affliction, the expression would be groans,
fear, and howling, which could never be tuned; but in
joy.
joy, pleasure and affection, they would be pleasant to hear, though not formed into music, from the ideas which they would excite in the hearers, in reflecting on their own happiness when similar effusions spontaneously escaped them in their most happy moments. wishing to renew such grateful sounds at pleasure, even by remembrance of what they had felt in uttering them, they would try to revive them in moments of tranquillity; and as nature gives more pleasing and touching voices to one creature of the same species than another, finding themselves listen to with pleasure by others, the natural fingers would consequently try to render their vocal expressions of internal satisfaction as pleasant as possible. Hence the first language, as well as first music, was intuitive, and all improvisation.

Of all to whom the invention of music has been assigned, there is none to whom we are more inclined to give our suffrage than another; all we could do was to present them to the readers, and beg of each to please himself by voting for him whom they shall deem the most worthy.

Musica Antiqua, It aut, music of the ancient Greeks and Romans down to the eleventh century, when Guido Aretino, about the year 1024, invent or revived music in parts, or counterpoint, which may, with propriety be called antica moderna; ancient with respect to the Greeks, and modern with respect to us.

Musica Arithmetica, that part of the science which considers sounds by the aid of numbers. These numbers are 2, 3, and 5, together with their composites. They are so called, because all the intervals of music may be expressed by such numbers. See INTERVAL.

This is now generally admitted by musical theorists. M. Euler seems to suppose, that 7 or other primes might be introduced; but he speaks of this as a matter doubtful and difficult. It is to be observed, that 2 corresponds to the octave, 3 to the fifth, or rather to the twelfth, and 5 to the third major, or rather the seventeenth. From these three may all other intervals be found.

A table of musical numbers within any proposed limit may be thus expeditiously formed.

Place the terms of the progression 1, 5, 25, 125, &c., in a column under each other; and multiply every term of this progression by 3, continually, till you foresee that the products will exceed the proposed limit. Then if all the numbers thus found be doubled continually, till it be foreseen that the doubled numbers would exceed the proposed limit; all these products together, with the powers of 2, will give the musical numbers required.

Thus, if we were required to find all the musical numbers within the compass of eleven octaves; that is, between 1 and 2048, form the column 1, 5, 25, &c. and multiply every term by 3 continually, as in the annexed example:

</tbody>
</table>

The numbers of which being doubled as often as possible within the limit 2048, and collected and ranged in order with the powers of 2, will give the following numbers, 1, 2, 3, 4, 5, 6, 8, 9, 10, 12, 15, 16, 18, 20, 24, 25, 27, 30, &c. as in the annexed table.

To understand this table, it is to be observed, that by dividing a given fretted slring or chord, by means of a moveable bridge, the sounds produced by its parts will be higher in pitch than those produced by the given chord. And on the contrary, if we multiply a chord, that is, by a moveable bridge lengthen the sounding part of a chord, we shall have sounds lower in pitch than the given chord. Hence we have the foundation of an ascending, and of a descending scale of musical sounds. The first column of each division of the table, marked Num, expresses the musical numbers; the second column, marked Afc, the names of the notes in the ascending scale; and the third column, marked Defc, the names of the notes of the descending scale. Thus, if the given chord be unity, and called F, then will 15 be E in the fourth octave, ascending of F; 45 will be B in the sixth octave of F, &c. In the descending scale, unity will be B; 15 will be C in the fourth octave.
tave descending from B; and 45 will be F of the fifth octave, &c.

The reason why unity is marked F in the ascending scale, and B in the descending scale, is, because, according to the received notation of what is called the natural scale among musicians, F has no fourth in ascending; nor B a fourth in descending. Now it is plain that no aliquot division of a string can give a fourth, or any of its octaves ascending; nor can any multiple of a string give the fourth, or any of its octaves, in descending. For the fourth being expressed by 2 in ascending, and by $\frac{1}{2}$ in descending, its octaves will be $2', 3', 4', &c.$ in the first case, and $\frac{1}{2}, \frac{1}{3}, \frac{1}{4}, &c.$ in the second case, none of which numbers can be multiples, or submultiples of a given string.

F and B being the given sounds, their octaves will be expressed by $F'$, $F''$, $F'''$, &c., and $B'$, $B''$, $B'''$, &c. which are respectively, the first, second, and third octaves, above the F, and below B.

A dot marked over a letter shews that it signifies a sound higher by a comma than the sound expressed by the letter itself. And a dot placed below, denotes the sound to be lowered by a comma. Thus, in the table I find 81 to be $A \mid G$, which denotes that A, or the sharp in the seventh octave of F, ascending, is raised a comma; and that G, or the sharp third from B, descending, is lowered by the fame interval.

If B in the descending scale be supposed to be a tritonus, that is, two tones major and one tone minor above F of the ascending scale, then will A in one of these scales correspond or be denoted by the fame numbers with G in the other scale, and C will correspond to E, but D in the ascending scale will not be expressed by the fame numbers as in the descending scale: for in the former, D will be a tone major above C; whereas in the latter, D must by analogy be a tone minor below E, and therefore only a tone minor above C, which is the reason why D is in italics in the descending scale.

Mr. Henfling has mentioned the distinction between an ascending and a descending scale in the Mefcal, Berolinfen. He places unity in the ascending scale in F, as it ought; but in the descending scale he places unity in E, which disturbs the analogy of the two scales.

The trumpet and French horn, not having (commonly) a compass beyond four octaves; and their sounds being formed in a manner analogous to those produced by the division of a string, it follows, that all the true notes of these instruments will be represented by the musical numbers 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, &c. This is a fact well known; and a confirmation of the truth of that theory, which derives all musical proportions from the elements 2, 3, and 5. Phil. Trans. N. 1795, and N. 481. See Trumpet.

Music, Chromatic, musica chromatica, among the Italians, is used to express that kind of music in which there are many chromatic signs, as flats or sharps, and intervals, &c. See Chromatic.

Music, Diatonic. See Diatonic.

Music, Didattic, musica didactica, that part of speculative music which only considers the quantity, proportions, and different qualities of sounds.

Music, Dramatic, musica dramatica, scenica, theatralis, among the Italians, is used to denote such compositions of music as are particularly made and fitted for theatres. See Dramatic and Recitative.

Music, Enharmonic. See Enharmonic.
notes, figures, pause, and all other signs and marks whatever, used in music.

Musica Tranfalpina, the title given by N. Yonge to a collection of Italian madrigals with English words, published in 1588.

"Musica Tranfalpina, Madrigales translated of four, five, and six parts, chosen out of divers excellent authors; with the third and second part of La Vignella, made by Maitur. Bird upon two Stanzas of Ariosto, and brought to speak English with the rest. The editor was an Italian merchant, who having opportunities of obtaining from his correspondents the newest and best compositions from the continent, had them frequently performed at his house, for the entertainment of his musical friends. Thefe being selected from the works of Palerminio, Luca Marenzio, and other celebrated masters on the continent, seem to have given birth to that passion for madrigals which became so prevalent among us afterwards, when the composers of our own nation so happily contributed to gratify it.

The translator of these madrigals, whoever he was, for the editor does not tell us, seems in general to have imitated the original Italian measure and structure of verse, as well as ideas; and though they abound with concerti, to which not only Italian poets, but those of all the rest of Europe, were then so much addicted, the general tale of the times was indulged in poetry as well as music, and metre and melody were at once furnished with new models.

In 1597, Yonge published a second collection of madrigals, out of sundry Italian authors; in which, among others, there are three by Creco, three by Luca Marenzio, and two by Ferabosco. The words of these have as little claim to poetical merit as those of the former set.

Musica, Vocal, musica vocalis, or that composed for the voice, in opposition to organical or instrumental, which is intended to be played on instruments only.

Musica-Shell, in Natural History, the name of a species of shell-fish of the murex kind, remarkable for its variegations, which confift of several series of spots placed in rows of lines, like the notes of music.

Musical Glasses. See Armonica.

MUSICAL INSTRUMENTS of India, or Indian musical instruments, in the hands of the performers. In Plate V. Musica, is the representation of a music-galler over a triumphal arch, through which the Great Mogul passed at Agra or Delhi, before his fall. The procession consisted of the emperor, mounted on an elephant; his wives and concubines, eunuchs, great officers of state, &c. all exquisitely painted. As to the heads of the females, Sir Joshua Reynolds and Sir Robert Strange, to whom the painting on ivory was shewn, thought each head sufficiently high finished to be set in a ring. This original painting is in the possession of Dr. Burney.

Musical String. See Strings.

Musicalement, Fr., in a musical manner, according to the rules of music.

Musician, a title given equally to him who composes and to him who performs music. The first is, however, more frequently and more civilly styled compose; which see.

Musicians, among the ancients, were poets, philosophers, and orators of the first class. Such were Orpheus, Terpander, Steichorus, &c. Nor would Boethius honour with the name of musician him who only in a servile manner practised music mechanically with his fingers or voice, but him who pollieved the science of music by reason and speculation.

"Musiciorum et cantorum Magna et dilectissima, Ite dicent, illi sciant, Quae componit musica, &c."

"Between a finger and musician
Wide is the distance and condition.
The one repeats, the other knows;
The sounds which harmony compose.
And he who acts without a plan,
May be defined more beast than man."

Guido has quoted these verses in the Prologue to his "Antiphonarum;" and in his short tract, "De Constitutionibus Musica," he is very severe on the fingers of his time: "Temporibus notris super omnem fatum cantores."

"And it seems," says Rouillé, "that to mount to an elevated expression in oratorical and imitative music, the human passions and the language of nature must have been made a particular study. However, the musicians of our times, bound for the most part by the practice of notes, and a few paffages, will not, it is hoped, be offended, if we should not hold them to be great philosophers."

MUSICE'S MONUMENT, the title given by Mace to his treatise on the lute. See MACE.

MUSILLIM, or MUSLIN ALI, in Geography, a numerous tribe of Arabians on the borders of the Persian gulf, between Omar and Lachfa.

MUSIMON, in Natural History, the name of an animal esteemed a species of sheep, described by the ancients as common in Corsica, Sardinia, Barbary, and the north-east parts of Asia. It has been supposed, whether the animal described under this name is now any where to be found in the world; not that it is to be supposed that any species of animal once created is become extinct, but that this probably was a spurious breed between two animals of different species, perhaps the sheep and goat, which, like the mule, not being able to propagate its species, the production of them may have been discontinued.

Belon also describes this species of goat, which has large horns bending back, close at their base, distant at their points, with circular rumps, the tragealbus, from the mixture it seems to have of the goat and deer. Buffon supposes it to be the sheep in a wild state; and as such described by Mr. Pennant. These animals live in the mountains, and run with great swiftness among the rocks. Those of Kamtchacka are so strong that ten men can scarcely hold one; and the horns are so large as sometimes to weigh 30 pounds, and so capacious, that young foxes often shelter themselves in the hollow of such as accident fall off in the defects. See Ovis Ammon.

MUSIMPOUR, in Geography, a town of Hindoostan, in Bahar, near the right bank of the Ganges; 14 miles S.E. of Patna.

MUSITAU, Charles, in Biography, a physician, was born at Calravalle, in Calabria, in January 1635. He received his medical education, and took the degree of doctor, at Naples, where he likewise fixed his residence, and obtained considerable reputation as a practitioner. He was honored
honoured by being elected into the different learned societies of Italy, and by the appointment to a professorship in the university of Naples. He combined the two profeffions of theology and phyfic in his own person; and as his succedefs excited the jealousy and rancour of his less fortunate brethren, the averted incendiery of this combination was made a pretext for attempting to interdict him altogether from the practice of medicine. His merits, however, obtained for him the patronage and protection of pope Clement IX, and of cardinal Pignatelli, archbishop of Naples, (and afterwards the sovereign pontiff, under the name of Innocent XII.) who permitted him to hear confessions. He lived in the general esteem of his fellow citizens, and died regretted in 1714, at the age of 97. In his pathological creed, he was a staunch adherent of the chemical ferment, and an avowed enemy to Galenism. His descriptions of disease are prolific and obscure; and his hypotheses and practice abound with the errors of the school, to which he was attached. The following is a catalogue of his writings. "Pyreologia, feu de Pebribus," Naples, 1683. "Del Mal Francelo," in four books, 1697. "Chirurgo Theoretico-practica, feu. Truitina Chirurgico-phyllica," Genev. 1698. "A pologia celeberrimorum Virorum," ibid. 1700. "Tru tina Medico-phyllica," ibid. 1701. "Mantilla ad Hadriani a Mnifici Thfaurum et Armamentarium Medico-phylicum," ibid. 1702. "De Morbis Mullerum," 1709. These works were published collectively at Geneva, in two vols. folio, 1701, and in two vols. folio, 1716. The latter edition contained also some other tracts by the author. Eloy Diet. Hilt. de la Med.

MUSITRAN, in Geography, a town of South America, in the province of Tucuman; 42 miles S.E. of Rioja.

MUSIVUM ARGENTUM. See ARGENTUM.

MUSK, Moschis, derived from the Arabic moscha, murf, whence was formed the common Greek μυρχά, μυρή, a kind of perfume of a very strong scent obtained from various animals; only agreeable when moderated by the mixture of some other perfume.

Musk is found in a kind of bag, or tumour, growing about the bigens of a hen's egg under the belly, the corporal parts of a wild beast of the same name; and appears to be nothing else but a kind of bilious blood there congregated, and almost corrupted. It is formed of a membraneous and mucular substance, provided with a splinter. Many glands are observable within, which separate the humour.

The animal, which produces it, is very common in the kingdom of Bantam, Tonquin, and some others, as Cochinchina, &c. But the most esteemed are those of Tonquin and the kingdom of Thibet. See MOSCHITFEM Animal.

They inhabit the woods and forests, where the natives hunt them down: when the beast is killed, they cut out the bladder under the belly, separate the coagulated blood, and dry it in the sun, where it is reduced into a light friable substance almost of the nature of a powder, and of a dusky reddish colour, and acquires a very strong and disagreeable smell. It is then tied up again in bladders, and exported to other countries; and the musk which we use.

The musk itself is dry, with a kind of unctuity; of a dark reddish-brown, or rufly-blackish colour; in small round grains, with a very few hard black clots; perfectly free from any sandy, or other visible foreign matter. Chewed, and rubbed on paper, it looks bright, yellowish, smooth, and free from grittinches. Laid on a red-hot iron it catches flame, and burns almost entirely away, leaving only an exceeding small quantity of light greyish ashes: if any earthy substanines have been mixed with the musk, the quantity of the residuum will discover them. Genuine musk ought to be confused totally upon hot coals. From 30 grains of musk, water extracts 12 grains, and spirit of wine ten grains. Spirit of nitre and oil of vitriol totally dissolves it: the former destroys the whole of its smell and the latter the greatest part of it. Spirit of salt, diluted spirit of vitriol, and vinegar, have no effect upon it. Spirit of fial ammoniac diffuses a little of it. Oil of tartar fiercely acquires any tinge from musk, but extricates from a putrid urine from musk. Musk is not soluble in oils expressed or distilled. By distillation in a retort it yields the animal principles, enypneumatic oil, volatile spirit, and falt.

In the distillation of odoriferous waters and spirit, a small portion of musk, included in a linen cloth, is generally hung in a still-head, the vapour of both liquors extracting its fcent. Spirit, distilled with musk immersed in it, acquires little of its smell; but water by this method acquires both the smell and talle. A minute portion of musk greatly improves the fragrance of the distilled odoriferous waters, as thofe of lavender and rosemary, and heightens the smell of other odoriferous ingredients, without communicating any of its own peculiar smell. The quantity of liquor, which may be flavoured by macerating a certain known proportion of musk, for a few days, in rectified spirit of wine, appears to be the best criterion of the genuinenes and goodnids of this commodity; a commodity, which is not only said to vary according to the seon of its being taken from the animal, but which is sometimes so artfully sophicated, that the abutes cannot be discovered by any external characters, or by any other means than the degree of its specific smell and talle, which the above experimen affords the best method of estimating. Neumann and Lewis.

From the result of chemical experiments, musk appears to contain albumen, gelatine, muriate of ammonium, phosphat of soda, and an uncombined acid; but the greater part of it consists of a resin combined with a volatile oil, and a mucilaginous extractiv trait.

Musk is in considerable use among the perfumers and confectioners, though much less now than it was formerly. It is supposed to fortify the heart and brain, and is good against deafness, and is now received in general practice in different convulsive disorders; and its dose has been increased with advantage to a scruple and half a drachm, every four or fix hours.

Musk and other perfumes of the fame tribe, have been long celebrated as antipafmodics, but were formerly ordered in such small quantities as to have little effect. Practitioners thought four or five grains a large dose. But the Chinese have taught us to be more bold; the tenth part of an ounce is a useful dose among them. The remedy in the East for the bite of the mad dog contains 16 grains of musk, and this they repeat frequently.

The effects of musk are easy from pain, quiet sleep, and a copious diaphoresis. Hence it has been found of great use in fpasmatic disorders, petechial, malignant, putrid fevers, the gag disenter, hiccoughs, subfluenza typhus, &c. For the particular cases, we refer to the Philosophical Transactions, N° 474. § 18. and vol. xlv. p. 75. &c. Illnaces occur in which it has been of very great benefit in convulsive disorders, in the London Med. Obs. &c. vol. iii. art. 21. 31.

It has also been found useful in fpaumatic disorders given by way of clyster, as Dr. Wall observes, in that Tranfaction. The operation of musk, in some refpefts, resembles that of opium; but is in this much preferable, that it does not leave behind it any fflor or languidness, which the latter oftentimes does. Musk, therefore, licens likely to answer in thes
those low cafes where sleep is much wanted, and opiates are improper.

It is said to be used in a bolus, and that those, who are most averse to perfumes, may take it in that form without inconvenience. For as Etmuller and others have long ago observed, the smell of the perfume is often found to be of assistance, where the plaintive inwardly taken produces good effects.

It is pity, that a medicine of this consequence should be so liable to adulterations, and that the criteria of its genuineness are ill settled.

In a paper read before the Royal Society, March 17, 1747—8, several cures performed by musk, on distempered cows, were mentioned.

When musk begins to decay, it is a practice used in the East Indies to put it into a bladder or bag, in which many small holes are made with a needle, and hang it in a necessary-house, but not low enough to touch the filth. Others keep it wrapped up in linen, well moistened with rank urine.

Mr. Boyle says, of his own knowledge, that musk has greatly contributed to the preservation of flesh. Works, 8th vol. i. p. 30.

Musk-Ant. See Ant.
Musk-Boar, in Zoology. See Tlacu.
Musk-Hyacinth. See HYACINTH.

Musk-Mixture. See Mixture.
Musk-Rat. See Rat.
Musk-Seed, in the Materia Medica, the name of the feed of the alca Egyptiona villa; or hoary Egyptian vervain mallow. See Syrian Mallow.

It is a small feed of about the bigness of a pin's head, of a greyish-brown in colour, and of the shape of a kidney, and when fresh it has a perfumed smell. It is brought into Europe from Egypt, and from Martinico. The Egyptians use it internally as a cordial and provocative; but in Europe it is of very little use, being wholly neglected in medicine; but the perfumers in France and Italy use it among their compositions.

Muskerry, in Geography, a barony in the county of Cork, Ireland, the chief town of which is Macroom. It is situated on the river Sullane, and is in the new road from Cork to Killarney. Its cattle is very ancient, having been built in the reign of King John; but having been much injured by fire in 1641, it was altered into a more modern structure by the lords of Clancarty; 141 miles S.W. from Dublin, and W. from Cork.

Musket, or Musquet, properly a fire-arm borne on the shoulder, and used in war; to be fired by the application of a lighted match.

The length of the musket is fixed to three feet eight inches from the muzzle to the touch-pan, and its bore is to be such as may receive a bullet of 14 in a pound, and its diameter differs not above 1/35th part from that of the bullet.

Musquets were anciently borne in the field by the infantry, and were used in England so lately as the beginning of the civil wars. They are said to have been first invented in the year 1520 or 1521.

The Spaniards in the time of Philip II. caused muskets to be made of a very great calibre, and such that a strong and vigorous foot-follower might carry them; but they were too heavy, that they could not be prefented, without the assistance of slaves. And pointed at the bottom, and which they fixed into the earth, making use of a fork that was at the top, as a prop to sustain the end of the musket. Of these they made use, not only in sieges to fire over the walls, but also in battles: these large muskets carried to a great distance, and by the fize of their balls inflicted dreadful wounds: but on account of their weight, they left off using them in the field, and restricted them to sieges. The inconveniences of the introduction of the musket, which was a long, heavy piece, carrying large balls, and on account of its fire and weight fired on a kind of fork, called a rest; the rest continued in use for a considerable time; but on certain occasions, being found unwieldy and inconvenient, a lighter kind of piece was introduced, generally known by the name of the caliver, which was fired without any such assistance. This caliver was a lighter kind of matchlock piece, between a harquebaufe and a musket, and fired without a rest. But before the entire diffusion of the rest, divers attempts were made to convert it to a defence against cavalry, whilst the musketeer was loading, by arming it with a projecting spike from one of the prongs of the fork, serving for the head, or part on which the musket was laid; or by enclosing a tuck in the shaft of the rest, which, on opening a full valve, sprung out: rests thus armed were called the Swines or Swedish feathers, and were contrivances preceding the use of the bayonet. At present muskets are little used, except in the defence of places; fences, and fire-locks, having taken their place and name.

From an ingenious and military treatise, entitled "English Military Discipline," and printed in 1680, we learn that the fusil or firelock was then in use in our army, especially among the fusiliers and grenadiers; and probably the appellation of fusiliers was given to those troops that were armed with fusils. Perhaps the fusilier regiments were originally a sort of grenadiers, as like them they wear caps, and have no ensigns. Fusiliers are foot-foldiers armed with fusils with slings to fling them. There are four regiments in our army, which have always been called fusiliers, and pass under the name of English, Scotch, Irish, and Welsh fusiliers: but now we have none but fusiliers abroad, for the pikes are quite laid aside. The first design of fusiliers was to guard the artillery, to which end the regiment of fusiliers, commanded by Sir Charles O'Hara, was first raised. To supply the want of pikes, and to secure themselves against horse, the fusiliers used to carry turnpikes along with them, which in a camp were placed along the front of a battalion, and on a march were carried by the foldiers, each carrying one of the short pikes, and two, by turns, the fpirr through which they are thruf, so that they were quickly put together. According to Millan's succeffion of colonies, the 7th regiment, or royal English fusiliers, were raised June 11th, 1685; the 21st regiment, or royal North British fusiliers, 23d September, 1679; the 23d, or royal Welsh fusiliers, 15th March, 1688; but there is no Irish regiment bearing the appellation of fusiliers. (See Fusilier.) The use of cartridges, which seems to have taken place about the same time as the firelock, introduced the cartridge-box instead of the bandoleers, which is a great improvement, both with respect to the more commodious carriage of the ammunition, and also the quickness of firing, as the feller may fire at least three times the number of shot which he could discharge when loading from his bandoleers.

Musket-Baskets, in Fortification. See Baskets.

Musketeers, foldiers armed with muskets; which were formerly fired with matchlocks.

Musketeers of the reign of James and Charles I. carried their powder in little wooden, tin, or leather cylindric boxes, each containing one charge. Twelve of these fixed
to a belt worn over the left shoulder were called bandeleers; a contrivance which seems to have been borrowed from the Dutch or Walloons. See Match.

MUSKETON, a musket shorter, though thicker, than the ordinary musket. It is fired by the collision of a flint and flint in the lock: whereas the musket is fired by a match. Its bore is a thirty-eight part of its length, and carries five ounces of iron, or a carded and half of lead, with an equal quantity of powder. This is the shortest fort of musketry. See Fire-lock.

MUSKINGUM, an Indian name denoting the "Elk's eye," in Geography, a county of the state of Ohio, bounded N. on the Indian boundary and Columbiana, S. on Washington, E. on Columbiana, Jefferson, and Belmont; and W. on Fairleigh.—Also, a large river of the state of Ohio, the principal branch of which, called the "Taiacsaw," rises from a small lake near the head-waters of the Cayahoga, a boatable river emptying into lake Erie, with a portage of 7½ miles between the two rivers. After purifying its course in a gentle current, without much overflowing its high banks, it falls into the Ohio, 181 miles below Pittsburgh, as the river runs, and is 250 yards wide at its mouth. This river is supplied by a variety of considerable streams, which, when the waters are high, extend the navigation in various directions into the interior of the country. This river also forms a communication with the lakes, which will in time become very serviceable to the growing settlements on its fertile banks. The plains and hills bordering on the river and its various branches are replete with being of superior quality to any in the state. Near it are some productive and valuable falt-hips; and its banks, in some places, contain immense beds of pit-coal, and in others, a variety of ochres and pigments. The river abounds with fish, of which the yellow cat andurgeon are the most esteemed. Harris's Tour 1807.

MUSKOGEEs. See Creek.

MUSKONGUS, a small river of America, which springs from ponds in the town of Maine, in the county of Lincoln and state of Maine, and enters the sea, after a course of about 20 miles, through the adjoining town of Wedelborough.

MUSKONGUS Bay, a bay formed by Britol or Pamquid point on the W. and Meduncok plantation on the E. In this bay is an island of the same name, containing about 1000 acres. This Indian name is also applied to a grant or claim of land called "Muskongus Patent."

MUSLIN, or Musslin, a fine fort of cloth, wholly cotton; so called as not being bare, but having a downy nap on its surface resembling moss, which the French called mouf.

There are various kinds of muslins brought from the East Indies, chiefly from Bengal; betels, tannatans, mulmul, tanjebas, terrindams, doreas, &c.

Jacconott, or jacconett, is a species of muslin of fabric between the coffas and mulmul, being lighter and thinner than the former, and flouter than the latter. The name is said to be a corruption of Jaggarmout, the dialect in India where muslins of this description are chiefly made. The jacconott is perhaps the most universal fabric of the lighter descriptions of muslin, being more flouy and open than the coffas, long-cloths, or cotton cambries, and more durable than the musls and bukes. It is also from this quality the best fitted for the ornamental figures of tambour and needle-work, the lighter fabrics, although very beautiful when well executed, being too flinny to bear the fatigue of washing, drefling, or clearing often, when loaded with needle-work of any kind, and the opacity of the flouter fabrics diminishing very sensibly both the shaw and beauty of the work. Jacconott muslins are, therefore, made in great abundance both in England and Scotland. In England, besides those which are worn plain, a very great number is used for the finer kinds of printed goods, both as garments and shawls. In Scotland, besides plain wearing and printing, they are employed for the needle-work of various kinds, of which that country is the chief seat of manufacture. The Scotch jacconotts are in general made considerably lighter in the fabric than those of England, and this is very proper when the different uses to which they are generally applied are taken into consideration. A very great proportion of the jacconotts made in England are either worn plain or used for printing; in both these cases a close flout fabric is most economical, and in the latter the colours will appear with more brilliancy and effect than where a close body to receive and absorb the colour in considerable quantity. In every species of needlework, on the contrary, the lightness and transparency of the fabric forming a contrast with the close appearance of the work, gives it a degree of what painters call relief, which greatly heightens its appearance.

MUSMURREAH, in Geography, a town of Hindostan, in the circuit of Gohud; 10 miles W. of Calpy.

MUSNIKI, a town of Lithuania, in the patinate of Wilna; 14 miles S. of Wilkomierz.

MUSO, a town of South America, in the viceroyalty of New Granada; 70 miles N. of Santa Fe de Bogota.

MUSOLENTE, a town of Italy, in the Trevisian; 9 miles S.E. of Cimone.

MUSONE, a river of Italy, which runs into the Adriatic, at a small distance N.E. of Loreto.

MUSONIUS, in Biography, ranked by Eunapius as one of the most virtuous and excellent of the modern Cynics, a Babylonian by birth, flourished in the second century of the Christian era. He was an excellent philosopher; and Philodorus speaks of him as next to Apollonius in wisdom. He was at Rome during the reign of the emperor Nero, who, by animadverting on the vices of the court, he excited the resentment of the tyrant, and was committed to prison. His confinement was, probably, not very severe, as he was enabled, during its period, to contract a friendship with Apollonius, and to enter into a correspondence with him. He was, however, at last banished into the island of Greece, and condemned to daily labour with the spade, in a state of slavery. While he was in this condition, he was visited by Demetrius of Corinth, who deplored the unworthy treatment to which he was subject; upon which Mufonius, striking his spade firmly in the ground, exclaimed, 'why do you lament to see me digging in the Isle of Sparta? You might, indeed, have just cause for lamentation, if you saw me, like Nero, playing on the harp.' Julian speaks with applause of the magnanimity of this philosopher. The time of his death is uncertain, and none of his writings have come down to us. Einfld Hist. Phil. vol. ii.

MUSONIUS, Callus, commonly Rufus, a Stoic philosopher. A Tucan by birth, of the equestrian order, who enjoyed military honours. He took much pains to disseminate the principles of his philosophy, and the precepts of sound morality among the Roman youth, particularly among the officers of the army. On this account, he excited the ridicule of some, while he gave offence to others. He likewise incurred the displeasure of Nero, probably because he had the virtue to speak the truth respecting that sovereign, and truth being then, as it is now, regarded as a heinous offence, though intended to correct the manners of the age, the philosopher was banished. A more virtuous prince, Vel- patian, recalled Mufonius, and took him into his favour.
His philosophy, like that of Socrates, was adapted to the practical purposes of life and manners, as has been inferred from a differential which he left, "On the Exercese of the Mind," which is preferred in Stobaeus' Collection. Moret. Enfeld Hiit. Phil.

MUSQUADASTON LAKE, in Geography, a lake of Canada.笔记本 51' 30". W. long. 87' 30".

MUSQUAKIES, Indians who inhabit the southern shore of lake Michigan, having, for a few years, 200 warriors.

MUSQUATONS, Indians inhabiting the vicinity of lake Michigan.

MUSQUITEERS, Mouquitaers, in France, are troopers who fight sometimet on foot, sometimes on horseback: they are gentlemen of good families, and are divided into two troops, the one called the grey-musquiteers, the other the black musquiteers, from the color of their horses.

MUSQUETEERS, Indians inhabiting the vicinity of the outfall of the Mississippi, in 1829.

MUSSE, Mora. See Moor.

Gen. Ch. Cal. Perianth superior, in five deep, taper-pointed, deciduous segments. Cor. of one petal, funnel-shaped; tube long, cylindrical, more or less hairy; limb flat, in five deep, ovate, acute, equal segments. Stam. Filaments five, very short, inserted into the tube; anthers awl-shaped, long and narrow, concealed within the tube. Pet. Germen inferior, ovate; style thread-shaped; stigma two, simple. Petio. Berry ovate, of two cells, crowned with a margin. Seeds very numerous, minute, dotted, dispersed in four series, on cloven receptacles.

—Native of Ceylon, and one of the few of the East Indies. We have a specimen gathered by the Moravian missionaries at Tranquebar. Stem shrubby, with round hairy branches. Leaves opposite, on shortish hairy footstalks, ovate or elliptical, two or three inches long and one broad, with a small, narrow, taper point; entire, but slightly wavy, at the margin; furnished with a mid-rib, and numerous transverse, curved, parallel veins: more or less hairy on both sides, especially the rib and veins; paler beneath. Stipules between the footstalks, simple, hairy, broad at the base, with a taper point. Panicle terminal, forked, corymbose, hairy, especially at the forks. Bracteas small, alternate at each division of the panicle, very hairy. Flowers erect. Germen obovate, clothed with scattered hairs. Segments of the calyx upright, half as long as the full-grown tube of the corolla, linear, taper-pointed, very narrow, hairy externally, smooth within; one of them, in two or three of the fliril flowers, transformed into an elegant white long-talkeed leaf, of the shape of the proper foliage, but rather larger, and having its principal veins or ribs springing chiefly from the base; its margin and veins hairy. Tube of the corolla above an inch long, gradually swelled upwards, densely clothed in every part with longish lax hairs; limb three quarters of an inch broad, horizontal, or rather deflexed, externally downy or hairy, internally, in our dried specimen, of a rich orange colour, granulated or glandular, with a dense pale-yellow tuft about the mouth of the tube, its segments abrupt, each tipped with a small taper point.

We have been particular in the description of this plant, which seems rare and but little known, though it appears to be the original M. frondosa of Linneus, who in his synonyms confounded it with the following, which is what most authors mistake for it. Burmann's figure is characteristic, and the only one that accords with our specimen.

2. M. gluira. Smooth-leaved Muffledena. Vahl. Symb. v. 3. 38. Willd. n. 2. (M. frondosa; Lamarck Dict. v. 4. 395. t. 157. f. 1.) Folium principiep; Rumph. Amb. v. 4. 361. f. 1. 51. Belb. Rheedee Malab. 2. 27. t. 18.—Calyx-teeth ovato-lanceolate, unequal, many times shorter than the tube of the corolla, one of them often frondose. Hairs of the corolla erect.—Native of various parts of the East Indies. The Malays call it Dawn putri, and a species so named is preferred, as M. frondosa, in the Linnean herbarium; but this specimen is of later date than the publication of the Species Plantarum. The present species is much smoother in its branches, leaves, and flalks, than the foregoing, and the panicle appear to be more numerous or aggregate. The germen are more ribbed or angular. Segments of the calyx widely different, being unequal, spreading, scarcely a fifth part so long as the tube of the flower, broad at the base, and suddenly tapering to a blunt point. Tube of the corolla an inch long, clothed, principally in the upper part, with erect or close hairs; limb one-third the size of the former, moderately spreading, downy, described by Rumphius as deep yellow. The leaf which is sometimes produced by the calyx instead of a fifth tooth, is of a broader and shorter figure than in M. frondosa. The few or narrow-leaved species of Rumphius, represents a more variety, bell answering to our plant. The synonym of Rheedee belongs either to this, or to a third species, certainly not to the first, if the calyx be faithfully drawn. The flowers are there described as of a beautiful scarlet.

3. M. palpebema. Chienele Muffledena. Dryandr. in Ait. Hort. Kew. ed. 2. v. 1. 372.—"Branches and leaves downy. Tube of the corolla many times longer than the segments of the calyx."—Native of China. Brought in 1805 to Kew, where it is kept in the greenhouse, flowering from May to September. We know nothing more of this species, which seems molt akin to the last, though more downy.

4. M. arcuata. Jasmine-flowered Muffledena. Poirret in Lamarck Dict. n. (Landia religiosa; Commert. MSS.) —Leaves elliptical, smooth. Calyx-teeth linear, nearly equal. Limb of the corolla externally smooth; tube with five hairy lines.—Native of the island of Mauritius. Lam. Commeron met with it cultivated in the gardens of Java. This is a nearly smooth form, with elliptical, pointed, heart-shaped leaves. Panicle smooth, forked. Flowers fragrant, resembling...
bbling some of the larger species of _Jasminum_, described by Commerson as white, with a yellow eye; in a dried state the limb is entirely yellow, smooth externally, but glandular on the upper side, with five hairy, radiating flary points; tube smooth on the outside, except five hairy lines. Segments of the calyx linear, smooth, a little recurved, not one-fifth so long as the tube, somewhat unequal, but it does not appear that any of them, in this or the remaining species, is ever transformed into a leaf. Fruit obovate, smooth, the size of a small gooseberry. An ascending curvature in the base of the _flower-flask_ gave occasion to the specific name.—This plant was called _Landia stelligera_ by Commerson, in compliment to his friend De la Lande, the astronomer, who had no preconceptions to botanical honours. The _flowers_ in Lamarrck's t. 157. f. 2, are much like this species in their limb and its dimensions, though done for the following, with which their calyx, all the dissected parts, and the leaves agree.

5. _M. Landia_. Broad-leaved Mussenda. Lam. n. 2. Illust. t. 157. f. 2.—Leaves broad-ovate, smooth, with hairy ribs. Calyx-teeth ovate, with long recurved points. Corolla externally silky; internally downy; its segments taper-pointed.—Native of the isles of Mauritius and Bourbon. The _leaves_ are of a broad or roundish ovate form, entire, smooth or nearly so, with hairy veins, their dimensions sometimes eight inches by four. _Footstalks, flower-flasks_, and _germen_ clothed with scattered close-preffed hairs. _Stipular_ cloven, hairy in the same manner. Segments of the calyx more densely hairy, ovate, with a long recurved point of their own length. _Corolla_ probably white; its tube above an inch long, being four or five times the length of the calyx, densely clothed with close silky hairs; segments of the limb an inch long, ovate, with long taper points, their outside silky, inner finely downy, with an elevated central line; throat lined with soft hairs. _Style_ briefly. The _flowers_ in Lamarrck's figure are too small, and the tube in the separate corolla is scarcely long enough, nor the segments sufficiently pointed.

6. _M. bolosferica_. Silky Mussenda.—Leaves ovate, pointed, silky beneath. Calyx-teeth ovate, acute, fraight. Corolla externally silky, internally downy, its segments taper-pointed.—Gathered by Commerson in the isle of Bourbon. This is the plant alluded to in Lamarrck, under the description of the leaf. We are at a loss to account for his being possessed of a few detached flowers only, when there are magnificent specimens from Commerson in the herbarium of the younger Linnaeus. The _leaves_ are oval, about four inches or more in length, tapering into a long sharp point; their upper surface clothed with minute, de-preffed, scattered hairs; the under finely silky; ribs and numerous veins on both sides hairy. _Stipular_ hairy, in two deep, narrow, taper-pointed divisions. _Footstalks, flower-flasks_, bracteas, and young branches, finely silky. _Germin_, _calyx_, and tube of the corolla, more densely covered with rather longer hairs. _Pandie_ forked, corymbofo, many-flowered. Segments of the calyx shorter, and much broader, than in the leaf, acute; but not taper-pointed, nor recurved. _Corolla_ said to be white; its tube two inches long, segments of the limb one inch, taper-pointed, hairy at their backs, finely downy at the margins, as well as on the upper side: round the mouth are five apparently reddish spots, fringed with long radiating hairs. _Style_ briefly. This is a very handsome shrub, not unlike some of the finest species of _Gardenia_.

7. _M. lanceolata_. Lanceolate Mussenda. Lam. n. 3.—Leaves lanceolate-wedge-shaped. Flowers opposite, race-mose. Calyx abrupt, with five small teeth.—Native of the island of Mauritius.—We have from that country a specimn partly answereing to the description in Lamarrck, but we dare not take it for the same plant. The _corolla_ is described as smooth, and the _infoliceaceae_ as racemose, neither of which characters have occurred to our observation in any true _Mussenda_.

8. _M. cirrifolia_. Citron-leafed Mussenda. Lam. n. 4.—Leaves three in a whorl, ovate, nearly seifile. Calyx-teeth long and permanent.—Native of Madagascaer, where it is called _charbo_. The _corolla_ of this is said to be smooth, and the _fruit_ a dry _capsule_, both circumstances adverse to the generic character. The _flowers_ are described as cymose, small, yellow, and very numerous. _Leaves_ coriaceous; smooth and shining above; slightly downy beneath.

9. _M. longifolia_. Long-leafed Mussenda. Lam. n. 5.—Leaves three in a whorl, crowded, lanceolate or oblong. Capsule ribbed, crowned with the calyx.—Native of Madagascaer, where it is called _tambala-racha_. Said to remove the leaf, except that its leaves are narrower, and twice or thrice as long. _Capsule_ pear-shaped, membranous, with fix or eight longitudinal ribs.

10. _M. glomerulata_. Tufted-flowered Mussenda. Lam. n. 6.—Leaves ovate, acute. _Flowers_ terminal, in dense round heads.—Gathered by Richard in Guiana. The habit is said to resemble the _Tackia_, in _Aublet's_ t. 29, but the infoliceaceae, by the above character, is totally dissimilar. _Corolla_ slightly downy at the outside.

Poiret, who described the leaf, seems to have been doubtful of its genus; and though Lamarrck himself determined the two immediately preceding, it is manifest that they have not the characters of _Mussenda_, at least as we understand the genus. We have seen no certain specimens of any of these four leaf, and therefore infer them here merely for future enquiry, as they are not in Willdenow.

_M. spinosa_ and _formosa_, Linn. Mant. 45. Jacq. Amer. t. 49 and 48, are now referred to _Gardenia_.

MUSSAHIR, in _Oriithology_, a bird mentioned by Arabian writers. It is said that this creature, after having employed the day in seeking its food, spends the whole night in singing; its notes are said to be so melodious as to banish all thoughts of sleep from those that hear them.

MUSSALEE, in _Geography_, a town of Hindoostan, in the Carnatt, 16 miles W.N.W. of Trichinopoly.

MUSSAON, a town of Hindoostan, in Baglama; 35 miles S. of Damacen.

MUSSARA, a town of Bengal; 50 miles N.W. of Midnapour.

MUSCATO, _Albertino_, in _Biography_. See _Albertino_.

MUSXAXO _Cosa_, in _Geography_, a town of Aflatic Turkey, in the province of Diarbekir; 40 miles S.W. of Tercit.

MUSCHENBROECK, _Peter de_, in _Biography_, an eminent mathematician and natural philosopher, was born at Leyden in 1692. He became professor of mathematics and natural philosophy at his native place, in which departments he greatly distinguished himself. He was elected a member of the Royal Society of London, and also of the Academy of Sciences at Paris. He died in 1761. His Course of Natural and Experimental Philosophy is a very valuable work, and has been popular in this country. Mussenbroeck was author of " _Tentamina Experimentorum: " _Institutionibus Physica: ;" and " _Compendium Physice Experimentalis._"

MUSSELBURGH, in _Geography_, a sea-port town and borough, situated on the southern coast of the Frith of Forth, in the county of Midlothian, Scotland, derived its name from an extensive...
MUSSELBURGH.

extensive muscle-bank, which lies in the sea below the town, and was probably the cause of its early population. This place may be said to consist of three villages. On the east side of the river Esk, and near to the shore, stands Musselburgh, properly so called, consisting of a broad well paved street, with some adjoining lanes. The houses here are mostly two or three storeys high, and are all built of stone, and covered with slate or tiles. Above Musselburgh, more inland, but connected with it by detached houses, is the village and church of Inveresk, which gives name to the parish; and along the shore, on the western bank of the Esk, is the village of Fisherton. This last is upwards of half a mile in length; and here the only port or harbour belonging to the town is situated.

Musselburgh is not a royal borough, but what is called a borough of regality; that is, an incorporation in which a subject, vested with regal privileges, is the superior. Previous to the reformation, the abbot of Dunfermline was the lord of regality. It afterwards became the property of the family of Lauderdale, and continued in their possession till the year 1709, when it was purchased by the duchesses of Monmouth and Buccleugh. Accordingly, the borough now holds of her descendant, the present duke of Buccleugh, as superior lord, and pays to him certain sums annually in name of quit rent, or pew duty. The government is vested in a council of eighteen members, ten of whom are chosen for Musselburgh, and eight for Fisherton. These elect their own successors, and also nominate from among themselves two bailies and a treasurer. The bailies, by virtue of their charters, of which the oldest extant is dated in 1563, are empowered to hold a court of record, and to issue precepts for the execution of their decrees, and of contracts registered in their books; but enfeoffments of property must be recorded in the county register. Upon the whole, however, this borough possesses all the immunities of any royal borough in Scotland, except those of voting for a member of parliament, and sending a delegate to the convention of boroughs. Its annual revenue is estimated at somewhat more than 1500l. arising from the few duties paid by all proprietors of houses within their territories, and from their land and mills, and the shores of their harbour. The houses of the late years considerably increased, the consequence of the great increase of shipping with grain for the Clements-Well distillery. It is not a little remarkable, that this town, though excellently situated for the purpose, carries on no extensive manufacture. Some small manufactories, however, of cloths, soap, flax, and pottery, have been established, and all sorts of ordinary tradesmen are to be found here as in any country villages. In Fisherton are a number of small works, but all upon a very trifling scale, where their whole produce being either sold to dealers in the neighbourhood, or carried by the women in creaks to Edinburgh, where they generally dispose of it, by crying it about the streets in the same way as fish are by fish-women. Of the latter a great number likewise belong to this town, who still retain the same character and manners which distinguished them a century ago. They are the wives and daughters of fishermen, who generally marry in their own craft or tribe. On the days not occupied in carrying, their business is to gather bairs for their husbands, fathers, or brothers, and to bait their lines. In their dealings with the public, they still pertinaciously retain the ancient practice of small traders, of demanding three times the sum they will take for their goods. This, however, is not the result of a dichtenet principle, but merely of custom, for it is remarked by those who have studied their character, that in all other transactions they are strictly honest; and that though facetious to a proverb in their language, they are nevertheless virtuous and chaste in their persons. From the active share these women have in the maintenance of their families, their sway in them, as might be supposed, is great. As their work is menial, so are their sentiments and manners. Their strength is not inferior to that of their husbands, nor are they less capable than they of enduring fatigue, or the severities of a northern climate. On holidays, their chief amusement is playing at golf, and on Shrove Tuesday there is always a flanding match, at foot-ball, between the married and unmarried women, in which the former are generally the winners. This match usually takes place on the "links," or open downs, lying between Musselburgh Proper and the shore, where are likewise held the annual fair, and the horse races.

Musselburgh contains four places appropriated to public worship; the parish church, the episcopal meeting-house, a burghe's feeding meeting-house, and a church of relief. The duke of Buccleugh is patron of the established church. Here is also an excellent grammar-school, under the patronage of the magistrates and town council, who allow the master a salary of 25l. per annum, in addition to the fees he receives from his pupils, which in the aggregate are pretty considerable. Several private seminaries in this town are likewise in high estimation, and there are Sunday-schools supported by the duchesses of Buccleugh, and other charitable ladies, both in Musselburgh and Fisherton. The market day in the former is Friday, and in the latter Tuesday.

In this town and its neighbourhood, many Roman remains have been discovered at different times; which Chalmers, in his Caledonia, says, "threw that the Romans had a poilt at Fisherton, and a poilt at Inveresk." Some Roman coins, and an altar with this inscription, Apolloni Grani, were found in levelling the adjacent grounds several centuries ago, and within these last twenty years, the ruins of a Roman bath were laid open by the workmen employed to erect a new parterre to the mansion of the proprietor of Inveresk villa. Similar ruins of hypocausta have been since discovered nearer to the shore, besides many foundations of private houses.

The church of Inveresk has been lately rebuilt, and is said to be one of the finest parish churches in Scotland. The old structure, however, was more interesting as an object of curiosity; its antiquity being undoubtedly very remote. At the east end of Musselburgh formerly stood the chapel of Loretto, a cell to the abbey of Dunfermline. Of this building there are very few remains, except one small apartment covered by an artificial mount in a garden of a villa still called the Loretto. It muft, however, have been an ediifice of very considerable extent, as the present tokbooth of Musselburgh was wholly built from its materials. Near the east end of the town is the house in which the great Randolph, earl of Murray, died in 1352. Among the other remains of antiquity in this town, the bridge is the most remarkable, being, according to Dr. Carlyle, most probably a work of the Romans. The Scottish army passed over this bridge on the day of the fatal battle of Pinkie, which was fought near the house so called, formerly the residence of the Setons, earls of Dunfermline. Carberry hill, immediately adjoining to the scene of action, was afterwards noted for the conference held by the unfortunate queen Mary with Kirkcaldy of Grange, which terminated in placing her person in the power of Morton, and the confederate lords, who, regardless of their renewed oaths of allegiance and fidelity, confined her a prisoner till she was enabled to effect her escape from Lochleven castle.
The situation of the parish of Inveresk is one of the most beautiful in Scotland; and so celebrated is the village for its healthy climate, and the delightful prospects it commands, that it was distinguished of old by the name of the Montpellier of Scotland. Musselburgh, as a fashionable summer retreat, however, is now comparatively abandoned for Portobello, situated between it and the metropolis, where large and commodious baths have been lately erected. The site of this now populous village, only a few years ago was a desert and barren heath.

MUSSIDAN, a town of France, in the department of the Dordogne, and chief place of a canton, in the district of Riberauc. The place contains 1176, and the canton 6454 inhabitants, on a territory of 140 kilometres, in 10 communes.

MUSSIN, a town of the duchy of Warfaw; 10 miles S. of Pofen.

MUSSINA, in Botany, dedicated, by Willdenow, to the honour of the Russian count Mün Pufkin, who undertook an arduous expedition to the Caucasus in pursuit of botany, and in which he discovered many new plants. This genus consists of several species referred by Thunberg to Gorteria. Wild. Sp. PI. v. 3. 2463.—Claf and order, Syngennia Polygonia Frayfranca. Nat. Ord. Composita Capitale, Linn. Corymbifera, Jull.

Gen. Ch. Common calyx of one leaf, cylindrical, naked, toothed in the margin. Cor. compound, radiated. Florets of the disk numerous, perfect, with a funnel-shaped five- cleft corolla; those of the radius fewer, female, with a lacinulate lanceolate one. Stem. (in the perfect florets only) Filaments five, short; anthers united into a cylindrical tube. Fil. (of the perfect florets) German hairy; style thread- shaped, the length of its own little corolla; stigma cloven. In the female florets, the germen is obsolete and abortive; style none; stigma none. Peric. none, except the calyx, falling off entire. Seeds to the perfect florets only, solitary, roundish. Down simple. — Recept. villous.

1. M. linearis. Wild. (Gorteria linearis; Thunn. Prodr. 162. Act. Soc. Nat. Scrip. Haf. v. 4. t. 1.)—Leaves linear, smooth, with fringed teeth at the base. Stalks single-flowered. This, as well as all the following species, are natives of the Cape of Good Hope.—Leaves pointed. Flower-flake longer than the leaves. Calyx-teeth linear-spatulate, very long, fringed at the bottom.

2. M. uniflora. Wild. (Gorteria uniflora; Linn. Suppl. 382. Thunn. Prodr. 162. Act. Soc. Nat. Scrip. Haf. v. 4. t. 1.)—Leaves oblong-elliptic, entire, downy beneath. Stem decumbent. Stalks single-flowered. Lin- eanous suffused this to be a variety of Gorteria rigesa, which he says it greatly resembles in appearance. Stem about a span long, simple, herbaceous, decumbent, hairy on all sides. Leaves alternate, sessile, lanceolate, undivided, entire; white and downy beneath. Stalk single-flowered, terminal, longer than the leaves. Radius yellow. Wildenow describes this species as having the leaves of Gorteria rigesa only undivided, and sometimes, but rarely, trifid. Radius narrow, lanceolate. We have seen no specimen.

3. M. speciosa. Wild. (Gorteria rigesa 3; Thunn. Act. Soc. Nat. Scrip. Haf. v. 4. t. 1. f. 1.)—Leaves either pinnatifid or undivided, downy beneath; segments linear-

lanceolate. Stalk single-flowered. Calyx downy — Root subdivide, fibrous. Leaves entirely radical; green above and slightly downy; white with down beneath; revolute at the margin. Stalks downy, single-flowered, twice as long as the leaves. Florets of the radius yellow, with a flight streak on their lower side, and a dark spot at their base on the upper. Wildenow observes, that this differs from Gorteria rigesa, in the structure of its calyx, in having no flaps, as well as on account of its annual root, and whole habit.

4. M. incisa. Wild. (Gorteria incisa; Thunn. Prodr. 162. Act. Soc. Nat. Scrip. Haf. v. 4. t. 1.)—Leaves either pinnatifid or undivided, hairy, downy beneath. Stalk single-flowered, the length of the leaves. Calyx smooth.— Root annual, descending very deep. Leaves mostly radical, on stalks, oblong, entire; when pinnatifid, their segments are ovate-oblong, green and rough above, downy and white beneath, with reflexed margins; they are all erect, about three inches long, their stalks and ribs sprinkled over with white hairs. Stalk round, slightly frayed.

5. M. obscura. Wild. (Gorteria obovata; Thunn. Prodr. 162. Act. Soc. Nat. Scrip. Haf. v. 4. t. 1.)—Leaves pinnatifid, smooth. Stalk single-flowered. Calyx turbinate.—Of this we find an unnamed specimen in the Lin- eanese herbarium. It has no flaps. The leaves are all radical, two or three inches long, smooth, and somewhat glaucous, deeply pinnatifid; their segments linear, with a cartilaginous, prickly-toothed margin, and a terminal bristle. Flower-flake four inches high. erect, simple, with one linear bracte a above the middle. Flower terminal, solitary, erect, an inch in diameter. Calyx frayed, smooth, with two rows of marginal teeth; the innermost furnished with long points but much shorter than the radius, the florets of which appear to be yellow, with a brown fruited underneath.

6. M. pinnata. Wild. (Gorteria pinnata; Thunn. Prodr. 162. Act. Soc. Nat. Scrip. Haf. v. 4. t. 1.)—Leaves pinnate, villous, downy-white beneath; leaflets eliptical, the terminal one larger and subdivided. Stalk sin-

gle-flowered. Calyx villous — Having no specimen of this, and being obliged to rely on Wildenow for his reference of the present, as well as of all the other species, to the Co- penhagen Transact., we are unable to describe it further than the specific character.

MUSSITAND, in the Greek church. While the priest stands with his face towards the ecall, and repeats the prayers in a subdued voice, the choir is almost constantly singing hymns, without the congregation being supposed to pray themselves, or hear his prayers. (Rites and Ceremon. of the Gr. Church, by Dr. King, p. 46.) Perhaps the mu-

cical performance in the churches of Italy, during the mutti-

tand, or muflé-buffa, had the same name.

MUSSE, COrNELIUS. In Biography, a famous Italian pre-

late, and one of the most celebrated preachers of the 16th century, was born at Placentia in the year 1511. When but nine years old, he was permitted to dedicate himself to the order of St. Francis, and entered a monastery in his native city. He speedily discovered an excellent genius, a prodigious strength of memory, and talents apparently well adapted to the pulpiz. He was accordingly educated in such a way as to render him qualified as a preacher. He was in due time sent to Venice with letters of recommendation, and though his exterior was much against him, yet he had fearcly entered upon the services of the church when he affected all unfavourable impressions, and captivated his audience by the charms of his voice, the sublimity of his conceptions, and the graces of his delivery. He now found many zealous patrons, and was particularly honoured with
the friendship of the famous Peter Bembo, afterwards cardinal, who afflicted him in his rhetorical studies. He, at this period, applied himself diligently to the oriental languages, after which he returned his pupil labours, and refuted all the most-decided pre-eminence among his contemporaries. He obtained the affection of the duke of Milan, Francis Sforza, by whom he was appointed professor of metaphysics at the university of Pavia, and he even condescended to attend his lectures. Upon the death of the duke, Maffo was chosen professor of metaphysics at Bologna. Here he likewise read lectures on the epistles of St. Paul. In 1541 he was, through the intercess of cardinal Campeggio, appointed by pope Paul III. bishop of Bertinovo, in the Romagna; but, after this, purely on account of his merit as a preacher, he was translated to the see of Bitonto, in Apulia; and in 1545, the pope lent him to the council of Trent, where he distinguished himself by a Latin sermon at the opening of the council. After the death of pope Paul III, he was selected by the two succeeding pontiffs as domestic prelate and amanuensis. In 1560, he was sent nuncio into Germany with the pope's neapole, and executed his commission at the court of Ferdinand with great reputation. He was, after this, employed at the court of Rome, on various subjects, till the dissolution of the council of Trent, when he returned to his bishopric, and applied himself to the reformation of abuses, and the diligent discharge of the duties of his holy calling. Having resided ten years on his see, he went again to the metropolis, and was detained by pope Gregory XIII. as his amanuensis, till his death, in 1574, when he was in the sixty-third year of his age. He was author of several theological works, which were printed after his death, among which are "Commentaries upon St. Paul's Epistle to the Romans," in Latin; an Italian "Commentary upon the Magnificat," "De Historia Divina," &c.; the works for which he is most celebrated are his "Sermons," published at Venice, in four volumes 40o. in 1582 and 1590. He is mentioned by Dupin as a "polished and eloquent writer;" and Tiraboschi says, in speaking of his sermons, if they do not prove that the bishop of Bitonto was the first reformer of pulpits eloquence, they at least testify that he contributed greatly toward such a reformation. They abound in solid matter, beautiful images, and eloquent expressions. Gen. Biol.

MUSULMAN, or MUSULMAN, written in Arabic مسلم, Muslum, or Musulmam, a title by which the Mahometans distinguish themselves; signifying, in the Turkish language, true believer, or orthodox.

The appellation was first given to the Saracens; as is observed by Leunclavius. There are two kinds of musulmans, very averse from each other; the one called Sunnites, and the other Shiites. The Sunnites follow the interpretation of the Koran given by Omar; the Shiites are the followers of Ali. The subjects of the king of Persia are Shiites; and those of the grand signior, Sunnites. See Sonna, and Aecoran.

Some authors will have it, that the word musulman signifies faroud, that is, predelimited; and that the Mahometans give themselves the appellation, as believing they are all predelimited to salvation. Martinus is more particular as to the origin of the name; he who derives it from the Arabic مسلم, musulm, faroud, finched out of danger; the Mahometans, he observes, establishing their religion by fire and sword, massacred all those who would not embrace it, and granted life to all that did, calling them musulmans: g. d. crepti e periculo: whence the word, in course of time, became the distinguishing title of all those of that sect, who have affixed to it the significiation of true believer.

MUSOS, in Geography, a town of France, in the department of the Aube, and chief place of a canton, in the district of Bar-fur-Seine; 9 miles S.S.E. from it. The place contains 1691, and the canton 9068 inhabitants, on a territory of 1147 square miles, in 8 communes.

MUSSYR, one of the Kurile islands, which is round and rocky, and lies at the distance of 35 versts from Syakut; its diameter is not more than three versts. It is defi
ted of water, but is nevertheless frequented by great numbers of birds. Sea-lions abound here.

MUST, MUSUM, sweet wine newly pressed from the grape; or the new liquor pressed from the fruit before it has worked or fomented.

Murst of Rhenish Wine. This is a liquor that, though drank by some, is found extremely to affect the brain; for not having passed the natural effervescence which it would have been subject to, in the making of wine, its effects are locked up, till the heat of the Romach setting them to work, they raise their effervescence there, and send up abundance of subtle vapours to the brain. The Rhenish must is of two kinds, being made either with or without boiling. That made with boiling is only put up to close in the vessel, that it cannot work; this is called Rhenish wine. That by boiling is thus prepared: they take about vessels not quite filled, and putting them into a cellar, they make a fire mild at first, but increased by degrees, and afterwards they gradually lessen it again, that the boiling may cease of itself. This operation is finished in thirty-six or forty hours, according to the size of the vessel; and the wine-boilers, instead of common candles, which would melt by the heat, use thin pieces of split beech wood. These also serve for a double purpose, not only lighting them, but giving them notice of the boiling being enough; before that time, the quantity of vapours thrown up with them burn dim; but as soon as it is finished, the vapours ascend in less quantity, and the lights burn brisk and clear. About seven or eight days after this boiling, the must begins to work, and after this working it is called wine. They have also another kind of Rhenish must, which is thus prepared: they boil the liquor to half the quantity, and put into it the medicinal ingredients which are most fond of; such as orange-peel, ele
corn-root, and juniper-berries, or the like; being thus medicated, the whole works much more slowly than it other
cwise would. If the boiled must, by too violent an effe
rvarcence, call out its bese, it will on this become rapid and dead, unless this separation is dropped by some fatty sub
stance, such as fresh butter, or the like: they put this in
upon a vine-leaf, or else apply hard to the mouth of the vessel.

A Must for artificial Wine may be thus made: take twenty pounds of fine sugar, five gallons of water, four ounces of white tartar, finely pulverized, or cream of tartar, and boil them in a large vessel over a gentle fire.

MUSTACEUM, among the ancient Romans, a kind of cheese-cake. It was composed of cheese, anisced, cum
min, and fust added to flour, moistened with myrrh, or new wine.

MUSTACHIO, or Mustacho, a Venetian measure for fluids; 38 mustachi make a mudd, and 76 an amphora.

MUSTAF A PACHA KEPH, in Geography, a town of Europe of Turkey, in Romania, on the Maru, over which is a celebrated stone-bridge, built by Mustapha Pach; 18 miles N.W. of Adrianople.

MUSTAF A Pacha Palauka, a town of European Turkey, in Bulgaria; 56 miles W.N.W. of Sofia.

MUSTAN,
MUSTAN, a town of Hindoostan, in Bengal; 32 miles N.N.E. of Nattore.

MUSTAPHA I., in Biography, emperor of the Turks, ascended the throne, in 1668, at the age of twenty-five, on the death of his brother Achmet, but his neglect of public business and excess of luxury, caused him, in four months, to be deposed, and committed to the state prison of the Seven Towers. His successor and nephew, Ofman, was as little adapted to the duties of government as his predecessor, and was, in 1623, deposed and put to death. Mustapha was now taken from the dungeon, and replaced on the imperial throne, but he had scarcely been in that situation fifteen months, when he was again deposed, and brought to an ignominious end, being carried on an ass through the streets of Constantinople, conducted to his former prison, and strangled.

MUSTAPHA II., son of Mahomet IV., succeeded Achmet II., his uncle, in 1695. He was in the prime of life when he ascended the throne, and was impatient to distinguish himself as a warrior; his principal action was with the imperialists, whom he defeated at Temefvar. He made war with succefs against the Venetians, Poles, and the Russians; but at length fortune turned against him, and he was obliged to make peace, under the mediation of England and Holland. This treaty, which is called that of Carlo-witz, was signed in January 1699. Mustapha returned to Constantinople, humiliated in the eyes of his subjefts, committed the management of public affairs to his vizier, and retired into the country, where he spent his time in hunting and other amusements. Discontents at length broke out among the soldiers, which produced a complete revolution in the government of Constantinople. The emperor was soon after deposed by his subjefts, and died, in 1703, of melancholy. He was well disposed, and possessed talents superior to most of his successors.

MUSTAPHA III., the son of Achmet III., succeeded to the throne in 1757, having lived in a state of confinement ever since the deposition of his father in the year 1730. He had contracted all the luxurious habits of an inmate of a seraglio; but his great passion was his love of money. He was, nevertheless, humane and just, and displayed great moderation towards his Christian subjefts. But with all his good qualities his reign was unfortunate, because the public affairs were left to the management of his ministers, and the control of a filter, who possessed an unbounded influence over him, but who was ill calculated for the business of a state. The disturbances in Poland occasioned a war with Russia in 1768, which was attended with numerous disasters, such as the loss of Bender and Crim Tartary, the revolt of the Greeks in the Morea, and the destruction of a Turkish fleet in the Dardanelles. He died in January 1774.

MUSTAPHABAD, in Geography, a town of Hindoostan, in the cirrcc of Sirhind; seven miles N. of Tannafar. - Also, a town of Hindoostan, in Oude; 10 miles N.N.W. of Mimbichour. N lat. 25° 58'. E. long. 81° 36'.

MUSTAPHINA, a town of Russia, in the government of Ophra; 11 miles S. of Sterlitamak.

MUSTARAH, a town of Hindoostan, in the circe of Gooty; 33 miles S.W. of Gooty.

MUSTARD, in Botany, Gardening, and the Materia dietetica and Medicina. See Sinapis.

MUSTARD, in Agriculture, a plant of the annual kind, sometimes cultivated in the field as a crop. It is a kind of plant that may, in some places, where the soil is fittable, be grown to much advantage.

It has been stated by Mr. Young in his Calendar, that in breaking up the rich common of Marthland Smeeth, in Norfolk, the crop that was supposed to pay better than any other, was mustard. The soil is a rich loam, and clay, worth 60s. an acre. It was ploughed once and harrowed twice, and worn one-fourth of a peck of the feed per acre, from Candlemas to the end of March, according to the weather. Few farmers have a soil that answers for this crop, but where markets are promising, they should have it in their minds. It may also be added, that it is hand-hoed twice. The crop is reaped in the beginning of September, being tied in sheaves, and left three or four days on the stubble. It is then stackled in the field. It is remarked that rain damages it. A good crop is a fix; or seven combes an acre; the price from 7s. to 10s. a bushel. Three or four crops, it is observed, are taken running.

And in Kent, according to the survey of Mr. Boys, white mustard is cultivated for the use of the feedmen in London. In the tillage for it, the ploughed land is harrowed over, and then furrows are ticken about eleven or twelve inches apart, fowing the seed in the proportion of two or three gallons per acre in March. The crop is afterwards hoed and kept free from weeds. It is usually ripe about July, when it is reaped and threshed out upon a flail cloth in the field.

In order to save the seeds of this plant, fow a spot of ground with it in the spring; thin the plants when they have about four leaves, and at the same time hoe down the weeds, as is practised for turnips. This hoeing is to be repeated in about a month after, and the plants are then to be left about eight or nine inches alunder, which will be sufficient space for the growth of this species. If these hoings are well performed, in dry weather, they will keep the ground clean till the mustard seeds are ripe. The stalks of this plant, which are branched and hairy, will then be about two feet high, and the ripening of its seed is indicated by the pods changing to a brown colour; immediately after which they should be cut down, dried upon cloths for two or three days, and then threshed out for use. And the larger kinds of mustard are to be treated in the same manner; excepting that, as they grow much larger, a proportionately greater space must be left between the plants; and as their seeds will not ripen so soon as those of the smaller kind, three hoings, or rather good deep flirrings of the ground, may be requisite.

The common mustard grows naturally in many parts of this kingdom; but is cultivated in the fields for its seeds, of which the condiment called mustard is made:

In the Annals of Agriculture, Mr. Young suggests, that mustard seed sometimes turns out prodigiously profitable, that is, three or four, and even five quarters, at 4l. a quarter. But it is hazardous, and has a very great evil, of rising afterwards in succive cops, and is hardly ever completely eradicated afterwards from the land.

MUSTARD. Baylard. See Cleomis.

MUSTARD Buckler, or Baylard Mithridate. See Biscutella.

MUSTARD, Hedge. See Erysimum and Sisymbrium.

MUSTARD, Hedge, in the Materia Medica. The Erysimum officinale, referred by some botanical writers to Sisymbrium, is common on dry banks and wafe places, and flowers from June till September. The tale of this herb, and particularly of the tops of the flower spikes, is somewhat acid. Its seeds are considerably pungent, and appear to possess the same quality with those of mustard, in a weaker degree. It is laid to be antiseptic, expectorant, and diuretic, and has been strongly recommended in chronic coughs and hoarse

M. Rundelius informs us, that the latter complaint, occasioned by loud speaking, was cured by this plant in three days. Other testimonies of its good effects in this disorder are recorded by writers on the Materia Medica, and among other...
MUS

others by Dr. Cullen, who, for this purpose, recommends the juice of the erysimum to be mixed with an equal quantity of honey or sugar. In this way it is also said to be an useful remedy in ulcerations of the mouth and throat. In most cases of disease, perhaps the seeds of erysimum, as being more purgant, should be preferred to its leaves. The Erysimum alliarum, sauce-alone, or flinking hedge-mullard, is common on hedge-banks, and flowers in May and June. The leaves of this plant have a moderate acrimony, and a strong flavour resembling that of garlic or onions; they give the same kind of taint to the breath as these roots, and have been used for the same culinary purposes; whence the name alliarum. On drying, however, theirensible qualities are considerably diminished, or entirely lost. "The juice, expressed from the fresh leaves," says Lewis, "is strongly impregnated with their active matter, but loses the greatest part of it on being imbibed to an extract with the gentile warmth; in its liquid state, duly secured from the air, it may be kept uninjured for many months. On diluting the fresh herb with water, there arise a small portion of essential oil, which taints and smells very strongly. The medicinal character of alliarum is that of a powerful diaphoretic, diuretic, and antiscorbutic; and as purgative of the qualities of garlic; it has been deemed useful as an expectorant and deobstruent, in humoral afflames, and other cases of dyspepsia. It has also been much esteemed as an external application, to promote suppuration; and Boerhavene informs us, that he cured a gangrene of the leg, arising from a neglected fracture and contusion, by applying the bruised leaves of alliarum with wine. Woodville Med. Bot.

This species of erysimum was formerly eaten as a fallad herb by the poorer sort of people, who gave it the name of Sauce-alone. The only official preparation of this plant is the "Syrupus de erysimum." It is recommended by Dr. Stahl for flintero-cancerous tumours, taken internally, and also applied externally to the tumours. We have an account of its good effects by M. Bingert, in Act. Med. Berol. Dec. 3, vol. I. p. 59.

MUSTELA, in Natural History, a genus of the class Mammalia, and order Ferra. The general character is, that it has five upper fore-teeth, erect, acute, distinct; and five lower, which are much obtuse, and crowded; two are placed within; the tongue is smooth.

In a variety of circumstances otters and weasels resemble each other; their bodies are long, and of the same thickness; their feet are short, hair thinly, and claws immovable; they burrow in the ground, proud and prey by night; but the otters live mostly in water, swim on the surface, and under it, and feed chiefly on fish. They do not climb, nor leap with the body curved, and tail stretched, like the weasels; the head is larger and thicker; the tongue is armed with soft prickles; otters have five grinders in each jaw, on each side; weasels have four, five or six.

Naturalists are very much divided in their methods of classifying animals of the kind now under consideration. Mr. Pennant, who is followed by Dr. Shaw, unites the genus Mustela with the Viverra; but Mr. Pennant includes in his genus the race of otters; Dr. Shaw prefers the otters or lutres distinct from both. We shall in this cafe, as in others, follow the Linnaean division, and, according to Gmelin, there are 28 species, which are divided into those that have hind-feet palmate, as otters; and those whose feet are cleft, as in the case of weasels.

A. Hind feet palmate. Otters.

Species.

LUTRIS; Sea-Otter. In this species there are two varieties; 1. Hind-feet hairy; tail one-fourth part as long as the body. 2. Black, with a yellow spot; the first inhabits the coasts of Asia and America; the second is found in the rivers of South America. This is one of the largest of the otters, measuring about three feet from the nose to the tail, and the tail is thirteen inches long. The colour of this species is a deep, glossy, brownish-black; the fur being extremely soft and very fine; the hind-feet resemble those of the seal, the toes being connected by a strong granulated membrane, with a skin flirting the outward toe, as in some of the water-fowl; the tail is short, broad, depressed, and pointed at the end. The sea-otter has been found to weigh 70 or 80 pounds. It is met with in great abundance in Bering's islands, Kamtchatka, the Aleutian and Fox islands, between Asia and America. They will sometimes come on shore in the Kurile islands, but are never seen in the channel between the north-east of Siberia and America. They breed once a year, and are supposed to bring but one at a time; they are extremely harmless animals, and singularly affectionate to their young. This animal is killed for its skin; which is one of the most valuable of furs, being sometimes folded for 25 l. to the Chinese. Sea-otters are sometimes taken with nets, but more frequently destroyed with clubs and spears. They feed chiefly on lobsters and other shell-fish.

PARAGUENIS. This species is mixed with grey and black; the feet are palmate. It inhabits on the Rio de la Plata; is the size of a cat; the fur is velvety, and the flesh very delicate.

CHILENSIS. The tail of this species is long, round; the feet very hairy. It is found on the coasts of Chili.

* Lutra; Common Otter. The hind-feet of this species are naked; the tail is half the length of the body. This is the Greater Otter of Pennant, and is found in almost every part of Europe, as well as in the colder regions of Asia; inhabiting the banks of rivers, and feeding principally on fish. It is also to be met with in the northern parts of America, where it grows to a much larger size than the European species; but in the river Euphrates, it is found no larger than a common cat; this, perhaps, is a different species, though sometimes denominated the Lutra. The usual length of the common otter is nearly two feet, with a tail of sixteen inches. The colour of the whole animal is brown, with some patches of different colours; the head is broad and flat; the mouth small; the teeth strong; the lips very mucular; the ears short and rounded; the eyes are small, and the neck very thick; the legs are short and thick, loosely joined to the body, and so placed as to be capable of being brought on a line with the body, and of performing the office of fins; the toes, which are five in number on all the feet, are connected by broad strong webs, and the whole foot is naked, or without hair. The otter has a great facility in forming its habitations; it burrows under ground, in the banks of some river or lake; and always makes the entrance of its hole under water; working upwards to the surface of the earth; and, before it reaches the top, makes several lodges, that in case of floods it may have a retreat; to all these lie forms an orifice for the admission of the air. The natural food of the common otter is fish, but when the weather is hard, and it is hardly driven for food, it will attack the 3 l. smaller
smaller quadrupeds, as well as poultry. The female produces four or five young at a birth; it is said that otters, when taken very young, may be trained up to hunt and fish for their matters. The male calls the female by a soft murmuring cry.

**Canadensis.** This is black; the fur is smooth; the tail long and tapering. It inhabits North America, particularly Canada, and is about two feet long; the tail ten inches.

**Lutra.** Lesser Otter. The specific character of this is, that it has very hairy feet, equal toes, and a white mouth. This species very much resemles the M. lutra, but is considerably smaller; the body is of a dully colour, but with a tawny call; the chin and throat are white; the ears are roundish; the feet broad, webbed, and covered with hair, instead of being naked, as in the former animal. In North America this species is known by the name of minx, and is said sometines to leave the water, and prey on poultry, &c. in the manner of a pole-cat; but in Poland and other parts of Europe, where it is found, it lives chiefly on fish, frogs, &c. Its fur is very valuable, and next in beauty to that of the fable.

**Cayennensis;** Cayene Otter. Toes on the fore-feet, unconnected; tail long, taper, naked. This species inhabits Cayenne, and is fifteen inches long.

**Minx.** The body of this species is of an entirely deep chestnut. It inhabits North America, on the banks of rivers; feeds on fish, birds, and mice, and sometimes haunts farm-yards.

---

**B. Feet short. Weasels.**

**Barbata;** Guinea Weasel. Black; a white three-jobbed spot under the neck. This species is found in Guinea and Brazil; and is the size of a martin. The hair is coarse, the ears rounded and hairy; the space between the eyes is cincereous; it has four teats.

**Galera;** Brown Weasel. The body is uniformly brown. It inhabits Guinea and Madagascar; burrows like a rabbit, and is destructive to game and poultry. The body of this species is shaped like a rat.

**Afra;** Madagascar Weasel. The body above is brown, beneath it is of a pale yellow; the tail is blackish at the tip. It inhabits, as its trivial name imports, the island of Madagascar; and also the interior parts of Africa.

**Visor.** The body of this is bright tawny; tail dusky. It inhabits North America; and resembles the martin, which will soon be described.

**Canadensis;** Pekan. Body blackish-tawny; but on the breast there is a white spot. It inhabits Canada, and is about two feet long, the tail is ten inches in length.

* Foina; * Martin. Body blackish-tawny; throat and breast white. This is an animal of very elegant appearance. Its length from nose to tail is about eighteen inches, and the tail is ten inches. It is a native of most parts of Europe, inhabiting woods and fields, and preying on birds and other small animals. If taken young it may be easily tamed, and even rendered domestic. It breeds in the hollow of trees, and brings forth from three to five young at a time. The skin is valued as a fur.

**Martes;** Pine-Martin. Body blackish-tawny; throat and breast yellow. This species is found in the northern parts of Europe, Asia, and America, and is very rarely found in the south; it preys by night; lives by day in hollow trees, and squirrels' nests: it feeds on young squirrels, mice, berries, ripe fruits and honey: in the winter it will watch for and devour pigeons and poultry; it brings forth seven or eight young at a time.

**Guinea.** Dark-brown; the forehead is white; the neck has a long narrow stripe along the side. It inhabits Guinea, is about two feet long, with a tail of five inches. The fur is sprinkled with black and white.

**Langer;** Woolly Martin. The body of this species is covered with woolly hair; the tail is long and tapering. It inhabits Cayenne, and is sixteen inches long, with a tail of five inches.

**Zhelleria;** Sable. There are three varieties of this species: 1. Body dark-tawny; forehead white; throat cincereous; the 2d is snowly white; the 3d has a collar of white or yellow spots round the neck. This species inhabits the northern parts of Asia and America, Siberia, Kamtchatka, and the Kurile islands. It fleeps by day; preys by night on smaller weasels, squirrels, and hares; in winter on birds, particularly on partridges; in autumn on berries; its fur is very precious. Formerly, in the Russian empire, the hunting of these animals was the task imposed on those exiles who were banished into Siberia. As that country became more populous, the fables have, in a good measure, quitted it, and retired into the desert forests and mountains. They usually reside on the banks of rivers, or on the small islands near them. At present the fable hunters form themselves into parties or troops, from five to forty each; the last subdivide into leffer parties, and each chooses a leader, but there is one commander-in-chief that directs the whole.

---

A small covered boat is prepared for each party, laden with provision, a dog and a net for every two men, and a vessel to bake their bread in. Each party has also an interpreter for the country they intend to penetrate. Every party then gets out, according to the course their leader points to them. They ascend the rivers, drawing up their boats, till they arrive in the hunting country. There they flop, build huts, and wait till the waters are frozen, and the season commences. Before they begin the chase, their leader assembles them; they join in a prayer to the Almighty for success, and then separate. The first fable each party takes is called God's fable, and is dedicated to the church.

---

The fables are employed to bring it on sledges from the places on their route, where they are obliged to form magazines. The traps are a fort of pit-falls, with a loose board placed over each, baited with fish or flesh. When fables grow scarce, the hunters trace them on the new fallen snow to their holes, place their nets at the entrance, and sometimes wait, watching two or three days for the coming out of the animal. It has happened that these poor people have, by the failure of their provisions, been so pinched with hunger, that, to prevent the cravings of appetite, they have been reduced to take two thin boards, one of which they apply to the pit of the stomach, the other to the back, drawing them tight together by cords placed at the ends. Such, says Mr. Pennant, are the hardships our fellow creatures undergo, to supply the wantonness of luxury!
report to their leader the number of fables each has taken, make complaints of offenders against their regulations, punish delinquents, and share the booty. They then continue at the head-quarters till the rivers are clear of ice; when they return home, and give to every church the dedicated furs. The price of these furs varies from one to about ten pounds sterling. Fine and middling skins are sold without the bellies; the coarse ones with them. The finest fables are fold in pairs perfectly similar; and such pairs are dearer than single ones of the same goodness; for the Ruffians want those in pairs for facing caps, cloaks, and tippets. The blackest are reputed the best. Sables are in season from November to February; those caught at any other time of the year are short-haired. The hair of fables differs in length and quality. The more a skin has of such long hairs, and the blacker they are, the more valuable is the fur. The very best have no other but those long black hairs. Below the long hairs there are, in the greater part of fable furs, some shorter. Besides various other particulars respecting the fur, the furbusters attend much to the size, always preferring, ceteris paribus, the bigger, and thofe that have the greatest glos. The glos vanishes in old furs; the freth ones have, what dealers in furs call, a bloomy appearance; the old ones are said to have done browning. The dyed fables always lose their glos, and become black, whether the common hairs have taken the dye or not, and the hairs are commonly twisted or crisped, and not so straight as the natural ones. Some fume the skins to make them look blacker; but the smell, and the crisped condition of the long hair, betray the cheat; but dyeing and fumeating are both detected by rubbing the fur with a moist linen cloth, which grows black in such cases. The Chinenfs have a way of dyeing the fables, so that the colour not only bleeds, which is more than the Russian cheat can effect; but the fur keeps its glos, fo that the fraud can only be detected by the crisped hairs.

The country about the river Ud affords sometimes fables, of which one is often fold for twelve or fourteen pounds sterling. The bellies of fables, which are fold in pairs, are about two fingers' breadth, and are, like the skins, tied together in parcels of forty each. One of these parcels fells from one to two pounds sterling; tails are fold by the hundred; the very bell furs muff have their tails, but ordinary ones are often cropped. A hundred fell for from four to eight pounds. White fables are rare; they are not common merchandise, but bought only as curiosities. Some are yellowish, and are bleached in the spring on the snow. The common fables are scarcely any thing better in hair and colour than the marten.

The fable is also found in North America. The Ruffians have often discovered the skins mixed with those of martins in the fur drefles, which they get from the Americans by way of exchange. Their fur is more glossy than that of the Siberian fable, and of a bright chestnut colour, but of a coarser quality. The length of the American fable is about twenty inches; the trunk of the tail is only five; but from the rump to the end of the hair eight. His ears are more pointed than thofe of the Atlantic fable; its feet are large and hairy, both above and below; it has five toes, with white claws on each foot. The colour of its head and ears is whitish; its whithers are short and black; its whole body of a light tawny; its feet are brown.

AMERICANUS; American Sable. Body light and tawny, head and ears whitish. It inhabits North America, and is about 20 inches long.

NIGRA; Fisher Weefel. Back, belly, legs, and bulky tail black; the fides are brown. This is a native of North America, where it is supposed to be pretty common, as not less than five or six hundred skins have been brought, in one season, from New York and Pennsylvania. Though the general colours are those that have been described above, yet they vary, and in some instances the animal is nearly black.

* * * * *

Putorius; Pole-cat. Body blackifh-yellow; mouth and ears white. This is one of the most remarkable of the weefel tribe; its colour is an extremely deep blackifh-brown, with a tawny cast slightly intermixed. It is about fifteen inches long, exclusive of the tail, which measures fix inches. It is found in most countries of Europe, and also in many parts of Asia, and in Siberia; it forms itself a subterraneous retreat, sometimes beneath the roots of large trees, sometimes under hay-ricks, and in barns. It preyis indiscriminately on the smaller animals, and is very destructive to poultry. During the summer it frequents rabbit warrens, or the hollow trunks of trees, and other places of the same kind. It is a strong and active creature, and will spring with great vigour and celerity when preparing to attack its prey, or to escape from its pursuir. It emits a smell proverbially fetid, being furnifhed, like several others of the weefel tribe, with certain receptacles which secrete a thickifh fluid of a peculiarly strong and offensive odour. The fur is beautiful, and when properly dressed, is numbered among the commercial furs used as articles of drefs.

Furo; Ferret. Eyes red and fiery; this animal, in its general form, resembles the pole-cat, but is a good deal smaller. It is a native of Africa, and supports with difficulty an European winter; it is, however, famed in Europe for the purpose of catching rats and rabbits. It also breeds in this and other European countries, and hence is regarded as natural to us. It sleeps almost continually, and when awaked, immediately begins to search for food; it is usually fed with bread and milk, but its favourite food is the blood of the smaller animals. The ferret was brought into Spain from Africa, probably for the purpose of freeing that country from the vall number of rabbits with which it was overrun, and from Spain it was gradually introduced into other European states. It is very irritable, and when irritated, his odour, which is at all times offensive, becomes far more so than usual. The general colour of the ferret is very pale yellowifh-brown, or cream colour.

Sarmatiana; Sarmatian Weefel. The upper part of the body is yellow and brown. It resembles the pole-cat, but is larger; the hair, excepting on the feet and tail, is shorter.

Sibirica; Siberian Weefel. The body is tawny; and the feet very hairy. It inhabits the woods of Siberia; is voracious, devours flesh, and kind ater butter from the nuts of the beeches; its tail is hairy, and darker than the body; the fur is long and loose; the face is black; the nostrils whitish; about the eyes it is spotted, and the throat is sometimes spotted with white.

* Emerina. Tail black at the tip: there are two varieties: in the first the body has a reddish tinge; this is the English Ioot: in the second, the body is white, and the tail is blackish at the tip; this is the ermine. It inhabits Europe, and the colder parts of America, Asia, and China; it lives in heaps of stones, banks of rivers, hollow trees, and forests, especially of beech; prey on squirrels, mice, and small animals. In Norway and in Siberia, the skins are a great article of commerce; most of the ermine or white Ioot-skins being brought from thence. In Siberia, the Ioot is said to be found in birch forests, and the skins are fold on the spot, at from two to three pounds per hundred. The animals are either taken in traps, or shot with blunt arrows.

* Vulgaris; Common Weefel. Body tawny-brown, be
neath white; the tail is the same colour as that of the body; there is a variety in which the body is white; tip of the tail with four black hairs. This species inhabits the temperate and cold regions of Europe, Asia, and America; in Russia it becomes white in winter; it is about half the size of the eel; it eats fish, flesh, mice, eggs, and fungi; but no other vegetables; it preys by night, gets into the holes of mice, and devours them, leaving the teeth only; in its habits it is ferret, dirty, and drinks often; it is very cunning, continually looks about, and is not easily destroyed by a cat. From the extreme flexibility of its body, and its wonderful activity, it readily ascends the fides of walls, and by this means pursues its prey into the most distant retreats, and it is a frequent inhabitant of barns and granaries. It brings forth four or five young at a time, preparing for them a bed of moss, grafs, &c.

MELINA; Yellow Weefel. Back and belly pale cinematous-yellow; face, crown, legs, and tail black.

QUIQU. Body brown; snout wedge-shaped. This species inhabits Chile, living underground, and feeding on mice; it is principally distinguished by its wedge-shaped snout; the ears are short and round, with a white spot in the middle; the legs and tail are short; the feet like those of a lizard; the length of the animal is from nose to tail about thirteen inches.

MUSTELA, in Ichthyology. See Gadus Mytfola.

MUSTELA AFRICANA, in Zoology. See Sciurkus Palmeram.

MUSTELA CAUROICA, &c. See Lepus Alpinus.

MUSTELA FLAVILIS, in Ichthyology. See Gadus Lota, and Eel-Pout. See also Petromyzon.

MUSTELA FISHTA. See Coitii Fishtas.

MUSTELA LUMPENUS, a name given by Artedi, from Ray and others, to that species of blennius, called simply lumpen at Antwerp, and by Gefner galus.

It is distinguished, by Artedi, from the other blennii, by a specific name, expressing that it has four bifid cirri or beards, growing under the throat, and transverse aroele or fteaks on the back. It is found in the clayey and sandy bottom of the European seas, and conceals itself among the fuci on the shore, where it depusts its spawn in July. It is smooth, with small rounded scales, of a palifh colour, the head yellowish, the body narrow, and the spinnen radius of the dorsal fin are marked backwards. See Blennius.

MUSTELA MARINA. See Petromyzon Marinus.

MUSTELA VIVIPARIS, the Blennius viviparus. See El-Pout.

MUSTELINUM GENUS, in Zoology, the name of a class of animals, so called from their general likeness to the weefel in shape: they are all carnivorous animals, and are distinguished from the other quadrupeds of that fort by their smallnes, the length of their bodies, and the smallnes and narrowness of their heads. Their feet are small, and their legs short, whence they are formed for running into holes or crannies; their teeth are less numerous than in many quadrupeds; in the dog kind there are forty, and in thee but thirty-two. Their intestines are short and simple; they have no colour nor colurn, nor any distinction of great and small enus. Ray.

MUSTELUS SPINAX, in Ichthyology, a name given by Bellonius, and some other writers, to the fish called galus acanthus, a species of halarus. See Squalus Acanthias, and Spinax.

MUSTELUS LEVIS, a name by which Aldrovandus, and some others, have called the fish distinguished by others by the name of galus levis, the smooth lump fish. See Squalus Mytfola.

MUSTELUS LEVI, a name of a kind of shark, called also the callus galus, and canola. See Squalus Galeus.

MUSTER, in Geography, a town of the duchy of Conland; 56 miles S.E. of Seelburg.

Muster, in Military Language, denotes a review of a body of military forces under arms, in order to take account of the numbers, condition, accoutrements, arms, &c.

The word is formed of the French, mustre, specimen, a show or exhibition. See Review.

It is needful to enquire into the antiquity of musters, since they must have existed ever since an army has been assembled. Without a muster it would not be known whether the feudal tenants, or others liable to furnish soldiers, had provided their due number, nor could a general otherwise know the true strength of his army, the ground they would occupy, the quantity of provifion and forage neceffary for their subsistence, and that of their horses; nor the money required for paying them. The object of a muster was not only to ascertain the number of men and horses, but likewise to examine their armour and weapons. Great abuses having crept into the practice of mustering the troops half-yearly, so that the real effective strength of the army could never be exactly ascertained, a new regulation has taken place, in virtue of which the several regiments and corps are mustered every month by the regimental paymaster, and detachments of regiments in the respective districts in which they are stationed, by an officer called paymaster of the district. These have superceded the commissaries of musters; and the pay-lifts and muster-rolls of the army are thus made to tally with each other. By 49 Geo. III. c. 12. every regiment, troop, or company is to muster twice a year, at least.

Muster, False. See False.

Muster-master-general, or Commisary-general of Musters, is an officer in the army, who takes account of every regiment, their number, horses, arms, &c. In the ordinances of war made by king Henry V. this officer is mentioned, and his power and duty are defined. See Commissary.

Muster Rolls are lists of the soldiers in every troop, company, regiment, &c. delivered by the captains to the commissary: by which they are paid, and the strength of the regiment known.

MUSTERED of Record (flat. 18 Hen. VI.) denotes a being enrolled in the number of the king's soldiers.

Musterering, in Sea Language, is the act of calling over a list of the whole ship's company, or any particular detachment thereof, who are accordingly summoned to answer by their names on the occasion.

MUSTEWAH, in Geography, a mountain of Algiers; 40 miles S. of Conlistanta.

MUSTY GANNIM, MOSTAGAN, or Meleggan, a sea-port town of Algiers, in the province of Mafecara and Trebec, supposed to be the "Cartenna" of Pliny and Ptolemy. It is built in the form of a theatre, with a full prospect of the sea; but in every other direction it is surrounded with hills. In one of the vacant spaces about the middle of it are the remains of a Moorish castle. The N.W. corner of the city, which overlooks the port, is surrounded with a wall of hewn stone; and it has another castle built in a more regular manner, defended by a Turkish garrison; however, the chief security of the place depends upon the citadel, which is built on one of the adjoining eminences, and commands both the city and country. The town is well supplied with water, and its harbour is commodious and safe. Nevertheless, though it is one of the largest towns in the province of Mafecara, it is neither beautiful, nor has any flourishing trade or manufacture. Behind it rises mount Magharaba, so called from a people of that name, who inhabit it. This mount extends itself
MUT

MUT: in Geography, a town of Hindooftan, in Bahar; 25 miles S. of Patna.

Durum

The same series of sounds in the octave and 15th would have the same names.

Naturale

See Solmisation, Gammut, and Harmonic Hand.

MUTABILIS LAPS, in Natural History, a name given by some to the semi-pellucid gem, more commonly called occlus munia.

MUTABILITY is opposed to immutability.

MUTARE ARMA. See Arma.

MUTATION, the act of changing, or sometimes the change itself.

It is one of the laws of nature, that the mutation of motion is ever proportional to the moving force impressed. See Nature and Motion.

MUTATIONS, in Music, are the changes in the names of the notes in falsifying by the hexachords. In a series of five sounds, in the hexachord of G durum, or G with a major 3d, no change of name is required ascending or descending. Ut, oct, de, ni, si, sol, la: la, sol, si, ni, re, do, are the names of all the intervals in that compass; but in completing the octave, which cannot be done without encroaching on the hexachord of C natural, the mutations begin. It is the same in the hexachord of C; when a 7th sound is wanted, it must, if minor or flat, belong to the moll hexachord of F; if major, or natural, to G. See Hexachords.

Dominico Pedro Ceroni, in an elaborate work, written in the Spanish language, and published at Naples 1613, has taken great pains to throw a light upon the subject, which he says he found, by his own experience, extremely dark and difficult. He minutely goes through all the seven hexachords, shews their connection with each other, and gives scales to manifest the mutations, which, in ascending beyond a hexachord, are made by the syllables re, and, in descending, by la.

MUTA-
Mutationes, among the Romans, lofty stages, or places where the public couriers were supplied with fresh horses.

The mutationes were wholly designed for the use of these couriers, or messengers of flates; in which respect they differed from manufacnes.

MUTBUNNY, in Geography, a town of Hindoostan, in Bahar; 23 miles S.S.E. of Bettiah. N. lat. 26° 28'. E. long. 85° 2'.—Allo, a town of Hindoostan, in Bahar; 15 miles N.E. of Durbungah. N. lat. 26° 20'. E. long. 85° 16'.

MUTCHANG, a town of Meckley; 104 miles S.S.E. of Munnpour.

MUTCHKN, a liquid measure used in Scotland; it contains four gills, and is the fourth part of a Scotch pint.

See Pint, Measure, &c.

MUTE, Dumb, denotes a person that cannot speak, or has not the use of speech. See Dumb.

Mutes and dwarfs make their fortune in the grand signior's seraglio. The mutes serve as executioners to take off persons of the first rank.

Mute, in Law, a person that stands dumb or speechlets, when he ought to answer or plead.

A prisoner may stand mute, two ways. 1. When he speaks not at all: in which case it is inquired, whether he stand mute of malice, or by the act of God; if by the latter, then the judge, ex officio, ought to inquire whether he be the same person; and of all other pleas, which he might have pleaded if he had not stood mute. 2. When he pleads not directly, or will not put himself upon the inquest to be tried. If he be found to be obstinately mute, then, if it be on an indictment of high treason, it is clearly settled that standing mute is equivalent to a conviction, and he shall receive the same judgment and execution. So likewise, in petty larceny, and in all misdemeanors, standing mute is equivalent to conviction. But in appeals or indictments for other felonies, or petit treason, it was the custom till of late not to consider him convicted, so as to pass judgment for the felony; but for his obstinacy he was to receive the terrible sentence of penance, or paene forte et dure. Before this was pronounced, the prisoner was allowed not only irina admonitio, but also a convenient repitue for a few hours, and the sentence was distinctly read to him, that he might know his danger; and, after all, if he continued obstinate, and his offence was criminal, he was allowed the benefit of his clergy, even though he was too stubborn to pray it. But in this respect the law is now altered; for by 12 Geo. III. cap. 20, standing mute in felony or piracy is made a conviction.

To advise a prisoner to stand mute is an high misprison, a contemp of the king's court, and punishable by fine and imprisonment.

Mute, in Grammar, a letter which is not founded, or heard in the pronunciation; or a letter which yields no sound of itself, and without a vowel.

The consonants are ordinarily distinguished into mutes, and liquids or semi-vowels. See Conniant, Liquid, &c.

The mutes in the English alphabet are eleven; viz. B, C, D, F, G, J, K, P, Q, T, V. They are called mutes, because a liquid cannot be founded in the same syllable before them, as pro; but a mute may be pronounced in the same syllable before a liquid, as pro.

MUTEFERRA, a body of horse kept up in Egypt, in the service of the grand signior; there, with the chasses were originally the guards of the sultans of Egypt. This is a body of the greatest dignity, and is expressed by the word, which signifies a chosen people.

MUTTON, in Entymology, a species of fish resembling cals, in Hudson's Bay. They are principally caught in winter with hooks, through openings made in the ice.

MUTHIEL, Johann Godfried, in Biography, a German musician settled at Riga, who, though but little known in his own country, was a musician of great abilities both as a compositor and performer. He was a worthy disciple of Sebastian Bach, and had resided some time at Schwerin before he went to Riga. When a student at Leipzig, he vanquished all the difficulties to be found in the lessons and organ pieces of his master and of Handel; then he seems to have made Emanuel Bach his model of composition. Should a young professor on keyed-instruments, who had subdued all the difficulties of his predecessors, lament, like another Alexander, that nothing more remained to conquer, we would recommend to him, as an exercise for patience and perseverance, the compositions of Mühl, and perhaps Beethoven, which are so full of novelty, taste, grace, and masterly designs, that we should not hesitate to rank them among the greatest productions of the last and present age.

The first of Mühl's works that we can trace were odes, printed at Hamburg in 1759; the rest, which are all for the harpsichord, appeared in the following order: three fantasias and two airs; with twelve variations, Nuremberg 1760. Two concertos, printed by Hartknoch, Riga and Mittau, 1767. Dueto for two clavichords, or two harpsichords, or two piano fortos; printed by Hartknoch, Riga, 1771.

Though the style of this composer resembles that of Emanuel Bach more than any other, the passages are entirely his own, and reflect as much honour on his head as his hand. Indeed his productions abound with difficulties, which to common hearers, as well as common players, must thirty years ago, have appeared too studied and elaborate; for even his accompaniments are so charged as to require performers for each instrument of equal abilities to his own, which is expecting too much, in musicians of this nether world.

"Odi s'io son faccio; Ancor mi ferra bella, Ma non mi ferra quale Che paragon non ha." 

Metastasio.

"Nor do thy strains, though sweet, At present so excel, As those which blame defeat, And have no parallel."

From having, in 1772, seen few of the works of Vanhal or Haydn, and none of Mozart, except his childish productions which Bremner printed on speculation; we admired the taste, invention, high finishing, complication, and equality of grace and melody which he gave to all the parts of his concertos, and praised them so highly: speaking at the same time of the difficulty of their execution, in such a way as frightened students, and perhaps some able masters, from attempting them. But after having lost them for many years, on recovering and deliberately examining them, we find the two great laws laid down by Roufeuf, and generally adopted, infringed: the want of symmetry and phrasology in the number of bars, and unity of melody. But "what can we reason, but from what we know?" These laws, we suppose, were unknown in Germany at this time. Mühl's passages are new and difficult; more in the style of his fellow student Emanuel Bach than any other; but left untaught and graceless. His choruses are now become antique. His graces are unapplied. Shakes and trills on the flint and last notes of a bar have been long banished. Indeed, we believe
lieve they have had no admission in the vocal music of Italy since the time of Piccini and Sacchini, who never admitted them. But the elaboration of his several parts surpasses us now as much as ever; though the difficulty of their execution, in some measure, arises from the want of phrasing and punctuation. How difficult it would be to read Milton's blank verse without stops; or even Dryden's and Pope's heroic verse, if printed like prose! We should like to see his concertos scored. He found, doubtless, that his duet could not be executed from single parts; and it has been only in looking at single parts of his concertos that we have discovered what will now be called defects, from laws posterior to the time when Müthel's compositions were printed. Roufau's would admire his passages; but say, that simplicity was wanting. In "La Paflione di Jouelli," which we tent him, he said it was, "a composition worthy of being ranked with the productions of Pergolese, except in simpli-
city;" and he was right.

After having ranked Müthel so high thirty-four years ago, it is necessary that we should assign reasons for the warmth of our eulogy. It judged by laws which did not exist in 1772, or at least were not established throughout Europe until after his death, it might doubtless admit of some exten-
nuation. Grace, the principal feature in music, (and perhaps in all the fine arts,) depends on phrasing, symmetry, and correspondent arrangement of passages with respect to time. This frequently happened by chance in Italy. We believe it was constant and infallible in Corelli; but not from reflection or principle. Handel, from feeling, seldom was deficient in phrasing.

Both Müthel's concertos were published in 1767: Roufau's Lettre fur la Musique Françoise in 1751, sixteen years anterior. His first, concerto concertato, consists of cembalo, two violins, tenor and bafe. The second of cembalo concertino, accompanied by two violins, two bassoons or violonceli, tenor, and ripieno bafe.

We think Mullet much inferior to Emanuel Bach in grace; but superior to him in the folio parts given to the harpsichord, in which there are many common and unmeaning divisions; which, after the refinement and invention of his fumian, as he calls them, dedicated to the princesses Elisa of Prussia, suprised and disappointed us. But in no one of his works are his concertos in parts so much common or vulgar passage to be found. He is, we believe, the first who wrote appropriate in large notes, the exact length they should be played. The double dot, if not the first who used it in Germany, he was, at least, the second after EMa-
uel Bach. We used it in 1760 in a book of lessons, before we had seen the productions of either.

Having made these remarks on his concertos, and reco-
vered his duet for two piano forte, harpsichords, or clavi-
chords, printed in a four-tailf score, we shall examine it with equal rigour.

Roufau saw the too great research and want of simpli-
licity in Jouelli's Miserere, and in the Mattutina di morti
of Perez. Our friend Roufau, (as a writer on music,) pushed simplicity, and unity of melody, perhaps too far; there are effects produced by harmony and modulation, occasion-
ally, quite independent of melody.

Müthel's works are become very scarce, and, on account of their difficulty, were never much known. We cannot afford plates for examples of what we now object to him; and these remarks are added to his article here to account for our unqualified praise at one period of refinement in the art of music, and confounding him not free from cenure at another. The duet is still a curious composition, manifesting a powerful hand, great fertility of invention, and a taste and refinement unknown, at the time, to all Europe, except to the Bach school.

MUTILATED CORNICE. See Corniche.
MUTILATED MEDAL. See Medal.
MUTILATED ROOF. See Roof.
MUTILATION, the retouching, or cutting away, any member of the body. See MAIEN.

The use of the word is also extended to statues and buildings, where any part is wanting, or the projection of any member, as a cornice, or an impoit, is broken off.

MUTILATION is sometimes also used in a more immediate manner, for caltration.

MUTILLA, in Natural History, a genus of animals of the order Hymenoptera. The generic character is, an-
ten先 filiform; feelers four, of which the articulations are obconic, feated on the tip of the lip; the jaw is mem-
 branaceous at the tip; the lip is projecting obconic; in mott species there are no wings; the body is pubescent; the thorax retube behind; the fling is pungent and concealed.
There are nearly forty

Species.

Helvolia. The colour of this species is pale claret-red; the abdomen is cylindrical, pubescent at the tip; and the thighs are compressed. It inhabits the Cape of Good Hope.

Coccinea. Scarlet; abdomen is marked with a black belt. It inhabits North America. The wings are black, but in general it is an aperous insect.

Antiqua. This species is scarlet; tip of the abdomen black, with white streaks. It inhabits Antigua.

Guineensis. Thorax subpinous, variolous, piceous; abdomen black, with two white dots, and an interrupted band. It inhabits Guinea, and is large.

Diadema. Black; abdomen with two large yellow dots at the base, and an interrupted band in the middle; the tip has a white line. It is found in Surinam, and is large.

Americana. Black; abdomen with four yellowish spots, and three white lines. Found in South America.

Formicaria. Black; abdomen with a line of whitish dots down the back. It inhabits New Holland. There is a specimen of it in the museum of Sir J. Banks.

Exulans. Black; abdomen with two yellow dots at the base, an interrupted streak in the middle, and a line behind. It inhabits America.

Aurata. Bluish; abdomen with a large spot. In-
habits New Holland, and may be seen in Sir J. Banks' museum.

* Europa. Black; thorax rufous; segments of the abdomen with white margins. This is described in Mr Donovan's interesting work on English insects. The ab-
domen has two white bands, the second is interrupted.

Atrata. Black; upper part of the thorax rufous; abdomen blue, with two white bands. It is an African in-
sect.

Maurea. Black; abdomen with four white spots; tho-
rax rufous. Found in divers parts of Europe.

Hungarica. Black; front cinereous; thorax rufous; abdomen with six white dots, and a streak behind. Found in Saxony.

Cokonata. Black; front cinereous; thorax rufous; abdomen with a silvery white dot, with two streaks. Found in Saxony.

Halensis.
Halensis. Hairy and black; thorax rufous; abdomen with two white dots, and a band behind. It inhabits a foreign country.

Arenaria. Hairy, black; front and back of the thorax white; abdomen with four white spots. Found in the sandy plains of Spain.

Barbary. Hairy and black; fore-part of the thorax white; abdomen with two white bands. It inhabits Barbary.

Ephippium. Hairy and black; thorax rufous on the back. Inhabits Saxony.

Italica. Hairy and black; second segment of the abdomen rufous. Inhabits Italy.

Paezmontana. Hairy and black; fore-part of the thorax cinereous; abdomen with two cinereous bands; the second segment rufous. Inhabits Italy, and is as big again as the M. Italica.

Versicolor. Abdomen black at each end, and rufous in the middle, with a white band, in which is a black dot. It inhabits America.

Regalis. Hairy, black; front cinereous; thorax rufous; abdomen with four white dots; the middle one elongated. Found in Hungary.

Ruficollis. Hairy and black; thorax rufous. Found in Italy.

Ciliata. Hairy, black; thorax rufous; segments of the abdomen edged with a cinereous fringe. It inhabits Saxony.

Erythrocephala. Hairy and black; head rufous; abdomen with three gold bands.

Glabella. Glabrous, black; thorax and abdomen rufous beneath. It is found in the East, and is a small insect.

Refines. This species is hairy and black; antennae, thorax, and legs rufous; abdomen with a white dot, and two approximate bands. It inhabits Saxony, and is small.

Melangecephala. Hairy and rufous; head and tip of the abdomen black. It inhabits France.

Nigripes. Rufous; the tail is black, with approximate white stripes; legs black. It inhabits the East.

Indica. Black; abdomen with a pale yellow band and white line. Found in the East Indies and South America.

Brutia. Black; thorax rufous; abdomen with fix silvery-white spots and band. It inhabits Calabria.

Littoralis. Black; thorax rufous; fore-part of the abdomen with a two-lobed white spot; the five hind segments edged with white. This also is found in Calabria.

Spinosa. Whitish, varied with black; thorax with four spots on each side; the second segment of the abdomen has two tesselated spots. It inhabits America.

Cephatotes. Head large and black, spinous on each side; abdomen with a gold spot, and three white interrupted bands. Found in Georgia.

Bifasciata. Black; head and thorax red; abdomen with two red bands; the wings are violet-black. Found in New York.

Punctata. Black; thorax sublunular, immaculate; abdomen with three whitish dots on each side. It inhabits Africa.

Maculata. Black; thorax rufous above; abdomen with a row of three whitish spots on each side. It inhabits India.

Mutilus, the name given by some to the common mule.

Mutila, in Ancient Geography, a municipal city of Gallia Cispadana, situated towards the east, and near Scultena. It received a Roman colony about the year 572; now Mutina, which fee.

MUTINY, in a Military Sense, denotes an insurrection against authority.

An act is annually passed by parliament, called the mutiny act, to punish mutiny and defection, and for the better payment of the army and their quartermasters.

This regulates the manner in which they are to be dispersed among the several inn-keepers and victuallers through the kingdom, and establishes a law martial for their government. By this, besides other things comprised in the Articles of War, enumerated and enforced in this act, (see 10 Geo. III. c. 12.) it is enacted, that if any officer or soldier shall excite, or join any mutiny, or, knowing of it, shall not give notice to the commanding officer; or shall desert, or lift in any other regiment, or fleece upon his poff, or leave it before he is relieved, or hold correspondence with a rebel or an enemy, or strike or use violence to his superior officer, or shall disobey his lawful commands; such offender shall suffer such punishment as a court-martial shall inflict, though it extend to death itself.

After the abdication of king James II., and the accession of king William III., the military code obtained the function of parliament, though passed only from year to year, under the denomination of the mutiny act. The first of these acts passed on the 12th of April 1689, and was to continue in force to the 10th of November in the same year. See Army.
MUTIS.

Some of its ministers were wise enough to see the probable advantages to be derived from its natural resources in the new world, if the light of science were to be directed that way. And although the Spanish throne was encumbered and polluted with the very dregs of royal satiety and depravity, the baleful withering yeons of a rotten worn-out flock, swarming with the vermin which there find their natural abode; still the influence of those honest and patriotic characters was occasionally felt. We have mentioned the invitation given to Linnaeus to settle in Spain, and the mission of his pupil Locclliso to South America. (See LINNAEUS and LOCCLELLISIA.) In 1760, the Marquis Della Vega, being appointed Viceroy of New Granada, solicited Mutis to accompany him, as his physician. This proposal was joyfully accepted; not probably with any view to a final settlement in that distant region, but rather as a step to future advancement at home, after his curiosity had been in some measure gratified abroad.

Previous to his departure, the subject of our memoir spent some time with his friends at Cadiz, where it fortunately happened that the Swedish consul, Mr. Bellman, was a man of information and taste in the sciences in which his countrymen have always been pre-eminent. This gentleman procured for Mutis some of the works of Linnaeus, and introduced him to an epistolary correspondence with that great man, which continued till his death in 1778, of which melancholy event an account was transmitted to Mutis that year by the younger Linnaeus, in a letter, of which a copy is now before us. The writer takes an opportunity of describing to his learned correspondent the wonders of the Hedyfarum gyrans, then just raised in the stufe at Utopal.

On his arrival at Santa Fé de Bogota, the capital of New Granada, our ardent and intelligent young philosopher immediately anticipated the probability of his communicating, as well as acquiring, knowledge. By the permission of the Viceroy, he undertook to introduce the mathematics as a branch of study in the university; and his lectures on that subject were received with enthusiastic attention and admiration. But it was not to be expected that the monkish professors should equally relish such novelties. To acquire or to diffuse knowledge was neither their aim nor their ambition, and it was certainly not for their interest nor their peace. On this subject the Christian church, in every country and in every age, has been uniformly and firmly resolute, exactly in proportion to its degree of corruption. Yet we mean not to attribute even this species of fagacity or vigilance to the monks of Bogota. It was natural that the hardy adventurer, who disturbed their dreams and feared away their fumbers, should, like those who first roused the bats and owls in the caves of Elephanta, be befavoured with their filth. They declared, what perhaps they believed, that Mutis was a conjurer, who, by an alliance with the devil, taught a magical, divinatory, and diabolical art, unwarranted by law and prohibited by religion. "How else," said they, "could a mortal measure the distance of the sun or of the moon, or foretell eclipses?" Their representations were not without effect. Some well-meaning, but not well-informed, person forbade their children to frequent the schools of a necromancer, and thus the usefulness of the new professor was limited, and his fame in part eclipsed; for such prohibitions could not fail to foster a certain mass of prejudice, against him and the more enlightened party, which daily increased under his genial influence. Nor was the power of the inquisition allowed to be idle in so holy and just a cause. From this however the higher power of the Viceroy was able to shield the intended victim, who gradually rose superior to prejudice and persecution, and was at length, by the authority of the Spanish government, established Professor of Philosophy, Mathematics, and Natural History, at Santa Fé. It is to be presumed that his own character and conduct were, meanwhile, irreproachable, conformable to the purity of his principles, and the exemplary tenor of his subsequent life, against which malice, even in the days of his adversity, never dared again to aim its darts.

Mutis, like a true patriot, was anxious to turn his own knowledge to the practical service of his country. Considering the gold and silver mines as the most important national objects in Mexico and Peru, he directed his attention to a more successful mode than had hitherto been practised, for working the mines of the laft-mentioned metal. Gold is procured chiefly by patience and manual labour, in a metallic state, from the sands of the rivulets; but silver can be obtained by chemical means only, from recondite sources in the bowels of the mountains. Its mines are not only, like those of gold, a fort of lottery, but to derive a due profit from its ores, requires knowledge and observation, as well as labour and considerable expense. All mining countries abound with traditions of their former riches, and liberal conjectures respecting their latent stores. By these our philosopher was misled. He spent many years of indefatigable application, and exhausted his pecuniary resources, with the zeal and the disappointment of an alchemist.

He reaped indeed abundance of experience and of natural knowledge, as he explored the recesses of the Cordilleras, and investigated the productions of their soil, as well as the secrets of their geology; but his worldly prospects were ruined. The he might have retrieved by accepting some civil employment or magistracy, offered him by his constant friend the Viceroy, to whose propensities of this kind he is reported to have anfevered, that "he aspired after no government, but that of himself, nor any authority but over his own pailions." In conformity to such sentiments, he found the clerical professor more congenial to his feelings; and to that he for a while devoted himself, as it appears, exclusively, refiding for some time in the capital. But a miner seldom gives up his pursuits, and the former propensities of Mutis revived, as he anticipated afehr the means of indulging them. His sucesse was fruitless, as before, with regard to its original object, but not as to the future happiness and utility of his life. The refidence he had choen, for the prosecution of his purpose, was fortunately one of the most delightful in the world, at Sapo, in the government of Mariquita. His house flood on a rising ground, commanding the most enchanting prospects, over an extensive valley, watered by the meandering river Lucia. The groves of palm-trees, and the rural scenery of the valley, are encompassed by a chain of hills, whose proud tops rife one above another, till they are lost in the clouds. Here our philosopher enjoyed a pure air and temperate climate, equally remote from the cold of the mountains, and the oppressive atmosphere of the vale below. In this sequestered abode he divided his time between the superintendence of the mines, and the study of natural history; while he fulfilled his clerical duties, and benefited his neighbours by the exercise of his original profession. He was soon confided for his disappointment in the first of these objects, by the general esteem and respect which his character and conduct inspired; so much that he refused himself for life to this delightful retirement, without a figh for the vanities or the bustle of the world. Here botany constituted his most favourite amusement. The country within his reach was found rich in plants, of peculiar beauty as well as singularity, which indeed may be said in general of all the vegetable producions
ductions of New Mexico. Splendid compound flowers, shrubs whose shining leaves are invested beneath with a dense woolly clothing, giving a great peculiarity as well as richness of habit, are striking characteristics of the Mexican Flora; which is further enriched by no small proportion of the magnificent tribe of Palms. To these last Mutis paid particular attention; but the history of them, which he is said to have prepared, has, as yet, not been given to the public. His correspondence with Linnaeus was as frequent as circumstances would permit, but it appears that many of their letters and communications never reached their respective destinations. To him he sent numerous dried specimens, many manuscript descriptions, and a whole volume of Indian ink drawings, quoted in the Supplementum. Among the specimens were several of the noble Mutisia, first described in that work, to which several new species have since been added; see the next article.

On the 12th of September 1778, Mutis addrest a long and very interesting letter to the younger Linnaeus, in answer to that in which the latter had informed him of his father's decease. By this it appears that he had not settled at Sapo till the year 1776. He complains of having suffered much, in the following leafoon, from the attack of an insect of the Ostrus, or Gad-fly, kind, very common in that neighbourhood, which, having lodged itself in his leg, produced a tumour. To this he applied the juice of tobacco, with the milk of a plant which he terms Mutisa guinaeefia. But the application, though useful among the country people, nearly cost him his life, by producing a violent inflammation and suppuration. He gives the following very curious account of the parent fly. "It is not larger than the Mutisa donjonftica. The abdomen is covered with a series of little tubes, resembling a wasp's nest, in which above fifty minute larvae are lodged. The lichen of this fly to what is so very common and harmless, causes its pernicious design not to be suspected as it settles on the human body, till its brood has, with great celerity, found a lodgment in the skin. It however its attack be speedily perceived, the evil may be removed without difficulty or danger."

The year 1778 makes an epocha in the life of Mutis. That year a new archbishop, Don Antonio Caballero y Gorgora, arrived at Santa Fé, who, among the numerous letters of congratulation from the subordinate clergy on his arrival, had penetration to discover, and good sense enough to admire, in that of Mutis, something very superior to the rest. He visited the writer in his retirement, and his favourable prophecies were confirmed. He determined that such a man should be made useful to his country; and as Mutis had embarrassed his circumstances afloat by his mining projects, the good archbishop obtained, from the government at home, a sum for the payment of his debts, a handsome pension, and the appointments of Botanist and Alphanumeric to the king. He now became the head of a botanical school as it were, the superintendent of a tribe of botanical adventurers employed by the Spanish government to investigate the plants of America. From their labours have originated several publications, especially the splendid Flora Peruvian; and the names of Eucalton, Pavo, Ruiz, Valenzuela, and Zea, are now celebrated in the botanical history of that country. Mutis, attended by some of his pupils, and several draughtsmen, made a tour through the kingdom of New Granada in 1783. By his diligence much new light was thrown upon the history of the Peruvian bark, or Cinchona, and its various species, as there had already been upon that of the Balsam of Peru, the Ipecacuanha, the Elastis gum, &c. He also taught his countrymen the culture and the value of Indigo. His health having suffered from the climate of Mariquita, he was directed to repair to Santa Fé, and to fix on some of his pupils, whose youth and constitution might be more adequate to such labours. In 1791 or 1792, Zea was sent to collect living plants and seeds, for the establishment of a public botanic garden at Santa Fé. But in the political ferment of that period, new inquirers arose, as wise as those who had condemned Mutis for a magician. The innocent Zea was feized, and laid in prison, under the charge of some rebellious conspiracy, till the year 1797, when, with other victims of malice or folly, he was brought over to Spain to be tried. Their innocence was readily proved, they were honourably acquitted, and each was reinstated in his former situation. Mutis, with his accustomed vigilance, took advantage of this opportunity to visit Paris, to consult with Jussieu, and the other eminent botanists of that capital, concerning the compilation of a Flora Bogotensis, and to make himself master of all the new improvements and discoveries. He remained at Paris till 1801, when he went back to Madrid. Whether he subsequently returned to his native country, we know not, but in 1804 he was appointed to the Professorship of Botany, and superintendence of the royal garden at Madrid, in the place of Cavanilles, whose lamented death happened that year.

The venerable Mutis was now established in fame and reputation, but his advancing age made reposé in some measure necessary. He continued however to be serviceable to the government of his native country, and to the prosperity of that in which he had so long been naturalized. He was regularly consulted by the Viceroy, on all difficult and important questions, and conscious that the happiness of the people was the real interest as well as duty of the government, he made it the leading object of all his advice. We hesitate not in the case of such a man to conclude, that his richest temporal reward was the prosperity of those around him, and the affection and veneration with which they amply returned his cares. He lived to an advanced age, but of the precise date of his death we are not informed. A pleasing and well executed portrait of this excellent man, his head encircled with a diadem of flars, is prefixed to one of the late splendid botanical publications of his countrymen, which we have occasionally seen, but which is not at present within our reach. We ought not to conclude this article without recording, that Mutis was the means of introducing strawberries into the country of New Granada. He mentions in a letter to Linnaeus, that, on his departure from Spain, he advised the Viceroy to take with him some of that fruit in a dried state, the seeds of which vegetated in America, and the subsequent propagation and increase of the plant were truly wonderful. He adds that the tables were daily furnished at Santa Fé with this delicious fruit, and with other products of the kitchen-garden, all the year round, which the Italians might envy. Our preceding account is taken from a paper by Don Pedro d'Oribe y Vargas, in Sims and Kunig's Annals of Botany, v. 1. 490, as well as from the manuscript letters of Mutis himself. S.

with lanceolate scales, the inner ones longest. Cor. compound, radiated. Florets of the disk thrice as numerous as those of the radius, tubular, two-lipped; the inner lip in two deep, linear, equal segments; outer ligulate, three-toothed. Florets of the radius about eight; their claw linear, erect; limb horizontal, elliptical, three-toothed, often brily at its base. Stem. Filaments in the florets of the disk five, capillary; anthers united into a cylinder, each with a pair of dependent bristles at its base; in the florets of the disk sometimes present in an imperfect tate. P. Germ in all the florets short; style thread-shaped; stigma cloven, acute. Peric. none, except the permanent calyx. Seeds oblong, slightly quadrangular. Down soft, feathery. Recept. naked.

Eff. Ch. Receptacle naked. Seed-down feathery. Calyx cylindrical, imbricated. Florets of the radius elliptical, three-toothed; those of the disk two-lipped. Anthers with a pair of bristles at their base.

Obf. Cavanilles remarks, that he once found the receptacle slightly villous, in what he deemed a variety of his *M. inflexa.* He also, in mentioning the bristles which are attached to the base of the anthers, allerts that no preceding author had noticed that character. We find it however in the Linnaean description. The florets of the disk were first properly described by Cavanilles, as two-lipped, a character fearely known perhaps but in some American Syngeneese.

* Leaves pinnate.*

1. *M. Clematitis.* Woolly-leaved Mutisia. Linn. Suppl. 373. Wildn. 1. *Cavan. Ic. v. 5. 63. t. 492.*—Leaves pinate, with tendrils; leaflets elliptical, densely woolly beneath.—Discovered by Mutis in the country of New Granada, in the year 1762. According to Cavanilles, it was gathered by Lewis Née, in florny places, not far from San Buenaventura el viejo, in Peru, flowering in June and July. This noble plant does not appear to have been seen alive in Europe, any more than the rest. Fine specimens are in the Linnaean herbarium. The stem is hairless, branched, leafy, fliated, climbing by means of tendrils to a considerable extent; very woolly when young. Leaves alternate, pinate; their common stalks ending in a long three-cleft spiral tendril; leaflets about four pair, nearly fleshy, not quite oppoite, elliptical, or ovate-oblong, obtuse, entire, from one to two inches in length, nearly one in breadth; their upper surafce clothed when young with deciduous wool, but when fully grown green, naked, and smooth, except the rib and veins; the under densely covered at all times with thick soft matted wool, reddish or rusty in the dried plant; but probably white when fresh. A similar woollineal, but partly deciduous, is found on the branches, stalks, and calyx. Stipulas ovate, in pairs at the bottom of the common stalk, like the leaflets, but much smaller. Flower-stalks axillary, solitary, single-flowered, shorter than the leaves, bearing one or two linear bracteas. Flowers dark red, or purple, with conspicuous yellow anthers, very handome, veyeing with the *Tagetes* or the *Dahlias,* but more remarkable for their imbricated woolly calyx, two inches in length. The claws of the marginal flowers are of the same length, their limb one inch.

2. *M. pedunculata.* Long-stalked Mutisia. Cavan. Ic. v. 5. 62. t. 491. Wildn. 2.—Leaves pinate, with tendrils; leaflets lanceolate, fmoreh, alternate. Flower-stalks axillary, very long.—Gathered by L. Née, in the same part of Peru with the preceding, flowering in July. This is smooth in all its parts. The leaflets are ten or twelve on each side of the common stalk, alternate, lanceolate, acute, somewhat decurrent, near an inch and half long, half an inch wide. Tendril three-cleft. Flower-stalks axillary, foliary, a foot long, much exceeding the leaves, each bearing a small lanceolate bracteae near the summit. Flower nearly as large as the foregoing. Calyx smooth. Radiant florets scarlet, their terminal teeth very minute; those of the disk yellowish-red, about fifteen in number. Seeds of both all fertile. Cavanilles.

3. *M. viscosa.* Vetch-leaved Mutisia. Cavan. Ic. v. 5. 62. t. 490. Wildn. 3.—Leaves pinate, with tendrils; leaflets lanceolate, smooth; the lower ones opposite. Flower-stalks terminal.—Found near Valparaiso, in Chili, flowering in May. We have a specimen from Cavanilles. This is very nearly akin to the last, but smaller in all its parts, and it appears to us that the flowers are almost always at the ends of short, lateral, more or less leafy, branches. The lower leaflets are not always opposite, though usually so. The buds, young branches, and sometimes the young footstalks, are rather woolly. The teeth at the ends of the radiant flowers appear scarcely different from the last, of which species the present is perhaps a variety.

** Leaves simple.**

4. *M. ilicifolia.* Hext-leaved Mutisia. Cavan. Ic. v. 5. 65. t. 493. Wildn. 4.—Leaves roundish-heart-shaped, clasping the stem, bordered with spinous teeth. Tendril $—$Native of dry hilly places in Chili, flowering in January. The stem is thorny, branched, climbing, fliated, reddish, three feet or more in height. Leaves alternate, fessile, clasping the stem but not decurrent, roundish-heart-shaped, an inch wide, and somewhat more in length, coriaceous, bordered with strong, spreading, spinous teeth, their termination singularly abrupt, with two much longer divaricated teeth; their upper surface smooth; the under somewhat downy and glaucoes, especially when young; their mid-rib terminates in a simple spiral tendril, thrice the length of the leaf. Flowers purple, on short, solitary, simple terminal stalks. Calyx smooth, barely more than an inch in length; its scales yellowish, with a membranous edge. Radiant flowers narrower than in any of the pinnated species.

5. *M. runcinata.* Lion-toothed Mutisia. Wildn. 5. (M. retorta; Cavan. Ic. v. 5. 65. t. 498.)—Leaves oblong, runcinate, decurrent; woolly beneath. Tendrils clowen.—Gathered by L. Née, flowering in December, in dry barren situations, near Port Defire on the coast of Patagonia. Stem thorny, vingay, a foot and half long, branched, round, not winged, except as far as the bales of the leaves extend. Leaves lanceolate-oblong, about three inches in length, acute, strongly runcinate, somewhat revolute; smooth above; densely woolly beneath; decurrent and tapering at the base; tipped with a divided tendril, about their own length. Flowers terminal, yellow. Calyx about an inch long; its scales with acute recurved points. Radiant flowers narrow, as long as the calyx.

We prefer Willdenow's name, though we should not, of our own accord, have changed the original one. His arrangement of the species is also preferable to that of Cavanilles.

6. *M. fumata.* Blunt-toothed Mutisia. Cavan. Ic. 66. t. 449. Wildn. 6.—Leaves linear-oblong, bluntly toothed, decurrent. Tendril simple.—Gathered by the same botanist on the Cordillera del Planchón, Chili in dry situations, flowering in January.—Similar in habit to the last, as well as in the colour of its flowers; and the pointed scales of its calyx; but the marginal flowers appear by the plate to be broader and shorter. The leaves are bordered with much smaller, and far more numerous, blunt, prominent, not run-
cinete, teeth, and are usually quite smooth on both sides. Their tendril moreover is undivided. *Stem zigzag, smooth.

7. *Mythia. Sharptoothed Mutisia. Cavan. Is. v. 5. 6d. t. 459. Wild. n. 7.—Leaves linear, sharply toothed; arrow-shaped at the base. Tendrils simple. Stem winged. Gathered by L. Née, near the town of Gua-
mantanga, in Peru, flowering in July; and on the Cordillera del Planchón, in February. The *stem is about a yard high; furnished with three leafy sharply-toothed wings. *Leaves selsile, elapsing the stem with their fightly arrow-shaped bafe, which is connected with the wings of the stem, but not properly decurrent, or tapering; they are long or somewhat lanceolate, with numerous sharp, rather spinous, teeth, and a simple tendril. *Flowers large and handiome, solitary, on a short terminal bracteate stalk; their radius yellow, or sometimes purple; disk yellow. Scales of the calyx with reflexed points. Cavanilles does not distinctly say that the leaves are downy beneath, but his reference to the descriptions preceding seems to imply it.

8. *Fajitata. Arrow-leaved Entire Mutisia. Wild. n. 8. (M. hafta; Cavan. Is. v. 5. 6d. t. 459.)—Leaves lanceolate, entire; arrow-shaped at the base. Tendrils simple. Stem winged.—Native of the highest mountains of Chili, flowering in January. Née also found it in Peru. —*Stem two feet high, or more, downy, with four leafy downy wings, whose teeth are sharp and hooked. *Leaves four or five inches long, quite entire, woolly beneath, elapsing the stem with their broad arrow-shaped base, gradually tapering from the base to a narrow point, ending in a long simple tendril. *Flower terminal and solitary, as in all the simple-leaved species. *Calyx an inch and half long, its scales with broad reflexed points, hairy on the upper side at their base. *Florcs of the radius often ten, purple, without any barren stemotes. Wildenow justly thought himself obliged to change the name given by Cavanilles, as the leaves are by no means hafta; *squarrosa would have been a still more expressive appellation than that he has chosen.

9. *M. decurrens. Decurrent Entire-leaved Mutisia. Cavan. Is. v. 5. 65. t. 497. Wild. n. 9.—Leaves elliptic-lanceolate, decurrent, entire, smooth. Tendrils cloven.—Native of the Cordillera del Planchón above mentioned, flowering in February. —*Stem smooth, round, zigzag, branched, two feet high. *Stem elliptic-oblong, entire, smooth, coriaceous, decurrent to a considerable extent at their base. *Tendrils divided, and varicacitd. *Flower large, with about twelve radiant florets, which are purple, as well as the disk. Scales of the calyx without any spreading points.

10. *M. infaexa. Narrow Curve-leaved Mutisia. Cavan. Is. v. 5. 65. t. 496. Wild. n. 10.—Leaves linear, very nar-
row, deflected at the base, incurved. Tendrils simple. *Bracteas awl-shaped.—Native of various places in Chili. *Stem branched, climbing to the height of 10 or 12 feet, frayed, angular, smooth. *Leaves numerous, scattered, selsile, linear, thick, very narrow, smooth, three inches long; deflected at the base, then ascending. *Tendrils simple. *Flower large, with several awl-shaped bracteas. *Calyx an inch and half long, its scales with reflexed tips. *Florcs of the radius eight, deep purple; disk yellow.—In some of the mountain specimens, Cavanilles found twelve radiant florets.

11. *M. linearis. Linear Clove-leaved Mutisia. (M. linearifolia; Cavan. Is. v. 5. 66. t. 500. Wild. n. 11.)—Stem erect. *Leaves linear, revolute, selsile, spinous-pointed, without tendrils.—Native of the mountains of Chili. This is singular in its genus, for the want of tendrils. The *stem is shrubby, a foot high, slightly branched. *Leaves numerous, crowded, selsile, or clove-preted, about an inch long, linear, revolute, tipped with a small spinous point. *Flowers terminal, selsile, solitary, smaller than any of the foregoing, their radius apparently purple in the dried specimens. *Calyx-scales obtuse, close.

*Mutius, or *McCius, *Caicus, in Biography, surnamed *Caucus, famous in the early history of Rome, was born of an illustrious family, at the time of the siege of the city by Porfenna, king of the Etruscans, about the year before Christ 507. During the blockade of the capital, when he found there was no hope of relief, he determined to render himself illustrious by some great act; he accordingly, with the permission of the senators, crossed the Tiber, and entered the enemy's camp, with a concealed dagger under his garment; at length he obtained an admission into the royal tent, at the moment when the king was paying his soldiers, with his secretary by his side. Mutius mistaking the minister for the monarch, laid him dead in a blow, and then in the confusion attempted to make his escape. He was, however, seized and brought before Porfenna, in whose presence, he without any hesitation, avowed his name and purpose, and expressed a readiness to endure any suffering that the king might choose to inflict on him, adding that he was but one of a band of Roman youths prepared to make a similar attempt. Porfenna, enraged at the daring behaviour of the young man, called for fire, in order to extort from him whatever he might know of further meditated treachery. "Behold," said the young patriot, "how little bodily pain is endured by those who profess true glory," and instantly thrust his hand into the flame of an altar kindled for the purpose of sacrifice. The king, in admiration of the reso-

*Mutius-Scevola, *Quintus, called the "Augur," a Roman of great authority as a lawyer, married the daughter of Labeus, and was the father-in-law of Lucius Cauius. He was praetor in Asia, and consul in the year B.C. 117, with L. C. Metellus, with whom he had the honour of a triumph. On various occasions he performed great services to the state, and though, at that period, far advanced in years, he took part with Marius against Sylla. Cicero was instructed by this venerable person in the principles of wisdom, and in gratitude for his attentions to him, he made his preceptor one of the interlocutors in his first dialogue, "De Oratore.

*Mutius-Scevola, *Quintus, an eminent Roman, who was tribune of the people in the year B.C. 166, and consul in 95 B.C. with Caicus Licinius Cauius. He was praetor in Asia, over which he ruled with so much prudence and justice, that he was propsoed as a model for all future go-

gen.
ledge, with which he unquestionably polished a most masculine eloquence. Caesius, in Cicero's dialogue "De Oratore," blythes him the bel pepper among lawyers, and the bell lawyer among the orators. Quintilian gives the same character of him. He was killed in the civil wars between the Marius and Sylla factions, in the year B.C. 83, in the temple of Veia, and his body was thrown into the Tiber. He is thought to have been the first peron who reduced the civil law to a methodical systlem. On this subject he wrote eighteen books, which are often referred to by the ancient lawyers.

**MUTIUSCHICA,** in Geography, a bay or gulf in the Frozen sea, on the N.W. coast of Nova Zembla. N. lat. 75° 50'. E. long. 57° 14'.

**MUTNANG,** a town of Bengal; 20 miles W. of Torec.

**MUTOVA,** one of the Kurile islands, 47 versts from Rock Koke; about 30 versts long, and of the same breadth.

On the S. side flands a very lofty mountain, from whose summit a thick black smoke is continually rising, and which occasionally casts up red-hot fumes, spreading danger and defoliation round it. To the N., valleys rich in herbs and habitable plains extend, where various kinds of edible roots and wild fruits grow. The only land animals in this island are foxes. Peacocks subject to the tribute are here numbered at 63.

**MUTQUIN,** a town of South America, in the province of Tucuman; 25 miles N.E. of Fernando.

**MUTSCOUR,** a port of Peru, in the province of Tron; 35 miles N. of Ifpanan.

**MUTSCHEN,** or MUTZCHEN, a town of Saxony, in the circle of Leipic, in the neighbourhood of which is a species of crystal, which bears the name of Mutzchen diamond; 22 miles W. of Meissen. N. lat. 51° 41'. E. long. 12° 48'.

**MUTSCHNITZ,** a town of Germany, in the principality of Coburg; nine miles N.E. of Coburg.

**MUTT,** a town of Hindoostan, in Bahar; 37 miles S.S.W. of Arrah.

**MUTTABARROW,** a town of Hindoostan, in Guzerat, at the mouth of the Surfooty; 25 miles N.W. of Puttan-Sumnaout.

**MUTTAMUSKEET,** a lake of North Carolina; 20 miles long and five wide, three miles N. of Pamico Sound.

**MUTTEAH,** a town of Hindoostan, in Bahar; 10 miles N.N.W. of Bettiah. N. lat. 26° 55'. E. long. 84° 35'.

**MUTTEARY,** a town of Hindoostan, in Bahar; 22 miles S.E. of Bettiah. N. lat. 26° 38'. E. long. 85° 10'.

—Alfo, a fort of Hindoostan, in Bahar; 36 miles N.N.W. of Crippurah. N. lat. 26° 17'. E. long. 84° 28'.

**MUTTEN,** a town of Switzerland, in the canton of Schweitz, situated in a valley called Muttenthal, watered by a small river called Mutten, which runs into the lake of the four cantons, six miles E. of Schweitz.

**MUTTEN BAY,** a bay on the N. side of the river St. Lawrence, on the coast of Canada. N. lat. 48° 25'. W. long. 69°.

**MUTTERSTADT,** a town of France, in the department of Mont-Tonmerre, and chief place of a canton, in the district of Spire. The place contains 1415, and the canton 9481 inhabitants, in 17 communes.

**MUTTRA,** a town of Hindoostan, in the fubah of Agra, on the Jumna; 36 miles from Agra.

**MUTTY,** a town of Hindoostan, in Guzerat; 60 miles W. of Noanaugar.

**MUTTEYRA,** a town of Bengal; 14 miles E. of Kilineagur.

**MUTU,** in Ornithology, a name by which some call a large Brazilian bird, of the gallinaceous kind, more usually called mita. See CRAN AETER.

**MUTUAL,** a relative term, denoting something that is reciprocal between two or more persons.

Thus we say, mutual assistance, mutual averton, &c.—There are mutual or reciprocal duties, offices, &c. between superiors and inferiors; as the king and his subjects, the master and his servants, &c.

Vaugelas makes a dlifinction between mutual and reciprocal; mutual, according to him, is understood of what is between two only; and reciprocal of what is between more than two; but this dislinction is little regarded in common use.

**Mutual Testament** is that made by two persons who leave their effects reciprocally to the survivor.

**MUTUALES,** See Mutauxes.

**MUTUAPOLLAM,** or MOOTAPOLLAM, in Geography, a town of Hindoostan, in the Carnatic. Near this town Hayder Ally, on occasion of a battle fought with Sir Eyer Cootie, in July 1781, was defeated with the los of 4000 men; five miles S. of Cuddalore.

**MUTULE,** in Architecture, a part of the Doric cornice, appearing to support the corona and the superior members, formed by three vertical parallelograms at right angles, and an inclined plane which descends towards the front of the cornice, until it meets the rectangular vertical plane, the inclined plane being the foffi, and the two vertical parallel planes being at right angles to the surface of the frieze, and the vertical plane on the front parallel thereto.

Mutules had their origin from the ends of rafters in the original wooden structures, and are, therefore, properly represented with a declination towards the front of the corona; though represented by an architecte of the last cenury with a level foffi.

In Grecian architecture, a triglyph is placed at each angle of the building, and, consequently, a mutule over each triglyph at the same place, and a triglyph and a mutule are placed over each intermediate column; also, over each inter-column there is only one triglyph, except in the Doric portico, which has two in the middle intercommunications, in order to allow greater room for passage. The mutules are the same breadth as the triglyphs.

Of all the buildings now remaining of Roman antiquity, the theatre of Marcellus is the only one in which any specimen of the Doric order is to be found; but this example is fo void of original character as to have a denticulated corona, which is peculiar to the Ionic or Corinthian. The mutules are only carved on the foffi, and not seen in front under the corona.

In the Grecian Doric three rows of drops, parallel to the front of the corona, are hung from each foffi of a mutule; the number in each row being fix, agreeing with those in the architrave under the triglyphs.

**MUTUUM,** in the Civil Law, denotes a loan simply so called; or a contract introduced by the law of nations, whereby a thing confiding in weight, as supplee bullion; in number, as money; or in measure, as corn, timber, wine, &c. is given to another, upon condition that he shall return another thing of the same quantity, nature, and value, on demand.

This, therefore, is a contract without reward; so that where use or interest arises, there must be some particular article in the contract whereon it is founded.

**MUTWAL,** in Geography, a river of Ceylan, called also Calana.
Calana Gangá, one of the branches by which the Mulickadder falls into the sea, about three miles from the fort of Columbo, after having nearly surrounded a large tract of level country in that neighbourhood, of which it forms a very beautiful peninsula. The country along the banks of the Mutval for many miles is extremely picturesque and delightful.

MUTYBARA, a town of Bengal; 33 miles N.N.E. of Pursehah.

MUTZA, or MUSA, a town of Italy, in the department of the Adda, on a river of the same name; three miles S.E. of Lodito.

MUXACAR. See MUXAR.

MUXILLONES, a small island in the South Pacific ocean, near the coast of Chili; 8. lat. 29° 30'.

MUXOODPORUM, a town of Bengal; 14 miles S.E. of Mahmudpour.

MUXOODPOUR, a town of Hindostan, in Bahar; 30 miles S.W. of Bahar.

MUYDEN, a town of Holland, feated on the river Vecht, near the Zuyder fsee; which has a flute by which the adjacent country may be inundated. Salt is the chief manufacture of the place; 6 miles E. of Amsterdam. N. lat. 53° 35', E. long. 4° 55'.

MUYS, Wyen-William, in Biography, a physician of the mathematical feft, was born at Steenwyck, in Overfeyl, in January 1692, where his father practiced the fame profession. His early education was obtained in his native town; and he then passed three years at the college of Kempe, for the study of the classics, and afterwards was instructed in the first principles of medicine, algebra, and geometry at Vollenhove. At the age of sixteen he commenced his studies at Leyden, and went from thence to Utrecht, where he received the degree of doctor in 1701. He settled at first in his native town, and afterwards removed to Arnheim, where he practiced with reputation and success. An offer of a professorship at Groningen was at first rendered void by the disputes of a cabal; but his dis- appointment was repaid by an election to the mathematical chair in the university of Franeker, in 1709, and to the medical chair in the same faculty in 1712, which he exchanged for that of chemistry in 1720. He was afterwards chosen professor of botany, which comprehended the inspectorship of the botanic garden. The house of Orange frequently retained him as consulting physician, with a considerable salary, which he received to the end of his life. He was cut off by a lingering disease, in April 1744, at the age of 62. He had been five times rector of the university of Franeker, and was a member of the Royal Academy of Sciences of Berlin. His writings were partly medical and partly philosophical, and bore the following titles: "Oratio de Ufio Matheos in periciendo ingenio et judicio," Franeker, 1711. "Elementa Phyficus methodo mathematico demonstrata, quibus accedunt Difertationes de: prior, de caufa soliditate corporum: posterior, de caufa refistente fluidorum," Amst. 1711. "Oratio inauguralis de Theoria ufu, atque reélta illam excelsi ratione," Franke, 1714. "Difertatio et Observations de Salis Amoniaci praecario ad feptem intertemptas ufu," ibid. 1716. This is laid to merit attention in a practical view. "Dif- putationes de: Materia Luminis, feu Ignis, Caloris, et Lucis natura," ibid. 1717. "Inquisition Fabricae quæ in partibus muscularis comparibus existat," Leyden, 1738, 1741, and 1751, in quarto. This is a laboured and copious compilation of all that had been previously discovered respecting the structure of the muscular fihes and its fibres, the divisions and subdivisions of which he had traced with extreme minutenefs, and illustrated by three good microfopic plates, drawn by himfelf. After his death a work of his was published in French, entitled, "Difertation fur la Perfection du Monde corporel et intel- ligent, ou l'on demontre en detail le merveilleux mechanisme par lequel Dieu a voulu que les efpeéces des Hommes, des Animaux, et des Plantes fe perpetuent pendant un temps determiné, etc." Leyden 1745 and 1750, in 12mo. And also "O palpacula pophysma, feu Sermones Academici de fectis Materiis, &c," 1749, edited by his fon.

John Muys, the father of the preceding, who removed to Leyden, and practiced physic there, was author of a work entitled "Praxis Medicina-chirurgica rationalis," which was published in twelve decades, between the years 1684 and 1690; and "Podabrius redivivus," a supplement to the former work, in 1686. Eloy Dit. Hif. de la Med.

MUZA, in Ancient Geography, a port of Arabia Felix, in the country of the Elifiari, placed by Ptolemy between Sacaca and the port of Solippus. Arrian places it 12,000 fadia S. of Derencie.

MUZANA, a town of Asia, situated N. of Melitené, on the bank of the river Melas and near the mountains.

MUZILLAC, in Geography, a town of France, in the department of Morbihan, and chief place of a canton, in the district of Vannes; 12 miles S.E. of it. The place contains 3015, and the canton 14,100 inhabitants, on a territo- ry of 1875 kilometres, in 6 communes.

MIZUMAS. See ZIMAS.

MUZIO, Girolamo, in Biography, an Italian writer, was born at Padua in 1496. He was educated at his native place till he was eighteen years of age, when, owing to the death of his father, he was obliged to seek a maintenance in the courts of different princes. For a number of years he led a wandering life, and in one of his letters, he complains that he has been obliged to gain his bread by serving sometimes in the armies; sometimes in the courts of popes, emperors, kings, and other princes; sometimes in Italy; sometimes in France, and sometimes in Germany. The nature of his services has never been clearly ascertained; he is said to have been a doctor of laws, and an eminent jurist, but none of his writings are upon legal topics. By pope Leo X. he was honoured with the title of Cavalier. He was in the service of the marquis del Vafio for several years, who lent him to reside with the duke of Savoy. After the death of the marquis, he passed into the service of Don Ferdinand Gonzalez, whose affairs he managed at several Italian courts. The duke d'Urbino next appointed him governor to his son, afterwards duke Francis II. About the year 1569 he was at Rome, where pope Pius V. retained him with a handsome pension, to be employed solely in writing, for he had by this time distinguided himself as a vigorous adversary of the reformers. The death of that pope deprived him of his pension, and he was reduced to circumstances of great distress, which, in truth, was the chief complaint of the greater part of his life. After this he was admitted into the service of cardinal Ferdinand de Medici. He died in 1576, at the age of eighty-fix. He left behind him very many works, of which we may notice his "De Arte Poetica," in three books, composed in blank verse; this was very much valued at the time in which it appeared, as well for the elegance of its language, as for the excellence of its precepts. In 1566, he entertained an idea of composing an epic poem on the subject of the recovery of Jerusalem by the knights under Godfrey of Bouillon. As a profe writer he left "Letters," "Histories," "Moral Treatises," and several tracts against those whom he chafed to flyle innovators in religion.

MUZIRIS.
MUZIRIS, in Ancient Geography, a sea-port town of India, on the western or Malabar coast, 40 days' fall from Oceis (Gella) in the Red Sea, just within the limits of Bab- el-Mandeb. This was the first port of merchandize, by which the ancients carried on their commerce between Bere- nicè down the Red Sea with India. From Berenicè to Oceis it was reckoned 30 days' navigation, and from thence to Muziris 40 days' fall; and as they left Berenicè about Midsummer they might arrive in India in the latter end of August, when the violence of the S.W. monsoon was abated and the coasting navigation safe and easy. Muziris is said by Pliny to have been an incommodious place of merchandize, because the shallowness of the port, or river's mouth, made it necessary to discharge or take in the cargo in small boats, at a distance from theemporium; and besides, there was danger from the pirates at Naxirin. It is not easy to ascertain the precise site of the ancient Muziris; but major Rennell, from an attention to the several circumstances mentioned by Pliny and Ptolemy, concludes that Muziris was the place now denominated Meerzaw or Merje; he ob- serves that they bear some affinity in the found; and their situation is similar, both being the sea and at a some distance from the sea. See Meerjee.

MUZOS, in Geography, the name of a people in New Granada, who inhabit a province of the same name, celebrated for rich mines of the most precious emeralds in the world. They are neighbours and enemies of the Mocos or Muecas. Their country is mountainous, hot and moist; and from the fumes may be discerned the polar stars, both of the north and south; while towards the end of August and the middle of March, the sun throws no shade at noonday. This savage tribe is distinguished by many singularities. They have among them a fabulous tradition, that in ancient times there was on the other side of the great river Magdalen, a kind of shadow of a man called Ari, who, having amused himself with making in wood faces of many men and women, threw them into the river, and when they came out alive, he married them and taught them to cultivate the earth; after which they dispersed and became the parents of all the Indians, who are inferior to the Europeans, because their heads were made of wood. They had no deities, nor did they adore the sun and moon, as other people of Bogota did; thefe splendid bodies having been created, according to their creed, after the wooden men, and merely to give them light. When girls arrived at the age of sixteen, they were married by their parents, without any previous notice. The husband then went to care for his wife, when he received him with blows of a cudgel; but in a short time became appeased, and prepared his victuals, though during the honey-moon they were obliged to sleep together without confum- mating the marriage. In case of adultery, the husband broke all the vellums of wood or clay that were in the house, and retired to the mountains, till the wife should have re- placed them. The dead were dried before a flow fire, and not interred till the end of a year; the widow being obliged to cultivate the ground for her sustenance, till her relations took her home after the interment. Ellalla cited by Parkerton in his Geog. vol. ii.

MUZLE of a Gun or Mortar, the extremity of the cylinder, where the powder and ball are put in. The metal which surrounds the extremity of the cylinder is likewise called the muzzle. See CANNON.

MUZLE, a term applied to the nose of a horse or other animal. It also signifies a kind of halter put upon the nose of a horse or mule, to prevent eating or biting improperly.

MUZLE of a Plough, in Agriculture, a term sometimes applied to the cope or part to which the draught is attached in these tools.

MY.—Per My & per Tout. See Per my.

MYA, in Conchology, is a genus of the Vermes testacea clads and order, of which the generic character is given under the word in the article Conchology. The animals included in this genus perforate into sand and clay at the bottom of the sea, burying themselves and their shells wholly or in part. There are twenty-six species enumerated in Gmelin's half edition of Linnaeus's Sytem of Nature.

Species.

* Truncata. Shell ovate, truncate, and gaping greatly behind; tooth projecting forwards and very obtuse. It inhabits the European seas; is two inches and a half long; the shell is of a dirty-white covered with a yellowish-brown skin; the inhabitant is frequently eaten, and is the principal food of sea-fers. It is described and figured, as are several of the following species, in Pennant's Brit. Zool, vol. iv.

* Declivus. The shell of this species is brittle, semi- transparent; slopes downwards near the open end; the hinge is slightly prominent. Found about the Hebrides; the fish is in general estimation among the inhabitants of thefe islands.

* Arenaria. Shell ovate, rounded behind; tooth pro- jecting forwards, rounded and furnished with a lateral smaller one. This species is found in the European seas, under the sand; is two inches and a half long, and of a yellowish reddish-brown.

Pictorum; Painter's Mya. Shell ovate; with a fingle, longitudinal, crenulate tooth in one hinge, and two in the other. There are several varieties of this species, described by different naturalists; some of them are found in the fresh waters of this country, and other parts of Europe, and Barbary, and fome in Tranquebar. The shell, which is nearly four inches long and half as broad, is commonly used to put water colours in, whence we have its name; it is covered with a brownish or blackish coat, under which it is yellowish or green; it is very thin and brittle, and does not gape at either end.

Margaritifera; Pearly Mya. Shell ovate, a little contracted in the middle of the thinner margin; primary tooth of the hinge conic; protubering parts near the hinge decorticated. It is found in many parts of the arctic circle, and generally in the rivers and about the cataracts; it is five inches broad and half as long; the shell is thick, coarse, opaque, black on the outide, and often corroded by worms; the hinge is, without lateral teeth, the primary tooth being received into a broad cleft tooth of the opposite hinge. This shell is celebrated on account of its producing large quantities of mother-of-pearl and pearl; the latter being a debase of the silt analogous to that occasioned by a stone in the human body. The river Conway in Wales was formerly famous for producing pearls of great size and value.

Perna. Shell oblong, dilated, the narrower base com- pressed. It inhabits the Magellanic straits and shores of Barbary; it is said to resemble a ham or leg of mutton; it is smooth, blue and white, and open at one end.

Vulseella. Shell tongue-shaped; the hinge is terminal, depressed, and semiorbicolar. The shell of this species varies in form according to its age.

Arctica. Shell flat; the valves with two subapinial ridges; hinge without teeth. It is found in the North-sea among alges, is the size of a bean, and of a pale yellow, and milk-white within.
Edentula. Shell oval, equivalve, wide, gaping, and 
frigate; hinge without teeth. It inhabits the sandy shores 
of the Calfian seas, and is about an inch long; the shell 
is thin, white, with about thirty-three friza in each valve.

Radiata. Shell equivalve, pellucid, very finely frigate 
transferably, yellowish-green with vivid rays; valves very 
broad on one side and very narrow on the other. There is 
a variety which is brownish, with blue radiate lines. It 
inhabits the rivers of Malabar.

Oblonga. Oval-oblong; one valve with a broad strong 
tooth let into a hollow of the other valve, and a lefser tooth 
infert between two small ones of the opposite valve.

Anatina. Shell globular, snowly, pellucid; primary 
tooth of the hinge prominent and rounded. It inhabits 
Guinea, and resembles the Solen anatina; which bee.

Nicobarica. Shell equivaive, snowly, oval-oblong, with 
decusitate friza; tooth of the hinge single, broad, pendicu- 
lar, and poin-shaped. It inhabits, as its name implies, in 
the Nicobar islands.

Australis. Shell ovate-compressed, closed; hinge with 
two lateral teeth. Found in New Zealand.

Gaditana. Shell rounded, flattish, transferably frigate. 
It inhabits the shores of Cadiz.

Corrugata. Shell rhombic, green; the protuberant 
parts wrinkled. It is found in the rivers of Coromandel, 
and is nearly an inch long.

Rugosa. Shell is oval, wrinkled, outwardly it is green-
ith, and within pearly; primary tooth of the hinge cren-
ulate, with a longitudinal lateral one, double in the other 
valve. It inhabits the rivers on the coast of Coromandel.

Nodosa. The shell of this species is oval, thin, green-
ith; the protuberant parts knotty.

Norwegica. Shell oval, longitudinally and thickly frigate; 
one end rounded, the other truncate; the protuberant 
parts are decorticated.

Spuria. Shell rhombic, green; the protuberant part is 
glabrous. It is found in the rivers of Tranquebar, and re-
fembles the M. corrugata in every thing but its size, being 
twice as large as that.

Glycera. Shell gaping at both ends, very thick, 
lamellous, oblong-oval, with transverse wrinkled friza; 
primary tooth in the hinge very thick. It inhabits the Eu-
ropean oceans, particularly the Spanish and Mediterranean 
seas. It is five inches long and ten broad, and resembles a 
Solen.

Syrmatophora. Shell ovate, depressed; margin of the 
hinge with a fultulate projection near the primary tooth; 
that of the other valve dilated. It is found in the rivers of 
Guinea.

Nittida. Shell oval, white, smooth; with an obtuse 
tooth in each hinge. It inhabits Norway:

Membranacea. Shell ovate, membranaceous, white, 
with a protracted reflected margin at the proboscis.

Byssisfera. The shell of this species is scarce and thick; 
oblung, frigate, convex; hinge without a tooth. It is found 
in the fissures of rocks on the Greenland coast, and is ge-
nerally found affixed by a byssus or mass of filaments.

Dubia. In this species the shell is found with an oval 
and large hiatus opposite the hinge, and the rudiment of a 
tooth within one valve. It is found near Weymouth. The 
shell is brown and brittle; the length of a horn-bean, and 
shaped like a pili-cay nut.

From certain observations on the growth of these shells, 
and the number of their annual lamæ or scales, it has been 
imagined that this fish will attain to a great age, and that 
fifty or sixty years is a very moderate computation.

Linnaeus has shown that the mya will bear removing, and 
that, by a particular process, it may be put into a flate 
of producing pearls at pleasure in the referivors to which it is 
transferred, the old pearls being removed to make way for 
the formation of new ones.

Mya, in Geography, an island in the East Indian sea, 
about ten miles long and four broad. N. lat. 1° 14'. E. long. 127° 27'.

Myagrum, in Botany, a word adopted from Dios-
cordes, whole Linnaeus nevertheless is very obscure, nor does 
that author say anything which may lead to the meaning of 
the name; except indeed that he describes the plant as mak-
ing a rude fort of candles. "The fat feeds, roasted and 
bruited, are ranged over the twigs, which then," says he, 
"serve in the place of lamps." Such artificial lights are well 
known to attract flies to their destruction; and therefore 
perhaps Tournefort's derivation of the word, from μυα, 
a fly, and ὑπερα, to catch, or enfane, may be true, rather 
than the received one, from μυα, a mouse. (See Muscipula.) 
Tournefort however justly observes that this explanation is 
not fuitable to our Myagrum.—Linn. Gen 331. Schr. 434. 
t. 99. Lamarck Illufr. t. 553. f. 1. Gét. t. 141. Clafs 
Cruciferae, Juff.

Gen. Ch. Cal. Periath of four ovate-oblong, concave, 
gaping, coloured, deciduous leaves. Cor. cruciform, of four 
flat, roundish, obtuse petals, with narrow claws. Stam. 
Filaments fix, as long as the calyx, the four opposite ones 
rather longer; anthers fimple. Pyl. Germen superior, 
ovo; style thread-shaped, the length of the calyx; stigmas 
oblate. Peric. Pouch involerly heart-shaped, slightly compor-
ted, terminated by the rigid conical style, coriaceous, 
without valves, having one fertile cell, and two empty in-
flated ones above. Seed solitary, elliptic-oblong, pendulous. 
Efi. Ch. Pouch without valves, crowned with the conical 
style, single-feeded, with two empty cells above.

This genus is very miscellaneous in Linnaeus as well as 
Willdenow and others. Twelve species are found in the 
writer's list named, of which the 11, M. perrenne, the 28, 
orientalis, and the 12th, egyptum, properly belong to Dimor. 
The 4th, hispanicum, is Cardiocarpus pancei, Prodr. Fl. 
Grac. v. 2. 33; the 6th, chlorofolium of Willdenow, seems, 
in the opinion of the author himself, to be of a distinct 
genus, and certainly the description he gives of the fruit is 
not that of a true Myagrum; the 7th, faturum, was long ago 
referred to Alysium by Scopoli, as well as in the Flora 
Britannica; and the 8th, dinautium, is of the same genus, if 
not the same species; the 10th, paniculatum, constitutes the 
genus Rapistrum, adopted from Tournefort in Gartner, and 
Prodr. Fl. Grac. v. 2.1; the 9th and 11th, having a pouch 
of two cells, with several seeds in each, can have nothing to 
do with the genus in question. The only remaining species 
therefore is

(M. monotiperon latifolium; Bauh. Pin. 109. Prodr. 52. 
51. M. hortense monotiperon; Bell. Eyll. 267. ord. 10. t. 8. f. 1.)—Native of corn-fields in the south of 
Europe. The root is annual, tapering. Stem one and a 
half to two feet high, alternately branched, smooth, round, 
leaves. Leaves alternate, oblong, obtuse, flatly and irregularly 
toothed, glaucous, smooth, from four to six inches long, 
clipping the stem with their heart-shaped base; their midrib 
pale. Flowers numerous, small, pale yellow, coriaceous. 
Fruit very copious, in long lax clusters, smooth. It is diffi-
cult
Mycena, in Botany, from the vase, *A. porus*, which is *alliacus* of Sowerby, t. 81; also *A. tenus*, Sowerb. t. 33.

Mycena, in Ancient Geography, a town of Greece, in the ancient kingdom of Argos, or Argolis, which, in process of time, became the seat of the kingdom, and is celebrated by Homer for its riches, as its rival Argos was for its horses. As to its situation, some difference of opinion has subsisted among ancient geographers. Strabo placed this town towards the S.W. of Argos. Paulyanias mentions some circumstances that serve to ascertain its position more precisely. Perrea came from Larissa to Theffaly to Argos, and he is said to have received an extraordinary adoration from the gods to build a city on a particular spot, with which he speedily complied. M. d'Anville suggests, that this spot lies in the N.E. of Argos, because it was situated on the route of Perrea, and that position is confirmed by the description of Paulyanias. Some historians have ascribed the separation of the kingdom of Mycenae from that of Argos to Acarius, who was its first king, and who began his reign in the year 1534 B.C., and who reigned 31 years; whilst others say, that his son Perrea, who succeeded him in the year 1513 B.C., and who reigned 32 years, built the city of Mycenae, and founded the kingdom. The fifth king of this separate state was Agamemnon, who began his reign in the year 1201 B.C., and reigned 18 years. The kingdom of Argos had been translated to this little state, situated on the river Inachus, which parted it from Arcadia on the west, and which had the gulf of Lepanto on the south, as some say, by Acarius, but according to others by Perrea; so that this metropolis became in a short time more populous and opulent than the other; but it fell into such decay pretently after the dislocation of the Mycenaean, or, as it is commonly called, the kingdom of Agamemnon, that, as Strabo informs us, there were scarcely any foot-steps left of it in his time, though some Roman historians seem to hint

as if some part of that once famed city were still standing when the Romans conquered Macedonia. In the reign of Areus, which commenced 1266 B.C., the Heraclides, being the sons and descendants of Hercules of the line of Perrea, claimed the kingdom of Mycenae, from which they had been driven by Eurytheus. Agamemnon, who succeeded his father Areus 1201 B.C., was reckoned at that time the wealthiest and most powerful potentate in all Greece. This king, after the destruction of Troy, having encountered several difficulties, arrived at last at Mycenae, where he was murdered by his cousin Agilthus and his wife Clytemnestra. Agilthus seized upon the kingdom 1183 B.C., and, after a reign of seven years, was murdered by Orestes, Agamemnon's son, and succeeded by him 1176 B.C. Orestes was succeeded by Egyptus, or rather Egyptus, who gained the kingdom in 1160 B.C., and by his liberality engaged the affections both of the nobles and the people; but this liberality proved ultimately fatal to the regal dignity; the subjects grew daily more and more encroaching, and the kings more tenacious of their prerogative, till the contlict ended in the extinction of monarchy, and a total change of government. Among other ancient remains, besides those which were destroyed before the time of Paulyanias, we may enumerate the tomb of Electra, those of Clytemnestra and Agilthus, which were without the walls, about fifteen stadia from Mycenae, and at the foot of mount Eubza; on the left was the temple of Juno, the road to which was watered by the streams that flowed from the fountain Eleutera, which served the priests for their purifications, and for the sacred functions of their ministrations. A large space before the temple was called "Proflume," and over-against it was a mountain called Acrea. The Acheron flowed at its base, and precipitated itself into a gulf. The front of the gate of the temple was decorated with many female statues of the priests and statues of women that had been employed in the service of Juno, and others of heroes, particularly of Orestes. At the left of the vestibule of the temple were statues of the graces in ancient tale: the statue of Juno, of gold and ivory, executed by Polycleites, of an extraordinary size, seated on a throne at the entrance of the temple. On the head of the goddess was a crown, on which were exhibited the Hours and the Graces. The statue of Hebe, also of gold and ivory, was near that of Juno. Within the temple was a silver altar, on which were engraved, in bas-relief, the mupitals of Hercules and Hebe. Here were also a golden peacock, encrusted with precious stones, which had been presented by the emperor Adrian, and also a crown of gold with a purple veil, given by Nero. For further particulars, see Paulyanias Corinthi. l. x. c. 17. The tomb, treasury, or temple of Agamemnon, which still exists, probably in the state in which it was left by the Argians, after the destruction of the city in the 7th Olympiad, 460 years B.C. deferves particular notice, as this edifice is perhaps the most singular in Greece, and on account of the state of preservation in which it still exists, being entire as to the building, though defaced of its internal decorations: Paulyanias says, that envy on the part of the Argians, because the inhabitants of Mycenae feared with the Laecdmemonians the glory of Themoulyce, was the occasion of its destruction. The nature and description of the above-mentioned edifice is doubtful. Paulyanias says, that the tomb of Agamemnon, erected about 1200 years B.C., was among the ruins of Mycenae; whereas this is at some distance from the walls. He also describes the subterraneous treasury of Areus and his descendants as being in the same place; and hence it has been inferred, that this building, constructed of the same materials as the walls, and coeval with the time of their

Vol. XXIV.
erection, was the treasury of Atreus. It is a cone of fifty feet in diameter, and as many in height. It is composed of enormous masses of a very hard breccia, or sort of pudding-flone; the black in particular, over the door-way (which diminishes very much in breadth at the top, after the Egyptian manner), is no less than thirty feet in length, fifteen in breadth, and five in thickness. This edifice has obviously been raised by the projection of one stone over another, and they nearly meet at the top; the curved form and smoothness being previously given to each. The central stone at the top has been removed, along with two or three others; and yet the building remains so durable as ever, and will probably last till the end of time; which would scarcely appear likely, if this had been the key-stone and support of the whole edifice. The treasury of Minyas at Orchomenus, in Boeotia, said to have been built about 1300 years B.C., is supposed to have been constructed in a similar manner, and the central stone which covered it, is thought to have had nothing more to do with the reef, than as it might regulate the symmetrical form of each. Hence it has been inferred, that neither the one nor the other of these edifices can warrant the conclusion, deduced from them by M. Dutens, in his “Recherches sur le tems le plus reculé de l’Usage des Voutes, chez les Anciens,” that we cannot defire stronger proofs of the existence of arches from the most remote ages. Edinburgh Review, N 14.

MYCETITES, in Natural History, the name of a species of fca-coral, which is usually of a conic shape and fibrous texture; always small, and usually found adhering to fishes, or large corals. See Porites.

MYCETITES Diffusa, a name given by Dr. Woodward to those kinds of foliaceous corals which on the generality of writers has called, after Dr. Pott, porpita. These are usually small, and of a roundish, but flattened figure; they are hallowed on one side with a fort of umbilicus, and fr rate on the other; they are found on the ploughed lands in Oxfordshire, and some other of our midland counties, and in other places, buried in the solid drata of stone; they are sometimes yellowish, sometimes brownish, and are from the breadth of an inch to a fourth part or less of that size; when broken, they are usually found to consist of a kind of spar, not unlike that of which the shelly coats of the echinins, or the lapides indeci, and other spines of echinus, consist in their fossil state; and in some of them the ridges and stria are thick set with little knobs and tubercles. The bases in some of these is flat, as it is in others riving in form of a circular elevation from the umbilicus, and others have a circular cavity in the same place.

MYCONI, in Geography, one of the Cyclades in the Grecian Archipelago, about 21 miles in circumference, situated between Iosia or Naxia and Delos. This is the ancient Myconus, which, by fabulous relation, was the tomb of the Centaurs that were killed by Hercules. Some ancient writers have called the inhabitants of Myconus bald heads, aëterting that this defect was natural, and that it was a kind of edemal disease, with which almost all of them came into the world; but no appearances of it now remain. They were also reckoned great parapites; and men, who presented themselves at feasts without being invited, were proverbially called “guests of Mycon.” In a harbour known by the name of “Tourlon,” is an anchorage frequented by ships falling through the Archipelago, in order to repair to Smyrna and the north of Turkey. They are here safe from the winds that proceed from the N., N.E., S., and S.E.; but the others blow right in here, and raise a heavy sea. When navigators seek a shelter against these winds, they seek it off the small town or village of Myconoi; but they are there buffeted by those which cannot penetrate into the anchorage of Tourlon. The Greeks of Myconoi are great navigators; traversing the sea that surrounds them in their boats, some of which are large. Addicted to maritime occupations, they neglect the culture of their lands, from which, though dry and mountainous, they might derive considerable advantage. All the productions which they yield, though in small quantity for want of culture, are of a very good quality, such as wheat, barley, raffins, figs, olives, and cotton. Wine and fruits are here excellent; but though wine is almost the only article of commerce in Myconoi, it is mixed with water in order to increase its quality, whilst its real value is thus diminished. Game abounds; the most delicate birds arrive in numerous flights twice a year, in spring and autumn; and, in short, the island affords in profusion all the necessary or agreeable articles of life. But water is scarce, and, during the great heat of summer, every thing is dry in the fields, and bears the aspect of aridity. This drought has, without doubt, refigured the operations of agriculture, and induced men to seek abroad means of existence more certain and less laborious. The inhabitants, who are about 3000, are chiefly Greek Christians, governed by a cadh; the women are principally occupied in spinning cotton which grows in their island, and manufacturing it into flocokings or cloths. An uninhabited foal, to which the Myconites lend flocks, affords a good anchorage a league E. of Myconoi: it is called “Tragond,” i.e. He-goat island, because it formerly, in all probability, contained both he and the-goats; but none are now seen there. Lower, and a little farther from Myconoi, are two points of arid rocks, which the Greeks call “Stapedia,” and the navigators, “Le Deux Frères,” or “The Two Brothers.” N. lat. 37° 27’. E. long. 25° 32’.—Alloa, a town or village on the W. coast of the fore-mentioned island. N. lat. 37° 26’. E. long. 25° 20’.

MYCONOIDES, from mycon, a nolfril, and eos, resemblance, in Surgery, a term anciently applied to ulcers, which were covered with a large quantity of matter like mucus.

MYCTERIA, the Jabiru, in Ornithology, a genus of birds belonging to the order of Grallae. The bill is long, bending upwards and acute; upper mandible triangular; the nostrils small and linear; there is no tongue, or a very small one; and the feet have four toes. There are three species.

AMERICANs, or American Jabiru. White; quill and tail-feathers purplish-black. It is about the size of a turkey. The bill is long, stout, and of a black colour; the whole plumage is white, except the head, and about two-thirds of the neck, which are bare of feathers, and of a blackish colour; the remainder is also bare, and of a fine red; on the hind-head are a few greyish feathers; the legs are strong, of a great length, and covered with black scales; wings and tail even at the end. Thus this is found in all the savannas of Cayenne, Guiana, and other parts of South America. It is migratory and gregarious. It makes its nest in great trees, which grow on the borders of rivers; lays two eggs, and brings up the young in the nest till they can defend to the ground. The colour of the young birds is grey; the second year it changes to rose-colour, and the third to pure white. They are very wild and voracious, and their food is fish, which they devour in great quantity. The flesh of the young birds is said to be good eating, but that of the old is hard and oily.

ASIAcA, or Indian Jabiru, is of a large size, the bill is dusky, almost straight above, and gibbous near the forehead;
head; the under mandible swelled beneath; and from the base of the bill there pales through and beyond the eye a black break. The general colour of the plumage is white; the lower half of the back, the prime quills, and tail, are black; the legs a pale red. This species inhabits the East Indies, and feeds on snails.

Novi Hollandiae, New Holland Jabori. Body above purplish-green, but beneath, also on the neck and shoulders, it is white. It is found in New Holland. There was a specimen in the Leverian Museum. The head is purplish, spotted with white; the neck is feathered; the irides yellow; first quill-feathers white; tail black and white.

MYDEN, in Geography, a town of Candahar, capital of a district in Cabulistan; 24 miles S.W. of Cabul.

MYDON, from woode, to grow padr, in Surgery, fungous flesh in a vitulose ulcer.

MYDORGE, Claude, in Biography, an able mathematician of the 17th century, was born at Paris in 1635, and was educated to the law. He became councillor to the Chatelet, and afterwards treasurer of France in the generosity of Amiens. These places he held more on account of the rank which they conferred on him, than for the profit which they yielded. He was too much attached to mathematical pursuits; and master of too ample a fortune, to pursue his profession with that kind of eagerness, which can only infuse success. He was the friend and acquaintance of Des Cartes, and entered into a vindication of him, in the dispute which he had with M. Fermat, and was afterwards a mediator of the peace which was made between those learned men in 1658. In the same year Mydorge published a Latin treatise "On Conic Sections," in four books, which Merffenne has infected in his "Abridgment of Universal Geometry." In 1614, he and Des Cartes received an invitation from Charles Cavendish to settle in England, which he declined, on account, as it is supposed, of the breaking out of the civil wars in this country. He died at Paris in 1647, in the sixty-third year of his age. He was a practical mechanic, as well as an able mathematician, and with so much zeal was he inspired for the interests of science, that he spent more than a thousand crowns on the fabrication of glasses for telescopes, burning mirrors, mechanical engines, and mathematical instruments. Moreri.

MYDRECHT, in Geography, a town of Holland, in the department of Utrecht; 12 miles W.S.W. of Utrecht.

MYDRIASIS, from posco, to abound with juice, in Surgery, a preternatural dilatation of the pupil; so named, because it was supposed to proceed from a redundance of moisture, or humours. It is an ordinary symptom of the gutta serena, apoplexy, compriision of the brain, &c.

MYEDZYREE, in Geography, a town of Poland, in Volhynia; 42 miles N. of Conflantinow.

MYERTOWN, a town, or rather village, of America, in Dauphin county, Pennsylvania, situated on the N. side of Tulpehocken creek, and containing about 25 houses; 77 miles from Philadelphia.

MYGBAOTH, in the Arvish Antiquities, a kind of mitre worn by the priests. See CEDARS.

MYGDONIA, in Ancient Geography, a province of Asia, in Mopotamia, so called, according to Theodorot, from the river Mygdonis; but, according to Pliny (l. vi. c. 12.) it derived this name from the Mygdonians of Macedonia, who seem to have sent this a colony. Strabo (l. xvi.) concurs in this opinion; and informs us, that Mygdonia extended along the Euphrates from Zeugma to Thaphacus, and contained Nifis, which was denominated "Antochia Mygdonia." Hence it appears that Mygdonia of Mopotamia comprehended the western part of Mopotamia.

Alfo, a country of Macedonia, bounded on the N. by Pelagonia, on the E. by Cantida, on the S. by Paeonia, and on the W. by the province of Euphorus. Herodotus, Phylus, and Ptolomy mention this province. See MACDONIA.

MYGDONIUM, a name given by the ancients to a species of marble much used in their larger buildings. It was white variegated with black; but that black rather diffused in clouds and spots than veins. It is confounded with the documenmum marmor, by some writers; but that was always of a pure white, without the leaf variegation.

MYGDONIUS, in Ancient Geography, a river of Mopotamia, which was formed of many streams, and discharged itself into the Chaboras.

MYGENES, in Geography, one of the smallest, and the most westerly, of the Faroe islands, in the North sea. N. lat. 61° 33'. E. long. 13° 21'.

Gen. Ch. Cal. Periathan inferior, very small, or one leaf, in four deep equal segments, permanent. Cor Petals four, alternate with the segments of the calyx, equal, roundish, flat, widely spreading; their claws broad, and sometimes cohering. Stam. Filaments four, awl-shaped, erect, or spreading, shorter than the corolla; anthers roundish. Pyl. German superior, roundish; styles four, erect, short, more or less combined at their base, which is subfuscule-tongated; stigmas acute. Peric. Drupe globulo. Sfre. Nut ovate, acute, of one cell.

Eff. Ch. Calyx in four deep segments. Petals four, alternate with the calyx, broad at the base. Drupe superior, globulo.

1. M. urugaga. Downy-leaved Myginda. Linn Sp. Pl. 161. Jacq. Amer. 24. t. 16. Steph. Prod. 39. (Rhamina Crotopetalum; Linn. Sp. Pl. 169. Crotopetalum; Browne Jam. 145. t. 17. f. 1.)—Leaves ovate, acute, finely serrated, downy, as well as the branches and flower-flaks. Native of South America, and the West Indies. Jaccquin found it very plentifully about Carthagena, where the root is esteemed for its powerful diuretic qualities; as well as in St. Martin's, one of the Caribbean islands; generally growing not far from the sea. Browne gathered it in Jamaica, in the woods below Marta-Bree river, in St. James's, growing among rocks. This is an upright herb, three or four feet high near the shore, but almost twice as much in the woods, with few branches; which, when young at leaf, are square and finely downy, with spreading hoary hairs. Root thick, woody, solid, whitish, and very bitter; its bark orange-coloured internally. Leaves mostly opposite, an inch long, more or less, on short, reddish, downy foot-flaks, ovate, acute, finely and softly serrated; occasionally somewhat heart-shaped at the base; clothed on both sides with fine, soft, spreading, shortish hairs. Flower-flaks axillary, shorter than the leaves, opposite, slender, downy, two or three times forked. Flowers small, of a very deep shining red. Fruit red, soft, the size of a small pea.
When the herbarium of Sir Joseph Banks was, in 1786, compared with the Linnean collection, the original specimen of Jacquin in the former, (purchased by Sir Joseph, with his herbarium, many years before,) was found to accord precisely with that of Browne in the latter, which had been bought, amongst Browne's plants, by Solander, and sent to Linæus. This last proves to be the very identical specimen, drawn by Ehret for Browne's plate. That drawing nevertheles, in its total smoothness, as well as the form of the leaves and notches, agrees better with the species we shall next describe, which has therefore been generally taken for the plant of Browne, on which the _Rhazoma Crocifolium_ of Linæus depends. The disagreement between the two original investigators of this plant, as to the number of its styles, may be accounted for from the elongation which takes place in the combined bafes of those organs, as in _Renia arvensis_, and several other flowers, subsequent to impregnation. The _styles_ are indeed so much united, that perhaps the genus ought to be reckoned monogenic, especially if we were to judge by the second species; yet even about that botanists differ, as we shall presently see.

Dr. Swartz has confirmed the generic identity of the shrubs in question, but not having seen Browne's specimen, was misled by this figure to perfilt in the old error.

2. _M. Rhazoma_ Smooth-leaved variegated Myginda. Swartz Ind. Occ. v. 1, 134; excluding the synonyms. Jacob Coll. v. 4, 177. Ic. Rat. 311. Wild. n. 2.—Leaves elliptic-ovate, obtuse, crenate, smooth; paler beneath. Styles combined at the base.—Native of the sunny sea-coast, on the west side of Jamaica. _Swartz_. We have specimens from Dr. Wright, who observed that the flowers had certainly four styles. Jacquin, in his beautiful plate, represents them as united nearly all the way up, and So Swartz describes them. This _furb_ is very bushy, two or three feet high, smooth in all its parts, except perhaps the partial _flower-flanks_, and minute _brothæs_. The bark is ash-coloured. _Leaves_ from half an inch to an inch long, elliptical or somewhat obovate, obtuse, crenate; much paler beneath, at least in the dried specimen. _Flower-flanks_ scarcely more than once divided, or three-flowered. In other respects this much agrees with the foregoing. Swartz describes the claws of the _petals_ as united into a tube, and their border fringed. This last character we cannot discover, either in the present or former species, though upon it Browne founded his name of _Croci-solium_.

3. _M. latifolia_. Broad-leaved Myginda. Swartz Ind. Occ. v. 1, 134; Vahl, Symb. v. 2, 32. Wild. n. 3.—Leaves elliptical, emarginate, slightly crenate, smooth. _Stigma_ fiddle.—Native of the West Indies. Mr. Maffon gathered our specimens in the island of Nevis. This appears to be a larger _furb_, in all its parts, than the foregoing, with numerous _branches_, crossing each other. Every part is quite smooth. _Leaves_ copious, opposite, about an inch and a half long, and an inch broad, coriaceous, elliptical, obtuse, emarginate, slightly and rather dilantly crenate; of a pale, opaque, and somewhat glaucous green, on both sides. _Flower-flanks_ much shorter than the leaves, forked, scarred; more than three-flowered, the two lateral _flowers_ divericuated, the central one fiddle. _Petals_ reflexed. _Germin_ elliptical. _Stigma_ from two to four, fiddle, broad and obtuse. 

4. _M. pallens_. Pale-leaved Myginda. Banks MSS.—Leaves elliptical, very obtuse, crenate, smooth, nearly fiddle. _Styles_ combined. _Petals_ wavy.—Gathered in Antigua by the late Mr. Maffon, and communicated by Sir Joseph Banks. This is the size of the plant, with which it agrees in habit, but the _flowers_ are of a lighter more yellowish-green, on shorter flanks, and in some degree scattered; the adult ones paler beneath. The _flower-flanks_ are twice forked; the _central flower_ as well as the reit, elevated on a slender smooth partial flaky. _Calyx_ broad and flat. _Petals_ widely spreading, more or less undulated at the margin. _Styles_ as much united as in _M. Rhazoma_, with similar acute _stigma_.

The first three species are said to have been introduced into the English gardens, between the years 1750 and 1798. They are kept in the flower, and are evergreen, flowering at various times. Jacquin says the second bloomed with him the year after the seed was committed to the ground, the plant not being above six inches high. We have never heard of the fourth being brought to Europe. S.

_MYIAGRUS Deus_, in the Hebraic Mythology, a name given sometimes to Jupiter, and sometimes to Hercules, on occasion of their being sacrificed to for the driving away the vall number of flies which infested the sacrifices on certain public occasions. The word is usuallly spelt _My- 
igrus_; but this must be an error, as this word does not express the word of descry, but the mouth of destroy; and we have it sufficiently testified by the ancients, that flies were the only creatures against whom this deity was invoked. Pliny calls this deity also _Myiades_, and tells us, that the flies which use to pester the Olympic river went away in whole clouds, on the sacrificing a bull to this god. We find in Athenæus also, that this sacrificing to the god of flies, at the Olympic games, was a confant custom. Some distinguish these two deities, and tell us, that the latter, or _Myiodes_, used to visit the nations in vengeance, with a vast multitude of flies; and that, on paying him the due honours of a sacrifice, they all went away again; and this seems to agree with what Pliny tells us in some places.

At the time of the Olympic games, Jupiter was worshipped under the name of the _Aponyas_, or _Myiagrus Deus_, to supplicate the destruction of those troublesome creatures. This happened only once in many years, when the sacrifices were performed there; but the Eleans worshipped him continually under this name, to depurate the vengeance of heaven, which usually went, as they expressed it, an army of flies, and other infests, towards the latter end of the summer, that infested the whole country with sickness and pestilence. See _Beelzebub_.

_MYIODIES Deus_, a name given sometimes to Hercules, but more frequently to Jupiter, to whom a bull was sacrificed, in order to make him propitious in driving away the flies that infested the Olympic games.

_MYLA_, in Ancient Geography, a river of Sicily, which ran, according to Livy, between Syracuse and Leontium.

_MYLE_, or _MYLES_, now _Melusa_, a town of Sicily, situated towards the West. This small town has been recognized as the place near which the fleet of Augustus, under the command of Agrippa, obtained an advantage over that of the younger Pompey. Also, a strong town of the _Thessaly_, which, however, was taken, and abandoned to pillage.

_MYLANDIA_, a promontory of the isle of Rhodes, in which was the town of Camirus.

_MYLAON_, a small river of Arcadia, W. of Megalopolis, which ran from the S.W. to the N.E., and emptied itself into the Alpheus.

_MYLASA_, or _MYLASSA_, a town of Achaia Minor, in Caria. According to Steph. Byz. this town was founded by Mylanus, son of Chrysalis; and according to Heroditus, it was not to ancient as the temple of the Carian Jupiter, built in its vicinity. Mylais was for some time subject to kings, but it partook of the vicitudes to which Caria was
was subject. It was taken by Mithridates, and afterwards by Labienus, whose father was a lieutenant of Caesar. The Romans left it free, whereas Pliny calls it "Mylafis Libera." Strabo informs us, that it was one of the most magnificent cities of antiquity, and one of those which was admired on account of its porticoes and various monuments; a quarry of white marble in its neighbourhood furnished ample material for the construction of its numerous edifices. The Milefians had two temples dedicated to Jupiter; one situated in the city, appropriated to Jupiter Ofogo or Ogoa, and another at Laprandia, on the road to Alabanda, which was consecrated to Jupiter Stratius, or the warrior. This was much rapturized by the Carians, who came hither from remote parts to offer their vows: a caufeway, called "the sacred way," 60 fadia in length, led from Mylafis to this temple. Between these temples there was another dedicated to Angulius and the divinity of Rome. Pococke saw it entire; but it has since been its temple destroyed, and the materials have been used for constructing a mosque.

MYLASENSE MARMOR, in the works of the ancients, a name used for a species of marble dug near a city of that name in Caria. It was of a black colour, but with an admixture of purple; the purple not difposed in veins, but diftributed through the whole mass: it was much used in building among the Romans.

MYLAI, or MYLIA, in Geography, a town of Saxony, in the Vogtland, on the Goflaf; eight miles N.E. of Plauen.

MYLE, a word used by some authors as a name for the patella or limpet, and by others to express what we call a mole, or false conception, in the uterus.

MYLES, in Geography, a town of the island of Samos; two miles W. of Cora.

MYLI E, or MYLIA, in Ancient Geography, a country which originally made a part of Greater Phrygia, but, in process of time, it was referred to Lycia.

MYLOGLOSSI, in Anatomy, a pair of muscles, thus called, because arising about the backside of the molares, or grinding-teeth, and inserted into the ligament of the tongue: helping to pull it upwards.

These are the same with what Mr. Cowper calls styloglossi.

MYLO-HYOIDEUS, a muscle belonging to the os hyoidei. See DEGLUTITION.

MYLON, in Ancient Geography, a town of Egypt, mentioned by Athenaeus and Steph. Byz.; which gave name to the Mylopolete nome.

MYLON, in Surgery, is used for the largest tumours of the staphylomata kind in the corner and uvea of the eyes. See STAPHYLOMA.

MYLO-PHARYNGEUS, in Anatomy, a name given to some of the fibres of the constrictor pharyngis superior.

MYLOTHROS, in Ancient Music, the name of a Greek song, proper for millers and bakers. The same, perhaps, as the Epinaxis.

MYNAMA, in Geography, a town of Hindoofan, in Bahar; 17 miles S.E. of Darbunghah. N. lat. 26° 1'. E. long. 86° 21'.

MYNAMIES, or MIKONAMIES, a tribe of Indians, who, with the tribes of Chippeways and Saukees, live near Bay Puan, and about 20 or 30 years ago could furnish 550 warriors. The Muonamies have about 300 fighting men.

MYNAR, a town of Hindoofan, in Bahar; four miles N.E. of Bettiah.

MYNATNAGUR, a town of Bengal; 25 miles N.W. of Boglipour.

MYNATPOUR, a town of Hindooftan, in Bahar; 32 miles N. of Darbunghah. N. lat. 26° 38'. E. long. 86° 17'.

MYNDER, a town on the banks of Musaffar, near the coast of the island of Celebes. S. lat. 2° 12'. E. long. 118° 55'.

MYNDS, or MINDUS, in Ancient Geography, a small town, with large gates, of Asia Minor, in Caria, situated at the extremity of an illmus, N.W. of Halicarnassus.

MYNSIOTT, ADRIAN VON, M.D., in Biography, count palatine, consulting physician to the duke of Mecklenburg and several other princes, was celebrated for his knowledge in chemistry, about the beginning of the 17th century. He was the author of a work upon this subject, which was in great vogue in its time, and passed through numerous editions. It was entitled "Thesaurus et Armamentarium Medico-chemical, hoc est, felceitriflorum, contra quosvis morbos, pharmacorum conficiendorum secreta et ratio, cui in fine adjunctum eft Telligentum Hadrianianus de aureo Philophorum Lapide," Hamburgh, 1631, &c.

There is a great deal of credulity, and not a little mystery, in the description of the various chemical, medicinal, and alchemical processes, which this work contains, and of the potent virtues ascribed to them in the treatment of diseases. Several of his preparations, however, came into common use, and were long retained in the dispensatories.

MYO, in Geography, a small island in the East Indian sea, formerly inhabited; but now not occupied by a prohibition of the Dutch, left fields should be smuggled; subject to the king of Ternate. N. lat. 1° 13'. E. long. 122° 20'.-Algo, a town of Mexico, in the province of Culican; 110 miles N.W. of Culican.

MYOCEPHALON, from μύς, a fly, and κέφαλη, the head, in Surgery, a tumour, formed on the iris, and resembling the head of a fly. See Iris, Prolapfus of.

MYOCEPHALUS, a name given by some authors to the diptemperature of the eyes, commonly known by the name of a staphyloma.

MYOCTONUM. See ACONITE.

MYODES, PLATISMA, a name given by some anatomical writers to what is called by others the quadratus gene, it is a muscular expansion in the neck.

MYOLOGY, MYOLOGIA, one of the technical divisions of anatomy: the part which includes the muscles. See MUSCLES.

MYOMANCY, a kind of divination, or method of foretelling future events by means of mice.

Some authors hold myomancy to be one of the most ancient kinds of divination; and think it is on this account that Isaiah, lxvi. 17, reckons mice among the abominable things of the idolaters. But, be that as it may, it is not certain, that the Hebrew word תֶּפֶל is used by the prophet, signifies a mouse; it is evident it is not the divination by that animal, but what it will, that is here spoken of; but the eating of it.

MYONIA, in Ancient Geography, a town of Greece, belonging to the Locri Ozioli, situated on a lofty mountain, which had a sacred wood and an altar dedicated to the gods or gods. The sacra were offered in the night. "Polidion" was a place near this town, dedicated to Neptune, where was a temple dedicated to this deity, but without statues, according to Pausania.

MYONIMA, in Botany, so called by Cleomeron, from
MYO

Gen. Ch. Cal. Perianth superior, very small, nearly entire. Cor. of one petal; tube short, cylindrical; limb in four deep, equal, blunt segments. Stam. Filaments four, inserted into the tube of the corolla, alternate with the segments of the limb; anthers oblong, projecting beyond the corolla. Pist. German globe, inferior, style short, cylindrical; stigma capitate. Peric. Drupa dry, roundish, depressed, delittite of any crown or rim. Seed. Nut of four cells, with four kernels, which are externally convex.

1. M. obovata. Broad-leaved Rat-fed. Willd. n. 1. Lamarck, fig. 1. Leaves obovate, obtuse, with a small point. Fruit obscurely quadrangular. —Gathered by Commerce, as well as by Sonnerat, in the isles of Bourbon and Mauritius. A smooth frutic, with numerous opposite branches, whose bark is cracked and greyish. Leaves on short flalks, opposite, near two inches long and one broad, obovate, obtuse, obtuse, with more of less of a short point; their upper surface shining as if varnished; the under opaque and paler; both beautifully reticulated with transverse interbranching veins. Flower-flalks axillary, opposite from the uppermost leaves, mostly two or three-flowered, scarcely so long as the leaves. Calyx sometimes obscurely four-toothed. Corolla hardly half an inch in diameter. Fruit reddish, the size of a small grape. Bractæs small, acute, opposite at the division of the flower-flalks.

2. M. lanceolata. Myrtle-leaved Rat-fed. Willd. n. 2. (Myrtifolia; Lamarck n. 2. fig. 2.) Leaves elliptic-lanceolate, acute. Fruit fissional.—Native of the island of Mauritius. The leaves are much smaller than in the foregoing, and of a narrower more lanceolate shape, somewhat revolute, entire, their upper surface highly polished. Fruit reddish, more exactly globular than in the former species.

MYONNESOS, in Ancient Geography, a town of Ionia, between Teisos and Lebedus. Steph. Byz. Strabo makes it a peninsula, and Livy a promontory. It was an island of the Teisans, according to Thucydides. It appears to have been placed on the coast N.W. of Lebedus, and that the land projected in form of a peninsula.—Alfo, an island of Thethialy, over-against Lardia, according to Strabo.

MYOPARO, among the Romans, a kind of ship, which partly resembled a merchant-ship, and partly a ship of war, and was that which pirates mostly used.

MYOPIA; Myopiahiasis, from μυος, to shut, and μη, the eye, in Surgery, that kind of strabismus, in which the eyes are half shut, and continually winking.

MYOPORUM, in Botany, a name contrived by Dr. Solander, to express the minute pulvillus spots, for which the foliage of the genus we are about to describe is remarkable. The word is formed of μυος, to shut up, and πορος, a pore; those spots being, as it were, pores cloised with some transparent fulilance. Forff. Prod. 44. Schreb. 424. Willd Sp. Pl. v. 3. 381. Mart. Mill. Dict. v. 3. Brown Prodr. Nov Holl. v. 1. 515. (Pogonia; And Repof. v. 3. 212. Andreufa; Venten. Malacif. 108.)—Clafs and order, Didynamia Angioferma. Nat. Ord. Perjontate, Linn. Vites, Juif. Myoporine, Brown.

Gen. Ch. Cal. Perianth inferior, of one leaf, in five deep, ovato-lanceolate, acute, erect, permanent segments. Cor. of one petal, somewhat falver-shaped; tube short, rather bell-shaped; leaf in five deep, nearly equal segments, generally hairy within. Stam. Filaments four, awl-shaped, shorter than the corolla, inserted into its tube, two of them rather the shorter; anthers vertical, arrow-shaped. Pist. German inferior, elliptic-oblong, compressed, style cylindrical, curved, the length of the flaments; stigma capitate. Peric. Drupa pulpful. Seed. Nut solitary, of four or five cells, with solitary kernels; or of two cells, with two kernels in each.

Obf. We have found five cells in all the fruits we have examined. Willdenow is mistaken in supposing this genus not distinct from Citharexylum. The latter has a tubular calyx, with short teeth, and two separable nuts, of two cells each; nor is the shape of the corolla like that of Myoporum. Those who called some of the species Pogonia and Andreufa, were by no means aware of the original name published, many years before, by Forffler.

Section 1. Leaves alternate, entire.

1. M. ellipticum. Elliptical Myoporum. Brown n. 1. (Pogonia glabra; And Repof. t. 283. Andreufa glabra; Venten. Malacif. t. 108.)—Leaves elliptic-lanceolate, pointed, tapering at the base. Branches smooth. Segments of the calyx lanceolate, very sharp. Mouth of the corolla slightly hairy; limb smooth.—Native of the tropical regions of New Holland, as well as of the country near Port Jackson. It was raised from seed in 1790, by the late Mr. Robertson at Stockwell; it is readily propagated by cuttings, and flowers freely in January or February, though rather more impatient of damp and cold than some other shrubs of New South Wales. The leaves are smooth, like the whole of the genus. Flowers axillary, mostly solitary, on foot-flalks, drooping, white, the size of lily of the valley, but not of the same hemispherical form, their corolla being rather contracted in the middle, its limb spreading suddenly. There are no bractæs nor stipulis in the whole genus.

2. M. triennis. Narrow-leaved Myoporum. Forffl. Prod. 44. Br. n. 2.—Leaves lanceolate, with long taper points. Branches smooth. Segments of the calyx lanceolate, acute. Corolla smooth.—Native of the tropical part of New Holland. Gathered in the Sandwich islands by Mr. Menzies. —Differ from the former in having much narrower and more tapering leaves; several flowers, for the most part, together; whole corolla is not hairy, and the segments of whole calyx are shorter and more ovate.

3. M. arnusium. Pointed-leaved Myoporum. Br. n. 3.—Leaves broadish-lanceolate, with a small point; tapering at the base. Branches smooth. Segments of the calyx ovato-lanceolate. Corolla bearded.—Found near Port Jackson, New South Wales. The dried leaves have a glaucous hue, and there are several drooping flowers together from the bofon of each.

4. M. montanum. Mountain Myoporum. Br. n. 4.—Leaves linear-lanceolate, very sharp; tapering at the base. Branches smooth. Segments of the calyx linear, acute. —Gathered in New South Wales by Mr. Brown. We have seen no specime.

6. *M. parvifolium*. Small-leaved Myoporum. Br. n. 6.—"Leaves linear, blunter; tapering at the base; sometimes toothed at the extremity; glandular, as well as the branches. Flower-flasks here and there deeply divided, above half the length of the leaves. Stem diffuse."—Native of the same country, and suspected by Mr. Brown to be perhaps but a variety of the last.

Section 2. Leaves alternate, serrated. Fruit swelled. 

Nout of four cells.

9. *M. pubescens*. Downy-leaved Myoporum. Forst. n. 2. Willd. n. 2.—"Leaves oblong-elliptical, serrated, downy."—Found by Forster in the same country as the last. This appears to be the only species that has any pubescence, except in the flower.

10. *M. gracillimum*. Thick-leaved Myoporum. Forst. n. 3. Willd. n. 3.—"Leaves fleshy, oblong, slightly serrated."—Native of Botany island. Forster.

11. *M. inflata*. Fiddler Myoporum. Br. n. 8.—"Leaves lanceolate; tapering at the base; serrated at the end. Branches smooth; glabrous when young. Stem erect."—Gathered by Mr. Brown in the south part of New Holland.

12. *M. ferreum*. Serrated Myoporum. Br. n. 9.—(Pogonia tetrandra; Labill. Nov. Holl. v. 1. 50, t. 82.)—Leaves lanceolate, very sharp, serrated. Branches smooth. Gathered by Labillardiere in Lewin's land, and by Mr. Menzies at King George's Sound. Mr. Brown also observed it in the neighbouring parts of New Holland. The leaves in our specimen are rather broader, and more oblong, than in the figure cited. Flowers many together, erect.

13. *M. tuberculatum*. Tubercular Myoporum. Br. n. 10.—"Leaves lanceolate, acute, serrated. Branches covered with glandular tubercles."—Gathered by Mr. Brown in the south of New Holland. We have seen no specimen of his plant, but we pose one, brought by Mr. Menzies from the Sandwich Islands, which answers to this character, except that the leaves are entire. If this be confirm; our plant should be introduced between the first and second species. Its corolla is internally smooth. Segments of the calyx ovato-lanceolate, with very sharp points. The leaves are three or four inches long, and one broad, elliptic-lanceolate; their pores minute.

Section 3. Leaves alternate, toothed. Fruit compressed. Not frequently with but two cells.

16. *M. debile*. Slender-stemmed Myoporum. Br. n. 13. (Pogonia debile; Andr. Repof. t. 212.)—Leaves lanceolate; toothed at the end; entire at the base. Fruit slightly compressed, shorter than the calyx. Flower-flasks solitary. Stem prostrate. Native of the country near Port Jackson, from whence it was sent to England in 1793, by colonel Pateron. The stem is said to be naturally prostrate, but it may be trained to a considerable extent, against a fitch or trellis. The branches are alternate, purplish, warty. Leaves smooth, toothed here and there, but many of them are quite entire. Flowers axillary, on short flanks, erect, for the most part solitary, very rarely two together. Calyx large, with broad lanceolate segments. Limb of the corolla purplish-blue, with a white downy mouth. This blooms in the greenhouse from April to September, and ripens seed, by which, as well as by cuttings, it is readily increased, if affixed by heat.

17. *M. diffusum*. Spreading Myoporum. Br. n. 14.—"Leaves lanceolate, with somewhat recurved teeth at their base; toothed or entire at their extremity. Stems diffuse, glandular. Flower-flasks solitary. Fruit slightly compressed, shorter than the calyx."—Gathered by Mr. Brown in the tropical part of New Holland. It seems very nearly akin to the 13th species; but we have seen no specimen by which to form a judgment.

Section 4. Leaves opposite.

The stem in every known species is shrubby. Young branches, and tender leaves, often coloured and viscid. There is scarcely any pubescence, except within the flower, whose style, as well as corolla, is often bearded or hairy. The leaves of our ninth species only are described as downy.

*Myopes*, *Myopis*, a peron who is short-sighted; or, as we popularly call it, *purblind*.

The word is Greek, μυος, compounded of μυοι, mouse, and αις, eyes; because, we suppose, the same configuration of the eye is observed in mice.

Myopes are properly such as see remote objects confusedly, and near ones distinctly. Those who labour under the opposite defect are called *presephtos*.

The defect of myopes is not in the optic nerve, the pupil, or the like; but in the form of the cornea or crystalline, or the distance of the retina from the same. The crystalline or cornea being rounder or more convex than ordinary, the rays will be rendered more convergent than ordinary, in passing through the same. (See Refraction.) By this means they will be brought to meet or concur at a less distance from the crystalline; so that if the retina be at its usual distance, they will concur before they reach it. It is the too great nearness then, of the retina to the crystalline, that constitutes the myopia.

*Myops*, in Natural History, the ευ φυς, an insect usually confounded with the breeze-fly, but really differing very much from it. This is common in woods and about paths, and never fixes on any other creatures except oxen. It has a long and somewhat flat body, and is of a blackish grey colour.

*MYOSIHALON*, in Surgery, a clorefe of the pupil. See PUPIL.

*MYOSHORMOS*, in Ancient Geography, a sea-port of Egypt, placed by Plutarch and Pherecy the Red sea. Arran says, that it was one of the most celebrated ports of this sea. It was also called the "Port of Venus."

*MYOSOTIS*, in Botany, derived from μυος, mouse, and αις, a little ear, the diminutive of αις or εις, an ear, has been applied by the ancients, as well as by many more modern botanists, to several plants whose leaves, in their shape

Gen. Ch. Cal. Perianth inferior, five-cleft half way down, oblong, erect, acute, permanent. Cor. of one petal, filar-shaped; tube cylindrical, short; limb flat, half cloven into five, emarginate, obtuse segments; throat cloeled, with five, convex, prominent, little valves or scales. Stam. Filaments five, in the neck of the tube, very short; anthers very small, concealed by the scales. Pist. Germans separior, in four number; style thread shaped, as long as the tube of the corolla; stigma obtuse. Peric. none, except the enlarged, erect calyx. Seeds four, ovate, pointed, smooth.

Eif. Ch. Corolla filar-shaped, five-cleft, slightly notched; its orifice closed with concave valves.

Obf. In some species the seeds are furnished with hooked bristles, though in general they are smooth.

Three varieties of this plant are enumerated in Dr. Smith's Flora Britannica, the last of which, M. forcipoides, is now determined to be a new species, and called M. palustris. The other two, $\beta$ and $\gamma$, may also be distinct from it, but as yet nothing has been decided respecting them: $\beta$ is found on dry banks and walls, with minute, yellow flowers; $\gamma$ occurs in shady situations, and is distinguished by larger, blue flowers, and a taller, more lax habit.—Linnaeus characterizes the leaves of M. forcipoides as callous at the tip, which mark however is not very generally perceptible in what we are now describing, nor are the lobes of the corolla so constantly notched as his generic definition implies.

2. M. palustris. Water Scorpion-grafs. Roth. Germ. v. 1. 87. v. 3. 30. Catal. v. 3. 30. Engl. Bot. 1. 1973. and t. 480. uncoloured. (M. forcipoides palustris; Linn. Sp. Pl. 188. Sm. Fl. Brit. 212. 6.)—Seeds smooth. Leaves oblong, clusters many-flowered, without bracteas, calyx funnel-shaped, its hairs straight and close-pressed. Common about rivers, clear streams, and ditches, in most parts of Great Britain, flowering in the summer. We are not surprised at Dr. Smith's feeling great pleasure in deciding upon this species conformably to Dr. Roth's opinion of it, "because," he says, "that acute botanist, applying our own principles, first suggested with regard to Menisie, to the present cafe, has found the pubescence of the calyx confirm all the other late decisive marks." The peculiarly distinctive characters of M. palustris are the creeping, perennial root, and the funnel-shaped calyx, clothed all over with straight, rigid, shining, close-pressed hairs, and having its teeth broad, triangular, shorter than the tube. The corolla also is conspicuous, and generally admired for its enamelled brilliancy. It is of a beautiful pink flesh-colour before expansion, afterwards bright blue.

3. M. nana. Dwarf Scorpion-grafs. Sm. Prodr. Fl. Græc. v. 1. 112. Willd. n. 3. Villars Dauph. v. 2. 450. (M. tergoventis; Hacq. Pl. Alp. 12. t. 2. f. 6. Wild. Lithofenperm alpium tomentosum minimum; Tourn. Int. 137.)—Seeds smooth, ferrulated at the margin. Stam. simple, with few flowers. Leaves oblong, villous.—Found on the summits of the Alps by Villars, who says it is very rarely to be obtained, as growing amongst the moss elevated craggy rocks. A native also of Greece.—Stems about two inches high, extremely slender. Leaves very small, obtuse, and woolly. Flowers rather fragrant, and of a beautiful bright blue colour, which they retain for a long time after drying. Seeds three or four, sometimes five, triangular, embossed with a sort of membranous fellet at the edge.

5. M. spatulata. Spatulate Scorpion-grafs. Willd. n. 5. Forl. Prodr. 12.—Seeds smooth, leaves spatulate, bifid. Stalks axillary, foliate, fiddle-flowered.—Native of New Zealand. This species is taken up by Willdenow from Forl. Prodr. 12. from another of his authors having described it, and we have no specimen before us, we are unable to furnish any further description of it.

6. M. rupelris. Rock Scorpion-grafs. Willd. n. 6. Pallas It. v. 2. 716. t. 1. f. 3.—Seeds smooth. Leaves linear, villous, Clusters alternate.—A very common little plant in flons, exuberant situations, on the hills of Dauria, where it produces a succession of flowers from May through the summer. Root perennial, simple, thread-shaped. Stam. three inches long, spreading and ascending, rather hairy. Radical leaves crowded together, obovato-lanceolate, obtuse, bifid; those of the stem alternate, oblong-linear, white with hairs, and fringed at their edges from the base to the middle. Flowers of a deep azure colour, with a yellow throat. Seeds ovate, pointed, white.

7. M. virginiensis. Virginian Scorpion-grafs. Linn. Sp. Pl. 189. (Cynoglossum virginianum; Morif. Hist. v. 3. 449. febr. 11. t. 30. f. 9.)—Seeds with hooked prickles. Leaves obvate-oblong. Branches divericated.—Native of Virginia, and cultivated before 1699, by Mr. Jacob Babart. Stam. slender, annual. Leaves alternate, ovate, pointed at both ends, green on both sides. Flowers clustered, terminal, red. Seeds small, prickly, brown, and according to Linneus "naked on the inside, angular, erect, fixed at the base like thole of the following species. Fruit drooping."

bright blue. Sepals dotted, convex on one side, angular on the other, and mucrinated at the edges with a double row of hooked prickles. Both Gartner and Villars remark that the whole habit and character of this plant greatly resemble those of a *Cynoglossum*.

9. *M. squarrofa*. Squirrofe Scorpion-gras. Willd. n. 9. Retz. Olib. f. c. 2. — Seeds angulated, with hooked bristles. Leaves lanceolate, hairy, callous at the tip. — Found in Siberia, near the river Wolga. Root annual. Branched. Stem (when cultivated) two feet high, roundish, hairy, densely branched; lower branches shorter. Leaves alternate, lanceolate, entire, obtuse, callous at the tip, furnished with close-rolled hairs, callous at their base. Flowers in long, loose clusters, alternate, small, blue, with a yellow throat. Bracteas minute, linear-lanceolate. Seeds beautifully beset at the angles with two rows of unicnated brrilles. The above description is from Retzious, who seems to think that what Pallas mentions as a variety of *M. Lappula*, growing near the Wolga, is the present species. See Pali. t. v. 3. 718. note.

11. *M. pinacarpas*. Thorny-feeder Scorpion-gras. Willd. n. 11. Vahl. Symb. p. 2. 32. (Anchusa pinacarpas; Forl. Defer. 41. — Seeds mucrinated and fipinous. Clusters leafy; flowers remote. Leaves linear, hairy. Found near Alexandria. Stems woody at the base, spreading, branched in a forked manner towards the top, thickly covered with darkish hairs, as is the whole plant. Leaves f, e, as long as the st, rather obtuse, spreading at the top. Flowers small, white. Fruit pyramidal, mucrinated all over, angular, and fipinous at the base, with larger tubercles.

13. *M. australis*. New Holland Scorpion-gras. Brown. Prodr. Fl. Nov. Holl. v. i. 495. — *Hippid*. Leaves oblong-lanceolate. Calyx as long as the tube, clothed with spreading, hooked bristles." Gathered by Mr. Brown at Port Jackson, and in Van Diemen's land. We have a specimen from the former country. The plant is eighteen inches or more in height, clothed with little, rigid bristles, of which those on the stem are deflexed. Leaves with a blunt, callous point. Flowers numerous, small, blue, in terminal, aggregate clusters, whose stalks are clothed with ascending bristles.

Mr. Brown classifies this genus as differing from *Anchusa* merely in the want of bracteas. He would therefore refer to

vol. XXIV.
the latter *M. pathulata* of Forster, and *ruptrifis* of Pallas. He conceives that the Linnaean species, which have an echinoid fruit, ought to constitute a distinct genus, very near to *Cynoglossum*, on account of the prickly cuts or seeds attached to the central column, compressed not depressed, and the clusters furnished with bracteas. The essential character of the genus *Myosurus* is given by this ingenious author as follows: "Calyx deeply five-sect. Corolla filaceous-shaped; throat clofed with concave valves; limb in five, deep, ob- tupe fegments. Stamens included with peltate anthers. Stigma capitate. Nuts four, distinct, umbilicated at the base.

Clusters simple, without bracteas." *M. apula,* Linn. Sp. Pl. 189, is now referred by Wildenow, and Dr. Smith, in the *Prodromus Flora Graece*, to *Lithospermum*.

Gen. Ch. Cal. Perianth in-fior, of five, almost lanceolate, obtuse, reflexed, coloured, deciduous leaves; each spurred at the base, below their infertion. Cor. Petals five, shorter than the calyx, very small, concave at the base, confiding of a honey-bearing, tubular claw, and a short, spreading, lanceolate border. Stam. Filaments five (or more), the length of the calyx; anthers oblong, erect. Ptl. Germens superior, very numerous, covering a very long conical receptacle; stylus none; ligmas simple. *Peric.* none. *Recept.* very long, columnar, imbriacated with numerous, oblong, pointed feeds.

Obf. The number of flaments in this genus is extremely variable. There is also a great affinity between it and *Ranunculus*, especially between the restingiferous claw of the petals in that genus, and the tubular claw of *Myosurus*. Linnæus and other authors have considered these parts of the flower as sectaries, but we are rather inclined to regard them as petals, as they were originally described.

Eff. Ch. Calyx of five leaves, each with a spur at the base. Petals five, with a tubular, honey-bearing claw. Seeds numerous. naked.

The first author observes "this affords a remarkable and rare instance of a very great disproportion of males to females in the same flower, and yet the latter are generally all prolific. The *feds* are justly described by Linnæus as

naked:
naked; for the part which Jussieu denominated a capsule, is
surely nothing more than a thickened inseparable coat, as in
Ranunculus."

Mr. Curtis, in remarking the singularity of structure in
the fructification of this delicate little annual, cautions the
young botanist to be careful in distinguishing the corolla
from the flaments.—Mr. Hudson says the leaves are occasi-
onally hairy. Professor Martyn mentions a specimen of
this plant, which grew in a good soil, and had above fifty
flower-stalks of different lengths, from three to seven inches,
and leaves about three inches and a half in length, but there
was no trace of hairiness on them. This plant flowered in
April and May, but had not shed its seeds towards the mid-

MYOTOMY, MYOTOMIA, the dissection of muscles.
This name has been given to some anatomical works on the
muscles: as Cowper's myotomia reformata.

MYOXUS, DORMOUSE, in Zoology, a genus of quad-
rupeds of the order Gliridae. The generic character is, front-
teeth two, the upper ones are wedged; but the lower ones
are compressed sideways, whistlers long; tail hairy; round,
thick towards the tip; the feet are nearly equal in length;
the fore-feet have four toes. The animals of this genus all
remain torpid during winter; they walk or rather leap on
their hind legs, bounding three or four feet at a time, in
which they are assisted by a long stiff tail; they feed only
on vegetables, burrow under ground; sleep by day, watch
by night, carry food to the mouth by the fore-paws, and
drink by dipping the fore-palms in water. There are four

Species.

Glis; Fat Dormouse. Body hoary, beneath whitish.
This species, the Glis of Pliny and the old naturalists, is
a native of France and the south of Europe. It also occurs
in Ruffia, Auffria, &c. feeding on trees, and leaping from
bough to bough in the manner of a squirrel, though with a
less degree of agility. It feeds on nuts, acorns, fruit, &c.
and during great part of the winter remains torpid in its
nest, which is prepared in the hollows of trees, with dried
leaves, moss, &c. During its state of torpidity, it is said
to be very fat, contrary to the nature of most of the hy-
bernating or sleeping animals; which are observed, on their
first emerging from that state, to be far leaner than before its
commencement. It is probable, however, that this ani-
mal awakes at intervals, and indulges in the use of its col-
lected stores of provisions.

The size of this elegant species is not very far from that of a squirrel, measuring from nose to tail near six inches,
and the tail four and a half. It is an animal of a much thicker
form, in proportion, than a squirrel, and is of an elegant
ash-colour, white on the under parts and inlaid of the limbs;
the tail is very villose or furry, and of a slightly
spreading form, like that of a squirrel; the eyes are large
and black; the ears thin, rounded, and very lightly haired.
Sometimes the upper parts of the body have a light dun
brown, and sometimes a ferruginous tinge. Its general manners
resemble those of a squirrel, but it is not easily tamed.
The young are reared about the middle of summer, and are
eight to twelve in number.

Dryas; Wood Dormouse. Body above tawny-grey;
beneath dirty-white; a straight black line from ear to ear
crosses the eyes. It inhabits several parts of Europe.

Nitella; Garden Dormouse. Body above tawny;
beneath whitish; a black circle round the eyes, and a black
spot behind the ears. The garden dormouse is a native of
the temperate and warmer regions of Europe and Asia, and
is commonly found in gardens, feeding on various kinds of
fruit, particularly peaches and apricots. It makes its nest,
like the rest of this genus, in the hollows of trees, and some-
times in thofe of walls, or even in the ground about the roots
of trees, collecting, for this purpose, dried leaves, grans,
mosses, &c. In autumn, it collects a quantity of nuts,
mail, &c. and deposits it in its hole; and during the greatest
part of the winter remains in a state of torpidity, awaking
only at distant intervals. Its general length is about four
inches and a half, and the tail rather less. It is of an elegant
rufous or ferruginous colour above, and yellowish-white be-
neath; the eyes are imbedded in a large black patch or
spot, which extends to some distance beyond each ear;
the tail is somewhat wider towards the end, and sharpens at
the extremity, and is marked on that part by a longitudinal
black stripe, having the edges white. These animals pro-
duce their young about the middle of summer, which are
about five or six in number, and are fed to be of a very
quick growth.

Muscardinus; Common Dormouse. Body tawny;
throat whitish; hind-thumbs without claws. The size of
this animal is nearly equal to that of a mouse, but is of a
more plump or rounded form, and the nose is more obtuse
in proportion; the eyes are large, black, and prominent;
the ears broad, thin, and semi-transparent; the fore-feet
have four toes, and the hind-feet five, but the interior of
these latter are dititute of nails; the tail is about two
inches and a half long, and is closely covered on all sides
with hair, which is rather longer towards the tip than on
the other parts; the head, back, fides, belly, and tail, are
of a tawny-red colour; the throat white; the fur is remark-
ably soft, and the whole animal has a considerable degree of
class in its appearance. It sometimes happens that the
colour is rather brown than reddish.

Myra, in Geography, a town of Asiatic Turkey, in
Natolia, on a river of the same name, which runs into the
Mediterranean: 54 miles S.S.W. of Satalia.

Myracopon, a name used by some authors for an
ointment intended to be used to the whole body to prevent
laziness. It is described by Galen.

Myrcinus, in Ancient Geography, a town of Thrace,
placed by Herodotus and Thucydides on the banks of the
Styrmon; Appian places it near Phylippi; and Tzetzer says,
that it was anciently called "Hedonis."

Myre, a town of Asia Minor, in Lycia.

Myrepsus, Nicholas, in Biography, a physician,
and one of the last who wrote in Greek, was a native of
Alexandria. He appears to have flourished in the thirteenth
century, as his writings are quoted by other authors early
in the fourteenth. The impurities of his style abundantly
prove the decaying state of the Greek as a living language.
A dispensatory, which he composed, became very early the
rule of pharmacy throughout Europe. In Paris, in 1532,
all apothecaries were ordered by parliament to have a copy
of his "Antidotarium" in their possession. The Greek
copies are numerous, in MS. in different libraries; but the
work has been printed only in Latin translations; the last
of which is that of the learned Leonart-Fuchs, entitled
"Opus medicamentorum in sectiones quadrangulatarum dige-
tum," first printed at Basle, 1549, folio, and several times
reprinted. It is included in the collection of the "Medicin
Artes Principes." This work of Myrepsus is a vast far-
rage of the compositions of the Greeks and Arabs, in-
termixed with much superfluous, and full of obscurities.

MYRIAD.
MYRIAD, the number of ten thousand. Whence myriarch, a captain or commander of ten thousand men.

MYRIANDRI, in Ancient Geography, a people of Syria, upon the banks of the river Amanus, according to Pompianus Mela.

MYRIANDRICUS SINUS, the name with the "Sinus Ilicius."

MYRIANDRUS, a commercial town of Syria, erected and inhabited by Phenicians, situated in the S.E. part of the gulf called "Ilicius."

Female, Cal. and Cor. . . . Berry inferior, pulp), of twelve or fourteen cells. Seeds numerous, winged.

1. M. arboreus. Beauv. Ow. et Ben. 17. t. 11. 12. Native of the kingdom of Benin, in the tropical parts of Africa.—A tree as large as an apple-tree; with a white bark. Leaves alternate, flaked, fringed, resembling those of the Horfe Chefnut; the leaflets fix, oblong, toothed. Flowers in a corymbose panicle; the males very minute, white, in very close spikes, at the top of the divisions of the panicle. Fruit the size of a large apple. Wildenow.

What is above described the calyx of the male flowers, would probably have been termed corolla by Linnaeus; but at least if we are right in the natural order.

MYRICA, a name borrowed from the ancient Greeks, whose μυριανθος however appears, by the imperfect description in Dioscorides, and especially by what he says in the following chapter, (of γλυκη being like it, but much smaller,) to be the Tamarian, Tamaria gallaec. This Pliny confirms, and all modern writers have so understood it; nor do we find, in the writings of Linnaeus, any reason for his having first applied this name to the genus before us, except that he preferred it to the Dutch word Gale, adopted by Tournefort: See Fl. Lap. ed. 2. 307. —Linn. Gen. 518. Schreb. 682. Mart. Mill. Dict. v. 3. SM. Fl. Brit. 1796. Jull. 456. Michaux Boreale. Amer. v. 2. 227. Lamarck Illust. t. 509. Gartn. t. 39.—Cliffs and order, Dioscia Tetrandria. Nat. Ord. Amianthaceae. Linn. Juff.

Female, Cal. as in the male. Cor. none. Pfl. Germen superior, nearly ovate; styles two, thread-shaped, longer than the calyx; stigma simple. Peric. Berry of one cell. Seed foliary.

Elf. Ch. Male, Calyx the scale of a catkin, concave. Corolla none.

Female, Calyx the scale of a catkin, concave. Corolla none. Stves two. Berry with one seed.

Obf. M. Gale. The original species, has four flaments, and a dry berry, which coriaceous crust is compressed and three-lobed at the summit.

M. cerifera, has mostly six flaments, and a globular juicy berry.

As to the very great affinity ("famna affiniti") between this genus and Pijstacia, mentioned by Linnaeus, we confess ourselves unable to perceive it, either in the habit, inflorescence, or characters of the fructification.

1. M. Gale. Sweet Gale, Gale, or Dutch Candleberry Myrtle. Linn. Sp. Pl. 1453. Engl. Bot. t. 562. Pl. Dan. t. 327. (Myrtus brabantica, five Eleagnus Cordi; Ger. em. 141.)—Leaves lanceolate, with shallow ferratures. Fruit crowned. Stem shrubby.—Abundant in bogs throughout the north of Europe, especially about the bases of mountains, as well as in flat countries, where the soil is gravelly and the water clear. It is found on several wet moors in Norfolk. The catkins are fully formed in March; they expand in April, after which the leaves come forth, and in August or September the branches are laden with ripe fruit, whose scent is very agreeable, not unlike that of red cedar. This odour redides in the shining resinous particles, scattered over the berry, which easily rubs off; and is very durable, even in dried specimens, though it allumes, with age, the flavour of candied citron peel. Linnaeus says, the fruit is used as a substitute for hops, by poor people in the north, and that wax may be obtained from it, as from the next species, by boiling. The flum is not above three or four feel high, shrubby, buffy, forming a round head of numerous, smooth, round, dark-brown twigs. Leaves alternate, lanceolate, inclining to obovate, acute, chiefly ferrated towards the point, minutely downy, veiny, paler beneath, about an inch and a half long, deciduous. The young catkins are axillary formed in the course of the former for the ensuing spring. Michaux met with this species in America, as well as the following.

2. M. cerifera. American Candleberry Myrtle. Linn. Sp. Pl. 1452. (Myrtus, Brabantique similis, carolinensis baccifera, fructu racemo, &c.; Phuk. Phyt. t. 48. f. 9. Cateby's Carolin. v. 1. 69. t. 69; also 13. t. 13.)—Leaves elliptic-lanceolate, somewhat ferrated. Stem arboreous, Berries globose.—Native of North America. Hardy in our gardens, flowering in May and June. Larger than the foregoing, with broader, more elliptical, scarcely ferrated or notched leaves. The berries are much fewer, and larger, than those of our Englih species. Their form is globo, their pulp of a waxy nature, enclosing an oval hard nut. When dried they resemble Coriander comfits, as their waxy subfabel, frised from the watery particles of their pulp, then allumes the appearance of white meal. By boiling these berries, a quantity of wax is procured, which floats on the water, and serves in America to make candles, but its dirty green colour is unsightly, and its flame far less brilliant than even that of a good tallow candle.

3. M. Faya. Azorian Candleberry Myrtle. Ait. Hort. Kew. ed. 1. v. 3. 397.—Leaves elliptic-lanceolate, somewhat ferrated. Male catkins compound. Female flowers diffus. Fruit elliptical, coarly granulated.—Gathered in Madeira and the Azores, by Mr. Maffon, who sent it, in 1777, to Kew, where it is hardly, flowering in June and July. The leaves have a few very shallow and occasional ferratures. The male catkins are laid to be compound, but these we have not seen. The female ones are extremely lax, looking like very loose spikes, of a ruffly hue; we are not sure that they are not compound also, though only one flower in each little partial branch comes to perfection. The fruit is twice the size of the leaf, and less abundant, elliptical, granulated, covered with more or less of the same waxy subfabel. It's seed a very hard nut, laid to have four cells, but this we find not conftantly the case.

4. M. ethiopica. African Candleberry Myrtle. Linn. Mant. 298. (Myrtus, Brabantique accedens, africana, baccis carens, conifera; Phuk. Phyt. t. 48. f. 8.)—Leaves lanceolate, strongly toothed, the lowermost entire. Female flowers diffus. Fruit globose, coarly granulated.—Native of the Cape of Good Hope. Akin to the two last, but
but more downy, and distinguished by the strong prominent teeth of its upper leaves, the lower ones being entire. The male catkins we have not seen; the female ones are like rather lax spikes, simple, with a hairy talk. Fruit copious, the size and shape of M. cerifera, very coarsely granulated, but we perceive no remains of wax upon our specimen.

5. M. Nagi. Japan Candleberry Myrtle. Thunb. Jap. 76. Linn. Syll. Veg. ed. 14 884. (Nageia japonica; Gertr. v. 1 191. t. 39. f. 8. Na vulgo Nagi; Kämpfl. Amoen. 773. t. 874.—Leaves lanceolate, entire, without ribs. Fruit globose, smooth.—Native of Japan, but rare. Kämpfler says it is considered as a good tree of good, and planted in the courts of homes. The leaves are evergreen, firm, and veined, like that of the Rufus racemofus, or Alexandrian laurel. Female catkins whitish, hairy, dense. Fruit generally solitary, globose, dark purple, the size of a sweet-water grape, smooth, with a little inripid pulp, and one large seed whose shell is hard, but thin. Nothing is said of its yielding any wax. Though Gartnner makes a genus of this, he urges its very near affinity to Myrica.

6. M. quercifolia. Oak-leaved Candleberry Myrtle. Linn. Sp. Pl. 1453. (M. folius oblongis, opacte finnatis; Burm. Afr. 262. t. 98. f. 1. Laurinus africana minor, quercifo folio; Comm. Incrt. v. 2. 161. t. 81.—Leaves oblong, deeply frinate.—Native of the Cape of Good Hope. It has been cultivated in our greenhouses for above fifty years, blossoming in May and June; but is chiefly valued for its evergreen oak-like leaves, which are fragrant when rubbed. The male and female catkins are often found on the same plant. The latter are rather short and clothe. Fruit nearly globular, coarsely granulated.

7. M. montana. Arabian Candleberry Myrtle. Vahl. Symb. v. 2. 99. (Buxus dioica; Forlk. Ægypt.-Arab. 159.—Leaves lanceolate, ferrated; not dotted beneath. Catkins globose.—Gathered by Forskall on mount Barah in Arabia. By the description of Vahl, this is a fruber, with round smooth branches. Leaves an inch long, lanceolate, narrow, tapering at each end, smooth, with five or six minute, sharp, crowded serratures near the extremity. Flowers small, in round fleshy heads, or catkins. Calyx of four minute lanceolate leaves. Berry the size of a pepper-corn; according to Forskall it is of a brownish-purple, and not estable. The four-leaved calyx in this, similar to what Gartnner attributes to M. Nagi, is mentioned by Vahl, as indicating some generic difference between these two plants, and the true Myrica. To this we cannot but assent, provided the description be correct; and the smoothness of the fruit may perhaps confirm such difference.

8. M. cordifolia. Heart-leaved Candleberry Myrtle. Linn. Sp. Pl. 1454. (Alternoides ilicis folio crasso hirsuto; Walth. Hort. 3. t. 3. Thithymali facie planta ethiopica, ilicis acutato folio; Pluk. Almagent. 373. Phyt. t. 319. f. 7.—Leaves nearly heart-shaped, ferrated, fefile.—Native of the Cape of Good Hope. A small bushy fruber, whose young branches are hairy, beset with numerous, alternate, small, roundish, bluntly-toothed leaves, thick at the edges, and curiously dotted beneath. Male catkins small, dense, axillary, shorter than the leaves.—M. folius subcordatus, integris, felliibibus; Burm. Afr. 264. t. 98. f. 3. is cited by Linnaeus as a variety. By this plate the fruit appears to be globose and smooth.

9. M. trifoliata. Three-leaved Candleberry Myrtle. Linn. Sp. Pl. 1453. Amurin. Acad. v. 6. 112.—Leaves ternate, toothed.—Native of the Cape of Good Hope. "A fruber, with alternate, ilaxed, ternate leaves: the whole leaves are fessile, lanceolate, pointed, strongly toothed, downy beneath. Fruit in a cluster, not a spike, pubescent, rough." Linn. This is one of those Cape plants upon which Linnaeus founded his dissertation, entitled "Planta Africana Rariores," published in 1762, and reprinted in the Am. Acad. These plants were merely thrown him by the younger Burmann, and from so transient an acquaintance with them, it is not wonderful if he made some mistakes. A Myrica with ternate leaves, and racemose berries, is truly paradoxical, nor have we seen any thing to confirm its excellence.

MYRICA, in Gardening, comprehends plants of the deciduous and evergreen shrubby kinds, of which the species cultivated are sweet gale, sweet willow, or candleberry myrtle (M. gale); the American candleberry myrtle (M. cerifera); the oak-leaved candleberry myrtle (M. quercifolia); and the heart-leaved candleberry myrtle (M. cordifolia).

With regard to the first fort, it is said, that "the northern nations formerly used it instead of hops," and that "it is still in use for that purpose in some of the western isles, and a few places of the Highlands of Scotland," where it is known by the names of sweet gale, goats, gales, sweet willow, wild myrtle, and Dutch myrtle.

Method of Culture.—The two first forts may be raised from seed, and the two last by layers. The fruber kind requires a boggy moil situation, or to be cultivated on bog earth in such circumstances. The seeds should be procured from their native situation, and sown in pots of rich earth, in the spring, to the depth of half an inch, watering and shading them during the following summer; and on the approach of winter, placed in a warm sheltered situation, or under a common frame. When the plants have attained some growth, they should be planted out in the spring in nursery-rows, to remain till proper size to be planted out in the pleasure-ground, where they succeed best in a soil that is not too dry.

The two last forts are mostly raised by laying down the young shoots in the latter end of summer, or in the autumn, twitting them at a joint, and watering them well during the following summer, when the fesehen is dry; and when they have formed good roots, which is seldom the case till the second year, they should be taken off, and planted in small pots filled with loft loamy earth, being placed under glasses in a common frame, and shaded from the mid-day sun till fully rooted, when they may be removed into a warm sheltered place during the summer, and in the autumn removed into the greenhouse, being afterwards managed as other plants of that kind.

The fruber forts are likewise sometimes raised by planting the suckers of the roots in nursery rows, as above, in the autumn; and all the forts occasionally by cuttings, though they strike root with great difficulty. In this last way the young shoots are the most proper, which should be planted in pots, and plunged in a hot-bed, covering them clothe with glasses. They may be introduced, the two first in sheltered clumps and borders of the greenhouses kind, where they afford fine fragrance in their leaves.

MYRNA, in Ancient Geography, Paliacastra, a town on the northern part of the island of Lemnos, W.N.W. of Hephæstia.—Alfo, a town of the Troade, probably the same with that referred by some geographers to the Æōride.—Alfo, a town of the island of Crete.—Alfo, a town of the Æōride.

MYRINX, a word used by some to express the membrane of the tympanum in the ear.

MYRIOPHYLLUM, in Botany, is derived from myrios, innumerable,
MYRICACEAE

innumerable, and $\phi \lambda \mu \alpha \theta \nu \alpha \iota \kappa \eta \zeta$, a leaf. This Limnanthus genus appears to be the very plant so called by Pinny, and other ancient writers. From the description of $\mu \nu \sigma \omega \lambda \varsigma \kappa \alpha \iota \nu \alpha \iota \kappa \dot{\circ}$ in Dioscorides, we have no doubt of its being the identical plant of that author. Millfoil.—Linna. Gen. 493. Scheele. 642. Wildl. Sp. Pl. v. 4. 406. Mart. Mill. Dict. v. 3. Sw. Fl. Brit. 102. Att. Hort. Kew. ed. 1. v. 3. 354. Michaux. Boreal-Amer. v. 2. 159. Jull. 18. Lamark Illistr. t. 755. Gartn. t. 68. Vaill. Mem. Par. 1719. t. 2. f. 3. (Pentapterophyllum; Dill. Gen. 125. t. 7.)—Clafs and order, Monocca Polyantria. Nat. Ord. Inundates. Linno. Niaiaides. Jull.

2. M. Verticillatum. Verticillate Water-Millfoil. Linn. Spc. Pl. t. 10. Engl. Bot. t. 218. Fl. Dan. t. 1046. — All the flowers in axillary spikes.—Native of Europe, in swampy places; but not so common in this country as the last. It flowers in July. The flowering-floas of this floating herb rise above the surface of the water, and are leafy up to their very summits. Leaves whorled, as in the last, but in fives, those at the upper part of the stem less finely cut than those which are immersed. Flowers axillary, whorled, occasionally hermaphrodite; but mostly female in the lower whorls, male in the upper. Petals oval, concave, green, soon falling off. Stigmas short, spreading, and finely tufted. The root and lower part of the stem much resembfe those of Speciactum.

3. M. indicum. Indian Water-Millfoil. Wildl. n. 3. — Lower leaves pinnated, capillary; upper lanceolate, wedge-shaped, somewhat cut at the tip. Flowers axillary, whorled.—This species is a native of Ceylon and Coromandel. Stem two feet high, round, about as thick as a pigeon's quill. Lower leaves pinnated, four in a whorl; leadets capillary; the upper ones gradually narrower; the uppermost lanceolate, either slightly toothed or entire at the tip. Flowers in whorls, at the axis of the leaves. In

habit very similar to the last. Willdenow adopted the present species on the authority of his friend Klein, who observed that its flowers were hermaphrodite, and described it as follows: "Calyx in four, ovato-lanceolate, minute segments. Corolla of four, ovate, deciduous, petals. Filaments eight, thread-shaped, the length of the corolla. Anthers linear, as long as the filaments. Germs four, forming an arch. Styles none. Capsules four, fingered."

4. M. Scabratum. Rough-Water-Millfoil. Michaux Boreal-Amer. v. 2. 190. Wildl. n. 5.—Leaves pinnatifid. Flowers all whorled and axillary; the males with four filaments. Fruit with eight ribs, disposed in pairs. This is a native of Carolina and Georgia, and is suspected by Michaux to be the Petasogenon sinnatum of Walter's Flora Carolina.

5. M. Polyphyllum. Various-leaved Water-Millfoil. Michaux ibid. 191. Wildl. n. 4.—Lower leaves pinnate, capillary, the upper floral ones oval, sharply ferrated. Male flowers with five filaments.—From the same country. Supposed to be Petasogenon verticillatum of Walter.

MYRISTICANA, from $\mu \nu \rho \iota \iota \varsigma \iota$, innumerable, and $\sigma \varsigma \epsilon$, a cell; Jull. 15. Poiret in Lamark's Dict. v. 4. 493. See MARATTIA.

M. Poir. unjustly censures what he mistakes for a wilful alteration of the name. Swartz published Marattia in his Prodrumus in 1788, of which Jullieu was ignorant when he called the same genus Myristica, the following year, in his Genera Plantarum; but most succeeding writers have properly adopted the original name, and Lamark and Poiriot ought to have done so.

There is some want of precision in the learned Jullieu's character of this genus. p. 15, and still more in his referring it, p. 447, to the Cenepetis of Bergius. (See DAREA.)

Thee errors possibly led M. Poiriot to compare the genus in question to Pteris, from which it is equally unlike in character and appearance.

Gen Ch. Male, Cal. Perianth of one leaf, coriaceous, three-cleft; the segments ovate, acute, not folding over each other in the bud. Cor. none. Stam. Filaments completely united into a cylindrical columnar tube, shorter than the calyx; anthers from three to twelve, linear, cohering lengthwise, of two cells, curving longitudinally externally. Pijfl. No rudiments of any.

Female, Calyx three-cleft. Corolla none. Capsule nearly globose, fleshy, of one cell and two valves. Seed solitary, in a many-cleft tube.

The characters of this valuable genus have but lately been made known to scientific botanists. The history of the different species, as far as they were known to him, is indeed
indeed fully given by Rumphius, but he has said nothing explanatory of the structure of their flowers. The fruit is so extraordinary, that nothing of the affinity of the genus could be conjectured from thence; nor was any information, respecting so precious an article of commerce, to be expected from the Dutch, while it was in their power to conceal the truth. This difficulty is now removed, by other nations having got access to the spice islands, and botanists are at present furnished with sufficiently good specimens, of several of the species.

As we are not yet possessed of the volume of Willdenow which contains this genus, we cannot profit by his labours. We derive, as usual, light from Mr. Brown, who is inclined to keep separate from Myristica two genera which have been referred to it. These are *Kema* of Loureiro, whose anthers are unconnected, spreading in the form of a star, (and which appears to be the *Myristica* globularia, Lamarck n. 3, as well as *M. microcarpa* of Willdenow;) and *Virola* of Aublet, t. 345, which Mr. Brown observing, in the original specimen of that author, to have but three anthers. (See *Kema* and *Virola.*) On the other hand, *Horstfelia* of Willdenow, differing only in having an oblong stigma, which, as Mr. Brown remarks, was perhaps "but obscurely seen," is reduced by him to *Myristica*.

We shall at present attempt the botanical history of the two species which we have seen, and which we have not as yet found clearly defined, subjoining lighter mention of some others.

2. *M. tomentosa.* Long Nutmeg. Thunb. Diff. 4. (M. philippensis; Lamarck n. 2.) Nux myristica mas; Rumph. Amboin. v. 2. t. 4. f. 5. Clus Exot. 14.)—Leaves oblong, with numerous simple parallel veins. Flower-flanks aggregate, scarcely the length of the calyx, downy, like the calyx and fruit. In Banda, Amboyna, and New Guinea, flowering in May. Mr. C. Smith sent it, under the name of New Guinea Nutmeg, or Long Nutmeg, from Banda in 1797. The branches and footstalks are very much thicker than in the preceding. Leaves four times as large, often a foot in length, and three or four inches broad, oblong or somewhat obovate; soft and scarcely visibly downy beneath; their veins much more copious, straight and parallel. Flower-flanks in little dense axillary tufts, about a quarter of an inch long, and very thick. Calys nearly globular, somewhat larger. Both these parts are densely clothed with fine silky pubescence, of a rich golden brown in the dried specimen. The fruit also is described as downy, but this we have not seen. The seeds are of a much longer form and proportion than the first species, and are sometimes sold in the shops, by the name of Long Nutmegs, though generally reckoned inferior in quality to the former. Rumphius figures and describes three or four more species or varieties of these plants, of which nothing is certainly known to us.

3. *M. daudzeoides.* Malabar Nutmeg. Gärtn. v. i. 195. t. 41. f. 2. (M. malabarica; Lamarck n. 3.) Fruit inodoro; Linn. Zeyl. 229. Panam-palka; Rheede Hort. Malab. v. 4. t. 5.)—Leaves oblong, with numerous simple parallel veins. Flower-flanks aggregate, longer than the calyx. Fruit oblong, downy.—Rheede describes this as common everywhere in the woods of Malabar, bearing fruit twice a year, in June and December. Lamarck well observes that it seems very near our second species, but, if the details in the Hortus Malabaricus be faithful, must be distinct. One circumstance in the figure is striking enough, the panicked flowers; but the description does not confirm it, and we suspect some mistake; otherwise that character would be decisive. The fruit and seed appear much like the preceding, but the latter has scarcely any taste or smell, though the mace is not without some flavour. Rheede says "the Turkish and Jewish merchants," (as if they were the only cheats in India,) mix these nutmegs with the true long ones, and the mace with good mace, felling them together. They also extract from these inferior articles, an oil, with which they adulterate that of a more genteel quality.

The author last quoted describes a second New Holland species, by the name of *M. infisida*; but this he himself suspects to be a *Kema*. Gärtners has a *M. Irya*, f. 3, whose seed is globular, and a *M. Iryagbhi*, f. 4, more like the Long Nutmeg; but these, as well as some species of Lamarck, we are obliged to pass over, for want of more sufficient materials to fix their specific characters.

MYRISTICA MOEFICATA. See Nutmeg. MYRISTICACEAE, a natural order of plants, first established as such by Mr. R. Brown, Prodr. Nov. Holl. v. i. 309, and named from its principal genus, *Myristica*; see MYRISTICACEAE. The characters are as follows. *Flowers dioecious, (without any rudiments in each of the other sex.)* Perianth of one leaf, three-cleft, the segments meeting by their edges in the bud, not overlapping each other. Male. Filaments closely united into a column. Anthers from
MYR
from three to twelve (definite in number), either cohering or distinct, of two cells; bustling longitudinally at the back, or outer side.

Female. Perianth deciduous. German superior, dilated, nipple, of one seed, the rudiments of which are erect. Style very short. Stamina somewhat lobed.

Berry? capsular, bivalve. (We esteem it rather a corymbous or fleshy corymb.)

Seed hardish like a nut; invested with a tunic which is cloven into many deep segments. Albumen eroded (as it were) internally, of a firm febacous texture. 

Embryo small; cotyledon leafy; radicle inferior; plumula conspicuous.

This order consists of tropical trees, often exuding a reddish juice. Leaves alternate, without stipules, falcate, entire, coriaceous: when full grown often clothed beneath with minute cloth-pressed down; their surface not dotted. Inflorescence either axillary or terminal, racemose, tufted, or pedated, each flower accompanied by a small short hooded bractea. Perianth coriaceous, smooth within, in many instances downy externally, the pubescence sometimes falcate.

Mr. Brown remarks that this order is properly not nearly skin to any other. The anthers appear to be always definite in number, either as many as the segments of the perianth, or twice, thrice, or four times that number. Their true nature is best seen in Kneiss, where they are separate, for which reason Mr. Brown is disposed to keep that genus distinct.

MYRLEA, in Ancient Geography. See Apamea.

MYRMECIA, myrmecia, in medicine, from myrmex, the ant, because the flowers are stung by the little ants, and are more strongly observed by them than by any other kind of animal. (From myrmek, a term applied to the Cimmerian Bosphorus.)

This small species of Ants, which have been named by the ancients, is very rare in this country; the eggs are small, and are inclosed in a bivalve case, which is produced by the female ant, and is often found in the base of the nests. The entrance to the nest is at the bottom; the female ant is about the size of a small pea, and has two black eyes, which are situated on the sides of her head. Her body is covered with a scaly skin, and is about an inch long, and half an inch broad. She has six legs, and is provided with a pair of jaws, which she uses in cutting the wood for her nest. She is a very active animal, and is always on the look-out for food. She feeds chiefly on insects, and is particularly fond of beetles, which she catches by means of a sticky substance, which she produces at the tip of her proboscis. She is also fond of small fruits, and is often seen feeding on the berries of the apple-tree. She is a very hardy animal, and is able to endure great heat and cold. She is a very useful animal, and is often employed by the farmers to destroy the insects which are injurious to their crops. She is a very sociable animal, and is always found in colonies, which are called ant-hills.

MYRMECON. See Apamea.

MYRMECITES, in Natural History, a town of the Tauric Chersonesus, on the banks of the Cimmerian Bosphorus, according to Strabo, Pauy, Mea, &c. No vestiges of it now remain.

MYRMECION, in Ancient Geography. A town of the Tauric Chersonesus, on the banks of the Cimmerian Bosphorus, according to Strabo, Pauy, Mea, &c. No vestiges of it now remain.

MYRMECOPHAGA; Ant-eater, in Zoology, a genus of quadrupeds of the order Bruta. The generic character is, teeth none; tongue cylindrical, extensile; mouth lengthened into a somewhat tubular form; body covered with hair. The animals of this genus live entirely on insects, more particularly on the various kinds of ants: in order to obtain which, they extend their tongue, which is of a very great length, and of a roundish or worm-like form, into the nests of these insects; and when they come near the body of the insect, they seize it with their sharp pointed teeth, and swallow it. Among the genera of the myrmecophaga, the species of ant-eaters are very numerous, and are found in all parts of the world. They are generally small animals, and are provided with a very long and slender body, which is covered with a thick and glossy skin. Their heads are small, and are provided with a pair of large, black eyes, which are situated on the sides of their heads. They have six legs, and are provided with a pair of strong and sharp-pointed claws. They are very active animals, and are always on the look-out for food. They feed chiefly on insects, and are particularly fond of beetles, which they catch by means of a sticky substance, which they produce at the tip of their proboscis. They are also fond of small fruits, and are often seen feeding on the berries of the apple-tree. They are very hardy animals, and are able to endure great heat and cold. They are very useful animals, and are often employed by the farmers to destroy the insects which are injurious to their crops. They are very sociable animals, and are always found in colonies, which are called ant-hills.

MYRTIS. See Myrtus.

MYRTUS. See Myrtus.
preying on ants, by means of its long tongue, in the manner of other species. It is a native of Guiana; walks slowly on its heels; feeds only in the night, and emits no cry.

**Tridactyla.** Three toes on the fore-feet, and four on the hind; the tail is bushy. It is found in divers parts of India; travels slowly; climbs trees, and defends itself against the attacks of flies by its broad tail.

**Junata; Great Ant-eater.** Four toes on the fore-feet, and on the hind five; the tail is bushy. There is a variety with a shorter face and shorter legs. This, as its name imports, is by much the largest of the genus, being seven feet in length from the tip of the nose to the end of the tail; but if measured to the origin of the tail, it is no more than about five feet and a half. It is an animal of an uncouth appearance; the head is small; the snout very long; the eyes small; the ears short and round; the shoulders thick and muscular, from whence the body tapers towards the tail; but the thighs are thick and flat. The colour of the animal is a deep grey, with a very broad band of black running from the neck downwards, on each side of the body, growing gradually narrower as it paffes down. This black band is accompanied on the upper part by a streak of white; the fore-legs are of a lighter colour than the hinder, and have a patch or spot of black in front, not much above the foot; the tail is black, extremely long, and bushy; the hair on the whole body, but especially on the tail, is very harsh and coarse; the two middle claws of the fore-feet are extremely large and strong, which render this creature, though deft of teeth, a very formidable adversary; since it has been known to destroy animals of much greater apparent strength than itself, fixing its claws upon them, and exerting such powerful strength as to kill them by continued laceration and pressure. It is a native of Brazil and Guiana. It is chiefly nocturnal, and is said to sleep during the greater part of the day in retired places. Its pace is somewhat slow, and its manners dull and heavy. It is said to swim with ease, at which time it flings its tail over its back. A living specimen was some years ago brought into Spain, and kept in the royal menagerie at Madrid. In this state of confinement, it would readily eat raw meat cut small, and was said to swallow four or five pounds in a day. Its length was six feet from the nose to the end of the tail, and its height was two feet.

**Tetradactyla.** Four toes on the fore-feet, and on the hind-feet there are five; the tail is naked. It inhabits South America; wanders only in the night, sleeps by day; when angry, it fixes a fiek, and fights fitting on its hindlegs. The tail of this animal is bald at the extremity, by which it is able to suspend itself from the branches of trees. It has a black stripe on the breast and side.

**Pentadactyla; Striped Ant-eater.** Five toes on the fore-feet; the tail is long, flat, and entirely covered with hair. It is about thirteen inches long, and ten high.

**Capensis; Cape Ant-eater.** Four toes on the fore-feet; the front is long; the ears are large and pendulous; the tail is shorter than the body, and tapering to the tip. It is found at the Cape of Good Hope; is larger than the other species, and nearly of the size of a hog, weighing about an hundred pounds. It burrows in the ground, sleeps by day, and prowls by night.

**Aculeata; Aculeated or Porcupine Ant-eater.** Body covered with long sharp spines; tail short. The aculeated ant-eater is one of those curious animals which have been lately discovered in New Holland, and is a striking instance of that beautiful gradation, so frequently observed in the animal kingdom, by which creatures of one tribe or genus approach to those of a very different one. It forms a connecting link between the very distant Linnean genera of hyбри (porcupine) and myrmecophaga (ant-eater), having the external coating and general appearance of the one, with the mouth and peculiar generic characters of the other. This animal, so far as may be judged from the specimens hitherto imported, is about a foot in length. In its mode of life it resembles the rest of the ant-eaters, being generally found in the midst of some large ant-hill. It burrows with great strength and celerity under ground, when disturbed; its feet and legs being strong and short, and wonderfully adapted to the purpose. It will even burrow under a pretty strong pavement, removing the stones with its claws, or under the bottom of a wall. During these excursions, its body is strengthened or lengthened to an uncommon degree, and appears very different from the short or plump aspect which it bears in its undisturbed state.

**Myrmeleon, Lion-Ant, in Entomology, a genus of insects of the order Neuroptera. The generic character is, mouth furnished with jaws; teeth two; feelers four, elongated; sternalia nune; antennæ elevated, of the length of the thorax; wings deflected; tail of the male furnished with a forceps, confiding of two straignt filaments.**

This genus includes sixteen species, separated into two divisions.

A. Hind-feelers longer; jaws one-toothed; lip membranaceous, square, truncate, emarginate.

**Libelluloides.** Wings grey, spotted with brown; body spotted with black and yellow. It inhabits the Cape of Good Hope.

**Pardalis.** Wings white, with feetered black dots; thighs yellow. It inhabits Coromandel. A specimen is preferred in the museum of Sir Joseph Banks.

**Panthérinus.** Wings white, spotted with black; body yellow; abdomen variegated with black. This species is found in Austria, and other parts of Germany.

**Lyceus.** Wings hyaline, with a black marginal spot at the tip, in the middle of which is a snowly one. It inhabits Sierra Leon.

**Formicaleo.** Wings clouded with brown, with a white marginal spot. This species is better understood than any other of the genus myrmeleon. Its larva has been long celebrated for its ingenuity in preparing a pit-fall, for the destruction of such insects as happen unnaturally to enter it. The myrmeleon formicaleo, in its complete or fly state, bears no incomparable resemblance to a small dragon-fly; from which, however, it may readily be distinguished by its antennae. It is of a predacious nature, flying chiefly by night, and pursuing the smaller insects in the manner of a libellula. It depots its eggs in dry sandy situations, and the young larva, when hatched, begin to exercise their talent of preparing, by turning themselves rapidly round, a very small conical cavity in the sand. Under the centre of the cavity the little animal conceals itself, suddenly rushing forth at intervals, to seize any small insect which, by approaching the edge of the cavity, has been so unfortunate as to fall in; and, after fucking out its juices, throws it, by a sudden exertion, to some distance from the cavity. As the creature increases in size, it enlarges the cavity, which at length becomes about two inches, or more, in diameter. The larva, when full grown, is more than half an inch long, and is of a flattened figure, broad towards the upper part, and gradually tapering to an obotuse point at the extremity.
It is brown, and beset with numerous tufts of dusky hair, which are particularly conspicuous on each side the anulii of the abdomen; the legs are slender; the head and thorax rather small; the tubular jaws long, curved, serrated internally, and very sharp pointed. The whole animal is of an unpleasing aspect, and, on a cursory view, bears a general resemblance to a flat-bodied spider. When magnified, its appearance is highly uncouth.

Reamur and Redi have given accurate descriptions of this larva, and its extraordinary history. It is one of those whose term of life, like that of the libellule and ephemera, is protracted to a considerable space, since it survives the frost winter in its larval state, taking no nourishment during that time, and in the spring it passes its usual manner of preying. In preparing its pit, it begins by tracing an exterior circle of the intended diameter of the cavity, continuing its motion in a spiral line, till it gets to the centre; then marking, as it were, several volutes in the sand, revolving the impulsion in a large fluted shell; and after having sufficiently deepened the cavity, it smooths the sides into a regular shape, by throwing out the superfluous sand lying on the ridges: this it does by closing its forceps in such a manner, that, together with the head, they form a convenient file, with which it throws the sand with some motion out of the cavity, that the grains often fall to the distance of near a foot beyond the brink. The depth of the pit is generally equal to the diameter. When full grown, and ready to change into a chrysalis, the animal envelopes itself in a round ball of sand, agglutinated and concreted by very fine silk, which it draws from a tubular process at the extremity of the body; with this silk it also lines the internal surface of the ball, which, if opened, appears covered by a fine pearl-coloured film. It continues in the state of chrysalis about four weeks, and then gives birth to the complete insect.

**Catta.** Wings hyaline, with faint brown spots; the nerves are foetid with black. Found in Madeira.

**Punctatus.** Wings hyaline; the nerves with alternate black and white spots. It inhabits India. A specimen is in the cabinet of Sir Joseph Banks.

**Formiculinx.** Wings immaculate; body brown. It inhabits Africa and America.

**Thorinhus.** Wings hyaline, immaculate; body brown; margin of the thorax and legs yellow. It inhabits New Holland.

**Caninus.** Wings hyaline, immaculate; body brown; head and thorax spotted with yellow. It is found in Guinea.

B. **Feder nearly equal; jaw ciliate; lip horned, rounded, entire.**

**Species.**

**Barbarus.** Wings reticulate, yellowish-hyaline, with two brown spots. It inhabits Europe and Africa.

**Longicornis.** Upper wings hyaline, with a double yellow spot at the base; lower ones yellow, black at the base. It inhabits Italy.

**Capesius.** Wings white, reticulate with black; the tail is forked. It inhabits the Cape of Good Hope.

**Appendiculatus.** Wings white, immaculate, one-toothed at the base. Its country is not known. There is a specimen in the British Museum.

**Abstrusus.** Wings white, with a black marginal spot; the body is variegated. It inhabits the southern parts of Europe.

Vol. XXIV.
rected to be given in substance from half a dram to four drams, and in infusion or flight decoction from four to twelve drams; but they have long been discarded from practice in this country.

**MYROBALANUS, in Batsy, from μυρος, balsam, and βαλσαμ, an acorn, or some similar fruit; a genus founded by Gærtner, upon three or four different dried plums, which go under the above name, and are now among the most obfolute rubbish of the apothecaries' shops. Their flowers are unknown, but from what little can be made out of the history of the plants, they have always been taken for species of Terminalia. Nor does Gærtner himself much invalidate this opinion. He gives the character as follows.

Eff. Ch. Flower ... Drupa pulpy, its coat with rounded angles and furrowed, of one cell. Seed almond-like, inverted, with leafy, spirally convolute, cotyledons.

The species he enumerates are

1. **M. bellirica**. Gærtn. v. 2. 90. 1757. f. 2. (Tani; Rhee Ch. Hort. Mal. v. 4. 23. t. 10.)
2. **M. Choebula.** f. 2.
3. **M. citrina.** f. 3.

The two last he designates may be varieties of one species. M. indica of the shops, he believes to be nothing else than unripe citrina, before the seed is formed.

The same author adds, "if we consider the spiral convolution of the cotyledons as the essential character of Terminalia, according to the opinion of the late Koenig, Badamia," (a preceding genus figured by him in the same plate, "as well as all the species of Myrobalan, ought to be referred to that genus."

**MYROBATIPUM**, so called by Vaillant, from μυρος, a fragrant balsam, βαλσαμ, a thorn or bramble, and indicum, Indian; a synonym of some prickly species of LANTANA. See that article.

**MYRODENDRUM**, so named by Schreber, from μυρος, a balsam, or fragrant ointment, and δέντρον, a tree, because it is celebrated in Guiana for abounding with a red, resinous secretion in its trunk and branches, of the sweet flavour of florax. This juice, after expiation, becomes a reddish, transparent resin, which is used by the natives for fumigations, and is also successfully applied, according to Aublet, as a vulnerary, like the Balsam of Peru. Schreb. 1758. IND. v. 2. 1751. MART. MILL. DICT. v. 3. (Houmli; Aubl. Guian. v. 3. 53. Houmli; Jaff. 1552. Lamarck Illus. t. 402.)—Clasf and order, **POLYANDRIA**, Nat. Ord. uncertain.

Gen. Ch. **Cal.** Perianth inferior, of one leaf, tubular, coriaceous, tearing irregularly at the margin, without any uniform teeth, permanent. Cor. Petals five, inserted into the receptacle, oblong, oblique, obtuse, recurved and spreading, tapering at the base, longer than the calyx. Stam. Filaments united into a long slender tube, the filaments, dilated and parted at the summit, with five teeth; anthers numerous, kidney-shaped, filiform, crowded about the top of the tube. Pd. German superior, ovate; style almost obliterated, recurved, swelling at the top, rather longer than the filaments; stigma large, capitate. Somewhat petalate. Perc. Drupa nearly globose, dry and fibrous, abrupt and crowned with the base of the style, of two or three cells. Seeds foliary, angular at one side, convex at the other.

Gen. Ch. **Cal.** Perianth inferior, of one leaf, leafy, coriaceous, tearing regularly at the margin, with a upright uniform teeth, permanent. Cor. Petals five, oblong, acute, spreading, much longer than the calyx. Stam. Filaments twenty, capillary, inserted into the receptacle; anthers round. Pd. German superior, roundish, small; filaments long, incurved, villous; stigma capitate, five lobed. Peric. Capsule of five cells. Seeds foliary.

1. **M. laevis**, obovata, f. 2. 817. (M. angustifolium; Wild. Houmli balsamifer; Aubl. Guian. v. 3. 225.) — Native of woods in Cayenne and Guiana, where it flourishes in April. This tree, which is fifty or sixty feet high, is called Taurus, and also Houmli, by the Caribs. Its trunk is about two feet in diameter. Branches chiefly towards the top, long, and widely spreading. Leaves alternate, soon deciduous, and obovate, obovate-oblong, serrate, entire, reddish when young. Flowers coriaceous, axillary and terminal, white, furnished with a scale at the base of each flake.

The negroes cut slits of the bark to use as a sort of torch, and its wood is employed by the natives for building houses, especially for roofs.

Aublet's figure represents the leaves clasping the stem, which is hardly the case in his own specimen, nor in a more perfect one for which we are obliged to Mr. Rudge.

**MYODIA**, so named by Prof. Swartz, at the fuggelation of the late Mr. Dryander, from μυρος, a fragrant balsam, and clava, to smell; alluding to the powerful and fragrant scent of the whole plant, even after it has been long dried, which refembles that of melilot ointment. Swartz. Prodr. 1758. IND. V. 2. 1225. Schreb. 472. Wild. Sp. Pl. v. 3. 843. MART. MILL. DICT. v. 3. (Quaranthea; Aubl. Guian. 1757. Jaff. 274. CAN. DICT. 1757. POR. IN LAM. DICT. v. 6. 22. Lamarck Illus. t. 571.)—Clasf and order, **MONADELPHIA**, NAT. ORD. "Malvasiae, or rather perhaps "Myrtaceae." Jaff.

Gen. Ch. **Cal.** Perianth inferior, of one leaf, leafy, coriaceous, tearing irregularly at the margin, without any uniform teeth, permanent. Cor. Petals five, inserted into the receptacle, oblong, oblique, obtuse, recurved and spreading, tapering at the base, longer than the calyx. Stam. Filaments united into a long slender tube, the filaments, dilated and parted at the summit, with five teeth; anthers numerous, kidney-shaped, filiform, crowded about the top of the tube. Pd. German superior, ovate; style thread-shaped, furrowed, swelling at the top, rather longer than the filaments; stigma large, capitate. Somewhat petalate. Perc. Drupa nearly globose, dry and fibrous, abrupt and crowned with the base of the style, of two or three cells. Seeds foliary, angular at one side, convex at the other.

Gen. Ch. **Cal.** Perianth inferior, of one leaf, leafy, coriaceous, tearing irregularly at the margin, without any uniform teeth, permanent. Cor. Petals five, inserted into the receptacle, oblong, oblique, obtuse, recurved and spreading, tapering at the base, longer than the calyx. Stam. Filaments united into a long slender tube, the filaments, dilated and parted at the summit, with five teeth; anthers numerous, kidney-shaped, filiform, crowded about the top of the tube. Pd. German superior, ovate; style thread-shaped, furrowed, swelling at the top, rather longer than the filaments; stigma large, capitate. Somewhat petalate. Perc. Drupa nearly globose, dry and fibrous, abrupt and crowned with the base of the style, of two or three cells. Seeds foliary, angular at one side, convex at the other.

Calyx cylindrical, one-third the length of the flamines.—

Gathered by Aublet, on the banks of free-water rivers in Guiana, bearing flowers and fruit in May. That botanist describes it as a forub, only eight or ten feet high; its trunk three or four inches, at molt, in diameter; wood white and soft; the bark grey and cracked, filamentous, and capable of serving for cordage. This last circumstance perhaps induced Julieu the more readily to range the genus under Malvaceae. The branches are long, flexible, straight, and subdivided. Leaves alternate, smooth, green, phalie, elliptic-oblong, pointed, entire; the largest nine inches long, and three broad. Footstalks short and thick, with a pair of filipulas, that soon fall off. Flowers axillary; their stalks sometimes inserted into that of the leaf, two, three, four, or five together forming, or intermixed in any long, cylindrical, without any lid (as far as we can perceive), an inch and half long, opening with three, four, or five teeth, or sometimes splitting down at one side. Petals white, wavy, recurved, above twice the length of the calyx. Tube of the flamine thrice as long as the calyx, curved, white, slender; anthers about nine, yellow, accompanied by four or five green glandular bodies, many more of which are divided a little way down the tube. Stigma prominent, divided. Fruit dry, green, coriaceous, an inch and half long, with two seeds. The parts are all somewhat diminished in Aublet's plate. He says nothing of the seent, which Swartz describes, and we perceive, in this as well as the former. The want of a lid to the calyx, if constant, is a remarkable difference between this species and the other.

MYROPOLIS, in Ancient Geography, a town of Greece, near the drains of Thermopylos, over against Heraclea.

Gen. Ch. Cal. Perianthus superior, of three equal, oblong, channelled, entire, membranous leaves. Cor. of one petal: tube very short; outer limb in three deep, equal, oblong, spreading, entire, three segments, each with a dark spot at the top; inner in five deep unequal segments, the two uppermost short, oblong, unequally margined, the three lowermost longer, three-creep at the summit, cut, the middle one shorter than the other two. Stam. Filament one, either quite unconnected, or attached to the edge of the central segment of the lower lip, awl-shaped, membranous at the base; another terminal, erect, ovate, compressed. Pif. Germin inferior, triangular, style thick, short, depressed, triangular, longitudinally split, partly hairy; stigma gaping, with a dilated lip. Peric. Capsule triangular, of three cells and three valves. Seeds several, angular.

1. M. canesraria. Linn. Suppl. 82; excluding the synonym. (Myrjma 120, nova; Linn. Pl. Surin. 5. Amaz. Acad. v. 8. 251.)—Gathered by Dalberg in Surinam. The root is creeping, with long hairy fibres, and infiltrated with very sheathing scales. It appears to be perennial. Stem herbaceous rather than shrubby, clothed in the upper part with fine deflexed hairs. Radical leaves several, ovate, acute, entire, three or four inches long, smooth, with one rib, and numerous, fine, oblique, transverse veins, as in the root of this natural order. Footstalks erect, broad, sheathing, flat, inrolled, three inches long, suddenly contracted at the top into a hairy knob, close to the leaf. At the summit of the stem, of whose height we are unable to judge, is a larger leaf, from within which several footstalks spring the flower-stalks, of the same length, bearing a small drooping leaflet, of eight or ten flowers, whose broad pale imbricated bracts resemble the catkin of the Hop. Each of these is about as long as its corresponding flower, and is accompanied by a smaller and narrower internal bracteum. The corolla seems to be white or yellowish.

This was one of the plants which made a part of the Scurry collection, preferred by Pittis, presented to Linneus by king Guatavus III. Nothing is recorded of the properties or uses of the Myrjnoa.

MYROSPERMUM, so named by Jacquin from μυρος, balsam, and οσμος, a scent, alluding to the balsamic exudation from the seed and seed-veil, which, in the species he described, is of a strong and disagreeable scent. See Myroxylox, in which this genus of Jacquin, and its name, are now sunk. —Schreber and Willdenow seem to have been led into this measure by the authority of Linnaeus, of whose work they properly considered themselves as but the editors, and still more perhaps by that of Mutis, the reputed author of the name Myroxylox. Yet as the name appellation had previously been given by Fortler, in his Genera, t. 63, to a different genus, the original name of Jacquin might as well have remained for this. So indeed have J. thieu and Lamarck actually decided the matter, and a confusion of synonyms, in this as well as too many other instances, needlessly encumber the science. In this dilemma we prefer following the Linnean writers, and shall retain, for Fortler's genus, Schreber's name of Myroxema; for that article hereafter.

Gen. Ch. Cal. Perianthus inferior, of one leaf, bell-shaped, with five flight shallow teeth. Cor. Petals five, unequal, irregular, with claws inserted into the receptacle; the upper one broad, inerely heart-shaped, reflexed; the rest lanceolate, narrow, straight, shortly spreading; claws narrow, linear, the length of the calyx, or longer. Stam. Filaments ten, thread-shaped, fiosmooth, the length of the calyx, erect; others erect, oblong, with a furrow at each side, a notch at the base, and a small terminal point. Pif. Germin inferior, filched, hanging far out of the flower, feiform-shaped, compressed, tapering at the base; style awl-shaped, short, aeding; stigma simple, obtuse. Peric. Legume two-edged, oblong, compressed, tapering at the base, dilated towards the top, of one cell, not burling. Seed almost always solitary, roundish-oblong, compressed, situated near the end of the legume.

Eff. Ch. Calyx bell-shaped. Petals five; the upper one larger. Germin flaked, longer than the corolla. Legume with a single seed near the top.

1. M. persicifolium. Balfam-tree of Peru. Linn. Suppl. 233. Willd. n. 1. (Hoitzolxi; Herand. Mex. 51. Cabreusa. the second species; Pif. Brau. 57. 119, the figure in the latter place erroneous.)—Leaflets pointed, emarginate. Claw of the larger petal twice the length of the calyx. — Native of the warmest parts of Mexico and Peru, in mountainous situations. Hernandez says the Mexican kings culti

3 P 2

vated
vated in their gardens; and that if the trunk or bark be wounded, at any time of the year, but especially at the end of the rainy season, the celebrated and valuable balsam of Peru diffils from the wound. "This is of a dark or blackish orange colour, of an acrid and somewhat bitter taste, with a most powerful but highly agreeable smell."

Linnæus was always, as his son records, peculiarly anxious to ascertain the plant which yields this precious balsam; but he never had the satisfaction of knowing it. After his death, Mutis sent specimens of the leaf, flowers and fruit to the younger Linnaeus, which are now before us, and from which the description in the *Supplementum* was made. The tree is said by Hernandez to be the size of a lemon-tree. The *leaf* in our specimens is not complete, wanting the lower part. What remains consists of five leaves, each on a short, round, downy stalk, and is disposed on a partially downy common stalk, as to shew they are naturally alternate, only occasionally and imperfectly opposite, one of them being terminal. It is however not to be wondered at, that the younger Linnaeus, judging by this specimen alone, took the leaf to be abruptly pinnate, and hence an important disagreement appears between this species and the two following in the descriptions of authors; which however proves to be unfounded, for they all have alternately pinnate leaves, with a terminal leaflet. The *leaflets* in the present species are near an inch and half long, ovate-oblong, with a broad, elongated, obtuse and emarginate point; their margin entire, though somewhat crumpled or wavy; both sides smooth and rather shining, bright green, with one rib, and many fine reticulated veins. When held against the light, they appear full of singularly elegant pellucid spots, most of them small and roundish, but some linear, larger than the rest. *Flowers* numerous, in a long, downy, simple cluster, on slender feathered flasks, scarcely an inch long, with a minute circular *base* at the base of each. We know not on what authority Linnaeus describes the *flafters* as axillary. The *calyx* is hoary with fine soft down. *Petals* and *flaminis* whitish. *Germin* smooth, green, hanging out of the flower in a remarkable manner. *Legume* a foot long, and about an inch broad, thick-edged, with a short oblique point. Mutis says in his letter, that the fructification of this plant is nearly the same as that which yields the Balsam of Tolu. Of this we have never seen either a specimen or figure; nor do we know on what their generic distinction is properly founded. See *Toluiperia*.

2. *M. pedicellatum*. Long-flaked Balsam-tree. Willd. n. 2. (Myropermum pedicellatum; Lamarck Dict. v. 4. 191. Illusr. t. 341. f. 1.)—Leaflets elliptical, abrupt, emarginate. Claw of the larger petal the length of the calyx; flalk of the legume longer.—Gathered by Joseph de Julieu in Peru. Lamarck's figure and description were made from the drawing and specimens he brought from thence, nor have we any other materials than what Lamarck's works afford; but these abundantly suffice to distinguish the species.

This is a large tree, called in its native country Quina guina, like the Peruvian bark or Cinchona, and vulgarly *Sarminos*. The *trunk* is said to be two feet thick, with an ash-coloured bark; the wood very hard, used for building, as well as for contructing sugar-mills; whitish, with a red or blackish heart. *Leaves* alternate, of from seven to fifteen alternate flaked leaves, with an odd one, all of equal size, elliptical, oblong, emarginate, entire, near an inch and a half long, full of pellucid dots or lines. *Inflorescence* much like the former. *Flowers* similar, except that the claw of the larger petal is not represented longer than the calyx. The *legume* however appears to be of a much shorter proportion than in *M. frutescens*, and abrupt, not tapering, at the base; its flalk is slender, longer than the *calyx*, whose rim only seems to be deciduous. *Seed* solitary, oblong, curved. Nothing is said respecting any balsamic quality or exudation in this species. The specific name is not very good, but we scarcely know how to find a better, unless we had more information from some former who had compared this with the other related species. If it be really not balsamic, *inodorum* would be a suitable appellation.

3. *M. frutescens*. Factid Balsam-tree. Willd. n. 3. (Myropermum frutescens; Jacq. Amer. 122. t. 172. f. 24. Lamarck Illusr. t. 341. f. 2. Dict. v. 4. 191, excluding some of the synonyms.)—Leaflets elliptical, abrupt, emarginate. Stalk of the legume shorter than the calyx.—Gathered by Jacquin, in dry bushy places, at the foot of a mountain near Carthagena, South America. Stem thrubby, eight or ten feet high, not much branched. *Leaves* deciduous, alternately pinnate, with an odd leaflet, the leaflets all uniform, elliptical, strongly emarginate, smooth, about the size and shape of the leaf. *Claspers* lax, nearly terminal, erect. *Flowers* pale rolo-coloured. *Legume* about three inches long, as in the last, with scarcely ever more than one *seed*, which, like the legume itself, discharges a balsam of a strong and factid odour. The fruit remains long on the tree, after the leaves are fallen.—Lamarck improperly confounds this species with the first, though he rightly judged that there must be a terminal *leaflet* in both. He errs moreover, and Willdenow follows him, in saying the *legume* is factid. Jacquin expressly describes the germin as italked, though by his figure it is evident that the flalk, in the ripe fruit, does not extend beyond the *calyx*. See *Ceylon*.

**MYRHH, MYRNA, from gr., ἕρμη, *myr, I run or trickle* a kind of gum resin, flowing by incision, and sometimes spontaneously, from the trunk and larger branches of a tree growing in Arabia, Egypt, and especially in Abyssinia.

Authors are not agreed about the tree which produces this gum; it is true they all make it small and thorny; but they disagree about the form of its leaves. In several respects it resembles the *occisa vera*, which is the *Mimosa Nilotica*; and this agrees with the description of the tree given by Dioscorides. The trees producing *myrhh* grow on the eastern coast of Arabia Felix, and in that part of Abyssinia which is situated near the Red sea, and called by Mr. Bruce Troglydote. It is imported to us in chaff, each of which contains from one to two hundred weight. The Abyssinian *myrhh* comes to us through the East Indies, and that produced in Arabia is brought by the way of Turkey.

The druggists have been accustomed to fell two kinds of myrhh, viz.: *myrhh in tears*, which they call *flats*; the other *ungulate*, or in nails.

Of the first kind, the bell is bright, yellow, and in transparent drops, fragile, light, of a strong dirty, reekable smell; but this is very rare, and most of that in use is the *ungulate* myrhh, so called from little white spots observed therein, much like those on the nails of the fingers.

The bell is in little masses, or tears, reddish and transparent; the small pieces of myrhh, when broken, are sometimes found to contain a kind of alcoholic liquor, the most precious part of the myrhh, and the real *flats* of the ancients.

But though Pliny and Dioscorides speak of *flats* as if it was fresh or liquid myrhh, it is said by Mr. Bruce, that they could never see myrhh in that state; because it is said by the natives to harden on the tree instantly as soon as it is exposed to the air; and, therefore, the *flats*, he supposes, must have been a composition of myrhh and some other ingredient. The quality of myrhh depends on the age and health.
health of the tree, the manner of making the incision in it, the time of gathering the myrrh, and the circumstances of the climate in which it was gathered.

In order to have myrrh, and still or molot perfect fort, the savages choose a young vigorous tree, whose bark is without moss, or any parasite plant; and, above the first large branches, they give the tree a deep wound with an axe. The myrrh, which flows the first year, through this wound, is myrrh of the first growth, and never in very great quantity. This operation is performed some time after the rains have ceased, or from April to June; and the myrrh is produced in July and August. The sap, once accustomed to issue through this gash, continues to do so spontaneously, at the return of every season; but on account of the tropical rains, which lodge water and dirt in the gash, the tree has begun to rot, and become foul in the wounded part, and the myrrh issuing in the second year is of a second quality; and sells at Cairo about a third cheaper than the first. The myrrh, also, produced from the gashes near the roots, and in the trunks of old trees, is of the second growth and quality, and sometimes worse. This is, however, the good myrrh of the Italian shops, every where but in Venice; it is of a very dark brown colour, solid and heavy, losing little of its weight by being long kept; and it is not easily distinguished from that of Arabia Felix. The third and worst kind is gathered from old wounds or gashes, formerly made in old trees; or myrrh that, passing unnoticed, has hung upon the tree ungathered for a whole year; black, and earth-like in colour, and heavy, with little smell and bitterness; and is apparently the caulis of the ancients. Mr. Bruce farther observes, that the preservatives of myrrh is owing to the faviours using goat-skins, anointed with butter, for suppling them, in which they put their myrrh when gathered; in which skins remain, and is brought to market; so that this is a mark that myrrh is freely gathered, which is the best quality that myrrh of the first sort can have. Mr. Bruce further says, that Saffa gum is fraudulently mixed with the myrrh. Phil. Trans. vol. lxxx. pt. ii. art. 40. p. 408.

Myrrh has somewhat of a fragrant odour, and bitter aromatic taste. Those pieces of an irregular shape, called tears, are a concretion, of a reddish-yellow colour, brittle, breaking with a resounding fracture, and easily pulverized. It does not melt when bruised, and is not very inflammable. Its specific gravity is 1.560. Such are the characteristic properties of good myrrh: but it is often adulterated, and is then opaque, and either white, or of a dark colour approaching to black, with a disagreeable odour. Myrrh is partially soluble in water, alcohol, and ether. In boiling water it almost totally dissolves, but as the liquor cools a portion of refrinant matter subsides.

By evaporating the aqueous infusion, an extract is obtained; and by distillation, with a boiling heat, the whole of its aromatic spirits, partly impregnating the distilled water, and partly collected and concentrated in the form of an essential oil; which is in small extremely fragrant, in taste remarkably mild, and so ponderous as to sink in the aqueous fluid; whereas the oils of molot, perhaps of all, of the other gummys refin swim. Triturated with soft or distilled water, almost the whole will be dissolved, and form an opake yellowish solution: the greatest part, however, will be decomposed by heat, and more than one-third of the gum-refin will be dissolved. The alcoholic tincture is rendered milky and opaque, when mixed with water, but no precipitate appears.

If some powdered myrrh be inocled in the white of a hard boiled egg, and set in a monot cellar, the liquor, into which the egg will be gradually resolved, will extract nearly all the smell and taste of the myrrh. This liquor, which is commonly called oil of myrrh, is deliquium, may be precipitated and congealed by spirit of wine; and this coagulum is soluble by water. Rectified spirit dissolves less of this concrete than water, but extracts myrrh more perfectly than that in which its bitternerss, flavour, and virtues reside.

Ether digested in powdered myrrh dissolves three parts in eight; and the tincture evaporated in water deposited 24 grains of very bitter resin, and half a grain of extractive matter, which also tailed bitter. The part insoluble in ether was almost wholly soluble in water, and afforded a solution resembling that of acacia gum; but different from it inasmuch as it was precipitated by solutions of muriate of mercury, and of superacetic acid of lead. Hence it has been concluded, that myrrh contains of resin, essential oil, extractive matter, and mucus rather than gum.

This bitter, aromatic, gummy resin, enters a great number of medicinal compositions; it is a warm corroboration, deodorant, and antiseptic: it is given from a few grains to a scruple and upwards, in uterine obstructions, cachexies, putrid fevers, &c. and often employed also as an external antiseptic and vulnerary. It has been successfully employed in phthisis, as a disciplinary effect in pulmonary consumption, and in treating the symptoms of hectic fever. It does not run in the skin, and though allied to some of the balsams, it is found to be more efficacious and less irritating to the system. As a tonic, in cases of debility, as anorexia, chlorosis, and convulsions, myrrh is advantageously combined with aloe, cinchona, or other bitters and chalybeates; and in phthisis with nitre, digitalis, opium, camphor, and the sulphate of iron or zinc. Combined with oxyz of zinc it has been found extremely useful in the peculiar cough which sometimes accompanies pregnancy, when it continues after abortion.

As an expectorant, myrrh is often employed in humoral affections and chronic catarrh, and it has been given with the same view in phthisical affections. As a local stimulant the alcoholic solution of myrrh diffused in water is used as a lotion in a spungy state of the gums, and for correcting the febrile discharge of vesicated ulcers, especially when connected with caries of the bone, and as a gargoyle in cancharce maligna.

Its bitterents renders it good for the stomach, and against worms, and it is chewed to prevent infection from contagious diseases. Dr. Quincy says, it is useful to cleanse and strengthen the womb, and against tickling rheuma, as a good detergent; and, as much used externally in unguents for the healing of wounds: it makes the principal ingredient in embalming.

It is an apothegm of chemists, derived from Van Helmont, that whatever can make myrrh soluble by the human body, has the secret of prolonging his days. And Boerhaave owns there seems to be truth in this from its refining putrefaction. He himself, and other chemists before him, have given methods for making solutions of myrrh, but only by means of alcohol. It seems not a little surprising that such great chemists should never find out that myrrh is soluble in common water.

Myrrh is administered in substances, or in the form of watery infusion, or tincture properly diluted. A watery extract is ordered in some foreign pharmacopoeias, and preferred by many physicians, under a notion that it is less irritating than the gum-refin; but others conceive that, whilst it is agreeably bitter, it does not differ from a diminished dose of the myrrh.

The official preparations are as follow: viz. compound mixture of iron; for which see Mixture:—Alotice pills.
pills with myrrh, called "pilulæ Ruff," pills of iron and myrrh, compound galbanum pills, compound saffodita pills, and compound rubarb pills; for each of which, see PILLS:—Tincture of myrrh, compound tincture of aloë, and etheeral tincture of aloë: for which, see TINCTURE.

MYRRHEN, in Ancient Geography, a town of Aisa, in Mesopotamia, situated on the eastern bank of the Euphrates.

MYRRHIN, in Antiquity. See Murrine.

MYRRHIS, in Botany, μῦρις; of Dioeceres, or at least very near it, a genus of umbelliferous plants, retained by Bauhin, and several of the modern systematic writers; but funk by Linnaeus, for the most part, as well as by Jussieu, in Scandix and Charophyllum.—Tourn. Ill. t. 166. Lamarck Fl. Franc. t. 3. Hall. Hill. t. 329. Michaux Borel-Am. pl. 1. 170. Gartn. t. 22. Clafs and order, Pentandria Digynia. Nat. Ord. Umbellate.

'Tournefort distinguishes Myrrbis from Charophyllum by the furrows of its fruit, which are wanting in the latter genus. Lamarck on the contrary makes a hairy fruit, without φρια, the character of Myrrhis. Haller agrees with Tournefort. Gartn. defines the essential characters thus.

Umbel compound. General involucrum none. Fruit oblong, somewhat beaked. Kernel as long as the seed.

Michaux copies this word for word. It is evident therefore that the ideas of all the above authors do not comprehend one and the same genus. The most natural conception of the genus seems to us that of Gartn. which depends on the want of a real beak to the seed. But when we consider how various this appendage is in the different species of Scandix, and that there is an external appearance of it, as acknowledged by Gartn.'s definition, even in his Myrrbis, we cannot but be content to adopt the latter, though we allow the quinelle to be one of the most difficult in this difficult order. The species which Gartn. enumerates and figures are four.

4. M. canadensis; Rv. Pent. Irr. t. 54. (Sifon canadensis; Linn. Sp. Pl. 365.)

To these Michaux adds:

5. M. Claytonii; Mich. Borel Amer. v. 1. 170.—"Footstalk deeply three-cleft; partial ones with three to five oblong-oval, lobed and somewhat pinnatifid leaflets. Umbel of few rays, spreading. Fruit elongated, round, smooth."—Native of the Alleghany mountains. Stem nearly two feet high, erect. Leaves downy, but not hoary. Flowers—flats terminal, in pears. General as well as partial umbels divaricated and lax when in fruit; their rays very few, from three to five, very long. Fruit about two to each partial umbel" Michaux.—We believe this is a plant sent by Kalm to Linnaeus, and confounded by the latter, in his herbarium, with Charophyllum temulentum. We have always thought it a new species of Scandix.

MYRRHITES LAPIS, in Natural History, a name used by many of the ancient authors for a semi-pellucid stone of the nature of the agate, and seeming to have been the yellow cornelian of the moderns.

Gen. Ch. Cal. Paranth inferior, small, in five deep, nearly ovate, segments, permanent. Cor. of one petal, divided half way down into five, rarely but four, equal, semi-ovate, obtuse, approximating segments. Stam. Filaments five, very short, inserted into the middle of the corolla, opposite to each segment; anthers exert, awl-shaped, emarginate at the base, of two cells opening lengthwise. Pyt. Germen superior, nearly globose, almost filling the corolla; style cylindrical, protruding a little beyond the corolla; stigma prominent, large, lobed or jagged. Peric. Berry roundish, depressed, of one cell, with a brittle coat, with the rudiments of four or five seeds, attached to a globular central receptacle, all of them but one abortive. Seed solitary, nearly globose, "affixed obliquely to the bottom of the berry, taking place of the original central receptacle, which in the ripe fruit dissolves into a soft pulp." Gartn.

1. M. africana. African Myrrine. Linn. Sp. Pl. 285. (Vitis Idea aethiopica, myrti tarentine folio, flore atropurpureo; Comm. Hort. v. 1. 123. t. 64)—Leaves elliptical, distantly toothed, acute. Native of the Cape of Good Hope, from whence it was one of the first plants introduced into the gardens of Europe. It is a hardly greenhouse shrub, flowering in the spring very plentifully. The stem is bushy, three or four feet high, alternately branched, clothed more or less with short, rusty, prominent, rigid pubescence. Leaves numerous, alternate, flat, placed, rather above half an inch long, elliptical, acute at both ends, somewhat revolute, with a few slender filamentous teeth, or teeth, smooth; their upper surface of a dark shining green; the under much paler, opaque, with a prominent simple mid-rib. Stipulae none. Flowers small, few, together, in fertile axillary umbels, somewhat drooping. Bracteas small, concave, reddish, smooth, at the base of each flower, which is red and smooth, angular, scarcely so long as the flower it bears, and both together hardly equal a quarter of an inch. The calyx and corolla are red or purplish, besprinkled with glandular dots. Berry the size of a pea, pale at first, then of an elegant purple, crowned with the style.

2. M. reticulata. Round-leaved Myrrine, or Tamaja. Ait. Hort. Kew. ed. 1. v. 1. 271. Vent. Hort. Cels. t. 86. (M. scabra; Gartn. v. 1. 282)—Leaves roundish-obovate, obtuse, ferrated, with several notches of the extreme. Brought by Mr. Maskin from the Azores, in 1778. It requires the same treatment as the former, flowering in June. Mr. Brown hints that these two species are scarcely distinct. The present differs chiefly in having rounder leaves, ending, not in a point, but in a toothed notch. The flowers are like those of M. africana. The stigma in both is remarkably large, and copiously lobed and fringed.

3. M. variabilis. Variable-leaved Myrrine. Brown n. 1. Leaves obovate-oblong, entire or toothed. Umbels axillary, sessile. Anthers sessile. Flowers occasionally four-cleft. Gathered by the late Mr. David Burton, as well as by Mr. Brown near Port Jackson, New South Wales. A larger shrub than the foregoing species. Leaves near three inches long, bluish, with various shallow teeth in their upper
upper part; the base tapering and entire; both sides are smooth, and of a light green, reticulated with numerous veins. Footstalks thick, smooth, angular, about three quarters of an inch long. Umbels of about eight or ten flowers; their flanks angular, one-third of an inch in length, rufly in our specimens, like the *caryx* and *corolla*. The latter is very deeply divided. The young shoots and leaf-buds are clothed with rufly down.

4. *M. crisifolia*. Thick-leaved Myrsine. *Brown* n. 2. "Flowers axillary, aggregate, nearly sessile. Leaves obovate, nearly entire." —Gathered by Mr. Brown in the tropical part of New Holland. The leaves are two or three inches and a half long. The almost sessile flowers form a distinguishing character.

5. *M. arcuata*. Cup-flowered Myrsine. *Brown* n. 3 — Leaves lanceolate-oblong, entire. Umbels axillary, sessile; stalks smooth. Flowers four-cleft, Corolla of the male pitcher-shaped, longer than the flaments. —Gathered by Mr. Joseph Banks in the tropical part of New Holland. Mr. Brown observes that it nearly agrees in character with *Waltheria laurifolia*, Swartz Ind. Occ. v. 1, 248, but the inflorescence of the latter is a terminal panicle.

6. *M. Mangifera*. Laurel-leaved Myrsine. (Bumelia Mangifera; Wild. Sp. Pl. v. 1, 1167. Mangifera; Juss. 151. Caballera; Pl. Perv.).—Leaves elliptical, obtuse, entire. Umbels axillary, sessile; stalks smooth. Anther sessile.—Found by Dombey in great plenty about Lima in Peru, growing near rivulets and flowering in May. It has the aspect of the Cherry Laurel, and rises to the height of 12 feet. Leaves three or four inches long, on short thick stalks, exactly elliptical, quite entire, evergreen, smooth. Flowers about six in each umbel, five-cleft, smooth; in all their parts. This shrub is taken at Lima for the Paraguay tea, which it leaves resembles, but the seeds are very different. Dombey named it *Dumbellia*, misconceived probably that Hughes was already confequently to the memory of the great French physiologist of vegetables.

Mr. Brown mentions several other species or genera of different authors, as really belonging to *Myrsine*; *Achrolephyllum* of Loureiro; *Sideroxylon Melanophloios*. Linn. Mant. 48, which is *Romeria* of Thunberg's "Nova Genera; *Samara cordesia* of Swartz; *S. pentandra*, Ait. Hort. Kew. ed. 1. v. 1, 160; *S. floribunda*. Wild. Sp. Pl. v. 1, 665, which is *Rupana* of Aublet, t. 146; Badula Juss. 429, excluding the syonym of Bumann; as well as several supposed *Ardisia*, whose flaments are divided, and their germs with four or five seeds.—*Ardisia* itself is very near *Myrsine*, differing in having all perfect or united flowers, a simple flagment, a germe with an inordinate number of seeds, above five, and approximated anthers. *Pyrgus* of Loureiro is said by Mr. Brown, on the authority of an original specimen, to be an *Ardisia*.

*Myrsine*, in Gardening, comprehends a plant of the evergreen exotic shrubby kind, of which the species cultivated is the African myrsine (M. africana) Method of Culture. This plant may be increased by fowing the seeds in spring on a hot-bed, and when the plants are fit to transplant, planting them out singly into small pots of good mould, due shade and water being given, and in the autumn they may be removed into the greenhouse for protection during the winter season.

They may also be raised by planting cuttings of the young shoots in pots in summer, due shade and water being given. They afterwards require the management of other greenhouse plants.

They afford variety among collections of plants of the greenhouse kind.

*Myrsine*, in Botany, a natural order of plants, called from the principal genus which enters into it; see the preceding article. Ventenat, who founded this order, in his *Jardin de Cetis*, p. 86, named it *Opisthiaserae*: from the long, oblique, and undulating form of the embryo, fimeaw calls it a snake, or rather like the eels, which microscopic writers describe as found in vinegar. This idea seems to have been fogellled by Garten's name and plate of *his Angustaria*, one of the order in question; but Mr. Brown proceeds the above appealion, not only because it is convertible to the practice of Julienne, but also because in many of these plants, the embryo is straight.

The characters of the *Myrsine* are thus given, in Brown's *Predr. Nov. Holl*. v. 1, 532.

*Flowers* either united or polygamous.

*Calyx* in five, sometimes four, divisions, permanent.

*Corolla* of one petal, inferior, in five, sometimes four, equal segments.

*Stamen* five or four, opposite to the segments of the corolla, and inserted in their base. Filaments distinct, rarely combined, sometimes wanting; in some inflorescences accompanied by five intermediate barren ones, resembling petals. Anthers attached to the filaments by their emarginate bases, each of two cells, which burst longitudinally.

*Germe* solitary, or one cell, with the rudiments of several seeds, which are either determinate or indeterminate in number, peltate, and inserted into the cells of a central unconnected receptacle. Style one, often very short. *Stigma* either lobed or uniovulate.

*Drupa* or *Berry* mostly with one seed, sometimes with from two to four.

*Seeds* peltate, with a hollow scar, and a simple integument. *Albumen* horny, of the shape of the seed. *Embryo* transverse with respect to the scar, nearly cylindrical, mostly curved. *Cotyledons* short.

*Radicle* (when several seeds come to maturity) inferior. *Plumula* incoepusious.

These plants are either *trees* or *shrubs*, with alternate, undivided, coriaceous, smooth leaves, either serrated or nearly entire; sometimes they are very humber *shrubs*, with opposite or alternate leaves. *Inflorescence* umbellate, *corymboid*, or panicled, axillary, rarely terminal. *Flowers* small, white, for the most part marked with fink glandular dots or lines.

Mr. Brown observes that "Ventenat could hardly understand the true structure of the fruit, as he was ignorant of the plurality of germs at an early stage, as well as of their maturitie; for the embryo, which, with respect to the scar, is always transverse, because the seed is peltate, with respect to the fruit, becomes transverse only in those cafes where a single germ comes to perfection; for where the fruit perfects many seeds, as in *Jacquinia* (which belongs to this order) the embryo is erect. Hence, through the medium of that genus, there appears a great affinity in the order of *Myrsine* to the *Supana*; and thence to the *Primus* as far as this genus is concerned, and the similar glandular lines of that part, as well as on account of the flaments of that genus being opposite to the segments of its corolla."*"}

The same intelligent author adds, that "in a certain tribe of trees, growing about the shores, chiefly of tropical climates, and formerly all erroneously huddled together under the name of *Rhizophora*, because the embryo germinates before the seed falls, the respective affinities are by no means to be made out by an examination of the ripe fruit, but, as far as those affinities depend upon the fruit, by that of the internal structure of the germe. From a neglect of this, *Julfien*
Jullieu has been led into the error of referring Rhizephora and Bruguiera to his order of Loranthceae."

Examples of the order before us are Myrtina, Ardisia, Bladidia, Wallania, Agectaras of Gartnert, and of Kong in Annals of Botany, v. i. 131, (Rhizephora corniculata of Linnaeus.) Jacquinia, &c.

The Jacquinia edulis, Swartz Prodr. 47, is not only very distinct from the several original species as to genus, but even in natural order, being one of the Rubiaceae.

Venetanet, besides what he has given us, respecting this subject, in the Jardin de Cels above quoted, has made many excellent remarks upon it under the Ardisia crenulata. 28th. 6. of the elegant work entitled Chois de Plans, which he left unfinished at his death, in five Nos. of six plates each.

—Some genera, which he first indicated as belonging to this order, are by Mr. Brown not only retained here, but actually sunk in the genus to which it owes its name. See MYRTINE.

MYRTHE, in Geography, a town of Hindostan, taken and destroyed by Timur-Beg in the year 1399. The men were slain alive, and the women and children carried for slaves; 120 miles E. of Delhi.

MYRT, in Botany, an elegant natural order of plants, named from the most familiar genus among them; see MYRTUS. This is the 89th in Jullieu's system, or the 7th of his 14th classes. For the characters of that class see LEASTOME and FICODINE.

Characters of the Myrti.

Calyx of one leaf, cup-shaped or tubular, superior, rarely half superior, either naked, or furnished with two scales, at the base. Petals definite, inserted into the top of the calyx, equal in number to its segments, and alternate with them. Stamens indefinite, inserted into the same part, below the petals; anthers small, roundish, curved, bordering the summit of the dilated filaments. Germ simple, inferior, rarely half inferior; style simple, or rarely divided. Fruit pulpy, either a berry or drupes, in some few instances capsular, inferior, or rarely half inferior, of one cell or many, each cell containing one or numerous seeds. Corolla either straight or curved, defusitate of albumen. Stem arborescent or shrubby, its branches usually opposite. Leaves mostly opposite and simple, rarely alternate, in very many instances dotted.

Section 1. Flowers either axillary, or oppositely disposed on many-flowered stalks. Leaves mostly opposite and dotted. Alangium of Lamarck, Wild. Sp. Pl. v. 2. 1774.

Dodecas, Melaleuca, Leptospermum, Guajarium of Jullieu, Pfudum, Myrtus, Eugenia, Caryophyllus, Dacmaria, Puniaca, Philodendr, Sonneratia, Pitha, Cainga.

To these are to be added Bacca of Linnaeus, mistakenly referred by Jullieu to his Onagra; Eucalyptus of L. Heritier; and Galphimias of Swartz, though each of these three genera forms an exception to some part of the above characters, the first in its flowers, which are definite in number (eight); the second in their corollas, which do not confide of distinct or definite petals; that of Eucalyptus being a corolla, mostly conical, lid or cover; that of Calphimias a more membranous and flatish lid. These two genera differ widely from each other in their fruit, Galphimias resembling Myrtus in that respect, Eucalyptus nearly approaching Meliaceae, another new genus, which is likewise to be added to the present section, and has all the proper characters of the order. The sequel of Mr. Brown's Prodromus will perhaps still augment the above catalogue, New Holland being rich in Myrti, many new species of which may be found described in Tract. of the Linne. Soc. v. 3. 255, and among them two more genera in addition to the above: these are Farrancia and Imbricaria; to which we refer the reader in their proper places; as well as to Eucalyptus and Meliosperma. — Imbricaria, it must be observed, has definite filaments, they being equal in number to its petals. Hence appears the necessity of new modelling the above characters of the order, in what regards the filaments and corollas.

Section 2. Flowers racemose, alternate. Leaves mostly alternate, and not dotted. Butonica, which is Barringonia of Forster and the younger Linnaeus; Stirradium & Jullieu, a genus formed of the Linnaean Eugenia racemosa and acuminata, &c.; Pirigera of Aublet, see Gustavia; Couroupita of Aublet; and Leptomyrt of all authors.

MY RTIDANON, a word used by the old Greek writers on medicine, but in a different sense by different authors. Hippocrates calls it a round fruit, which the Persians in his time called pepper, and which probably had the heating qualities of that fruit. Dioscorides expresses it by an excrecence common on the trunk of the myrtle, and which, as he observes, is more dirigator than the myrtle itself. Myrtidiana vinum also signifies wine impregnated with myrtle.

MYRTIFORM GLANDS, in Anatomy. See GLANDS.

MYRTIFORMES CARUNCULAE. See CARUNCULE.

MYRTIFORMIS NASI, a name given by Sartorius, and some others, to one of the muscles of the face, called by Albinus depressor alae nae, and by Cowper and others, depressor labii superioris, contractor alae.

MYRTILUS, in Ancient Geography, Mertolus, a town of Spain, in Lusitania, situated on the right of the Anus, S.E. of Pax Julia; called also "Julia Myrtillus."

MYRTILLUS, in Botany, a name applied to the Whortleberry, Vaccinium, on account of the resemblance of its round blue-purple berries to those of the Myrtle. It is still retained as the specific appellation of our Bilberry, Vaccinium Myrtillus, to whose fruit the above comparison is most applicable.

MYRTIS, in Ancient History and Biography, a Greek lady of distinguished abilities in poetry, of whom Pindar had his first instructions in his art. It was during this period that Pindar became acquainted with the poets of Corinna, who was likewise a student under Myrtis. Plutarch tells us, that he profited from the lessons, which Corinna, more advanced in her studies, gave him at this school. It is very natural to suppose, that the first poetical effusions of a genius so full of fire and imagination as that of Pindar, would be wild and luxuriant; and Lucian has preserved the verses, said to have been the exordium of his first lay, in which he crowned almost all the subjects for song, which ancient history and mythology then furnished. Upon communicating this attempt to Corinna, the told him smiling, that he should bow with the hand, and not empty his whole face at once. Pindar, however, soon quitted the leading-rivets of these ladies, his poetical muses, and became the deipoly of Simonides, now arrived at extreme old age; after which he soon surpassed all his masters, and acquired great reputation throughout Greece; but, like a true prophet, was less honoured in his own country, than elsewhere; for at Thebes he was frequently pronounced to be vanquished, in the musical and poetical contests, by candidates of inferior merit.

MYRTITES, the name of a composition in the ancient pharmacy made of fine honey, and the depurated juice of myrtle-berries boiled up together to a consistence.

MYRTLIE, in Botany. See MYRTUS.

In Cornwall and Devonshire, where the winters are more favourable
favourable than in most other parts of England, there are large hedges of myrtle, which have been planted for several years, and are very thriving and vigorous; some of which are upwards of six feet high.

**Myrtle, Candleberry.** See **Myrtica.**

The common Dutch myrtle grows wild in watery places, and abounds in the isle of Ely; the leaves, flowers, and seeds of this plant have a strong fragrant smell, and a bitter taste. They are said to be used among the common people for destroying moths, and cutaneous infectis; internally, in infusions, as a homuncul and vermifuge; and as a substitute for hops, for preserving malt liquors, which they render more inebriating, and consequently less alimonial, which quality is said to be destroyed by boiling. Lewis.

**Myrtle-Berrics, **Myrtillus, the fruit of the myrtle, with which we are supplied from the southern parts of Europe. The fruit is at first green, but becomes black gradually; within it is a white seed, in form of a crescent, lollid, hard, and of an aromatic taste; while the fruit continues on the trees, it is succulent and smooth, and only becomes hard and wrinkled, because dried in the sun for the convenience of carriage.

Myrtle-berries are rough and aromatic, and are chiefly recommended in alvine and uterine fluxes, and other dis-orders from relaxation and debility; and appear to be among the milder refringent and corroborants, in the way of syrup, as a strengthener against fluxes and abortion. The perfumers likewise use them in their perfumes, and draw an essence from them. The German dyers make a blue colour from them. In some places the leaves and branches are also used in the tanning of leather.

A myrtle crown was worn by the general to whom an ovation was decreed, the reason of which, according to Plutarch, in his life of Marcellus, was, that as an ovation was decreed for some remarkable successe obtained by treaty, or without much bloodshed, it was proper, that the general, at his public appearance, should be crowned with the tree faetic to Venus, who, of all the deities, was supposed to be most averse to the horrors of war.

**Myrtle-Leaved Sumach, in Gardening,** the common name of a plant of the sumach kind. See **Coriaria.**

**Myrtle Island, in Geography,** one of the Chandelire islands, in Naflau bay, on the coast of Florida, on the W. side of the peninsula.

**Myrtocchelides, a name given by some authors to the nymphæ in the female pudenda.**

**Myrto-Cistus, in Gardening,** the common name of an ornamental plant. See **Hypericum.**

**Myrtos, in Ancient Geography,** an island of the Aegean sea, on the western side of the fouthlyer side of the island of Euboea. Phiny says, that it gave name to that part of the Aegean sea called "Myrtum Mare."**

**Myrtunium Mare,** a sea or lake of Greece, between the coast of Acrania, the coast of and the island of Leucada to the west, according to Strabo.

Gen. Ch. Cal. Perianth superior, of one leaf, in five bluish permanent segments; elevated internally into a slightly downy rim. *Gen. Petals five, large, ovate or roundish, entire, concave, inserted into the calyx shorter Filaments numerous, capillary, the length of the corolla, inserted into the rim of the calyx; anthers small, roundish. Pet. Germ, inferior, roundish, of two or three cells; style simple, thread-shaped; stigma obovata. Peric. Berry oval, crowned with the concave base of the calyx, of two or three cells. Seeds few, kidney-shaped.

Obv. In some influences the calyx is four-leaf, and petals but four.

Eff. Chi. Calyx five-leaf, superior. Petals five. Berry of two or three cells, with several seeds.

Of this elegant and celebrated genus, only one real species was known to the older botanists, of whose varieties, as they are now esteemed, Tournefort and the writers of his time made various species, which still make a figure in gardeners' catalogues, and indeed are, some of them, very different from each other in their foliage. In the first edition of his Species Plantarum, Linnaeus defines seven species of *Myrthus,* and in his second 1737. Of these several have been removed to other genera; and especially the last, *M. Glamastrom.* Sp. Pl. 676, was subsequently made a distinct genus by Linnaeus himself. (See **Melaleuca.) In the Mantissa, 74, is an additional *Myrthus,* named angulyifolius, for which see **Mesodihолос, species ninth.—Myrthus brasiliensis of Linnaeus, is the same as his Eugenia uniflora; his *M. Cominitinc, Chrytraulus, and Zygizum are now referred to Swartz's new genus of Callipteranthes; (see **Myrthus;** but the discoveries of the botanist Paet named, and of others, have so far augmented the original genus of *Myrthus,* that Willdenow enumerates 25 species. There is frequently some ambiguity between this species and Eugenia, (see that article) it not being easy at all times to discover, in dried specimens at leaf, their essential difference, which consists in the single flower of Eugenia. By this character *Myrthus Greggi* of Swartz, Willd. n. 20, perhaps belongs to that genus, though the germen has two cells. This is *Greggia aromatica, Gartn. t. 33.* Several of Swartz's *Myrthus* are defbreaker with foliary seeds, and, as we conceive, are on that account doubtful.

The following are genuine examples of *Myrthus.*

**M. communis.** Common Myrtle.—Flowers solitary, with a two-leaved involucrum. Leaves smooth.—Linn. Sp. Pl. 673. (M. latifolia romana; Mill. t. 184. f. 1.) This with several of its varieties may be found in Ger. em. 1411, 1412. The most remarkable is the small-leaved kind, equally common in collections with the other. The double-flowered is also not uncommon, but more tender and difficult to propagate than the rest. These plants grow wild throughout the south of Europe, north of Africa, and temperate parts of Asia, chiefly on the sea-coast. The Mediterranean is bordered with natural thickets of Myrtle, even within the spray of the sea, which poets have frequently sung; and all admirers of plants have noticed. Its situation perhaps, even more than its beauty, caused this shrub to be dedicated to Venus; and as the neighbourhood of the sea-shore was so often chosen for the éclat of her temples, thickets of myrtle are still the common accompaniment of their ruins. The height of the climbing *flora* in such situations is seldom above three feet. The leaves are evergreen, more or less ovate, entire, smooth, of a rich and polished green; darker in the small-leaved variety, which is preferred in Italy for clipped edges in gardens, and being to treated, rises to the height of 12 or 14 feet. The flowers grow on simple axillary stalks, and are white, with a frequent tinge of red externally. The *berries* are of little a small pea, violet, sweetish, with the aromatic flavour, which
which pervades the whole plant. They are eaten in the Levant, but a white variety is preferred to the purple.

M. tomentosa. Woolly-leaved Myrtle. Ait. Hort. Kew. ed. 1. v. 2. 159. Curt. Mag. t. 250. (Arbor fininis, canellae folio minore trinervi, &c.; Pluk. Amathl. 21. t. 372. f. 1.)—Stalks one or two-flowered. Leaves triple-ribbed, downy beneath.—Native of China, from whence Mrs. Norman, a lady long celebrated for her love of plants, and the value of her collection, is said to have obtained this beautiful species about the year 1776. It flowers in the summer, and may be treated as a greenhouse plant, but suc-ceeds best in a stove, where we have sometimes seen it four or five feet high, covered with a profusion of flowers. These are axillary, rofe-coloured, an inch and a half broad, with deep-crimson flavens and yellow anthers. The germenis, calyx, and flalis, are delicately hoary. Leaves elliptical, ob-tuse, soft and downy, of a hoary green.

M. diffusa. Globe-berried Myrtle. Swartz Ind. Occ. v. 2. 584. Sims in Curt. Mag. t. 867.—Stalks axillary, many-flowered, shorter than the leaves. Branches spreading. Leaves two-ranked, ovato-lanceolate, drooping.—Gathered by Dr. Swartz on the mountains of the north part of Jamaica. The negroes, he tells us, call it wild coffee, not only from the resemblance of the berry, but from a similar flavour in the recent feeds, to the real coffee. This is a shrub often fix feet high, with horizontal spreading branches. Leaves remarkably drooping, on short stalks, ovate, pointed, smooth, shining, dotted beneath, furnished with one rib, and many transverse veins. Flower-flals turned upwards, each bearing three or four small, pale bluish-coloured flowers. Berry the fize and colour of a black currant, of three or four cells, and of many seeds, though sometimes all but one prove abortive. This is with us a hardy flove plant, but of no great fpendour.

M. Pimenta, Pimento, Alippice, or Jamaica pepper. Linn. Sp. Pl. 676. Woodv. Med. Bot. t. 26. Sims in Curt. Mag. t. 1236. (M. arborea aromatica, folis glabris; Slosson Jam. v. 2. 76. t. 191. f. 1.)—Flowers in three-forked panicles. Leaves oblong-lanceolate.—Native of the Weft Indies. It succeeds well in our floves, if allowed a fuming heat, flowering copiously in May and June. The ftem is aromatic, and many opposite, often three together; it is not easy to account for Linneas’s having defined them as alternate. Flowers very abundant, but small, greenish-white, with a profusion of white anthers. The fruit, about the fize of pepper, is well known by the name of Alippice. The whole plant partakes of the fame aromatic pungent flavour, which refides in a fine effentiai oil.

Several new species of Myrtus have been found by the Spaniards in Chili and Peru. We are also poffeffed of various undetermined tropical species, whose genus however is uncertain, for want of a fufficient knowledge of the ftructure of their germen, and number of their feeds.

Myrtus, in Gardening, comprises plants of the evergreen shrubby kind for the greenhouse and ftove, of which the species cultivated are, the common myrtle (M. communis); the woolly-leaved myrtle (M. tomentosa); the two-flowered myrtle (M. biloba); the thinning myrtle (M. lucida); the dioecious American myrtle (M. dioica); the Ceylon myrtle (M. zeylanica); the fumach-leaved myrtle (M. coriacea); and the pimento, Jamaica pepper, or allipice (M. pimenta).

Of the fift fort there are several varieties, the principal of which are the common broad-leaved Roman myrtle, which grows to the height of eight or ten feet in this climate, but much higher in Italy, where it is the principal under-ground of the forest; the leaves are broader than most of the other varieties, being an inch in breadth; they are an inch and a half long, of a lucid green, ending in acute points, and are sub-feliee, or on very short footstalks; the flowers are larger than those of the other varieties; on pretty long slender peduncles, from two to four at the fame axil; the berries ovate, and of a dark purple colour. It is termed by some the flowering myrtle, because it flowers more freely here than the others, and Roman myrtle, because it abounds about Rome.

The box-leaved myrtle, which has the leaves oval, small, fellee, of a lucid green, and ending in obtuse points; the branches weak, and frequently hanging down, when per-mitted to grow without shortening; the bark is greyish; the flowers are small, and come late in the fummer; the berries small and round.

The common Italian myrtle, which has ovate-lanceolate leaves, ending in acute points; the branches grow more erect than in either of the preceding, as also the leaves, whence it is called the gardener’s upright myrtle. The flowers are not large; and the petals are marked with purple at their points, whilf they remain clofed; the berries are small, oval, and of a purpel colour.

There is a sub-variety of this with white berries; and the nutmeg myrtle seems, according to Miller, to be only a sub-variety of it.

The orange-leaved, or what is sometimes termed bay-leaved myrtle, which has a fronger flalk and branches, and rife to a greater height; the leaves are ovate-lanceolate, in clufiers round the branches, and of a dark green; the flowers are of a middling fize, and come out sparingly from between the leaves; the berries are oval, and smaller than thofe of the firft variety, but it is not f0 hardy as that.

The Portuga/ myrtle, which has the leaves much smaller than thofe of the next, being less than an inch long, and not more than half an inch broad, lanceolate-oveate, acute, of a dull green, not pretty clofe on the branches; the flowers are fmall; and the berries small and oval.

The broad-leaved Dutch myrtle, which has leaves much less than thofe of the common fort, and more pointed, standing clofe together on the branches; the midrib on the under fide of the leaves is of a purple colour; they are of a darker green, and fit clofer to the branches; the flowers are fsmaller, on fofter peduncles, and come out a little later than thofe of the common fort.

The double-flowering myrtle, which is probably a sub-variety of this; the leaves and growth of the plant, the fize of the flowers, and the time of the flowering, agreeing better with this than any of the others.

The rosemary-leaved, or thyme-leaved myrtle, which has the branches growing pretty erect; the leaves small, narrow, acute, fellee, and of a lucid green; the flowers are small, appearing late in the feafon.

These varieties are confant; but there are others which are propagated in gardens and nurseries for fale, which are les confiderable and more variable, as the gold tipped broad-leaved myrtle; the broad-leaved Jew’s myrtle, having frequently the leaves in threes; the gold-tipped orange-leaved myrtle; the silver-tipped Italian myrtle; the tipped box-leaved myrtle; the silver-tipped rosemary-leaved myrtle; the silver-tipped nutmeg myrtle; and the cock’s comb, or bird’s-nest myrtle.

The ninth species affords the berries which are fo much ufed in culinary operations. They are chiefly imported from Jamaica, whence the name Jamaica pepper; and they have also the name of allipice, from a notion of their taste being compounded of feveral other fpices.
MYRTUS.

The tree begins to bear fruit in three years after it is planted, but does not arrive at maturity until seven, then often yielding one thousand pounds weight of fruit from an acre.

According to Martyn, "the berries are generally gathered in July in their green state, by twisting off the twigs with the hand, or a pole left at one end; and are laid on cloth spread over the barbacues or terraced floors raised a little above the ground, inclosed with an upright ledge of eight or ten inches in height, and divided by transverse partitions into four or more square compartments, that each may contain a day's picking. During the first and second day they are turned often, that the whole may be more exposed to the sun; but when they begin to dry, they are frequently winnowed, and laid in cloths to preserve them better from rain and dews, still exposing them to the sun every day, and removing them under cover every evening, till they are sufficiently dried; which usually happens in ten or twelve days, and is known by the darkens of their complexion, and the rattling of the seeds; they appear at this time wrinkled, and changed to a very dark brown. In this state, being ready for the market, they are flowed in bags or casks.

Some planters also kiln-dry them with great success.

Method of Culture.—The first species, and all the different varieties, are capable of being increased by planting cuttings of the long young shoots of the same year, making them about six inches long, clearing about three inches of the bottom parts, then twisting them, and setting them into pots filled with light rich earth, closing it well about them, and watering them to settle it. The pots should then be plunged in the tan hot-bed, under glasses, carefully shading them from the sun. This should be done in the beginning of July, or in the early spring. It is likewise useful to cover them cloëc with small glusses.

They may also sometimes be stricken in pots in the natural earth, under a shallow frame, and glusses in the summer months, as well as in the open ground in a warm situation. And flies let out and treated in the same manner as the cuttings, often strike root, and produce good plants.

After the plants, raised in any of the modes, are well-rooted, and begin to shoot, they should be gradually inured to the open air, so as to be set out in it towards the latter end of August in a warm sheltered situation, being brought under the protection of the greenhouse in the beginning of autumn, and placed in the left warm parts of it, having free air admitted when the weather will permit. They should be gently watered during the winter, removing any decayed leaves that may appear upon them, and the mould of the pots kept quite clean. The plants also succeed perfectly when placed under a common frame in the winter season, air being frequently admitted in fine weather. And in the succeeding spring the plants should be removed carefully with balls of earth about their roots into separate small pots of rich light earth, watering them well at the time, and letting them under a frame, or in the greenhouse, till perfectly established, when they may be removed into the open air, being placed in a warm aspect.

Towards the beginning of autumn they should be examined, and such plants as have their roots proceeding through the holes in the bottoms of the pots should be removed into others a size larger, loofening the mould and matted roots, afterwards filling the pots up with fresh rich earth, and watering them well. They should then be placed in a sheltered situation, trimming them to a regular figure, and turning them upright, when they have a tendency to croak, by proper sticks. When thus carefully trained while in their young growth, the items will afterwards contain a straight without support.

These plants are also capable of being increas'd by layers. All such plants as are furnished with young bottom shoots low enough for laying, may have them laid in spring, in the usual way, when they readily emit roots, and become fit to be transplanted into separate pots in the autumnal season.

And when seed is made use of, it should be sown in spring in pots of light mould, and plunged into a moderate hot-bed: the plants soon come up, which, when two or three inches high, should be potted off separately into small pots, and be managed afterwards as the others.

It may be proper to observe, that as the plants advance in growth, some new varieties may, perhaps, be produced. Those who raise large quantities of these plants annually, should always keep some strong bushy plants, in order to furnish slips or cuttings for the purpose.

The double-flowering and orange-leaved myrtles are the most difficult to raise by cuttings; and the last sort, and those with variegated leaves, are more tender than the others.

The common broad-leaved, and broad-leaved Dutch, as well as the Portugal sorts, succeed in the open ground in warm situations and dry soils.

Where they are intended to have bushy heads, the lower shoots should be trimmed off, and the plants only suffered to branch out at the top in different directions, so as to form handsome heads. Those which are designed to be shrubby should have their lateral branches encouraged, so that they may be well feathered from the top to the bottom. They should afterwards, in general, be left to take their own natural growth, except just taking off the rambling shoots. When their heads become thin and drooping, those shoots which are proper for sending out new shoots to fill up the vacancies, and produce regularly, should be shortened by the knife.

The practice of clipping the shrubs with garden shears into globes, pyramids, &c. as is sometimes done, is very injurious; the necessary trimming should always be performed with the knife, and that only as above, as the plants appear to the most advantage when they grow naturally.

Whenever the heads of the plants become very irregular, or thin and flabby, they may be renewed by heading down all the branches pretty short in spring, and thrusting them into larger pots of fresh mould, with the balls of earth about their roots, giving plenty of water during summer, when they will branch out again finely, and form handsome full heads.

In respect to the general culture, as the plants advance in stature they should annually be removed into larger pots, according to the size of their roots; but care should be taken not to put them into pots too large, which cau'ses them to shoot weak, and sometimes proves the destruction of them. When they are taken out of the former pots, the earth about their roots should be pared off, and that within the ball gently loofened, that the roots may not be too closely confined; and then they often may be replaced in the same pots, when not too small, filling up the sides and bottom with fresh rich earth, and giving them plenty of water to fettle the earth to their roots; which should be frequently repeated, as they require to be often watered both in winter and summer, and in hot weather they should have it in large quantities.

The proper season for shifting these plants is in April and August; for if it be done much sooner in the spring, the plants are in a flow growing state, and not capable to strike fresh roots again quickly; and when done later
in the autumn, the cold weather coming on prevents their taking root.

In the autumn, when the nights begin to be frosty, the plants should be removed into the greenhouse; but when the weather proves favourable they may remain abroad until the beginning of November; for if they are carried into the greenhouse too soon, and the autumn should prove warm, they make fresh shoots at that season, which are weak, and often grow mouldily in winter. When the weather is too severe as to require the windows to be kept closely shut, they are often also greatly defaced; on which account they should always be kept as long abroad as the weather will permit, and be removed out again in the spring before they shoot out; and while they are in the greenhouse should have as much free air as possible when the weather is mild and proper for the purpose.

The tender kinds are mostly increased by seeds; but when any of them are pretty branchy, they may also be tried by layers and cuttings. And the eighth fort succeeds best in this way.

The feed should be procured from abroad, preferred in fand, &c. and be tawn in spring in pots of fresh mould, plunging them in the bark-bed; the plants come up the same season; which, when two or three inches in height, should be planted out in separate small pots, and plunged in the bark-bed, supplying them with water, and managing them as other woody plants of the fame kind.

As the second fort often branches out low, some of the young shoots may be laid in spring, by flat-laying or wiring, plunging the pots in which they are laid in the tan-bed; when they will probably be well rooted in one year, though it is sometimes two before they strike good root, when they should be potted off into separate pots and be managed as the others.

The fall fort is best raised in this way.

The cuttings of some of the short young shoots should be made from such of the plants as afford them, planting them in pots of fresh compost in July, plunging them in the bark-bed, and covering them close with a low hand-glafs, giving due water. They moftly take good root the same year, and are fit to plant out in separate small pots in the following spring.

In regard to the general management of these forts it is only that of keeping them always in the flowe, except a month in the heat of summer, when they may be set out in the open air. They should be suffered to shoot nearly in their own way, keeping them, however, to upright items, and allowing their heads to branch out according to nature, except just reducing the very irregular branches, giving frequent waterings in common with other woody plants of the fame kind, and shifting them occasionally into larger pots.

The first species and varieties are highly ornamental for the borders and greenhouse, and the other tender forts in the flowe collections.

**Myrurus Pimenta.** See Pimenta.

**Myrurus Syzygris, the wild myrtle,** a name given by some authors to rafines, or butcher's bross, from some faint resemblance of its leaves to those of the myrtle.

**Myrtum Marx, in Ancient Geography,** a name given by the Greeks to the sea which bathed the Scylian promontory, situated S. E. of the Argolides.

**Myrus, in Geography.** See Murrina Myrus.

**Myrs, a name given by Rahan, Apian, and many others, to the hill called capriciaus by the later writers, the capias and choront of others of the ancients.** See Capricus and Goat-sall

**MYSA, in Geography,** a river which rises in Bohemia, on the confines of Bavaria, and discharges itself into the Muldeau, near Prague.

**MYSECROS, in Ancient Geography,** a river of Arabia Felix, placed by Pline in the southern part of that province.

**MYSHAL, in Geography,** a small post-town of Ireland, in the county of Carlow, at the foot of mount Lemen. It is 47 miles S. by W. from Dublin.

**MYSSIA, in Ancient Geography,** a small country of Asia Minor, is said to have derived its name from the Lydian word mysa, signifying a beech-tree, with which tress the country abounded. It was divided according to Strabo, into the Greater and Lesser My sia. The latter, or Lesser My sia, lay on the Propontis, and from thence extended to mount Olympus, bounded by Bithynia and the Propontis on the N. and W., by Phrygia Minor on the S., and by Phrygia Major on the E. The Greater My sia was bounded on the N. by Phrygia Minor, on the S. by Asia, on the E. by Phrygia Major, and on the W. by the Aegean sea. What Strabo calls My sia Minor, Polymyia denomiates My sia Major; the former is also named Olymepia, from mount Olympus, and Helleponrtica, because some towns anciently belonging to it were seated on the Hellepont. That part of My sia, which lay between Ancyra of Phrygia and the river Rhynacus, is called by Strabo Abrettana, and the remaining part Morena. The former denomination is often given to all My sia. In the part of My sia which lay on the Propontis were the following cities, viz. Cyzicus, Parium, and Lampactus, which is still in a tolerable good condition, situated in a pleasant plain, and surrounded with vineyards, that produce excellent wine. The Greeks call it Lampae, and the Turks Lepteck. (See each of these towns respectively.) The Midland My sia lay between the river Rhynacus and mount Ida. Here Stephanus places the city of Apollonia. On the banks of the Rhynacus, which rises from a lake bearing the name of the city, now called the lake of Abouillon, 25 miles in compass and eight miles wide, interposed with several islands, the largest of which is three miles in circuit, and called Abouillon. See Apollonia.

The chief rivers of My sia Minor are the Rhynacus (which see) and the Ganeicus, which rises in mount Ida, and discharges itself into the Propontis, below Parium and Cyzicus. This river was crossed by Alexander at the head of 30,000 Macedonians, in face of the Persian army, which was 600,000 strong, and notwithstanding the height and steepness of its banks. It is now called the Soufoughirli, the name of a village which it waters. In this part of My sia falls mount Olympus, called Olympic My sorum, to distinguish it from several other mountains of the same name. It is one of the highest in Asia, and for a great part of the year covered with snow.

The city of greatest note in My sia Major was Pergamus, which see. On the coasts of this My sia were seated the cities Antandrus, Scethus, and Adramytium, and Pitane.

The soil of this country is one of the finest and richest of Asia, and is celebrated as such by the ancients. It abounded in corn and wine, and was well stocked with cattle, and had a great many large plains for pasture. It was pleasantly watered with small rivers running down from mount Ida and Olympus.

As to the origin of the My sians, Herodotus informs us, that they were Lydiaus by descent. Others derive them from the Phrygians, and show us that My sius, from whom their name is said to originate, was not a Lydian but a Phrygian. Strabo deduces the Asiatic My sians
MYS

fians from those of Europe, inhabiting that part which lies between mount Hermes and the Danube, and is now known under the names of Bosnia, Servia, and Bulgaria. As to the character of the ancient Myrians, it must be considered at different times, for they seem to have been once a war-like people. However in later ages they degenerated from the valor of their ancestors, so as to be looked upon as the most contemptible and insignificant nation on earth; insomuch that the Greeks had no expression to signify more emphatically a person of no worth or merit than to call him "the left of the Myrians." They were addicted to tears, and on that account employed by the Greeks to attend their funerals and lament over the deceased. Their language was probably the Thrygian and Trojan, with frequent variation of dialect. Nothing is known concerning their manners, customs, arts and sciences. That they were commercial we may infer from their situation and their wealth; for they are represented by Philostratus as being in ancient times the most opulent nation of all Asia. As to their religion, it was much the same with that of this Phrygians, with whom they vied in superlition. They worshipped the same deities, and used the same religious ceremonies, whereas have concluded that they were originally Thrygians. Cybele had a flate temple at Cyzicus, and there was another dedicated to Apollo Actaeus near Parium. Nemesis was also one of their deities; and Priapus was worshipped by the more modern Myrians, but unknown to them even in the time of Hefiod. The Mylian priests abstained from flesh, and were not allowed to marry. Upon their initiation into the priesthood, they sacrificed a horse and ate its entrails. With regard to their government, it was not always monarchical; for no mention of their kings occurs till the Argonautic expedition, though some authors suppose they had them long before that time. After the destruction of Troy, and dispersion of the Trojans, the Myrians took possession of a great part of that country, which they held till they were conquered by Creusus, king of Lydia. Anc. Un. Hill. vol. iv.

MYSIA was also a small country of the Peloponnesus, in which, according to Pausanias, there was a temple dedicated to the Thrygian Ceris.—Allo, a town of the Troade, placed by Strabo near Adamyttium.—Allo, a town of Parthia, which Ptolemey places between Barbaria and Cheras.

MYSIA, MYSIUS, in Antiquity, a festival in honour of Ceris, called Myia from Myius, an Argian, who dedicated a temple to her, in a place about ten itada distant from Pallene, in Achaia; or, according to Phurrnenus, from μυς, to cloy, satisty, or be well fed, because Ceris was the first who taught men how to use corn. The festival continued for seven days, upon the third of which all the men and dogs were shut out of the temple, whilst the women, together with the bitches, remained within, performing during the night the accustomed rites; on the following day, they returned to the men, with whom they passed away their time in jelling and laughing together. Potter, Archzal. Grac. lib. II. cap. 20. tom. i. p. 415.

MYSLOWITZ, in Geography, a town of Silisia, in the lordship of Pifcz, on the Brzemia; 15 miles N. of Pifcz.

MYSOL, an island in the East Indian sea, of a triangular form, about 100 miles in circumference, governed by a rajah. S. lat. 20. E. long. 129.

MYSON, in Biography, a native of Sparta, and one of the seven wife men of Greece. When Anacharius consulted the oracle, in order to know who was the wisest man in Greece, he received a reply, the person who is now ploughing his fields: this was Myoton.

MYSORE, or Myssoor, in Geography, a province of Hindoo-
British army. In 1799, Coimbatore, Canara, and other
districts were added; but hostilities did not terminate till
the reduction of Seringapatam, capital of Mysore, when
Tippoo himself fell. The whole force of Tippoo has been
reckoned at 75,000, of which 22,000 were superior to any
that have been raised and disciplined in India.

Of the countries that form the south-western parts of Hind-
dooft, to which our attention has now been directed in this
article, Travancore, Malabar, and South Canara, alone escaped
Mahometan conquest, until the two latter were invaded by
Hyder in 1763-6. The earliest Mahometan army that ever
crossed the Kistna was led in 1510-11 against the capital of the
sovereign of the Carnatic, about 105 miles N.W. of Se-
ringapatam. In 1726, this capital, called Doormumooder,
was finally destroyed, and the fest of government removed to
Tounor, better known by the name of Mootee-Talab,
or the lake of Pearls, 12 miles N. from Seringapatam.

It is needless to relate the romantic origin of the Hindoo house
of Mysore: nor are we able to trace the number of genera-
tions that subsisted between the founder of this family and
Chow-Rai, whose succession is fixed in 1507. A subfequent
raja made, during his life-time, a partition of his domi-
nions between his three sons, and to one he gave Mysoor,
then called Pooragurry. A fort was either first erected or
repaired in 1724, to which was assigned the new name of
"Mahelh-Aloor," the buffalo-headed monfieur, usually pro-
nounced Mahelhore, and now contracted to Mysoor. After
a succession of rajas, of whom little is known that is worth
detailing, Hyder Ally, in 1759, assumed the government.
From this time the raja became a fatigue prisoner, and died
in 1766, and by Hyder's command his son was placed upon
the throne. On his death, in 1796, Tippoo declined nomi-
nating a successor. The young Mysore raja, placed on the
throne since the capture of Seringapatam, is the only
child of Chianon-Raajee, who had been elected in 1733;
and the place of his residence is fixed at Mysore.

Mysore, a town and fortified pobl of the above province,
and its ancient capital; about six or eight miles to the south-
ward of Seringapatam.

MYSTAGOGUES, in Mythology, a name given to the
ministers who performed the principal part in celebrating the
Mysteries; which see.

MYSTERY, MYSTERIUM, something secret or hidden;
impossible or difficult to be comprehended: or, in other
words, such a doctrine as exhibits difficulties, and even ap-
parent contradictions, which we cannot solve or explain.

The word comes from the Greek μυστήριον, and that, ac-
cording to some etymologists, from μύς, claudo, tacere, I
shut, I am silent, and ρόσσος, mouth; but then whence comes
the r? Muft the in in ρόσσος be converted into an r? The
word seems derived, with more propriety, from the Hebrew
רְמֶל, fatur, to hide; whence is formed רֶמֶל, misfar, a
hidden thing.

Mystery is primarily used in speaking of certain truths re-
vealed in Scripture, into the full understanding of which
human reason cannot penetrate. Such are faid to be the
doctrines of the Trinity, the Incarnation, &c.

We have an epitome of the mysteries of faith, or the
mysteries of Chriftianity, in the symbols or creeds faid to
have been compofed by the apostles, the council of Nice,
and St. Athanasius. See CRED.

In some of these, mention is made of the mystery of the
Trinity; the mysteries of the incarnation of the Son of God,
his death and paflion, and his defcent into hell, for the
redemption of mankind; of his reurrection the third day; his
exaltation into heaven, his fitting on the right hand of God,
and his coming again to judge the world; of the divinity and
equality of the Holy Ghost with the Father and the Son;
of the unity of the church; of the communion of faints; the
participation of the fcraiments; and the general reurrection.
Such are the principal mysteries of faith; which the church
declares neceffary to be known and believed, in order to fa-
vation.

From the earliest ages there have been particular festivals
inftituted in honour of these mysteries; to return thanks to
God for having revealed them, and to oblige the ministers
and pastors to instruct the people in them.

Another ufe of the word, though not fo univerflal as pref-
tent, is often to be met with in ecclesial writers of former
ages, in foreign writers of the present age, which is to
fignify fome religious ceremony or rite, efpecially thofe
now denominated fcraiments. In the communion-office
of the church of Englond, the elements, after confeoration,
are sometimes termed "holy mysteries." But this ufe fes
not now to be common among Protetlants, fels perhaps in this
country than in any other. Indeed in the fourth, and fome
fuccedent centuries, the word μυστήριον was fo much in vogue
with the Greek fathers, and "myfterium," or "fcra-
mentum," as it was often rendered, with the Latin, that it
would be impoffible to fay in what meaning they ufed the
words; nay, whether or not they affixed any meaning to
them at all. In every thing that related to religion, there
were found "myfleries" and "fcraiments," in defcrip-
tions and precepts, in ordinances and petitions; they could even
difcover numbers of them in the Lord's prayer. Nay, fo
late as father Pollevarini, this unmeaning application of the
term has prevailed in fome places. That Jefuit is cited
with approbation by Walton, in the "Prolegomena," to his
"Polyglott," for faying, "Tot eje in Hebraica Scriptura
fcraimenta, quot literae; tot myfteria, quot puncta; tot
arcana, quot apices;" a fentence which father Simon ac-
knowledges to be to him unintelligible. See the next article.

Such are the feals of the mystery of the Incarnation, called
also Chriftmas; thofe of the Circumcifion, Paflion, Resur-
rection, &c. See INCARNATION, CIRCUMCISION, EASTER,
and EPIPHANY.

The heathens also bad their mysteries, particularly thoje
of Ceres (see Eleusinia), the Bona Dea, &c. The
Egyptian priests concealed the mysteries of their religion
and philosophy under hieroglyphics; which fee. Thofe who
revealed the mysteries of the Bona Dea were fervely punifh-
ed; and none were trufted with them but thofe feemly
initiated, and fwnorn to fecrecy.

But thofe were not called mysteries, as being incompre-
henfible, or raifed above the power of reafon; but becaufe
they were covered and difguifed under types and figures, to
raife the greater veneration in the people.—The mysteries of
paganifm were ufually celebrated in caves and grottos, fitter
for the concealment of crimes than the celebration of mys-
teries.

The temples in these fecret receffes were fo conftucted as
to favour the artifices of priests. Some veftiges of these
fubterraneous apartments, which by their gloom diffused an
air of folemn secrecy, and by the hieroglyphic paintings
and sculptures that covered their walls, anfwered the fame
purpose, have been discovered by fome modern travellers.

Each of the Pagan gods had, fays bishop Warburton, be-
sides the public and open, a fecret worship paid them; into
which none were admitted but thofe who had been feleoted
by preparatory ceremonies, called initiation. This fecret
worship was termed the mysteries. The firt and original
mysteries of which we have any account, were thoje of Ift
and Osiris in Egypt (see Egypt, Isis, and Osiris); from
whence they were derived to the Greeks, under the prefu-
dency
dency of various gods, such as the insti- 
tutor thought most 

suitable to his purpose. (See Bacchanalia, Eleusinia, 

Greece, and Orpheus.) In process of time these mys-
teries were disseminated through the northern and western 
nations of Europe. See Celts and Druids.

The learned prelate above named observes, that the na-
ture and end of all these mysteries were the same, viz.
to teach the doctrine of a future state. He represents the 
design of them in general to have been, to engage men to a 
 holy and virtuous practice, to give them just notions of reli-
gion, and to detect the error of the vulgar polytheism.

And he concludes his account of the mysteries with observ-
ing, that there were three things about which they were 
 principally concerned: viz. 1. The rise and establishment 
of civil society, 2. The doctrine of a future state of rewards 
and punishments. 3. The error of polytheism, or the prin-
ciple of the unity. Which latter was the object of the 
greater mysteries, in which the whole delusion of paganism 
was disclosed, and the initiated were instructed, that Jupi-
ter, Mercury, Venus, Mars, and the whole rabble of li-
centious deities, were only defined mortals; and that God 
alone was the creator of the universe, who pervaded all 
 things by his virtue, and governed all by his providence: 
whereas in the lesser mysteries, which were preparatory to 
the other, the general belief of a providence and future 
state, and its consequent engagements to a virtuous life, were 
inculcated. But as these mysteries, according to the bishop's 
 hypothesis, were an institution of the state for the benefit of 
the people, it is natural to inquire into the reasons of their 
being kept secret, which, he says, were the following: 
nothing stimulates curiosity like that which retires from ob-
 servation, and seems to forbid search; and yet there was a 
necessity of teaching some things to the initiated, not expe-
dient for others to know; hence he observes, that the 
secret in the lesser mysteries was some hidden rites and 
flows, to be kept from the people, only to invite their curiosity; 
and that the secret in the greater was some hidden doctrines 
to be kept from the people for the contrary purpose. Be-
 sides, as the legislators had been principally concerned in the 
rise of the vulgar polytheism, this circumstance furnished 
another reason for the secrecy attending these mysteries. 

And that these mysteries were invented, established and sup-
ported by the legislature, he argues from the place of their 
origin, which was Egypt, where all religious worship was 
formed and propagated by state-men, and directed to poli-
tical ends, because the fages who brought them out of 
Egypt, and propagated them in Asia, Greece, and Britain, 
were all kings or legislators: because the state predilec in 
the mysteries; because, according to their original institu-
tion, neither slaves nor foreigners, who had no concern, no 
property, and no country, were to be admitted into them; 
because an institution which taught the necessity of a strict 
and holy life, must be the invention of legislators, to whose 
scheme virtue and the prospect of immortality were to ne-
cessary; and hence they were actually of infinite use to the 
state; and finally, from the express testimony of Plutarch, 
who, in his Treatise of Isis and Osiris, ascribes them to this 
original. However, these mysteries, in process of time, 
greatly degenerated; one cause of their corruption seems to 
have been the faction in which they were performed, and the 
profound secrecy observed in them; for the night gave op-
portunity to wicked men to attempt evil actions: and the 
secrecy, encourages to perpetrate them. Another cause 
of their depravation was their being sometimes under the 
patronage of those deities who were supposed to inspire and 
profane over irregular passions, such as Bacchus, Venus, and 
Cupid; to which the bishop adds the hierophants' with-

drawing himself from the care and inspection of the civil 
magistrate.

Such is the ingenious and plausible scheme largely diffu-
ced and maintained by Dr. Warburton, in his Divine Le-
gation, and book ii. sec. 4.

However, other learned writers have advanced a very dif-
ferent opinion on this subject. Some who have allowed that 
the mysteries originated in Egypt, which is the most 
probable opinion, have ascribed their institution to the priests: who established them, from 
motives of priestcraft, to aggrandize their order, to extend 
their influence, and to increase their revenues. According-
ely, they annexed to the observance of them every circum-
stance that tended to delude the multitude, to gratify their 
feehes and passions, and to promote among them the influence 
of superstition and enthusiasm. At a subsequent period, it 
is not at all unlikely that princes and legislators would avail 
themselves of the advantages which they might derive from 
these institutions for establishing their own power, and ac-
complishing their own plans of government. Molheim, in 
his edition of 'Cudworth's Int. Syll.' suggests that the 
mysteries were altogether commemorative; and that they 
were established with a view of preserving the remembrance 
of heroes and great men, who had been deified in considera-
tion of their martial exploits, useful inventions, and public 
virtues; and more especially in acknowledgment of the 
benefits conferred by them on their contemporaries. To this 
purpose, he conceives, that the mysteries of Mithras in par-
ticular were instituted. (See Mithras.) And he ascribes 
to the same origin the mysteries of the Egyptians, Phoeni-
cians, Greeks, and Etruscans, and indeed all other similar 
insitutions throughout the world. But it does not appear 
from any historical records, that this design was ever declared 
and avowed in their original appointment; and we know, 
that the names and illusions deeds of the heroes of antiquity 
were commemorated, with professed intentions, by festivals, 
games, sacrifices, hymns, and other such institutions, ob-
erved in honour of them.

Dr. Leland, in particular, has very accurately examined 
the origin and end of the system of mysteries. Accord-
ing to this writer they seem to have been originally 
tended to tame and civilize the rude and barbarous people, to form 
and polish their manners, and by thows and representations, 
which were fitted to strike the imagination, to bring them to a 
greater awe and veneration for the laws and religion of 
their country; which, among the Pagans, was always re-
garded as a necessary ingredient in a virtuous character. On 
this account they are highly commended by Cicero, de Leg. 
lib. ii. cap. 14, as they tended to reclaim men from a rude 
and savage life; and they were called initia, because they 
fulfilled the first principles of a human and civilized life. 
But whatever was the original intention of these mysteries, 
there is great reason to apprehend, that upon the whole, they 
proved rather detrimental than advantageous to the cause of 
virtue; and the corruption of them seems to have been owing 
to a fundamental defect in their original constitution.—Dr. 
Leland farther examines whether, and how far the mysteries 
were designed to detect the error of polytheism, and to in-
struct the initiated in the knowledge of the one true God. 
With respect to this point, he maintains, that the whole evi-
dence, produced by bishop Warburton, amounts only to this; 
that in the mysteries the initiated were instructed that the 
popular deities had been once men; but no proof is brought, that 
the mysteria overthrew the vulgar polytheism, the worship of 
dead men: nay, the initiators of the mysteries, whilst they 
taught the initiated, that the gods, commonly received, had 
been once men, took care that the public religion should not 

funder by it, by letting them know, that, notwithstanding this, they ought to be regarded as gods, and to have that divine worship and honour rendered to them, which ancient tradition and the laws required. The Christians, indeed, argued from the history of the heathen gods to disprove their divinity: and this was probably the reason why the myths and fables were very careful in their entrance on the celebration of the mysteries, that no Christian should be present at them.

Dr. Leland farther contends, that the doctrine of the unity was not taught in the mysteries. With this view he examines the testimonies adduced by the bishop, which, he says, afford no sufficient evidence that they taught the doctrine of the unity. Besides, there is great reason to think, that the notion given of the Deity in the mysteries was not very right and just: and moreover, if they had taught just notions of God, there could be of no great use, because they taught this part of the secret doctrine of the mysteries to very few persons. It is farther urged, that the legislators and civil magistrates, who first instituted the mysteries, and who regarded not truth but utility, could never, in good earnest, attempt to draw the people off from that polytheism, which they themselves had encouraged for the establishment and welfare of the state, and to keep the people under a greater veneration for the laws. And the mysteries seem to have been designed, not to difcard the worship of the deities, to whom they were appropriated, but to add a greater solemnity to it. To which it may be added, from fact and experience, that though the mysteries were generally celebrated in almost all the heathen nations, and especially throughout the whole Roman empire, no effect of them appears in turning any of the people from their polytheism or idolatry; nor is it conceivable, if the design of the mysteries was as laudable as Dr. Warburton represents, that the ancient Christian writers should have so universally exclaimed against them. Many of these had been converted from Heathenism to Christianity, and while they were Heathens had been initiated into both the lesser and greater mysteries; so that they were thoroughly acquainted with their nature and design. If they had known that the mysteries obilged those who were initiated to lead a virtuous and holy life, and that they were designed to overturn polytheism, and to profylete men from the worship of idols to that of the one true supreme God, they must have had a good opinion of them; and in their apologies for Christianity, they would naturally have been induced to speak favourably of them. Whereas, in discourses addressed to the Heathens themselves, they frequently speak of the mysteries in terms of the greatest abhorrence, as impure and abominable, and as tending rather to confirm the people in their idolatry than to draw them from it. On this occasion it will be sufficient to select the testimony of Clemens Alexander, who was a man of learning and probity. From the accounts which he gives from his perfect knowledge of them, it appears, that the representations made in the mysteries were agreeable to the fabels of the poets and mythologists, concerning Jupiter, Bacchus, Ceres, Proserpina, and other deities; that in the Eleusinian fables, they celebrated the rage of Proserpina, the lamentations of Ceres, her wanderings in quest of her daughter, her congregs with Jupiter, and supplications to him, with several other particulars, which were both ridiculous and obscene. He calls those who brought these mysteries from Egypt into Greece, "the fathers of an execrable perfefition; who sowed the seed of wickedness and corruption in human life;" and says "the mysteries were full of delusion and portentous representations, calculated to impose upon the people." He concludes his account of them by saying, "these are the mysteries of atheistic men. I may rightly call those atheists, who are deftitute of the knowledge of him, who is truly God, and most impudently worship a boy discerped, or torn in pieces by the Titans, a woman la- menting, and the parts which merely forbids to name." And he repeats it again that they are ignorant of God, and do not acknowledge that God who is or really exists. Clem. Alex. Cohort. ad Gentes, p. 13. 14. 19. 20. Ed. Potter Eufebius transcribes and approves this description of the mysteries by Clemens. The account which Arnobius, who had been a learned Pagan, gives of the mysteries, particularly of the Eleusinian mysteries, celebrated at Athens, coincides with that of Clemens. In order to evade the force of these testimonies, the learned Prelate observes, that the ancient Christian writers bore a secret grudge to the mysteries for their injurious treatment of Christianity at its first appearance in the world; but this apology intimates, that the mytla- gogues and managers of the mysteries did what they could to uphold the common polytheism and idolatry; and that this was the cause of their enmity to Christianity. They represented the Christians as atheists, because they declaimed against the worship of the publicly adored deities. Whereas if the design of the secret doctrine of the greater mysteries had been to detect the error of the vulgar polytheism, and to teach the initiated that the popular deities were really no gods, the charge might have been retorted upon themselves. Nor is it sufficient to allege with the bishop, that the ancient fathers of the church, after all which they said against them, stupidly and formally transferred the terms, phraffes, rites, ceremonies, and discipline of these odious mysteries into our holy religion; for the Christians, though they did not consider them as designed to detect and overthrow the popular polytheism, but the contrary, were fully apprized of the veneration that was generally paid to them, and therefore applied to their own use the terms made use of in those myster- ies, to better gain upon the Heathens, and to shew that Christianity did in reality effect that which the Pagan mysteries vainly pretended to do. See Leland's Advantage and Necessity of the Christian Revelation, vol. i. pt. i. c. 9.

Mystery, in Scripture Language, is used with some latitude. Sometimes it denotes any thing not to be known without divine revelation. It is also used to denote the secret things which God has discovered by his ministers, the prophets, Jesus Christ, and the apostles.

Dr. Campbell, in his "Preliminary Differtations," observes, that, after the most careful examination of all the passages in the New Testament, in which the Greek word μυστήριον occurs, and after confulting the use made of the term by the ancient Greek interpreters of the Old, and borrowing aid from the practice of the Hellenif Jews, in the writings called Apocrypha, he can find only two sentences nearly related to each other, which cannot, strictly be called scriptural. The first and leading sentence of the word is "arcanum," a secret, any thing not disclosed, not published to the world, though perhaps communicated to a select number. This is totally different from the current fende of the English word "mystery," or something incomprehensible. In the former acep- tation, a thing was no longer a mystery than whilst it remained unrevealed; in the latter, a thing is equally a myster, after the revelation, as before. To the former we apply, properly, the epithet "unknown"; to the latter, we apply, in a great measure, apply the term "unknowable." Thus, that God would call the Gentiles, and receive them into his church, was as intelligible, or comprehensible, as that he had once called the descendants of the patriarchs, or as any plain proposition, or historical fact. Yet, whilst undis- covered, or, at least, veiled under figures and types, it re-
MASTERY.

mained, in the scriptural idiom, a "mystery," having been hidden from ages and generations. But, after it had pleased God to reveal this his gracious purpose to the apostles, by his spirit, it was a mystery no longer. The terms communication, revelation, manifestation, connected with that of mystery, and bearing relation to it, plainly shew the import of the term μυστήριον, to which they are applied. This is a point that seems to be universally acknowledged by the learned, and therefore it is merely necessary to refer the judicious reader for further proof of it from the New Testament to the following passages, viz. Rom. xvi. 25, 26. 1 Cor. ii. 7, 8, 9, 10. Ephes. i. 9. iii. 3. 6. 9. vi. 19. Col. i. 26, 27; in which it will be plainly perceived, that the apostle treats of things which had been concealed for ages (and for that reason called μυστήριον), but was then openly revealed; and not of any thing, in its own nature, dark and inconceivable. According to the usage of the LXX, we shall find, that in the prophecy of Daniel, (xi. 16, 19, 27, 28, 29, 30, 47. iv. 9,) the word μυστήριον occurs not fewer than nine times, answering always to the Chaldee MYN, res arcana, and used in reference to Nebuchadnezzar's dream, which was a "secret," even to the dreamer himself, as he had foretold it. In the common version it is uniformly rendered secret, and it is found connected with the verbs ἐγγράφειν, ὁρκίζειν, and ἀποκαλύπτειν, in a manner similar to the usage of the New Testament already noticed. In the apocryphal writings, the word μυστήριον frequently occurs in the same sense, and is used in reference to human secrets, as well as to divine. Indeed, in the New Testament the word is not confined to divine secrets. Thus, the apostle, speaking of the antichristian spirit, says (2 Thess. ii. 7), "the mystery of iniquity doth already work." The spirit of antichrist hath begun to operate; but the operation is latent and unperceived. Both the gospel of Christ and the spirit of antichrist are equally denominated "mystery" or secret, whilst they remained concealed.

It must be allowed, however, that in the doctrines of religion there is something, which is not, in all respects, perfectly comprehensible by us, or with regard to which difficulties may not be fuggeted, of which we may not be able to give a clear and acceptable explanation. In all science, and particularly in natural theology, as well as in revelation, there are many truths of this kind. This acknowledgment is not at all inconsistent with the scriptural acceptation of the word μυστήριον, which relates merely to the secrecy for some time observed with regard to any doctrine, whether mysterious, in the modern acceptation of the word, or not. To this purpose we may observe, that the apostles are denominated μυστήριον, "bearers of the mysteries of God" (1 Cor. iv. 1.), i.e. dispensers to mankind of the gracious purposes of heaven herebefore concealed, and therefore termed secrets. Thus also our Lord, in the course of his ministry, says to his apostles, "To you it is given to know the mysteries of the kingdom of heaven," i.e. no secret relating to this subject, is withheld from you; "but to them it is not given," i.e. not yet given. (Matt. xii. 41.) For these very apostles were commanded, upon receiving their commission, to disperse to all the world the whole mystery of God, his secret counsels in regard to man's salvation. (Matt. xxviii. 19. Mark, xvi. 15.) We are hence enabled to explain phrases that occur in the epistles, expressing the whole Christian institution, "the mystery of the gospel," "the mystery of the faith," "the mystery of God," and "the mystery of Christ," "mystery, in the singular number, not mysteries, in the plural, which would have been more conformable to the modern import of the word, as relating to the incomprehensibility of the different articles of doctrine. But the whole of the gospel, taken together, is denominated "the mystery." The grand secret, in reference to the silence, or concealment, under which it was formerly kept; as, in like manner, it is styled the revelation of Jesus Christ, in reference to the publication afterwards enjoined.

In the New Testament the word μυστήριον sometimes bears another meaning. It is sometimes employed to denote the figurative sense, as distinguished from the literal, which is conveyed under any fable, parable, allegory, symbolical action, representation, dream, or vision. In this case the term is used comparatively; the meaning being obscure compared with the literal sense. To this import of the term our Lord probably refers (Mark, iv. 11.) when he says to his disciples, "To you it is given to know the mystery of the kingdom of God; but to them that are without, all these things are done in parables." The apostles were let into the secret, and got the spiritual sense of the familiar, whilst the multitude amused themselves with the letter, and searched no further. In this case μυστήριον is used Rent. 20. xiii. 7. Ephes. v. 32.

Dr. Campbell observes (ubi supra), that the earliest version of this word μυστήριον from its genuine and original sense, a "secret," or something concealed, was the application of it to denote some solemn and sacred ceremony. What led to this use of the term was a resemblance in one particular between some rites of Christian worship and those performed by Heathens in honour of their deities, and denominated from their secrecy mysteries. Although these ceremonies to which we refer, and which were practised in the Christian church, were essentially different from all Pagan rites, yet they so much resembled the latter in the exclusion of the multitude as to give the Heathens occasion to style them the Christian mysteries. The term would probably be first applied, in this sense of it, to what was called in the primitive church the "Eucharist," or as it is now denominated the "Lord's supper," and afterwards extended to "baptism," and other sacred ceremonies. The name seems to have originated with the Heathens, and in process of time was adopted by Christians themselves. (See SACRAMENTS.) One passage has been mentioned in which the word μυστήριον seems to have been used in the modern sense of the English word mystery, and to denote something which, though revealed, is inexplicable, and, to human faculties, unintelligible. The words are, "Without controversy great is the mystery of godliness, &c." (1 Tim. iii. 16.), which, as they occur in our version, differ from the reading of the two most ancient versions, the Syriac and the Vulgate, and some of the oldest MSS. The purport of this sentence is conformable to the sense above given of the term μυστήριον; and it is plainly this, "Great unquestionably is the divine secret, of which our religion brings the discovery, &c." A popular preacher of the last century, after observing that a mystery, in the Scripture sense of it, is a thing that natural reason could not discover, and, consequently, which must have been unknown, if God had not revealed it, nevertheless acknowledges, that of this kind there are several doctrines in the Christian religion; before the revelation was given they were mysteries; but ceased to be mysteries now they are revealed. To this purpose he cites Mark, iv. 11. Rev. xvi. 25. 1 Cor. xv. 51. Hence this writer infers, that mysteries, i.e. things which reason cannot discover, and which are not revealed, are, according to the language of Scripture (Deut. xxix. 29) "the secret things that belong to God," and what we have nothing at all to do with; or, in other words, though certain things are parts of our religion that were mysterious, it is not our duty to believe or practise any thing that is still a mystery. To believe doctrines
Mystery.
frequently required the representation of some allegorical personage, such as Death, Sin, Charity, Faith, Hope, and the like, by interpreters of these unlettered ages; towards the fifteenth century, they began to form complete dramatic pieces, confining entirely of such personifications. These they entitled moral plays, or moralities. The mysteries were very inartificial, representing the Scripture stories singly according to the letter. But the moralities are not devoid of invention; they exhibit outlines of the dramatic art; containing something of a fable or ploy, and even attempting to delineate characters and manners. From hence the gradual transition to real historical personages was natural and obvious. It may be also observed, that many licentious pleasantries, of which neither the writers nor the spectators perceived the impropriety, were sometimes introduced in these religious representations. This might imperceptibly lead the way to subjects entirely profane, and to comedy, and perhaps at an earlier period than is generally imagined.

In France all dramatic pieces were indiscriminately called "mysteries," whether a martyr, or a heathen god, whether St. Christopher, or the tripods of the aborigines; in country, the religious mysteries, often called "Pitoues," the "Pi- tous," were very fashionable, and of high antiquity, though not more ancient than those of the English. The French mysteries were chiefly performed by the religious communities. In France, as well as in England, it was customary to celebrate the feast of the boy-bishop, during which "morality" were presented, and shows of "miracles," with farces and other fports, but compatible with decorum, both in France and in England. See Boy Bishop.

Mr. T. Warton, in the second volume of his "History of English Poetry," has introduced some discussions with regard to the probable causes of the rise of the "mysteries." "About the eighth century," he says, "trade was principally carried on by means of fairs, which lasted several days. Charlemagne established many great fairs of this fort in France; as did William the Conqueror, and his Norman successors, in England. The merchants, who frequented these fairs in numerous caravans or companies, employed every art to draw the people together. They were therefore accompanied by jugglers, minstrels, and buffoons; who were hired for the season, to attract attention, and excite all their skill, on these occasions. As now but few towns existed, no public spectacles or popular amusements were established; and as the sedanary pleasures of domestic life and private society were yet unknown, the fair-time was the season for diversion. In proportion as these shows were attended and encouraged, they began to be set off with new decorations and improvements; and the arts of buffoonery, being rendered still more attractive by extending their circle of exhibition, acquired an importance in the eyes of the people. By degrees the clergy, observing that the entertainments of dancing, music, and minstrelly, exhibited at these protracted annual celebrations, made the people less religious, by promoting idleness and a love of futility, proscribed these Sports, and excommunicated the performers. But finding that no regard was paid to their cenures, they changed their plan, and determined to take these recreations into their own hands. They turned actors; and instead of profane minstrels, prefent fories taken from legends in the Bible. This was the origin of sacred comedy. The death of St. Catherine, acted by the monks of St. Dennis, rivalled the popularity of the professed players. Music was admitted into the churches, which served as theatres for the representation of holy farces. The festival among the French, called "La Fête de Fous, de l'Ane," &c. and "Des Innocens," at length became great favourites, as they certainly were more capricious and arbitrary than the invidious of the buffoons at the fairs. These are the ideas of a judicious French writer, who has investigated the history of human manners with great comprehension and facility," Our author adds, "Voltaire's theory on this subject is also very ingenious, and quite new. Religious plays, he supposes, came originally from Constantino ple; where the old Greecian flage continued to flourish in some degree, and the tragedies of Sophocles and Euripides were represented, till the fourth century. About that period, Gregory Nazianzen, an archbishop, a poet, and one of the fathers of the church, banished Pagan plays from the fage at Constantinople, and introduced select fories from the Old and New Testament. As the ancient Greek tragedy was a religious spectacle, a transition was made on the same plan: and the chorusses were turned into Christian hymns. Gregory wrote many facred dramas for this purpose, which have not survivd those inimitable compositions over which they triumphed for a time; one, however, his tragedy called Υφή, παιδόος, or, "Till God's Swell," is still extant. In the prologue it is said to be in imitation of a Christian spectacle which at that time the Virgin Mary has been produced on the fage. The fashion of acting spiritual dramas, in which, at first, a due degree of method and decorum was preferred, was at length adopted from Constantinople by the Italians; who framed, in the depth of the dark ages, on this foundation, that barbarous species of theatrical amusement called "mysteries," or sacred comedies, and which were soon afterwards received in France." This opinion is supposed, by Mr. Warton, to derive confirmation from the early commercial intercourse that subsisted between Italy and Constantinople. In further defence of this hypothesis, it may be observed, that the "Feast of Fools," and "of the Afs," together with other religious farces of that sort, so common in Europe, originated in Constantinople. They were instituted, though perhaps under other names, in the Greek church, about the year 990, by Theophylact, patriarch of Constantinople, probably with the design of weaning the minds of the people from the Pagan ceremonies, particularly the bacchanalian and calendrical solemnities, by the substitution of a farce of the same spirit and licentiousness. This practice was fruitful in the Greek church 200 years afterwards. We may here remark, that in the fourth century it was customary to make Christian parodies and imitations in Greek, of the old Greek classicks, for the use of the Christian schools. This practice prevailed much under the emperor Julian, who forbade the Pagan poets, orators, and philosophers, to be taught in the Christian seminaries. Apollinaris, bishop of Laodicea, wrote Greek tragedies, adapted to the stage, on most of the grand events recorded in the Old Testament, after the manner of Euripides. On some of the familiar and domestic stories of Scripture, he composed comedies in imitation of Menander. He wrote Christian odes on the plan of Pindar. In imitation of Homer, he wrote an heroic poem on the history of the bible, as far as the reign of Saul, in twenty-four books. Mr. Warton mentions a much earlier and more regular specimen of a theatrical representation of sacred history than that which is mentioned by Voltaire. Some fragments of an ancient Jewish play, now under their leader, and prophet Moses, are yet preserved in Greek iambic. The principal characters of this drama are Moses, Sapphira, and God speaking from the burning bush. Moses delivers the prologue, or introduction, in a speech.
speech of sixty lines, and his rod is turned into a serpent on the stage. The author of this piece is Ezekiel, a Jew, who is called the tragic poet of the Jews; and, according to Huetius, he lived at least before the Christian era. Some say, that he was one of the LXX, under the reign of Ptolemy Philadephus. Warton thinks, that he composed this play after the destruction of Jerufalem, and in the time of Barocbas, as a political spectacle, with a view of animating his dejected countrymen with the hopes of a future deliverance from their captivity under the conduct of a new Moles, like that from the Egyptian servitude. See Clem. Alex. lib. i. Strom. Eusebius Prepar. Evang. cap. 28, 29. Euthathius ad Hex. The above-mentioned fragments are collected and translated into Latin by Fr. Morellus, Paris, 1580. See also Corpus Poet. Gr. Traite & Come, Geneva, 1614, fol. Poet Christ. Græc. Paris, 1609, Svo. Scaliger ad Eueeb. and Euefb. Demonf. Evang.

Boileau, on the authority of Menefrier, seems to think, that the ancient pilgrims, on their return from Jerufalem, introduced these sacred exhibitions into France, among whom are reckoned St. James of Compostella, St. Bourne of Provence, St. Reine, &c. &c. who composed fongs on their adventures; intermixing recitals of passages in the life of Christ, descriptions of his crucifixion, of the day of judgment, of miracles, and of martyrods. To these tales, which were recommended by a pathetic chant, and a variety of gesticulations, the credulity of the multitude gave the name of "Visions." These were recited by the pious itinerants, with accompaniments which formed a sort of theatrical spectacle. At length their performances excited the compassion and charity of some citizens of Paris, who erected a theatre for their exhibition of these stories, with the additional advantage of scenery and other decorations. At length professed practitioners in the histrionic art were hired to perform these solemn mockeries of religion, which soon became the principal public amusement of a devout but undiscerning people.

Upon the whole, Mr. Warton concludes with observing, that the "mysteries" appear to have originated among the ecclesiastics; and were probably first acted, at least with an degree of form, by the monks. This was certainly the case in the English monasteries. As learning increased, and was more widely disseminated from the monasteries, the practice migrated to schools and universities, which were formed upon the monastic plan; and it is well known, that the practice of acting Latin plays in the colleges of Oxford and Cambridge continued until Cromwell's usurpation. Many instances of its occurrence in schools and seminaries of an inferior nature, both in England and France, might be enumerated; and it has been perpetuated to the present day.

**MYSTERY. Addition of.** See ADDITION.
**MYSTES.** See HYDROMYSTES.
**Mystic Theology** denotes a refined and sublime kind of divinity, professed by the mystics.

It consists in a knowledge of God, and divine things, not acquired in the common way, but infused immediately by God, and which has the power to move the soul in an easy, calm, devout, affecting manner; to unite it ultimately to God; to illumine the understanding, and to warm and enliven the will in an extraordinary manner.

Among the writings attributed to Dionysius the Areopagite is a discourse of "Mystic Theology." Several others have written on the same subject, both ancient and moderns. See Theology.

**MYSTICAL, MYSTICS.** Mystic, somethings mystical, or allegorical. See Mystery, Allegory, &c.

The commentators on the Scripture, besides a literal, find also a mystical, and a moral meaning. The bible, they contend, is a book written both withinfide and withoutfide: withinfide, in respect to the mystical, internal, sublime, and hidden sense; and withoutfide, in respect to the literal and grammatical sense immediately expressed by the words.

Indeed, several of the ancient fathers, and doctors of the church, understand the books mentioned in Ezek. ii 10, and in the Apocalypse, i.e. which were written both withinfide and withoutfide, of the Scriptures; and take the literal and mystical sense to be here fairly intimated.

The sense of Scripture, say they, is either that immediately signified by the words and expressions in the common use of language; or it is mediate, substantive, and mythical; wherein the things themselves signified are made to signify still other and farther things, according to the particular design and intention of God, and of the prophets and apostles inspired by him.

The literal sense they again divide into proper literal, which is contained in the words taken simply and properly: and metaphorical literal, where the words are to be understood in a figurative and metaphorical sense: as, where the right eye is commanded to be plucked out, &c.

Wherever the proper literal sense contains anything absurd or indecent, there recourse must be had to the metaphorical literal sense.

All Scripture has a true literal sense, but it has not always a mystical one. We must ever understand it in the literal sense, when it speaks immediately of any of the laws of nature, of charity, of doing good; when it gives us instructions for the conduct of life, for regulating our manners; and when it relates any matter of fact, or point of history.

The same passage of Scripture has sometimes several senses, expressed and signified immediately by the words taken in their proper, and their figurative sense, and which appear to have been all intended, by the inspired person who spoke them, as having been so understood by others likewise inspired. As those words in Psalm ii. Thou art my son, this day have I begotten thee; which St. Paul understands, according to the first letter, in Heb. i 5, of the generation of Jesus Christ in time; and in Acts, xiii. 32, he takes them in a metaphorical sense, and applies them to our Saviour's resurrection. Thus, in Horeb, xi. 1, the words of the prophecy, I have called my son out of Egypt, are understood literally of the children of Israel, whom God brought out of Egypt, under the conduct of Moses; and yet in Matt. ii. 15, they are understood metaphorically of Jesus Christ. See **accommodation and prophecy.**

The mystical sense of Scripture is that in which the things expressed by the words do farther signify; or it is a second signification held forth and signified by the first; this second being expressed immediately by the first; and mediately by the words themselves. Some writers allow of three kinds of mystical senses in the word of God: the first corresponding to faith, and called **allegorical;** the second to hope, called **anagogical;** and the third to charity, called **topographical sense.**

The four senses, and their applications, are included in the Latin dillicit: "Littera gelfa docet, quid credas allegoria, Moralis quid agas, quo tendas anagogia." Sometimes the same word in Scripture is to be taken in all the four senses. Thus the word *Jerufalem* literally signifies the capital of Judea; allegorically, the church militant;
MYS

tant; tropologically and morally, a believer; and analogically, a heaven.

So that which in Genesis, Let there be light, and there was light, signifies, according to the letter, corporeal light; by the allegory, the Messiah; in the tropological sense, grace; and analogically, beatitude, or the light of glory.

Mystical Poetry, which is a figurative mode of expressing the fervour of devotion, or the ardent love of created spirits towards their beneficent Creator, has prevailed from time immemorial in Asia; particularly among the Persian theologians, both ancient Huzhangis and modern Sufis, who seem to have borrowed it from the Indian philosophers of the Vedanta school (see Vedanta); and their doctrines are also believed to be the source of that sublime, but poetical, mythology, which glows and sparkles in the writings of the old academicians. (See Academics.) "Plato travelled into Italy and Egypt," says Claude Pleyry, "to learn the theology of the Pagans at its fountain head." Its true fountain, however, was neither in Italy nor in Egypt, (though considerable dreams of it had been conducted thither by Pythagoras, and by the family of Misra,) but in Persia or India, which is the fountain of the East, as it is the fountain of fpecies and felligens. (See Islamic Sci.) What the Grecian travellers learned among the fages of the East hath not been fully explained; but they seem to have adopted and introduced to their disciples a singular species of poetry, which consails almost wholly of a mystical religious allegory, though it appears, on a transient view, to contain only sentiments of a wild and voluptuous libertinism. Now, admitting the danger of a poetical fyle, in which the limits between fervice and enthusiasm are fo minute as to be hardly distinguishable, we must beware of conceiving it feverally, and must allow it to be natural, though a warm imagination may carry it to a culpable excess. An ardently grateful piety is congenial to the undepraved nature of man, whose mind, finking under the magnitude of the subjed, and struggling to express its emotions, has recourse to metaphors and allegories, which it sometimes extends beyond the bounds of cool reason, and often to the brink of absurdity. Passages might be selected from the eminent Dr. Barrow's sermon Of the Love of God; (Works, vol. i. ferm. xxiii.) bordering, indeed, on quizzum and enthusiastic elevation. The same spirit had diffused, in the mystical theology of the Sufis and Yogis, as the flowers and fruits of Europe differ in scent and flavour from those of Asia; or as European differs from African eloquence. The fame strain, in poetical measure, would rise up to the odes of Spenser, "On Divine Love and Beauty," and in a higher key, with richer embellishments, to the songs of Hafiz and Jâvâdeva, the raptures of the Misra, and the mysteries of Bhagavat. See Sufi, Yogi, Jâyadeva, Mesnevy, and Shi Bhagavat.

Another specimen of more modern date might be selected from a late work of the celebrated M. Necker, which would serve to exhibit the similarity of European theology to that of the Persians and Indians, but want of room obliges us to omit it.

If the passages to which we have referred were translated into Sanskrit and Persian, the Vedantis and Sufis would consider them as an epitome of their common fyllem; for they concur in thinking, that the souls of men differ infinitely in degree, but not at all in kind, from the divine spirit of which they are particles, and in which they will ultimately be absorbed; that the spirit of God pervades the universe, always immediately present to his work; and that the soul is perfect benevolence, perfect truth, perfect beauty; that the love of him alone is real and genuine love, while that of all other objects is absurd and illusory; that the beauties of nature are faint resemblances, like images in a mirror, of the divine charms; that from eternity without beginning to eternity without end, the supreme benevolence is occupied in bestowing happiness, or the means of attaining it; that men can only attain it by perforring their part of the primordial covenant between them and the Creator; that nothing has a pure absolute existence, but mind or spirit; that material substances, as the ignorant call them, are no more than gay pictures presented continually to our minds by the sempiternal artist; that we must beware of attachment to such phantoms, and attach ourselves exclusively to God, who truly exists in us, as we exist solely in him; that we retain, even in this forlorn state of separation from our beloved, the idea of heavenly beauty, and the remembrance of our primordial vows; that sweet music, gentle breezes, fragrant flowers, perpetually renew the primary idea, refresh our fading memory, and melt us with tender affections; that we must cherish those affections, and by abstracting our souls from vanity, that is, from all but God, approximate to his essence, in our final union with which will constitute our supreme beatitude.

If these principles flow a thousand metaphors and poetical figures, which abound in the sacred poems of the Persians and Hindoos, which seem to mean the same thing in substance, and differ only in expression, as their languages differ in idiom.

Some theologians have supposed, that the reciprocal love between pious men and their benevolent Creator, which Barrow describes with a glow of expression perfectly oriental, is that which our most orthodox theologians believe to have been mystically shadowed in the Song of Solomon, while they admit, that, in a literal sense, it is an epithalamium on the marriage of the sapat king with the princess of Egypt. The very learned author of the predictions on sacred poetry, declared his opinion that the canticles were founded on historical truth, but involved an allegory of that sort, which he named mystical; and the beautiful Persian poem on the loves of Laius and Majnun, by the inimitable Nizami, (to say nothing of other poems on the same subject,) is indisputably built on pure history, yet avowedly allegorical and mysterious, for the introduction to it is a continued rapture on divine love; and the name of Laius seems to be used in the Vedanta, and in the odes of Hafiz, for the omnipotent spirit of God.

It is still a question whether the poems of Hafiz must be taken in a literal or figurative sense; but the question does not admit of a general and direct answer; for even the most enthusiastic of his commentators allow that some of them are to be taken literally, and his editors ought to have distinguished them, as our Spenser has distinguished his four odes on Love and Beauty, instead of mixing the prose with the divine, by a childish arrangement according to the alphabetical order of the rhymes. Hafiz never pretended to more than human virtues, and it is known that he had human propensities, for some amorous frolics of his youth are on record, and are, indeed, alluded to in his odes. After his juvenile passions had subsided, we may suppose that his mind took that religious bent which appears in most of his compositions. Several ditties might be selected from different odes, that relate to the mystical theology of the Sufis, if it were consistent with the limits to which this article must be restricted.

A volume might be filled with passages of a similar kind to those that occur in the works of the writers already mentioned, from the Sufi poets; from Saib, Orf, Mir Khoit, Jami, Hozin, and Sabik, who are next in beauty of composition to Hafiz and Sadi, but next at a considerable distance from Mefti, the
the most elegant of their Turkish imitators; from a few Hindoo poets of their own times, and from Ibnub Fared, who wrote mythical odes in Arabic.

This notice of the mythical poets of the Asiatics, is taken from an essay on that subject in vol. iii. of the Aiat. Ref. by Sir W. Jones. It is introductory to a translation of the Gita Govinda, some account of which curious poem is given under Jayadeva, the name of its author. An extract from it is given under Krishna.

It is easier to account for the rhapsodies of the myths of the Ebl and Wel, than wholly to defend them. Some have doubtless derived spiritual consolation from such illusions, but a greater number must have been misled thereby to their own discomfort; and it might be, as well if such extacies were confined to the breech which engenders them. On the whole, such warmth of sentiement and expression appears not deserving of commendation; although, on the other hand, it seems not to require such forcible reprehension, as some of our pious divines have seen fit to stigmatize it with.

Dr. Watts, of whom Dr. Johnson said, "he was a man who never wrote but for a good purpose," acknowledges that in his early writings he gave into the track of those who express the fervours of devout love to our Saviour, in the style of the Song of Solomon; but in mature age he disapproved of it. But he did not, like some other well-meaning writers, apply to it such epithets as "secret pantings after mortal love"—"mythical disillusionest"—"spiritualized concupiscence, invented by carnal and wanton appetites, polluting the soul with lascivious images," &c. The middle course here, as in most other warmly contended points, seems the fadest.

We shall close this article with some judicious observations of an anonymous writer. (Quarterly Rev. No. x.) He describes mythical poetry to be that in which the various workings of the religious passion are typified by the hope and fears of an anatory attachment; a style of composition, which has, in all ages, captivated the luxurious imagination of Oriental rhapsodists. It is very possible for mythical poetry to be in fact, as it is in profession, devotional; but by many of those who have cultivated it, the veil of fancifulness, has unquestionably been employed, like the secrecy and seclusion of the ancient mysteries, only to conceal the indulgences which it was ostensibly designed to exclude. The hierophant has lighted his altar with fires, not only less holy than those of heaven, but less real than the chaste though cold flame of fancy: and for histories of devotion, in the disguise of love, have been substitutted histories of love in the disguise of devotion. If, in some cases, this abuse has been the effect of design, in others, the poet, instead of intending to deceive, has, in effect, deceived himself; and, perhaps, has been the only person deceived. On the whole, therefore, this is a style of which the general use can scarcely be encouraged; and, which, even where there exists the most unexceptionable purity of purpose, can be managed only by a firmness and delicacy of hand, rarely possessed in combination.

MYSTICETUS, in Zoology, a species of Balena; which see. The mysticus, or common whale, has the nostrils flexuous, or much contorted, and situated in the middle of the fore-part of the head, and the back without fin. Of this species there are the following varieties:—a. B. Mysticetus granoandica, or Greenland common whale, which is of a blackish colour on the back, and white on the belly:—b. B. Mysticetus islandica, or Iceland common whale, of a black colour with a whitish gloss:—γ. B. Mysticetus major, or larger common whale, which has no spiracle.

The common whale inhabits the Arctic seas, especially about Greenland and Spitzbergen: it is of enormous bulk, measuring from 50 or 60, to 70, 80, and even 100 feet in length: it swims with great velocity, and, yet, notwithstanding its immense size, having no weapons either of offence or defence, it is exceedingly shy and timid. It subsists chiefly on the cancer pedatus and oculatus, argonauta arctica, and cloo bitenculata: the second, or Iceland variety, which is smaller and more slender than the Greenland kind, feeds on medusa and clupeus. It is probable, that the description of the third variety, or larger common whale, as being without any spiracle, which is admitted by Ray, on the authority of Sibbald, is either totally erroneous, or founded on mistake, as it differs so completely from the general analogy of the whale genus, as well as from the whole cetaceous order. The female whale has two proportionally small paps situated on the abdomen near the vagina, which she has the power of retracting; she is supposed to go nine or ten months with young, and produces mostly one, seldom two, at a time, which she suckles and takes care of with great affection. The flesh of the whale is extremely dry and inapetent, except about the tail, which is more juicy, yet still very tafteless: between the skin and the flesh the whole body is surrounded with a vast layer of fat or blubber, of which 70 or 80 butts, or large barrels, are sometimes procured from one whale. Whales are hunted with great eagerness, on account of this blubber, for the sake of a coarse oil, which is extracted from it; and it appears that this trade was considerable in the time of Hidore and Vincentius, it being mentioned as common and very profitable on the French coast by Brito, a poet of the 12th century.

The horny lamina, which are found in the upper jaw of the whale, are likewise a valuable article of commerce, under the name of "whale-bone;" they, from frequent use, serving to catch the food of the animal, are split at the margin and the extremity into long, thick brittle; there are about 700 lamina of this substance in the mouth of each individual, and when the animal is full grown, the middle lamina, which is the longest, measures from eighteen to twenty feet in length.

The head of the common whale is nearly one-third part of the animal, being flat and on the upper part, and surmounted by a tubercle or projection, in which the spiracle, or breathing-pipe, is situated; the mouth is very large, and stretches far backwards, almost as far as the eyes, in form of the letter S; the lower jaw, especially about the middle, is very broad; the tongue is very soft, being composed almost entirely of fat; it is of a white colour, spotted with black at the sides, and adheres by its under surface to the lower jaw; the eyes are placed at a great distance from each other, on the sides of the head, over the entrance to the cars, and are very little larger than those of an ox; the skin is about an inch thick, and the scurf-skin about the thickmens of parchment: this latex is very smooth, seldom entirely black, or variegated with white and yellow; and very rarely of a white colour; the tail is horizontally flattened, and slightly divided into two lobes, from the middle of which a short, and somewhat sharp, angular ridge runs up to the middle of the back, but without any proper dorsal fin.

MYSTICS, Mystic, a kind of religious sect distinguished by their professing pure, sublime, and perfect devotion, with an entire disinterested love of God, free from all selfish considerations.

The Mylimics, to exclude their fanatic extacies, and licentious
tious extravagancies, allege that passage of St. Paul, "The Spirit prays in us by sighs and groans that are unutterable." Now, if the Spirit, say they, pray in us, we must resign ourselves to its motions, and be swayed and guided by its impulse, by remaining in a state of mere inaction.

Passive contemplation is that state of perfection to which the Mystics all aspire. See Quietism.

The authors of this mystic science, which sprung up towards the close of the second century, are not known; but the principles from which it was formed are manifest. Its first promoters argued from the known doctrine of the Platonic school, which was also adopted by Origen and his disciples, that the divine nature was diffused through all human souls, or that the faculty of reason, from which proceeded the health and vigour of the mind, was an emanation from God into the human soul, and comprehended in it the principles and elements of all truth, human and divine. They denied that men could, by labour or study, excite this celestial flame in their breasts; and, therefore, they disapproved highly of the attempts of those, who, by definitions, abstract theorems, and profound speculations, endeavoured to form distinct notions of truth, and to discover its hidden nature. On the contrary, they maintained that silence, tranquillity, repose, and solitude, accompanied with such acts as might tend to extenuate and exhaust the body, were the means by which the internal word was excited to produce its latent virtues, and to instruct men in the knowledge of divine things. For thus they reasoned; those who behold with a noble contempt all human affairs, who turn away their eyes from terrestrial vanities, and that all the avenues of the outward senses against the contagious influences of a material world, must necessarily return to God, when the spirit is thus diffengaged from the impediments that prevented that happy union. And in this blest frame they not only enjoy inexplicable raptures from their communion with the Supreme Being, but also are imbued with the ineffable privilege of contemplating truth undisguised and uncorrupted, in its native purity, while others behold it in a vittated and delusive form.

Towards the close of the fifth century, the Mystics, pretending to higher degrees of perfection than other Christians, drew every where to their party, particularly in the eastern provinces, a vast number of the ignorant and inconsiderate multitude, by the striking appearance of their singular and antie piety. It is impossible to describe the rigour and severity of the laws which these fanatics imposed upon themselves, in order, as they alleged, to appease the Deity, and to deliver the celestial spirit from the bondage of this mortal body. They not only lived among the wild beasts, but also lived after the manner of these savage animals; they ran naked through the lonely deserts with a furious aspect, and with all the agitations of madness and phrenzy; they prolonged the life of their emaciated bodies by the wretched nourishment of grafts and wild herbs, avoided the sight and conversation of men, retained motionless in certain places for several years, exposed to the rigour and inclemency of the seasons; and towards the conclusion of their lives, flut themselves up in narrow and miserable hut's; and all this they considered as true piety, the only acceptable method of worshipping the Deity, and rendering him propitious. The Mystics, for the most part, were led into the absurdities of this extraordinary discipline, not so much by the pretended force of reason and argument, as by a natural propensity to solitude, a gloomy and melancholy cast of mind, and an implicit and blind submission to the authority and example of others. For the defects of the mind, as well as those of the body, are generally contagious, and no pestilence spreads its infection with a more dreadful rapidity than superstition and enthusiasm. In the ninth century, the doctrine of the Mystics, the origin of which is falsely attributed to Dionysius the Areopagite, which had been for a long time in vogue among the Greeks, and especially among the monastic orders, was diffaminated in the western churches. The Latins had hitherto escaped the contagious influence of this doctrine: but when the Grecian emperor, Michael Balbus, or the Stammerer, sent to Louis the Debonnaire, in the year 824, a copy of the pretended works of Dionysius the Areopagite, now universally allowed to be spurious, even among the most learned and impartial of the Roman Catholic writers, this present kindled the flame of mysticism in the western provinces, and inspired the Latins with the most enthusiastic admiration of this new religion. The translation of these works into Latin, by order of the emperor Louis, contributed much to the progress of mysticism. By the order of the same emperor, Hilduin, abbot of St. Denys, composed an account of the life, actions, and writings of Dionysius, under the title of "Areopagita," in which work, among other impudent fictions, utiful in those times of superfluxion and imposture, he maintained, in order to exalt the honour of his nation, that Dionysius the Areopagite, and Dionysius, or St. Denys, the bishop of Paris, were one and the same person. This fable was received with avidity by the credulous multitude, and its credit is hardly extinct at this day. As the first translation of the works of Dionysius, that had been executed by order of Louis, was probably in a barbarous and obscene style, a new and more elegant one was executed by the famous Johannes Scotus Eriigena, at the request of Charles the Bald; the publication of which considerably increased the partisans of the mystic theology among the French, Italians, and Germans. Scotus himself, called "The Wife," was so enchanted with this new doctrine, that he incorporated it into his philosophical system, and upon all occasions, either accommodated his philosophy to it, or explained it according to the principles of his philosophy. Thus philosophical enthusiasm, born in the East, nourished by Plato, educated in Alexandria, matured in Asia, and adopted into the Greek church, found its way, under the pretext and authority of an apostolic name, into the western church, and there produced many injurious effects.

In the twelfth century, these mystics took the lead in their method of expounding Scripture; and by searching for mysteries and hidden meaning in the plainest expressions, forced the word of God into a conformity with their visionary doctrines, their enthusiastic feelings, and the system of discipline which they had drawn from the excursions of their irregular fancies. In the thirteenth century they were the most formidable antagonists of the schoolmen, who, as they were less popular, endeavoured to recommend themselves by extolling, illustrating, and defending the sentimental system of their adversaries; towards the close of the fourteenth century, many of them declined, and propagated their tenets almost in every part of Europe. They had, in the fifteenth century, many prelates of distinguished merit in their number: and in the sixteenth century, previous to the reformation, if any sparks of real piety fulfilled under the despotic empire of superstition, they were only to be found among the mystics. For this sect, renouncing the subtlety of the schools, the vain contentions of the learned, and all the acts and ceremonies of external worship, exhorted their followers to aim at nothing but internal sanctity of heart, and communion with God, the centre and source of holiness and perfection. Hence the mystics were loved and respected by many persons who had a serious sense of religion, and a devotional frame
frame of mind. Yet, as they were not entirely free from the reigning superftitions, but associated many vulgar errors with their practical directions and precepts; and as their excessive passion for contemplation led them into chimerical notions, and sometimes into a degree of fanaticism that approached to madness;—more effectual succeurs than theirs were necessary to combat the inverterate errors of the times, and to bring about the reformation which was expected with such impatience.

The principles of this sect were adopted by those called Quetskils in the sixteenth century; and, under different modifications, by the Quakers and Methodists. Mohn. Eccl. Hist. Brucker's Hist. Philos. by Enfield.

MYSTOCEROS, in Ichthyology, a name given by Geffen and some others, to that species of the silurus which we call the great-fish. It is the genus of Plisy, and the reef of the old authors; the silurus of Rondeletius, and others. It is distinguished by Ariscond by the name of the silurus with four heads under the chin. It is plainly to be known from the fish called the lake, by this character, that having only one beard; it is a genuine species of the silurus which see.

MYSTYRUM, among the Ancients, a liquid measure, which was the fourth part of the cyathus.

It weighed about two drams and a half of oil; and of water or wine, two drams two scruples. It was much about our small spoonful.

MYSTUS, in Ichthyology, a species of Glipea; which see.

MYSTUS Fluviatilis, a name by which some writers, particularly Bellonius, have called the common barbel. See Cyprinus Barbula.

MYSTUS Marinus, the Sea-barbel, the name of a fish caught in the Adriatic, and common in the markets of Venice. It is of an oblong figure, and in colour of a flivery-white, variegated on each side with ten obliquely transverse black lines; its belly is very white; its tail is forked, and its head long; its back has part of its rays prickly, part soft to the touch; its eyes are not large, and their irises are yellow; its lips are prominent, thick, and soft, and only ferrated in the place of teeth; but in the hinder part of its mouth has several rows of short and large molaries or grinders; its scales are large, and adhere firmly to the flesh. It is a very well-tailed fish.

MYSTUS Nileicus, a name given by Bellonius to a fish of the barbel kind, caught in the Nile. Its body is thick and short, and its belly very broad; it grows to a large size as to weigh twenty pounds. Probably this may be no other than the common barbel growing to a larger size, as we see many fish in some places more than others. See Silius Mylius. For other species of mylius, see Silius.

MYSZ, in Geography, a town of Lithuania, in the palatinate of Novogrudek; 36 miles S. of Novogrudek.

MYTACISM, МУТНИЗМУ, in Rhétoric, the too frequent repetition of the latter M; thus, mannam ipsem amque meam animam.

MYTENS, Daniel, of the Hague, in Biography, was an admired painter in the reign of James I and Charles I. to the latter of whom he was made picture-drawer in ordinary, in May 1625. He continued to hold this station at the arrival of Vandyke in England; but upon that artist being made principal painter to his majesty, he asked leave to retire. The king, however, retained him for some time longer in his service, and the two rivals, if they may be so called, lived amicably together. Mytens faw and acknowledged the high degree of Vandyke's talents, and benefited by the observance of his productions.

There are a great many excellent portraits by Mytens in this country, which are distinguishable by the neat smoothness, and clearness of their finishing; and their great air of nature. We have none of his pictures painted after 1630. The period of his death is not exactly known.

MYTHOLOGY, ΜΥΘΟΛΟΓΙΑ, signifying a discourse or description of fables, from μῦθος, fabula, and λογία, discours, the history of the fabulous gods and heroes of antiquity; with the explanation of the mysteries or allegories couched under it.

Lord Bacon thinks that a great deal of concealed instruction and allegory was originally intended in most parts of the ancient mythology; he observes that some fables discover a great and evident limititude, relation, and connection, with the thing they signify, as well in the structure of the fable as in the meaning of the names, whereby the persons or actors are characterized.

The same writer thinks it may pass for a farther indication of a concealed and secret meaning, that some of these fables are fo absurd and idle in their narration, as to shew an allegory even afar off; but the argument of most weight is, that many of these fables appear by no means to have been invented by the persons who relate them: he looks on them not as the product of the age, nor the invention of the poets, but as sacred relics as he terms them, gentle whitewash, and the breath of better times, that from the tradition of more ancient nations, came at length into the flutes and trumpets of the Greeks. He concludes, that the knowledge of the early ages was either great or happy: great, if they by design made this use of trope and figure; or happy, if, whilst they had other views, they afforded matter and occasion to such noble contemplations.

Mythology, which leads us into an acquaintance with the gods and fables of ancient times and remote nations, is of such importance, that notwithstanding the obscurity and uncertainty in which it is involved, and the scope which it affords for conjectures and differences of opinion, that the study of it cannot be wholly disregarded; more especially by persons who peruse the writings of the Greeks and Romans, and particularly those of their most celebrated poets. It likewise bears relation to various branches of literature and science; and will be a means to guide and affilit the researches of historians, antiquarians, and of artists of various descriptions. Whilst the classical scholar finds it necessary to acquaint himself with the Pagan gods and fables, the fictions of antiquity, and the numerous monuments that record them, daily examined, will serve to amuse and instruct those who investigate them; and mythology will thus subserve many useful purposes in chronology, history, sculpture, painting, and other arts and sciences. It will require, indeed, a considerable share of judgment to guard against delusion, correctly to interpret the fables that present themselves, and to form a just opinion of the rank, attributes, and character, as well as of the number and variety, of the deities which were acknowledged as such in different ages and nations. Mythology has additional claims on our attention, if we allow, with some writers, that the fables of antiquity are not mere fictions, but that they have a real connection with the history of the first ages; and comprehended some of their most considerable transactions; and that most of the gods had been men, whose history forms a part of that of the particular nations in which they became objects of veneration, and even of worship. As fables contribute the proper subjects of mythology, it may not be amiss to introduce in this place a few remarks on their origin, nature, and design, and the proper method of explaining them. Simple and unornamented truth, addressed merely
merely to the understanding, is seldom sufficiently interesting and impressive to engage the attention of mankind. Philosophers, historians, and poets have, therefore, recurring, in all ages of the world, to those embellishments, which the imagination supplies, and which are adapted to excite and call forth into exercise the feelings and passions of the human frame. Hence they have been led to use forms and modes of expression that have been specious to them, either by possible objects, or by circumstances that are rare and uncommon, and that serve to excite admiration, and to impart amusement and pleasure. Fables are compositions of this kind: they are more easily understood, more likely to command attention and to impress the mind, and better fitted for conviction and persuasion, than abstract truth; and therefore they have been more generally adopted, especially in the earlier periods of time, and in a less cultivated state of society than mere reason. Among the orientals, whose climate and disposition were peculiarly favorable to it, this practice very much prevailed; and of course their mythology has been distinguished by its boldness and extravagance. Some other circumstances contributed to the first rise, and subsequent diffusion of mythology. The inhabitants of the eastern nations were much addicted to the personification of inanimate objects, and abstract ideas; and this propensity would naturally lead them to the use of fable and allegory. Among all the hieroglyphics and enigmatical modes of expression were very common; and in the adoption of these they nearly approximated to fiction and fable. Among ingenious and learned writers, we find a considerable difference of opinion as to the best method of explaining those fables, that are the subjects of this article, or such as relate to the Pagan gods, and the rites of their worship. The Platonic philosophers pretended that these fables were mere allegories, concealing great mysteries, none of which would appear either absurd or licentious, when duly developed. Plato himself seems to have originally framed this fable. Other learned persons, at a later period, among whom we may reckon Kircher, recur for the investigation of the true meaning of those fables to the hieroglyphics, or sacred language, of the Egyptians; but it is unfortunate for his hypothesis, that the fables which require explanation were not all of Egyptian origin. The celebrated Bochart thought that most of the fables might be explained by the equivocal words of the ancient Phenician language; the fables, however, were not all invented by the Phenicians. Others refer all the fables to scripture misunderstandings, or to corrupted traditions. But many of these fables abound with circumstances that have no manner of connexion with the facts recorded in the sacred books. The fable of those who reduce fables to ancient history, though disfigured by the poets, who were the first historians, serves to explain a great number of fables, though it is not practicable to reduce all to history; since some fables are no more than pure allegories. Nevertheless, this fable appears to M. Banier, under some restrictions, to be the most rational and most satisfactory; provided that we do not attempt to explain all the circumstances of every fable; and if we do explain them, we must take them from poets of the greatest antiquity, such as Homer and Hesiod, who have given them in a more simple state, together with a more natural description of the facts to which they refer, and without those ornaments that were superadded to them in after ages, either to make them more venerable, because they were a part of religion, or more surprising, because it is natural for mankind to delight in the marvellous.

We may here observe, that most of the Greek fables are obtained from Egypt and Phenicia. The fables are interwoven with religion, and were, indeed, the foundation on which it was reared; it was fable that introduced a multiplicity of gods, which they fabricated in the room of the true one; so that the Greeks, by learning the religion of the Egyptians, learned their fables likewise.

The learned Bryant, in the preface to his "Analysis of Ancient Mythology," rejects as fabulous the supposed heroes of the first ages in every country. No such conquests, he says, were ever achieved, as are ascribed to Orpheus, Dionysus, and Sotades. The histories of Hercules and Perseus are equally void of truth. Cadmus, as this writer affirms, never brought letters into Greece, and no such person ever existed as the Grecians have described. Ninus and Semiramis are, in his opinion, as ideal as Sotades and Orpheus. Never there were such expeditions undertaken, or conquests made, as are attributed to these princes; nor were any such empires constituted as are supposed to have been established by them. He makes as little account of the histories of Saturn, Janus, Pelops, Atlas, Dardanus, Minos of Crete, and Zoroaster of Bactria. With respect to Greece, our author gives credit to very few events, which were antecedent to the Olympiads; nor does he give the least attention to the story of Puryxus, and the golden fleece. He denies that there were any such persons as the Grecian argonauts, and he rejects the expedition of Jason to Colchis as a fable.

As the theology and mythology of the ancients are inseparably connected, we refer for an account of both to the article THEOLOGY; and for the mythology of different nations to their respective articles. See CHALDEAN PHILOSOPHY, CILTS AND DRUIDS, HINDOOS, and the next article.

Theology of the Hindoos. With this people mythology is so intimately blended in all their writings, that unless the student hath some information on that point, he will be continually at a loss in comprehending the allusions so frequently recurring. The whole of their popular religion, their history, and literature in general, even the sciences and mechanical arts, are buried in a mass of mythological allegory. It is, indeed, all-pervading; and if we deem it worth while, as it surely is, to examine the stories of Indian learning, a knowledge of its mythology is no less necessary than a knowledge of its languages. One cannot indeed be acquired, without acquiring, at the same time, some knowledge of the other. This has been so much felt, that our most celebrated Oriental scholars have profitably employed themselves in the investigation of this curious and comprehensive subject. It affords also considerable elucidations of the primeval traditions of the human race. It illustrates what is extant, and faggots some parts of what is lost in the history of almost every nation of antiquity. The analogy between the Hindoo, and Grecian and Roman mythology, has been copiously developed by Sir W. Jones, Mr. Colebrooke, major Wilford, and other writers in the different volumes of the Asiatic Researches. Coincidences too strong and numerous to be accidental may be traced in the fabulous histories of India, Egypt, and Peru: the two latter, probably, being the intermediate countries through which the stream of allegory flowed to Greece, Rome, and to the Gothic and other nations of Europe; among all of whom a similarity of tradition and popular superstition is found to have prevailed. Even in Ireland, some amusing inferences of relationship have been discovered. Which is the parent country of these widely spread impressions, is not altogether agreed on. India seems to have strong claims to this honour, such as it is,
and it is accordingly strongly claimed for her. The mode and course of their propagation still afford farther scope for the industry of research, and the exertion of analogical deduction.

Among the many writers who have discussed the subject of this article, we may notice the Rev. Mr. Mau-; who, in his Indian Antiquities, and Ancient History of India, has brought together many coincidences of opinion in different nations, and discussed them learnedly and at length. Sonnerat and Bartolemo, not to mention Baldeus and other early Roman travellers, have entered pretty fully into the popular legends of Indian mythology; and the Hindoos, recently published, contains a great number of exact representations of the deities, personifications, and symbols, with descriptive illustrations, of this superstitious polytheism. But it is in the Asiatic Researches, that we are still to look for the most satisfactory and authentic developments of this interesting subject.

The system of the Hindoos forms a series of endless personifications, and the invention rather of poets than of priests; but in early ages the poet and the priest were, perhaps, generally combined. It has animated all nature. It has peopled the heavens, the air, the earth, and waters, with innumerable tribes of imaginary beings, arrayed in tints corresponding with the fervid imagination of tropical climates; and we are disposed to contemplate Hindoo mythology as a well-stored magazine, whose poets may supply themselves with an almost infinity of imagery and incident.

In this work we have availed ourselves of the labours of those, who have written on the affairs of India, as well as of some sources of original information; and in reference more particularly to its mythology, we have given, or shall give, under their appropriate names and heads, an account of some hundreds of Hindoo deities, or personifications of attributes and powers; as well as sketches of their religion, literature, &c. Such articles are too numerous to be referred to at length, they amount indeed to several hundreds; but a few here follow, and references are made from them to many others. See Brachilians, Casts, Hindoos, Hindoostan, Ganges, Jagannath, Jaina, Jumry, India, Kali, Kama, Krishna, Lakshmi, Linga, Mahabarat, Matri, Maya, Meru, Narayana, O'm, Parkavi, Pavana, Purana, Rama, Saraswati, Siva, Surya, Thirumurti, Vishnu, Yama, &c. &c.

**MYSILUS**, the Mussel, or Mufcle, in Conchology, a genus of the class and order Menves-tellacea; the generic character is this; the animal is allied to an afedea; the shell is bivalve, rough, generally affixed by a byflus or bed of silky filaments; the hinge is moist without teeth, with generally a subulate excavated longitudinal line. There are about forty-four species included in this genus, separated into three distinct families or diviisions.

A. Paraphysal; affixed as it were by Claws.

**Specie**.

**Crista-galli**. Shell plaited, spicous; both lips rough. It inhabits the Indian ocean and Red sea, and is affixed to the gorgonia; the shell is of a purple-violet, pale cinnamon or bay, rough, raised with dots; within of a honey colour; nearly oval, and closed with from five to ten oblique or straight acute plates; at the hinge it is triangular.

**Hyotis**. Shell plaited and imbricate, with broad compressed scales; both lips smooth. This species inhabits the ocean, on beds of coral; the shell is of a dirty-greenish-yellow, lamellate, the plates curved here and there, and befet with hollow grooved nuclei.

**FRONS.** Shell plaited, smoothish; one lip rough. It inhabits the American ocean, on coral beds; the shell is reddish, blueish, or brown, generally oval, with the margin plaited on each side, and denticulate; the lower valve is glabrous, and grooved in the middle; the upper valve is rough, with raised dots at the margin, and an elevated rib in the middle.

B. Flat or compressed into a flattened form, and slightly eared.

**Species**.

**Margaritiferus**; Pearl Mufcle. Shell flattened, nearly orbicular, with a transverse bafe, imbricate with toothed tunicas. It is found in the American and Indian seas, is about eight inches long, and still broader than it is long. The inside is beautifully polished, produces the true mother-of-pearl, and frequently the most valuable pearls; the outside is sometimes tea-green or chefnut, or bloom colour, with white rays; when the outer coat is removed, it has the fame perlaceous luteo in the inside; the younger shells have ears as long as the shell of the scallops.

**UNGIS.** Shell longitudinally riferate, pellucid and slightly eared. This species inhabits the Mediterranean; the shell is thin and hyaline, with very fine perpendicular frize about the size of a man's nail; some perils imagine that this is a species of the genus Ophrea, which fee.

C. Ventriotes or convex.

**Lithophages.** Shell cylindrical, rounded at both ends. It inhabits European, American, and Indian seas, penetrating and eating away corals, rocks, and even the hardest marbles; it is about an inch broad, and three inches long, marked with arched transverse frize; the shell is dark blue, with a greenish tint, but within it is opal-blue, filvery-white, or perlaceous. The European specimens have a thin brittle shell; the Indian ones are softer, and nearly coriaceous.

**Rugosus.** The shell of this species is rhombic oval, brittle, rugged, antiquated, and rounded at the ends. It inhabits the northern seas and lakes, and is usally found lodged in great numbers in lime-flone, each in a separate apartment, with apertures to small for the shell to pass through without breaking the fiones; the shell is about the size of the half joint of a man's little finger; its colour is of a dirty grey, and within it is half blue and half white, marked with very small longitudinal frize croling the transverse wrinkles.

**Bilocularis.** Shell blue fricate, with vaulted knobs and a white diffiicent or partition. It inhabits the Nicobar islands, and is covered with a green skin.

**Exustus.** Shell convex, one of the margins angular; the frontal extremity erenate. This species is found in the American ocean, and in the Red sea; it is about an inch and a half long, and has a hinge with four or five lateral teeth.

**Barbatus.** Shell smoothish, frragious on the outside, and beared at the tip. It inhabits the Mediterranean seas, adering to the lithophytes; is about three quarters of an inch long, and under the skin it is reddish-furfinous, blue, or whitish.

**Edulis; Edible Mufcle.** Shell smoothish violet, the valves slightly recurved on the obtuse side, and somewhat angular on the acute side; the beaks are pointed. It inhabits the European and Indian seas; is two or three inches long, but larger within the tropics, and smaller as we proceed northward. Found in large beds, and generally adhering to other bodies, by means of a long silky beard.

**Incur-
MYTILUS.

*Incurvatus.* The shell of this species is very crooked on one side near the beaks, then greatly dilated; within it is marked with a violet tinge. Found on the Anglesea coast; the shell is covered with a thick rough fin.

*Pellucidus.* Shell oval, transparent, and very elegantly radiate lengthways with purple and blue. This, like the last, is found at Anglesea, in oyster beds, and is about two inches long.

*Umbilicus.* Shell contracted into a deep rugged cavity opposite the hinge, forming a deep hollow when the valves are closed. It is found at Anglesea, and is nearly five inches long; the shell is oval, resembling the M. modiolus, described farther on, but it is distinguished by the remarkable indentation near the beaks.

*Curtus.* Shell short, ventricose, obtuse at the beaks, and of a dirty yellow. It is found at Weymouth.

*Ungulatus.* The shell of this species is smooth and slightly curved; hind-margin inflected; hinge terminal and two-toothed. It inhabits the Mediterranean and Cape of Good Hope. There is a variety of this species found at New Zealand, which resembles the M. edulis, but is full five inches long, and two inches and a half broad; the valves are very convex, inflected without the hinge of an ox.

*Bidentis.* Shell flat, slightly curved, the hind margin inflected; the hinge terminal and two-toothed. It inhabits the Mediterranean, Ethiopian, Atlantic, and Magellanic seas.

*Modiolus.* Shell smooth and blackish, obtuse at the smaller end, and rounded at the other, one side near the beaks is angular. Two varieties are noticed by Linnaeus. It inhabits the European, American, and Indian seas, adhering to fucis and zoophytes; is fixed in thick growths, and about half as broad; the shell is red or orange, and eatable.

*Cygneus.* Shell ovate, very brittle, and transversely wrinkled; the anterior end compressed; the other rounded, the hinge terminal. Two varieties of this species are noticed by Linnaeus. It is frequently found in rivers and ponds; is about two or three inches broad and three inches long; the shell is deep, and within it is white, opaque, and often rough with small pearls.

*Anatina.* Duck Mussel. The shell of this species is oval; a little compressed, very brittle and semi-transparent, with a membranaceous margin; the beaks are decicuated. It inhabits the fresh waters of Great Britain, and of other parts of Europe; it is about five inches long, and half as broad. Ducks and crows are extremely fond of this species, and of the M. cygneus, and the crows, when the shell is too hard for their bills, fly up with it to a great height, drop the shell on a rock, and pick out the meat after the shell is thus broken.

*Viridis.* Shell smooth, ovate, membranaceous, and pellicid, with a terminal hinge. It inhabits the Southern ocean; the shell is green, very thin, and about the size of a man's nail.

*Rubra.* Shell wrinkled, the valves oblique and dilated in front; margin of the hinge equalising the tip. It inhabits the Southern ocean. The shell is red and convex, but very minute, with a short compressed tooth in the hinge.

*Albus.* Shell transversely flat; beaks gibbous; hinge lateral. It inhabits the shores of Chili. The shell is about six inches long and three and a half broad, covered with a blue skin, under which it is snowy, with a blue tinge; the fish is white, and very excellent food.

*Ater.* Shell grooved and scaly behind. It inhabits Chili; shell rough, like a penna, less than the last, dull blue; the fish is black and not eatable.

*Discors.* Shell oval, horny, sub-diaphanous; the extremities are fiatrate longitudinally, the middle transversely. This species is found in the European and Southern oceans, affixed to rocks and other shells by its beard; the shell is small, brittle, and semi-transparent; the fish is not eatable.

*Hirundo.* The shell of this species is smooth; the valves are two-lobed. It inhabits the Indian, American, Mediterranean, and Atlantic seas, in great varieties of size, thickness, form, colour, and markings; the shell is contracted at the base, with very fine and crowded transversal wrinkles; within pearly.

*Philaenis.* Shell oblong, more obtuse on the fore-part, rough, with transverse wrinkles. It inhabits the North seas, and penetrates beds of coral and rocks, like the phlosis; which is. It is about 1 1/2 inch long, and 1 1/4 broad; the ends are not quite closed; the hinge is without teeth, or with a very small one.

*Striatulus.* The shell of this species is very finely fiatrate; the hinge is terminal, and one-toothed. It inhabits the Northern and Indian seas; is 1 1/2 inch long, and 1 1/4 broad.

*Vulgaris.* Shell flat, on one side, and inflected, with convergent incurved beaks; the hinge is one-toothed. It inhabits the American ocean.

*Placatus.* Shell rhombic, transversely fiatrate and wrinkled; beaks incurved. It inhabits the Nicobar islands.

*Niveus.* Shell ovate, sub-diaphanous, with very fine longitudinal tinge; margin acute; hinge two-toothed. Inhabitats the Nicobar islands, but is very rare.

*Smagadinus.* The shell of this species is nearly triangular and flat; the hinge is two-toothed in one valve, and one-toothed in the other. It inhabits Tranquebar, is green, and a little percarose within. There is a variety of this species found in Guinea; brown, with a green margin, and sometimes a few spots on the disk.

*Versicolor.* Shell nearly triangular and flat; the hinge is one-toothed; the margin glabrous and acute. This is found on the shores of Guinea; resembles the M. aser, is three inches long, and more than two broad.

*Coralliphagus.* The shell is carinate in the middle, and crenate at the margin, with an obtuse knob. It inhabits the Indian and American oceans, and perforates rocks like the phlosis; it is about 3/8ths of an inch long.

*Lineatura.* Shell triangular, and dilated outwards, with angular asdiculate and coniculated lines; the hinge is one-toothed. It is a very minute shell, yellow, with a mixture of green, and within it is a little fibres.

*Faba.* The shell of this is oval, rufous, fiatrate, with a crenulate margin. Inhabitats the seas about Greenland, affixed to rocks by a hyfus or beard, and is the food of the Anas hyemalis, or hyfornica.

*Fluvialitis.* Shell thin, slightly wedged, within reddish; beaks recurved and large. It inhabits the fresh waters of Europe; resembles the M. anatina, and is thought to be a variety of the same species.

*Fusus.* Shell oblong, narrow, with very fine transverse tinge; one side emarginate, the other rounded; beaks prominent, and curved.

*Mammarius.* Shell broad, short, and rounded behind; beaks conic, protuberant.

*Percius.* Shell broad, and covered with a rough yellow coat; within it is milky. It inhabits the Perhau sea, and is thicker as broad as it is long.

*Pictus.* Shell broad and very smooth; flammeous or rofe colour, with white bands; the beaks are obtuse. It inhabits Portugal, and, like the last, is thicker as broad as it is long.
Fasciatus. Shell pellucid, shining, blueish, with a claret colour, and pale red bands. It inhabits the Brasils, and is about twice as broad as it is long.

Unica. Shell broad, and rounded at both ends, claret colour, with undulate blue sheen and greenish tigris; margin serrate. It inhabits the sea about Portugal.

Purpureus. Shell rounded behind; pale flesh colour, purple within, the margin denticulate. It inhabits the shores of Brazil.

Saxatilis. Shell ear-shaped, with granulate wrinkles on the outer side dilated and rounded. It inhabits Ambonya, is fixed to rocks, and is eaten by ducks and swine; it is shorter and broader than the joint of the finger.

Argentinus. Shell transversely irrate, rounded at each end, brown, silvery within; beaks rounded.

Fulgida. Shell narrow, shining, blueish colour, with violet spots at the sides; the beaks are rounded and dilated. It inhabits the seas of Magellan, and thins like mother-of-pearl.

Azurus. Shell gibbous, azure, with yellowish stripes beneath; beaks obtuse.

Murinus. Shell mouse colour, with violet spots, and a broad rounded rosy margin; beaks pointed, straight. Inhabits Girmania.

Testaceus. Shell long and narrow, covered with a tubercular skin, under which it is shining-silvery, varied with blue, red, yellow, and brown.

Virgatus. Shell dilated outwardly, greenish-yellow, with rosy stripes; the beaks are obtuse and curved.

Cordatus. Shell oblong, very thin, white, with oblong oblique tigris; with a heart-shaped gape behind. It inhabits the Indian and Southern oceans, adhering to corals, and marine substances.

Stagnalis. Shell oval, flat, and transversely ribbed; it resembles M. Cygnus, but is eight inches broad, and four and a half long.

Zeillensis. Shell oval, convex, rounded behind, elongated and obtusely pointed before; the beaks are oblique. It inhabits the flagrant waters of Germany.

Roseus. Shell suborbicular, with fifteen triangular crested grooves, and alternate triangular teeth. It inhabits Africa.

Punicus. Shell gibbous, pointed, with fifteen grooves; margin toothed. Inhabits Africa.

Mycus. Shell flat and thin, with fine grooves; covered with a black skin, under which it is milky, and finely polished. Found also in Africa. The shell is very thin, is about an inch and half long, and has about 120 grooves in it.

Legatus. Shell flat and smooth, covered with a thick fleshy skin, under which it is rosy. It is found in Africa.

Durius. Shell transversely wrinkled, obtuse at each end, fleshy, within pearly; the beaks are oblong, and the hinge is without teeth. It inhabits the fresh waters of Senegal, is five inches broad and two long.

Polymorphius. Shell five-celled; valves carinate and flatish on the incumbent side; the beaks are oblong and inflated.

Caniculatus. Shell smoothish, chestnut-brown; within partly-coloured;ocket of the hinge canaliculate. It inhabits New Zealand.

Rostrum. Shell oblong, thin, greenish, truncate; beaks sharp and carinate; valves gaping at the end. Habits Ambonya.

Camelli. Shell oblong, thin, greenish, truncate; beaks thin and crested; valves completely closed. It is found at Japan.

Mytis, a name used by some writers to express the black place found in the mouth of the sepias, or cuttle-fish, with which it colours the water when in danger of being taken, and by this means often makes its escape. It is also used by Hippocrates as the name of a sea-fish different from the sepia.

Mytoton, a word used by the ancients to express a mixed sort of country food, made of garlic, onions, eggs, cheese, oil, and vinegar. It was much eaten by the labouring people among the ancients, and accounted a very wholesome dish.

Myurus, Myurus, in Medicine, denotes a pulse which is continually weakened by insensible degrees, so that the second beat is fainter than the first, the third than the second, &c. See Pulse.

The word is compounded of μῦρος, mouse, and τόος, tail; the diminution of the pulse being supposed like that of the thickened tail of that animal, which grows less from the root to the tip.

Myus, or Myxone, in Ancient Geography, a town of Caria, which had an excellent sea-port at the mouth of the river Meander; but in a course of years the mouth of the river was so filled up, that the town was about three leagues from the sea. It was situated N.E. of Miletus, and S.E. of Priene. The Greeks took possession of this town on their arrival in Ionia; and it became the fort of their other colonies. Artaxerxes Longimanus gave it to Themistocles, in order to furnish his table with meat. When the entrance of the gulf of Latmus was filled up, the waters formed a lake, which produced such a number of insects, that the inhabitants abandoned the place, and retired to Miletus. Paeanias says, that in his time there existed a marble temple of Bacchus in this town.

Myutes Lapis, in Natural History, a name given by some authors to a fleshy body, part of an afterpodium, which they have thought in single joints somewhat resembled the ears of a mouse.

Myxa, in Botany, a sort of plum, which Pinny fays grew in Syria, near Damascus, and that a kind of wine was made from this fruit in Egypt. The Venetians appear to have introduced these plums, in a dried state, from Alexandria to Europe, and they found their way into the apothecaries' shops, as a gentle purgative medicine. The Alexandrian bird-lime, as the Venetians termed it, was made of this fruit. See Conope.

Myxine, the Hag, in Natural History, a genus of the class and order Vermes intellis. Its generic character is this: it has a slender body, carinated beneath; the mouth is at the extremity, and serrated; the two jaws are pinacated; it has an adnate or rayless fin round the tail and under the belly. There is but a single species.

Glutinosa. This is about eight inches long. It inhabits the ocean; enters the mouths of fishes, and totally devour the whole, excepting the skin and bones. There has been attributed to it the property of changing water into glue.

Myxolydian, in Ancient Music, the first species of the diapason.

Myxon, in Ichthyology, the name of a fish of the mullet kind, called by others baculus.

It much resembles the common mullet; but its head is less pointed, and its body is covered, beside the scales, with a mucous matter; it has a remarkable irregularity in the manner of its swimming, and looks red about the lips and covering of the gills.

Myxosarcina, from μῦχος, mucus, and σάρκας, flesh, in Surgery, a tumour, composed partly of a fleshy sub stance, and partly of a matter like mucus.
N.

NAA

A liquid consonant, or semi-vowel, and the thirteenth letter of the Greek, Latin, English, &c. alphabets.

The N is a nasal consonant; its sound is that of a d, puffed through the nose: so that when the nose is stopped by a cold, or the like, it is usual to pronounce d for n. M. l'Abbe de Dangeau observes, that in the French the n is frequently a mere nasal vowel, without any thing of the sound of a consonant in it. He calls it the Sclavonic vowel.

The Hebrews call their N, Nám, which signifies child, as being supposed the offspring of M; partly on account of the resemblance of sound, and partly that of the figure. Thus from the m, by omitting the last column, is formed n: and thus from the capital N, by omitting the first column, is formed the Greek minufene n. Hence, for Byzantium, &c. the Latins frequently use Bínœs, &c. and the same people convert the Greek, at the end of a word into an m; as, Αργυρός, pharmaceut. &c. See M.

N before p, b, and m, the Latins change into m, and frequently into l and r, as in ludus, illudus; in rigo, irigo, &c. in which they agree with the Hebrews, who, in lieu of nun, frequently double the following consonant; and the Greeks do the same, as when for Μαντιος, they write Μάλιος, &c.

The Greeks, also, before r, γ, χ, θ, changed the ρ into ρ: in which they were followed by the ancient Romans, who for Angulus wrote Angulus; for aonps, aonpes, &c. The Latins retained the a from Greek nouns ending in α: as λακα, λακη, Δρακο, Draco. On the contrary, the Greeks add it to the Latin ones ending in a: as Κατα, Ναντι, for Cato, Nero.

In English, N has an invariable sound: as no, name, &c. After m it is sometimes almo bft, as condemn, &c.

N, among the Ancients, was a numeral letter, signifying 900; according to the verse in Aenianus,

"N quoque nongentos numero defignat havendos."

And when a line was struck over it, N, nine thousand.

Among the ancient lawyers, N, L, stood for non liquet, i.e. the cause is not clear enough to pass sentence upon. N. P. was used among the Romans for notarius publicus. N. C. for Nerio Caesar, or Nero Claudius. N. B. is used for Nota bine. In marine language, N stands for north.

N, or Nth, in Commerce, &c. is used as an abbreviation of numero, number. Thus also, in Medicine, carvophyllum N vij, signifies six clowers. N on the Greek coins, denotes thefourth struck at Montpelier.

NAAGRAMMA, in Ancient Geography, a town of India, on the Ganges, placed by Ptolemy between Budaia and Camigera.

NAAGRAMMUM, the metropolis of the island of Taprobana, which Ptolemy places in the interior of the country between Anurogrammum and Adisamum.

NAAM, or NAM, Namium, in Law, the taking or distraining another man's moveable goods. This is either lawful or unlawful and prohibited.

NAAM, Lawful, is a reasonable diffus, proportionable to the value of the thing distrained for; and it is therefore called either vius or morti, as it was made of quick, or dead chattel.

Lawful Naam is to either by the common law; when a man takes another's beasts doing damage in his ground; or by a man's particular fact, as on account of home contract, &c.

NAAM, Unlawful, vetitum namium. See Namium.

NAAMAN, in Geography, a small island in the Red sea. N. lat. 36°. E. long. 35° 30'.

NAAMAN'S GREEK, a small stream of America, in Pennsylvania, which runs south-easterly into Delaware river, at Marcus's hook.

NAAMANISH, a town of the Arabian Irak, on the Tigris: 18 miles N. of Vafit.

NAARDEN, or NAARDE, a sea-port town of Holland, situated at the S. part of the Zuyder see. It is the capital of a small country called "Goyland," which includes Naarden, Muyden, and Wesp, with 16 villages. This town has undergone many vicissitudes from the time of its being first built in 1566 to the period of its capture by the French in 1795: 11 miles E. of Amsterdam. N. lat. 52° 23'. N. long. 5° 2'.

NAAS, a market and post-town of Ireland, in the county of Kildare and province of Leinster. It was a borough before the union, and is now the affize town of the county, but is small and of little importance. The county gaol and the assizes house are here, and during the civil wars it was a strong hold. It was anciently the residence of the kings of Leinster, and several parliaments were held here after the establishment of the English. There were also three market days, some of the ruins of which are still visible. Naas is 15 1/2 miles S.W. from Dublin on the Great Southern road.

NAAS, a town of Sweden, in Dalecarlia; 34 miles S.W. of Falun.

NAB, a river of Bavaria, which rises from mount Hochtelberg, in the principality of Bayreuth, and runs into the Danube, 4 miles W. of Ratisbon.

NAB's BAY, a bay on the W. part of Hudson's bay, N. of cape Elginmaux.

NABAGANA, a river of Africa, which runs into the Indian sea, S. lat. 29° 30'.

NABAL, a town of Africa, in the country of Tunis, on the S. side of the peninsula of Dakhul, in the bay of Hamam-et.
Hamam-et. According to Dr. Shaw, the town is thriving and celebrated for its potteries. It is about a mile distant from the sea, and about a furlong W. of the ancient city of Neapolis; 10 miles N. of Hamam-et. N. lat. 36° 20'. E. long. 10° 45'.

NABALIÁA, a small island of Egypt, in lake Menzaleh; three miles S. of Tennis.

NABAN, a town of Egypt, on the left-bank of the Nile; five miles S.S.W. of Benifuef.—Alfo, a town of Arabia, in the province of Oman; 168 miles W. of Julfar.—Alfo, a town of Peria, called "Nabend," in the province of Lariitan, near the gulf; 76 miles W. of Lar. N. lat. 27° 30'. E. long. 52° 20'.

NABARI, a town of Japan, in the island of Niphon; 15 miles S. of Iga.

NABATHÉA PETRA, in Ancient Geography, a town of Arabia, according to Strabo; who places it between the Arabian gulf and Babylonia. This is the town mentioned by Ptolemy, under the name of Petra, in Arabia Petrea.

NABATHÉA SILIQUA, in the Materia Medica, a name given by the interpreters of Avicenna, and other of the Arabian physicians, to the jambot, or aljambot, of those authors.

It appears, from the accounts they have given of this drug, that it was a long and slender pod, produced on a thorny tree. It has been generally supposed to be the same with the carob, or siliqua dulcis, but very erroneously. The same authors who mention this aljambot, or nabathéea filiqua, mention that also under the name of the alnabati, or Syrian filiqua, as it is interpreted.

The Syrian filiqua, they say, purges, and is good in colics.

The nabathæan they recommend to us as an astringent in hemorrhages. It is plainly to be inferred from this, that the nabathéea filiqua is different, in the greatest degree, from the Syrian pod, or carob fruit; and by its virtues, and the description they give us of the thorny tree which produces it, it seems very probable that it was the pod of some species of the acacia.

NABBURG, in Geography, a town of Bavaria, situated on the Nab; 10 miles E. of Amberg. N. lat. 49° 27'. E. long. 12° 3'.

NABGIN, or Tumbo Namin, a small island in the Persian gulf; five miles S.W. of Tumbo.

NABHANA, a town of Africa, in Tunis; 40 miles from Cairoon.

NABIS, in Biography, a famous tyrant of Lacedæmon, who attained to the supreme power about the year 206 B.C., after the death of Machanidas, and while the lawful king Agespolis was living in exile, is represented as one of the worst and most cruel of men;—the enemy of all noble and virtuous perfons, and intent only to fill his treasury, and aggrandize himself by the most unjustifiable means. He, however, is said to have performed, with regularity, the functions of a chief magistrate, and he, probably, made his government acceptable, on the whole, to the body of the nation, since he was able to employ a large public force, and to extend his dominion into the neighbouring states. During the war between Philip, king of Macedon, and the Romans, that monarch not being able to retain Argos, which he had taken, delivered it to the keeping of Nabis, who began to practice every exertion to enrich himself with its spoils. He compelled the magistrates to pass two decrees, one for cancelling old debts, the other for an equal division of lands, by which he hoped to ingratiate himself with the lower classes. He obliged, by force, the principal male inhabitants to surrender all their jewels and other valuables; while he deputed his wife on a similar errand with respect to the females. After this he made an alliance with the Romans, but when the final defeat of the Macedonians had restored liberty to Greece, and Nabis was left in possession of Argos, which was considered as indeferable to the Romans, the senate decreed that their general, Quintus Flaminius, should carry on war upon him. As, however, the Roman general could make no impression upon that city, he led his forces to Sparta itself. Nabis prepared for a vigorous resistance, and to secure himself from internal treachery, he infamously massacred eighty young men of the principal families of his state. The Roman army laid waste the country around, and reduced several places on the sea-coast, especially Gythium, the flation of the Lacedæmonian maritime force. Nabis fled for peace, but the terms proposed by the Roman general were so severe, that he preferred to risk the consequences rather than submit to them. He was, however, a coward as well as tyrant, and was obliged to supplicate for peace on any terms. Scarcely had the Romans withdrawn themselves, when Nabis began to plan the recovery of his power, but in the event he was slain, which happened in the year 193 B.C., after he had, during fourteen years, acted a considerable part in the affairs of Greece.

NABLOUS, or Naplosa, in Geography, a town of Syria, and capital of a hilly country, anciently celebrated under the name of the kingdom of Samaria, but at present called the country of Nablous. This town, situated near to Sichem, and on the ruins of the Neapolis of the Greeks, is the residence of a feichek, who farms the tribute, for which he is accountable to the pacha of Damascus, when he makes his circuit. The state of this country is similar to that of the Druzes, with this difference, that its inhabitants are such zealous Mahometans, as not willingly to suffer any Christians to reside among them. They are dispersed in villages among the mountains; the soil of which is tolerably fertile, and produces a great deal of corn, cotton, olives, and some filks. The town has several mosques; and carries on a considerable traffic with Damascus and the coast: it has a cotton manufacture. Jews of the Samaritan sect are numerous. Although a nominal deputy be appointed by the pacha of Damascus, the town is really governed by the inhabitants; 20 miles N. of Jerusalem. N. lat. 32° 16'. E. long. 35° 22'. Volney's and Browne's Travels.

NABLUM, in Hebrew noel, an instrument of music among the Hebrews. The Seventy, and the Vulgate, translate it sometimes by nablum, and at other times by palfierion, or lyra, or even cithara.

The nablum was a stringed instrument, very near of the form of a ∆, which was played upon by both hands with small sticks, like the dulcimer. See Calmet's Dictionnaire, concerning the musical Instruments of the ancient Hebrews, prefixed to the second volume of his Commentary on the Psalms.

Kircher supposes it was the same as the palfierion.

Baptist Folengius, on the 33rd psalm, says that this instrument was esteemed the most noble of all. Because, when the seventy symphonists who blew the trumpet, and played the organs, the cymbals, and the lyre, were assembled to play in concert, the king played alone upon the nablum. " Rex folius palterio regii eaneat."—Achilles Tatius, in the first book of the Loves of Leucippus and Clitophon, describes a banquet, and says, that at the end of the repast a beautiful youth advanced with an instrument which he called the cithara, and playing the strings with his hands, he made them sound a little; then seizing the plectrum, he united his voice with the instrument.
NABO, or Nebu, in Ancient Geography, a town of the tribe of Reuben, which, being in the vicinity of the land of Moab, was taken possession of by the Moabites, and belonged to them, as we learn from the prophet Jeremiah. — Also, a town of the tribe of Judah, about eight miles from Hebron, which appears to have been a defeat in the time of Euephus and Jerome. — Also, a mountain placed by Moses in the land of Moab, though feated on the other side of the Arnon, and, consequently, in the kingdom of Sihon. On this mountain Moses died. Deut. xxii. 49.

Nabo, or Nebu, in Mythology, a deity of the Babylonians, who pooffeed the next rank to Bel. It is mentioned by Isaiah, ch. xxxi. 1. Voelius apprehends that Nabo was the moon, and Bel the sun; but Grotius supposes that Nabo was some celebrated prophet of the country, which opinion is confirmed by the etymology of the name, signifying, according to Jerome, one that predizes over prophecy. Most of the Babylonish kings bore the name of that god joined to their own; as Nabonassar, Nabuchadnosofer, &c.

NABOB, the name of a viceroy or governor of one of the provinces of the Mogul's empire in India. Nabob, or more properly kaubab, is the plural of nāb, a deputy.

As the term is used in Bengal, it has the same meaning with Nazim; which see. This title is given to the wives and daughters of princes, as well as to princes themselves.

NABOBENGENE, in Geography, a name given to several towns of Hindostan, in Bengal, Allahbad, and Oude.

NABOBESPAR, a town of Bengal; 24 miles N.E. of Calcutta.

NABOA, a town of New Mexico, in the province of Mayo; 32 miles N.E. of Santa Cruz.

NABONASSAR. The era of Nabonassar is famous: we know but little of the history of that prince; only that he was king of Babylon, and was also called Beldebus; though some will have him the Baladan mentioned in Isaiah, xxxix. 1. and 2 Kings, xx. 12. Some even conjecture that he was a Mede; and that he was set on the throne by the Babylonians, upon their shaking off the government of the Medes.

The beginning of this prince's reign is of great importance in chronology; because Ptolemy affirms us, there were astronomical observations made by the Chaldeans from Nabonassar to his time; and Ptolemy, and the other astronomers, account their years from that epoch. See Astronomy.

From the observations quoted by Ptolemy, it follows, that the first year of this era is the 747th year before Jesus Christ; and the 356th of the Julian period. See Eorbia.

The years of this epoch are Egyptian years, of three hundred and sixty-five days each; commencing on the 29th of February, and reckoned, according to the computation of astronomers, from noon.

NABOPOLASSAR, in Biography, a prince of Babylon, named with Athyges against Syria, which country they conquered, and having divided it between them, founded two kingdoms, that of the Medes under Athyges, and that of the Chaldeans under Nabopolassar, in the year B.C. 626. Necho, king of Egypt, jealous of the power of the latter, declared war against him, and defeated him. Nabopolassar died after a reign of 21 years.

NABOTH, Egg of, in Anatomy, a kind of ovary near the neck of the womb, discovered by Naboth, professor of medicine in the university of Leipic.

NABTE, in Geography, a town of Arabia, in the province of Hedsjas; 110 miles W.N.W. of Medina.

NABUCHADNEZZAR, in Biography. See Nabu-chadnezzar.

NABUNAL, Elias de, a French cardinal, who flourished in the fourteenth century, and took his surname from the place of his nativity in the province of Perigord. He embraced the religious life in the order of the Friars-minors, and after several influences of church prelacy, he became archbishop of Nicofia and patriarch of Jerusalem. In 1342 he was promoted, by pope Clement VI, to the dignity of cardinal-prael, with the title of St. Vitus. He died at Avignon in 1367. He was author of several works, as: "A Commentary on the four Books of Sentences of Peter Lombard;" "A Commentary on the Apocalypse;" "A Treatise concerning a contemplative Life;" and "Sermons explanatory of various Passages in the Evangelists." Morei.

NABUSTA, in Geography, a town of Hindostan, in Oude; 12 miles W.N.W. of Currash.

NACA, a town of Japan, on the E. coast of the island of Ximo. N. lat. 32° 12'; E. long. 132° 6'.

NACABA, a town of Japan, on the S.E. coast of the island of Niphon: 40 miles E. of Awa.

NACACHEZ, a town of Louisiana, on the Red river. N. lat. 32° 20'; W. long. 93° 26'.

NACAQUES, an instrument of music, which, though often mentioned by the old poets both of France and England, it is not certain whether it was an instrument of percussion, or a wind instrument. In the Roman d'Alexandre, it is said:

"Calcun a port trompe ou vielle atemptre,
Nacaires et tabors de grande renomme." 32

Du Cange describes nacara to be a kind of brazen drum used in cavalry, yet Chaucer names it in the company of military wind instruments:

"Pipes, tromps, nakeres, and clariounes
That in the battle blown blody foues."

NACAMERI, in Geography, a town of New Navarre; 190 miles S. of Cafa Grande.

NACANTA, a town of Japan, in the island of Niphon; 20 miles N. of Mogani.

NACAT, a town of Japan, in the island of Ximo; 40 miles S.E. of Kokura.

NACHEGO, a lake of South America, in the province of Quioto; 60 miles E. of Francisco de Borja.

NACHELO, or NAKEL, a sea-port town of Peru, in the province of Parilihan, on the N. coast of the Perisan gulf, inhabited by Turks, independent of the crown of Peria, the inhabitants of which are chiefly employed in fishing for pearls; 175 miles S. of Schiras. N. lat. 27°; E. long. 55° 20'.

NACHITOCHEES, a French settlement of Louisiana, on the Red river, about 140 leagues N.W. of New Orleans, of small extent, but tolerably populous. Its inhabitants, like those of Louisiana, are lively, well-formed in their persons, and inured to fatigue. They often attend their rivers with their families to the distance of four or five hundred leagues, and spend on these painful expeditions 18 or 20 months. Hunting the bear is one of their favourite pursuits, which is chiefly practised in the winter season, when this animal is particularly fat, and in condition to furnish a large quantity of oil. N. lat. 32° 11'; W. long. 93° 46'.

NACHO, Naco, or Puerto de Cavillos, a town of Mexico, in the province of Honduras; 30 miles N. of Gracias a Dios. N. lat. 15°; W. long. 89° 36'.

NACHOD, a town of Bohemia, in the circle of Koniggratz;
NAD

NADEEGSDA, the most southerly of the Kuril-islands, in the Russian charts.

NADELESTEIN, in Mineralogy. See TITANIUM.

NADEH, in Geography, a town of Perzia, in the province of Kerman ; 53 miles E. of Kabiis.

NADELDA, a town of Sweden, in the government of Abo ; seven miles W. of Abo.

NADERBAR, a cirkar of Hindoostan, in Candiliff, situated on each side of the Taptee, N. of Baglana, and E. of Guzerat.—Also, a town from which the cirkar derives its name ; 55 miles E. of Surat.

NADEONG, a town of Hindoostan, in Goondwanah ; 10 miles N. of Nagpouir.

NADEHA, a town of Perzia, in the province of Kerman ; 80 miles N.N.E. of Sirgian.

NADEMSKOI, a town of Ruffia, in the gulf of Oblfaja, into which the river Nadim runs, and the government of Tobolik. N. lat. 66°. E. long. 68° 26′.

NAFIN, a fortrefs of Dalmatia, situated on a montain, and now belonging to Italy.

NADIR, a town of Egypt, situated on the W. branch of the Nile ; 20 miles N.N.W. of Cairo.

NADIR, in Astronomy, a point in the heavens diametrically opposite to the zenith.

The word is pure Arabic, in which language it signifies the faime.

The nadir is that point directly under our feet : or a point in a right line drawn from our feet through the centre of the earth, and terminating in the under hemisphere.

The zenith and nadir are the two poles of the horizon, each being 90° di&ant from it, consequently each in the meridian.

NADIR, Sun's, is the axis of the cone projected by the shadow of the earth; thus called, because that axis being prolonged, gives a point in the ecliptic diametrically oppofite to the fun.

NADIR-IL-BIFI, in the Turkish Offices, the superintendant over the wardrobe.

NADIR-SHAB, in Biography. See KULI-KHAN.

NADEOTHE, in Geography, a town of Hindoostan, in Lahore, on the Beyah ; 30 miles S.E. of Nagorkote, and three miles N.W. of Bompal.

NADOR, a town of Africa, on the S.W. part of Algiers, inhabited by Arabians ; 80 miles S.E. of Oram.

NADOUT, a town of Hindoostan, in Guzerat ; 16 miles S. of Champaire.

NADRAMA', a town of Africa, in the country of Bledulgerid ; 45 miles S. of Beni Mezzab.

NADSAR, a mountain of Thibet. N. lat. 27° 26′. E. long. 87° 29′.

NADUM, a town of Hindoostan, in Cochlin ; 30 miles E. of Crangonore.

NAEFELS, a town of Switzerland, in the canton of Glaris, inhabited by Roman Catholics; four miles N. of Glaris.

NAEFF, in Rural Economy, a provincial term applied to the nave of a wheel of the cart or other kind.

NENIA, in Mythology, a goddes who presided over lamentations and funeral ; and who had a temple near Rome. Nenia is also used for a funeral dirge or long, sung on funeral occations.

NEVIUS, Claudius, in Biography, an ancient Roman poet and historian, was a native of Campania, and served in the first Punip war. Of this war he wrote a history in Saturnian verse, and he was the second Roman who brought dramatic compositions on the stage. His firft comedy was acted about the year 235 or 228 B.C. It gave offence to some of the leading
NÆV

leading men at Rome, and on account of it he was thrown into prison. He was finally obliged to quit Rome, and died at Utica in the year 203 B.C. Only some fragments of his works have come down to modern times.

NÆVUS, a mole or freckle on the skin. Nævi materni signify the little spots, excrescences, or swellings, with which many children are born. There are two kinds, viz. small red tumours, which gradually increafe to a large fize; or brown flat marks, not rising in the leat above the surface of the skin. Mr. Latas fays, he once faw in a child two years old, a tumour of this kind weighing fourteen inches, which, at the time of birth, was only equal in fize to a large bean, and which, for a year afterwards, did not enlarge much; but then grew to the magnitude already specifed. The other species of nævi materni, or fuch as rife but little above the skin, are of various forms, and have been compared with cherries, grapes, &c. and have all been fuppolied to arise from fome impreflion made on the mind of the mother during pregnancy, or at the time of conception. The settlement of this difputed point we leave to speculative writers.

Those nævi materni, which are mere spots, or marks, give no inconvenience, and of course do not require the interference of Surgery. But fuch nævi materni as elevate themfelves above the surface of the body, increafe in fize, and seem likely to become troublesome, fould be entirely removed with a knife. Many of them feem to confift of a congeries of dilated veffels, and, after they have acquired a certain fize, are apt to burst, and bleed profufely. John Bell has named this kind of difeafe _aneurism by anatomoftis_ the defcription and proper treatment of which we fhall next confider, as the subjeét is not treated of in the article Aneurism.

By the term "aneurism by anatomoftis," Mr. John Bell, of Edinburgh, means a species of this difeafe, which refembles fuch bloody tumours, or nævi materni, as appear in new-born children, grow to a large fize, and, ultimately burfting, emit a confiderable quantity of blood. The aneurism by anatomoftis often affects adults, increafing from an appearance like that of a mere fpot, or pimple, to a formidable difeafe, and being composed of a mutual enlargement of the smaller arteries and veffels. The difeafe originates from some accidental caufe; is marked by a perpetual throbbing; grows slowly, but uncontrouably; and is rather irritated, than checked, by compreflion. The throbbing is at first indifferent, but when the tumour is perfectly formed, the pulsation is very manifest. Every exertion makes the throbbing more evident. The occasional turgid flates of the tumour produce faces of blood in the cellular fubftance, or dilated veffels, and these fizes form little tender, livid, very thin points, which burft, from time to time, and then, like other aneurisms, this one bleeds fo profufely, as to induce extreme weaknefs.

The tumour is a congeries of active veffels, and the cellular fubftance, through which these veffels are expanded, re-embles, as Mr. John Bell describes, the grills of a turkey cock, or the fubftance of the placentæ, spleen, or womb. The irritated and incessant action of the arteries fills the cells with blood, and from these cells it is re-absorbed by the veffels. The fize of the swelling is increased by exercife, drinking, emotions of the mind, and by all caufes which accelerate the circulation.

Mr. John Bell fites, that the hemorrhage from the aneurism by anatomoftis ufurps, in the female subjeét, the place of menstruation.

"This aneurism," obferves the above writer, "is a mere congeries of active veffels, which will not be cured by opening it; all attempts to obliterate the difeafe with caufes, after a fimple incifion, have proved unfruitful, nor does Vol. XXIV. the interrupting of particular veffels, which lead to it, affect the tumour; the whole group of veffels muft be extirpated.

In various veffels, or in aneurisms of individual arteries, or in extravafations of blood, fuch as that produced under the fcalp from blows upon the temporal artery, or in fuch aneurisms, produced in schoolboys by pulling the hair, and also in fuch bloody effusions from blows on the head, which have a diluent pulsation, the procés of cutting up the varix, aneurism, or extravafation, enables you to obliterate the veffel and perform an easy cure. But, in this enlargement of innumerable small veffels, in this aneurism by anatomoftis, the rule is not to cut into, but to cut it out. Three purple and ill-looking tumours, because they are large, beating, painful, covered with fcafs, and bleeding, like a cancer in the laft stage of ulceration, have been but too often pronounced cancers! incurable bleeding cancers! and the remarks which I have made, while they tend, in some measure, to explain the nature and eonfquences of the difeafe, will remind you of various unhappy cafes, where either partial resection ony had been practiced, or the patient left entirely to his fate."  See John Bell's Principles of Surgery, vol. i.

Mr. Abernethy cured a nævus maternus upon a child's arm by means of pressure with a bandage. See his Surgical Works.

A tumour of the fame nature, situated in the orbit, and causing a displacement of the eye, violent headaches, &c. was cured by tying the carotid artery of the fame fide. See Medico-chirurgical Translations, vol. ii.

NAFTA, in Geography, a town of Africa, in Biledulgir.

NAFTMAN, an ifland in the Capefian fea, in the gulf of Balkan. N. lat. 40° 45'.

NAFWALSIO, a town of Sweden, in the province of Småland; 33 miles S.E. of Jonköping.

NAG, a provincial term applied to a horse of a small fize, for the faddle: this fort of horse is very useful for many purpojes of husbandry, while light labour is required to be performed. See Hony.

NAGA, in Geography, a town of Japan, in the ifland of Ximo; 5 miles N. of Nangafaki.

NAGAOCIL, a town of Hindooftan, in the cirrar of Guntoor; 20 miles N.N.E. of Junocanda.

NAGAI, an ifland in the North Pacific ocean, near the W. coast of North America, fo named by the Ruffians. N. lat. 55° 10'. E. long. 199° 14'.

NAGALAVERAM, a town of Hindooftan, in Maida; 32 miles E. of Coipletta.

NAGAMUNGALUM, a town of Hindooftan, in Myford; 23 miles N. of Seringapatam. N. lat. 12° 59'. E. long. 76° 40'.

NAGAR, a town of Hindooftan, in Mewat; 20 miles E. of Cottihal.

NAGARA, a town of European Turkey, in Romany, near the Straits; 10 miles S.W. of Gallipoli.

NAGARITZ, a town of Thibet; 42 miles S. of Laffa.

NAGATCH, a town of Hindooftan, in Marwar; 9 miles N.N.W. of Ramanapour.

NAGAVSKAIA, a town of Russia, in the country of the Cofacks, on the Don; 148 miles E.N.E. of Azof.

NAGAZ, or Naguit, a town of Candahar, near the river Cow-mull; repaired or rebuilt by Timur Bec; 58 miles E.S.E. of Ghizni. N. lat. 33° 16'. E. long. 69° 31'.

NAGED, a town of Perfia, in Farsitlan; 27 miles S.S.W. of Schiras.
NAGEIA, in Botany, Gard. v. i. 191. t. 39, a genus established by that botanist, upon the Nagei of Kämpfer, Amoen. Exot. 773. t. 874, its name being formed from that Japanese word. Gartner himself remarks that this plant differs but little in the characters of the fruit from Myrica, to which other writers have referred it. See Myrica.

NAGEMUL, in Geography, a town of Hindooftan, in Myfore; 30 miles N.N.W. of Serimgapatam.

NAGEMULUS, in Ichthyology, a name given by some of the German authors to the fish called by Willughby and others, the lisiperca, or pile-perch. See Perca Lisiperca.

NAGERAN, in Geography, a town in Arabia, in the province of Yemen; 10 miles N.W. of Saude.

NAGGERA, a town of Hindooftan, in Oude; 40 miles W. of Kairabad.

NAGGERY, a town of Hindooftan, in the Carnatic; 10 miles S.E. of Bomrauzapollam.

NAGI, in Botany, a much admired Japanese tree, planted frequently in the courts of houses. See Nageia and Myrica.

NAGLES MOUNTAINS, in Geography, a ridge of mountains in the county of Cork, Ireland, extending some miles E. and W. south of the river Blackwater.

NAGLIANO, a town of France, in the department of the Tanaro; 4 miles N. of Alba.

NAGO, a small island in the gulf of Bothnia, near the S.W. coast of Finland. N. lat. 60° 22'.

NAGODIN, a town of European Turkey, in Servia; 16 miles W.N.W. of Widdin.

NAGOES, a tribe of Whidah negroes on the Slave coast of Africa, whose language, though understood by the Papaws, or Whidah negroes, differs in many particulars from the Whidaw language.

NAGOJA, a town of Japan, in the island of Nippon; 80 miles E. of Meaco.

NAGOLD, a town of Wurtemberg, on a river of the same name, in the Black Forest, near which is a medicinal spring; 22 miles S.W. of Stuttgart. N. lat. 48° 30'. E. long. 8° 47'.

NAGONE, a town of Hindooftan, in Bundelcund; 26 miles S.E. of Pennah.

NAGOORDILL, a town of Hindooftan; 10 miles S.E. of Travancore.

NAGOR, Antiope Reduna, in Zoology, the antelope with a reddish colour, fluff upright hair, and the horns bent forwards at the ends. Schreber. This is the red antelope of Pennant. It inhabits Senegal, and at the Cape of Good Hope. Its length is about four feet, its height two feet three inches, the horns about five inches and a half long, with two flight smooth rings at the bales, and bent gently forwards; the ears are almost as long as the horns; the general colour is a pale reddish, palest on the chest. This species, according to Gmelin, is the kara of Elian.

NAGORDUSSE, in Geography, a town of Hindooftan, in Bahar; 16 miles S. of Durbungah.

NAGORCOTE, or Kate Kangrah, a fortresses and celebrated pagoda of Hindooftan, in the country of Lahore; 86 miles N.E. of Lahore. N. lat. 32° 20'. E. long. 75° 48'.

NAGORE, or, as it is sometimes called, Birboom, a town of Bengal, in the circuit of Birboom; 100 miles N.W. of Calcutta. N. lat. 23° 37'. E. long. 87° 26'.—Also, a circuit of Hindooftan, in the country of Agimere:

bounded on the N. by the soubah of Delhi and Moutlan; on the E. by Mewat and Jynagar; on the S. by the circars of Agimere and Joodpour; and on the W. by the circuit of Bickaneer.—Also, a town in this last mentioned circuit; 42 miles N.W. of Agimere. N. lat. 27° 9'. E. long. 74° 48'.—Also, a town in the Carnatic; 15 miles S. of Tranquebar.

NAGORPAL, a town of Hindooftan, in Lahore; 27 miles N.N.E. of Jullindar.

NAGORSKOI, a town of Russia, in the government of Tobolik, on the Oby; 92 miles S.S.E. of Berezov.

NAGOWRA, a town of Hindooftan, in Oude; 35 miles E. of Nijibabad.

NAGPOUR, a circuit of Hindooftan, bounded on the N. by Torre and Ramgur, on the S. by Silhee and Tomar, on the E. by Orifis, and on the W. by Orfis, and the circars of Chuta and Palamow; about 40 miles long, and 32 broad. The capital is Doeca.

NAGPOUR, a town of Hindooftan, the capital of the circuit of Goondvana, or, as it is now called, the province of Nagpour, in the soubah of Berar, is a city of modern date; and though very extensive and populous, is mainly built, and is open and defenceless, except only that it is guarded by a small citadel of incomconsiderable strength. It is the residence of the chief of the eastern Mahrrata flote. The county about it is fertile and well cultivated, intermixed with hills of a moderate height; but the general appearance of the country at large, and particularly between Nagpour and Bahar, is that of a forest, thinly set with villages and towns. N. lat. 21° 10'. E. long. 79° 46'.

NAGRAGINSKOI, a town of Russia, in the government of Tobolik, on the Konda; 176 miles N. of Tobolik.

NAGREE, a town of Hindooftan, in the circuit of Chandali; 32 miles E. of Makonoa.

NAGROTAH, a town of Hindooftan, in Lahore; 22 miles N. of Jummo.

NAG'S HEAD, a cape on the S. end of the W. coast of the island of St. Christopher. N. lat. 17° 20'. W. long. 62° 43'.

NAGUALAPA, or St. Pedro, a river of Mexico, which passes by Colima, in the province of Mecocanan, and runs into the Pacific ocean, N. lat. 19° 50'.

NAGUARACHI, a town of New Mexico, in the province of Hiaqui; 140 miles E.N.E. of Rucichco.

NAGURKEY, a town of Bengal; 38 miles S.S.E. of Cutruckdeagh. N. lat. 23° 53'. E. long. 86° 40'.

NAGYBANIA, a metal town of Hungary, and one of the royal free towns, the gold and silver mines of which have been productive; 50 miles N. of Zamos.

NAGY-CAROLY, a town of Hungary, with a castle; 12 miles S.W. of Zamos.

NAGYFALU, a town of Hungary, near the Theys; 3 miles E.S.E. of Tokay.

NAGYKETSKY, a town of Hungary; 8 miles N.E. of Gros Warden.

NAGYMYH KAL, a town of Hungary; 18 miles W.S.W. of Ugvar.

NAGYSCOLOS, a town of Hungary; 12 miles E.S.E. of Munkacs.

NAHANT POINT forms the N.E. point of Boston harbour, in Massachusetts; 9 miles E.N.E. of Boston. N. lat. 42° 27'. W. long. 70° 57'.

NAHANTIK, a bay of the state of Connecticut; 3 miles W. of the mouth of the Thames.

NAHAR el Berd, a river of Syria, the ancient Elutherus, which runs into the Mediterranean; 9 miles N. of Tripoli.

NAHARLYK,
NAI

NAHARLYK, a town of Poland, in the patalinate of Kiev; 24 miles E. of Bialackerie.
NAHAR-MALEK, a town of the Arabian Irak, near the Euphrates. N. lat. 31° 20'. E. long. 45° 30'.
NAHR VALI, or NAHRVALES, a people of Germany, who had a confederate grove, whose priest was dreed like a woman. The Romans believed that the gods worshipped in this grove were Caffor and Polibus, as they were both brothers, and both young. See Tacit. de Mor. Germ. Num. 45.
NAHEL, or MAHAM, a town of Arabia, in the province of Oman; 50 miles N.N.W. of Oman. N. lat. 24° 20'.—Also, a town of Egypt; 16 miles S.E. of Cairo.
NAHIA, a town of Persia, in the province of Kerman; 70 miles S. of Sirgian.
NAHIL, a river of Africa, which rises in the desert of Barca, and runs into the Mediterranean, N. lat. 32° 10'. E. long. 40° 10'.
NAHR el ANSAR, a town of the Arabian Irak, on the Euphrates, the residence of an Arabian shecck; 5 miles N. of Corna.
NAHR TERE, a town of Persia, in the province of Chasitan; 20 miles S.E. of Ahaz.
NAHRAHM, EL, a town of Asiatic Turkey, in the province of Diarbekir, on the Khabur; 40 miles N.E. of Kerkis.
NAHUAPO, a town of Peru, in the Audience of Quito; 45 miles W. of St. Joachim de Amaguas.
NAHUM, or, the Prophecy of Nahum, a canonical book of the Old Testament. Nahum, the seventh of the twelve leffer prophets, was a native of Elkofhaid, a little village of Galilee. The subject of this prophecy is the destruction of Nineveh, which he describes in the most lively and pathetic manner: his style is bold and figurative, and can hardly be exceeded by the most perfect masters of oratory. His prophecy forms a regular and perfect poem; the exordium is not merely magnificent, it is truly majestic: the preparation for the destruction of Nineveh, and the description of its downfall and desolation, are expressed in the most vivid colours, and are in the highest degree bold and luminous. This prophecy was verified at the siege of that city, by Alfyages, in the year of the world 4378, 622 years before Chrift.
The time of Nahum's death is unknown; the Greek meteorologists, and the Latin martyrologies, place his festival on the first day of December.
NAHUNKEAG, in Geography, a small island of America, in Kennebeck river, 38 miles from the sea. The name denotes, in the Indian language, the place where eels are taken.
NAIA, in Zoology, the name of a species of coluber, the scuta of whose abdomen are one hundred and ninety in number, and the squama of the tail sixty.
NAJAC, in Geography, a town of France, in the department of the Avignon, and chief place of a canton, in the district of Villefranche, on the Averon; nine miles S. of Villefranche. The place contains 2181, and the canton 9040 inhabitants, on a territory of 185 kilometres, in 17 communes.
NAIADES, or NAIDES, in Botany, a natural order of plants, the 6th in Jussfle's first class, and so named by him, not only from Naias, which is one of them, but because they are inhabitants of ponds and rivulets.
The character of the clafs is to have no cotyledons; that of the order is thus given.

Calyx entire or divided, superior or inferior, rarely wanting. Stamens definite (perhaps inserted into the calyx).

NAI

German superior or inferior, single or four-fold; ftyle simple to each germen, rarely double, or none at all; Rigma one or many. Seeds solitary or several, either naked and superior, or enclosed in a pericarp, which is either superior or inferior. Leaves generally opposite, or whorled. Flowers in some cases hermaphrodtic, in others monocious or dioocious. Plants all herbaceous, and, except Sauerus, aquatics.

Section 1, fruit inferior, contains only Hippuris.
Seef. 2, fruit superior, with one or four seeds, consifits of Choros, Ceratothyllium, Myriophyllum, Naias, Sauerus, Aponegeton, Potamogena, Ruppia, Zanichella, and Calliclha.

Seef. 3, fruit superior, with a small, but infinite, number of seeds, consifits of Lemma only, called by Jussieu Lenticula.

The characters of this order are vague, and the author seems not satisfied with it himself. He hints that several of its genera probably ought to be removed from the Actylochones. (See Myriophyllum) Mr. Brown, Prodr. Nov. Holl. v. i. 345, considers Naias, Lemma, and Chara as allied to the order of Hydrocharides; fee that article.

NAIADUS, or NAIDUS, Naiades, derived from ναίδης, I flow, or from ναος, I inhabit, in Mythology, a sort of nymphs, or heathen divinities, suppoed to preside over fountains and rivers.

The Naiads had their sacrifices sometimes of goats and lambs, with libations of wine, honey, and oil, and frequently of nothing but milk, fruits, and flowers; and their festivals, in the rustic ceremonies of which, milk, honey, and oil flowed in abundance.

Strabo says, the Naiades were priestesses of Bacchus.
What we learn of them in general, is, that they were suppoed to live in the palaces of the preuding deities of fountains, lakes, and rivers. We have the names of no less than sixteen of these deities, given us by Virgil, Georg. iv. ver. 336 to 340; and 343 to 345, in his account of Cirene's apartment only, in the watery palace of Peneus; and Ovid, lib. iii. cl. 6. ver. 64, speaks of a hundred, at least, in the river Anio. They had often a name from the particular river they inhabited. They are described with long, bright hair, flowing down their shoulders; their faces should have a thinning, humid look, not unlike the Venus Anadonumae, of Apelles: their shape should be fine, and their limbs well turned. Their robes, when they wear any, for they are most commonly quite naked, should be of a greenish color; varied at pleasure, some to lighter, some to darker shades; and so thin, that you might discover all the turn of their limbs, and the finecnes of their skin through them. They have sometimes little flying veils, in gems of the ancients, over their heads; like thee godd frustrated of the air, which the Romans call Aura, and which we call Sylphs. It was the usual employment of the Naiades to attend at feasts, and they seem to have been little better than so many domestics to the preuding water-deities. Spence.

NAIANT, or NATANT, g. d. swimming; a term in Heraldry, used in the blazoning of fitches, when drawn in an horizontal posture; fefs-wife, or tranfverfy, acros the efufceon; that being their natural swimming pofture.

NAJARA, in Geography, a town of Spain, in Old Cafle, containing three churches and three convents; 36 miles E. of Burgos; N. lat. 43° 20'. W. long. 45°.

Illutr.
1. *N. marina*. Marine Naias. Linn. Sp. Pl. 1441. Fl. Suec. 345. (N. monosperma; Willd. Sp. Pl. v. 4. 331. *Fluvialis latifolius*. fructu minus obtuso, monospermo; Mich. Gen. 11. t. 8. f. 2. F. pipana, foliis denticulatis; Bauh. Hilt. v. 3. 771, the broad-leaved figure.)—Leaves opposite or ternate, erect, linear, deeply toothed.—Native of lakes and ditches, especially near the sea in Italy; and in the fresh waters of Germany, Switzerland, &c. In the sea itself on the coast of Sweden. Mr. Menzies gathered it in Owyhee, and Commeron in the isle of Bourbon. The whole plant floats under water, having the slender branched stem, and narrow pellucid leaves of a Potamogeton. The latter grow two or three together, feathery or somewhat fathreeing at each joint, and are from an inch to an inch and a half long, linear, with very sharp teeth or serratures, and very deep intermediate fringes. *Flavescent helvus*, feathery, foliaceous, minute. *Capula* elliptical, not a quarter of an inch long, single-feaded. This was the only species known to Linnaeus. He originally considered it as monoeocious, but was induced, by the observations of Bernard de Jussieu, to remove the genus to *Difcia*, which however every other person has found to be a mistake.

Michel describes another species, t. S. f. 1, as having four seeds, and some soft teeth upon the stem. Willdenow, trudging, very wabbly, to this excellent author, has adopted this by the name of *N. tetrasperma*, but it appears to us to want confirmation. We can find but one seed in any specimen, that has fallen in our way, from any part of the world, and this agrees with Mr. Brown's ideas of the genus.

2. *N. minor*. Leffler Naias. Albion. Pedem. v. 2. 221. (Caulina fruthe; Willd. Sp. Pl. v. 4. 182. Ann. of Bot. v. 2. 39, t. 1. f. 2. *Fluvialis minor*, foliis angustissimis dentatis, de frutibus reflexis, fructu acuto tenueri monospermo; Mich. Gen. 11. t. 8. f. 3. F. pipana, foliis denticulatis; Bauh. Hilt. v. 3. 771, the narrow-leaved figure.)—Leaves opposite or ternate, linear-awl-shaped, recurved, rigid, with triangular spinous teeth.—Native of lakes and ditches in Italy, France, and Germany. We have also specimens gathered in Switzerland by M. du Cros, but Haller knew it not; the former, which is his No. 356, flapping on the authority of Lachenal alone, who found it near Baill. This species is much smaller than the preceding, and, as Willdenow observes, remarkably brittle. One of our Swiss species has a considerable earthy incrustation, like what is usual in Chora. The leaves are more or less recurved, strongly toothed, but so narrow that there is no room for any intermediate fringes. *Capula* of a more slender figure than in *N. marina*.

3. *N. indica*. Indian Naias. (Caulina indica; Willd. Sp. Pl. v. 4. 182. Ann. of Bot. v. 2. 39, t. 2.)—Leaves opposite or ternate, linear-awl-shaped, wavy, erect; the younger ones with bristly teeth. Stipulas fringed.—Native of pools at Tranquebar, in the East Indies, where our specimens, in fruit, were gathered in 1799, by the Rev. Dr. Rottler. This has much the aspect of some of the most narrow-leaved Pondweeds, but the leaves are furnished with very fine bristly deciduous teeth, so as to form a minute resemblance of *Fucus acutus*, nor are there any intermediate fringes. The membranous stipulas, attached to the base of each leaf, are bearded, or fringed at the summit. *Capula* not half the size of the former, elliptical.

4. *N. tenuefolia*. Fine-leaved Naias. Br. Prodr. Nov. Holl. v. 1. 345.—"Leaves opposite, linear-awl-shaped, with bristly teeth. Stipulas fringed. Calyx of the male flowers entire at one side. Anthers flaked, of one cell."—Found near Port Jackson, as well as in the tropical part of New Holland, by Mr. R. Brown, who doubts whether it be truly distinct from the third species. We have seen no specimen.

5. *N. striata*. Striated Naias.—Leaves opposite or alternate, linear-awl-shaped, with bristly teeth. Stipulas abruptly toothed. *Capulae* longitudinally striated.—Gathered in the ditches of Lombardy, in 1787. The habit of this is very near *N. indica*, nor do we find much distinction in the leaves. The stipulas are rather toothed than fringed, and we think there is a clear difference in the *capulae* of the present being marked with numerous longitudinal ribs, which, added to the difference of their native countries, induces us to separate the two species.

6. *N. flexilis*. Short-leaved Naias. (Caulina flexilis; Willd. Sp. Pl. v. 4. 182. Ann. of Bot. v. 2. 50, t. 1. f. 1.)—Leaves whorled, linear; entire in their lower part; minutely toothed, and spreading, at the extremity. Sent by the Rev. Dr. Muhlenberg, from pools and ditches near Lancaster, in Pennsylvania. It is readily known from all the rest by its leaves growing from three to five at each joint, and their being of a broader shorter figure, entire, except near the extremity, where they are minutely and copiously toothed, but not fringed. The fruit is elliptic-oblong, smooth. Herb partly encrusted with an earthy deposition.

**NAILAY**, in Geography, a town of Nubia; 16 miles S. of Syene.

**NAID-CHOKEY**, a town of Himbofian, in the Carnatic, near the coast of Ceeamandey; 25 miles N. of Pullicare.

**NAILING of Cannon**, the driving of a nail, or iron spike, by force into the touch-hole of a piece of artillery; so as to render it safe to use. **NAILERS**, in Geography, a town of France, in the department of the Vende; 6 miles W. of Fontenay le Conte.

**NAILLOUX**, a town of France, in the department of the
the Upper Garonne, and chief place of a canton, in the
district of Villefranche: 6 miles S.W. of it. The place
contains 1168, and the canton 4225 inhabitants, on a terri-
torial of 130 kilometres, in 8 communes.

NAILS, in Anatomy, a kind of horny excrecences,
growing over the end of the fingers and toes of men, and
several other animals; much of the same nature with the
hoofs of horses. See Integuments.

The Romans were very curious in the cutting and forming
the nails, and had it done by artists, who made an employ-
ment of it.

The Chinese doctors and literati pique themselves on the
excellent length of their nails. F. le Compte says, some of
them wear nails nearly as long as their fingers.

Nails of Animals. Under this head may be comprised
the human nails, and the claws, talons, and hoofs of ani-
mal.

These substances differ from horn; the latter con-}
NAILS.

able to get the heading finished, whilst they were sufficiently hot. The length of the nail is regulated by a stop, fixed at a certain distance from the edge of the chisel, so that the point of the nail being applied to this, determines the proper place for the edge of the chisel. The size of the mould withinside, and the dimensions to which the point of the nail is reduced by hammering, causes the cut end to project above the surface of the mould more or less; so that the head will be thicker or thinner, and have its quantity of metal regulated, by the degree of taper given to the point: therefore, the art of the workman is displayed in striking with a due force, so that every nail shall be made of the same fixe, by a certain number of blows. In this manner the great number of all nails are made; but the great expense of labour has induced many manufacturers to turn their attention to inventions which would diminish the labour, so as to enable them to bring their nails to the market at reduced prices, or of a better quality. Many patents have been taken out for these inventions, some of which we shall briefly notice.

Mr. W. Finch of Wimboorne, in Staffordshire, obtained a patent in 1790, for manufacturing nails by machinery. He proposed, by means of a water or steam-mill giving motion to a main shaft or axis, to actuate a number of small hammers, to work either in a tilt or lift manner. By these hammers the nails were to be forged; but the operation was to be divided among three people for headed nails: thus, one to attend the fire, and carry the rods, as fall as they were properly heated, to the second perfion, flattened before the hammer, who would make the nails in the most expeditious manner, by only turning the rod about under the hammer; when cut off, they were taken by the third perfion, who finished the heads in a tool as above described, but by means of a hammer worked by machinery, instead of hard labour. By these contrivances, in consequence of the more speedy motion of the machine hammers, several nails were to be made at once heating of the rod; whereas by the old method, only one, or two at most, could be made; thus making a great saving of labour; and as the operation required no strength, children might easily make the largest spikes; the motion of the hammer being so regular, that they could easily acquire a dexterity in turning the rods properly to receive the blows.

In the year 1790, Mr. Thomas Clifford, of the city of Bristol, obtained two patents for the manufacture of nails of every kind. The principle on which his first invention was founded, was that of making the nails in a die, that is, by having a die, or the impression of the nails to be cut, formed in one or more pieces of steel; and the iron, of which the nails are to be formed, is drawn or rolled into the proper form or thickness, and, by a force adapted to the purpose, pressed into a cavity or die, so as to form the nails either complete, or so nearly complete, as that they can be finished with very little labour. This operation may be done in several ways, but the one particularly recommended by Mr. Clifford is by rollers of iron or steel, and worked either by water, steam, wind, horses, &c.

The two rollers are to be made of iron, and caled with fleed, each of the same diameter, which is proportioned to the length and size of the nail intended to be made. Each roller should have a cog-wheel on it, the cogs of one roller to work into those of the other, so that both the rollers may perform the same exact revolution. One half the impresse of the nail is to be cut in the surface of one roller, the other half in the other, so that the two impressions form a cavity or die of the exact form of a nail, extending the lengthways of the nail on the circumference of the rollers; and as many impressions of the same kind may be cut in the rollers, one at the end of the other, as will complete their circumference, and continue the cavity all round the rollers; the point of one nail joining the head of the next, or the two points and two heads joining each other. The rollers must, in this as in other cases, be made to work very true and close to each other.

The mode of operation is this: a rod of iron, previously rolled or drawn to a convenient fixe, is to be heated, and, while hot, the end of it is put between the rollers into the cavity or die which forms the impression of the nail. The rollers, being now put in motion, will draw the iron through, and pressing it into the cavities or dies, forms the iron into nails, one joined to the other, which must afterwards be separated, by means of instruments acting as nippers, shears, chisels, &c. The rollers being made to work very close to each other where the edge of the nail is formed, will prevent much of the metal from being pressed out on each side of the nail, and what is pressed out may be cut off by instruments adapted to the purp-se. Several pairs of rollers may be made to work together, and each pair may have several rows of dies cut on them, so as to form the impression for several fixes of nails; and a rod of iron being put into each of them, will roll out as many fixes of nails with one revolution of the rollers. A pair of rollers may also have the greater part of their surface cut with dies, and a fiat bed made to press between the rollers so as to form sheet nails; all of them connected to one another by thin plates of the iron of which they are composed; and this would require each nail to be cut out, or separated from the sheet by proper instruments.

Mr. Clifford's second invention consists, 1st, in drawing the iron or other metal into a tapering or wedge-like form, according to the length and thickness of the different fixes of nails to be made. 2dly. The nails are to be cut out of those wedge-like or tapering plates by means of a punch, the face of which is made according to the fixe, taper, and form of the nail to be cut out; as also having a hollow bolster, the hollow or aperture of which must also be made of the fixe and form of a nail, and consequently to fit and receive the punch above-mentioned. The punch, thus fitted to the bed, and sliding in a proper frame to keep it steady, will, by a blow, or by pressure, cut or force part of the taper plate into and through the aperture of the bed fitting to it, and by which the nail is formed. This operation is by the manufacturers of buckles, buttons, &c. called cutting out. 3dly. To form the heads of horse nails called rofe heads, and others of nearly a similiar kind: after the operations of drawing and cutting out, the nail is to be put into a heading tool, also called a bed, which bed receives the nail, excepting a small portion at the thick end, out of which the head is formed by a punch or die. This die, by blow or pressure, forms the head as required, and when the nails are made of hard iron, after they are cut in the way described, the thick end is made hot before they are put into the bed, or heading tool. 4thly. Another method adopted in the manufacture of nails is, by cutting them out of or from plates of equal thickness, and afterwards to joint them either by hammer or other pressure. 5thly. In making nails that are of a triangular form, the plate or strip of iron is pressed or flamed into a die, having impressions cut to the form of such nails, after which they are cut out by a punch.

About 15 years ago, a very extensive trade was established in Birmingham and Sheffield of cut brads; that kind of nails called brads having no head, or at least only a small projecting leaf on one side, was easily cut out by machinery, without the trouble of forging, but latterly the method has been improved,
improved, so far as to produce all kinds of small nails. The iron is rolled out to large thin sheets, of the proper thickness to form a nail; this is cut up by strong shears into parallel slips or ribbands, the width of them being equal to the length of the intended nails, which are cut off, one at a time, from the end of the slip: the cutting line is not exactly perpendicular to the length of the piece, but rather inclined, so as to make the nail, which is cut off sharp at one end; the next time the cutting line is inclined the other way, so that the head of one nail is cut from the same edge of the slip as the point of the next, and so on alternately. The cutting is performed by the Fly-prest (see that article), proper dies or cutters being applied in it: the lower or fixed die consists of a cutter or bar of steel set up edgways, and one of the angles of its upper side is ground to a sharp straight edge. The slider of the prest carries a die, consisting of a square bar of steel moving perpendicularly by the action of the screw, and when it is forced down, one of its flat sides applies exactly against the straight edge of the fixed cutter above-mentioned; but when the moving cutter is raised up to the highest, a part is observed, where its flat side is cut away, in such a manner as to leave a considerable space between its face and the edge of the fixed cutter at one end of the edge, but touching it at the other. By this means, when the end of a slip of iron is pressed against the face of the moving cutter in its reduced part, a short piece of the edge of the slip will project over the edge of the fixed cutter, and the moving cutter being forced down by the screw of the prest, the shouder of the part which is cut away comes down upon the end of the slip, cutting it off to the line of the edge of the fixed cutter, and therefore removing a small piece from the end, which being of a proper breadth at one end, and regularly tapered away to nothing at the other, makes a very good brad. The circumference of its being parallel in the other direction, is the great recommendation to this kind of nail, because it will drive without first making any hole in the wood and does not split: the point of a nail of this kind is like the edge of a chisel, and the length of this edge being set across the grain of the wood, when driven down it cuts through, and divides all the fibres of the wood it meets with, and by turning the divided ends of them down, as it is driven deeper, their elasticity binds the nail forcibly between them, so that this nail will hold in the wood faster than any other kind, but being parallel in the other direction, does not tend to open or split the wood in the direction of the grain.

In making small nails by this method, the workman or woman is seated before the prest, which is the same as is shown in fig. 1. Plate XXVII. Mechanics, holding the handle, or, of its fly in the right hand, and the slip of iron in the left: by pushing the handle back, the moving cutter is raised up, and the end of the slip is pressed up to the cutter; then by drawing forwards the handle, the cutter is pressed down, carrying with it a nail, as before mentioned: the handle is then pushed back to cut another, but the slip of iron or bar must first be turned over, to bring the other side upwards: by this means, the bar will at the second time be cut with an inclination in an opposite direction to what it was the first time, so that the head of one nail will come from the same side of the bar as the point of the last, and this alternately of the whole. A woman will, by this method, cut small nails at the rate of 40 or 50 per minute, and if they are intended for brads, they have a small leaf at one side of the head is cutting, by a particular shape of the dies.

For nails which require heading, the pieces or nails, cut as before mentioned, are taken to another woman, who fixes them one at a time in a vice, over which a heavy hammer is placed, being fitted on an axis, that it may rise and fall with precision upon the head of the nail in the vice; its weight is suspended by a wooden spring pole, and the woman, when she has fixed the nail, raises the head of the hammer a little, and then brings it sharply down on the nail, so as to head it at one blow. The shape of the head is determined by an indention made in the face of the hammer, and its thickness depends upon the quantity which is left flicking out above the chaps of the vice.

Mr. Wilmot and Tomk obtained a patent, in 1808, for a method of cutting nails, which they have thus described.

They take a nail rod, of a size suitable to that of the nail intended to be manufactured, and applying it to a common screw-prest, mounted with proper cutters, cut off from the end of the rod two pieces at once, obliquely across the rod in one place, and directly across it in another. Two flods or tops are set up, which are attached to the prests, and are moveable in the direction of the rod, for the purpose of afcertaining the length of the nail; and both flods are adjustable in the cross direction of the rod, so that the obliquity of the cut according to the kind of nail to be made, is thereby determined, as well as the length of the nail. This is called the first operation.

The second operation is to anneal the pieces so cut off, if they should not be sufficiently rigid, which is done in the usual and well-known manner. The third operation is that of heading, which, for clasp head nails, consists of two parts, one for gathering, and the other for forming the head of the nail. The first part of this operation is performed by putting a piece, cut off the rod of iron as before described, into a pair of clams, leaving much of the thick end projecting above the clams as is sufficient to form the head. These clams have steel bits let into them with sharp edges, which prests only against the two opposite sides of the piece, and which have the effect of two chisels, when the punch of the prests is brought down upon the piece with considerable force, and raise or gather up iron towards forming the head. The second part of this operation is to put the nail, thus prepared, into another pair of clams, having bits to correspond to the under side of the head; and the punch, having the impression of the upper side of the head engraved or sunk into it, is brought to prest strongly upon the head in the clams, and thereby the clasp head is properly formed.

In making nails inteded to have rose heads, or any other kind of heads, except clasp heads, the head part of this heading operation is not absolutely necessary, but the bits which for clasp nails must have sharp edges, must for the other nails have blunt edges, to prevent the under-cutting. For the second part of this operation, the piece is put either into a pair of clams, or into the tool commonly called a bore, and then pressed with punches properly engraved, or sunk, according to the kind of head wanted. By the first of all these operations, the piece cut off the rod of iron is formed something like a mortise chisel. The fourth operation is to point it, which is done by putting the piece into a bed of steel, in which is cut a nick or groove having parallel sides; but the bottom rising towards the end, where the nail is to be formed; the end of the punch, which presses upon the point of the nail, is made to project more than the other part, so as to meet the corresponding part of the bed, when the punch is brought upon the nail. The groove or nick in the bed should be just wide enough to receive the nail easily, but prevent it from twisting when the impression is made. The nail is put twice into the nick, once within the chisel, from the end lying horizontal, and next turning a quarter round to press the chisel edge into a pointed form. If the nails, by the strong pressure which is necessary in this operation,
tion, should become too hard to clench, they are to be annealed in the usual way, which may be called the fifth operation. The third, fourth, and fifth operations, above described, are applied to nails, or pieces cut off from sheet or rolled iron in the ordinary way; but as, in consequence of the fifth operation, which is necessary to give them the quality of clenching, they are apt to be too soft to drive well, a sixth operation is applied, viz. quenching them in water when red-hot, which gives them firmness enough to drive without rendering them too brittle to clench.

The Americans appear to have carried the invention of cutting nails by machinery to a greater perfection than has been done in this country. From some letters, published in 1816, by the American secretary to the treasury, in his report on the manufactures of that country, it appears that they have invented machines which perform the cutting and heading at one operation, and with such a rapidity, that one machine will furnish upwards of a hundred nails per minute: he says, "the importance of nailing machinery in Massachusetts, and of all that relates to rolling and fitting mills, with which nail machinery is immediately connected, requires that a particular account should be given of them. In old countries nails are forged, here they are cut, and it is curious to trace the progress of American genius through the various steps of this invention. Twenty years ago some men, now unknown, and then in obscurity, began by cutting flakes out of old hoops, and by a common vice, gripping these pieces, headed them with several strokes of the hammer: by progressive improvements rolling-mills were built, and the shears and the heading tools were perfected, yet much labour and expense were requisite to make nails. In a little time, Jacob Perkins, Jonathan Ellis, and a few others, put into execution the thought of cutting and of heading nails by water, but being more intent upon their machinery than upon their pecuniary affairs, they were unable to prosecute the business. At different times other men have spent fortunes in improvements, and it may be said with truth, that more than a million of dollars have been expended; but at length these joint efforts are crowned with complete success, and we are now able to manufacture at about one-third of the expense that wrought nails can be manufactured for, and nails which are superior to them; for at least three-fourths of the purposes to which nails are applied, and for most of these purposes, they are full as good. The machines made use of by Odlewe, those lately invented by Jonathan Ellis, and a few others, present very fine specimens of American genius."

"To northern carpenters it is well known, that in almost all instances it is unnecessary to bore a hole before driving a cut nail; all that is requisite is, to place the cutting edge of the nail across the grain of the wood: it is also true, that cut nails will hold better in the wood. These qualities are, in some rough building works, worth twenty percent. of the value of the article, which is equal to the whole expense of manufacturing. For sheathing and drawing, cut nails are full as good as wrought nails: only in one respect are the bent wrought nails a little superior to cut nails, and that is where it is necessary they should be clenched. The manufacture of cut nails was born in our country, and has, within its bosom, advanced through all the various stages of infancy to manhood; and, no doubt, we shall soon be able, by receiving proper encouragement, to render them superior to wrought nails in every particular."

"The principal business of rolling and fitting, mills is, rolling nail plates; they also serve to make nail rods, hoops, ties, sheet iron, and sheet copper: in this State we have not less than twelve.

"These mills could roll and fit 7000 tons of iron a year: they now, it is presumed, roll and fit each year about 3500 tons, 2400 tons of which, probably, are cut up into nails and brads, of such a quality, that they are good substantives for hammered nails, and, in fact, have the preference with most people for the following reasons, viz. on account of the sharp corner and true taper with which cut nails are formed; they may be driven into harder wood, without bending or breaking, or hazard of splitting the wood, by which the labour of boring is saved, the nail, one way, being of the same breadth or thickness from head to point." We are informed that J. C. Dyer, esq. who has had the American machinery communicated to him, to be introduced into this country, has lately taken out patents in Great Britain, with a view of establishing the trade in this country.

Nails were anciently used for cancelling bonds; and for this purpose they were driven through the writing: to which practice there seems to be an allusion in Col. ii. 14., where God is said "to have blotted out the hand-writing of ordinances that was against us, and to have taken it out of the way, nailing it to His cross." For the Roman ceremony of driving the annual nail, see Annalii Clavus.

Nails, in the M.orge. The different position of the nails of the bridle, or left hand of the horseman, gives the horse a facility of changing hands, and forming his departure and stop; by reason that the motion of the bridle follows such a position of the nails. To give a horse head, you must turn the nails downwards. To turn the horse to the right, you must turn them upwards, moving your hand to the right. To change to the left, you must turn the nails down, and bear to the left. To stop the horse, you must turn them upwards, and lift up, or raise your hand.

Nail is also a sort of long measure, chiefly used in the commerce of cloths; containing the sixteenth part of a yard.

NAIM, in Geography, a town of Arabia, in the province of Oman; 60 miles N.W. of Hafsek.

NAIN, a Moravian settlement on the east coast of Labrador, near the entrance of Davis's Straits, S.S.W. of Cape Farewell. From observations made here in 1778, 1779, and 1780, the mean temperature seems to have been 3°-54. The greatest heat observed in 1780 was 84, viz. in July; and the greatest cold in 1779 was —56°. There is no appearance of summer before July; though the winters are said to be less severe than formerly. Kirwan's Estimate, &c. N. lat. 57°. W. long. 61° 30'—Alfo, a Moravian town, established in 1763, on Lehigh river, in Pennsylvania.—Alfo, a village of Pelaseline, at the foot of Mount Hermon, formerly a city, celebrated for the miracle of our Saviour's restoring the son of a widow to life; 10 miles S. of Nazareth.

NAINA, a town of Bengal; 22 miles S.S.W. of Calcutta.

NAJOO, a small island in the East Indian sea, near the west coast of the island of Celebes. S. lat. 1° 29'. E. long. 124° 25'.

NAIRANGIA, formed from the Arabic alnāran, the plural of alnār, light, a kind of divination, in use among the Arabs, drawn from the several phenomena of the sun and moon.

NAIRES, NAHERS, or NAYERS, in Modern History, a name which is given by the Malabarians to the military of their country, who form a very numerous clafs or tribe, one of which the sovereigns of Malabar choose their bodyguard.

NAIRN, or ISKIEEL, in Geography, a small post-town of the county of Donegal, Ireland, on the western sea coast,
NAIRNSHIRE, one of the northern counties of Scotland, is bounded on the north by the Moray firth, on the east by the shire of Elgin, and on the south and west by the county of Inverness. It extends about 20 miles in length from north to south, and 22 in breadth from east to west. The hilly parts of the county are divided into two portions by the natural divisions of its surface. For the breadth of the country there is usually level and extremely fertile; but as it recedes farther from the coast, it becomes very bleak and hilly. The soil on the level grounds, on the east side of the county, is a free loam on a sandy or gravelly bottom; and on its western portion, either a rich, flint clay, or a gravelly mould. The climate here is as favourable as in any part in Scotland, for the fame reason which has been mentioned under the article Morayshire. (See Morayshire.) In the hilly parts, the climate and soil are very different from what they are along the coast; the former being cold and stormy, and the latter a poor sandy loam, full of gravel and small stones. Only a few spots, indeed, on the declivities, skirting the narrow vales, in which the rivers run, are under cultivation, or perhaps susceptible of it. Agriculture, as a science, is little understood in any part of the county, probably less so indeed than in any other in Scotland. The farms are usually small, and mott generally unmixed; and, with a few exceptions, held upon leases ad libitum, which can scarcely fail to retard the progress of improvement. The inferior tenants being for the most part too poor to purchase proper implements of husbandry, those they employ are of their own contrivance, and consequently, as may be supposed, of the rudest kind. Sheep and black cattle are reared in considerable numbers in Nairnshire, and chiefly fed

Vol. XXIV.
on the natural paupillage, either in the downs along the shore, or in the moors towards the bottom of the mountains. The sheep are of the small white-faced kind, with very fine wool, which is either consumed by the farmers themselves, or sold into other districts, there being no manufacture yet established in this county.

There are few mineral substances in Nairnshire, which can be applied to any practical purpose. All the indications of coal, lead, and iron, which have induced adventurers to attempt the discovery of mines of these substances, have hitherto proved illusory. Neither is there any lime-stone found in the county; but its absence, in an agricultural point of view, is left to be lamented, as marl exists in vast quantities at different places, and particularly in a small loch called Conan, and in the vale of Litte, where it is of the purest and most valuable kind. In this vale is the extensive heath of Hoar-moor, which Shakspere has consecrated as classic ground, by making it the scene of the meeting of Macbeth and the weird-filers, in the celebrated play which bears the name of that blood-stained usurper. In the surrounding hills are some quarries of freestone; and in one part of the county there is also one of a dark blue-stone, which flames in the fire, but its bulk is not apparently diminished. After incineration, it does not fall down into powder, but remains solid as before.

The only rivers worthy of notice in this county are the Findhorn and the Nairn. The former takes its rise in Inverness-shire, pales entirely through this county into that of Moray, and discharges itself into the sea at the bay formed by the sand-hills of Culm. The Nairn also, beginning its course from a lake in Inverness-shire, flows through a considerable angle of Nairnshire, and falls into Moray with near the county town. This river flows, in its progress, the western side of the field of Culloden, in which terminated the rebellion of 1745, when the hopes of the Stewart family were frustrated. There is a small salmon fisheries on the Nairn, the property of Mr. Brodie of Brodie.

Nairnshire contains four entire parishes, viz. Ardclaucan, Aultearn, Calder, and Nairn; and parts of five others, viz. a part of the parish of Dyke, in the county of Moray; a part of Urquhart, in Ross-shire; and a small portion of Inch, of Moy, and of Petty, in the shire of Inverness.

In the parliamentary reports of 1801, this county is stated to contain 1072 houses, and 8295 inhabitants; in 1811, the number of houses had increased to 2031; but the inhabitants are returned as amounting to 8251. There is probably some error in one of these returns. Aultearn is a borough of barony, and is memorable as the scene of one of the most celebrated victories of the duke of Montrose over the covenanters, under lieutenant-general Harry, in 1645. Several handsome residences are dispersed over the county, of which the chief are Brodie, Holme, Boath, Lethen, Cantray, and the Castle of Kilravock. Nairnshire is represented in parliament along with the small county of Cromarty; each county alternately elective their joint representative.

Several remains of antiquity in this county, besides those mentioned in the preceding article, may very properly claim attention. Castle-Combe and that of Kilravock, which are both in an entire state, are objects of considerable antiquity and interest: so are likewise the ruins of Penic, Inshaghe, Moinefs, and Loughnadburt. Moinefs appears to have been one of the most extensive monasties in Scott-land, and Loughnadburt is remarkable for having sustained a siege against kings Edward I. and II. It is situated near the centre of a deep lake, in the higher parts of the county, and about 15 miles from any inhabited region; so that it is very difficult to conceive a state of society which could give it importance, either in a political or military view. North-west from this castle, about four miles, in a narrow and solitary vale, in which the river Findhorn flows, stands a very curious monument of the obelisk kind, about half the height of the celebrated one near Forres. The style of this monument is fo highly praised by Mr. Leffis, that it might be carried to some distance, by two vigorous men practised in such exercises. It is set up by the tide of a cairn of stones, supposed to be piled over some grave; but whether really a memorial of the dead, or of some memorable event in history, is uncertain. Tradition, however, represents it as the monument of two lovers, a Highland chiefman and a Norwegian prince, who were drowned in the river, in the act of eloping to secure to themselves that happiness which the hostility of their families denied them. The sculpture on this obelisk is nearly the same on both sides. In the lowest compartment are two human figures, evidently in the Highland dress, in the attitude of embracing, or struggling with each other. On each of the sides is a circle in bold relief, about a foot in diameter, the surface being occupied by eight or ten small globular figures placed round a cup in the centre. The remainder of the sculpture consists mostly of foliage, tendrils, &c.

This monument has no mark or emblem upon it referring to the doctrines or customs of Christianity, and is therefore presumed to be of anterior date to the introduction of that religion into Scotland. General View of the Agriculture in the Counties of Nairn and Moray, by the Rev. W. Leffis, Svo. 1811. This is a very interesting volume, and contains much information respecting towns, villages, customs, and antiquities, in addition to the agricultural department. It is evidently the work of a man of talent and extensive reading. See also Beauties of Scotland, vol. iv.

NAIS, in Natural History, a genus of the Vernes Molleus, claus and order, of which the generic character is, body creeping, long, linear, pellicid, and depressed; the peduncles or feet have small bristles on each side; it has no tentacula or feelers; sometimes two eyes, and sometimes without any. There are ten species; three of them common to the flagrant waters of our country, the others for the most part found on the shores of the North seas; generally only a few lines long, and attached to the stalks of aquatic plants.

Species.

VERMICULARIS. This species is well represented in Plate V. Vernus, fig. 5—11, in its natural and magnified state; it has no lateral bristles, but the chin is bearded. It is found in flagrant waters, adhering to duck-weed; it is only about a quarter of an inch long; the head is sub-elliptical; it has no eyes, and the peduncles have five or six bristles.

SPERLLPINA. Body serpentine, with red spiral intestines, and triple black collar. It inhabits Europe, in flagrant waters; is about an inch in length; the peduncles are warty, with three hooked bristles. This species is finely represented in the plate already referred to.

PROMICRONA. This has single lateral bristles, and a very long proboscis. It inhabits clear flagrant waters, and is about three quarters of an inch long. (See Plate V. figs. 12 and 13.) The body is hyaline, with a blackish flexuous intestine; the segments with a single length bristle on each side; the head is forked, and armed with a mouth and tongue; the vent is terminal, and it feeds on invisible aquatic insects.

ELINGUS. This has single lateral bristles, and no proboscis; it is met with in river water, about half an inch long, and
and narrower than the last. The mouth is placed before, and is obtuse; the vent is lateral.

* Digitata. This also has single lateral bristles, with a laciniate tail. It is found in stagnant waters, or the sandy sediment of rivers, with its head attached to the flanks of aquatic plants, and is not quite half an inch long. The body is marked with a reddish vein down the middle, and furnished beneath with a double row of very minute ciliate proterubances; it has no eyes, and the tail is rounded, and furnished with five unequal retractile prococes.

Barbata. Lateral bristles faciculate, and without a prebasit. Found in the wet hollows of damp woods; not half an inch long; and it is generally met with adhering to flowers. The body in the lower part is furnished with hairs; the segments with four divergent bristles on each side; it has two eyes.

Ceca. This is without eyes, and has lateral warts that are bristly. Inhabits the Northern seas, and is thought to be the same as the Nereis Ceca; which fea.

Littoralis. This species has generally no lateral bristles, but sometimes they occur single, double, or faciculate. Found on the sandy shores of Copenhagen. The body is long, filiform, equal, red, very fragile, and composed of numerous crowded annulations, with numerous segments, each furnished with a lateral bristle.

Marina. The body of this is furnished with single lateral bristles, and furnished with an extensile tube. Found on the shores of Greenland, under marine conrives; fearfully an inch long, and it resembles the Nereis Prolifera; which fea. The body is of a whitish colour, with a yellowish-grey line down the middle; the part is convex, and underneath it is flat, and pointed behind; it has two eyes.

Quadricuspisata. Lateral warts blistly and bristly. The abdomen is furnished with cirri; the tail is four-chief. It inhabits the sandy coasts of Iceland, and is usually found under stones; it is about two inches and a half long. The body is composed of 109 annular segments, sometimes red-green, sometimes of a reddish-grey, with a longitudinal purple line, which is of a stronger colour beneath; it is tapering towards both ends, and flatter beneath; it has neither eyes nor feelers, and its tail ends in four prococes.

Naiserra, in Geography, a town of Hindoostan, in Guzerat; 30 miles N.N.E. of Champaner.

Naissant, in Heraldry, is applied to a lion, or other animal, shewing only the head, shoulders, fore-feet, and legs, with the tip of the tail; the rest of the body lying bide under the shield, or some charge, or ordinary tincture from which it appears to be inflating or arising.

Naifant differs from insignis; as the animal in the former case influes out at the middle, and in the latter at the bottom of the field or charge.

F. Menea’s says, naifant is only used for animals, which shew the bare head as arising out of the extremity of the chief, or from above the fesse.

Naiston, in Geography, a town of Persia, in the province of Irak; 80 miles N. of Ipshah.

Naivete, in Retoric, French term denoting the highest degree of simplicity, of the import of which term, having no corresponding one in our language, it is not easy to give a precise idea. It always expresses a discovery of character. M. Marmontel, who has given the best account of it, explains it thus: “That sort of amiable ingenuity, or undisguised sagacity, which seems to give us some degree of superiority over the person who shews it: a certain infantile simplicity, which we love in our hearts, but which displays some features of the character that we think we could have art to hide; and which, therefore, always leads to the perfons who discovers this character.” La Fontaine is given as the great example of such naivete. This, however, is to be understood as descriptive of a particular species only of simplicity; which fea.

Naka Laben, in Geography, a town of Mingrelia; 20 miles N.W. of Cotatis.

Naked, in Architecture. Naked of a wall, &c. is the surface of a plain, from whence the projections arise; or which serves as a ground to the projections.

Thus, we say, a pilaster ought to exceed the naked of the wall by so many inches; and that the foliage of a capital ought to answer to the naked of the column.

A flooring is said to be naked, before the bosses are laid over the joints; the naked roofing or carasing is applied to the roof before the tiles are laid on the rafters.

Naked Fire, is a term used by chemists for an open fire; or where the containing vessel is immediately exposed to the fire.

Naked Flowers, in Botany, are such as are furnished with a corolla, but defitute of a calyx; such are the Tulip, Hyacinth, and many others of the Lilaceous order. Some botanists do not allow of any flowers of this description, because when only one covering is present, they are pleased to call it invariably a calyx. Jullieu therefore applies the term naked flowers to those which have no bracte or floral leaf.

Naked Leaves are defitute of all kind of clothing or hairiness, like molt of the Orchis tribe.

Naked Seeds are such seeds of plants as are not inclosed in any pod, or capsule.

Naked Stems are those which bear no leaves.

Nakel, in Geography, a town of the duchy of Warsaw; 40 miles N.N.W. of Gneina.

Nakgivan, a town of Persia, in the province of Arokbage; 30 miles S.W. of Arokbage.

Nakia, a town of Syria; 10 miles N. of Acre.

Nakib, in the Oriental Dignities, the name of an officer who is a deputy to the calidzhier, or, as he may be called, the lord high chancellor of Egypt, appointed by the grand signor. His office is to carry the standard of Mahomet.

Nakir, a word used by some medical writers to express a violent flatulence which passes from one limb to another, and is always attended with pain.

Nakkila, in Geography, a town of Sweden, in the province of Abo; 10 miles S.E. of Borneberg.

Nakous, an Egyptian musical instrument, made like two plates of brafs, and of all fizes, from two inches to a foot in diameter; they hold them by ftrings falleden to their middles, and strike them together fo as to beat time. They are used in the Coptick churches, and in the Mahometan proceedings.

Nakra, in Geography, a town of Persia, in the province of Khorasan; 9 miles N.E. of Herat.

Nakrash, a town of Egypt, on a canal formed from the Nile to the lake Marseotis; 10 miles N.W. of Skabur.

Nakvay, a town of Africa, in the kingdom of Yani.

Nal la Appella, in Botany, a name used in the Hortus Malabaricus to express an Indian shrub, or tree, from the roots of which they obtain an oil of a gold-yellow colour, and very agreeable smell, called appel oil. It is of a bitterish and sharp taste, and is in great esteem among them in pains of the head.

Nala Sunkra, in Geography, a branch of the Indus, which
which separates from the main stream, 14 miles S.W. of Naferpou, and runs into the sea; 35 miles W. of Boogooge.

NALABOOG, a sea-port on the west coast of Sumatra. N. lat. 4° 16'. E. long. 95° 5'.

NALADIDY, or NALDOROOG, a town of Hindoostan, in Marwar; 35 miles N.W. of Ramanadapuram.

NALLDOROUK, or NALDOOG, a town of Hindoostan, in Dowladabad; 76 miles E. of Vithiapour. N. lat. 17° 27'. E. long. 76° 45'.

NALIBOK1, a town of Lithuania; 25 miles N.E. of Novogrodek.

NALIKAN, a town of Afrom Turkey, in Natoia; 25 miles E. of Edik-sheher.

NALLABIGA, a town of Hindoostan, in Bahar; 33 miles S.W. of Bahar.

NALLACOOD, a town of Hindoostan, in Goconda; 21 miles S. of Combamet.

NALLAGUNGE, a town of Bengal; 6 miles S.W. of Chilmary.

NALUGU, in Botany. Rheede Hort. Mal. v. 2. 43. t. 26. See LREA SAMBUCINA.

NALUS, in Geography, a country and people of Africa, between the rivers Nuna, Triltao, and Rio Grande, bordering on the country of Sierra Leone; not far from the Atlantic, between 10° and 11° of N. lat.

NAM. See Naam.

NAMA, in Botany, a Greek name adopted, as it appears, without much reason, by Linnaeus; nor can we offer any thing satifactory refpefting its origin or application.

Gen. Ch. Cal. Perianth inferior, of one leaf, permanent, cloven into five, lanceolate, acute, straight, spreading segments. Cor. of one petal, wheel or valver-shaped; tube short, limb divided into five, ovate, obtuse segments, the length of the calyx. Stem. Filaments five, thread-shaped, ovate at the base, inserted into the middle of the tube, shorter than the segments of the limb, and alternating with them; anthers oblong, cloven at the base, revolute, incumbent. Fil. Germen superior, ovate; styles two, capillary, erect, as long as the stamens; stigma capitate. Peric. Capsule ovate-oblong, obtuse, compressed, furrowed on both sides, of one cell, two valves, and shorter than the calyx. Seeds numerous, very small, affixed to the flat receptacle in the middle of the partition.

Eff. Ch. Calyx very deeply five-cleft. Corolla five-cleft. Capsule with one cell, and two valves.

1. N. juniferetia. Linn. Sp. Pl. 327. (N. reclinata villosa, folia ovatis, petalis marginatis recurventibus, flores foliariis; Browne Jam. 185. t. 18. f. 2.)—Native of Jamaica; cultivated in garden, as well as in waste fliny places. Root annual, simple, thread-like. Stem from two to six inches in height; subdivided, procumbent, downy, branched from the axils of the leaves. Leaves opposite, wedge-shaped at the base, ovate, or roundish, entire, downy, their flanks deciduous. Flowers axillary, from two to four in a cluster, each on a separate, short stalk, small and white.

—Browne remarks, “that this little plant spreads about the root, that all its parts are somewhat hairy, and that the stalk and bracts are margined.”

N. zeuzantha, Linn. is now referred to HYDROLEA; see that article.

NAMACUL. in Geography, a town of Hindoostan, in Barraumal country; 45 miles S. of Dasempury. N. lat. 11° 22'. E. long. 78° 5'.

NAMAGANG, a small island in the East Indian sea. S. lat. 6° 43'. E. long. 152°.

NAMAMTIA, in Ichthyology, a name given by the French to the minait, or seewon. See TRICHECUS MA-MAMTIA.

NANDA, in Geography, a town of Japan, in the island of Nippon; 42 miles S.S.W. of Iga.

NAMQUAS, in Ornithology, a species of Tetra (which fee), in the dry deserts of Africa inhabited by the Namsqas.

NAMQUAS, in Geography, a people of Africa, near the W. coast, N. of the Cape of Good Hope.

NAMASKET. See MIDDLEBOUGH.

NAMATION, NAMATIO, in Laws, the act of disfraining or taking a dixrefa; which fee. See also Naam.

In Scotland the word is particularly used for impounding. See POUND.

NAMPALLA, in Geography, a town of Peru, in the audience of Quito; 40 miles N.W. of Jaen de Bracamoros.

NAMBE, a town of New Mexico; 40 miles N. of Santa Fe.

NAMBOOR, a town of Hindoostan, in My fore; 20 miles W. of Erroad.

NAMBU, a sea-port of Japan, on the E. coast of the island of Nippon; 200 miles N. of Jedo. N. lat. 38° 58'. E. long. 142° 20'.

NAMDO, an island in the Baltic, near the E. coast of Sweden. N. lat. 59° 55'. E. long. 18° 10'.

NAME denotes a word by which men have agreed to express some idea; or which serves to denote or signify a thing or subject spoken of.

This the grammarians usually call a noun, nomen, though their noun is not of quite so much extent as our name. See NOUN.

Seneca, lib. ii. de Beneficiis, observes, that there is a great number of things which have no name; and which, therefore, we are forced to call by other borrowed names. "Ingens eft," says he, "rerum copia fine nomina, quas cum propriis appellabantur signare non potuisse, alienis accommodatis utimur:" which may shew why, in the course of this dictionary, we frequently give divers Tenes to the same word.

It was Adam who, probably under a divine direction, first gave things their names. Genesis, ii. 19.

Names are distinguished into proper and appellative.

Proper names are thofe which repreffent fome individual thing or perfon; fo as to diftinguish it from all other things of the fame species. As Socrates, which repreffes a certain Philofophcr.

Appellative, or general names, are thofe which signify common ideas; or which are common to feveral indivifuals of the fame species; as horse, animal, man, oak, &c.

Proper names are either called Christian, as being given by us at baptism; or names: the firft, impofed for diftinétion of perfons, having to the Roman prenomen; the second, for the diftinétion of families, answering to the nomen of the Romans, and the patronymicum of the Greeks.

Originally every perfon had but one name; as among the Jews, Adam, &c.; among the Egyptians, Biftirs; among the Chaldees, Ninus; the Medes, Aflzagés; the Greeks, Diomedes; the Romans, Romulus; the Gauls, Divitiacus; the Germans, Ariovitius; the Britons, Caffivelan; the English, Hengil, &c.; and thus of other nations, except the
the savages of Mount Atlas, whom Pliny and Marcellinus represent as "anonymi," namely.

The Jews gave the name at the circumcision, viz. eight days after the birth: the Romans to females the same day, and to males on the ninth; at which time they held a feast, called nominalia.

Since Christianity has obtained, most nations have followed the Jews, baptizing and giving the name on the eighth day after the birth, though this is far from being an uniform practice; our English ancestors generally baptized and gave the name on the birth day.

The first imposition of names was founded on different views, among different people; the most usual was to mark the good wishes of the parents, or to entitle the children to the good fortune a happy name seemed to promise. Hence Victor, Caesar, Paulus, Statarius, Probus, &c.

Accordingly we find such names, by Cicero called bona nominis, and by Tacitus favela nominis, were full first instilled, and ranged in the Roman mullets; first called to serve at the first sacrifices in the foundation of colonies, &c. And on the contrary, Livy calls Attius Umbert, abominand omnis nomen: and Plautus, on occasion of a person named Lyco, i. e. greedy wolf, says:

"Voluit nunc faciæ conjecuram, cæterum
Quid id fit hominis, cui Lyco nomen fiet."

Hence, Plato recommends it to men to be careful in giving happy names; and the Pythagoreans taught expressly that the minds, actions, and successess of men, were according to their names, genius, and fate. Thus, Panormitan, Ex bono nomine oritur bona praesumption; and thus the common proverb, Bonum nomen bonum omen: and hence the foundation of the Omenari, which fee.

The abbe Barthelemy, in his "Travels of Anacharsis," (vol. v.) mentions it as a circumstance worthy of attention, that the greater part of names found in Homer comprehends marks of distinction. They were given in honour of the qualities most esteemed in the heroic ages, as valour, fire, strength, swiftness, prudence, and other virtues. From polemos, signifying war, have been formed Tlepolemos, i. e. able to support the labours of war, and Arechpatelinos, i. e. able to direct the labours of war. By adding to the word meches, or battle, certain prepositions and different parts of speech, which may modify the sense in a manner always honourable, are composed the names Amphimachus, Antimachus, Promachus, Telemachus, &c. He adds, that we find scarcely any degrading names in Homer.

Our Camden takes it for granted, that the names in all nations and languages are significative, and not simple sounds for mere distinction fake. This holds not only among the Jews, Greeks, Latin, &c. but even the Turks; among whom Abdallah signifies God's servant; Soliman, peaceable; Mahomet, glorified, &c. And the savages of Hifpanola, and throughout America, who, in their languages, name their children Gliding Light, Sun-bright, Fine Gold, &c. And they of Congo, by the names of precious stones, flowers, &c.

To fumpfe names given without any meaning, however by the alteration of languages their significatio may be lost, it is not a learned author thinks, is to reproach our ancillors; and that contrary to the sense of all ancient writers. Porphyry notes, that the barbarous names, as he calls them, were very emphatical, and very concile; and accordingly it was esteemed as a duty to be epnéuvs, or su nominis homines: as Severus, Probus, and Aurelius are called sui nominis imperatores.

And it was the usual way of giving names, to with the children might discharge their names. Thus, when Gunthram, king of France, named Clotharius at the foot, he said Crefiof puér et hujus fuit nominis executor.

The ancient Britons, Camden says, generally took their names from colours; because they painted themselves; but these names are now lost, or remain hid among the Welsh. When they were subdued by the Romans they took Roman names, some of which still remain, corrupted; though they are, for the greatest part, become extinct, upon the admission of the English Saxons, who introduced the German names, as Cridda, Penda, Osvald, Edward, &c. The Danes, too, brought with them their names; as Swayne, Harold, Knute, &c.

The Norman, at the Conquest, brought in other German names, as originally using the German tongue; such as Robert, William, Richard, Henry, Hugh, &c. after the same manner as the Greek names, Alphafius, Boethius, Symmachus, &c. were introduced into Italy, upon the division of the empire. After the Conquest, our nation, which had been averse to foreign names, as deeming them unlucky, began to take Hebrew names, as Matthew, David, Samson, &c.

The various names anciently, or at present, obtaining among us, from what language or people foever borrowed, are explained by Camden in his Remains.

Of late years it has obtained among us to give furnames for Christian names; which some dislike, on account of the confusion it may introduce. Camden relates it as an opinion, that the practice first began in the time of Edward VI. by such as would be godfathers, when they were more than half fathers. Upon which some were persuaded to change their names at confirmation; which, it seems, is usual in other countries. Thus, two sons of Henry II. of France, christened Alexander and Hercules, changed them at confirmation into Henry and Francis.

In monasteries, the religious assume new names at their admittance; to shew they are about to lead a new life, and have renounced the world, their family, and even their name; e. g. Stifter Mary of the Incarnation, Brother Henry of the Holy Sacrament, &c.

The popes also change their name at their exaltation to the pontificate; a custom first introduced by pope Sergius, whose name, till then, as Plutina informs us, was Swinefoot. But Baronius refers it to pope Sergius I. and Onuphius to John XII. or XIII. and at the same time adds a different reason for it from that of Plutina, viz. that it was done in imitation of St. Peter and St. Paul, who were first called Simon and Saul. Indeed pope Marcellus, of late, refused to change his name.

In Italy; it is frequent to join the name of some saint, in a kind of devotion, to the Christian name; as Joannes Baptista Spinola, &c.

Among the ancients, those defied by the heathen consecrations had new names given them, as Romulus was called Quirinus; Melcerus, Portunus or Portunus, &c. New names were also given in adoptions, and sometimes by tetrach: thus L. Aemilius, adopted by Scipio, took the name of Scipio Africanus; and thus Augustus, who at first was called C. Octavius Thurinus, being adopted by the tetrach of Julius Caesar into his name and family, took the name of Caius Julius Caesar Octavianus. Names were also changed at enfranchisements into new cities. Thus Lucumo, at his first being made free of Rome, took the name Lucus Tarquinius Priscus, &c. and flaves, when made free, usually assumed their masters' names.

Those called to the equestrian order, if they had base names, were always new-named, nomine ingenuorum veterumque.
que Romanorum. And among the primitive Chriftians, it was the practice to change the names of the catechumenos; thus, the renegado Lucianus, till his baptnism, was called Lucius.

Towards the close of the fifteenth century, some of the literati and wits of that period, particularly in Italy, changed their baptismal into classical names. This was done by Platina, the historian at Rome, who assumed the name of Callimachus, instead of Philippus, and thus awakened the fufpicion of pope Paul II. This literate ecclefiafic, conceiving fome bad, but mysterious purpofe, in this practice, wished to difclove the secret, and with this view had recourse to violent methods. Platina was cruelly tortured on this frivolous pretext; and as he had no confefion to make, the pope, having ineffectually endeavoured to convict him of heresy, fedition, &c. and having kept him for a long time in prison, at length releafed him.

NAME. General. See GENERAL.
NAME. Specific. See SPECIFIC.
NAME. of the, is a phrase frequent among Historians and Genealogists, to denote proper of the fame quality and name. It is near one thousand years since the emperors of the Weft first began to dignify themselves in this manner by their number; and in the Italia Sacra of Ughellus, we meet with a charter of the emperor Louis le Debonnaire, ann. 818, wherein that prince styles himfelf the first of the name. Le Blanc mentions a charter of the year 1084, wherein the emperor Henry III. styles himfelf king of Italy, the fourth of the name: and emperor the third of the name.

Some French writers obferve, that in a manuscript preferved in the king's library, their Lewis XI. is only folled the ninth of the name; Louis le Debonnaire, and Louis the Stammerer, not being then reckoned in the number, becaufe they were emperors, as well as Kings of France; on which footing, the late king, instead of the fourteenth, fould only be the fifteenth of the name.

NAMETZKY, in Geography, a town of Moravia, in the circle of Brumm; 8 miles N.E. of Szar.

NAMESTI', a town of Moravia, in the circle of Olmutz; 10 miles W. of Olmutz.—Alfo, a town of Moravia, in the circle of Znaym; 30 miles N. of Znaym.

NAMINGATA, a town of Japan, in the ifland of Niphon; 56 miles N.W. of Firusa.

NAMM, NAMM in Law. See NAMM.

NAMM, Vellum, or prohibited Namn, is an unjust taking the cattle of another, or driving them to an unlawlful place, pretending damages done by them.

Such, e. g. is that when the bailiff of a lord diftrains bealls or goods, and the lord forbids his bailiff to deliver them, when the sheriff comes to replevy them; and to that end, drives them to places unknown. Or when, without any words, they are to be ejected, as that they cannot be repleved. Divers lords of hundreds, and courts-baron, have power to hold plea de vito namn.

In fuch cafl, the owner of the cattle may demand fatisfaction for the injury, which is called plactum de namn with vettis.

NAMMESTA, in Geography, a town of Norway, in the diocfe of Aggerhusa; 28 miles S.S.E. of Christiania.

NAMNAGUR, a town of Hindooftan, in Bahar; 58 miles S.S.W. of Patna.

NAMPHIO, NAMPHI, or Naphs. See NAPHS.

NAMSEN, a river of Norway, which runs into a bay of the North sea, to which it gives name, N. lat. 64° 35'. E. long. 11° 25'.

NAMSLAW, a town of Silefia, in the principality of Breflaw, having a strong cattle, situated among moraffes, on the river Weyda; 12 miles S.E. of Oels. N. lat. 51° 37'. E. long. 17° 45'.

NAMUSOS, a town of Peru, in the diocfe of Truxillo; 120 miles S.E. of Chacopas.

NAMUR, County of, lately one of the Catholic provinces of the Netherlands, now a part of France, confituting the department of the Sambre and Meffe; which fea.

NAMUR, a city of France, late of the Netherlands, and capital of the county of Namur, now capital of the department of the Sambre and Meffe, situated in a valley at the confluence of these two rivers, the greater part being on the right side of the Sambre, between two hills. Some fay that it derived its appellation from "Nam," an armed idol, supposed to be Neptune. This city was defended by a strong castle, feated on a fharp rock on the oppofite fide of the Sambre, which castle was rendered an almost impregnable defence by Fort William and other confiderable forts. In 1692, Louis XIV., with an army of 100,000 men, laid fief to this city, that moity of the army which covered the siege being entruled to the command of the duke of Luxembourg. The garrifon, confiding of 5000 men, was commanded by the prince of Brabant. The affaiants, though apprized that king William would attempt the relief of the city, and that it was well supplied, profecuted their attacks with fuch vigour, that in seven days the place capulated, and the garrifon withdrew to the citadel. The besiegers, encouraged by the prefence of their monarch, and aflilited by Vauban, their engineer, purfued their attack with fuch impetuofity, that the fort of Coehorn was surrendered after an obftinate defence, and the famous engineer Coehorn himfelf dangerously wounded. On this occasion, Vauban and Coehorn exhausted the whole fience of attack and defence, and although the befieged performed wonders, the affaiants prevailed, and the citadel surrendered in fight of king William's army, confiding of 100,000 effective arms, encamped within cannon-shot of Luxembourg's army, which lay on the other fide of the river. Namur remained in the pofteffion of the French until the year 1695, when king William determined to make every poftible effort for retaking it. The affault was desparate and fanguinary, and the garrifon was defended with equal spirit and perseverance. On the 11th of July the trenches were opened, and on the fcond day of September the capitulation was completed. Such had been the French king's confidence in the strength of the place, that he caufed to be placed over one of the gates this inscription; "Redui, non vinci, potes?" that is, you may be surrendered, but cannot be conquered. After the death of Charles II. of Spain, the French feized Namur, together with the rest of the Netherlands, and kept pofteffion of it till the treaty of Utrecht, when the comte, town, and cattle, were given up to the States General, to serve as a barrier against France; the sovereignty and revenues being referred for the elector of Bavaria, and the crown contributing its quota to the maintenance of the Dutch troops and fortifications. In 1746 this fortress was taken posfeffion of by the French, but by the peace of Aix-la-Chapelle it was ceded to the emperor; since that time the fortifications have been demoftrated, except the citadel, which was captured by a detachment of the French army under general Valence, in December 1792, and again surrendered in the following year. In 1794, after the defeat of general Clairfait near Louvain, on the fifteenth of July, the Netherlands were found untenable by the allies. On the 20th, the keys of the city were prefented at the bar of the national convention. Namur is the fee of a biffop, erected in the year 1559 by pope Paul IV. Before the reformation commenced by the late
late emperor Joseph, it had four abbeys of Benedictines, fourteen of Cistercians, one of the order of Premontré, one abbey, and two priories of canons regular, seven chapters of canons, three chapters of noble canons, together with a number of religious houses both for men and women, and several hospitals. Its two divisions, N. and S., contain 16,000 inhabitants; the first 11,500, and the second 4,500, and its canton 11,328, on a territory of 172,666 acres; 45,000, and its canton 11,328, on a territory of 172,666 acres; 25 miles S.W. of Liege. N. lat. 50° 26'. E. long. 5° 54'.

NAND Marble. See Luctelle Marble.

NAMUSA, in Geography, a small island in the Pacific ocean, belonging to the cluster called Moaiges. N. lat. 17° 11'. E. long. 126° 35'.

NAMUSSO, a town of Mingrelia; 10 miles S. of Aragvia.

NANDAW, a town of Hindooftan, in Oude; 32 miles S. of Fyzabad.

NANDA RAK, a town of Well Greenland. N. lat. 61° 1'. W. long. 37° 23'.

NANAS, a town of Hungary; 4 miles S. of Tokay.—Also, a mountain of Carnola, between Wipach and St. Veit.

NANCASERAM, a town of Hindooftan, in Canara; seven miles S. of Mangalore.

NANAY, a town of France, in the department of the Cher; 18 miles N. of Bourges.

NANCHE, a town of the island of Formosa, on the W. coast. N. lat. 23° 52'. E. long. 119° 45'.

NANCY, a city of France, formerly the capital of Lorraine, now the capital of the department of Meurthe, near the river of that name, alternately capital with Luneville. It is situated in a beautiful and fertile plain, and divided into Old and New Town; the first small and ill built, the latter larger and better built, the streets being wider, and in a straight line. Before the revolution, it contained three colleges, three parochial churches, seventeen convents, an university, an academy of sciences, a medical college, an hospital, and a commandery of Malta. It was formerly fortified, but by the peace of Rywick, the fortifications of the New Town were destroyed. The three divisions of north, east, and west, contain 29,720 inhabitants; the first, 7542, its canton 12,742, on a territory of 1374,196 acres; 10 communities; the second, 11,189, its canton 13,422, on a territory of 70,765 acres; 19 communities; and the third, 11,009, its canton 15,547, on a territory of 1,674,576 acres; 11 communities. N. lat. 48° 42'. E. long. 6° 16'.

NANDBURGAM, a town of Hindooftan, in Myfore; five miles S.S.W. of Chinha Balabaram.

NANDLITETT, a town of Bavaria; 9 miles N.W. of Molfburg.

NANDENORE, a town of Hindooftan, in the Carnatic; 8 miles N.E. of Chittoor.

NANDER, a town of Hindooftan, in Dowrhatad; 132 miles N.N.W. of Hydrabad. N. lat. 19° 6'. E. long. 77° 35'.

NANDGEERY, a town of Hindooftan, in Visapur; 14 miles N.E. of Sattarah.

NANDGOM, a town of Hindooftan, in Balgana; 18 miles E.S.E. of Chandoor.

NANDI, a town of Bengal; 25 miles S.S.E. of Moorfieldabad.

NANDI ERAWATUM, in Botany, the name of a small shrub which grows in the East Indies, the whole of which is lacetent. The juice expressed from it, mixed with oil, causes pains of the eyes, if the head is anointed with it; the roof is irritated, and bold in the mouth, causes the toothache; and the same boiled in oil, makes a good ointment for all indifferent of the head, especially pain; bruised, and taken in water, it kills worms; bruised with the juice of lemon, and put into the eyes, it removes films.

NANDIGAW, in Geography, a town of Hindooftan, in the circuit of Condapilly; 15 miles N.W. of Condapilly.

Nand. Cal. Perianth inferior, of many leaves, inbricated in fix rows, and furnished with about fix, ovate, acute, smooth, calcicular foliole in each row. Cor. Petals fix, oblong, concave, acute, longer than the calyx, falling off. Stamens fix, very short; anthers elongate, erect; the length of the corolla. Fr. German superior, short, smooth; flat, triangular, very short; stigma triangular. Peric. Berry dry, globose, f. mo'tho. Seeds two, hemispherical, f. mo'tho.

1. N. domestica. Garden Nandina. Linn. Syll. Veg. ed. 14. 344. Sims in Curr. Mag. t. 1109. Thub. Japon. 147. Banks Ic, Kempf. t. 151. 14.—(Nandajok, vulgo Natten vel Nandin; Kempf. Amoen. 776.)—This ornamental plant is much cultivated both in Japan and China, and is of native of the latter, from whence it was introduced into the garden at Kew in 1804, by Mr. William Kerr. It flowers from May to July.—Root perennial. Stems numerous, shrubby, erect, leafy, branched at the top, about six feet high, and half an inch in diameter. Branches covered with the sheaths of the leaves, waved, leafy at the upper part. Flowers repeatedly compound; leaflets ternate, ovate, bristle-pointed, entire, with a reflexed margin; their petals remarkably compound, the divisions branching off nearly at right angles; at the lower ones more especially; the joints are sown into a kind of globular bulbs. Flowers in loose, terminal, compound panicles, white, with prominent, bright-yellow anthers. Berries red, the fize of a pea, membranous within. Seeds two, convex on one side, and concave on the other; Kempf compares them to what are called in the shops Crab’s-eyes; they are ash-coloured or reddish.

The leaflets of this plant are remarkable for falling off at the joints of their filaments, as soon as it begins to dry between paper.

NANDOLIY, in Geography, a town of Hindooftan, in Rohilcund; 30 miles W.S.W. of Pariyari.

NANDRAN, a town of France, in the department of the Oure, and chief place of a canton, in the district of Huy. The place contains 566, and the canton 10,222 inhabitants, on a territory of 3241,392 acres, in 28 communes.

NANDY-ALLEM, a town of Hindooftan, in Colcond; 22 miles S.E. of Carnool. N. lat. 19° 6'. E. long. 77° 35'.

NANDYOL, a town of Hindooftan, in Bengal; 10 miles S. of Goragot.

NANFI0, NANDIO, or NAMPLIA, an island in the Greecian Archipelago, situated S.W. of Stamagria, and little more than seven leagues in circuit. Its first name was Memblianis, derived from Membrana, a Phoenician, who, when his relation Cadmus went in quest of Europa, accompanied him,
him, and settled in the neighbouring island of Thera. It has since been named Anapha, which in Phoenician language, according to Bochart, signifies shaded and dark, an epithet which this island acquired from its gloomy and thick forests; or, as others say, from the Greek word ἀναφής, to appear, from the thunder having on a sudden occasioned it to arise from the bottom of the waters, in order to receive the fleet of the Argonauts on its return from Colchis, when affailed by a furious tempest. This fable of antiquity is the history of the formation of Naxos, which a voleano caused to appear suddenly above the sea, in the midst of a violent agitation of the atmosphere and of the waves, which has been the case with some other islands of the Archipelago. In memory of this event was built a temple, which was consecrated to Apollo Εὔγλετες, or dazzling with light. Mirth, wine, and pleasantry preceded at the festivities which were here celebrated. Small velliges of the temple still appear in the S. part of the island; and the marble of which it was constructed was taken from a steep rock, of frightful aspect, on whose summit is a chapel, dedicated to “Our Lady of the Reed,” or in modern Greek “Panagia Kalamītou.”

The forests which once darkened the island have disappeared, and have been succeeded only by some scattered shrubs. Its mountains are barren and naked, nor do its plains afford a much more brilliant vegetation. Agriculture languishes, and notwithstanding the fertility of the soil, barley is almost the only plant that produces any harvest. Some small plantations of vines yield good wine, and honey is common. Partridges formerly multiplied so prodigiously, that in order to preserve the corn, all the eggs that could be found were collected about the Easter holidays, and made into various sauces, and especially into amulets; and yet, according to Tournefort, coves of partridges were still very numerous. Their number seems now to be diminished. A small town built to the S. contains the whole population of Naxos; every thing bequeaths the wretchedness spread over the territory of the island. Here is no harbour; but in front of the town, ships find a very good road-head, protected by a small frond, which is called “Nanfo-Poulo,” or Little Naxos.

NANFRI, a river of Sicily, which runs into the sea, on the S. coast, N. lat. 37° 3’; E. long. 14° 6’.
NANGA, a sea-port town of the island of Niphon, situated on a bay on the S. coast; 55 miles S.W. of Jeda. N. lat. 35° 52’; E. long. 88° 48’.
NANGABUSAN, a town of Bengal; 33 miles S.W. of Calcutta. N. lat. 22° 12’; E. long. 88° 45’.
NANGALLY, a town of Hindoostan, in Myfore; 13 miles N. of Vencatigerry.
NANGAN, a city of China, of the second rank, in Yunnan; 1192 miles S.W. of Peking. N. lat. 24° 58’; E. long. 101° 23’.
NANGANIE, a river of Hindoostan, which runs into the Ambravetty; 11 miles S.W. of Caroor.
NANGASAKI, or NAGASAKI, a sea-port town of Japan, on the W. coast of the island of Ximo, at the end of a deep commodious bay. The harbour widens and deepens from its mouth towards the interior part, in which is a rocky island, where is good riding. About half a mile from the town are two imperial guards, enclosed with palisades, each of which consists of 500 men. Here are several forts, constructed along the harbour, but without cannon. The city lies at the widest end of the harbour, but it has no walls, castles, or other defence. The streets are neither straight nor wide. Three rivers run through the town, which descend from the neighbouring hills; but they scarcely afford water sufficient, during the greatest part of the year, to water their rice-fields and gardens; though these streams, after heavy rains, swell into torrents so impetuous, as to sweep away whole houses by their rapid current. The place is divided into the inner and outer town; the former containing 26, and the latter 61 streets, in which no strangers are allowed to dwell; but they are confined under strict watch to certain suburbs. The chief public buildings are five magazins, or large houses, near the shore, constructed of timber; in which are kept three imperial junks, or men of war, ready to be launched at command. The powder-magazine, the palaces of the two refining governors, and other princes and grandees; some of whom reside constantly, and others occasionally there; about 62 temples within and without the city; used partly for devotion, and partly for recreation; the goknia, or common prison, consisting of about 100 large and small cages, or huts, separate from each other, where prisoners are confined, put to the torture, and privately executed, according to their rank or crimes; the brothel, consisting of two handsome streets, shut at each end by strong gates, in which prostitutes are kept, and let out for hire, either to natives or foreigners. The houses are low and mean, though well inhabited, mostly by merchants, tradesmen, and mechanics. The market is well supplied with fowls and grain of various kinds, fish, and cattle; though provisions, as well as merchandizes, fell here at a dearer rate than at other parts. The water is bad, and is fad to occasion very violent and painful colics. The Portuguese were completely routed from Japan in the year 1639, and no further attempts were made on the part of the English till the year 1768, when the East India Company sent a ship to Nangasaki, with a letter from his Britannic majesty to the emperor of Japan. The emperor, probably under the influence of the Dutch, sent the English a medal, forbidding any intercourse with his dominions. Thus ended all communication with Japan, on the part of the English, until the year 1805, when a ship was sent on a mercantile speculation from Calcutta, which was refused admittance, and ordered to leave in 24 hours. In 1808, captain Pellew, in the Phaeton frigate, entered the harbour of Nangasaki under Dutch colours; but the event was unpropitious. N. lat. 32° 45’; E. long. 128° 46’ 15”, or 130° 6’.
NANGAXIMA, a town of Japan, in the island of Xi-coco; 20 miles N.E. of Tofa.
NANG-GE-SU, a small island near the coast of China. N. lat. 25° 6’; E. long. 119° 24’.
NANGIHAN POINT, the southern extremity of the island of Leyta. N. lat. 10° 2’; E. long. 123° 37’.
NANGIS, Guillaume de, in Biography, an ancient French historian, who flourished in the fourteenth century, was a Benedictine monk of the abbey of St. Denis. He wrote the lives of St. Lewis, and of Philip le Hard, and also two chronicles; the first from the creation to the year 1300, the second a chronic general of the kings of France. The lives were printed, for the first time, in Paris in the year 1561, and the chronicle from the year 1113 was published in the “Spicilegium” of D. Luc d’Arcerry, M. Serre.
NANGIS, in Geography, a town of France, in the department of the Seine and Marne, and chief place of a canton, in the district of Provins; 12 miles W. of Provins. The place contains 1699, and the canton 8023 inhabitants, on a territory of 324,521, in 19 communes.
NANG-KANG, a city of China, of the first rank, in the province of Kiang-si, on the lake Poy Yang. It has four cities of the third class under its jurisdiction; 637 miles S. of Pekung. N. lat. 29° 33’; E. long. 115° 39’.
NAN

NANGA, a town of Japan, in the island of Xino; 65 miles N. of Nangafaki.

NANGU, a town of Hindooistan, in Myloore; 35 miles N. of Rettingbery.

NANGER, in Zoology, the Antilope Dama, has its horns hooked forwards at the ends; the upper parts of the body tawny yellow, the under parts white, with a white spot on the chest. This is the doma of Flinny, Geifier, Ray, &c. the swift antelope of Pennant, and in his opinion, the Kpans, or Cenms, of Ælian. It inhabits Senegal. This animal is three feet ten inches in length, from the nose to the origin of the tail, and two feet eight inches high at the shoulder; the greater part of the body is white, but the back, upper parts of the sides, and the head, are tawny or yellowish; there are, however, varieties as to colour. Both sexes have round horns, about eight inches long, bent or hooked forwards, and sharp-pointed; there are only six fore-teeth in the lower jaw. The Nanger is very swift and is solely tamed. Ælian compares the flight of the Kpans, to the rapidity of a whirlwind.

NAN-HOANG-TCHIN-DAO, in Geography, a small island near the coast of China, in the Eastern Sea. N. lat. 38° 18', E. long. 120° 44'.

NANI, in Biography, an Italian historian, of a noble Venetian family, was born in 1616, and educated under the eye of his father, who took him to Rome in his suits, being appointed embassador from the Venetian republic to Pope Urban VIII. In 1641, Nani was admitted into the college of senators, and soon after was appointed embassador to France, where he resided five years. He was much esteemed by cardinal Mazarin, who was in the habit of consulting him on public affairs. In 1648 he returned to Venice, having obtained from the court of France a considerable aid of men and money for the defence of Candia against the Turks. The superintendence of the affairs of war and finances was then entrusted to him; and in 1664 he was sent embassador to the Imperial court, which he visited a second time on the accession of the emperor Leopold. In 1670 he was delegated upon a second embassy to the court of France, and on his return was nominated a procurator of St. Mark; and was soon after raised to the post of captain-general by the sea. The maritime service not agreeing with him, he continued to serve the state at home, and the office of historiographer was conferred upon him, and the manner in which he performed his duties rendered his name illustrious. He died in 1678. He was the author of the "Hilory of Venice from 1615 to 1671," of which the first part was published at Venice in 1652, and the second after his death in 1679. It is much esteemed for the veracity of the narrative, and for the depth and facility of the political reflections. To the new edition in the collection of Venetian historians, the life of the author is prefixed. It has been translated into the French and English languages. Moreni.

Nani, in Geography, a town of Candasbar: eight miles S.W. of Ghizni.

NANJAR, a town of Africa, in the kingdom of Burfali.

NANIMAN, a town of the island of Cuba; 75 miles W.S.W. of Havana.

NANINA, a town of Abyfina; 70 miles E. of Miné.

NANINO, Giovanni Maria da Valerano, in Biography, was admitted into the pontifical chapel, as a tenor singer, in 1577. He was a fellow Student and in strict friendship with Palestrina. These two excellent masters opened a music-school together at Rome, where they formed many great scholars, among whom was Giov. Bernardino. Vol. XXIV.

NANINO, a younger brother of Maria, according to Walther, but called by P. Martini his nephew, and Antonio Cifra. Antimo Liberati informs us of a circumstance, which will be readily believed; that Palestrina had no relish for the drudgery of attending a school, having his thoughts too much absorbed in his own studies; and that, leaving the care of the discipules to Nanino, his visits were not very frequent or long, calling only from time to time in order to explain to them such uncommon difficulties and doubts as impeded the progres of their studies, and to adjudge the disputes which arose among the professors, who in great numbers constantly attended the lectures there. Though Nanino was regarded by the Romans as one of the most learned musicians of his time, yet Schallian Raval, a Spaniard, then at Rome, thinking they were all mistaken, and that he was himself very much his superior, challenged him and his countryman Soriano, another friend of Palestrina, to a mortal combat, which was to be determined by a weapon they had both frequently wielded, the pen: in this engagement, however, the Spaniard was defeated. Many different fets of madrigals, by Nanino, were published at Venice during the latter end of the sixteenth century, which are now difficult to find; there are, however, in the "Studi di Palestrina, severals of his chants, which are excellent. P. Martini, "S'oria della Musica," has given in his catalogue of authors the titles of two very curious works: the first of these, by G. M. Nanino, is called "Centocinquanta sette Contrapunti e Canoni, a 3, 3. 4, 5, 6, 7, 8, 11 Voc. Supra de Cantofermo intitolato la Baie di Collanzo Festa," the second is cried "Trattato di Contrap., con la regola per for Contrapunto a mente, di G. M. Nanino e Bernardino Nanino, fuo Nepote."

NANINO, Bernardino, the younger brother of Maria, according to Antimo Liberati, was a person of very extraordinary abilities, who, by an inventive style joined to a perfect knowledge of harmony, had greatly improved the art of composition. The only productions which we have seen of this master, are two or three chants in the "Studi di Palestrina."

NANKA ISLANDS, in Geography, three small islands in the East Indian sea, the southernmost of which lies close to the western shore of the island of Banca. Sir Efraim Gower observed, that it was very desirable for ships to stop at the Nanca isles, as wood for fuel is very conveniently procured from thence; and was later thought preferable, for keeping, to any before discovered by the squadron in those seas. It discharges itself from three small rills into a deep reservoir. The tide rises and falls about 11 feet, and flows once only in the 24 hours. The latitude of the road is 2° 22' S., and the longitude 107° 41' E. This place is perfectly sheltered from S.W. by S. to the N.W.; and there can be no high sea with any wind, as the land is but at a short distance in the open points. The sea was very shallow close to these petty islands, and heaps of stone mixed with iron ore were, in many places, seen just rising above the surface, without the least covering of vegetation, and as if, at no very remote period, vomited up by the force of subaqueous fire. Stanton's Embassy to China, vol. i. p. 307.

NAN-KING, or Kiang-niing, a city of China, the capital of the province of Kiang-nan, is said to have been formerly one of the most beautiful and flourishing cities in the world. The Chinese, in speaking of its extent, say, that if two horsemen should go out by the same gate, and ride round it in full speed, taking different directions, they would not meet before night. Although this account is exaggerated, it is certain, says Grolier, that Nan-king surpasses in extent all the other cities of China. Its walls, it is said, are
are 5½ leagues in circumference. A French missionary gives the following account of its extent. The suburbs, he says, are very long, but not populous; the houses stand at some distance from one another, having reeds, pools of water, or plantations of bamboo between them. Viewing it from the 5th story of the porcelain tower, which commands an extensive prospect, it did not appear to be above two-thirds as large as Paris. In order to reconcile this appearance with the accounts that have been given of its immense extent, they found, upon travelling a full league from Nan-king, the walls of a city rising amid mountains, and appearing as if cemented to the rocks. These were the walls of Nan-king, which, leaving the city where it now stands, have, as it were, retired thither, to enclose a space of fifteen or sixteen leagues, twelve or thirteen of which are not inhabited.

This city is situated at the distance of a league from the river Yang-tse-kiang; it is of an irregular figure; the mountains within its circuit having prevented its being built on a regular plan. It was formerly the imperial city, and for this reason called Nan-king, i.e., the southern court; but since the fix grand tribunals have been transferred from thence to Pe-king, it is called Kiang-nin in all the public acts. It has lost much of its ancient splendour; no vestige now remains of its magnificent palace; other monuments of its grandeur have also disappeared. A third of the city is defeted, but the rest is all inhabited. Some quarters of it are populous, and full of business. The streets are less broad than those of Pe-king; but they are very beautiful, well paved, and bordered with rich shops. One of the great mandarins, called T'hung-gou, resided here, to take cognizance of all important concerns: the Tartars have a numerous garrison here, commanded by a general of their own nation, and they occupy a quarter of the city, separated from the rest by a plain wall. The palaces of the mandarins are not particularly distinguished from those of the capitals of other provinces; and here are no public edifices corresponding to the reputation of a city so celebrated, excepting its gates, which are very beautiful, and some temples, among which is the famous porcelain tower, 200 feet high, and divided into nine stories, to the first of which is an ascent of forty steps, and to each of the others twenty-one. The port was formerly rendered commodious by the breadth and depth of the river Yang-tse-kiang; but at present large banks, or Chinese junks, never enter it. In April and May excellent fish are caught in this river near the city, which are sent to court, covered with ice, and transported by barks kept for this purpose. This city is more than 200 leagues from Pe-king, and the boats arrive there in eight or nine days. This city, though the capital of the province, has only eight cities of the third class under its jurisdiction. N. lat. 32° 4'. E. long. 118° 24'.

NAN-NGAO-TCHING, an island near the coast of China, about 22 miles in circumference. N. lat. 23° 30'. E. long. 116° 49'.

NAN-NING-CHAN, a city of China of the first rank, situated in the most southern part of the province of Kiang-su; it is a beautiful, populous, and commercial city, and much frequented. It has dependent upon it four cities of the third class.

NANNI, Giovanni, in Biography. See Umede Giovanni de.

NANNI, or NANNUS, Peter, a critic and philologist, was born at Alcmea, in Holland, in the year 1500. He received an excellent education, and afterwards taught philosophy in his own country. He was chosen professor of the learned languages at Louvain, and in this situation palled eighteen years. He then obtained the canonry at Arras, which he kept till his death, in 1557. His principal works were "Meditationum Decas," containing annotations upon a number of ancient authors in ten books; "Dialogorum Heroinarum," reckoned his best work; "Annotationes in Institutiones Juris Civilis;" "Scholia in Cantica Cantorum," and translations of several works, chiefly from Greek authors. He is regarded as a "good critic, an in-eliminate poet, but an indifferent orator." Morelli.

NANNY, in Geography, a town of Peria, in the province of Itrak; 110 miles E. of Ipahan.

NAN-NING, a city of China, of the first rank, in the province of Quang-fù; 1145 miles S.S.W. of Pe-king. N. lat. 22° 44'. E. long. 107° 44'.

NANNO, in Biography, a girl celebrated for her beauty, for her talents in playing upon the flute, and for the poem which Minnemus made on the love with which he had inspired him, though he was arrived at an age when we are usually exempted from such passions.

"What is life and all its pride,
If love and pleasure be denied?
Snatch, snatch me hence, ye Fates, whene'er
The am'rous blifs I cease to share.
O let us crop each fragrant flow'r,
While youth and vigour give us pow'r;
For frozen age will soon deltroy
The force to give or take a joy;
And then, a prey to pain and care,
Detel'ted by the young and fair,
The fun's bleft beams will hateful grow,
And only shine on scenes of woe!"

NANNUCKLOO, in Geography, a small island near the E. coast of Labrador. N. lat. 56° 20'. W. long. 60°.

NANNY Town, Old, a deserted town of the island of Jamaica; 16 miles E.N.E. of the town of Kingston.

NANORE, a town of Bengal; 28 miles N. of Burdwan.

NANSA, a town of Spain, in Asturia; 18 miles S.W. of Santillana.

NANSA-CHE, a town of China, near the W. coast of the island of Formosa. N. lat. 25° 2'. E. long. 120° 39'.

NAN-SAN, a small island near the coast of China. N. lat. 26° 50'. E. long. 119° 20'.

NANSEMOND, a county of Virginia, on the S. side of James' river, and W. of Norfolk county, on the North Carolina line, about 44 miles long, and 24 broad, containing 11,127 inhabitants, including 4408 slaves.—Also, a short river of Virginia, flowing from Great Dismal Swamp; first in a N., then in a N.E. direction, and discharging itself into James' river, a few miles W. of Elizabeth river.

NAN-SHOO-FOU, the frontier city of the province of Quang-tong, according to Sir G. Staunton's Embassy to China. The Chinese Atlas places here a city, called Nan-yong, which is understood to be the same place. See Nan-yong.

NANT, a town of France, in the department of the Aveyron, and chief place of a canton, in the district of Milhaux; 10 miles S.E. of Milhaux. The place contains 2171, and the canton 8289 inhabitants, on a territory of 316 kilometers, in 9 communes.

NANT-T'AI-KI, a town of China, on the W. coast of the island of Formosa. N. lat. 24° 50'. E. long. 120° 20'.

NANTASKET ROAD, the entrance into the channels of Bolton harbour, in which a vessel may anchor safely in from seven to five fathoms. Two locks are erected here with accommodations for shipwrecked seamen.

NAN-TCHANG, a city of China, of the first rank, and capital
capital of the province of Kiang-ti. This city has no trade but that of porcelain, which is manufactured in the neighbourhoud of Jaw-teh-ten. It is the residence of a viceroy, and comprehends in its district eight cities, seven of the first class and one of the second. The adjoining country is so much cultivated, that the pastures which remain are scarcely sufficient for the flocks; 66 miles S. of Pe-king, N. lat. 28° 37'. E. long. 115° 30'. See K'ING-TI-CHING.

NANTERRE, a town of France, in the department of the Seine, and chief place of a canton, in the district of St. Denis; 5 miles W. of Paris. The place contains 2300, and the canton 11,000 inhabitants, on a territory of 54 kilometres, in 7 communes.

NANTES, a city of France, and capital of the department of the Lower Loire, formerly capital of a district, called Nantais in Bretagne. It is situated on the Loire, and has been reckoned one of the greatest trading cities in the kingdom: it is large and populous, containing six parts, and comprehending 73,649 inhabitants: its cantons are six, including 51,638 inhabitants, on a territory of 107½ kilometres, in 5 communes. Before the revolution, it was the seat of a bishop, the seat of an intendency, a chamber of accounts, or board of finances, a mint-office, &c. &c. In it were, exclusively of the cathedral, and a collegiate church, eleven parish churches, fourteen convents, two hospitals, one college, and an university founded about the year 1460, a society of agriculture and arts, a school of anatomy and surgery, and a large rope manufacture. Nantes has been accustomed to carry on a very large trade to the French colonies, to America, to Spain, Portugal, and other parts; though ships of burthen can come no further up the Loire than to Paimboeuf, a market-town, where the cargoes are transferred to smaller vessels, and conveyed to Nantes. The temperature of Nantes appears, from four years observations, to be 55° 53', and therefore differs very little from the standard, which is 55° 5'. N. lat. 47° 1', E. long. 1° 26'.

Nantes, Edict of, in Ecclesiastical History, a famous edict promulgated at Nantes in the year 1558, by which Henry IV. granted to the professors of the reformed or Protestant religion, the liberty of serving God according to their consciences, and a full security for the enjoyment of their civil rights and privileges, without persecution or molestation from any quarter. This edict restored and confirmed, in the fullest terms, all the favours that had ever been granted to the Protestants by other princes, and particularly by Henry III. To these privileges others also were added, which had never been granted, nor even demanded before: such as free admission to all employments of trust, honour, and profit, the establishment of courts and chambers, in which the professors of the two religions were equal in number; and the permitting the children of Protestants to be educated, without any molestation or constraint, in the public universities. This edict was revoked by Lewis XIV., at the instigation of the bishops and Jesuits, in the year 1685, a measure which, though accompanied with the applause of Rome, excited the indignation even of many Roman Catholics, whose bigotry had not effaced or subdued, on this occasion, their natural sentiments of generosity and justice. This revolution was followed by another measure, still more tyrannical and shocking, even an express order, addressed to all the reformed churches, to embrace the Roman faith. The consequences of this cruel and unrighteous proceeding were highly detrimental to the true interests and the real prosperity of the French nation, by the prodigious emigrations it occasioned among the Protestants, who sought, in various parts of Europe, that religious liberty, and that humane treatment, which their mother-country had so cruelly refused them. Those among them whom the vigilance of their enemies guarded so closely as to prevent their flight, were exposed to the brutal rage of an unrelenting soldiery, and were affrighted by every barbarous form of persecution that might tend to subdue their courage, exhaust their patience, and thus engage them to a feigned and external profession of Popery, which in their consciences they beheld with the utmost aversion and disgust. From this evil, however, good has ultimately proceeded. The event was very beneficial to almost all the Protestant countries of Europe; and more especially to the commerce of Holland, Brandenburg, and England. The number of refugees, who on this occasion fled from France, and carried their skill and industry in various manufactures to other countries, was, at a moderate computation, more than half a million.

The revocation of the edict of Nantes was followed by a persecution of the Huguenots, called, from the dragon troops employed in it, the "Dragonade." It is but justice to acknowledge, that this horrid persecution was condemned by the greatest and best men in France. M. d'Auguqueau, the father of the celebrated chancellor, resigned his office of intendant of Languedoc, rather than be a witness of it; his son repeatedly mentions it with abhorrence. Fenelon, Flechier, and Bossuet, confederally the ornaments of the Gallican church, lamented it. To the utmost of their power they prevented the execution of the edict, and softened its severities, where they could not prevent them. This practical condemnation of the refort to temporal power, in effecting religious conversion, does all these illustrious characters the greatest honour, as the doctrine of religious toleration was, at that time, little understood. We are constrained, however, to allow that Bossuet, the bishop of Meaux, seems to admit, in theory, the general right of Christian princes to enforce acts of religious conformity, by wholesome severities; and thus allows them, for effecting a spiritual good, a refort to temporal means, which the divine founder of our faith so explicitly disclaimed for himself.

Nantes, or Swimming, in the Linnean System of Zoology, is the name of an order of animals under the class of amphibia; the characters of which are, that they are pinnated, and breathe by lateral branchia or gills. This order comprehends fourteen genera, and seventy-six species. To this order belong the petromyzon, raja, squalus, &c.

Nanteuil, in Geography, a town of France, in the department of the Aisne, between Meaux and Chateau-Thierry.—Alfo, a town of France, in the department of the Marne; 6 miles N. of Epernay.

Nanteuil-le-Hanzouin, a town of France, in the department of the Oise, and chief place of a canton, in the district of Senlis; 9 miles E.S.E. of Senlis. The place contains 1420, and the canton 8980 inhabitants, on a territory of 170 kilometres, in 22 communes.

Nantial, a town of France, in the department of the Upper Vienne, and chief place of a canton, in the district of Bellac. The place contains 1570, and the canton 13,385 inhabitants, on a territory of 290 kilometres, in 12 communes.

Nanticoke, a town of America, in Suffolk county, Delaware, containing 1832 inhabitants.

Nanticoke Creek, a river of Upper Canada, now called Wavenny, which discharges itself into lake Erie, between Long Point and Grand river.

Nanticoke, a navigable river of the eastern shore of Maryland, which runs into Chesapeake bay.
NANTICOKEs, tribes of Indians, who formerly lived in Maryland, upon the above-mentioned river. They first retired to the Susquehanna, and then further north. By the shocking act of poisoning, in which they excelled, they almost extinguished the whole nation, and destroyed some of their neighbours. Thence, with the Mohickons and Conoys, about forty years ago inhabited Utsonango, Chagmet, and Oweey, on the E. branch of the Susquehanna. At that period the two said tribes could furnish 100 warriors each; and the Conoys 30.

NANTIGNI, Louis Chazot de, in Biography, celebrated for his genealogical writings, was born in 1692 in Burgundy. He studied at Dijon and Paris, and at the latter city he was entrusted with the education of some young men of rank.

Having a turn for historical researches, he employed all his leisure in drawing up genealogical tables, and from 1736 to 1738 he published the fruits of his labours in a work entitled "Genealogies Historiques des Rois, des Emperereurs, et de toutes les Maifons Souveraines," in four vols. 4to.

He also published "Tablettes Geographiques," "Tablettes Historiques, Genealogiques, et Chronologiques," and "Tablettes de Theismis." He supplied many articles for the supplement of Moreri, and supplied the genealogical part of the "Mercure." He died in 1755, but had the misfortune totally to lose his fight some time before his death.

NANTILDA. Fauchet relates that Dagonet, being as a vepers in the abbey of Romilly, heard a nun sing so exquisitely, that he entered into the convent to see her; and being equally charmed with her beauty as with her voice, he married her; and she merited, by her conduct and piety, a place among the saints.

NANTING-SU, in Geography, a small island near the coast of China. N. lat. 24° 10'. E. long. 118° 6'.

NANTRILL, E. and W., two townships of America, in Chelster county, Pennsylvania.

NANTUÁ, a town of France, and principal place of a district, in the department of the Ain; 36 miles W. of Geneva. The place contains 2791, and the canton 8249 inhabitants, on a territory of 137½ kilometres, in 10 communes. In the time of the Romans this town was called Nantuacum, and appears, by medals and fragments of inscriptions which have been found here, to have been a place of consequence before the revolution.

It had two convents, one for men and another for women. It has manufactures of gauzes, taffetas, Rockings, nankeens, and printed calicoes or chintzes. The adjoining lake, called by its name, and about four or five miles in circumference, abounds with fish. Its length is considerable; and on the S.E. side the mountains are abruptly and highly elevated; and towards the southern extremity of Nantua, there are quarries of different sorts of granite. N. lat. 46° 19'. E. long. 5° 41'.

NANTUCKET, an island of North America, belonging to the state of Massachusetts, and situated between 40° 13', and 41° 22' 30" N. lat., and between 69° 56', and 70° 13' 30" W. long., about eight leagues S. of Cape Cod, and E. of the island of Martha's vineyard. It is 15 miles long, and 11 broad, including Sandy point, but its general breadth is 31 miles. It has only one bay of note, formed by a sandy point, extending from the E. end of the island to the N. and W., on which was erected a light-house in 1784, and on the N. side of the island as far as Eel point. This is a fine road for ships, except when the wind is at N.W., which causes a heavy swell. The island confines a county of its own name, and contains 6117 inhabitants, and sends one representative to the General Court. It has ten furnaces of iron. The inhabitants are, in general, robust and enterprising, most of them being blacksmiths and mechanics.

The seamen are singularly expert whalemen. The whale fishery originated among the white inhabitants in 1690: and advanced to a considerable state of prosperity, which was almost ruined by the late war; but it has since revived and extended to the great Pacific ocean. The island had formerly plenty of wood. The people who inhabit it, and particularly the females, are much attached to it, and have no wish to emigrate. They are mostly Friends, or Quakers; but there is one society of Congregationalists. There are at present about 300 proprietors of the island; among whom the proportional number of cattle, sheep, &c. are put out to pasture, and the quantity of ground and sea granted to the rating of crops is subject to particular regulations; and proper officers are appointed who keep books for debiting and crediting the different proprietors.

NANTUCKET SKOAL, a bank which stretches out above 15 leagues in length, and fix in breadth to the S.E. of the island of its name.

NANTUXT BAY, a bay of New Jersey, on the E. side of Delaware bay, opposite Bombay Hook.

NANTWICH, or NAMPttWICH, a market-town in the hundred of Nantwich, and county palatine of Chester, England, is seated in a luxuriant vale, on the high road from London to Chester, at the distance of 170 miles from the former place, and 20 from the latter. The earliest mention of this town is in the reign of William the Conqueror, when a fanguinary battle between the English and Welsh is said to have been fought on its vicinity. In 1113 it was laid waste by the Welsh, and in 1146 we find a band of these mountaineers defeated here when returning homewards from a predatory excursio. From this time hitherto is silent concerning it, till the era of the civil wars between the king and the parliament in the seventeenth century, when it appears to have been fortified with mud-walls and ditches, and to have been several times taken and retaken by each of the opposing parties. Lord Byron besieged it for the king in 1644, but before he was enabled to reduce the garrison, his army was attacked and defeated by the parliamentary forces under Sir William Fairfax. Fire and pestilence have also produced very destructive effects in this town; for in 1648, almost every house was consumed by the former; and in 1604, the latter produced a mortality of upwards of 500 per sons.

Extensive felt-works were formerly established here; but these are nearly relinquished. Many of the lower classes of inhabitants now derive a livelihood from shoe-making for the London shops; and a small cotton manufactury has been lately established. The church of Nantwich is built in the form of a cross, having large pointed windows in the chancel and the sides, adorned with very elegant brickwork. The market-house is a neat modern edifice, occupying the site of an ancient fabric, which suddenly fell to the ground in the year 1739. There are various alm-houses, a workhouse, erected in 1780, and a free-school. It is said there were likewise formerly several hospitals, now gone to ruin, and their funds applied to other purposes. The petty feodoms for the hundred are held in this town; and the inhabitants poffeff an exemption from serving on juries except within its limits. Saturday is the market-day, and there are three fairs during the year. Nantwich, according to the parliamentary return of 1811, contained 873 houses, and 2999 inhabitants.

Adjoining to the town are seen the foundations of the castle, which was a ruin to early as the reign of Henry VI., when it was demolished, and the stones made use of for the purpose.
purposé of enlarging the parish church. The site is now the property of earl Cholmondeley, whose chief residence is situated about five or six miles further to the easterly. (See MALPA.) Cerew-hall, the seat of lord Cerew, lies to the west of Nantwich; and is a very fine specimen of the architecture of the 17th century. This mansion was garrisoned for the parliament at the commencement of the civil wars, but was taken, after an obstinate resistance, by the royal army under lord Byron, in 1643. A view of a curious flower-case in this house, with a history and description of the building, are published in Britton’s "Architectural Antiquities of Great Britain," vol. ii. Doddington castle, which stands four miles to the fourth of the town, is also remarkable for having been several times besieged and taken during the same unfortunate era. Lysons’ "Magna Britannica," vol. ii. 410.

NANU, a town of Peria, in the province of Iprak; 54 miles N.E. of Ipahan.

NAN-YANG, a city of China, of the first rank, in the province of Ho-nan. It is situated on the banks of a small river; and though neither large, rich, nor populous, its jurisdiction comprehends two towns of the second class, and six of the third class, and abounds with provisions, so that three thousands armies have remained in it without occasioning any perceptible scarcity. Lapis lazuli has been found in some of the mountains that surround it; 462 miles S.S.W. of Peking. N. lat. 33° 6'. E. long. 112° 14'.

NAN-YONG, or NANG-KIONG, a city of China, of the first rank, in the province of Quang-tong, situated in a fertile country at the foot of a mountain, which separates the province of Quang-tong from that of Kiang-hi, and carrying on an extensive trade. Its jurisdiction comprehends two towns of the third class; 922 miles S. of Peking. N. lat. 25° 10'. E. long. 113° 52'.

NANZOO, a town of the Birman empire; 16 miles W. of Ava.

NAOUAI, or NAOUAOI, the surname of Al-Schafi, in Biography, a musulman doctor, who wrote many works by which he acquired great celebrity, was born at Naoua, a small town within the jurisdiction of the city of Damascus, at which place he went to live at the age of thirteen, or, as others say, fifteen; this is the more probable, as it was at this early period of life he was created doctor of law. The musulman call him Imam abel Zamanehi, or the great Imam of his age, and they speak of him as a doctor intimately conversant in the knowledge of religion, who lived retired from the world, in the practice of all the duties of piety; who was thoroughly instructed in traditions, and a great master of jurisprudence. He died at Damascus in the year of the Hegira 676, or 1298 of the Christian era. He was buried at his native place, where he received the honours of a saintship. He was author of "Treatises on Jurisprudence;" "A Treatise on Musulman Traditions;" a work "On the Fundamental Principles of the Mahometan Religion;" and other pieces. He is sometimes referred to as "the doctor in traditions of the city of Damascus." Gen. Boy.

NAOUR, in Geography, a town of Nubia, on the Nile; 15 miles N.E. of Mocteto.

NAP, in Greyland, a cape on the W. coast of the island of Yell. N. lat. 69 56'. W. long. 1 31'.

NAPABEICIC, a town of Mexico, in the province of New Biscay; 160 miles N.W. of Parral.

NAPACAR, the town of the island of Calpentine, in the Indian Ocean. N. lat. 7° 56'. E. long. 76° 48'.

Gen. Ch. Cali. Perianth inferior, of one leaf, five-cleft, round, urn-shaped, permanent. Cor. Petals five, oblong, concave, spreading, connected by oblong claws. Stam. Filaments numerous, capillary, the length of the corolla, united below into a cylindrical column; anthers roundish, comprephèd. Pet. Germin superior, conical; style cylindrical, ten-cleft at the top, as long as the corolla; stigmas simple. Peric. Capsule ovate, composed of a number of sharpish, pointed cells, not burbling, finally deciduous. Seeds solitary, kidney-shaped.

Obs. Linnaeus, in his Generalis, and Murray, in the fourteenth edition of the Systema Vegetabilium, removed this genus to the class Diocasia, both the species proving to be dioecious by occasional or perhaps constant imperfection of the respective organs of impregnation. Cavanilles thought that this was the only point in which Napaea differed from Sida, but there appears to be a further difference in their fruit. "Linnaeus observes also that the petals of the genus before us are not oblique, neither is the flower-stalk jointed, whilst the calyx is broader at the base." Eff. Ch. Calix inferior, five-cleft. Petals five. Capsules roundish, deprephed, of many cells, not burbling. Seeds solitary.

1. N. levis. Smooth Napaea. Linn. Synt. Veg. ed. 14. 865. (N. hermaphrodit; Linn. Sp. Pl. 965. Sida Napa; Wild. Sp. Pl. v. 3. 766. Malva virginiana, Linn. folio.)—Stalks naked, smooth. Leaves l. bed, smooth. Native of North America, flowering from July to September, and ripening its seeds in autumn, when the stalks decay.—Root perennial, creeping. Stems three or four feet high, smooth. Leaves alternate, on longish, slender footstalks, acutely three-lobed, serrated, about four inches long at the bottom part of the stem, but gradually diminishing upwards. Stalks three inches in length, divided at the top into about three smaller ones, each bearing a single white flower.

2. N. scabra. Rough Napaea. Linn. Synt. Veg. ed. 14. 865. (N. dioica; Linn. Sp. Pl. 965. Amoen. Acad. v. 3. 18. Sida dioica; Wild. Sp. Pl. v. 3. 766.)—Stalks bracteated, angular, leaves pinnate, rough. Native of North America like the last, flowering and fruiting at the same time with that—Root perennial, composed of numerous, thick, flabby fibres, connected at the top into a large head, from which proceed many rough, hairy leaves, nearly a foot in diameter, deeply cut into fix or seven lobes, irregularly toothed. Stems seven or eight feet high, divided in the upper part. Stalks bearing several large, white flowers, in heads. Fruit orbicular, deprephed, consisting of eight or ten cells.

NAPAIA, in Gardening, contains plants of the hardy, herbaceous, flowery perennial kind, of which the species mostly cultivated are: the smooth napaia (N. levis); and the rough napaia (N. scabra).

Method of Culture.—These different plants are easily increased by seeds, which should be sown on a bed of common earth in the spring, keeping them clear from weeds till autumn, and then transplanting them where they are to remain. They fucceat well in a rich moist soil, in which they will grow very luxuriantly, and must be allowed room. And the soil for the same may also be mercerified by parting the roots, and planting them out where they are to remain in the autumnal season.
These plants afford variety among other plants in the borders and other places.

**NA.P.E.E.** In Mythology, nymphs who presided over the groves. See *Nympha.*

**NA.PASHISH,** in Geography, a lake of North America. N. lat. 62° 10', W. long. 99° 30'.

**NA.PATA,** a town of Nubia, near the E. coast of the Nile; 210 miles E.S.E. of Dongala.

**NA.PAUL.** See *Neapul.*

**NA.PAYOL,** or **NA.PAYELDA,** a town of Moravia, in the circle of Hradich; 8 miles N. of Hradich.

**NA.PE** is used for the hinder part of the neck; by reason, perhaps, of the soft short hair growing thereon, like the nap of cloth.

**NA.PE,** in Rural Economy, a provincial term applied to a piece of wood used for supporting the fore-part of a loaded wain.

**NA.PELLE.LUS,** in Botany. See *Acotitum.*

**NA.PHA,** a name given by many of the writers in phar-macy to orange-flower water.

**NA.PHI.THA,** in Chemistry, is an inflammable liquid of a yellow colour, being the most volatile and colourless part of petroleum, from which it is distilled. Hence naphtha appears to have the same relation to petroleum, which turpentine and tar have to the oil of turpentine, and what is called spirit of tar.

The word in the original Chaldee signifies *filthare,* or *dope,* or *naphtha,* according to Pliny, running like a kind of bitumen.

There seems to be a strong alliance between the volatile acids and naphtha, extending to all the volatile fluids distilled from the different species of bitumen. This, in all probability, is the natural state of this description of inflammable bodies; the vividity, solidity, and colour depending upon the agency of oxygen.

It is the general opinion that the oxygen becomes a component part of the volatile oil, in order to assume the form of resin. It is, however, much more probable, that the oxygen confuses the hydrogen, forming water, leaving the remainder a compound of hydrogen and carbon, with more of the latter element, to which it owes its colour, confidence, and fluidity.

Petroleum may, therefore, be regarded as naphtha rendered vifcid, and coloured by the air, from which the naphtha, still unchanged, being distilled, leaves a substance which contains a less proportion of hydrogen, and which is known by the name of asphaltum. See *Petroleum and Asphalum.*

Naphtha has been employed by Sir H. Davy for the purpose of preferring the metals potassa and silex, for which it seems particularly adapted, from two of its properties, namely, its small specific gravity, and its not containing oxygen. Although the specific gravity of potassa is but .77, it sinks in pure naphtha, which is sometimes not more than .7.

**NA.PIER,** in Biography. See *Nepe.*

**NA.PIER'S,** or *Neper's Bones.* See *Neper's Bones.*

Gen. Ch. cal. Perianth superior, of one leaf, small, concave, in six roundish, acute, permanent segments. Cor. Petals five, ovate, villous, inserted into the receptacle of the flower, opposite to the calyx. Stam. Filaments eighteen, inserted into the same part; anthers roundish, of two cells.

**PIFL.** German inferior, crowned by the calyx; styles three: figmas obtuse. *Peric. and Seed unknown.*

Eff. Ch. Calyx in five deep segments. Petals six, villous. Stamens three to each petal. German crowned with the calyx.

1. **N. guiana**. Aubl. t. 237.—*A tree,* whose trunk rises to the height of twenty-five feet, and is one and a half in diameter, with a reddish, wrinkled, and cracked bark. *The wood is white and soft. The branches spread in every direction. Leave alternate, on very short and slender stalks, elliptical, smooth, serrated, with a blust point. *Stigmas* small, in pairs at the base of the footstalks, deciduous. *Flowers* small, greenish, in slender, axillary, long-stalked spikes, each flower accompanied by a small seale-like bracteae.*

This tree is a native of the woods of Guiana, flowering in November. Juffieu ranges the genus next after *Homalium,* to which it appears to have some affinity; but the barbarous name is inadmissible, and it can only be tolerated till enough is known of the plant to establish its generic character with certainty.

**NA.PLE.S,** in Geography, a kingdom of Italy, comprehending ancient Samnium, Apulia, Campania, Lucania, and Bruttium, and bounded on the N.W. by the province of Campania di Roma, Umbria, and the marquifate of Ancona; on the N.E. by the Adriatic, and on its other parts by the Mediterranean. It lies between 37° 46' and 44° 55' N. lat., and between 13° 20' and 19° 1' E. long.; its greatest length from S.W. to N.E. being 190,870 Italian miles, its greatest breadth 140, and its circuit 1468. According to Zimmermann, it contains 20,534, square miles. This country is in general mountainous, or rather hilly; it is hot, and it is very rarely that ice, or even snow, is observed in the plains. The soil is exceedingly fertile, producing all kinds of grain, with the finest fruits and vegetables; but it is badly cultivated. It is calculated that the culture of corn employs ten percents, and that of the vine at least twenty.

Corn is chiefly exported from the provinces of Capitanata, Bari, Otranto, Abruzzo, Molise, Calabria, and Bafulia, which supply the internal consumption of the kingdom, and the foreign markets. The produce of the Terra di Lavora and Salerno is referred for the use of the capital. The exports of the kingdom of Naples are wheat, barley, legumes, Indian corn, hemp, linseed, cumin, fennel, and annulets; wool, oil, wine, cheeses, fish, salt flesh, honey, wax, fresh and dry fruit, manna, saffron, liqueurse, gums, locust beans, capers, lupins, macaroni of various sorts, salt, potash, brimstone, nitre, argall, pitch, tar, fumach, ikins, cattel, oranges, lemons, brandy, vinegar, metals, minerals, marble, flax, hemp, flax, cottons, and various sorts of manufactures. Horses and cattle might also become valuable articles of exportation, if the breed were duly regarded. The provinces that abound much in oil, are Bari, Otranto, Calabria, and Abruzzo. The best almonds are obtained from Bari, whence they are exported to Venice and Trieste. The annual produce of filk in the kingdom is computed at about 800,000lbs. weight, half of which is supposed to be wrought at home, and the other half exported raw. The exportation of thrown filk, upon an average of many years, amounts to 146,277 lbs. The best cotton is in the province of Otranto. In Calabria there are natural mountains of salt, which is stronger and more active than sea-salt. Among the chief articles imported into Naples, we may enumerate the following; viz. from England, woolen goods of all sorts, silk and worsted stockings, hats, tanned hides, lead, tin, pepper, hardware, linens, handkerchiefs, fans, canes, guns, dyeing woods, drugs, watches, clocks, mathematical in-
NAPLES.

While household furniture, salt cod, pilchards, herrings, coffee, tea, cocoa, sugar, and occasionally calices, and East India goods:—from Holland, cinnamon, cloves, nutmegs, pepper, medicinal drugs from the East and West Indies, fine cloths, particularly the fine, called Segovia, linen for shirts and other uses, muslins, chintz, calicases, several forts of cocoa, whalebone, tobacco, silk stuffs, and velvet:—from France, an immense quantity of sugar, indigo, coffee, dyeing woods, verdigris, Levant drugs, cocoa, hardware, silk stuffs, gold and silver fays of Le Mans, divers, cloth of Elbeuf, and all forts of women's apparel:—from Spain, es- corialine, dyeing woods, cocoa, hides, salted and in the hair, medicinal American drugs, Jefuits' bark, farfaparilla, jalap, balsam of Peru, spaccanaca, cloths of divers sorts, wine, tobacco, suff of Seville and Havanna, lead, gun-barrels, honey, &c.:—from Portugal, Brazil sugar, tobacco, cocoa, drugs, hides, &c.:— from Venice, books, cordovans, looking-glasses, crystals and glasses of all sorts, Padua cloths, called Venetian fays, for the consumption of the provinces, fine Verona cloths, equal to English scarlet, Rockings, woolen caps, fine hats, wax candles, white loaf sugar, fine linen, medicinal and Levant drugs, all sorts of paints, sulphure, cinnabar, quicksilver, turpentine, dragon's blood, iron of divers sorts of the manufactures of Germany and Brefcia, paper, &c.:—from Genoa, American goods from the Spanish main, and from the Portuguese East Indies, velvets, iron in great quantities, nails, ordinary hats, wax from Tunisia and the African coast:—from Leghorn, all sorts of goods at second hand from the Levant, Barbary woods, linens of Egypt, wax, and many silk manufactures;—from Petersburg, hides, wax, iron, flurs, &c.:— from Sardinia, an immense quantity of sunny fish and cheese:— from Germany, Sicily, and all forts, woods, cloths, di- verse manufactures, vitriol of Hungary, crysalis of Bohemia, large glasses for watches and windows, hats and goods of the new Vienna fabric, turpentine, quicksilver, hardware, manufactures of Olhauhog and Nuremberg, copper, tin plates, boards, cloth, &c. The duties in general upon goods imported into the city of Naples, amount to about 25 per cent.; sugar and wax pay 40 or 50 per cent. upon the market price. The duty upon sugar produces about 80,000 ducats annually. Calabria affords a great quantity of manna, which see; and also excellent saffron. Here also are obtained alum, vitriol, sulphur, rock crysall, marble, and quantities of minerals. Glass-works constitute a very beneficial branch of trade, and also the Neapolitan horsefis, which are much ef- teemed. The wool of the sheep is fine and good, and silk is exported to a considerable value. Of the filaments, or a kind of hair or wool, of an olive-green, growing on some shellfish, at Malta, Cortica, Sardinia, and the gulf of Ve- nici, are made worstcoats, caps, stockings, and gloves, warmer than the wool, and though not so fine and soft as silk, yet always retaining a peculiar gloss. The silk, woollen, and other manufactures, together with the improvement of arts, owe their first establishment to Ferdinand of Arragon, who patronised them in a very liberal manner. These manufac- tures, joined to the native produce, are a source of considerable trade to the kingdom of Naples.

Among the chief mountains of Naples are the Apen- nines, which extend through the whole length of the country, and terminate at the straits of Sicily. (See APENNINES.) Of rivers there is not any one of note in the kingdom; but small streams defend, in every direction, with rapidity from the interior parts, and lose themselves in the sea. The most remarkable natural curiosity is Vesuvius, an inflated moun- tain, well known for its fiery eruptions. (See VESUVIUS.) A considerable part of this country, as well as other pro-

vines in Italy, has been at remote periods affected by fire. This fact is sufficiently testified by the present appearance of the country. Naples, Rome, and most of the ancient Roman highways, are paved with lava, and the founda- tions of the houses in the subterraneous city of Hercla- neum, are composed of the same materials. All the moun-
tains and hillocks in the vicinity of Naples are merely a mafs of various sorts of matter vomited forth by volcanos which no longer exist, and whose eruptions, anterior to his tory, have probably formed the ports of Naples and Puz- zaoli. The Apennine mountains exhibit a considerable number of visible fires under different forms: and the earth- quakes to which this country is subject have distressed its inhabitants with frequent apprehensions and calamities. The swarms of lizards and scorpiions that infest it are likewise always alarming, and sometimes injurious and fatal. The provinces of which the kingdom of Naples confiding were formerly a part of the dominions of the Roman republic, and afterward of the emperors. After the fall of the Ro-
man empire, this part of Italy underwent various revolu-
tions. The powerful princes of Benevento survived the conquest of the north of Italy by Charlmagne; and with other potencies in this quarter acknowledged the supremacy of the Greek empire, from which Sicily had been wrested A.D. 828, by the Saracens, who possessed it till the year 1058. Both Saracens and Greeks were afterwards expelled by the Normans; and the Norman leaders became dukes of Apulia, Calabria, and Sicily; and Roger was named king of Sicily by the pope, A.D. 1130. The Norman line continued till their kingdom was subdued by Henry VI., em-
peror of Germany. After internal contests, Charles of Anjou became king of Sicily in 1266: after the Sicilian wars, 1282, Sicily was fetzed by a fleet sent by the king of Arragon; but Naples continued to acknowledge the line of Anjou, which expired in the infamous Jean, 1382. René of Anjou, king of Naples in 1435, was the father of Margaret, wife of Henry VI. of England; but the French line failed in 1481, in Charles count de Maine, who named Louis XI., king of France, his heir, whence sprung the pretensions of France to the kingdom of Naples. The Spanish line of Naples and Sicily continued till 1714, when they passed to the house of Austria; but were transferred to that of Bourbon in 1736, in the person of Don Carlos, duke of Parma and Placentia, son of Philip V. of Spain, and Elizabeth of Parma, who succeeding to the crown of Spain in 1759, conferred his Italian kingdom on Don Ferdinand, his third son, who married the lffer of the emperor of Germany in 1768. The kingdom of Naples, in consequence of subflebevolved revolutions, was affigned to prince Joseph, the brother of the French emperor, without a single struggle; the people having been too much op-

preffed by taxation, that a change of masters had become an object of indifference, if not of hope.

The Jews came into this kingdom about the year 1200, but in 1540 were expelled; however, they obtained here, as well as in Sicily, in 1740, exemptions and privileges be-
yond what they enjoyed in any part for many centuries past. The Neapolitan nobility constitute a numerous body; and they are excessively fond of splendour and show. This ap-
ppears in the brilliancy of their equipages, the number of their attendants, the richness of their deeds, the grandeur of their titles, and the magnificence of their entertainments. Dr. Moore, in his "View of Society and Manners in Italy," (vol. ii.) informs us, that the king of Naples counts 100 persons with the title of prince, and a still greater number with that of duke, among his subjects. Six or seven of these have eilates, which produce from ten
NAPLES.

To twelve or thirteen thousand pounds a-year; but the annual revenue of most is not above one or two thousand pounds. As to the inferior orders of nobility, they are much poorer; many counts and marquises not having above three or four hundred pounds a-year of patrimonial estate. The hereditary jurisdiction of the nobles over their vassals, substains, both in the kingdom of Naples and Sicily, in the full rigour of the feudal government. The peasants therefore are poor; and it depends altogether on the personal character of the masters, whether their poverty is not the least of their grievances. If the land was leased out to free farmers, whose property was secure, and the leaves of a sufficient length, to allow the tenant to reap the fruits of his own improvements, the vassals of the nobility would, without doubt, produce much more. The landlord might have a higher rent paid in money, instead of being collected in kind, which subject it to the salaries and impositions of a numerous train of rewar^s: and the tenants would be enabled to live much more comfortably, and to lay up, every year, a small pittance for their families. But such is the love of domineering, that many persons would rather submit to be themselves slaves to the caprices of an absolute prince than become perfectly independent, on the condition of giving independence to their vassals.

Although the Neapolitan nobility still retain the ancient feudal authority over the peasants, yet their personal importance depends, in a great measure, on the favour of the king; who, under pretence of any office, can confine them to their own vassals, or imprison them at pleasure; and who, without any alleged offence, and without going to such extremes, can inflict a punishment, which they will feebly feel, by not inviting them to the amusements of the court, or not receiving them with smiles when they attend on any ordinary occasion. The government of this kingdom is nearly despotic. The laws of it are contained in the "Codex Carolinus," published in 1754. The religion of Naples is the Roman Catholic, but the Neapolitans have always reluctantly opposed the introduction of the inquisition; and independently of this, no papal bulls or mandates can be made public without the king's "exequatur." The number of monasteries and convents is very great, and the clergy, who are very numerous, are wealthy, whilst the laity are poor. The number of archbishoprics in the kingdom is no less than 34, and that of bishoprics 125; but here is no univercity of any reputation. The ecclesiastics are computed at 200,000; and it is supposed that about one-half of the lands is in their possession.

The kingdom of Naples is divided into twelve provinces, called "Giulizzierati," or jurisdictions, containing 2057 univeritas, under the denomination of cities, towns, and villages. This division is commonly attributed to the emperor Frederick II. The provinces are Terra di Lavora, Principato Citra, Principato Ultra, Capitanata, Molise, Abruzzo Citra, Abruzzo Ultra, Ibar, Otranto, Basilicata, Calabria Citra, and Calabria Ultra; which see respectively. An estimate of the population of this kingdom is published annually by authority. In the year 1767, there were 1,819,267 males, 1,886,875 females, and 107,612 ecclesiastics, secular and religious, 81,898 males, and 76,770 females were born, and 123,041 of both sexes died: in 1777, 2,002,745 males, 2,124,030 females, and 94,728 ecclesiastics: in 1778, the number of inhabitants amounted to 4,564,445: in 1779, to 4,651,293.

Naples, the chief city of the above-described kingdom, situated in the country of Lavora, partly on a mountain, and partly towards the sea, and esteemed, after Confiantsnople, the most beautiful capital in the world. This city was founded by the Greeks, and their choice of its situation is one proof, among many others, of the fine taste of that ingenious people. The bay is about 30 miles in circumference, and 12 in diameter; it has been called "Crater," from its supposed resemblance to a bowl; which bowl is ornamented with the most beautiful foliage, with vines, olive, mulberry, and orange trees, with hills, dales, towns, villas, and villages. At the bottom of the bay, the town is built in the form of an amphitheatre, sloping from the hills towards the sea. Independently of its situation, Naples is a very beautiful city. Although the style of architecture is inferior to that of Rome, and Naples cannot vie with this city in the number of palaces, or in the grandeur and magnificence of the churches, the private houses in general are better built, and are more uniformly convenient; the streets are also broader and better paved. No street in Rome equals in beauty the Strada di Toledo at Naples; and still less can any of them be compared with the beautiful streets which are open to the bay. This, says Dr. Moore, is the native country of the zephyr; here the exceeit of the heat is often tempered with sea-breezes, and with gales, wafting the perfumes of the Campagna Felice. The houses, in general, are five or six stories in height, and flat at the top; on which are placed numbers of flower vases, or fruit trees, in boxes of earth, producing a very gay and agreeable effect. The fortresses of St. Elmo is built on a mountain of the same name, and the garrison stationed in it has the entire command of the town. A little lower on the same mountain is a convent of Carthusians, upon which a large sum has been expended in order to render the buildings and gardens equal in point of beauty to the situation. Although Naples is excellently situated for commerce, and no kingdom produces the necessaries and luxuries of life in greater profusion, yet trade languishes; the bell foundries come from Lyons, and the bellwollen goods from England. The chief articles manufactured here are silk stockings, soap, snuff-boxes of tortoise-shell, and of the lama of Mount Vesuvius, tables, and ornamental furniture of marble. They are thought to embroiler here better than in France, and their macaroni is preferred to that made in any other part of Italy. The Neapolitans excel also in lictures and confections. The walls of Naples form a circuit of nine Italian miles; but including the suburbs, the entire circumference cannot be less than 18 or 20 Italian miles. It is embellished by a considerable number of fountains, furnishing indifferent water, and water is also conveyed to the city, from the foot of Mount Vesuvius, by a very grand aqueduct. It swarms with princes, dukes, marquises, and other nobility, to whom are appropriated five large piazzas; and the commonalty have also their peculiar piazza; the citizens forming a society of their own perfectly distinct from the nobility. In the most respectable classes of citizens are the lawyers, of whom there is an incredible number in this town. The number of priests, monks, and ecclesiastics of all the various orders that swarm in this city is prodigious, possessing, as it is said, above one-third of the revenue of the whole kingdom, besides what some particular orders acquire by begging for the use of their convents. The unproductive wealth, which is lodged in the churches and convents of this city, amounts to a very large sum; and though the churches and convents of Rome surpass those of Naples in point of architecture, yet the latter are superior to the former in riches, in the value of their jewels, and in the quantity of silver and gold crucifixes, vellums, and implements of various kinds. The monasteries and convents of both sexes are computed at 149, besides which here are 34 houses for poor boys, girls, and
and women, 11 hospitals, 4 capital churches, 32 parish churches, 70 other chapels and churches, and upwards of 120 oratories or chapels of religious fraternities. Naples is the see of an archbishop, whose cathedral, called "Il Duomo," is a fine Gothic building. The greatest curiosity in it is the magnificent chapel, called "Il Teatro," where Januarious's head, and some of his blood are kept. (See JANUARIUS.) The "Lazzaroni," or blackguards, form a considerable part of the inhabitants of Naples; and these have, on some occasions, had the government for a short time in their hands. They are computed at above 30,000; most of them have no fixed habitations, but keep every night under por- ticos, piazzas, or any kind of shelter they can find. These of them who have wives and children, live in the subburbs of Naples, near Paulippio, in huts, or in cellars, or chambers dug out of that mountain. Some of them gain a subsistence by fishing, others by carrying burdens to or from the shipping; many walk about the streets ready to run on errands, or to perform any labour for a small remuneration. They have been generally represented as a lazy, licentious, and turbulent class of people: but Dr. Moore has a more favourable opinion of their character; ascribing their idleness to want of employment. The ecclesiastics are estimated at about 10,000; and the whole number of inhabitants at 350,000. There is not perhaps a city in the world with the same number of inhabitants, in which so few contribute to the wealth of the community by useful, or productive labour, as Naples; but the number of priests, monks, fiddlers, lawyers, nobility, footmen, and Lazzaroni, surpasa all reasonable proportion.

For the defence of the city, and keeping it in subjection, there are five castles, confining only of very strong walls. The Castello Nuovo communicates by a covered way with the king's palace, and on one side is contiguous to the sea. Its subterraneous works and mines are admirable. At its entrance stands a triumphal arch, of very curious sculpture. The Castello del Uovo, so called from its oval figure, is strong, and stands on a rock in the sea; of the castle St. Elmo we have spoken already. Provisions are plentiful and cheap at Naples, so that the inhabitants procure ample supplies with little labour. Many of the streets are crowded more than those of London and Paris by the number of idle people, who, having no public walks or gardens, amuse themselves with traversing the streets. But, notwithstanding their want of employment, riots and outrages seldom occur, which is partly owing to the national character of the Italians, and partly to the universal folly of the people. The great luxury of the inhabitants is icced water and lemonade; these are carried about in little barrels, and retailed in halfpenny's worth. Nothing would be more likely to cause disturbance than the want of ice, the monopoly of which is granted to certain persons, who sell it about 3s. 4d. a pound.

According to Diodorus Siculus, the founder of this city was Hercules; others say, that it was built by the Pho-ceans, and others ascribe it to Ulysses, who named it Parthenope, in memory of one of the Syrens, who, according to the fable, not being able to detain that hero by the harmony of her voice, was so irritated and despairing, that she threw herself from a precipice, and was buried on the spot where now stands the church of St. Gia Maggiore. Other authors deduce its name from Parthenope, daughter to a king of Thessaly, who conducted thither a colony from the island of Euboea. Others, again, attribute its origin to one Phalerus, tyrant of Sicily; whereas Strabo reports, that it was founded by the Rhodians long before the invention of the Olympic games. However this be, it is most probable that Naples was founded by the Greeks, and that it existed long before Rome itself. In 1799, Naples was taken by the French; 100 miles S. E. of Rome. N. lat. 40° 54'. E. long. 13° 30'.

Naples, with so many advantages over other great cities, in situation, climate, antiquities, harbour, &c. has likewise, at all periods of its history, distinguished itself by the cultivation of the arts, equally, if not in a superior manner, to any other city in Europe (see Vicente della Cottura, di Napoli Signorelli); but in none so much as music during the last century, by the numerous great composers and performers who have issued from its famous seminaries, the conservatories, under the direction of Alessandro Scarlatti, Leo, Durante, and Sala, whose echoes have not only done honour to Italy, but supplied all the rest of Europe with men of such eminence in their art, as no other city on the globe can boast; which will be readily allowed by all those who love and have cultivated music, when they are reminded that not only the two Scarlattis, Leo, Pergolesi, Durante, Porpora, Vinci, Jomelli, Perez, Piccin, Sacchini Anfosi, Traetta, Rinaldo di Capua, Gugliemi, Genaro Manna, Cioce de Maja, Laillita, Sala, Cimarosa, Paetello, were all Neapolitans.

These were composers; but the eruptions of Mount Vesuvius have not been much more wonderful than some of the Neapolitan fingers, such as Nicolini, Farinelli, Caffarelli, Aprire, De Amis, Millico and Pacciotterio.

Naples Tilirse, or Giallalino, is a porous, heavy, granular substance of an earthy nature; it is friable, adheres a little to the tongue, and, when exposed to the air, neither undergoes decomposition nor changes its colour, which is a pale orange yellow. Reduced to an impalpable powder it remains suspended in the water for a considerable time, and at half falls down as a puffy mass. Boiled in water the fluid acquires a faint tinge. It does not effervesce with acids, but is partly dissolved by nitro-muriatic acid; it is fused with difficulty, and in this state undergoes no change, except that its colour becomes rather more red. When fused with colourless glass the produce is a milk white enamel, which proves the absence of iron. When mixed with inflammable substances a regulus is obtained, which appears to be a compound of lead and antimony.

This article is principally brought to us from Naples; generally in the shape of an earthy crust, from three to four lines thick, and sometimes exhibiting the shape of the vessel in which it has been suffered to harden. It is also often seen as powder.

It is not known with certainty at what period this substance has become an object of commerce. Pomet is the first writer on drugs who makes mention of Naples yellow, and he observes that it is extremely brittle. Kunkel, who gives a pretty complete list of the substances used for colouring glass and enamel, is silent respecting Naples yellow or giallalino; but if the name of this production can be considered as a proof of its antiquity, it may be said to have been known in Italy as early as the end of the 16th century. Ferrante Imperato speaks of two sorts of giallalino, one of which appears to be the oxid of lead, called Maliscot, while the other is unquesionably the substance under consideration. But no writers on colours appear to have been acquainted with the nature of the true Naples yellow; some have considered it as a volcanic production of mounts Vesuvius and Etna; others as a variety of native ochre; Guettard (Mém. de l'Acad. des Sciences, 1763) mistook it for a bolar earth; but Pott (Lithogogique, p. 2.) is nearest the truth, for he suspects it to be the result of artificial preparation. Fougeroux (Mém. de l'Ac. des Sciences, 1766)
NAPLOSA. See NABLUS.

NAP, in Geography, a town of South America, on a river of the same name, in the audience of Quito; 200 miles S.E. of Quito. The river rises about 20 miles S. of Quito, and after a south-easterly course of about 360 miles, discharges itself into the river of the Amazons, S. lat. 50° 30'. W. long. 71° 10'.
NAR

NARAH, a town of Hindooftan, in Bahar; 45 miles E. of Bettinck.

NARADIPETTA, a town of Hindooftan, in the Carnatic; 8 miles S. of Chattoor.

NARAINUM, a town of Hindooftan, in Dowlatabad; 10 miles S.E. of Junere.

NARAINPOUR, a town of Bengal; 5 miles S. of Koonda.

NARAMPURKY, a town of Hindooftan, in Bahar; 32 miles S.E. of Bettinck.

NARAN, a town of Hindooftan in Bahar; 42 miles E. of Hajjpour. N. lat. 25° 41'. E. long. 86° 10'.

NARANGABAD, a town of Hindooftan, in Oude; 25 miles N.W. of Kaibabad. N. lat. 27° 50'. E. long. 85° 55'.

NARAPILLY, a town of Hindooftan, in Golconda; 10 miles E. of Hyderabad.

NARBETH, a market and poal-town in the hundred of that name, and county of Pembroke, South Wales, is situated at the distance of 229½ miles N.W. from London, and 12 miles N.E. from Pembroke. This place has greatly increased of late years, both in fize and opulence. In 1801, the number of houses and inhabitants in the town appeared, from the parliamentary returns, to amount to 340 of the former, and 1531 of the latter; but in 1811, the same authority states the houfes at 402, and the population at 1779 perfons. The market day is Thursday, and there are fix well attended fairs during the year, which privileges have been enjoyed since the reign of James II. A mail coach paffes through the town every day, and from London to Milford. Here are held the petty fessions for the hundred. The church is an ancient building, founded by Sir Andrew Perrot, in the reign of Henry II. The living is a rectory in the gift of the crown, and one of the most valuable preferments in the diocife of St. David's. On a coniderable finance, eile to the town, are the ruins of the castle of Narbeth, which are now of very small extent; but from the outline of walls that may ill be traced, it must at one time have been a very large and magnificent pile, and of great importance as defending one of the most frequented ways in the county. Hence it was frequently assaulted, and sometimes taken, by the Welsh princes, during their defolatory wars to repel the aggressions of the Anglo-Normans, and afterwards the English.

About two miles north-east from Narbeth stand the ruins of Lawdhen castle, anciently the palace of the bishops of St. David's, and consequently that from which they derived their title to a seat in the house of peers. This superb edifice crowned the summit of a steep, wooded hill, and though apparently placed on the very edge of a precipice, was moated and approached by a drawbridge, at the grand entrance, which was under a gate-way between two octagonal bastions of very massive architecture. The whole building has been formerly very spacious and magnificent; as is evident from the present remains, though it have been much deteriorated of late years by the barbarous practice of using its materials for the repair of the roads. It is constructed entirely of cut stone, and highly finished, and within it is an elegant chapel, which was built by bishop Vaughan. At what time this castle was erected is uncertain; but Mr. Fenton inclines to think that it is chiefly indebted for its grandeur to Thomas Beke, who was bishop of St. David's from 1320 to 1393, and made this the principal place of his residence. Attached to it is a large park and a forest, which Leland tells us were well flocked with red deer in his time. The keeps of this forest were frequently gentlemen of the first families in the county; a circumstance alone sufficient to indicate the high style in which the ancient bishops were accustomed to live. Two miles to the south-east of this castle is Slench hall, a very elegant mansion, which occupies the site of an ancient commandery of knights of St. John, though not a trace of the establishment of this church-militant now remains; it is a ruin, and the church itself, a very small but respectable edifice, standing close upon the river Cliddy, which skirts the pleasure-grounds, and contributes greatly to their beauty. Pitton castle, lying eastward from Slench, though built in the reign of William Rufus, is, by the hereditary attention of its possessors, still almost in as good condition as when first erected. This mansion of the noble family of Phillips is surrounded by very extensive plantations and gardens, laid out with great taste. Within these is an old encampment, called Castle-lake, a pool of considerable strength by nature, and rendered more so by a very high agger on its western side. At Templeton, a village south-east from Narbeth, is a chapel, now in ruins, which belonged to the knights of Slench, who are said to have much frequented this place during their hunting parties. In the centre of the main street are the ruins of an ancient crofs. The houses here, though thinly scattered, are well built, and preserve the vestiges of former opulence. Indeed there can be no doubt of this having been formerly a considerable village; and by some it is conjectured to have been early a manufacturing town subordinate to the great colony of Flemings, who established themselves at Tenby. Fenton's Historical Tour through Pembroke shire, 4to. 1811. Carlile's Topographical Dictionary of Wales, 4to. 1812.

NARIMSKOJ, a lake of Russia, 36 miles in circumference; 230 miles N.N.E. of Pervitchik.

NARBO, or Narbo Martius, in Ancient Geography, a city of Gaul, in Gallia Narbonensis. See NARBONNE.

NARBONENSIS GALLIA. See Gaul.

NARBONNE, in Geography, a town of France, and principal place of a district, in the department of the Aude, situated on a canal, which communicates with the Aude. When the Romans first entered Gaul, this was a flourishing city, and they made it a Roman colony, under the appellation of "Narbo Martius." About 116 years B.C., Julius Caesar sent lither a new colony of the veterans of the 10th legion; and under Augustus it was the capital of "Gallia Narbonensis." Under the kings of France, it was the seat of an archbishop, the feast of an admiralty, and the residence of a governor; and it contained two collegiate churches.
NA R

NARCISSUS, a name adopted from the poets, who have failed that the flower which bears it originated in the transformation of a beautiful youth, who pined away with admiration of his own image in a fountain. The origin of the word, nevertheless, appears to lie deeper, having been derived from Ναρκίς, a name, and alluding to the effects of the smell of a Narcissus. These are frequently an intense headache, and partial loss of recollection, to which the writer of this can bear witness in some of the species, as well as in Honey-suckles, and a few other very sweet flowers. The name of the youth might apply to the fluidity of his passion, and of the flower to its own properties, before Ovid elegantly combined them. The description of Dioscorides, so full, leaves no doubt of his being the same as ours, the "white species, purple within," answering exactly to the beautiful, though very common, Narcissus, of botanists. Linn. Gen. 161. Schreb. 216. Willd. Sp. Pl. v. 2. 34. Mart. Mill. Dist. v. 3. Ait. Hort. Kew. ed. v. 2. 214. Sm. Pl. Brit. 353. Haworth's Tr. of Linn. Soc. v. 5. 424. Salis. Prod. 220. Juss. 55. Lamarck Illuir. t. 229. Tourn. t. 185. — Ch. and order, Hexandria Monogynia. Nat. Ord. Spatheceae, Linn. Narcissus, Juss.

Gen. Ch. Cal. an oblong, obtuse, compressed, membranous sheath, splitting along its flat side, containing one or many flowers, permanent. Cor. Petals fix, ovate, pointed, flat, equal, inferted into the tube of the nectary on its outside, at some distance above the base. Nectary of one leaf, funnel-shaped, regular, cylindrical below, with a coloured border. Stam. Filaments fix, awl-shaped, inferted into the tube of the nectary, and shorter than its border; anthers rather oblong. Pist. Germen within the sheath, below the corolla, roundish, bluntly triangular; style thread-shaped, longer than the stamens; stigma three-cleft, concave, obtuse. Peric. Capsule roundish, with three blunt angles, membranous, of three cells, and three valves, with central partitions. Seeds several, globular.

This favourite genus has engaged the particular attention of several British botanists, especially Mr. Salisbury, Mr. Haworth, and the late Mr. Curtis; as well as of Mr. Ker-Bellenden, who, in his contributions to the continuation of the Botanical Magazine, has attended to this among other lilaceous genera, or their allies. He thus characterizes the habit of Narcissus, in p. 925 of that work.

Bulb inrolled with membranous tunic. Leaves several, in two ranks, linear-funnel-shaped, thickish, and somewhat succulent; usually flat, a little depressed above, keeled and ribbed beneath; sometimes rust-like, and half cylindrical, with a slight channel above. Flower-flask naked, central, thinly compressed, or two-edged. Flowers yellowish or whitish, or partaking of both colours. Style triangular, as if composed of three combined. Capsule membranous. It differs from Pantharatum in having the stamens unconnected with the central crown or cup of the flower, but more or less cohering with the tube.

The number of species is fourteen in the 14th edition of the Syll. Veg. of Linnaeus; Willdenow and Aiten have each...
NARCISSUS.

Each seventeen, but each has three species which the other omits. We shall chiefly take these authors for our guides, declining the great multiplication of species to which others are, in our opinion, rather too prone. Three Narcissi are found wild in England.

1. N. poeticus. Poetic Narcissus. Linn. Sp. Pl. 414. Engl. Bot. t. 275. Redout. Lilac. t. 160. (N. medio purpureus; Ger. em. 123; and with a double flower, 124.)—Sheath morels fingle-flowered. Cup of the nectary very short, wheel-shaped, membranous, crenate. Leaves bluntly keeled, reflexed at the margin.—Native of England, Germany, France, Switzerland, and Italy, on open, rather sandy, hills, flowering in May. Wheller mentions this species as growing on Helcine, and other hills in Greece, upon whose authority it was admitted into the Prodr. Fl. Græc.; for Dr. Sibthorp did not meet with the plant himself, though he very justly indicated it, in his manuscripts, as what Diocorides had mentioned. That ancient writer speaks of the root as emetic, and as useful for burns if applied with honey, or for injurious effects of the sun upon the skin, if used with nettles' feed and vinegar. He also celebrates its effects in cleaning ulcers and ripening abscesses.—With us the plant is chiefly valued for the beauty and fragrance of its flower, which is the largest of the white kinds, and known from all others, except the next, by the crimson border of its very shallow, and almost flat, cup of the nectary. The double variety is most frequent in gardens. Sometimes there are two flowers in a sheath.

2. N. angustifolius. Narrow-leaved Crimsons-edged Narcissus. Curt. Mag. t. 193. Ait. n. 2.—Sheath single-flowered. Cup of the nectary very short, cup-shaped, membranous, crenate. Leaves not broader than the flower-stalk.—Native of the south of Europe. Cultivated in England early as 1776, according to Lobel, and distinguished by the writers of that period, though confounded with the foregoing by Linnaeus, and other modern botanists, till lately. It differs in being scarcely above half so large, with leaves of a narrower proportion and flatter form, and the edge of the nectary more crenate The wooden cut of Dodonaeus, cited for this by Mr. Curtis, is what we have quoted from Gerarde under the former, to which it appears to us certainly to belong. Gerarde distinctly notices the present, and mentions its early flowering, which is in the beginning of April, full six weeks before the poeticus.

3. N. biflorus. Pale Narcissus, or Primrose peert. Curt. Mag. t. 107. Sm. Fl Brit. n. 2. Engl. Bot. t. 276. Willd. n. 11. (N. medio luteus; Ger. em. 124.)—Sheath two-flowered. Cup of the nectary very short, wheel-shaped, membranous, crenate. Leaves acutely keeled, inflexed at the margin.—Native of Spain, England, and Ireland. It was gathered on a rabbit-warren at Shorne in Kent, with the poeticus, by Mr. Jacob Rayner, but generally blooms a little earlier than that species, and is common in gardens, being valued for its beauty and scent, though the latter soon becomes oppressive in a room. From the frill species it differs in the texture of the leaves being triangular, and their edges inflected. The flowers usually two, sometimes one or three, from each flower; the petals of a cream-colour, or yellowish, not of a pure, snow-white; the nectary crenate, with a pale edge, but no crimson circle. All these marks are permanent and invariable, except the number of flowers. Their size is always less than that of the poeticus.

4. N. tenius. Slender Narcissus. Curt. Mag. t. 379. Ait. n. 4.—Sheath single-flowered. Cup of the nectary very short, cup-shaped, plaited. Leaves linear-awlshaped, channelled.—A native probably of Europe, but known to us only as having been procured from the gardens of Hol-land. Mefirs. Grimwood and Barrit are mentioned by Mr. Aiton, as having frill cultivated it in 1780. This is a hardy species, flowering in May, and most resembles the lax in colour, but the petals are rather more yellow, the edge of the cut crenate, more plaited, neither white nor membranous, but brown as the flower advances. The fragrance is considerable. The leaves gradually taper to a blunt point. Stalk round, slender, taller than the leaves, chiefly compressed above, and always single-flowered. Germin and tube of the flower slender, standing horizontally. Curtis.

5. N. incomparabillis. Peerlels Daffodil. Curt. Mag. t. 121. Willd. n. 2. Ait. n. 5. (N. amplis; Salis. n. 17. N. odorosus; Linn. Am. Acad. v. 4. 311. N. omnium maximus; Ger. em. 135.)—Sheath single-flowered. Cup of the nectary bell-shaped, plaited, crisped, half as long as the petals. Leaves acutely keeled.—Native of Spain and Portugal, according to Miller. Parkin and others of it as cultivated in 1629, but was it perhaps known here much earlier. He gives a sufficiently expressive figure of this plant, in his Garden of Pleasent Flowers, p. 73. It is known by the bell-shaped, wavy, and plaited cup of the nectary, which is much longer than any of the preceding, and of a rich orange colour. The petals are pale yellow, but sometimes almost white. The double variety, N. incomparabillis, Rob. ic. t. 20, in which the colours are most strongly contrasted, is most admired, and called the Butter and Egg Narcissus, or Orange Phænix. This species is very hardy, flowering in April. The bulbs of the double form should be taken up yearly, or they are apt to degenerate, or rather to return towards the natural single flate of the flower.

Curt. Mag. t. 148 is now confided by the editor a variety of this.

6. N. Pseudo-narcissus. Common Daffodil. Linn. Sp. Pl. 414. Willd. n. 3. Ait. n. 6. Engl. Bot. t. 173.) Pseudo-narcissus anglicus; Ger. em. 133. Pseudo-narcissus lutes sulphureus; ibid.)—Sheath single-flowered. Cup of the nectary bell-shaped, crenate, crisped, obscurly five-crenate, as long as the ovate upright petals.—Native of England, as well as of Germany, France, Switzerland, and Italy, in rather moist woods or thickets, flowering in March, when its growth being rapid, and duration short. The leaves are two or three, glaucous, bluntly keeled. Stalk compressed, two-edged, about the same height, which is scarcely a foot. Flower drooping, not pleasantly scented, with nearly erect petals, of a pale yellow, the long tubular nectary being of a golden hue. Such is the wild plant. The garden varieties differ in the fullness of colour, as well as in the shape and position of their numerous petals, and diversified nectary.

7. N. bicolor. White and Yellow Daffodil. Linn. Sp. Pl. 415. Curt. Mag. t. 1187. N. albivs, calyce flavo, fave tubo imbriato; Rubd. Elly. v. 2. 70. f. 7.)—Sheath single-flowered. Cup of the nectary bell-shaped, crenate, crisped, longer than the ovate, flat, spreading petals. Leaves slightly concave, nearly frignt.—Native of the Pyrenees. Common in old gardens, flowering in April or May, a month after the last-delivered, from which it differs in having less glaucous leaves, and yellowish horizontal petals; the tube of the nectary being scarcely longer than the petals, whereas in Pseudo-narcissus it is thrice as long. Its scent too is much sweeter.

8. N. major. Great Yellow Daffodil. Curt. Mag. t. 51 and 1321. (N. major totus luteus, calyce prælongo); Bâth. Pin. 52. Rubd. Elly. v. 2. 71. f. 9. N. bicolor ?; Willd. n. 4. Ait. n. 7. Pseudo-narcissus hispanicus; Ger. em. 133.)—Sheath single-flowered. Cup of the nectary bell-shaped, crenate, the length of the oblong oblique petals;
its margin spreading, lobed, and crenate. Leaves twisted.—
Native of Spain. Common with double flowers in gardens,
but rarely seen single. The twisted, somewhat glaucous,
leaves, very large flower, of an uniform golden yellow, and
the other differences expressed in the specific character, feem
to us abundantly sufficient to distinguish this from the bicolor.
It flowers in April, and is very hardy.
n. 5. Att. n. 8. Curt. Mag. t. 6. (N. parvus, tetus lut-
tibus; Rubd. Elyt. v. 2. 72. f. 11. Pseudo-narcissus minor
hispanicus; Ger. em. 133.)—Sheath single-flowered. Nec-
tary inconverial; its cup six-cleft, cropped, longer than
the lanceolate petals. Leaves spreading.—Native of Spain;
very hardy with us, flowering in March or April. As the
preceeding is the largest, this is the smallest of the Daffodils.
Its spreading, short, glaucous leaves, and the gradually
dilated nectary, not well delineated by the old authors, mark
the species well. The petals are of a pale yellow, the cup
darker. Mr. Saliby divides this species into two, by the
names of exiguus and pusillus, but we cannot satisfy
ourselfs of the propriety of so doing, nor has the meafure
been adopted by others.
Mag. t. 924 and 1300. (N. albuis; Haworth Tr. of Linn.
Soc. v. 5. n. 5. N. candidissimus; Redout. Liliac. t. 188.
N. albuis, calyce prolongo, flore pendente; Rubd. Elyt.
v. 2. 73. f. 16. Pseudo-narcissus albo flore; Ger. em. 134.)
—Sheath single-flowered. Flower drooping. Cup of the
nectary cylindrical, crenate, crenate, the length of
the oblong twisted petals. Leaves concave, glaucous.—
Native of Spain; kept in rather curious gardens, where it is
hardy, flowering in April. The long cylindrical cup, lon-
gitudinally carred, slightly contracted in the middle,
are a little dilated at the top, of the same length, and
cream-coloured white; as the spreading twisted petals well
marks this species. Mr. Ker-Bellenden is disposed to und-
ervalue the labours of Linnaeus with respect to this plant,
which is nevertheless correctly defined by that author,
from a living specimen, raised in the Uphal garden, and
preserved in the Linnaean herbarium; nor are we inclined
to exchange our great master’s “short phrases by way of
description,” to which he owes his deferred fame, and all
natural history its perfection, for the longer, and proportion-
ablely feeble, characters of this or other writers, who have
nevertheless their use and their merits. It is true that the
fynonyms of Linnaeus are not all correct, in this place any
more than in others, and the name of moschatus may have
been taken from fynonyms, certainly erroneous, of Bauhine
and Rudbeck. Mullkens is however one of the most var-
ious and evanent fflavours in the feent of plants. The
fragrance of N. moschatus is compared by Mr. Ker to ginger.
We have found it highly sweet and pungent, varying at
different hours of the day, as in other instances. We would
further observe, that the very frequent and wide alterations
in the opinion of the ingenious author last mentioned, in his
proceedings through the Botanical Magazine, as to the species
of Narcissus and their fynonyms, may excite some mildates
on the part of Linnaeus, who had not a tenth part of the
W. i. 7. Att. n. 10. Curt. Mag. t. 48. (N. cernuus;
S. 11. N. junecolius reflexus, flore albo; Ger.

RAW_TEXT_END
somewhat deflexed. The number of flowers is from three to fix, and they droop in some degree, though less than in the last species. A quantity of these flowers in a close room, especially in the evening, is to many people intolerably oppressive.

15. N. feroximus. Autumnal White Narcissus. Linn. Sp. Pl. 417. Willd. n. 16. Chuf. Hort. v. 1. 162. Desfont. Atlant. v. 1. 283. t. 82. (N. minor feroximus; Ger. em. 124.)—Sheath with one or more flowers. Cup of the nectary extremely short, crested. Petals lanceolate, Leaves flat.—Native of Spain, Italy, and Barbary. We have it from M. Descourtis, who most unaccountably speaks of it as a variety of N. Tazzetta hereafter described, from which surely no species can be more different. The leaves are in breadth much like those of Jonquilla, but flat. Whole plant very slender in all its parts. *Stalk* round. *Flowers* from one to seven, with a very slender tube, fixing white, lanceolate, long, and narrow *petals*, and an extremely small and short *yellow cup*, beyond whose wavy edge three of the *anthers* project. We have never heard of this plant in the gardens of Britain.

β. N. orientalis; Ait. n. 11. Curt. Mag. t. 946, 1011, 1298, 949.

7. N. italicus; Curt. Mag. t. 1188. (N. orientalis β; Curt. Mag. t. 948.)

2. N. papyracus; Curt. Mag. t. 947. (N. torus albus; Ger. em. 126.)

Sheath with very numerous flowers. Cup of the nectary bell-shaped, plaited, abrupt, one-third the length of the elliptical petals. Leaves nearly flat.—Native of the south of Europe and the Levant, as well as of the northern parts of the East Indies, and apparently of China and Japan. We have a wild specimen, gathered by Dr. Buchanan, at Narcissus, in Nepal, flowering in September. With us this is a hardy garden species, though often forced, to bloom in the winter or early spring. It is known by its large *bulbs* broad, nearly flat, deep green leaves, upright, two feet long; and the very numerous *flowers*, which compose a roundish umbel. The *petals* are, in a natural *flame*, yellow, the cup of the *nectary* orange, hemispherical, its margin undulated, but scarcely notched. See the figures we have cited first. The scent is very powerful, and sometimes oppressive, though, in moderation, agreeable. This being the flower in which Dr. Sibthorp found the plant in Greece, it appears to be that which Disdoreides describes "with a saffron-coloured centre," though he says the rest of the flower is white. It is probable that the flower to which this species returns, if left to naturalize itself, as it were, under the south wall of some cottage garden, when the petals usually become cream-coloured, and the cup of a *golden* yellow, may be its original appearance. So it is most generally represented in Chinese and Japanese paintings. We have disposed under three varieties the references, chiefly to the Botanical Magazine, which indicate what we do not find sufficient materials for establishing as species. This is one of those garden flowers, which the power of cultivation has transformed into numerous, but mostly evanescent, varieties. Long and repeated experiments would be requisite to determine whether any, of those to which we have referred, constitute permanent species. The opinion of the observing writer in the *Magazine* has from time to time varied respecting them. We agree with him that the *orientalis* of Linnaeus, of which we have no authentic specimen, may be our *bifrons*. Whether Mr. Ker's and Mr. Aiton's *orientalis*, whose synonyms Linnaeus has confounded with the former, be a good species, and which of the varieties we have noticed belong to it or to *Tazzetta*, must at present rest in great uncertainty. We premise to suspect that Mr. Ker's *bifrons*. Curt. Mag. t. 1186, 1299, is not a permanent species. We should, from observing its usual aspect, when first imported from the Dutch gardens, t. 1299, judge it a variety of *Tazzetta*; but Mr. Ker informs us, that t. 1186 is the appearance it affords after it has been several years with us, which therefore is, probably, rather an approach to its original or natural state. Hence it seems more akin to *odoros*, which the constantly fixed lobed cup confirms.

N. dafis. Gouan. Obs. 22. Willd. n. 14. is indeed too doubtful to be admitted upon truth, and has the signs of a variety of *Tazzetta*, at least as far as can at present be conjectured. N. angulifolius albus minor, Baut. Prod. 27. Rudb. Ely. v. 2. 61. f. 2. appears to be this plant, which is said, by Bauhin as well as Gouan, to grow wild near Montpellier. May this really be a good species, and the original of the Paper-white, or Italian, Narcissus, Curt. Mag. t. 947, which the younger Linnaeus thought different from *Tazzetta*?

17. N. Bulboceudum. Hoop-petticoat Narcissus. Linn. Sp. Pl. 417. Willd. n. 15. Ait. n. 17. Curt. Mag. t. 88. Redout. Lilac. t. 24. (N. angulifolius montanus minimus; Ger. em. 136. allo n. 7 and 8, 137. N. minimus, calycen campunaut; Rudb. Ely. v. 2. 76. f. 7.)—Sheath single-flowered. Cup of the nectary funnel-shaped, much larger than the linear petals. Stamens and style declining.—Native of Spain and Portugal, nearly in our gardens, though not common, flowering in May. The *leaves* are numerous, fless-cylindrical, narrow, dark green. *Stalk* round, a span high. *Flower* inodorous, of a golden yellow, very conspicuous for its large funnel-shaped *nectary*, surrounded by small *petals*, which gives it an appearance totally unlike the rest of its genus. This plant is subject to two or three variations, of which some botanists make species. See Salis. Prod. 222.

*Narcissus*, in *Gardening*, comprehends plants of the bulbous-rooted, perennial, flowering kind, of which the species cultivated are, the common daffodil (N. pseudo-narcissus); the poetic, or white narcissus (N. pecticus); the two-flowered narcissus, or pale daffodil (N. bifrons); the two-coloured narcissus (N. bicolor); the leafy daffodil (N. minor); the ruff-leaved narcissus, or reflexed daffodil (N. brillianus); the oriental narcissus (N. orientalis); the hoop-petticoat narcissus (N. bulbocodium); the polyanthos narcissus (N. tazzetta); the late-flowering narcissus (N. feroximus); the sweet-scented narcissus, or great jonquil (N. odorosa); the calamine yellow narcissus (N. calathinus); and the common jonquil (N. jonquin).

The frill has varieties with white petals, and a pale yellow cup, with yellow petals, and a golden cup, with a double flower; with three or four cups within each other; *Trade* cant's large double, long-tubed flowered; short-tubed, dwarf-flaked; and the peerless daffodil. And many other varieties have likewise been noticed by writers.

Of the second species there are also varieties with double white flowers, with purple-cupped flowers, and with yellow-cupped flowers.

And of the third there are two or three varieties, as with sulphur-coloured flowers, and with white reflexed petals, with gold-coloured borders.

The fourth species has a large variety, which approaches, in
in its general appearance, very near to the first fort; but it is a much taller plant, and has its leaves more twisted, as well as more glaucous: the flower, but especially the nectary, is much larger, and the petals are more spreading. It is of a fine deep yellow colour, having sub-varieties with double flowers, and is a native of Spain, flowering in April. This is sometimes known by the title of great yellow Spanish bulbous narcissus.

Of the sixth fort, there are varieties with the cup and petals wholly of a gold-yellow, with yellow, with a white cup, and with a white petal, with a yellow cup and a white petal, with yellow, and with various other combinations of the different varieties. And the flower catalogues contain about a hundred sub-varieties under these heads. It may be noticed that the varieties with white petals and white cups are not so much esteemed as the others; there are, however, two or three with large bunches of small white flowers, which are valuable for their agreeable odour, and for flowering late: than most of the others. There is also one with very double flowers, the outer petals white, those in the middle some white, others orange-coloured, which has a very agreeable scent, flowers early, and is generally called the Cypris narcissus, and is the most beautiful of all the varieties when blown in glasses in rooms, or other places in the houe.

The eleventh species varies with double flowers.

And the thirteenth also varies with double flowers.

Method of Culture.—All these different species and varieties may be increased with facility, by planting the off-set bulbs from the roots; and by bowing the feed in order to procure new varieties, which is chiefly practised for the fine sorts of polyanthus narcissus. But for this last purpose, the feed should be carefully faved from the beet and most curious plants, after being perfectly ripened.

With respect to fowing the feed, it should be done soon after it becomes ripe, as about the beginning of August, in shalow boxes, or flat pans, perforated with holes in the bottoms, and filled with fresh light sandy earth, being covered about a quarter of an inch deep with fine sifted mould, and placed in such situations as are only exposed to the morning sun, till the beginning of winter, when they should be removed, to have the full sun, and be sheltered from severe weather. In the spring, when the plants appear, they should be occasionally watered in dry weather, and screened from the mid-day heat, removing them into cooler situations as the warm season advances, keeping them free from all sorts of weeds. Towards the latter end of the summer, when their flesms decay, the surface mould of the boxes or pans should be fhrd or wholly removed, and some fresh mould ftted over the plants, being careful not to disturb the roots, and keeping them rather dry in a fhaded place.

And they should have the same management annually, till the period of their leaves decaying in the third summer, when they should be taken up, and the largest separated, and planted out on raised beds of light fine mould, in rows five inches apart, and three or four distant in them, having the depth of two or three inches. The smaller bulbs may be covered in on another bed with fine mould, to them till of sufficient feed to be planted out as above. They should afterwards be kept clean, and when they fhew flowers, so as to ascertain their properties, they may be removed, and managed in the manner directed below.

And the off-set bulbs of the old plants, especially the double sorts, should be separated from the roots annually, or at farthest every two or three years, in the latter part of the summer, when their leaves and flesms decay: planting their larger bulbs out at different times, from the end of August to the beginning of November, in order to afford variety; but the earlier they are planted, the stronger they blow. When left out of the ground till February, or later, they mostly appear weak.

These bulbs succeed best where the foil is of a light, dry, fresh, hazel, loamy quality: and the aspect forth-easterly; as, where inclined to moisture, they are very apt to be de-froyed. They afterwards only require to be kept free from weeds, and to have the ground limed above them in the autumnal feafon.

The small bulbs may be planted out in rows in nursery-beds to increase, for being planted in the fame manner as the others.

When these roots are planted in the open borders, or other places, in assemblage with other bulbous-rooted flowers, they should be deposited in little patches, about three or four roots in each, putting them in with a blunt dibble, or holing them in with a garden trowel, three or four inches deep; in which mode they display their flowers more con-fpicuously than when planted singly.

And where a large quantity is planted out alone in beds, in order to exhibit a full bloom, as is often practised with the fine polyanthus-narcissus, jonquils, &c., the beds should be four feet wide, with foot-and-half or two feet wide alleys between them. In these beds the roots should be planted in rows lengthways, nine inches a fquare, either with a blunt dibble or with a hoe, three or four inches deep, and fix dillan in each row, covering them evenly with the earth, and raking the surface smooth and even.

But in order to blow the polyanthus-narcissus and jonquil in the highest perfection, curious florists often bellow particular care in their culture; some preparing beds of compost, as for the fine hyacinths, &c., managing them in the same manner. But they succeed well in beds of light dry mould.

In cases where the bulbs of this sort are intended for sale, they should be lifted at farthest every two years, to prevent their becoming flattened by pressure, and of course less valuable.

The bulbs may be retained out of the ground two or three months, when it is necessary; but it is better to re-plant them in the above manner.

Method of Culture in Glaffes.—It is sometimes the practice to cultivate the polyanthus-narcissus, and some of the large jonquil kind, in glaffes in rooms, in order to blow in the winter or early spring season. For this purpose, dry firm bulbs should be chosen, and one placed in each inqle glaf or bottle provided for the purpofe, any time from October till the spring, being then filled up to the roots of the bulbs with soft water, and deposited in a light warm place. In this method the plants soon begin to grow, and fend forth flower-flesms, affording good flowers, which have a very ornamental appearance. The principal circumstances to be regarded in this management are thofe of keeping the glaffes well fupplied with fresh portions of water, fo as constantly to be up to the lower part of the roots, and changing the whole, to as to keep it always in a pure fiate.

And they may likewise be raifed in pots filled with light sandy mould, and placed in the same situations; also in hot-houses they may be made to blow early, when kept either in pots or glaffes.

Where planted out in the manner mentioned above, in the borders, clumps, and other parts of pleasure-grounds, they are
NARCISUS, in *Fabulous History*, a youth of exquisite beauty, born at Thebæ, a city in Boeotia, was deemed to be the son of Cepheus, a prince who gave his name to that river. According to the fable, he was enamoured with his own figure, which he saw in a well, and contemplating it for a long time, without perceiving that he saw merely his own shadow, he pined away with love and desire. Thus Ovid relates the fable. But Pausanias, rejecting this account as incredible, refers to another tradition, according to which Narcissus had a twin-sister, who perfectly resembled him, and with whom he fell in love; but having had the misfortune to lose her, while they were hunting together, he abandoned himself to melancholy, and frequented the bank of a fountain, whose water served as a mirror to reflect his own figure, which, resembling that of his sister, gave him some consolation. The flowers called narcissuses, however, are said to be more ancient than this adventure; and the origin of their name is reported to have been as follows: The daughter of Ceres was gathering flowers in a meadow, when she was ravished by Pluto; and the flowers she was gathering, and which Pluto used for seducing her, were narcissuses and not violets. It is said that the manner of Narcissus's death has no other foundation besides his name, which is derived from a Greek word that signifies "to be blemished," or "without fenation;" whence soporific drugs have been called "narcotics." Narcissus, it is added, having manifested only disdain of all persons who conceived an affection for him, *Love* himself is said to have taken vengeance upon him for his indifference, by causing him to be in love with himself; and Ovid, who always inclines to the marvellous, has considered this story in a light that better answered that end. After this adventure, the Thebians are said to have honoured *love* with a particular worship. Ovid adds, that as this youth was defined to have merely phantoms for the objects of his passion, and of those which he inspired, the nymph "Echo" fell in love with him, and that his disdain obliged her to retire into caves and rocks, where she retained nothing but the voice. See *Narcissus*.

NARCOMAND, in *Geography*, an island in the East Indian sea, about 20 miles in circumference. It is a mere barren rock, without vegetation, and without inhabitants; 75 miles E. from the great Andaman. N. lat. 13° 23'. E. long. 94° 40'.

NARCONIS, in *Ichthyology*, a name given by Johannes Cubi, and other writers, to the *trepidus*, or cram-fish; a species of rain, distinguished by Artedi by the name of the *rauis tota levii*, the wholly smooth rain. See *Trepidus*.

NARCONS, in *Medicine*, a stupefaction or insensible state, whether brought on by medicines, or happening from natural causes.

NARCOtic PRINCIPLE, in *Chemistry*, a peculiar vegetable sublimation obtained from several plants, such as the lettuce, the poppy, and other vegetables, to which they are said to owe their narcotic and stupefying qualities. It appears to be obtained in the largest quantity from the *papaver album*, "white poppy." The following is the process for procuring the above sublimation, given by Dérofne in the Ann. de Chim. vol. xiv. p. 263, to whom we owe its discovery.

Evaporate the aqueous solution of opium to the consistency of syrup, when a gritty precipitate begins to be formed, which is increased by dilution with water. This precipitate consists principally of resin, extract, and the narcotic principle. The extract in this process is rendered insoluble in water, by absorbing oxygen; and also nearly insoluble in alcohol. When, therefore, the latter is poured upon the above precipitate, the resin and the narcotic principle are dissolved, while the extract remains unaffected, and is separated. The solution being left to cool, the narcotic principle is deposited in crystals. These, by repeated solution and cryallization, become of a white colour, in the form of rhomboidal prisms. This substance is insoluble in cold water, but diffuses in 400 parts of boiling water, which, however, is deposited on cooling. It diffuses in 24 parts of boiling alcohol, and in 100 parts of cold. When water is added to this solution, the solution is decomposed, the narcotic principle being precipitated in the form of white powder. Ether dilutes it with heat, but it falls down on cooling. When heated alone in a retort, it melts like wax, becomes frothy, and gives out white vapours, which condense into a yellow oil. If the heat be raised, carbonat of ammonia, carbonic acid, and carboxetted hydrogen gas, come over, leaving behind a coaly sublimate, which, when burned, affords potash. The narcotic principle diffuses in acids, but it is precipitated in the form of white powder by the alkalies. The latter also render it a little more soluble in water. The volatile oil dissolves it; but on cooling, it is deposited in the form of oils, which afterwards cryallize.

When it is subjected to the action of nitric acid, it becomes red, and is diffused. Oxalic acid and a bitter sublimate are produced.

When potash is added to the aqueous solution of opium, the narcotic principle is precipitated, carrying with it a portion of the alkali.

It is the opinion of this chemist, that its solubility in water and alcohol, in the process for obtaining it, is owing to the presence of resin, and the extractive matter, by both of which it is rendered soluble.

This peculiar sublimation has all the properties of opium in a concentrated state. Dérofne made experiments with it upon dogs, and found it more powerful than opium. He also found that, like opium, its bad effects were counteracted by vinegar. This circumstance led him to suppose that the vinegar dissolved this sublimation. See *Opium*.

NARCOtICS, in *Medicine*, from *narcissus*, *draws*weeps, or *flour*, those drugs which occasion drawlins or sleep; such as opium, henbane, hemlock, &c. See *Opiate*.

NARDIECK, in *Geography*, a circa of Hindoostan, in the subah of Delhi, bounded on the north by Hiifar, on the eak by Balloghtan, on the south by Nagore, and on the west by Moultan; a woody district, containing few towns.

NARDEN. See *Naarden*.

NARDI, JACOPO, in *Biography*, an eminent Italian historian, was born of a noble family at Florence in 1476. After fulfilling several important offices in his native city, he was sent ambassador to the republic of Venice in 1527. Upon his return to Florence, he married a lady connected with the party adverse to the Medici family, and distinguished himself as well in councils as in arms. His opponents gaining the ascendency, he was imprisoned, and afterwards sent into exile, being first stripped of all his property. He was one of the emigrants, who, in 1535, laid their complaints before the emperor Charles V. at Naples; but the application proving fruitless, he retired to Venice, where he employed his latter years in cultivating literature, and composed various works. He was prevailed by his friend,
friends, and even by the grand duke Cosmo, to return to Florence; but it does not appear that he attended to the invitation. The time of his death is not known. He was alive in July 1555, when, in a letter, he modestly describes himself as ascending with his staff the laborious steep of the 8th year of his mispent life. Nardi wrote the history of Florence from 1494 to 1531, containing facts within his own observation; but it was not published till 1592, when it made its appearance at Lyons. It has been several times reprinted. He likewise composed the life of Antonio Giovanni Tebalducci Malepinii, printed at Florence in 1597. He obtained a high reputation by a translation of Livy, first published at Venice in 1546, which is accounted one of the best versions in the Italian language. He also translated Cicero's oration for Marcellus. He cultivated Italian poetry, and composed some "Canti Carcachiaieschi," printed in collections of poems; and a comedy in verse, entitled "L'Amicizia."

NARDINI, PIETRO, the favourite disciple of Tartini. His performance on the violin was very much in the style of his master, highly polished and correct. He composed several books of solos for his instrument, in which he could not approach his master so nearly as in playing; and even in his performance there was a want of that energy and fire, in which no one of Tartini's pupils could ever come near him. He lived many years at Leghorn; but in 1770 he removed to Florence, where he was placed at the head of the grand duke's band. He died in 1794, very much lamented by his private friends, who regarded him as a man of great worth and probity.

NARDINUM Unguentum, Ointment of Spikenard, an ointment greatly celebrated among the ancient writers in medicine. It seems to have been variously prepared, but always with a great number of aromatic ingredients, and always with spikenard for the balsam. Dioecedes says, that the malabathrum, or Indian leaf, was sometimes an ingredient in it, but that it was also sometimes made without it. It was generally, however, mixed with the oleum balanii, or amphilacinum, infiltrated with an addition of fuchnanth; and to increase its fragrancy there were added colclus, amomum, myrrh, and balsam of Gilead.

The finest, was accounted that which was of a thin consistence, and very fragrant smell. It was said to be annihilating and destructive, but somewhat acrimonious; and was sometimes, for particular uses, reduced to a solid consistence with resin.

NARDO, in Geography, a town of Naples, in the province of Otranto, the see of a bishop, suffragan of Brindisi, but exempt from his jurisdiction; 22 miles W. of Otranto. N. lat. 40° 27'. E. long. 18'.

NARDOLE, a town of Hindooistan, in the cirecer of Rajamundry; 12 miles S.W. of Rajamundry.

Gen. Ch. Col. Perianthus none. Cor. of two valves; enter lanceolate or linear, long, pointed, enclosing the inner, which is smaller, linear, and pointed. Nectary none. Stam. Filaments three, capillary, shorter than the corolla; anthers oblong, Fil. Germen oblong; style single, thread-shaped, long, downy; stigma simple. Petiol. none, except the closed corolla adhering to the seed. Seed solitary, covered, linear-oblong, pointed at each end, narrower on the upper part.

This grass is by no means celebrated either for its agricultural or medicinal properties. Linnaeus observed that it was fought after by crows for the sake of the larva of some Tipula which they find at the root. He afferts also that goats and horses eat it, but that crows and thieves will not touch it. From its English appellation this plant might be supposed to be very useful for the manufacture of mats or balkeis, but it appears that many grasses are better calculated for such purposes, especially Stipa tenacissima.

3. N. citrius. Fringed Mat-graft. Linn. Sp. Pl. 78. Willd. n. q. Spicile incurred, fringed. —Native of India. Leaves flat and grasy. Flowering-stalk a span in height. Spike composed of twelve or fifteen, alternate, creft flowers, all pointing one way; their outer valve ovate-oblong, awnlet, fringed along the edge with numerous rugged scales; on one side of the flower there is a short bristle. We know nothing of this species but from Linnaeus's description of it, nor are we aware that it is figured any where.

N. indica of Linnaeus and other authors is now become a new genus. (See Microchilus.) N. gigant is also removed by Dr. Smith to Rossellia.

Nardus Ruffica, a name attributed by some authors to the ararabaces, and by others to the baccharis Monspheliniun.

NAREA, in Geography, a country of Africa, in the southern part of Abyssinia, formerly governed by its own princes; but having been conquered, and converted to Christianity, part of it is become subject to the Abyssinian emperor. The conquered part, however, does not extend more than about 50 or 40 leagues either way. The whole kingdom is reckoned rich and fertile, producing great plenty, and vast quantites of cattle, and carrying on a very considerable commerce with the Cafrers, who convey thither abundance of gold, which they exchange for clothes, fats, and other commodities. The Nareans are allowed, by the Abyss-
Abbyssinians themselves, to be the best and handsomest people
in all Ethiopia, tall, stout, and well-shaped; and in their dealings,
honest, wise, faithful, and undisguised. They are also
brave and warlike, and have gallantly defended their
country against the incursions of the wild and barbarous
Gilles. The tribute they pay to the Abyssinian emperor
seems to proceed rather from their loyalty than from any
obligation or compulsion.

NAREDCOTTY, a town of Thibet; 28 miles S. of
Gangotri.

NARELLA, a town of Hindooftan; 15 miles N.N.W.
of Delhi.

NARENDRA, a town of Hindooftan, in Agimere;
9 miles N.E. of Roopnagar.

NARENGA, a town of Dalmatia, on a river of the
same name, formerly the capital of Dal-
matia, and one of its principal fortresses; governed by a
Roman proconsul and council, having many places under its
jurisdiction. At a succeeding period, the Slavonians, under
the appellation of Narentanti, settled here, and molested
the navigation of these parts till the year 937, when the Ve-
netians took possession of the town; but in 1479 they be-
came subject to the Turks. No traces of the ancient town
remain; but in its vicinity is Naretana, so called from a river,
and fortified by the Venetians, but dismantled in 1716;
36 miles N.N.W. of Ragusa. N. lat. 43° 34'. E. long.
18° 4'.

NARES, a river of Dalmatia, which rises near Mošćar,
and runs into the Adriatic. The adjoining territory is fer-
tile, but thinly inhabited on account of the infalubrious-
ness of the air, which has given occasion to the proverb, "Na-
vetana od Boga proljeti," Narenta curled of God. The
Narentine annual fevers are reckoned by Dr. Guiseppe
Pogati, a celebrated professor of physic in the university of
Padua, a species of plague.

NAREX, in Anatomy, the two (right and left) cavities
of the nose. The term is nearly equivalent to the English
word nostril. See Nose.

Nares, Dr., in Biography, organist and composer to his
majesty, and brother to judge Nares, was a studious and
found musician, who had distinguished himself at York as
an organ-player and composer of anthems, before his ad-
vancement to the chapel royal in 1758, as successor to
Travers. On the death of Bernard Gates, he was likewise
appointed master of the children of his majesty's chapel;
and in both these capacities, his diligence in composing for
the chapel, and instructing the children, to which he devoted
his whole time, acquired him great respect. Besides his
choral compositions, Dr. Nares published several books of
lessons for the harpsichord, a royal pastoral on his majesty's
nuptials, and a useful elementary treatise on singing. Dr.
Nares, dying in 1783, was succeeded in the chapel royal
by Dr. Arnold, and as master of the children by Dr.
Ayrton.

NARESBAD, in Geography, a town of Peršia, in the
province of Kerman; 126 miles E. of Kabis.

NAREW, a town of Poland, in the palatinate of Bielšk;
12 miles N. of Bielšk.

NARGHIN, a small island in the Caspian sea, near the
west coast; 10 miles S.E. of Baku.

NARGHIS, a town of Peršia, in the province of Far-
sišan; 100 miles S.W. of Schiras.

NARGON, a small island in the gulf of Finland. N. lat.
59° 30'. E. long: 24° 36'.

NARHAI, a town of Hindooftan, in Mewat; 35 miles
N. of Cotputly.

NARIWAI, in Zoology. See Monodon Monodon.

NARRATION, in Oratory and History, a recital, or re-earful of a fact as it happened, or as it is suppos'd to have happened.

NARRATION is of two kinds: either simple and historical: as where the auditor or reader is suppos'd to hear or read of a transaction at second-hand: or artificial and fabulous: as where their imaginations are raised, and the action is, as it were, re-acted before them.

The narration, according to the writers of rhetoric, makes the second part of a just speech, or harangue: viz. that immediately following the exordium, or introduction.

It makes the whole of a history: abating for the occasional reflections, episodes, and digressions.

Cicero, Orat. Part. c. 9. requires four properties in a good narration; viz. perspicuity, probability, brevity, and sweetness.

The narration is rendered perspicuous, by observing the order of time, by using none but proper and known terms, with short, though full and explicit sentences, joined by proper particles, showing their connection and dependence, and by reciting the action uninterruptedly, and with suitable transitions.

It is rendered probable by the credibility of the narrator, by the simplicity and openness of the narration, by avoiding everything far remote from the common sense and opinion of mankind, and by a precise detail of circumstances.

It is rendered brief, by taking it up no higher than is just necessary; nor fetting it back, as that impertinent author in Horace, Quemino bellum Troianum orditur ab 000; and by avoiding trivial circumstancies.

The orator should be careful, however, whilst he endeavours to avoid prolixity, not to run into obscurity. Accord-ly Horace, aporiz'd of this danger, says (Art. Poet. v. 25.) "by striving to be short, I grow obscure."

Laflly, it is rendered sweet, pleasant, or entertaining, by using smooth, numerous, and wellounding words; by arranging them so as to avoid any hiatus, or clashing; by the greatness, novelty, and unexpectedness of the things related; and by enriching it with tropes and figures; as frequent admirations, exclamations, interrogations, expectations, suspense, surpris'ing events, by grief, joy, fear, &c. See Numbers, Cadence, and Trope.

In pleadings at the bar, says Dr. Blair, (Leç. on Rhetoric, &c. vol. ii.) narration is often a very important part of the discourse, and requires particular attention. In narra-tion at the bar, there is a peculiar difficulty. The pleader must say nothing but what is true; and, at the same time, he must avoid saying any thing that will hurt his cause. The facts which he relates are to be the ground-work of all his future reasoning. To recount them so as to keep strictly within the bounds of truth, and yet to present them under the colour most favourable to his cause; to place, in the most striking light, every circumstance which is to his ad-vantage, and to soften and weaken such as make against him, demand no small exertion of his skill and dexterity. He must always remember, that if he discovers much art, he defeats his own purpose, and creates a distrust of his sincerity. Quotidian very properly directs: "Effugienda. &c.; i.e. in this part of his discourse, the speaker must be very careful to shun every appearance of art and cunning. For there is no time at which the judge is more upon his guard, than when the pleader is relating facts. Let nothing then seem feigned; nothing anxiously concealed. Let all that is said appear to arise from the cause itself, and not to be the work of the orator." Cleanliness and diffiniteness, probability and conciseness, are, as we have already shewn, the qualities which critics chiefly require in narration. Diffiniteness is particularly requisite in narration, which ought to throw light on all that follows. A fact, or a single circumstance left in obscurity, and misapprehended by the judge, may destroy the effect of all the argument and reasoning which the speaker employs. If his narration be improbable, the judge will not regard it; and if it be tedious and diffuse, he will be tired of it, and forget it. In order to produce diffinitenss, besides the study of the general rules of perspicuity, narration requires particular attention to ascertain clearly the names, the dates, the places, and every other material circums-stance of the facts recounted. In order to be probable in narration, it is material to enter into the characters of the persons of whom we speak, and to shew that their actions proceeded from such motives as are natural and likely to gain belief. In order to be as concise as the subject will admit, it is necessary to throw out all superficial circumstances; the rejection of which will likewise tend to make our narration more forcible and more clear. Cicero is distinguished by his talent for narration; and his orations furnish instructive examples of it. The narration, e. g. in the celebrated ora-tion for Milo, has been often and justly admired.

NARRATION, in Poetry, is used more particularly for the action, or event, that makes the subject of an epic poem.

F. Booff observes, that the actions in poetry are equally susceptible of the two kinds of oratorial narration, and that each constitutes a particular species of poetry.

Those under the artificial or active form, are now called dramatic. And those only related by the poet, who here perforates an historian, are called epic.

In the drama, the narration is the whole of the piece; in the epopea, it is only a part, though in effect it is the principal part, and the main body of the poem. It is preceded by the proposition and invocation, which Bohus calls the preludes; and is frequently interrupted by the poet's speaking in person, demanding pardon, favour, &c.

The narration includes the whole action, epitomised, with all its circumstances and its ornaments.

It is in this part that the action is to be begun, carried on, and ended. It is this which is to throw the causes of all that is related: in this the difficulties are to be proposed and resolved, and the persons, both human and divine, are here to shew their interests, their manners, and their qualities,
ties, by their actions, and their difcourfe; and all this is to be deferved with the beauty, the majesty, and force of verfe, flyle, sentiments, comparison, and other ornaments proper to the subject in general, and to each thing in particular.

The qualities of the epic narration are, that it be agreeable, probably, moving, surprizing, and active.

Horace speaks of the utile and dulce as on the same footing.

Boffer looks on the utile as an essential property; and the dulce as no more than an additional quality.

NARRICKEE, in Geography, a town of Hindoooltan; 20 miles E.N.E. of Agra.

NARROW, in the Maurya. A horse is said to narrow, when he does not take ground enough, or does not bear far enough out to one hand or to the other. If your horse narrows you must affist him with the inside rein, that is, you must carry your hand to the outside, and press him forward upon straight lines with the calves of your legs.

Narrow is also a term among bowlers. See BOWL.

NARROW ISLAND, or Stenoa, in Geography, a small and uninhabited island of the Grecian Archipelago, E. of Naxos, but near it.

NARROWS, The, a narrow passage from the sea, between Long and Staten islands, into the bay which spreads before New York city: nine miles S. of it. — Also, a strait about three miles broad, between the islands of Nevis and St. Christopher in the West Indies. — Also, a strait, called "Petit Droit," in the river St. Lawrence, in Upper Canada, between Grenadier island, and the township of Escoot, now included in Yonge.

NARRYTAMOE, a province of Thibet, N. of Napaul.

NARSAPOUR, a town of Hindoooltan, in the circuit of Ellore, on the Godavery; 40 miles E.S.E. of Ellore. — Also, a town of Hindoooltan, in the circuit of Ellore; 25 miles N.W. of Ellore. — Also, a town of Hindoooltan, in Golconda; 10 miles E.S.E. of Dampetta. — Also, a town of Hindoooltan, in Myloree; 22 miles N. of Bangalore.

NARSAAY, a town of Hindoooltan, in Mewat; 10 miles S. of Cutpura.

NARSES, in Geography, styled the Eunuch, a celebrated general, who was brought up in the palace of Justinian I. to thole domestic feminine services in which perfons of this condition are usually employed: by his imituation talents he obtained the favour of the emperor, who gave him the posts of his chamberlain and private treasurer. He was gradually introduced into public business, and in the year 538 was placed at the head of a body of troops to affit Belisarius in Italy, who was engaged against the Ostrogoths. Some differences between him, and the general associated in the same service, led to his recall, and from this time till 552 he continued to serve the emperor in a civil capacity. At this latter period he was sent to oppose Totila with unlimited powers. He met his antagonist on the Apennines, totally defeated his army, and slew Totila. Narces marched on to Rome, and having employed himself in repairing the ruined walls of the metropolis, he pursued the Goths, defeated, and slew their general Totila, and reduced his remaining forces to obedience. The Franks and Alamains entered the north of Italy as allies to the Goths, and spread like a torrent along the coast of the Adriatic to Apulia and Calabria. Narces, at first, gave way to an inundation that he could not stop, attending chiefly to the defence of the cities. But while the invaders were melting away from the effects of im-
temperance, and an unaccustomed climate, he was employing all his resources in affording an army, and courting it to military exercises, and in the ensuing spring he almost annihilated the barbarian army, and that with little loss on his own part. Previously to the battle, a leader of the Heruli, a people in the imperial service, had killed his servant for some trifling offence, Narces caused him instantly to be put to death; and while the Heruli were viewing marks of indignation at this exertion of authority, he called on them to march forward lest they should lose their place in the field of honour, and he was obeyed without a murmur, a circumstance that evinced his fortune, and the confidence which he had in the troops.

Having overthrown the dominion of the Goths in Italy, he was appointed to the supreme authority of that country, a post which he occupied for fifteen years, during which he acquired the habits of avarice, and accumulated vast riches by methods which rendered his government unpopular, and excited a complaint preferred against him before the throne of Justin II. He was recalled by the empress Sophia, who insulently defied "he would leave to men the exercise of arms, and refuse the drudgery which was fitted for the hands of an eunuch." To this he indignantly replied, "I will spin her such a thread as she will not easily unravel," and he informed the Lombards to that invasion of Italy which followed under Alboin. He returned to Naples, where he was visited by the pope, who persuaded him to return to Rome. He died in 575, at a very advanced age. "His death," says Gibbon, "though in the extreme period of old age, was unfeamful and premature, since his genius alone could have repaired the laft and fatal error of his life." Univer. Hist. Gibbon.

NARSINGAPATAM, in Geography, a town of Hindoooltan, in the country of Cattack, near the coast of the bay of Bengal; 45 miles S. of Cattack.

NARSINGUR, a town of Hindoooltan, in Bengal; 44 miles W. of Midnapour.

NARYSZSK, a town of Poland, in Volhynia; 64 miles N.N.E. of Zytomiers.

NASAGAR, a town of Hindoostan, in Lahore; 56 miles S.E. of Nagercote.

NASAL. something belonging to the nose, nafus. As, the nofe-piece of a helmet, anciently called the nafale.

NASAL. In Grammar, &c. is applied to those sounds, or letters, in whose formation the nofe is the principal organ; and particularly where the sound formed is passed through the nofe.

In moft English words, the sounds expressed by the characters an, en, in, on, un, are simple sounds, and proper nasal vowels. See M, N, &c.

NASALIS Labii Superioris, in Anatomy, a name given by Albinus to a few fibres of the orbicularis oris. See the defcription of that muscle in the article DELIUTION.

NASAMMONITES, in Natural History, a name given by the ancients to a filoe, which Pliny defcribes to have been of a blood-colour variegated with veins of black. We know no filoe which answers to this character at prefent, unlefs it be some of the agates, in a variegated flate.

NASAMONES, in Ancient Geography, a numerous people of Africa, who inhabited a part of Cyrenaica, which fea. According to Pliny, Silius, and Lucan, the Pfylli and Nafamones mufi have been feated near the greater Syrtis, or behind the Regio Syrtica and Cyrenaica, if we adopt Strabo's opinion. The Pfylli, as Herodotus informs us, having once had all their refervoirs of water dried up by the fouth wind, advanced into the Sahara, in order to make war upon that wind; but as it blew with extreme violence, they were overwhefmed with torrents of wind, and all perifhed. After this tragicall event, their neighbours, the Nafamones, annexed the territories which they poifoned to their own dominions. Heredotus represents the Nafamones as a powerful nation in his time, and remarkable for fome fignular customs then prevalent amongst them. During the fummer feafon, they left their cattle on the coft, and difpersed themfelves over the plains of Egypt or Augilia, in order to gather the fruit of the palm-trees, or dates, with which this place abounded. Here likewife they found a immense quantity of grathoppers, which, being dried in the fun, they pulverized, and infused into milk. The liquor compofed of these two ingredients was highly efteemed by them, as a molib pleafant beverage. They had many wives, whom they ufed in public, like the Mafagees, after having erected a flag to a mark. The bride amongft them lay the firft night with all the gueffes invited to the wedding; and received from each of them the next morning a preftent, which he had brought with him for that purpofe. When they took an oath, they laid their hands on the fepulchres of thofe who had been generally esteemed the moft Juflicious and excellent persons among them. At their divinations, they went to the tombs of their ancfors, where, after certain prayers, they fell asleep, and grounded their predictions on the dreams that then occurred to them. They pledged their faith to each other by mutually prefenting a cup of liquor. When they had no liquor, the parties took up dust from the ground, which they put into their mouths. According to fome authors, the Nafamones were regarded by the ancients as no better than a numerous gang of banditti; as they made frequent incursions upon the territories of their neighbours, which they plundered and ravaged in a barbarous manner. A people of the fame name, as we learn from Philonutrus, inhabited part of Ethiopia.

NASARD, a flop in the large cathedral organs of France,

NARWA, in Geography, a fea-port town of Russia, which, together with its suburbs, is fitated, according to a geographical division, partly in Ingrina, and partly in Elithonia; as the river Narova divides these two provinces; but in the division of governments established by the late empefors, is comprifed in Ingrina, or the government of St. Petersburg. Narva, fuppofed to have been built in 1224, flands on the Narova, nearly 100 miles from Petersburg, 24 from the point where that river issues from the lake Peipus, and eight miles from its mouth, where it falls into the gulf of Finland. The houses are built of brick fluecood white, and it has more the appearance of a German than of a Russian town. In the suburbs, called Evangorod, the colofal remains of an ancient fortrefs, built by Ivan Vafiliwvitsh the Great, impend in a picturesque manner over the fliep banks of the Narova. The principal exports are hemp, flax, timber, and corn; the imports are falt, tobacco, wine, falted herrings, fpiices, tea, fugar, and other grocery wares. The commodities which go to Narva along the Narova are oblied, on ac- count of the falls of that river (fee Narova), to be carried a great way by land. Near Narva is the spot celebrated for the victory which Charles XII., in the 16th year of his age, gained over the Russian army, A.D. 1700. On that memorable day Charles headed at lead 9000 men, and the Russians did not exceed 32,000. Six thousand Russians, including thofe that were drowned in attempting to pafs the Narova, fell in this engagement; but the confquences were still more fatal to the Russian arms, as the whole artillery was lofs, and the greater part of the infantry furrendered to the conqueror. The number of prisoners was fo great, that the officers were only detained; the reft were driven, like a flock of fheep, to the difance of a league from Narva, and difmiffed. N. lat. 59° 16'. E. long. 28° 3'.

NARVOUNPOUR, a town of Hindoostan, in Allahabad, on the Ganges; 17 miles E. of Gazypour.

NARWA, a town and fortrefs of Hindoostan, in the country of Agra, on the Sinde; 98 miles S. of Agra. N. lat. 25° 40'. E. long. 78° 18'.

NARWAI, a name given to a fish of the whole kind, more frequently called the tea-unicorn. See Monodon Menecera.

NARWIR, in Geography, a town of Hindoostan, in Gujerat; 21 miles S. of Daccaapur.

NAS, a town of Sweden, in the province of Upland; 21 miles S. of Uplaf.—Alfa, a town of Norway, in the province of Aggerhuus; 60 miles N. of Chriftiana.

NASACARA, a town of Japan, in the ifland of Ximo; 15 miles E. of Kokara.

NASADKA, a town of Russia, in the government of Perm; 16 miles S.E. of Perm.
an octave above the 12th. The pipes are of metal, with a
funnel or chimney at the top.

NASHAUN, in Geography, a river of North America, in
New Bieck, which joins the Sault in N. lat. 25°10'.
W. long. 102 31'. forming with it the Rio Palmas, which
runs into the gulf of Mexico, N. lat. 25°. W. long. 98
46'.

NASBINESL, a town of France, in the department of the
Lozere, and chief place of a canton, in the district of
Marvejols; 12 miles N.W. of it. The place contains 1571,
and the canton 5593 inhabitants, on a territory of 1775
kilometers, in five communes.

NASBY, a town of Sweden, in Nercia; 12 miles N. of
Orebro.

NASCA, a sea-port of Peru, in the archdiocese of Lima,
and jurisdiction of Ica, Pisco, and Nafea; the territory
of which is fertile in wine and sugar, and the harbour
good; but the town is in a state of decay; 192 miles S.E.
of Lima. S. lat. 14°48'. W. long. 76°. Alto, a river of
Peru, runs into the Pacific ocean, S. lat. 14°42'.

NASCALE, a port of Tellary, made of wool, cotton,
and the like, and introduced into the vagina, after being
impregnated with proper ingredients.

NASCARO, in Geography, a river of Naples, which
runs into the gulf of Squillace, N. lat. 38°58'. E. long.
17°5'.

NASCIMENTO, a small island in the Indian sea, near
the S.W. coast of Madagascar. S. lat. 25°15'. E. long.
42°0'.

NASE, a town of Norway, in the province of Ager-
hausen; 96 miles N. of Christiana.—Allo, a river of North
America, which runs into the Mississippi, N. lat. 37°20'.
W. long. 92°12'.

NASBERRY TREE, in Botany. See CHRSYSOPHY-
LUM.

NASEBY, or NASEBY, in Geography, a village in the
hundred of Guildenborough, and county of Northampton,
England, stands on an eminence which is supposed to be
the highest ground in the kingdom. Though small, it is,
on many accounts, interesting to the traveller, and will ever
be conspicuous on the page of history. Its geological features
naturally attract the attention of the philosopher; and
the political importance connected with the military scenes
displayed in its vicinity; peculiarly entitle it to topographical
notice. Six springs rise within the parish, the waters flowing
from which are collected in reservoirs, and form valuable
ponds. The lesser or upper Avon derives its source from
one of these springs; the Nene from another; and the rise of
the Welland has been referred to Naseby field. The parish
contains about five open fields, and is nearly twenty miles
in circumference. Naseby was formerly a market town, the
inhabitants having obtained a charter in the fifth year of king
John. The "mercato-crepos" is still standing. A consid-
erable manufacture of wrought stuffs, harratens, and
tamies was carried on here; but has greatly declined through
the immense increase of the cotton trade, and the prevalence
of muslin and calicoes. By the return to parliament under
the recent population act of 1811, the number of houses is
stated to be 120, which are inhabited by 598 persons.

Adjacent to this village, on Naseby lea, occurred the
memorable battle between the royal and parliamentary
forces, June 14, 1645; which proved so fatal to the royal
cause, and in which, according to lord Clarendon, both
king and kingdom were lost. The armies were nearly equal
in number, and the royalists had peculiar advantages, if
they had skilfully employed them. But they imprudently made
a forced march of four miles, and attacked the enemy in a
lofty, commanding situation, before their own cannon ar-
rived. After a conflict for three hours the royal army was
defeated, and about five thousand were killed or taken. The
king's cabinet of letters, containing the private ones, which
passed between him and the queen, fell into the hands of the
conquerors, who pursuing the routed royalists, cruelly maf-
aced above an hundred women, some of whom were the
wives of officers of great quality. See Nichols's History
and Antiquities of Leicester. Martin's History of
Naseby, 5vo. Beauties of England and Wales, vol. ix. and
vol. x. by J. Britton.

NASBWITZ, a town of Prussia, in the palatinate of
Culm; eight miles N.E. of Biechofferdor.

NAS, a county of Halifex district, in North Carolina,
containing 6975 inhabitants, of whom 2596 are females.
In this country there is a large and valuable body of iron ore.

NAS Points, a cape in the British channel, on the S.
coast of Wales, and county of Glamorgan. N. lat. 51°23'.
W. long. 4°30'.

NASHAUN, or NEWSHAUN, one of the Elizabeth
isles, at the mouth of Buzzard's bay, and three miles from
the extremity of the peninsula of Barnable county in Am-
erica. This island supports a considerable number of sheep
and cattle; and is famous for its wool and cheese.

NASHUA, a considerable river of Worcester county,
in the Massachussets, which enters Merrimack river at Dun-
table.

NASHVILLE, a post-town of Mero district in Ten-
neflee, pleasantly situated in Davidson county, on the S.
bank of Cumberland river, where it is 200 yards broad. It is
regularly laid out, and contains 345 inhabitants, a court-hou-
se, gaol, an academy liberally endowed, a church for Preby-
ternarians, and one for Methodists. It is the seat of the courts
held every half-year for the district of Mero, and of the
courts of pleas and quarter sessions for Davidson county; 185
miles W. of Knoxville. N. lat. 35°45'. W. long. 87°8'.

NASHWARTHISH, a river of New Brunswick, which
runs into the St. John. N. lat. 46°4'. W. long. 66°46'.

NASI OSSA, or Nafalina ossa, in Anatomy, the bones
of the nose. See CRANIUM.

Nasi, or Narium constrictor, a muscle of the nose. See
NOSE.

NASI Offa. Fractions of, in Surgery. See FRACTION.

NASILON, in Geography, a town of Lithuania, in the
palatinate of Wilna; -50 miles S.E. of Wilna.

NASIMA, a town of Japan. on the S.E. coast of Ni-
phon. N. lat. 34°26'. E. long. 134°S.—Allo, a small
island of Japan, in the lirat between Niphon and Xiecco.

NASINO, a town of Japan, in the island of Niphon; 70
miles N. of Jedo.

NASITAS, a word used by some authors to express a
speaking through the nose.

NASKEAG POINT, in Geography, a cape of Hancock
county in the state of Maine, being the eastern point of Pe-
nobscot bay, in the town of Sedgwick.

NASKOW, a town of Denmark, on the W. coast of
the island of Laland, of which it is the capital; anciently
well fortified, but now only encompassed with a wall. The
town is of a middling size, and handsomely built; the in-
habitants are wealthy, and carry on a considerable trade in
the produce of the country, which is fertile. The Jews are
allowed the exercise of their worship, and have a synagogue.
In the town are an hospital and a grammar-school, both well
endowed. The harbour is to be very good. N. lat. 54°51'.
E. long. 17°5'.

NASO, a town of Sicily, in the valley of Demona; nine
miles W. of Patti.
Nasow, in Geography, a town of Pomerania; eight miles N.E. of Corling.

Nassar. See Nazareth.

Nassaf, in Biography, a celebrated Mussulman doctor, was born in the year of the Hegira 461, at the city of Nékfcheb, which was in that part of the Persian territories which lies beyond the river Gihon, anciently called the Oxus. He was one of the most eminent of the sect of Hanifites, or followers of Abou-Hanifah, who is venerated as the principal Imam or chief of one of the four orthodox sects among the Mahometans. He obtained great celebrity, and among other distinguishing titles, that of " Sovereign doctor of Genii and Men." He died at Samarcand in the year 537 of the Hegira, deeply regretted by an immense number of disciples, who respected him equally on account of his learning and piety. To him are attributed nearly an hundred treatises on the Mussulman law and traditions, in which he is said to have confounded the excellencies of 550 preceding writers.

Nassaf, another celebrated Mussulman doctor of the same country with the preceding, but who flourished at a much later period. The foundness of his doctrine, and the exemplariness of his piety, are highly commended; and his writings on law and religion are held in much esteem. He died at Bagdad in the year 710 of the Hegira, and was author of many books, among which is a " Commentary" on the five books of the Mussulman law.

Nassarre, Pablo de Zaraqa, an ecclesiastic and organist of the royal convent in that city, author of a treatise on music in Spanish, entitled " Fragmentos Musicos," in four parts, or distinct treatises; in which are contained the general rules necessary for canto fermo, characters for time, in measured music, counterpoint, and composition. Madrid, 1400. 1700.

The work is written in dialogue: the quellions are pertinent, and the answers succinct and clear.

In the first dialogue on canto fermo, examples are given, in Gregorian notes, of all the eight modes of the church.

In the second dialogue, the clefs, characters for time, and their proportions in canto figurato, or measured music, are explained; in which the old time-table is united with the new, from the maxima to the semi-quaver. A considerable part of this section is now useless in practice, unless in deciphering very old music.

In the third dialogue, the technical terms used in counterpoint are defined, and its rules explained. In this part of the work the author's knowledge of the history of counterpoint appears to be very superficial. He quotes Bacchius Senior in his definition. All his examples are written on canto fermo on four lines. But this section advances no further in composition than plain counterpoint, and the use of concords.

In the fourth dialogue, however, the use of discords, passing-notes, ligatures, or binding-notes, is amply treated, and numerous short examples of fugue on simple subjects are given; but none of canon or double counterpoint. The passables are all ecclesiastical, and much more ancient than the date of the book.

Nassau, in Geography, a town of Germany, in the county of Nassau Dietz, fronting on the Lahn, in which is a church used in common both by Lutherans and Calvinists. Opposite to it, on the other side of a river, on a high mountain, formerly stood Nassauber, a very ancient place, the original house of the Nassau family, now a fief of Treves; 22 miles N.W. of Mentz. N. lat. 50° 17'. E. long. 7° 55'.

Nassau, a principality of Germany, situated in the Wetterau, about 48 miles long, and 28 broad, generally woody and mountainous, and yet containing fine arable and meadow lands. The founder of the present princes of Nassau was count Henry I., a great monarch, who at the time of his death (1465) was ruler of the whole county of Nassau, with all its lands. In the year 1455, they agreed to hold the parishes and towns and county of Nassau in community; but to divide the other part of the county, Weilburg, Wisbaden, and Idalen, became Walram's part; and that of the Nucifores, a branch of the Nassau family, the county of Nassau, and more, Nassau Saarbruck Uningen. All the branches are named from the principal towns in the several districts.

Nassau-Dietz, a county of Germany, situated on the Lahn, in the circle of the Upper Rhine according to Busingh, but in the kingdom of Welfphalia according to Berenger; formerly a fief of Treves. It contains a part of the style of the langvards of Heffe, but what interest they have will in it is as yet undetermined. The capital is Dietz.

Nassau, a small town of Germany, in the county of Nassau, and containing a German church, and about 35 houses; called also " Kempfton."—Alto, a river on the coast of East Florida, which runs into the sea, N. lat. 30° 44'. W. long. 81° 42'.—Alto, an island in the East Indian ocean, situated W. of Sumatra; about 50 miles in circumference. This island and " Poggy" are sometimes called Nassau islands, and sometimes Poggy islands. The inhabitants are all tattooed. S. lat. 3°. W. long. 100°.—Alto, a sea-port town of Providence, one of the Bahama islands.—Alto, a town of Germany, in the county of Hohenlohe; four miles N. of Weckenheim; Alto, a mountain of the island of Jamaica; 50 miles W. N.W. of Kingston.—Alto, a small island at the mouth of Byram river, in Long island Sound.—Alto, a large bay, called " Spirito Santo," on the coast of West Florida, about 70 miles from N. to S., in which are several islands, the most northerly of which is Myrtle island. N. lat. 27° 45' to 28° 10'. W. long. 82° 35' to 83°.—Alto, a large and open bay on the coast of Terra del Fuego island; E. of Falce Cape Horn, which forms the western limit of the bay; it is well sheltered from the tempests of the ocean, and capable of holding a fleet of ships. S. lat. 55° 38'.—Alto, a cape on the coast of Surinam, or N.E. of South America, N.N.W. of Essequibo gulf, and the E. point of the entrance into the river Puma-ron. N. lat. 7° 40'. W. long. 59° 30'.—Alto, a cape on the N. shore of Terra Firme, in South America.—Alto, a road on the coast of West Florida, W. of Mobile bay, N. of Ship island, and within the N. end of the Chaldeans or Myrtle island. This is one of the belt roads, most easy of access, and the best sheltered, for large vessels on the whole coast of Florida. This road was first discovered by Dr. Daniel Cox of New Jersey, who called it by its name in honour of the reigning prince, William III.

Nassauviana, in Botany, is named by Commerson, in compliment to " the Prince of Nassau," who is said to have been the companion of his herbarizing excursions about the shores of Magellan. The specific name given by him seems designed to combine the two ideas, of eminence in the perfon commemorated, and of the corymbiferous habit of the plant. Jiff. 1757. Wild. Sp. Pl. v. 3. 236. Lamark's Dict. v. 4. 432. Illusfr. t. 721. Callas and order, Syneqes Polymnia-freggata. Nat. Ord. Compote. Linn. Cimareephae, Juff. Gen. Ch. Common Calixe of several oblong, pungent, horizontal leaves, surrounding a cylindrical common receptacle,
and separating the tufts of flowers; perianth double; the outermost of three linear-lanceolate leaves; inner of five larger ones; all rather spinous-pointed. Cor. compound, tubular; florets four or five, equal, perfect, uniform; their limb two-lipped; the upper with three teeth, erect; lower with two, reflexed. Stam. Filaments five, capillary; anthers cohering, acute, about equal to the limb. Pila. Germs oblong, somewhat quadrangular, compressed; style-thread-shaped; stigmas linear, diverbrated. Peric. none, except the permanent calyx. Seed the figure of the germs; down of four or five soft, white, deciduous bristles, feecially extending beyond the calyx. Recept. finally naked.

Eff. Ch. Flowers in an oblong head, with sharp scales interperforated. Calyx four or five-flowered, double; the outer of three leaves, inner of five. Florets tubular, two-lipped. Down brilly, deciduous. Receptacle naked.

1. N. fluvcola. Willd. (N. coryphlea; Commenrer Mss.)—Native of the Straits of Magellan; communicated by Juffieu and Thouin, from Commenrer's herbarium. The root appears to be perennial. Stem decumbent at the base, then erect, a span high, leafy, with a few short lateral branches. Leaves squill, ovate, acute, ribbed, smooth, crowded, deeply toothed, or almost pinnatifid, in their upper part. Flowers terminating the main stem, in a dense, oblong, downy head, whose outer scales are broadest, all of them being entire and fiddle-rubbed, in which characters, and their downy tips, they differ from the foliage. The whole plant has much of the aspect of a Tussilago, or Butterbur, in its flowers, but the foliage is totally distinguishable, both in form, size, and situation, from every species of that genus, as is likewise the fruititious form.

This herb is said to be delightfully fragrant; but nothing of that kind is perceptible in our dried specimens. We prefer the specific name of Wildenow, alluding to this circumstance, because Commenrer's, though older, was never printed.

NASSIA, in Geography, a town of Sweden, in the province of Smaland; 18 miles S.S.E. of Jonkoping.

NASSIRABAD, a town of Hindoostan, in Oude; 25 miles N. of Munickpour.

NASSIR-EDDIN, in Biography, a very celebrated philosopher, alronomor, and various writer among the Mahometans. He was born in the year 572 of the Hegira. He cultivated literature and the sciences with great success, and was characterized as "the doctor who had acquired the highest reputation in all branches of knowledge." He is frequently called, by way of eminence, "The Martyr." The emperor of the Moguls, Holagou, placed him at the head of all the philosophers and astronomers whom he had given directions for pertaining, amidst the wars of depreciation which he carried on against the Mahometans; and he created him director, or superintendent of the revenues of all the colleges in the cities of which he was master. He afterwards ascended the city of Marayah, and commanded him to prepare those astronomical tables, which were entitled the "Imperial," and which have come down to our times. Natir-Eddin also published the most esteemed Mahometan editions, with commentaries, of Euclid's "Elements," and the "Sphera" of Theodorus and Menelius. He was author of "A Treatise on Moral Subjects," and other pieces.

NASSITZA, in Geography, a town of Selavonia; 17 miles N. of Brod.

NASSOGNE, a town of France, in the department of the Sambre and Meuse, and chief place of a canton, in the district of St. Hubert. The place contains 801, and the canton 3375 inhabitants, on a territory of 1974 kilometres, in 11 communes.

NASSUCK, a town of Hindoostan, in Guzerat; 56 miles S.S.W. of Surat. N. lat. 19° 50'. E. long. 73° 49'.

NASSURABAD, a town of Hindoostan, in Allahabad; 56 miles S. of Jumnpore.

NAST, in Agriculture, a provincial term applied to any fort of fowen, as well land under fallow.

NASTADT, in Geography, a town of Wales; 18 miles S. of Colbeut. N. lat. 50° 10'. E. long. 7° 43'.

NASTISTAK, an island of Raffia, in the mouth of the Lena, about 80 miles in length and 20 in breadth. N. lat. 71° 44' to 73° 50'. E. long. 115° 49' to 119° 34'.

NASTOLA, a town of Sweden, in the province of Vaaland; 47 miles E. of Tavjalhus.

NASTURTUM, in Botany, so called, according to Pliny, book 19, chap. 8, from nafus the nose, because of the pungent and disagreeable smell, with which it twinges or torments that organ; the Cref, or Nofe-smart. This appellation has been given to various plants, which range under different genera of the Tetradynamia Silicofila of Linnaeus. Tournefort however retains a genus under this name, which he distinguishes from Thalijf, merely by having the leaves divided into many segments, a principle of generic definition not admittible in modern botany, though there are cases in which such a difference of habit may lead us to expect and discover different characters in the fruitation.

NASTUS, a name borrowed by Juffieu from the ancient Greeks, whose χαλαμυς very however, arundo farba of the Latins, is described as having a fiddle stem, useful for making arrows; whereas the plant of Juffieu is no other than the bamboo, or Arundo Bambus of Linnaeus, well known to have hollow stems and branches, on which its peculiar use, for many domestic purposes, greatly depends. Hence Retzius, finding this valuable plant a distinct genus from Arundo, called it Bambos, altered by the classical Schreber, though surely most unfortunately, into Bambusa; fee that article. Gmelin in his compiled Syllveta, v. 2. 579, has Bambus, and in the next page Nafus, with a strange misconception of characters, for the very same thing. We are disposed to prefer Nafus to Bambuya, though the latter has been adopted by Schreber, Wildenow, and in Hort. Kew. Bambos, used by Retzius and Roxburgh, is perhaps preferable to either, and Mr. Dryander has given that name his faction in editing Dr. Roxburgh's work, though he has retained Bambuya in Hort. Kew. The professed plan of the second edition of this book was to follow Wildenow, and our departed friend, when he did not publish in his own name, on that account, (as he has often told us,) never aimed about any choice in nomenclature, which we have often greatly lamented.—Jaff. 34. Lamarch Illufr. t. 264. Bambos; Retz. Obf. fasc. 5. 24. Bambuifa; Schreb. 236. Wild. Sp. Pl. v. 2. 245. Ait. Hort. Kew. v. 2 316.)—Clafs and order, Hexandra Monogynia. Nat. Ord. Gra- mina.

Gen. Ch. See BAMBUFA.

—Native of the East Indies, delightful, according to Dr. Roxburgh, in a rich moist soil, such as the banks of 4 A rivulets.
rivulets and lakes, among the mountains. The *fles* are arborescent, from ten to a hundred from each perennial root, erect and straight to the height of ten or twenty feet, then bending gently to one side, with innumerable, alternate, very compound, drooping, twisted branches; both *fles* and branches are round, very smooth, green, tubular, with frequent joints, at each of which is an internal transverse partition. *Thorns* two or three together at some of the joints, prominent, curved, the central one often extended into a branch. *Leaves* numerous, two-ranked, linear-lanceolate, acute, with sheathing imbricated *panicles*, whole long drooping branches are spiked, the *fles* being disposed along them, two or three or more, together, in half whorls. Each *fikeli* is oblong, smooth, varying greatly, from two to twelve, in the number of *florets*. The outer glume of the *corolla* is pointed, not awned, and the style is represented by Dr. Roxburgh as smooth.—*This*, the most common fruit of Bamboos, is extremely useful in tropical climates for buildings, furniture, carriages, or any purpose where strength and lightness are wanted. Whether the idea of the flender clustered filleted columns, of Oriental and Gothic buildings, was taken from hints of bamboo, we leave to antiquaries to determine, or at least to conjecture. The large fresh joints of this plant minister to one elegant article of luxury, serving instead of a tin box to convey nosegays fresh, even for some hundreds of miles in India. The Bamboo is kept in our flours for curiosity, as well as for its elegance, but does not blossom. The *seeds* are said to serve as food, in the manner of rice. A singular subsistence is found within the hollow joints of the old *fles*, called Tabaxir, or Tabafheer, by the Moors, Arabians, and Turks, and termed salt or milk of the bamboo by the natives of India. This is a hard concoction, pretended to possess great medical virtues; but on being chemically examined by Mr. Macie (now Smithfon) it proved pure flinty earth, affording another proof, in addition to many, that vegetables, of the graves tribe especially, do actually secrete that sub stance. See Phil. Trans. for 1790 and 1791.

2. N. *floribundus*. Straight Bamboo. (Bambus floreaf; Roxb. Coromand. v. i, 58, t. 80. Arundarbor pinosa; Rumph. Amb. v. 3, 14, t. 22.)—*Flowers* whorled, in long spikes, Corolla awned. Style downy.—Native of the East Indies, but in different situations than the former. According to Dr. Roxburgh, it is certainly a distinct species; is not so near so large, has a much smaller cavity in the *fles*, and is very straight. "Its great strength, solidity, and straightness render it much fitter for a variety of uses than the common *fles*; and it is particularly employed by the natives to make shafts for their *spears*." The *leaves* appear to be more ovate than in the last, as well as shorter. A specimen in the Linnean herbarium, answering in every particular to Dr. Roxburgh’s account and plate, is very like what we have pointed out in Rumphius. In this the *leaves* are shorter, and more ovate, than the first species, and have many longitudinal ribs. The margin is rough with fine bristles, and fine appearance of teeth, all directed forwards, or towards the point; in the former Dr. Roxburgh says the upper side and margin of the *leaves* are “backwardly helped.” This would be curious and essential distinction, but we dare not rely on it without seeing specimens of both his plants.—Sufficient marks of difference will be found in the specific characters above.

3. N. *verticillata*. Lelba Bamboo. (Bambusa verticillata; Wall. Sp. Pl. v. 2, 245. Arundo multijex; Loureir. Cochinch. 58. A *arborca* tus, Lelba dicta; Rumph. Amb. v. 4, 1, t. 17.)—*Flowers* whorled, in simple erect spikes. Spines none. Stigmas three favehile. —Native of Amboina and Cochinchina. In the latter it serves for fences. The *fles* is shrubby, perennial, twelve feet high, branched, with very long hollow joints, defulte of thorns. *Leaves* linear-lanceolate. *Spikes* few, terminal, erect, each of several dilatant whors. Loureiro describes the *calyx* as single-flowered, which Rumphius’s figure, though not very perfect, seems to contradict. We cannot answer for the identity of their species. The character of the three festivity *fignas*, without any *fleye*, attributed by the former to his plant, is a most decisive difference with regard to the two foregoing.—It is extremely probable that several species of this genus are included in the descriptions of Rumphius, but the attention of a good botanist on the spot would be requisite to develop their distinctions, and to settle his *synonyms*.

4. N. *paniculata*. Panicled Bamboo. (N. fig. 1, 6, d; Lamark illuftr. t. 264.)—*Flowers* panicled. Glumes strongly ribbed, with short blunt points.—Gathered by Commeron on mountains in the isle of Bourbon. We know not what to make of Lamark’s fig. a, but our specimens from Thoim answer exactly to the figures we have cited. The panicled *fles*, and the large, strong, ribbed, rigid-pointed glumes of their *corolla*, abundantly distinguish this species; from which Jaffien took his generic character, but which no author has till now defined.

NASUA, in Zoology, a species of *Viverrna*; which fee.

NASUDDEN, in Geography, a small island on the W. side of the gulf of Bothnia. N. lat. 64° 49’. E. long. 25° 44’.

NASUS, in Ichthyology, a species of Salmo; which fee.

ALO, a species of *Cynips*; which fee.

NATA, in Geography, a town of the isle of Zante; seven miles N.W. of Zante.

NATA, or St. Jago de Nata de los Cavalleros, a town of South America, in the province of Panama, founded A.D. 1517, by Gaspare d’Elpinofa. It is inhabited by a mixture of Spaniards and Indians. The town is situated on the bay of Panama. The bay of Nata, which is spacious and deep, lies on the S. coast of the island of Darien, and on the N. Pacific ocean, and extends to the island Iguesos. The town is 50 miles S.W. of Panama. N. lat. 8° 35’. W. long. 81° 6’.

NATA, or Nata; Nafeba, or Napi, in Surgery, a wen with a narrow base.

NATACHEQUIN, in Geography, a river of Labrador, in North America, which runs into the sea, in N. lat. 50° 25’. W. long. 60° 45’. The little Natchqua is W.S.W. of this.

NATAL, a country of Africa, on the S.E. coast of Caffraria, so called by the Portuguese, who discovered it on Christmas day, A.D. 1498. Several capes or promontories of this country are called “Point Natal,” the principal of which is situated, S. lat. 37’. E. long. 27° 10’.—ALO, a river of Africa, forming the northern boundary of the country of Natal, and running into the Indian sea, S. lat. 29° 50’. E. long. 29°.—ALO, a small island in the Indies sea. S. lat. 30° 30’. E. long. 47° 5’.—ALO, a cape and town on the S. shore of the Rin Grande, on the N.E. coast of Brazil. On the point which forms the cape is the caille of the Three Kings, or Portofala des tres Magos. The town of Natal is three leagues from the cape, before which is good anchorage for ships in four to five fathoms’ water, well secured from winds.—ALO, the name of an English settlement in the country of Batta, in the island of Sumatra, called also "Natar." The English settled here about the 4th year.
NAT

Year 1752, and formed connections in that part of the country. It is inhabited by perfons settled there for the convenience of trade, from the neighbouring countries of Acheen, Rou, and Menangeshow, and by their concourse and traffic, it becomes populous and rich. A large quantity of gold is procured from the country, some of the mines lying within 10 miles of the factory, and a considerable vent is found for imported goods. Like other Malay towns, it is governed by Dattoos, one of whom is fixed Dattoo Buffle, or chief magistrate, and his sway is very great. Marfden's Sumatra.

NATALIS, Natalis dies, or Natalitium, properly signifies a man's birth-day. See Nativity.

The word was first used among the heathens, to signify the feast held on the anniversary of the birth-day of an emperor; whence it came, in time, to signify any sort of feast. And accordingly, in the Patti, we meet with natalis solis, natalis invicti, &c.

The primitive Christians, finding the word thus established, used it in the same manner; and hence we meet in the ancient martyrologists with natalis calvus, for the feast of the death of the martyr Calvus; natalis cathedral, for the pontificate of St. Peter; natalis or natalitium, of such a church, for the Feast of the dedication. The word genatilis is used by the Greeks in the same sense as natalis, or natalitium, among the Latins.

Natalis, Ludi, Natal games, were games introduced on the anniversaries of the birth-days of great men.

Natalium, Anuulns, Natal ring, was a ring only worn on the birth-day.

NATANGEN, or Old Natangen, in Geography, a province of Pruffia, bounded on the N. and E. by the Preigel, on the S. by Ermeland, and on the W. by the Frieche Hall. This country is well cultivated and populous, and consists partly of arable and partly of meadow land. Although it is in some parts very lofty, yet it produces better corn than Samland, or Little Lithuania. It abounds alo with wood, and yields variety of game, and plenty of fish.

The capital is Brandenburg.

NATANT LEAF, in Botany. See LEAF.

NATARA, in Geography, a town of Poland, in the palatinate of Kiev; 14 miles S. of Biakercrkev.

Natchez, a powerful nation of Indians, who formerly inhabited the country on the E. side of the Mississippi. Fort Rofalie, N. lat. 31° 49', is in the country which they possessed. Nothing now remains of this nation but the name, by which the country is still denominated. The Creeks, or Mulkokulges, reposes upon its ruins. The French completed their destruction in 1730. The tribe of the Natchez, according to Dr. Robertson, (Hist. of Am. vol. ii.) had advanced (as well as the people of Bogota) beyond the other uncultivated nations of America in their ideas of religion, as well as in their political institutions. The sun was the chief object of religious worship among the Natchez. In their temples, which were constructed with some magnificence, and decorated with various ornaments, according to their mode of architecture, they preferred a perpetual fire, as the purest emblem of their divinity. Ministers were appointed to watch and feed this sacred flame. The chief function of the great chief of the nation, every morning, was an act of obedience to the sun; and festivals returned at festival feasts, which were celebrated by the whole community with solemnity but unbloody rites. On the decease of their caxique or chief, a certain number of his wives, of his favourites, and of his slaves, were put to death, and interred together with him, that he might appear with the same dignity in his future station, and be waited upon by the fame attendants. Many of the deceased perfons' retainers offered themselves as voluntary victims, and courted the privilege of accompanying their departed master, as an high distinction. Others, however, laboured to avoid their doom, and several saved their lives by flying to the woods. As the Indian Brahins give an intoxicating draught to the women, who are to be burnt together with the bodies of their husbands, which renders them incapable of their approaching fate, the Natchez obliged their victims to swallow several large pills of tobacco, which produce a similar effect.

Natchez, the principal town of the Mississippi territory, on the E. side of the Mississippi; 300 miles N. of New Orleans by water, 150 by the lake road. It has a Roman Catholic church, and is defended by a fort. N. lat. 31° 34'. As Natchez is likely to become a metropolis of the back settlements, a centre of administration, of literature, and of traffic, we shall here subjoin a brief account of its productions. The maple commodity of the settlement of Natchez is cotton, which the country produces in great abundance, and of good quality. The manufacture of calico, and the cultivation of tobacco, were carried on with spirit some years ago, but they have both given way to the culture of cotton. The country produces maize, or Indian corn, equal, if not superior, to that in any part of the United States. The time of planting is from the beginning of March until the beginning of July. The cotton is generally planted in the latter end of February, and the beginning of March. Rye, which has been attempted, has succeeded in some places; but wheat has failed. Apples and cherries are scarce, but peaches, plums, and figs, are very abundant. The vegetables of the Middle States generally succeed here. The great number of artificial mounds of earth visible through the whole settlement of Natchez, it must, at some former period, have been well peopled; besides, in all parts where new plantations are opened, broken Indian earthen ware is found; some of the pieces being in tolerable preservation, and retaining distinctly the original ornaments, but none of it appears to have ever been glazed.

Natchkin, a town of Kamfchaka, in the vicinity of which is a mineral spring; 30 miles E. of Bolcheretta.

Natchting-Tong, a town of Corea; 18 miles W.N.W. of Han.

Natchtoches, See Natchtoches.

Natchitoches, or Natchitoches, a name given to Red river in Louisiana, which runs into the Mississippi, N. lat. 31° 15'; W. long. 91° 47'.

Natchus, a town of the state of Georgia. N. lat. 33° 27', W. long. 86° 40'.

Nateco, a town of Africa, in the kingdom of Bambook; 150 miles S.E. of Galam.

Nativos, a town of Peru, in the province of Irak; 60 miles N. of Ipanah.

Natemberbach, a town of Austria; eight miles W.N.W. of Eferding.

Natemberg, a town and castle of Bavaria, near the Danube; nine miles N.W. of Offerhosen.

Nates, in Anatomy, the buttocks, which are proportionally larger in man than in any animal, on account of the great size of the muscles concerned in maintaining the body erect. The convexities of the buttocks are formed principally by the glutei magni muscles, covered by a considerable flatum of fat. In the cleft between them the opening of the end of the intestinal canal is found. See Gluteus and Man.

Nates cerebri, are two circular protuberances of the brain,
brain, situated on the back side of the medulla oblongata, near the cerebellum.

NAT, in Geography, a town of the county of Tyrol; six miles W.S.W. of Innsbruck.

NATHAN, Isaac, in Biography, a learned rabbi who flourished in the fifteenth century, was the first Jew who made a Hebrew concordance to the Bible, on which he was occupied from the year 1438 to 1445, which, by his own acknowledgment, was not original, but for the most part copied from Latin concordances, so that the Jews themselves are indebted to Christians for their useful works of this kind. His publication was entitled "Light to the Path." It was first printed at Venice in 1524, and afterwards in a more correct state, with a Talmudical index, at Basle, in 1581, and at Rome in 1622, in four volumes folio. The most complete and valuable edition of it is that of Buxtorf, the elder, which was published at Basle in 1632, and which is said to have been superceded by one printed in the middle of the last century by the Rev. W. Romane, in four volumes folio.

NATHAN, in Geography, a town of Perû, in Irap; 60 miles N.N.E. of Irapan.

NATHE, a provincial term applied to the nave of a wheel.

NATICK, in Geography, an ancient township of America, in Middlesex county, Massachusetts, situated upon Charles river; 18 miles S.W. of Boston. The famous Mr. Elliot formed a religious society here; and at his motion the General Court granted the land in this township, containing about 6000 acres, to the Indians. In 1761 it was incorporated into an English district, and in 1781 into a township, and it now contains 694 inhabitants.

NATION, a collective term, used for a considerable people, inhabiting a certain extent of ground, included within fixed limits, and under the same government.

Each nation has its peculiar character; and it is proverbially said, Light as a Frenchman, Waggish as an Italian, Grave as a Spaniard, Serious as an Englishman, Fierce as a Scotchman, Drunken as a German, Idle as a Irishman, Deceitful as a Greek, &c.

NATION is also used, in some universities, for a distinction of the scholars, and professors of colleges.

The faculty of Paris consists of four nations; viz. that of France, that of Normandy, that of Picardy, and that of Germany; which are again, excepting that of Normandy, distinguished into tribes; and each tribe has its deacon. The German nation comprehends all foreign nations, English, Italian, &c.

When the procurator of the French nation speaks in public, his style is, Honorable Gallorum natio; he of Picardy says, Fideles Pancardorum natio; he of Normandy, Verenrandi Normanorum natio; he of the nation of Germany, Confuasti frumi Germanorum natio.

NATIONS, Law of. See Law.

NATIONAL Debt, is the debt due by the state to the public, on account of monies borrowed and funded for defraying the charges of the government.

In order to trace the origin of this debt, it is proper to be considered, that after the Revolution, when our connections with Europe introduced a new system of foreign politics, the expences of the nation, not only in setting up the new establishment, but in maintaining long wars, as principals on the continent, for the securitv of the Dutch barrier, reducing the French monarchy, settling the Spanish succession, supporting the house of Austria, maintaining the liberties of the German body, and other purposes, increased to an unusual degree; Insomuch as it was not thought advisable
June; the Nativity of the Holy Virgin, a feast established by pope Sergius I., who was advanced to the see of Rome in 687, and observed on the eighth of September, &c. When we say absolutely the Nativity, it is understood of that of Jesus Christ, or the feast of Christmas. See Feast, Christmas, &c.

Nativity, Nativity, in Ancient Law Books, signifies bondage, or servitude.

Nativity, in Astrology, the theme or figure of the heavens, and particularly of the twelve houses, at the moment when a person was born; called also the horoscope.

Calling the nativity, or by calculation seeking to know how long the queen should live, &c. was made felony, anno 23 Edz. c. 2.

Nativitiy Habendo, in Law, a writ directed to the sheriff, for a lord who claimed inheritance in any villain, when his villain was an away from him, for the apprehending and refunding him to the lord.

NATOLIA, Anatolia, or Anadolu, in Geography, a province of Asiatic Turkey, bounded on the N. by the Black Sea, on the E. by Caramania, on the S. by the Mediterranean, and on the W. by the Archipelago and the sea of Marmora; about 400 miles in its greatest extent from E. to W., and 350 from N. to S. Anatolia was anciently denominated Asia simply, or by way of peculiar excellence, as being the belt spot in this part of the world, and adorned with many opulent cities, and considerable fates. Afterwards it was distinguished from the whole Asiatic region by the epithet of Minor or Lesser, and accordingly denominated Asia Minor; it derived the name of Anatolia from its eastern situation, with regard to Europe, and it is still called the Levant. Anatolia, in its largest sense, comprehends the ancient provinces of Galatia, Paphlagonia, Bithynia, Pontus, Myasis, Phrygia, Lydia and Meonia, Æolis, Ionia, Caria, Doris, Pamphylia, Pisidia, Cappadocia, Lycia, Lycaonia, and Cilicia. Later geographers have divided it into four parts, according to their situation; viz. Anatolia, properly so called, on the western part; Caramania, on the southern; Aladula, on the eastern, and Amastra, on the northern. Anatolia, properly so called, is divided into the following districts, viz. Bithynia, Myasis, Æolis, Ionia, Caria, Doris, Lydia, Phrygia, Galatia, and Paphlagonia; which see respectively.

Anatolia, or Natolia, is now governed by a beglerbeg, who resides at Kütata, under whom are several fanjics. The soil is, in general, fertile, producing corn, tobacco, and fruits of various kinds; cotton and silk; and notwithstanding the indolence of the Turks, and the oppressive nature of their government, its commerce is considerable, particularly in carpets, leather, drugs, cotton, silk, and other articles of produce and manufacture. Most of the inhabitants are Osmanliots; with a considerable proportion of Chirilians, particularly of the Greek church, governed by patriarchs, archbishops, and bishops, who are tolerated by the Porte. Here are likewise many Armenians, and some Roman Catholics.

NATOLICA, an island in the Mediterranean, near the coast of Greece. Ptolemy, ii. lat. 38° 39'. E. long. 21° 20'.

NATRA, a town of Sweden, in Angermanland; 36 miles N.N.E. of Hernofand.

NATRAPOLLAM, a town of Hindoostan, in Myfore; 6 miles N. of Allambady.

NATRIX, in Zoology, the name of the common or water-snake, called also torquata, from the ring about its neck. See COLUBRUM Natrix.

NATROLITE, in Mineralogy, the name given by Klau proth (Mem. Acad Scien Berlin, 1809) to a fossil found at Hogau in Suabia, on the borders of Switzerland. It is deposited in the crevices, or clefs and cavities, of the famous porphyry (Klinginlein porphyry), from having a found, nearly metallic, which form the mountains and rocks of Ho enthual, Hohenkraken, and Mügdeberg. The colour of this fossil is a dirty ochreous yellow, approaching sometimes to an isabella yellow, or at other times to a yellowish brown, intermixed with concentric white lines. It is compact; its internal surface is a silky lustre; it breaks into wedge-like pieces, the edges of which possess little transparence; it is not very hard, extremely brittle, and its specific gravity is 2.200: 100 grains of this fossil, ignited in a silver crucible, yield 9 grains; it fuses quickly before the blowpipe into a transparent glafs, full of small air-bubbles, and in a porcelain furnace melts into a brown glafs; and in a charcoal crucible it afforded the same product, with minute globules of iron in the surface. From the analysis of Klau proth, 100 parts of the natrolite yielded

Siliceous earth - 48 grains,
Alumine - - 24.25
Oxid of iron - - 1.75
Soda - - 16.50
Water - - 9

99.50

NATRON, or Anatron, in Natural History, an earthy alkaline salt, or mineral alkali, taken out of lakes of stagnant water, in the desert of Nitræa, in Egypt. See CARBONATE OF Soda, and Soda.

Natron is much of the nature of nitre; whence it is by many called Egyptian nitre, and is supposed to be the proper nitre of the ancients. As our salt petre was unknown to them, they gave the name of nitre to this sub stance, described by the Arabs under the name of "natronum," of which we have made natron. In consequence of a want of due examining the passages of Theophrastus, Dioscorides, Galen and Pliny, several moderns have confounded nitre and natron, which are substances materially different. It is not possible to ascertain the extent of the lakes on which the natron is formed, as it varies according to the seasons. When the water is melt abundant, the two lakes are united into one, which is much longer than it is broad, and occupies a space of several leagues; at other times they are only ponds of no great extent. If Pliny, when he affered that the Nile acts on the falterns of Nitræa as the sea does on salt-water ponds, meant that the inundation of the river extended as far as the lakes, he was mistaken, as father Sicard has shewn. But if he meant no more than that there is a fort of conformity between the Nile and the lake, he suggests a fact, observed by the people of the country, and by them erroneously attributed to a communication that cannot exist between the waters of the Nile and the natron lakes. The rife of the latter is in an inverse proportion to the former; so that when the Nile begins to overflow, the lakes decrease so much as to appear only like small ponds, at the time when the river is at its greatest height. The waters, on the contrary, seem to return, when those of the Nile decrease, and inundate a long extent of the valley, while those of the river are at the lowest. In order to account for this fact, it should be considered, that the rife of the Nile, occasioned by the melted snow and rains in Abyphinia, begins at the summer solstice, that is, in the hotest and driest season in Egypt; and that at the time when the river has retured, or during the winter, the rains, nevertheless, fall very abundantly in the northern part of that country; and hence it will be obvious, that the seafon when
when the Nile increases must also be that in which the waters spread over the sands, dry up, and diminish; and that, on the other hand, the local rains, which can in no respect influence the overflow of the Nile, are sufficient to increase the springs that supply this body of water. When the two lakes separate, and their waters retire, the ground which they have inundated, and now leave exposed to view, is covered with a sediment that is crystallized and hardened by the sun; that is, the natron. The thickness of this layer of salt varies according to the longer or shorter continuance of the waters on the ground. In those spots which have been moistened only for a very short time, the natron exhibits a white efflorescence, resembling flakes of snow. It also appears, that at certain seasons the waters are covered with this substance. It is procured principally in the month of August; but is found likewise, in smaller quantity, during the rest of the year. It is digested from the ground by iron instruments, and carried on the backs of camels as far as "Terané," where it is shipped on the Nile to be conveyed to Cairo, or to the florshouses at Rosetta. The quantity annually collected amounts to near 25,000 quintals, and a great deal more might be obtained: it is usually sold at from 15 to 18 medines the quintal, delivered in either of these two towns.

Natron is seldom to be met with perfectly pure, independently of the earthy substances with which it is almost constantly mixed; it is not an alkali entirely undiluted; it is generally blended with marine salt, with Glauber's salt, and in some degree with vitriolic tartar. In the florshouses at Rosetta there are two forts, viz. the common and the "Sultanee," a word which corresponds to the epithet royal. This latter is whiter, better crystallized, and purer than the common fort: it is consequently stronger, and when used, a smaller quantity is sufficient. This mineral alkali possesses the same properties as vegetable alkali, or "fosa;" but it is said to possess them in a higher degree of strength. Its principal use is the bleaching of cloth and thread. The method pursued at Rosetta is as follows. The skeins of thread are arranged in a large copper, set in masonwork; above them is put a layer of natron; and then a sufficient quantity of cold water is poured into to soak both the thread and the natron. The whole is left in this situation for three days, at the end of which the thread is taken out and hung upon sticks placed over the copper. When it has drained, a fire is lighted under the copper, and the water, in which the thread was soaked, with the natron, is made to boil, after having received an addition of some lime. The thread is steeped and stirred about in this hot lye, and washed in it several times, without being left there. It is immediately taken to the Nile, in which it is washed and beaten; it is then spread out to dry. When the skeins are very dry, they are again washed in the whey which runs from cheese, and which, in Arabic, is called "Melch." This is a sort of softening that improves the cloth, and when the Egyptians handle a soft cloth, they say that it wants "melch." To bleach 100lbs. of thread, it generally requires 100lbs. of natron, and from 60 to 80lbs. of lime; observing, however, that the "Sultanee" natron, that is, the purer sort; being stronger than the common, a smaller quantity must be used; without this precaution, the thread, or linen, would be liable to be burnt. The natron trade, though pretty brisk with Turkey, and even with the state of Venice, where this alkali, mixed with sandy stone, makes the beautiful bluish glafs of Murano, was absolutely at an end, with regard to France; though in the year 1777 it appeared likely to be revived. It is not solely to the bleaching of cloths and thread, that the use of natron is confined in the country where it is formed. It is also used in dyeing, in the preparation of leather, in making glasses, in bleaching linen, in dough instead of leaven, for preferring meat and making it tender, and lastly, to mix with snuff, and make it more pungent. Natron is also found in another lake, less considerable than that called the lake of Terané, which is in the desert of Nitria, or of St. Macarius, viz. near Damanhour, and in other countries, besides Egypt. See CARBO.

NATRUDACOTTA, in Geography, a town of Hindooftan, in Tinelley; 16 miles E. of Tinelley.

NATTI, a provincial term applied to the hornless breeds of animals of the sheep and cattle kind. Thus we have the natt or Devonshire breed of sheep. It is sometimes written nat.

NATTA, Marcantonio, in Biography, a celebrated Italian jurist, was born of a noble family, at Atli, and studied law at Pavia in the early part of the sixteenth century, under Corti Maino and Décio. He was from a very early age extremely fond of literature, which, as he increased in years, became his only passion, and he made so great progress in it that he was admitted among the Jurif-confulti before he had attained the age of twenty-three, and was in the same time advanced to be senator at Calif. His fame was so high that he received invitations from several princes to settle in their dominions, and exercise among them various honourable offices. He published legal con- 

fulements, which were in high estimation, likewise theological pieces, and some tracts on philosophy. Among them, the principal are "De Pulchro;" "De Deo;" in fifteen books; "De immortaliitate Animi;" "De Fossilie Domini." Moreri.

NATTAL, in Geography. See NATA.

NATTAM, a town and fortes of Hindooftan, in the country of Madura; 18 miles N. of Madura. N. lat. 10° 10'. E. long. 78° 18'.—Alfo, a town of Hindooftan, in the Carnatic; 28 miles W.N.W. of Trichinopoly.

NATTENAT, an Indian village in Nootka found, in the vicinity of which to the northward is a remarkable cataract. N. lat. 48° 46'. W. long. 124° 6'.

NATTER-JACK, in Zoology, a species of Rana, which see. See also Toad.

NATTORE, in Geography, a town of Bengal, capital of the circar of Bettoorah; 115 miles N.N.E. of Calcutta. N. lat. 24° 25'. E. long. 89° 7'.

NATWROW, a town of the Birman empire; 10 miles N.W. of Ava.

NATUNA ISLANDS, a cluster of small islands in the Chinefe fea; 60 miles W. from the coast of Borneo. N. lat. 4°. E. long. 108°.

NATUPA, a town on the W. coast of the ifland of Panay. N. lat 11° 30'. E. long. 122°.

NATURAL, something that relates to nature; that arises from a principle of nature; or is conformable to the ordinary course and order of nature.

When a stone falls downwards, we vulgarly say it does this by a natural motion; but if it be thrown upwards, its motion is said to be violent.

Water suspended in a fucking pump is said to be out of its natural place: cures wrought by medicines, are natural operations; but the miraculous ones wrought by Christ, supernatural. See MIRACLE. &c.

NATURAL CAUSE. See CAUSE.

NATURAL CHILDREN, are those born out of lawful wedlock. See BASTARD.

NATURAL DAY. See DAY.

NATURAL YEAR. See YEAR.
NAT

NATURAL Functions, in the Animal Economy. See Functions.

NATURAL History, a description of the natural products of the earth, water, or air: as - gr. helmets, birds, fish, insects, worms, plants, metals, minerals, and fossils; together with such extraordinary phenomena as at any time appear in the material world; as meteors, monsters, &c. See Botany, Entomology, Geology, Ichthiobiology, Meteorology, Ornithology, Zoology, &c. &c. together with the articles above enumerated.

Besides general Natural History, as of Phylus, &c. there are particular ones; and of two kinds. The first, those which only consider one kind of things; such as the History of Shells, by Dr. Liller; of Fishes, by Willughby; that of Birds, by the same; that of Plants, by Ray; those of Insects, by Swammerdam and Muffet; that of Animals, by G€mer; that of Fossils, by Agricol, Mercatus, &c.

The second, those which consider the several kinds of natural things found in particular countries, or provinces: as the Natural History of Dauphinie, by Chorier; the Natural History of the Antilles, by E. Du Tertre, and M. Longville de Poincy; those of Oxfordshire, and Staffordshire, by Dr. Plott; that of Lancashire, by Leath; of Northamptonshire, by Morton; that of the Western Islands, by Martin, &c.

The natural history only of one particular place, is a subject very extensive in its materials, and not to be set about without great care and circumpection. Mr. Boyle has favoured the world with a list of the heads under which to arrange things; and what to enquire after on such an occasion.

The general heads under which he comprehends the articles of this history are four: the things which regard the heavens, the air, the waters, and the earth.

Of the first clafs are the longitude and latitude of the place; the length of the longest and shortest days and nights; the climates, parallels, &c. what fixed stars are seen, and what are not seen there.

About the air may be observed, its temperature, as to the first four quarters, and the measure of them; its weight, clearness, refractive power; its subtlety or cohesion; its abounding with or wanting an effuine flate; its variations according to the seasons of the year, and the times of the day; what duration the several kinds of weather usually have: what meteors it is moist or least apt to produce; and in what order they are generated, and how long they generally last; what winds it is most subject to; whether any of them are flat or ordinary; what diseases are paid to be epidemic, or depending on the state and condition of the air: what other diseases it is subject to, wherein the air may be supposed to have some share: what is the usual falsity and inabilituy of it, and what sorts of confitution it agrees with, what it does not.

About the waters, it may be proper to observe the sea, its depth, tides, currents, falls, and other qualities: next the rivers will come under confideration, their depth, length, course, inundation, and the goodnes of their waters, with their gravity, and other peculiar qualities. After these, the lakes, springs, ponds, &c. &c. are to be confidered, epecially the mineral waters, their kinds, qualities, and virtues, and the manner of trying them. The inhabitants of the waters may follow here; and the particular kinds of fish that are found there, whether of the sea or rivers, are to be mentioned, with an account of their flores, bignes, goodnes, flesions of perfection, haunts, peculiarities of any kind relating to them, and the manner of taking them, epecially when there is any thing singular in it.

The things relating to the earth are last to be examined; these, first, the earth itself, then its inhabitants and its various productions, whether external or internal. In the earth itself may be observed, its dimensions, situation, soil, seat, north, and south; its figure; its plains and valleys, their extent; its hills and mountains, and the height of the most lofty, both in reference to the neighbouring valleys and plains, and to the level of the sea; as also whether the mountains lie scattered, or are disposed in ridges; and of the latter kind, whether they run east, west, north, or south. What promontories also, and what fiery or smoking hills there is, if any: whether the country be coherent, or much broken into islands; what the magnetic declination is in several places, and the variation of that declination in the same place; and if thofe be considerable, what may be conjectured as the occasions of them, whether the vicinity of iron-mine, of subterraneous fires, or what else. What the nature of the soil is, whether clayey, sandy, or of good mould; and what vegetables, plants, and trees best agree with it and succeed in it, what work. By what particular contrivances the inhabitants improve the advantages, or remedy the disadvantages of the soil; and what hidden qualities the soil may have. The inhabitants of the earth are then to be considered, both natives, and strangers that have been long settled there; and in particular, their figure, colour, features, strength, agility, or defects of their; and their complexions, hair, beauty, and the like; their diet, inclinations, and customs, so far as they are not owing to education: the fruitfulness or barrenness of the women; their hard or easy labours; the diseases they are most subject to; and any remarkable symptoms attending them.

As to the external productions of the earth, the enquirys are to be made: what grappes, grains, and fruit it best produces: the herbs, flowers, and timber trees; and the copnices, groves, forests, and woods the country has, or wants: what peculiarities are observable in any of them; what stones they most like or dislike, and with what culture they thrive best. Then what animals the country has or wants: both as to wild beasts and birds of prey, and as to poultry and cattle of all sorts: and particularly, if they have any animals that are not common, or any thing particular in those they have. After these, the subterraneous flowers are to be examined; what minerals the earth affords, and what it wants: then what quarries of stone, and in what manner they lie: what clays and earths are found there; as clays, marles, fuller's earth, earths for tobacco-pipes, earth for potter's wares, medicinal earths: what other mineral productions it yields, whether coals, salt mines, or salt springs, alum, vitriol, sulphur, &c. What metals the country yields, with a description of the mines of them; their depth, numbers, situations, signs, waters, damps, quantities of ores, goodnes of the ores, and the ways in life for reducing them to metals.

To these general heads should be added, inquiries into traditions in the country, of any thing relating to it, whether peculiar to it, or only more common there than elsewhere; and where these require learning or skill in the discovery, the utmost care is to be taken to put the people in a way to give their accounts in a satisfactory manner; for a tale or bad account of any thing is always much worse than no account at all. Phil. Trans. N. 11.

The Linnean fytem of natural history, which we chiefly follow in the New Cyclopaedia, is divided into five branches, each subordinate to the other: these are

Clafs, Order, Genus, Species,
Species, and Varieties.

with their names and characters. Of the three grand divisions, viz. the animal, vegetable, and mineral kingdoms; the animal ranks highest in comparative estimation; the next is the vegetable, and the lowest is the mineral kingdom. See Botany, Classification, and Mineralogy; with regard to the animal kingdom: it is divided into six classes, formed from their internal structure.

**Clases.**

1. Mammalia
   - Heart with two auricles
   - and two ventricles
   - viviparous
   - blood warm and red
   - 88
2. Birds
   - Heart with one auricle
   - and one ventricle
   - blood cold and red
   - 39
3. Amphibia
   - Heart with one auricle
   - lung voluntary
   - have antennæ
   - 120
4. Fishes
   - Heart with one auricle
   - and no ventricle
   -have antennæ
   - 25
5. Insects
   - Heart with one auricle
   - and no ventricle
   - have antennæ
   - 13
6. Vermes
   - Heart with one auricle
   - and no ventricle
   - tentacle
   - 4

The above six classes are divided into orders, and the orders into genera, and the genera into species and varieties.

Such is the tabular view of the animal kingdom, according to the Linnean system; it must, however, necessarily be imperfect, as much as new species in the several genera are continually discovered, and not unfrequently new genera likewise are added to the orders. See the several orders and genera in the alphabetical arrangement of the dictionary.

For another mode of classification, and remarks on this of Linneus, &c. we refer to the article Classification.

**Natural Inclinations.** are those tendencies or motions of the mind, towards things seemingly good, which are common in a greater or less degree, to all mankind. See Appetite.

Natural inclination, according to F. Malebranche, is the same thing, with regard to minds, that motion is with regard to bodies; and as all the varieties in the material world arise from the several motions of bodies; so do all those of the intellectual world from inclinations: and as all motions are the result of impressions immediately communicated by the finger of the Creator; so all inclinations are certainly nothing else but continual impressions of the will of the Creator on that of the creature; and must therefore, of necessity be agreeable to his; and therefore can naturally have no principal end but his glory; nor any secondary one but their own preservation, and that of others, both still with regard to his will, who gave them being.

Now as, properly speaking, there is but one love in God; viz. that of himself; so he only impresses one love or desire in us; which is that good in the general. It is this general love, or desire, is the principle of all our particular ones; as, in effect, it is the will itself; the will being defined to be a continual impression of the Author of nature, which carries the mind of man to good in general. But the impression towards good in the general doth not only proceed from God; but also all our inclinations to particular goods; as, v. gr. self-preservation, &c.

**Natural Law.** See Law of Nature.

**Natural Liberty.** See Liberty.

**Natural Magic** is that which only makes use of natural causes. See Magic.
NATURAL ORDERS OF PLANTS, in Botany, are such as are founded on principles of natural affinity, bringing together, under one point of view, such genera as have certain characters in common, independent of all artificial modes of classification. Linnaeus first pointed out the difference between a natural and an artificial method of arranging plants. His sexual system is an example of the latter, though many of its classes or orders happen to be likewise natural affinities. It was very unfair in its early opposers, who are now with their criticisms gone off the stage, to complain of this system, as interfering with the manifest order of nature in several instances; as its pretensions are merely to be easy and commodious, not natural. It is equally unfair in those who have given all their attention to natural orders, and who by their joint labours have greatly advanced that interesting branch of knowledge, to condemn the imperfect attempts of him who first led the way to their acquirements, or at least first pointed out the importance of their pursuit.

The ideas of Linnaeus, on the subject before us, are best collected from a posthumous publication, compiled from his private courses of lectures, by his distinguished pupils Fabricius and Gifke, and given to the world by the latter, at Hamburg in 1792, under the title Caroli A Linnaeus Prelectiones in Ordines Naturales Plantarum. Linnaeus had long before published what he modestly termed fragments of natural orders, and had given, at the end of his Genera Plantarum, an enumeration of those orders, to the number of 58, with an arrangement of the known genera under them, but without any definition or character whatever. He was always perfused that no such could be given; at least not until all the plants in the world were known, and reduced to their respective orders. He also perceived that most of the orders which border upon each other, however distinct they may be on the whole, are frequently connected by some intermediate genus; and that such intermediate genera render the verbal definition of the orders nearly impassable, as they commonly form the most violent exceptions in character, to the orders to which they manifestly belong. Such is Eryngium, with its capitate flowers and thistle-like habit, among the most natural order of umbelliferous plants, with which its organs of fructification, as well as its sensible qualities, and its properties, agree. We would remark however that some of these supposed intermediate genera, ought rather to be considered as constituting intermediate orders, but this might lead to an immense and disproportionate multiplication of the latter, attended with more trouble than use. Linnaeus always considered his orders as forming a map, in which they were severally approximated by various points of affinity, rather than a regular series in which they followed each other in gradual distinction. He is careful to tell us, in his Clasfes Plantarum 489, that he has disposed his orders without any principle of natural connection between them, merely fluding to bring together under each the genera that belonged to it. He disclaims, in this arrangement, all rules taken a priori, from one part of fructification or another, being guided alone by the simple symmetry of all the parts, which however is often indicated by peculiar characters. For though some of those who may aspire to form a clue to his arrangement, he suggests that no general character is more to be relied on, than what depends on the situation of parts, with respect to each other, especially of the seed, and particularly in the seed itself. It is there to be observed whether the vegetating point, or embryo, perforates the seed longitudinally, being enclosed on either side; or whether it is placed at one side, externally or internally with respect to the cotyledons; whether in the base, near the base, at the side, or at the top of the seed. The base of the seed is the scar, by which it is attached to the pericarp, or to its own proper receptacle. In the work whence these remarks are taken, Linnaeus has not even given names to his orders; but in his own copy he from time to time supplied this defect; and in the Genera Plantarum each order appears with an appropriate, and generally descriptive appellation, of a single word. Here he takes care to inculcate, that such orders are designed to teach the nature or mutual affinities of plants, the artificial system being intended to make them out by; for which purpose the former, delimit of a key or clue, are necessarily inadequate, and do not of themselves constitute a system. He adds, that those who arrange plants after such imperfect fragments of a natural method, rejecting the artificial system, seem to him like persons overturning a commodious and well-covered house, to build another in its place, whose roof they are incompetent to complete. Linnaeus however advanced another step, subsequently to the publication of the last edition of his Genera Plantarum, and declared to Gifice in a conversation, that if he were to republish that book, he should not only make many changes in his natural orders, but alter their arrangement. He proposed to separate the whole into three great sections, which (as we may gather from his observations elsewhere) he would term classes. Thence are

1. Monocotyledones, comprehending orders - 1 to 11
2. Dicotyledones, (having two or more cotyledons), 11 to 59
3. Aecotyledones, (having none at all), 59 to 58

The last order (fungi) being perhaps altogether excluded.

He hinted further, a scheme of dividing the Dicotyledones according to some principle which seems to have been the embryo in his own mind. It was the only thing he concealed from Gifice in all his communications with him, except that he would never allow him to copy the manuscript alterations he had made in the arrangement of the genera under his various orders; doubtless because he considered his own ideas as progressive and unfixed.

In the conception of his orders Linnaeus ever kept the fructification solely in view, though the names of some few of them allude to the habit. We shall here enumerate these orders. An explanation of them, with a detail of the genera of each, and some of the above-mentioned manuscript alterations, will in general be found in their proper places, in our several volumes.

8. Seitanes. Annonum, &c.
15. Inundate. This order, which we have accidentally omitted in its place, consists of Zannichellia, Rupia, Patrogonetum, Myriophyllum, Ceratophyllum, Poojela, Elatine and Hippuris. To these are added, in manuscript, Chara, Naias, Aponogoton, Saururus Set, Callitrichie, Lemna and Piffia—rather a vagabond blage all together.

VOL XXIV.
16. Calyciiflorus. Ofris, Trophis, Hippophae and Elegans; with a manuscript hint of their affinity to Order 12th.
18. Bicorns. Plants whose pollen is discharged by two pores, or sometimes tubes, as Eria, Vaccinium, &c.
22. Caryophyllaceae. Pink, Campion, &c.
27. Rheedse. Poppy tribe.
32. Papilionaceae. Pea kind.
33. Lometae. Caffia, Mimosa, &c.
34. Cucurbitaceae. Gourd family.
35. Senticas. Rose, Bramble, &c.
37. Cullenifera. Mallow tribe.
38. Tricoceae. Euphorbiaceae, &c.
39. Siliceae. Cruciferae. This order Linneas indicates as having no relationship to any other. It constitutes the Tetradygium.
40. Peroniceae. Nearly equivalent to the Didymaemia Angio-
41. Asperifolia. Myosotis, Borago, &c.
42. Verticillata. Anterable to the Didymaemia Gymno-
43. Dumose. Rhamnus, Euryonymus, Ilex, Viburnum, &c., an allengage with which Linneas himself declares his difsatisfaction.
44. Sepaliaceae. The Jasmine tribe.
45. Umbellatae. Umbelliferous plants, properly so called, as Hemlock, Parley, &c.
46. Helianthaceae. Ivy and its allies, including Vitis.
47. Stellatae. Gatialm, Madder, &c.
48. Aggregata. Compound flowers with separate anthers, as Scabiosa, Prose, with one of their supped allies.
49. Compositae. The great family of compound flowers with combined anthers; divided into capitatae, as the Thistle: |strombose—Dandelion: |daisy—Tanfly, Ager, &c.: |cosmos—Sunflowers; and nectarines—Wormwood, Parthenium, Xanthium, &c. Some of this fraction have male flowers with distinct anthers, separate from the female. Gnaphalium and Xeran-
50. Amentaceae. Willow, Oak, &c.
51. Conifereae. Fir, Juniper, &c.
52. Cardunatae. Magnolia, &c.
53. Scabrideae. Nettle, Fig, &c.
54. Miscellaneae, a heterogeneous allengage, latterly much diminished. See Miscellaneae.
55. Filices. Ferns.
58. Fungi. The Fungus tribe.

At the end is a large list of genera, which Linneas found himself unable to refer to any of his orders, chiefly for want of sufficient materials to judge by. These are now, most of them, better understood, and easily reducible to some one or other of the foregoing tribes.

The Prælectores, published by Professeur Giteke as above mentioned, are an ample commentary on the arrangement we have just displayed, with much supplementary matter from the editor. The whole abounds with information, but is not without many errors and misconceptions, readily detected in the present more advanced state of this branch of the science, though very excusable when written. There is moreover, in this department, much room for hypotheses and fancy, so that various opinions are held by equal competent judges, and each has its day, like theories in medicine or chemistry, the science of natural classification being as yet very much in its infancy.

The great facility of the artificial, or sexual, systen of Linneas, which has made some of the best botanists of the world ever faw, seems to have taken off the attention of most of his pupils from the study of natural orders. This has been a misfortune, inasmuch as it has rendered them less competent to judge of natural genera, a talent only to be acquired by a critical observation of the principles of natural arrangement. It might seem invidious to point out the numerous examples of the defect alluded to, but the writer of this may be allowed to mention himself. He is well aware that a previous attention to natural orders, would greatly have lessened the labour and perplexity of studying genera, and though it happens that those he has founded have not been disputed, it is by the systen of Jullieu they must be tried. Whatever science may be imbibed in a practical familiarity with the artificial systen, and with the imitable technical style of its author, displayed in his generic and specific definitions, the study of that systen alone could hardly, at this time of day, lead to the establishment of any new genus with certainty, except in some particular classes and orders.

The difficulty of Linneas as to attempting definitions of his natural orders, was by no means the character of the French school of botany, which arose in opposition to him. The systen of the great and excellent Tournefort being found little capable of sustaining itself, against the overwhelming abundance of new acquisitions, and against the brilliant light, dawning from the north, which shewed but too clearly the imperfections of this and all other systens that had been contrived, had no chance of being defended in opposition to its rival. Vaillant was never forgiven for having even supposéd it could be amended, and especially for having, by his assertion of the sexual doctrine, contributed to lay the foundation of a rival school.

Bernard de Jullieu indeed, the father of the French botanists in this department, polishéd all the caution and dif-

Manuscript 18. plants of the order to discharge their pollen by two pores, or sometimes tubes, species, such as Erica, Vaccinium, and Eria. The family Rosaceae includes genera like Primula, which is closely related to Campion. The family Caryophyllaceae contains genera such as Fumaria. The family Palamine is related to Caprifoliaceae, represented by genera like Caprifolium. The family Multifiloidea includes genera like Helichorus, with unique flower structures. The family Rheedeae is associated with Poppy tribe, while Lurideae relates to the Nightshade tribe. Campanaceae are exemplified by Convolvulus, Campanula, and other genera. Contesse is linked with Aferlpias and Apocynum. Peperaceae is represented by Daphne and its allies. Papilionaceae includes Pea kind, Lometae are exemplified by Caffia and Mimosa, Cucurbitaceae is associated with the Gourd family. Senticas relates to the Rose, Bramble, and related genera. Pomaceae includes Apple, Plum, and other genera. Cullenifera relates to the Mallow tribe. Tricoceae is associated with Euphorbiaceae, and Siliceae with Cruciferae. Sepaliaceae is the Jasmine tribe, Umbellatae are Umbelliferous plants, Helianthaceae is the Ivy and its allies, including Vitis. Stellatae is associated with Galium, Madder, and related genera. Aggregata includes compound flowers with separate anthers, such as Scabiosa, Prose, and related genera. Compositae is the great family of compound flowers with combined anthers, divided into capitatae, such as the Thistle, Dandelion, Daisy, Tanfly, Ager, Cosmos, Sunflowers, Nectarines, Wormwood, Parthenium, and Xanthium. Amentaceae includes Willow, Oak, and other genera. Conifereae is associated with Fir, Juniper, and related genera. Cardunatae relates to Magnolia, and Scabrideae includes Nettle, Fig, and related genera. Miscellaneae is a heterogeneous allengage, latterly much diminished, see Miscellaneae. Filices are Ferns, Myphi are Mosses, Alge are Sea-weeds, Lichens, and Fungi are the Fungus tribe. At the end is a large list of genera, which Linneas found himself unable to refer to any of his orders, chiefly for want of sufficient materials to judge by. These are now, most of them, better understood, and easily reducible to some one or other of the foregoing tribes.
NAT

amusing, assumed an air of petulant hostility to that great man. An inherent love of paradox and affectation, prompted him, in the first place, to extol the artificial sytem of Tournefort as such, above that of Linnaeus, whose whole plan of botanical study and instruction, whether with regard to principles or execution, science or nomenclature, he studiously, and without any reserve, contemns and vilifies. Affections cost him nothing. He speaks of Ray as a judicious compiler, but no great botanist; and as if neither Linnaeus nor any one else had attempted anything on the subject, this vivacious Frenchman brings forward his own natural sytem, with an easy grace, not as a model or imperfect essay, but as an original and complete performance, calculated "to supercede all other systems, as comprehending the sum of all botanical knowledge." It belongs not to us to criticise his novel plan of orthography, which his countrymen have passed over in silent disdain; but we may complain of the additional difficulty, which arises from his arbitrary plan of nomenclature, which defies all precedent and authority, except what is inconvenient and absurd. Were it not for these contemptible airs and prejudices, the learning, penetration, and ingenuity of Adanfon, would long ago have procured him that distinguished rank amongst systematic botanists, to which he is doubtless entitled. His book abounds with original and instructive remarks, but his sytem, formed on technical characters, must necessarily be so far artificial, though it preserves abundance of natural combinations. By a singular but casual coincidence, it coincides, like the fragments of Linnaeus, of 58 orders, or, as the author terms them, families. These are given as mere lines of separation, subdivided into 1615 subordinate or secondary divisions, equivalent to genera, embracing 18,000 known species or varieties. The first are named in French, generally from the leading genus of each; as Lilafetes, Saltakaires, or from the leading character, as Labiate, Liguminales. They profess to be disposed in a natural series, and form a table where their distinctive characters range under the following heads.

Cotyledons wanting

Cotyledon one

- Stamens hypogynous
- - perigonous
- - epigynous

Stamens epigynous

- Apetalous
- - perigonous
- - hypogynous
- Corolla hypogynous

Stamens epigynous

- Monopetalous
- - epigynous
- - hypogynous
- - perigonous
- Stamine hypogynous

Stamens separate from the petals, insertion various,

The orders, mostly named from some leading genus, stand as follows.

Class 1.

1. Fungi.
2. Alge.
3. Hepatica.
5. Filices.
Class 2.
7. Aroicho.
8. Typhaceae.
10. Gramineae.
11. Palme.
14. Lilia.
15. Bromelie.
17. Narcissi.
18. Irides.
Class 3.
19. Musa.
20. Canne.
22. Hydrocharides.
Class 4.
23. Arisiochiae.
24. Elagania.
25. Thymelae.
27. Lauri.
28. Polygoneae.
Class 5.
30. Amaranthi.
31. Plantagineae.
32. Nygrine.

1. Name of each family.
2. Leaves, their form and situation; flipples, tendrils, flanks, &c.
3. Sex of the flowers.
4. Flowers, their situation with respect to the ovary, (that is, whether above or below the germen.)
5. Corolla, its figure and situation.
6. Stamens, their number, situation, and disk, (or what Linnaeus terms the receptacle of the flower.)
7. Ovaries, (gernems,) their number and disk.
8. Seeds, their number and situation.

Let any unprejudiced onlooker see how much of this is taken from even the artificial sytem of Linnaeus, and judge whether the main difference, of the leading characters being derived from the herbage instead of the fructification, be an advantage in favour of Adanfon or not. Those who with for an idea of his nomenclature and orthography, may take the first section of his Gramen, which he calls alsifles, and make it out as they can.—Kornukopla, Nardus, Milora, Sabab, Kapirola, Nasia, Falaris, Sticfauros, Abola, Vifia, Kalamagrojos, Apera, Valota, Sipa, Kilboul.

With far other aim and pretensions, the learned Antony de Jussieu ventured to publish, in 1789, his late uncle's sytem, in the form of a Genera Plantarum, sectandum Ordines Naturae disjuncta. In this work the classes, amounting to 15, embracing 100 orders, are very neatly distinguished; first by the number of Cotyledons (real or supposed); next the number of petals; and finally the insertion of the flamines or corolla. This is either hypogynous (below the germen); or epigynous, (into the calyx or corolla, which surrounds the germen, being itself inserted beneath that part); or epigynous, (above the germen.) This agrees with the idea, long before published, as we have mentioned, by Linnaeus, of the great importance of insertion, or the situation of parts with respect to each other, in forming the outline of a natural sytem. The classes of Jussieu form the following table.
The catalogue contains no others troubled Ruthe, Papaveraces, &c., being very properly and commodiously, subjoined in a different printed character. Sometimes indeed Juffieu and Linnaeus differ about what is inflorescence, and what a part of the flower: but these are occasional disagreements, between two great minds, contemplating the fame subjëct under different points of view. The work of Juffieu is an admirable companion to the writings of Linnaeus, supplying the defects inherent in his artificial system, and throwing a brilliant and distinct light on his details; but it is no more calculated to supersede that system, than a grammar can supersede a dictionary. Its excellent author has purveyed the subjëct in many subsequent essays, published by the National Institute of France, in which he has carried his enquiries, respecting the structure of various seeds, to a greater extent than before, and has thence reformèd the characters, or the places, of many genera. He has also somewhat changed the appellations of his orders, at least their mode of termination, reducing them to the feminine gender, and calling the Amaranthi, for instance, Auarantiiaceae; which is perhaps a more correct and unexceptionable mode of expression, and certainly preferable to the Liliæ and Proteæ of Mr. Salisbury.

This last-named botanist was the first in England who directed his attention to the system of Juffieu, and to a deep practical study of Natural Orders. On this principle he has arranged a catalogue, or Prodomus, of his own garden, published in 1796; except that he has taken his primary divisions from the artificial system of Linnaeus, which are founded solely on the number of flaminæ. This writer has prudently abated, like Linnaeus, from all definitions, or characters, of his orders. If Juffieu thought it incumbent on him to do otherwise, he has but displayed the difficulty of the enterprise, and the fallibility of human system when measured by the standard of nature. So many exceptions encumber most of his explanations, that they mean in fact little or nothing. They serve however to shew where nothing is, or can be, known or fixed, and it would be unjust to deny that they contain all the general information that is perhaps attainable.

Mr. Robert Brown in his Prodomus of the plants of New Holland, vol. i. published in 1812, has given true celebrity to the system of Juffieu, by whose leading principles that acute and learned work is arranged. In so totally new a field of observation, the principles of natural arrangement were requisite, at every step, for the patient and sagacious enquirer, and it is not to be wondered that he preferred them for the classification of his work. We hope, nevertheless, that he will hereafter, when his task is complete, favour the world with a Linnaean clue to his performance, in order to render the knowledge it contains generally accessible, and thus to unite, for the use of his countrymen, the talents of both those great leaders.

In the detail of his work, as far as is hitherto published, Mr. Brown has, in almost every instance, thrown more or less light upon the natural orders of Juffieu that fall in his way. We shall have particular occasion to shew this, when we come to treat of Orchideæ and Scitamineæ. He has, in several instances, subdivided the orders of the French author, or introduced new intermediate ones of his own. The definitions of his orders possess a clearness and precision, in our humble opinion, superior to what are found in any writer on the same subjëct. The inspection of the botany of a new world, as it were, in New Holland, where every thing is to different
different from what was already familiar to this botanist in Europe, afforded him prodigious advantages as to the enlargement of his conceptions of natural affinities. Perhaps in the detail of genera, we may sometimes think he has carried his distinctions too far, and in the definitions of species, that he has been prodigal of distinctive marks, instead of reeling on a few clear and sufficient ones. Every writer has a peculiar character and merits of his own, and the friend of whom we are endeavouring to speak without partiality or prejudice, has abundant merits to compensate any imperfections. He must ever rank in the first line of classical botanical authors, as a worthy pupil of Linnaeus as well as of Jussieu.

The system of Jussieu has found numerous followers among his countrymen; some of whom, as Ventenat and Decandolle, have the merit of original authors, in the numerous elucidations and corrections of their great model. It would lead us too far to enlarge on this subject. The world has long been in expectation of a new edition of Jussieu's Genera Plantarum from himself, which, from the vast additions and improvements that it could not fail to display, must prove almost a new work, and be of the greatest use to scientific botany. The science is now so generally cultivated, and by such various hands, that it will require frequently to be brought back to order and regularity, by some competent and duly constituted authorities. S.

Natural POLLUTIONS, in Agriculture, such as are produced by natural grages, in contradistinction to those formed by the artificial grages. See FUTURE.

Natural Philosophy, that science which considers the powers of nature, the properties of natural bodies, and their mutual action on one another: this is otherwise called physics. See PHILOSOPHY.

Natural Weeds, in Rural Economy, such as are raised in a natural manner, and not by planting. See Weeds.

Natural, in Heraldry, is used where animals, fruits, flowers, &c. are blazoned with the colours they naturally have. Those different from the common colours of heraldry; and this is to prevent the armorial being accused of falsity, when blazoned with the names of colours unknown in heraldry.

Natural. This word, in Music, has many acceptations; as natural tones, of the human voice, in opposition to the artificial tone of instruments. A melody or air is said to be natural, when it is smooth, easy, graceful, and sometimes when it is common. Harmony is said to be natural, when not loaded with discords, or deformed by extraneous modulation; but confined to the harmony of the key. Musick is likewise said to be natural, when it is clear and free from confusion, neither of difficult intonation nor execution; neither too high nor too low; too quick or too slow; nor affectingly loaded with accidental flats and sharps. The Italians always write recitative without flats or sharps at the clef; so that all the modulations are brought about by accidental flats and sharps.

Natural is also sometimes used for physical. In which latter sense, natural musick is that performed by natural organs, i.e., vocal musick; in contradistinction to artificial, or instrumental. See MUSIC.

Natural musick is more peculiarly used to denote a song that proceeds in the natural order of the notes, without flats or sharps.

Natural Harmony is that produced by the natural and essential chords of the mode. See HARMONY.

Natural Note is used in opposition to flat and sharp notes, which are called artificial notes. See NOTE, SCALE, &c.

The natural note, is used to contradict those flats and sharps that are set at the beginning of a staff; and, in such cases, you must take the natural note as it is in the gamut. Natural is also used for something coming immediately out of the hands of nature. In which sense it stands opposed to fictitious or artificial, which signifies something wrought by art.

Bishop Wilkins observes, that there appears a very great difference between natural and artificial things, when viewed with microscopes: the first ever appear adorned with all imaginable elegance and beauty; the latter, though the most curious in their kind, infinitely rude and unwholesome. The finest needle appears a rough bar of iron, and the most accurate engraving, or imboistment, as if done with a mattock, or trowel.

NATURALIST, a person who has studied nature, and is well verified in natural bodies, especially in what relates to metals, minerals, stones, vegetables, and animals.

Aristotle, Elean, Pliny, Solinus, and Theophrastus, were the greatest naturalists among the ancients; but they fell into abundance of errors, which have been corrected by the happy industry of the moderns. Aldrovandus is the most copious, but not the most accurate, of the modern naturalists: his work is in thirteen volumes in folio. The characters and works of Linnaeus are well known.

NATURALIZATION, in Law, the act of naturalizing an alien, or putting him into the condition of a natural-born subject, and incurring all the rights and privileges of such.

In France, before the revolution, naturalization was the king's prerogative: in England, it is only done by act of parliament.

But none can be naturalized, unless they have received the sacrament within one month before the bringing in of the bill, and taken the oaths of allegiance and supremacy in the presence of the parliament. A person who is naturalized may have lands by descent, as heir at law, as well as obtain them by purchase; but he is disbarred from being a member of the privy council, or parliament; or from holding offices, grants, &c. as well as a denizen, (see DENIZEN,) 7 Jac. I. cap. 2. 12 Will. III. cap. 2. No bill for naturalization can be received in either house of parliament without such disabling clause in it; nor without a clause disabling the person from obtaining any immunity in trade whereby, in any foreign country, unless he shall have resided in Britain for seven years next after the commencement of the session in which he is naturalized. (4 Geo. I. cap. 4. 14 Geo. III. cap. 84.) All children born out of the king's dominions, whose fathers were or are subjects of this kingdom at the time of their birth, are adjudged to be natural-born subjects of this realm, except children of parents attainted of treason, or that are in the actual service of a foreign prince at enmity with us. (4 Geo. II. cap. 21.) Every foreign seaman who, in time of war, serves two years on board an English ship, is, ipso facto, naturalized, under the like restrictions as in statute 12 Will. III. cap. 2. (13 Geo. II. cap. 3.) And all foreign Protestants and Jews, upon their residing seven years in any of the American colonies, without being absent above two months at a time, and all foreign Protestants serving two years in a military capacity there, or being three years employed in the whale fishery, without afterward abjuring themselves from the king's dominions for more than one year, and none of them falling within the incapacities declared by statute 4 Geo. II. cap. 21, are, upon the taking the oaths of allegiance and abjuration, or, in some cases, an affirmation to the same effect, naturalized to all intents and purposes, as if they had been born in this kingdom; except as to fitting
NAT

ting in parliament or in the privy council, and holding offices or grants of lands, &c. and therefore are admissible to all such privileges, and no other, as Protestants or Jews born in this kingdom are entitled to.

In France, Swifs, Savoyards, and Scots, need not any naturalization; being reputed regnicoles, or natives.

NATURALS, or NATURALS, in Medicine. In every animal, however sick or diseased, there is still remaining some degree of life and strength; and the causes and effects of each. These are called naturals, natural things, or things according to nature; and sometimes rarely nature; in contradistinction to non-naturals.

NATURE, NATUR, is a term variously used. Aristotle has a whole chapter written expressly to enumerate the various acceptations of the Greek word 

in the universer, or the affemblage of all created beings.

In which sense we say, the Author of nature: the sun is called the eye of nature, because he illuminates the universe; and the father of nature, because he warms the earth, and makes it fruitful. And thus we say of the phoenix, or a chimera, that there is no such thing in nature.

Instead of the word nature in this sense, Mr. Boyle, to avoid ambiguity, and abuse of the word, wishes to have world, or universer, substituted.

NATURE, in a more confined sense, is ascribed to each of the several kinds of beings, created and uncreated; spiritual and corporeal.

In which sense we say, human nature, meaning all men together who possess the same spiritual, reasonable soul; 

angelical nature; the divine nature, &c.

In this sense, the school-divines say, natura naturalis, 

and natura naturata, speaking of God, who is the nature naturans, as giving being and nature to all others; in opposition to the creatures, who are the natura naturata, as receiving their nature from the hands of another.

NATURE, in a still more refined sense, is used for the essence of a thing; or that which schoolmen call the quiddity thereof, that is, the attribute which makes it what it is.

In which sense, the Cartesians say, it is the nature of the soul to think; and that the nature of matter consists in extension.

And here the word essence Mr. Boyle would have obtain in him of nature.

NATURE is more particularly used for the established order, and course of material things; the series of second causes; or the laws which God has imposed on the motions impressed by him.

In which sense it is we say, physics is the study of nature; nature makes the night succeed the day; nature has rendered respiration necessary to life, &c.

Thus St. Thomas defines nature a kind of divine art, communicated to beings, which carry them to the end they are determined for. In which sense, nature is nothing else but that concatenation of causes and effects, or that order and economy, which God has established in the parts of his creation.

In this sense, too, we say, miracles are effects above the powers of nature: art is laid to force or furpafs nature, by means of machines, in regard these produce effects which exceed what we find in the common course of things.

NATURE, again, is taken for an aggregate of powers belonging to any body, especially a living one.

In which sense, physicians say, nature is strong, weak, or spent; or that, in such a state, nature left to herself will perform the cure.

NATURE is still more briefly used for the action of Providence, the principle of all things; or that spiritual power, or being, which is diffused throughout the creation, and moves and acts in all bodies, and gives them certain properties, and produces certain effects.

In this, which Mr. Boyle considers as the most usual sense, nature is nothing else but God, acting himself, and according to certain laws he himself has fixed.

This seems pretty agreeable to the opinion of many of the ancients, who made nature the god of the universer. To Panaetius, who presides over, and governs all things; though others owned this as an imaginary being, and by nature meant no more than the qualities, or virtues, which God has given his creatures, and which their poets and orators took occasion of personifying.

F. Malebranche says, that the nature so much talked of in the schools is fit for nothing but to lead us back to idolatry; the ancient heathens hereby understanding something, which, without being God, acts continually throughout the universer.

Thus the idea nature must be an actual principle, which, in concurrence with God, is the next and immediate cause of all the changes which befal matter. Which seems to fall in with the opinion of the aima mundi; as if nature were a sublimate of God, or a collateral cane with God, or a middle being between God and created things. See PLASTIC.

Aristotle defines nature, principium et causa natur et ejus in quo el primo per se, et non per accidens: a definition so obscure, that none of his commentators, with all their glosses, have been able to render it intelligible.

This principle, which the Peripatetics call nature, they supposed to act necessarily; and to be therefore delimit of knowledge, or liberty. See NECESSITY.

Thus also, the Stoics conceived nature as a certain spirit or virtue diffused throughout the universer, which gave every thing its motion; so that all must be dragged away by the invariable order of a blind nature, and an inevitable necessity.

In speaking of the action of nature no more is to be understood, but that bodies act on one another, in a manner agreeable to the general laws of motion which the Creator has established.

In this lies the mystery of that great word, which is only a compendious way of expressing the action of all bodies: but the mechanism of bodies would, perhaps, better express what is here meant by nature.

Some, Mr. Boyle observes, will have the nature of a thing to be only the law that it receives from the Creator, and according to which it acts on all occasions: But this is an improper and figurative expression.

The same author proposes a notion of nature as more fit than any yet given, to pass from the principal one of nature, with regard to which many axioms and expressions relating to that word may be conveniently understood. In order to this, he distinguishes between general and particular nature.

General nature, he defines the aggregate of the bodies which make up the world in its present state, considered as a principle by virtue whereof they act and suffer, according
to the laws of motion prescribed by the Author of all things.

Particular nature, of any subordinate, or individual, consists in the general nature applied to a distinct portion of the universe. Or, it is a convention of the mechanical properties (as magnitude, figures, order, situation, and local motion) of parts convenient and sufficient to constitute, or intimate to its particular species or denomination, the particular body they make up; the concourse of all these being considered as the principle of motion, rest, &c.

Nature, Guardians by, in Law. See GUARDIAN.

Nature, Law of: See LAW.

Nations, Laws of, are axioms, or general rules, of motion, and rest, observed by natural bodies in their actions on one another; and in all the changes which befal them in their natural state.

The laws of nature, and of motion, are, in effect, the same: cullum, indeed, has made some difference; and we find authors call the particular cases of motion, laws of motion: which see under Motion. The more general, and comprehensive ones, and those from which, as from axioms, the others are deduced, they call laws of nature.

Of these, sir Isaac Newton has established three:

1. That every body perseveres in the state, either of rest, or uniform rectilinear motion; except so far as it is forced to change that state by some foreign force.

Thus projectiles persever in their motions, except so far as they are retarded by the resistance of the air, and gravity: and thus a top, whole parts, by their cohesion, are continually drawing one another on: of their rectilinear motion, only ceases to run round because resisted by the air, and the friction of the plane on which it moves. And thus the larger bodies of the planets and comets prefer their progressive and circular motions a long time undiminished, in regions void of all sensible resistance. As body is passive in receiving its motion, and the direction of its motion, so it retains them or perseveres in them, without any change, till it be acted upon by something external. See VIS INERIE, RESISTANCE, and MEDIUM.

2. The change of motion is ever proportional to the moving force whereby it is effected, and in the direction of the right line wherein that force is impressed.

If a certain force produce a certain motion, a double force will produce double the motion; a triple force triple the motion; whether it be impressed all at once, or successively, and by degrees. And this motion (since it is ever directed to the same point with the generating force), if the body were in motion before, is either to be added to it, as where the motions conspire; or subtracted from it, as where contrary; or added obliquely, as where oblique; and is compounded with it, according to the determinations of each.

3. Reaction is always contrary and equal to action; or the actions of two bodies upon one another are always mutually equal, and directed contrary ways; and are to be estimated always in the same right line.

Whatever presses or pulls another, is equally pressed or pulled thereby. Thus, if I press a stone with my finger, the finger is equally pressed by the stone: if a horse draw a weight by a rope, the horse is equally drawn back towards the weight; for the rope being equally stretched each way, will, with an equal endeavour to relax itself, drive the horse toward the stone, and the stone toward the horse; and will hinder the progress of the one, as much as it promotes that of the other.

Again, if any body, by striking on another, do in any manner change its motion, it will itself, by means of the other, undergo also an equal change in its own motion, by reason of the equality of the pressure.

When two bodies meet, each endeavours to persevere in its state, and resist any change: and because the change which is produced in either may be equally measured by the actions which it excites upon the other, or by the resistance which it meets with from it, it follows that the changes produced in the motions of each are equal, but are made in contrary directions. The one acquires no new force but what the other loses in the same direction; nor does this last lost any force but what the other acquires; and hence, though by their collisions, motion passes from the one to the other, yet the sum of their motions, estimated in a given direction, is preferred the same, and is unalterable by their mutual actions upon each other.

In these actions the changes are equal; not those, we mean, of the velocities, but those of the motions, the bodies being supposes free from any other impediments. For the changes of velocities, which are likewise made contrary ways, inasmuch as the motions are equally changed, are reciprocally proportional to the bodies.

This law also obtains in attractions. See ATTRACTION.

Nature, in Mythology, is used by the poets sometimes for the mother, sometimes for the daughter, and at other times for the companion of Jupiter. She is described by the symbols of the Diana of Ephesus.

Nature, in Physics. A syllable is said to be long or short by nature, to signify that it is fo originally, and independently of any rule of grammar, which might render it fo by position or otherwise.

NAV, in Geography, a town of Italy, in the department of the Mela; 5 miles N. of Brescia.

NAV, La, a town of Spain, in the province of Leon; 22 miles S.W. of Valladolid.

NAVACE, La, a small island in the West Indies, between Jamaica and Hispaniola. N. lat. 18° 23'. W. long. 74° 50'.

NAVACOTTA, a town of Lamjung; 150 miles N. of Fyzabad. N. lat. 28° 56'. E. long. 83° 36'.

NAVAGERO, Andrea, in Biography, an eminent Italian poet and orator, was born at Venice, of a patrician family, in 1483. He was educated under Antonio Sabellico, and from an early age displayed very extraordinary powers of memory, and a decided turn for literary pursuits. He repaired to Padua, where he studied the Greek language with great affluence under Mufaro, and philosophy under Pomponazzi. In that university he formed connections with the celebrated Bembo, Contarini, Fracastorio, Torriano, and other distinguished characters, which continued unbroken through life. After this he spent some time at Pordenone, where the celebrated general Alviano had founded a literary academy; and then returned to Venice, and became a supporter of the learned labours of Aldo Manuzio, whom he assisted in the collection and examination of manuscripts, for the purpose of giving correct editions of the ancient writers. He was, on account of his eloquence, selected to recite the funeral orations of Alviano, the doge Lore, dano, and Catharina Cornara, queen of Cyprus. He was afterwards appointed keeper of the library of cardinal Befarion, and historiographer to the state. In the spring of 1525, he was sent to Spain on an embassy, where he remained about three years, when he set out on his return. Soon after his arrival at Venice, he was sent to France on an embassy, for the purpose of inviting Francis to return to Italy, to balance the power of the emperor. He had reached Blois, when he was attacked with a fever, which carried
carried him off in May 1529, at the age of 46. He was reckoned among the most polished writers of his time; and in Latin poetry he was distinguished by elegance, grace, and a kind of Grecian simplicity that denoted great purity of tale. His funeral orations are rather elegant and methodical discourses, than striking pieces of eloquence. His letters from Spain to Remusio exhibit him as a minute observer of everything curious presented by a foreign country, and as an antiquary and geographer. Soon after his decease, his funeral orations for Alivano and Loredo, and his Latin poems, were published, which were his only memorials till the year 1718, when the brothers Volpi published, at the Cominian press in Padua, a quarto volume, containing, with those pieces, all the works of Navagero that he collected; to which was prefixed a life of the author, by Gian-nantio Volpi.

Navagero, Bernard, an eminent cardinal in the 16th century, of the same family as the preceding, was born at Venice in 1507. He became distinguished for his talents as a man of business, and for great powers of eloquence, and was employed in the service of the republic. He was sent synodic to Dalmatia, apponted baily at Constantipolite, and afterwards nominated ambassador to Rome, to France, and to the court of the emperor. He was devoted to the purfuits of literature, and fearlessly quitted his study but to render service to his country. In 1561, pope Pius V. created him a member of the sacred college, and promoted him to the bishopric of Verona. After this, the pope sent him as his legate to the council of Trent. He died in 1565, and was author of some Hargueses, and of "The Life of pope Paul IV." Moreri.

Navagium, in our Old Writers, a duty incumbent on tenants to carry their lord's goods in a ship. "Libere fint ab omni carriagia, navagio, &c."

Naval, something relating to ships, or navigation; which see.

Naval Architecture. See Shipbuilding.

Naval Camp, in Antiquity, a fortification consisting of a ditch and parapet on the land side, &c, a wall constructed in the form of a semicircle, and extended from one point of the sea to another. It was sometimes defended with towers, and beautified with gates, through which they issued forth to attack their enemies. Homer hath left us a remarkable description of the Grecian fortifications of this sort, in the Trojan war, beginning at v. 436. Iliad."

"Then, to secure the camp and naval powers,
They rais'd embattled walls with lofty tow'rs:
From space to space were ample gates around,
For palling chariots; and a trench profound,
Of large extent; and deep in earth below
Strong piles incl'd flood adverse to the foe."
Pope's Transl.

Towards the sea, or within it, they fixed great pales of wood, like those in their artificial harbours; before thee the vessels of burden were placed in such order, as that they might be instead of a wall, and give protection to those within; in which manner Necis is reported by Thucydidus to have encamped himself; but this seems only to have been practiced when the enemy was thought superior in strength, and raised great apprehensions of danger in them. When their fortifications were thought strong enough to defend them from the assaults of enemies, it was frequent to drag their ships to shore, which the Greeks called zalix, the Romans salubres. Around the ships the soldiers disposed their tents, as appears every where in Homer; but this seems only to have been practiced in winter, when their enemy's fleet was laid up, and could not assault them; or in long sieges, and when they lay in no danger from their enemies by sea; as in the Trojan war, where the defenders of Troy never once attempted to encounter the Grecians in a sea-fight.

The adjacent places were usually filled with inns and flew, well flocked with females, that prostituted themselves to the mariners, merchants, and artificers of all sorts, who flocked thither in great numbers. This, however, appears to have happened only in times of peace.

Naval Crown. Corona Navalis, among the ancient Romans, a crown adorned with figures of prows of ships, con-ferred on persons who, in sea engagements, first boarded the enemy's vessel.

Though A. Gellius seems to speak in the general, where he says the naval crown was adorned with prows of ships, Lipius distinguishes two kinds of naval crowns; the one he calls simplex, the other rostrata.

The first he supposes plain, and given to the common soldiers, &c. The latter, much more glorious, adorned with prows of ships, and only given to generals, or admirals, who had gained some important victory at sea. See Crown.

Naval Engagement. See Engagement.

Naval Stores, comprehend all those particulars made use of, not only in the royal navy, but in every other kind of navigation: as timber and iron for shipping, pitch, tar, hemp, cordage, sail-cloth, gun-powder, ordnance, and fire-arms of every sort, ship-chandlery-wares, &c.

Perfons dealing or embezzying any of the king's naval stores to the value of 20s. are guilty of felony, without benefit of clergy. (31 Eliz. c. 4. 22 Car. II. c. 5.) And the treasurer, comptroller, surveyor, clerk of the acts, or any commissioner of the navy, may act as judges, in causing the offenders to be apprehended, committed, and prosecuted for the same. (9 Geo. III. c. 30.) And the treasurer and commissioners of the navy are empowered to inquire of naval stores embezzyed, and appoint perfons to search for them, &c. who may go on board ships, and seize such stores; and the commissioners, &c. may imprison the offenders, and fine them double value, the stores being under the value of 20s. (1 Geo. I. c. 25.) None but the contractors with the commissioners of the navy shall make any stores of war, naval stores, &c. with the marks commonly used to his majesty's stores, upon pain of forfeiting the fame and 200l. And perfons in whose custody such stores shall be found concealed, are liable to the same penalty. 9 & 10 Will. III. c. 45.

By 39 & 40 Geo. III. c. 89, perfons, other than contractors, receiving or having stores of war in their possession, shall, on conviction, be transported for 14 years, unless upon trial they shall produce a certificate, under the hands of three commissioners of the navy, expressing the number, quantity, or weight of such stores, and the manner of the same coming into their possession. If any perfon shall, either in this kingdom, or in any place belonging to it, burn or destroy naval, &c. stores, or any place where they are kept, he, and also his aids and abettors, shall be guilty of felony, without benefit of clergy. 12 Geo. III. c. 24. See All of Navigation.

Naval Tactics. See Tactics.

Navalcarnero, in Geography, a town of Spain, in Old Castile; 42 miles S. of Segovia.
NAVALIA, among the Romans, were docks or ports where ships used to be laid up after building.

NAVALPERA, in Geography, a town of Hindoostan, in Baglanța; 45 miles E. of Balfacen.

NAVAROQUE, a town of Spain, in Old Castile; 37 miles S. of Avila.

NAVÁN, a poilt-town of Ireland, in the county of Meath, situated on the river Boyne. Navan was an ancient palatinate, and in former ages was high in repute. It is beautifully situated, but very ill built: it has, however, been rapidly increasing in wealth and extent, and is much favoured by the Boyne having been rendered navigable to it. Its population was, many years ago, estimated at 4000, and has considerably increased: it is, according to Mr. Wakefield, chiefly Roman Catholic. The manufacture of sacking employs near 300 looms; here are likewise very extensive flour, cotton, and paper mills, a brewery, a distillery, with other manufactures incident to the situation and trade of the place. A good cattle fair is held four times in the year, and there is also a weekly market, which stands unrivalled in the county for live-Rock, bacon, hogs, butter, and every variety of rural produce, besides coarse linen, friezes, and yarn. Mr. Wakefield speaks of the wheat in this neighbourhood as excellent, but condemns the exhausting lyme that is pursued. The commons of Navan are very large, and very badly regulated, so that they are a public nuisance, by affording support to a number of unprincipled vagabonds. Navan has another nuisance, now, however, in a fair way of being removed by the legislature; a schoolmaster enjoying a large revenue, without making any return. The lands of the endowed school of this place are said to let for near 1500l. a-year, which income was converted into a fine council; but the commissioners appointed to investigate the state of public schools in Ireland, on the motion of Sir John Newport, bart., having exposed this and many similar abuses, measures have been taken to render the school's effective and useful. Navan is 24 miles N. by W. from Dublin.

NAVAPOUR, a town of Hindoostan, in Canara; 15 miles S.E. of Barcelore.

NAVARDUN, a town of Spain, in Aragon; 27 miles W. of Jaca.

NAVARÉDONDA, a town of Spain, in the province of Leon; 50 miles E.S.E. of Civid Rodrigo.—Alfo, a town of Spain, in Leon; 21 miles E. of Civid Rodrigo.

NAVARETTA, a town of Spain, in Old Castile, seated on a mountain; 9 miles W. of Logroño.

NAVARETTE, Fernández de, in Biography, was a millenary of the order of St. Dominic, in Spain, who flourished in the early part and middle of the 17th century. When he had filled some distinguished stations in his order, he, in 1646, left Spain for the purpose of promulgating the Christian faith in China. He went by way of America, where he was detained a considerable time, and did not arrive at the Philippine islands till 1648. He was appointed professor of theology at Manila, and was busily employed in making professed in those islands, and at Macassar, and at length reached China in 1659. He applied with so much affinity to the language, that he was soon able to speak and write it with great facility. In 1665 he was chief of the mission in the province of Che-kiang, when a persecution was excited in consequence of the "Ephemerides" of father Adam, a Jesuit; and the missionaries had orders to repair to Peking, whence they were sent to Canton, with permission to leave the empire. Navarette did not arrive at Madrid till 1672. He, soon after this, went to Rome, where he gave an account of the manner in which he had accomplished the objects of his mission. This did him so much credit, that he had the offer of returning thither with the episcopal dignity. This honour he declined, and in 1678 was consecrated archbishop of St. Domingo; and in the possession of this fee he died in 1689. He wrote an account of his travels in three volumes, of which the first appeared at Madrid in 1676. It has been esteemed one of the most faithful and curious accounts of that country, and has been given in our language in Churchill's "Collection." The second volume, while in the press, was suppressed by that curse of man, the Inquisition, which, to the joy of every feeling and virtuous mind, has been within these few weeks (February 1813) abolished in Spain, and we trust eradicated for ever from the world. It is not known what became of the manuscript of the third volume.

NAVARRÉ, Peter, in Biography, a celebrated warrior in the 16th century, was born in Biscay. He was brought up to the sea-service, but after a time engaged himself as valet to the cardinal Aragon, and then served in the army of the Florentines. He was next employed by Gonfallo de Cordova in the Neapolitan wars, as captain; and he contributed very much to the capture of Naples. On account of his good conduct, the emperor gave him large domains in Naples, from which he assumed the name of Navarre. He afterwards sailed against the Moriscos in Africa, and took possession of Oran, Tripoli, and other places. His campaigns in Italy after this were unfortunate, and he was taken at the battle of Ravena, 1512. Upon his liberation, thinking himself still treated by the Spanish king, he determined to enter into the service of Francis I. In his attempt to relieve Genoa, he was taken by the imperial troops; and for the space of three years languished in the dungeons of Étoff, till the treaty of Madrid set him free. He was taken prisoner at the retreat of Aversa, and again sent to the dungeon of Étoff. Here his life was spared by the duke of Orange, in compassion for his misfortunes and his valour. He died soon after, though it was asserted that he was strangled in his bed.

NAVARRE, in Geography, a province of Spain, which was anciently a kingdom, situated in the north of Spain, and shut in between the Pyrenees, Aragon, Old Castile, and Biscay. Its figure is an irregular quadrilateral; its mean length from east to west is 18 leagues, and its mean breadth from north to south is 14. On the west and south it is bounded by Aragon, on the south-west by Old Castile, on the north by the Pyrenees, and on the north by French and Lower Navarre. This country abounds in steep mountains, intermixed with vallies, and some small plains, which are very fertile. The mountains are part of the Pyrenees, forming the western extremity of that grand chain; and the principal valleys are those of Roncevaux, Lescou, Baifan, and Roncal. Navarre is watered by the Ebro, and eight small rivers. It has two bishoprics, one at Pampluna, the other at Tuda; two cathedral chapters, five collegiate chapters, 753 parishes, 70 religious houses, 12 hospitals, two asylums, a grand military government under the administration of a viceroy, a particular military government, a royal council, a chamber of accounts, an university, four colleges for the

NAV

education of youth, nine cities, 154 towns, and 653 villages. Its capital is Pamplona; which see. Navarre was formerly very populous, but towards the end of the 16th century there was a considerable emigration of its inhabitants, who removed into the province of France, which took its name. According to the enumeration of the years 1787 and 1788, the number of inhabitants ought to be now 287,582, in which number are reckoned 753 parish priests, 1,160 secular priests, 1,120 monks, 510 nuns, 13,054 nobles, 172 writers, 1,163 students, and 9510 servants. The country is mountainous and cold; the mountains are very lofty, and frequently steep, generally presenting to the view bare rocks. However, it has some considerable forests, and excellent pastures; and in some districts, the air is milder and more salubrious than in the neighbouring provinces of Spain. The fertile soil, capable of culture, is restricted to a certain number of vallies, and some hills and plains; and of course its productions are not sufficient for supplying the wants of its inhabitants. It yields wheat, rice, barley, maize, wine, a small quantity of oil, fruits, and pulp. The lands, that are of the best quality, are not rendered so productive as they might be made. The territory of Tudela is adapted to all sorts of tillage: it produces wheat, olives, barley, beans, excellent fruits, and hemp; but every thing is neglected for the sake of the cultivation of the vine. Among the wines of Navarre those that are most distinguished are the wines of Tudela, re<>mbling that of Burgundy, and those of Peralta, which are rich, and made with the grape called Berbes, and in colour like that of Sherry. Cyder is made in some of the vallies; the best being supplied by that of Baltan. The lands in the district of Pamplona are well manured, and the crops are changed alternately for four years in the following order, viz. wheat, beans, wheat, maize; so that the ground never lies fallow. The manufactures of Navarre have never been considerable. Of brandy there are some distilleries at Estella, Fuente de la Reyna, and Sangüeza. Cloth manufactories are not so frequently met with at Tudela as in other towns. At Tudela there are fix soap manufactories, and others of tiles, bricks, and pottery. Estella has some looms of coarse woollen. One league from Eguy there is a manufactury of cast-iron, bombs, and balls, on the king’s account; and the town of Corella, containing about 4000 inhabitants, has a manufactury of liqueur wine, which is extracted from the wood of this tree, of which they make a substitute: this is exported in great quantities to the north of Europe, and is called with us Spanish liqueur. The commerce of Navarre is entirely confined to imports. Of late the roads, which were formerly impediments to trade, have been improved; and the rivers Ebro and Bidazao afford an easy communication, of which the inhabitants might avail themselves as an incentive to industry and activity. Iron mines in this province are rather abundant. Near Pamplona there is a copper mine, which was worked about the middle of the 18th century. On the ground near Valtierra is a mine of white rock salt, which is very abundant, in layers of gypsum: the interior of this mine resembles an ancient church in the Gothic style. The mountains supply plenty of game, hares, rock-ducks, foxes, wolves, wild boars, &e. This province has various mineral waters. The arts and sciences have been but little cultivated in Navarre; and it has furnished few writers of any note. As to the disposition and character of the inhabitants, they are generally irreligious, reserved, proud, and brave; nimble in running, excellent leapers, and expert players at tennis. They are reproached with being obstinate, opinionated, irascible, imperious, quarrelsome, and violent; but, on the other hand, they are allowed to be witty, acute, ingenious, and laborious. They seem to have readily adopted the French manners; and their dress or costume is nearly the same with that of the Catalans. The language of Navarre is the Castilian, altered by a mixture of Biscayan, Catalan, and French.

As to the history of Navarre, we observe that in the fifth century, this province was free from the yoke which the Alant, Suevi, and Vandals had imposed upon the two Castiles, Galicia, Asturias, and Andalusia. In the year 450 or 472, Euric or Ervico, a Gothic king, who is said to have first given written laws to the Goths of Spain, took possession of Pamplona and the surrounding country, the inhabitants of which were Roman Catholics. At first the Goths manifested a spirit of toleration; but they afterwards exercised unwarrantable depotsin; till at length the people of Navarre and the neighbouring countries resolved to defend the faith to which they were attached, and caused an insurrection in 581 against Leovigild, the Gothic king; but they were subdued by this barbarous prince, and many of them, called Valones, passed over the Pyrenees, and settled in the territory which from those new occupiers was denominated Gaesony. Navarre was afterwards possessed by the Moors until the year 806, when they were expelled by Louis, king of Aquitania, the fon of Charlemagne; and from that period this country put itself under the protection of the French empire. In 832 Aznar, having been ill treated by Pepin, king of Aquitania, formed a party and took possession of Navarre, causing himself to be declared count. After his death, a court of Bigorre became the founder of a monarchy, which continued in his house for 500 years. In 1512 the kingdom of Navarre was dismembered. Its legitimate sovereigns were then confined to that part situated on the French side of the Pyrenees, and called Lower Navarre, and which was united to the crown of France by Henry IV. That part which has been subject to the kings of Spain, has still preferred the ancient form of its government and constitution. It is governed by a vicecy. The courts, in their form, powers, and legal proceedings, differ entirely from those of Spain. It is not only governed by its ancient laws, civil and criminal, but has preferred its own statutes, composed of the three orders, the clergy, the nobility, and the deputations of towns. The ancient money has also been preferred, viz. le cordano (half a maravedis), l’ocharco (two maravedis), and le gros (five maravedis), which are fractions of pence; la tarja or eight maravedis; and 45 tarjas, equal one real of vellor, or 2’d. Navarre also maintains the privilege of receiving the greater part of foreign merchandise without search or duty; nor is it subject to the cufoms, except when they leave Navarre for Old Castile; the first custom-house is at Agreda.

Louis, king of Aquitania, divided Navarre into five counties, which divisions still exist under the name of “ Merindades,” of which the chief places are Pamplona, the capital, Estella, Tudela, Sangüeza, and Olita. Labord’s View of Spain, vol. ii.

NAVARRE, Lower, a province of France, which now forms the department of the Lower Pyrénées.

NAVARRE, Nova, a province of New Mexico, on the N.E. side of the gulf of California, which separates it from the peninsula of California on the S.W. It is bounded on the N. by a country unknown, on the E. by New Mexico Proper and New Biscay, on the S. by Cuitnan, and on the W. by the gulf of California. The chief Spanish town is St. Juan Cualoa.

NAVARREINS, a town of France, in the department of the Lower Pyrénées; and chief place of a canton, in the
the district of Ncthés; 10 miles N.W. of Oleron. The place contains 1300, and the canton 11,044 inhabitants, on a territory of 355 square kilometres, in 27 communes.

NAVARU, a town of Hindooistan, in Viafapour; 16 miles S.E. of Viafapour.

NAVAS do Marques, Los, a town of Spain, in New Castile; 15 miles W. of Ecarial.

NAVASIA, a small island in the Windward passage, or strait between Cuba and Hispaniola, whether the inhabitants of Jamaica resort to kill guaras, a kind of lizard, whose flesh is firm and white, and sold by seamen to make good broth.

NAVASEQUE, a town of Spain, in Navarre; 22 miles S.E. of Pampluna.

NAVATIR, a town of Arabia Petraea; 18 miles E.S.E. of Adiabert.

NAVAZZA. See La Navace.

NAUCHELLE, a town of France, in the department of the Aveyron, and chief place of a canton, in the district of Rodès; two miles S.E. of Sauvetere. The place contains 867, and the canton 6333 inhabitants, on a territory of 207 square kilometres, in 20 communes.

NAUCLEA, in Botany, probably from Ouc, a slip or bark, and klea, to enclose or shut up, because the seed, or more properly the half capsule, is shaped like the hull of a vessel, and contains the kernels in its cavity. Linnaeus, the author of this name, has not given its derivation, nor has Professor Martyn attempted any explanation. Linnaeus, Enc. of Schreb. 119. Wild. Sp. Pl. v. 1. p. 928. Mart. Mill. Dict. v. 3. Juss. 209. Lamarck Illust. t. 153. Garnt. t. 30. (Uncaria; Schreb. 125. 822. Ouroparia; Aubl. Guian. t. 1. 177. t. 68.)—Clasf. and order, Pentandria Monogyenia. Nat. Ord. Aggregate, Linn. Rubiaceae, Juss. Gen. Ch. Common Calyx none. Common Receptacle globose, somewhat villous, entirely covered with flowers. Perianth of one leaf, oblong, incurving, or rather crowning, the germ, contracted and entire at the mouth. Cor. to each flower, of one petal, funnel-shaped, inserted into the mouth of the calyx; tube thread-shaped, elongated; limb shorter than the tube, in five deep, ovate, obtuse, spreading segments. Stam. Filaments five, very short, in the throat of the corolla; anthers ovate, as long as the tube. Pet. Germen in the bottom of the calyx, or more properly inferior, oblong; style capillary, erect, longer than the corolla; stigma large, of various shapes. Petal. Capsule coated, turbinate, oblate, tapering below, separating into two cells, each finally suffused by a thread at its summit. Seeds several, small, ovate, rather compressed, bordered with a membrane, tapering down into a brittle-shaped appendage, attached to the future.

Section 1. Heads of flowers terminal

2. N. purpurea. Purple Nauclea. Roxb. Coromand. v. 1. t. 41. t. 54. Wildl. n. 2.—Leaves oblong, tapering at each end. Thorns none. Flower-flalk terminal, swelling upwards. Stigma globose.—Native of moit valleys, among the lesser mountains of Coromandel, flowering in April, the beginning of the wet season. Roxb. A small tree, with more oblong and tapering leaves than the foregoing, and dull purplish flowers, whole stigma is globose, with many furrows.

Buncalus of Rumphi. Amb. v. 3. 84. t. 55, quoted by Linnaeus with doubt for the former, and by Welldenow without any hesitation for this, seems to agree best with that in the shape of its leaves.

3. N. parvifolia. Small-round-leaved Nauclea. Roxb. Coromand. v. 1. 40. t. 52. Wildl. n. 3.—Leaves elliptical, rounded, bluntish. Thorns none. Flower-flalk terminal, equal. Stigma obtuse, hooded at the base. Calyx downy.—Native of almost every part of the coast of Coromandel, but chiefly among the mountains, flowering in the cold season. We have specimens from Koenig and Roxburgh. This is a large tree, whose wood is of a light chesnut colour, firm and close-grained, but rotting if exposed to wet. The branches appear to vary in flatness, and the leaves in size; but their rounded, somewhat oblate, bluntish form is very unlike the two preceding. The flowers are of a dirty white, in smaller heads than the first species. Their stigma is very peculiar, oburate, concave, and bordered at the base, as if hooded, and hung upon the style.

5. N. latifolia. Broad-leaved African Nauclea.—Leaves roundish, smooth. Thorns none. Heads of flowers terminal, on short stalks. Stigma oblong, furrowed. Stipulas triangular, deeply divided.—Gathered by the late Mr. Smeathman at Sierra Leone. The leaves in our specimen are very much damaged, but enough remains to prove them several inches in length and breadth, though for whatever of their termination. The stipulas are small, broad, slightly downy, very deeply cloven, their two segments forming into a triangular figure. Flowers apparently orange-coloured; the segments of the corolla rounded. Stigma enclosed in the tube. Stigma long, acute; its lower part cylindrical and even; upper furrowed. Scales of the receptacle club-shaped, and elegantly fringed, nearly equal to the flowers.

6. N. cordatus. Combined Nauclea. Roxb. MSS.—Leaves heart-shaped, obtuse, somewhat downy. Thorns none. Heads of flowers terminal. Stigma pyramidal. Stipulas roundish, reticulated, combined at the base.—Communicated by Dr. Roxburgh from Calcutta, under the above name. The leaves are not unlike those of Ficus bengalensis in shape and colour, but leaf coriaceous. Stipulas large, near an inch long, almohd orbicular, apparently coloured, downy, with copious reticulated veins; combined at the base, so that they remain encroaching the branch after they break off from their point of infection. Flowers somewhat orange-coloured. Autors nearly equal to the limb. Stigma tumid and smooth at the base; furrowed and pyramidal above.

Section 2. Heads of flowers axillary.

7. N
7. **N. Gambiri.** Gambeer Nauclea. Hunter Tr. of Linn. Soc. v. 9. 218. t. 22. (Fonius uncatus; Daun Gatta Gambir angustifolia; Rumph. Amb. bin. v. 5. 63. t. 34. f. 2.)—Leaves ovate, pointed, smooth. Stem climbing. Branches round. Stipulas undivided. Flower-flasks axillary, becoming hooked spines.—Native of America; thickened and hinged on the coat. *Rumph.*

8. **N. acida.** Acid-leaved Nauclea. Hunter Tr. of Linn. Soc. v. 9. 223. (Fonius uncatus; Daun Gatta Gambir latifolia; Rumph. Amb. bin. v. 5. 63. t. 34. f. 1.)—Leaves ovate, pointed, smooth. Stem climbing. Branches quadrangular. Stipulas deeply divided. Flower-flasks axillary, becoming hooked compressed spines.—Sent by Mr. Hunter from Soongey Cloan in the Prince of Wales's island. It differs from the last, very essentially, in the deep divisions of its broad permanent *fipulas.* The flower-flasks are shorter, and when they become spines much broader and compressed, so much incurred as frequently to complete a circle. The leaves have an acid taste. If we are right in the citation of Rumphius, which there seems no reason to doubt, this species is very common in Ambonia. He says the flowers appear in February, and are of a dirty white, but much admired for their graceful and permanent scent, like oil of cinnamon, or like jasmine, which last is called Gambir. The leaves are chewed like Betel, and this author seems to have heard of the *Gutta Gambir* being prepared from this plant, though he was informed, from another quarter, of its being the produce of a totally different one; meaning perhaps *Mimosa Catechu.*

9. **N. scandens.** Climbing Hairy Nauclea. Buchan. MSS. (Fonius uncatus lasotius; Rumph. Amb. bin. v. 5. 65. t. 34. f. 3.)—Leaves ovate, hairy, as well as the branches. Stem climbing. Stipulas in two deep linear segments. Flower-flasks axillary, becoming hooked hairy spines.—Native of various parts of the East Indies; communicated by Dr. F. Buchanan. Distinguished from the two last by the rusty hairiness of its square branches, the narrowness of the deeply divided *fipulas,* and the roughness of the upper side of its leaves, whose under side is paler and more softly downy. Rumphius says the *branch* yield a limpid and pleasant fluid, which by keeping turns slightly bitter and astringent; and that the flowers are white, with a mixture of yellow, without any peculiar smell.

10. **N. aculeata.** Guiana Nauclea. Wild. n. 5. (Ouroparia guianensis; Aubl. Guian. v. t. 177. t. 68.)—Leaves ovate, pointed, smooth. Stem climbing. Branches quadrangular. Stipulas triangular, undivided. Flower-flasks axillary, becoming hooked compressed spines.—Gathered by Aublet on the banks of creeks and rivers in Guiana, flowering in May and June. This has a great affinity to the three last, as the editors of Aublet have noticed. It most resembles *N. acida,* in its square branches, smooth leaves, and compressed, greatly recurved, spines, but differs essentially in having undivided *fipulas.* Aublet says, it climbs to the tops of the loftiest trees, crowning them with flowers, which are extremely variable in colour, being either yellow, white, or of a more or less deep red, with a very sweet smell. The fruit is said to be soft and blue, the size of a red gooseberry, but of two cells, separated by a membrane, to which are attached numerous hard, coriaceous, black seeds. This founds very discordantly with the other species, and yet the fruit in question appears to be only a pulpy-coated capsule, between which, and that of the other species, there may perhaps be less difference, than between the various *fljas* of those which compose the first section.

11. **N. felerophylla.** Rigid-leaved Nauclea. Hunter Tr. of Linn. Soc. v. 9. 233.—Leaves elliptical, finely pointed, shining, rigid: reticulated and rough beneath. Stem climbing. Branches quadrangular, downy. Stipulas lunate, divided. Flower-flasks axillary, compressed, downy, becoming hooked spines.—Communicated by Mr. Hunter, from the top of the hill at Soongey Cloan, Prince of Wales's island. This is truly a magnificent species, remarkable for the great size of all its parts. The branches and *flasks* are all clothed with an extremely fine, close, foppish green. Leaves five inches long, and three broad, slightly heart-shaped at the base, wavy but hardly crenate, with a very slight blunt point; their substance rigid and coriaceous; their upper side smooth as if varnished; the under pale, opaque, with innumerable, repeatedly subdivided, reticulated, parallel, prominent, minutely rough veins, between which the whole leaf is exquisitely dotted. Flower-flasks two inches long, bright, rigid, rough, compressed, finely recurved and pointed. Head of flowers above two inches in diameter, with six lanceolate, whorled, deciduous *bracteas* under it, at the joint of the *flask.* *Calys* coriaceae: briefly within; downy and nili, like the *german* and *flasks,* externally. *Corolla* clothed with long, prominent, shining, tawny bristles. We have no account or specimen of the fruit.
NAU

Flower-flanks axillary, downy, usually in pairs.—Communicated by Dr. Roxburgh, from the mountainous parts of the coast of Coromandel, where it flowers in the wet season, the seeds ripening about April. The natives call it Caddaga. This is a large and valuable timber-tree, very different in habit from all we have hitherto described in this section. The wood is yellow, exceedingly beautiful, like box, but lighter, and at the same time very close-grained. It is excellent for furniture, but not liable when exposed to wet.

The branches form a very large shady head, and are roundish, somewhat compressed, tortuous, downy when young. Leaves on downy flanks, which are about two inches long, of a roundish heart-shaped figure, thin and plant, five or six inches long when full-grown, and nearly as broad, entire, wavy, bright green; roughish above; paler and downy beneath; with one rib, and numerous forked veins, whose ultimate ramifications are finely reticulated. Stipulas large, obovate, obtuse, undivided, downy, deciduous. Flower-flanks axillary, in pairs, combined at their base, slender, downy, near two inches long, with a joint towards the summit. Bractea at the joint, obtuse, simple or cloven, combined at the bottom, deciduous. Head of flowers about an inch in diameter, yellowish. Dr. Roxburgh says the number of flower-flanks varies from one to four. The capsule is slender, wedge-shaped, and abrupt. Seeds not imbricated, about six in each cell, inserted into its lower part, each tipped with a cloven membrane.

13. N. Adina. Myrtle-leaved Nauclea. Adina globiflora; Saff. Parad. 116. t. 115. — Leaves elliptic-lanceolate, pointed, smooth. Stem erect. Stipulas deeply divided, acute. Flower-flanks axillary, downy, solitary. Native of China. As it is said to have come up in the earth of a former plant, sent from Canton to the late Rt. Hon. Charles Greville, with whom it flowered in July and August. The stem is short, round, with numerous, opposite, spreading, slender branches, minutely downy when young. Leaves on short flanks, elliptic-lanceolate, two inches long, entire, thin, smooth, moderately veiny, tapering at the base, terminating in a blunt point. Stipulas deeply divided into two lanceolate, acute, spreading segments. Flower-flanks axillary, solitary, shorter than the leaves, flender like those of the last species, and, like that, remaining erect, not (as far as we have materials to judge by) becoming recurved or spinous. The head of flowers is smaller than in the last, yellowish. Capsule with four furrows, tapering at the base. Seeds two or three in each cell, fringed at the top with a jagged membrane. We cannot find grounds to separate this plant from Nauclea as the genus at present stands, the divided valves of the capsule, and especially the cloven stipularis, being by no means sufficient even to indicate a probable generic distinction. The aspect of the plant is indeed considerably unlike any of the foregoing species, which, moreover, differ greatly among themselves, and not but fitterfact that a more complete acquaintance with them might authorize some division of the genus, though Wildenow hints that Nauclea is not really distinct from Cephalanthus.

It is a curious circumstance, that Linnaeus has preferred in his herbarium a specimen of the last described species, for the true N. orientalis, which he described from Hermann's collection, it not being in his own. We cannot possibly say which of the two he intended as his Cephalanthus orientalis, Sp. Pl. ed. 1. 95, of which he had a specimen then before him; but there is no positive evidence of its having been this N. Adina. His son came nearer the truth, in taking N. parviflora of Roxburgh for the orientalis, which however are certainly distinct. S.

NAUCRARI, Naucrates, among the Athenians, a de-

fignation given to the chief magistrates of the demes, boroughs or townships, which were likewise called naucrates, because each of them were obliged, besides two horsemens, to furnish out one ship for the public service.

NAUDE, Gabriel, in Biography, was born at Paris in the year 1660. Shewing at an early age an attachment to letters, his parents sent him to a religious community, as well to learn the rudiments of grammar as the first principles of the Christian religion. Hence he was removed to the university, where he applied himself with great ardour to the pursuit of classical learning, and was created master of arts while very young. As soon as he had finished his course in philosophy, he remained undecided what profession to choose. His friends advised him to enter the theological habit, but he preferred physics, and after a while fixed upon that faculty. This election, on his part, did not prevent him from indulging his genius in other branches of learning. The plan of his studies was extensive, and suited to his comprehensive talents and indefatigable industry, and he soon made distinguished himself, that Henry de Mefmes, hearing his character, made him keeper of his library, and took him into his family. Nande was delighted with his new station, because it furnished him with the means and leisure to improve himself as he could wish. In 1626 he went to Padua, but on the death of his father, which happened soon after, he was obliged to return to Paris. In 1631 cardinal Bagno appointed him his librarian and Latin secretary, and took him to Rome in the spring of that year. Nande continued in his service till the death of the cardinal, which happened in 1641, and in the mean time made an excursion to Padua to take his doctor's degree in physic, in order to support the character of physician to Lewis XIII. On the death of his patron he engaged in the service of the magistrates of Florence, but as soon as Richelieu sent for him to be his librarian, he immediately returned to Paris; he was not however long in the service of that prince minister, who died in a few months after the arrival of his librarian, but he succeeded to the like post under Mazarine, for whom he formed a magnificent library, which, in the course of seven years, he raised from the first volume to 40,000. He next accepted an invitation from Chriflina to become her library-keeper, but he soon grew out of humour with his residence in Sweden, and quitted it loaded with presents from the queen and other persons of distinction. The fatigue of his journey threw him into a fever, which obliged him to flop at Abbeville, where he died in July 1653. He wrote a great number of books, a catalogue of which may be found in Nicorn's Memoirs; but of them all, the Apologie des grands Hommes acuues de Magie is said to be the only one that continues to be read.

NAUDE, Philip, a celebrated professor of mathematics at Berlin, was born at Metz, in Lorrain, in 1644. At the age of twelve he was taken to Rome, and became a candidate for the court of Elenach, in the capacity of pages, and attendant on the young princes. He remained in this situation about four years, after which we hear no more of him for several years, except that, during this interval, he made considerable proficiency in different branches of learning, particularly in the mathematical sciences. When the death of Nantes was revoked, he left France, with his wife and infant child, and went to Hanau, where he resided two years. From this place he removed to Berlin, and opened a mathematical school. In 1668 he was appointed to teach arithmetic and the elements of the mathematics at the college of Joachim. On the death of Langerfield he succeeded to the vacant posts of mathematician to the court, and tutor
to the pages, and at the same time obtained a professorship in the Academy of Sciences. He obtained other considerable employments before his decease, which happened in 1739, when he had attained to the age of 75. He was author of "Elements of Geometry," in 4to, written in the German language, and printed at Berlin, and of some other pieces, which appeared at different periods in the "Miscellanea Berolinensia." He was author of a great number of theological pieces, which had a high reputation at the time in which our author flourished.

NAUDERS, in Geography, a town of the Tyrol; eight miles N. of Grazentz.

NAUDEWSIES, or NAWOWIES, an Indian nation inhabiting lands between lakes Michigan and Superior. The number of warriors is 500.

NAVE, a town of Africa, in Bondou. N. lat. 14° 20'. W. long. 10° 40'.

NAVE, in Architecture, Navis Exclafes, denotes the body or place where the people are seated; reaching from the rail or balustrade of the choir, to the chief door.

Balus derives the word from the Greek, ναῦς, temple; which Salmasius brings farther from ναύς, ship; by reason the vault or roof of a church bears resemblance to a ship. The ancient Greeks called the nave pronaoos; the Latins frequently call it cella.

The nave of the church belongs to the parishioners: it belongs to them to repair it, &c.

Nave, of a wheel, is that short thick piece in the centre of a wheel, which receives the end of the axle-tree, and in which the ends of the spokes are fixed; it is bound at each end with hoops of iron, called the nave-bands: it has likewise in each end of the hole, through which the end of the axle-tree goes, a ring of iron called the swifter, which saves the hole of the nave from wearing.

Nave-Line, in Sea Language, is a sort of small tackle, depending from the head of the main-mast and fore-mast, and fastened to the middle of the parcel, immediately behind the mast, and communicating with the gears. It is used to keep the parcel directly opposite to the yard, and particularly whilst hoisting or lowering, as it would otherwise hang under the yard, and prevent it from being sufficiently braced.

NAVE, a part of the middle of the belly, by anatomists called umbilicus.

Navel-string by anatomists is called funiculus umbilicalis. See Funis, and Labour.

Navel-heads, in Ship-Building, large pieces of stuff fitted into the hawse-holes, to keep the cables from wearing them.

Navel-wort, in Botany. See Cyrtelidion and Cygnoclysum.

The greater navel-wort, with broad leaves, sharply indented, and growing alternate, and a branching stalk, with erect flowers, which has been used in medicine, grows upon old walls and buildings in many parts of England, particularly in Shropshire and Somersetshire, and was reckoned generally cooling and mollifying, refrigerating and astringent; useful in hot dillipers of the liver: and thought to provoke urine, and to take off the heat and sharpness of it. The juice of it outwardly applied, was esteemed servicable in relieving the stings, St. Anthony's fire, the pain and inflammation of the piles, and to be useful against kibes and chilblains: it is an ingredient in the unguentum populeon.

Navel-wort, Buffard. See Chassula.

Navel-wort, Venus's, the name of a genus of plants, called by authors omphalodes; which fee.

Navel-wort, Water, a name sometimes given to the hydrocotyle of botanists. See Hydrocotyle.

NAVESINK Harbour, in Geography, a port on the coast of New Jersey; five miles N.W. of Shrewsbury.

NAVETTE, in Botany, the name by which most of the European nations call the napus, or hulmum glabrescens of Lobel, the plant from the seeds of which the oil which we call rape oil, and the French and others navette oil, is expressed. The plant is cultivated in many parts of England, and in other countries, for the sake of the seed; the oil drawn from this is used by many artificers, and is of a fine yellow colour, and the smell is not offensive. The cake remaining after the expression of the oil, retains, like that of mustard, the acrimony of the seeds.

NAVEW. See NAPUS.

NAUGAMUNGLUM, in Geography, a town of Hindooftan, in Myfore; 28 miles N. of Serimgapatam.

NAUGARDTEN, or Neugarten, a town of Hinder Pomerania; 56 miles W. of New Stettin. N. lat. 53° 43'. W. long. 15° 5'.

NAUHEIM, a town of Germany, in the county of Hann Münzenberg, which has salt-works; taken by the French in 1792; 13 miles N. of Hanau.

NAVIA, a town of Spain, in the province of Atturias, situated upon the river called after it, the Navias, which waters a beautiful and fertile plain. Navia has a considerable harbour, which carries on some trade; and the inhabitants are perfued, that it was founded by Ham, one of the sons of Noah, who gave to the town, as well as the river, the name of his wife Navia; 36 miles N.W. of Oviedo.

Navia de Suanna, a town of Spain, in Galicia; 20 miles S.S.E. of Mondonedo.

NAVICULA, in Conchology, a name given by a late French author to the claws of shells called by us the nautilis. See Nautilus.

NAVICULARE Os, in Anatomy, a bone of the taursus. See Extremities.

NAVIDAD, in Geography, a town of Mechoacan, in Mexico, with a harbour on the North Pacific ocean; 156 miles W. of the city of Mexico. N. lat. 18° 51'. W. long. 111° 10'.

NAVIER, Peter Foussaint, in Biography, a distinguished physician and chemist, was born at St. Didier early in the eighteenth century, and settled in the practice of his profession at Chalons-sur-Marne. He was universally esteemed for the good qualities both of his head and heart, but particularly for his humane and active attendance on the poor of his vicinity, to whom he performed great services during several epidemics. He died in 1779. He distinguished himself by various chemical researches, especially by his discovery of nitrous ether, and by some curious observations relative to the composition of the animal fluids, which were published in his essay, entitled "Observations sur l'Amolibillement des Os," in 1755, foggegled by the remarkable case of Spanid. He was likewise the author of some anatomical and practical dissertations, particularly one on epidemic diseases, entitled "Difertation fur pluriares Maladies populaires, qui ont regne depuis quelque tems a Chalons-sur-Marne," 1756. Elsy Dict. Hist. Gen. Biol.

NAVIGABLE RIVERS. See River.

NAVIGATION, the art or act of sailing, or of conducting a vessel from one place to another, in the face, shortell, and most commodious way. This art, in the full latitude of the word, comprehends three parts: 1. The art of constructing and building ships. (See
NAVIGATION.

(See Ship-building.) 2. The loading of ships. And, 3. The conducting and guiding ships through the seas; which is in a peculiar sense called navigation or sailing; which fee.

In this restrained sense of the word, navigation is either common or proper.

Navigation, Common, usually called sailing, (which fee.) is where the ports are on the same, or very neighbouring coasts: and where the vessel is taken out of sight of land, or out of reach of sounding.

In this, little else is required but an acquaintance with the lands, the compass, and sounding line; each of which fee in its place, COMPASS, and SOUNDING.

Navigation, Proper, is where the voyage is long, and purveyed through the main ocean.

In this besides the requirements in the former, are likewise required the use of Mercator’s chart, azimuth, and amplitude compasses, log-line, and other instruments for celestial observations; as quadrants, fore-and-aft, &c. See each instrument, &c. in its place.

Navigation turns principally on four things; two of which being known, the rest are easily found from them by the table, scales, and charts.

These four things are, the difference of latitude, difference of longitude, the reckoning or distance run, and the course or rhumb sailed on.

The latitudes are easily found, and that with sufficient accuracy. See LATITUDE.

The course and distance are had by the log-line, or dead reckoning, and the compass. See LOG, COMPASS, COURSE, and DISTANCE.

Nor is there any thing wanting to the perfection of navigation, but to determine the longitude. The mathematicians of many ages have applied themselves, with the utmost affinity, to supply this grand desideratum; and in late times with a considerable degree of success.

For the various methods that now occasionally obtain at sea, for this purpose, and an account of the discoveries that have been made, see LONGITUDE.

The poets refer the invention of the art of navigation to Neptune, some of the ancients to Bacchus, others to Hercules, others to Japhet, others to Janus, who is said to have made the first ship. Historians ascribe it to the Egyptians, the Phoenicians, Tyrrians, and the ancient inhabitants of Britain. Some will have it, the first hint was taken from the flight of the kite; others, as Oppian, de Ptolebus, lib. 1. from the fifth called nautilus: others ascribe it to accident.

Scripture refers the origin of so useful an invention to God himself, who gave the first specimen thereof in the ark built by Noah. For the readiness the good man underwent on account of his enterprise, shews evidently enough, the world was then ignorant of any thing like navigation: and that they even thought it impossible.

However, history represents the Phoenicians, especially those of their capital, Tyre, as the first navigators; being urged to seek a foreign commerce by the narrowness of their country and poverty of a slip of ground they possessed along the coasts as well as by the convenience of two or three good ports; and by their natural genius for traffic.

Accordingly Lebanon, and the other neighbouring mountains, furnishing them with excellent wood for ship-building, in a short time they were masters of a numerous fleet; with which, constantly hazarding new navigation, and flogging new trades, they soon arrived at an incredible pitch of opulence and populousness; having rendered themselves masters of several commodious harbours toward the bottom of the Arabian gulf, and, after the example of the Egyptians, established a regular intercourse with Arabia and the continent of India on the one hand, and with the eastern coast of Africa on the other: so that they were in a condition to send out colonies, the principal of which was that of Carthage, which, keeping up their Phoenician spirit of commerce, in time not only equalled Tyre itself, but vastly surpassed it; purifying the course which the Phoenicians had opened, and fencing its merchant-fleets through Hereules’s Pillars, now the Straits of Gibraltar, along the western coast of Africa, to the south, almost to the tropic of Cancer, having discovered the Fortunate Islands, now known by the name of the Canaries, which were the utmost boundary of ancient navigation in the western ocean; and to the north along the coast of Europe, visiting particularly Spain, Gaul, and Britain: and, even if we believe some authors, to America itself; the discovery of which, so many years afterwards, has been so glorious to the Spaniards.

The progres of the Phoenicians and Carthaginians was not owing merely to the desire of extending their trade from one country to another: voyages were undertaken, the sole object of which was to discover new countries, and to explore unknown seas. Such, during the prosperous ages of the Carthaginian republic, were the famous navigations of Hanno and Himilco. Both their fleets were equipped by authority of the senate, and at the public expense. Hanno was directed to proceed towards the south, along the coast of Africa, and he seems to have advanced much nearer the equinoctial line than any former navigator. Himilco had it in charge to proceed towards the north, and to examine the western coasts of the European continent. Of the fame nature was the extraordinary navigation of the Phoenicians round Africa. A Phoenician fleet, we are told (Herod. lib. iv. cap. 42.), fitted out by Neche, king of Egypt, took its departure, about 604 years before the Christian era, from a port in the Red sea, doubled the southern promontory of Africa, and, after a voyage of three years, returned by the straits of Gades, to the mouth of the Nile.

Eudoxus of Cyzicus is said (Phn. Nat. Hist. lib. ii. cap. 67.) to have held the fame course, and to have accomplished the same dangerous undertaking. However, long after this navigation of the Phoenicians and of Eudoxus round Africa, Polybius, the most intelligent and well informed historian of antiquity, affirms, that it was not known, in his time, whether Africa was a continued continent, stretching to the south, or whether it was encompassed by the sea. (Polyb. Hist. lib. iii.) And it appears from the testimony of Pliny (Hist. Nat. lib. ii. cap. 68.), Strabo (lib. ii. p. 155. lib. xvii. p. 1180.), Ptolemy (Geogr. lib. iv. cap. 9.), that the accounts of those voyages were not fully credited. Robertson’s Hist. America, vol. i. p. 13. p. 354., ed. 1800.

Tyre, whose immense riches and power are represented in such lofty terms, both in sacred and profane authors, being destroyed by Alexander the Great, its navigation and commerce were transferred by the conqueror to Alexandria, a new city, admirably situated for those purpooses, proposed for the capital of the empire of Asia, which Alexander then meditated. And thus arose the navigation of the Egyptians, which was afterwards so cultivated by the Ptolemies, that Tyre and Carthage (which last, after having a long time disputed empire with the Romans, was at length subdued) were quite forgot.

Egypt being reduced into a Roman province after the battle of Actium, its trade and navigation fell into the hands of Augustus; in whose time Alexandria was only inferior
NAVIGATION.

in inferior to Rome; and the magazines of the capital of the
world were wholly supplied with merchandise from the
capital of Egypt.

At length, Alexandria itself underwent the fate of Tyre
and Carthage, being surprised by the Saracens; who, in
spite of the emperor Heraclius, overspread the northern coasts
of Africa, &c. whence the merchants being driven, Alex-
andria has ever since been in a languishing state, though still
it enjoys a considerable part of the commerce of the Chris-
tian merchants trading to the Levant.

The fall of Rome, and its empire, drew along with it not
only that of learning, and the polite arts, but that of naviga-
tion; the Barbarians, into whose hands it fell, contented
themselves with the spoil of the indurdy of their pre-
decessors.

However, one circumstance prevented commercial inter-
course with distant nations from ceasing altogether. Con-
stantinople, though often threatened by the fierce invaders,
who spread desolation over the reft of Europe, was so for-
tunate as to escape their destructive rage. In this city,
the knowledge of ancient arts and discoveries was preserved;
and commerce continued to flourish there, with the tafte for
elegance, and the luxuries of foreign countries, when it was
almost extinct in every other part of Europe. The citizens
of Constantinople did not confine their trade to the islands
of the Archipelago, or to the adjacent coasts of Asia: they
took a wider range, and, following the course which the
ancients had marked out, imported the commodities of the
Eait Indies from Alexandria. When Egypt was torn
from the Roman empire by the Arabians, the industry of
the Greeks discovered a new channel, by which the produc-
tions of India might be conveyed to Constantinople. They
were carried up the Indus, as far as that great river is nav-
gable; there they were transported by land to the banks of
the river Oxus, and proceeded down its stream to the Cap.
tian fea. There they entered the Volga, and falling up it, were
carried by land to the Tanais, which conducted them into
the Euxine fea, where vessels from Constantinople waited
their arrival.

But no sooner were the more brave among those nations
settled in their new provinces; fome in Gaul, as the
Franks; others in Spain, as the Goths; and others in Italy,
as the Lombards; than they began to learn the advantages
of navigation and commerce, and the proper methods of manag-
ing them, from the people they subdued; and this with fo
much fuccefs, that in a little time some of them became
able to give new leifons, and fet on foot new institutions, for
its advantage.

Thus it is to the Lombards we chiefly ascribe the inven-
tion and ufe of banks, book-keeping, exchanges, re-changes,
\&c.

It does not appear which of the European people, after
the settlement of their new masters, first betook themselves
to navigation and commerce. Some think it began with the
French; though the Italians feem to have the juifefe title to
it, and are accordingly ordinarily looked on as the re-
florers of this science, as well as of the polite arts, which
had been banifhed together, from the time the empire was
torn afunder.

The people of Italy, then, and particularly thofe of Venice
and Genoa, have the glory of this reforation; and it is
to their advantageous situation for navigation, they in a great
measure owe their glory.

In the bottom of the Adriatic were a great number of
marty islands, only separated by narrow channels, but thoefe
well screened, and almost inaccessible, the residence of some
fishermen, who here supported themselves by a little
trade of fish and salt, which they found in fome of these
islands. Thither, then, the Veneti, a people inhabiting that
part of Italy along the coasts of the gulf, retired, when
Alaric, king of the Goths, and afterwards Attila, king of
the Huns, ravaged Italy.

These new fiders, little imagining that this was to be
their fixed reftidence, did not think of composing any body
politic; but each of the seventy-two islands of this little
Archipelago continued a long time under its separate distinct
maller, and each made a distinct commonwealth. When
their commerce became considerable enough to give
ejaloufy to their neighbours, they began to think of uniting
into a body; and it was this union, first begun in the fifth
century, but not completed till the eighth, that laid the
true foundation of the future grandeur of the state of
Venice.

From the time of this union, their fleets of merchants
were sent to all the ports of the Mediterranean; and at
lait to thofe of Egypt, particularly Cairo: a new city, built
by the Saracens on the eastern bank of the Nile, where they
traded for their fpices, and other prodults of the Indies.

Thus they flourifhed, increafed their commerce, their na-
vation, and their conquests on the terra firma, till the fa-
mous league of Cambrai, in 1508, when a number of jealous
princes confined to their ruin; which was the more eaftly
effected, by the diminution of their Eait India commerce,
of which the Portuguefe had gained one part, and the French
another.

Genoa, which had applied itself to navigation at the fame
time with Venice, and that with equal fuccefs, was a long
time its dangerous rival, duped with it the empire of the
sea, and shared with it the trade of Egypt, and other parts
both of the Eait and West.

Jealoufy soon began to break out; and the two republics
engaging in a contelli, it was three centuries almost continual
war, before the superiority was affenzerted: when, towards
the end of the fourteenth century, the fatal battle of Chios
ended the noble life of the Genoese, who till then had unftially
the advantage, having now loft all; and the Venetians, al-
most become desperate, at one happy blow, beyond all ex-
peftation, secured to themselves the empire of the sea, and
superiority in commerce.

The cruflades (fee CROUSADES) contributed in a great
meafure to the revival, or at leat to the more rapid progrcfs,
of commerce and navigation; for the Genoese, the Pilans,
and Venetians, furnifhed the transports, which carried those
vail armies, composofe of all the nat ons in Europe, into Asia
upon this wild enterprize; and likewise supplied them with
provisions and military flores.

Other travels, besides thoefle whom religions zeal fent
forth to visit Asia, ventured into remote countries, from the
propect of commercial advantage, or from notions of mere
curiosity. The first and moft eminent of thofe was Marco
Polo, a Venetian of a noble family, about the year 1260; he
was fucedced about half a century after by ifir John Mande-
ville, an Englifhan. But the prefent art of navigation
owed its rife to the invention of the mariner's compafs, in the
beginning of the fourteenth century; and made confider-
able progress during the voyages that were begun in the year
1418, by Henry, duke of Vifeo. This learned prince,
brother to Edward, king of Portugal, was particularly
skilled in cosmography, and employed a perfon from the
island of Majorca to teach navigation, and to make instru-
ments and charts for the sea. Thcfc voyages, being greatly
extended
NAVIGATION.

The art of navigation was improved under the succeeding monarchs of that nation: in 1599, whereof Roderic and Joseph, physicians to King John II., together with one Martin de Bohemia, a Portuguese native of the isle of Fayal, scholar to Regiomontanus, about the year 1495, calculated, for the use of the sailors, tables for the sun's declination and recommended the almanac for taking observations at sea. About this time, Columbus, a native of Genoa, having thoroughly acquainted himself with the discoveries and observations of the Portuguese, and having also acquired considerable experience in the art of navigation, made a proposal to King John II. of exploring a passage to India, by sailing directly towards the west, across the Atlantic ocean. John rejected this proposal in a very dishonourable manner; and Columbus instantly quitted the kingdom, and going in Spain towards the close of the year 1494, he resolved to propose his plan to Ferdinand and Isabella, with whom, after repeated application and long delay, he ultimately succeeded. In August, 1492, Columbus, furnished with a small armament of three ships, set sail, and after an indirect voyage to the Canary Islands, from whence, holding his course due west, he stretched away into uncharted and unknown seas. After many difficulties, he at length arrived at Guanahani, one of the large cluster of islands called the Loguay, or Barat. He also discovered Cuba, Hispaniola, and several other small islands, and having left a small colony in the fort at Hispaniola, returned to Spain in March 1493. In September following he set out on his second voyage, and failed by the Leeward Islands to Hispaniola: in a third voyage, undertaken in the year 1498, he discovered the continent of America. In the same year, Vasco de Gama returned to Lisbon, from a voyage to the East Indies by the Cape of Good Hope. Columbus, it is said, before he attempted the discovery of America, consulted Martin de Bohemia, as well as others, and during the course of his voyage instructed the Spaniards in navigation: for the improvement of which art, the emperor Charles V. afterwards founded a lecture at Seville. This art was considerably improved by the discovery of the variation of the compass, and by the use of the cross-staff. At length there were published, in Spanish, two treatises, containing a syllhem of the art, which were in great esteem: the first by Pedro de Medina, at Valladolid in 1545, called "Arte de Navegar," the other at Seville, in 1556, by Martin Cortes, under the title of "Defens Conclingiendo de la Sphera, y de la Arte de Navegar, con nuevos Instrumentos y Reglas." This is said to have been composed at Cadiz in 1544; and a translation of it was published in London in 1651, which passed through several impressions. Besides the improvement which the art of navigation received from the proposals of Werner, and Gemma Frisius, for finding the longitude, it was much promoted by Pedro Nunez, or Nonius, who composed a treatise on this subject, so early as 1537, in the Portuguese language, which thirty years after was printed at Basle in Latin, with additions, under the title of "De Arte et Ratione Navigandi." In this work, the errors of the plane chart are expounded, and the problem of determining the latitude, from two observations of the sun's altitude, and the intermediate azimuth, is resolved. In 1577, Mr. William Bourke published his treatise, intitled "A Regiment for the Sea," and intended as a supplement to that of Cortes. See Log.

The mistakes of Medina were well exposed by Michael Conlama, a native of Antwerp, who, in 1581, published a small treatise, intitled "Instructions Nouvelle des Points plus excellents & necessaires touchant l'Arte de Navegar." Vol. XXIV.

In the same year Mr. Robert Norman published his discovery of the dipping-needle, in a pamphlet called the "New Attractive," to which is always subjoined Mr. William Burrough's "Discourse of the Variations of the Compass," in 1594, captain John Davis published a small treatise, intitled "The Seaman's Secrets," which was much esteemed in its time. The writers of this period complained much of the errors of the plane chart, which continued full in use, though they were unable to discover the cause of the phenomenon; till Gerard Mercator contrived his universal map (see Mercator's Chart), which he published in 1569, without clearly understanding the principles of its construction: these were first discovered by Mr. Edward Wright, who first gave an account of the true method of dividing the meridian from Cambridge, where he was a fellow, to Mr. Blundeville, with a short table for that purpose, and a specimen of a chart so divided. These were published by Blundeville in 1594, among his Exercises; to the later editions of which was added his "Discourse of Universal Maps," first printed in 1589. However, in 1599, Mr. Wright printed his "Correction of certain Errors in Navigation," in which work he shews the reason of this division, the manner of constructing his table, and its use in navigation. A second edition of this treatise, with farther improvements, was published in 1619, and a third edition by Mr. Moxon, in 1657. The method of approximation, by what is called the middle latitude, now used by our sailors, occurs in Gunter's works, first printed in 1624. About this time logarithms began to be introduced, which were afterwards investigated in navigation in a variety of ways by Mr. Edmund Gunter; though the first author who applied the logarithmic tables to the cases of failing, was Mr. Thomas Addison, in his "Arithmetical Navigation," printed in 1625. In 1635, Mr. Henry Gellibrand printed "A Discourse Mathematical on the Variation of the Magnetic Needle," containing his discovery of the changes to which the variation is subject. In 1631, Mr. Richard Norwood published an excellent "Treatise of Trigonometry," adapted to the invention of logarithms, particularly in applying Neper's general canon; and for the farther improvement of navigation, he undertook the laborious work of measuring a degree of the meridian, for examining the divisions of the log-line. Of this affair he has given a full and clear account in his "Seaman's Practice," first published in 1637; where he also describes his own excellent method of setting down and perfecting a sea-reckoning, &c. This treatise, and that of trigonometry, were continually reprinted, as the principal books for learning scientifically the art of navigation. What he had delivered, especially in the latter of them, concerning this subject, was contrived as a manual for sailors in a very small piece, called his "Epitome," which has gone through innumerable editions. About the year 1645, Mr. Bond published, in Norwood's Epitome, a very great improvement in Wright's method, by a property in his meridian line, whereby its divisions are more scientifically aligned than the author himself was able to effect; which he deduced from this theorem, that these divisions are analogous to the excesses of the logarithmic tangents of half of the respective latitudes augmented by forty-five degrees above the logarithm of the radius: this he afterwards explained more fully in the third edition of Gunter's works, printed in 1653; and the demonstration of the general theorem was supplied by Mr. James Gregory of Aberdeen, in his "Exercitationes Geometricas," printed at London in 1663; and afterwards by Dr. Halley, in Phil. Trans. N.° 219, and by Mr. Cotes, Phil. Trans. N.° 388. In 1700, Mr. Bond, who imagined that he had discovered the longitude, by having found out the true theory
of the magnetic variation, published a general map, on which were delineated curve lines, expressing the paths where the magnetic needle had the same variation. The positions of these curves will indeed continually suffer alterations; but they should be corrected from time to time, as they have already been for the years 1744 and 1756, by Mr. William Mountaine, and Mr. James Dodson. The allowances proper to be made for lee-way are very particularly set down by Mr. John Bucker, and published in a small tract first printed in 1702, intitled "A New Compendium of the whole Art of Navigation" written by Mr. William Jones.

As it is now generally agreed that the earth is a spheroid, whose diameter at the poles is shorter than the other, Dr. Murdoch published a tract in 1741, in which he accommodated Wright's failing to such a figure; and Mr. Maclarin in the same year gave a rule, in the Phil. Trans. N° 451, for determining the meridional parts of a spheroid, which speculation he has further prosecuted in his Fluxions, printed at Edinburgh in 1742.

The principal foreign writers on navigation are Bartolomew Crefcenti, of Rome, in 1607; father George Fourniac, at Paris, in 1633; John Baptift Riccioli, at Bologna, in 1661; father Millet Dechales, in 1674 and 1677; the Sieur Blondel St. Aycin, in 1671 and 1673; M. Dallier, in 1683; M. Sauveur, in 1692; Mr. John Bouguer, in 1698; father Pezenas in 1733 and 1741; and M. Peter Bouguer, who, in 1753, published a very elaborate treatise on this subject, entitled " Nouveau Traité de Navigation," in which he gives a variation compass of his own invention, and attempts to reform the log, as he had done in the Memoirs of the Academy of Sciences for 1747. He is also very particular in determining the lunations more accurately than by the common methods, and in describing the corrections of the dead reckonings. This book was abridged and improved by M. de la Caille in 1760: to these we may add Don George Juan of Spain, in 1757. For an account of the several steps that have been purified for the discovery of the longitude, see LONGITUDE. For an account of Hadley's quadrant, and its use in nautical observations, see QUADRANT. For the method of making artificial magnets, and their use, see MAGNET, COMPASS, and NEEDLE.

Those who are desirous of perusing a fuller account of the progress of navigation, may consult Dr. James Wilson's preface to Dr. Robertson's "Elements of Navigation," in two volumes, octavo, 1772: a work deservedly held in the highest estimation.

But to return to the history of navigation in its connection with commerce. About the same time that navigation was retrieved in the southern parts of Europe, a new society of merchants was formed in the north: which not only carried commerce to the greatest perfection it was capable of, till the discovery of the East and West Indies, but also formed a new scheme of laws for the regulation of it, which still obtain, under the name of "Utfca and customs of the sea."

This society is that famous league of the Hans-towns, commonly supposed to have begun about the year 1164. For the modern state of navigation in England, Holland, France, Spain, Portugal, &c., see COMMERCE, COMPANY, &c.

We shall only add, that in examining the reason of commerce's passing successively from the Venetians, Genoese, and Hans-towns, to the Portuugeze and Spaniards, and from these again to the English and Dutch, it may be established as a maxim, that the relation between commerce and navigation, or, if we may be allowed to say it, their union, is so intimate, that the fall of the one inevitably draws after it the other: and that they will always either flourish or decline together.

Hence so many laws, ordinances, statutes, &c., for its regulation; and hence, particularly, that celebrated act of navigation, which an eminent foreign author calls the Palladium, or tutelar deity, of the commerce of England; which is too important not to be here mentioned: as it is the standing rule, not only of the English among themselves, but also of other nations with whom they traffic.

Navigation Acts are those statutes which have been passed at different times by the legislature of this country, for the protection and extension of navigation.

But by the Navigation Act, particularly and emphatically so called, is meant the statue 12 Charles II. c. 18, entitled "An act for the encouraging and increasing of shipping and navigation:" all subsequent laws on this subject are but comments on this, modifying or explaining its different regulations, but leaving untouched its general and fundamental principles.

Before we proceed to examine the foundations of the principles on which the navigation acts are grounded; the necessity or expediency of their first enactment; the immediate consequences which resulted from them; the permanent benefits which they are said to have bestowed on this country; and the policy of their continuance on the statute-book, it may be proper to give a brief and rapid sketch of their history.

The first act, which had avowedly and exclusively for its object the augmentation of the navy of England, was passed in the reign of Richard II.; by the statute 5 Richard II. c. 3, it was enacted that none but the king's liege people should ship any merchandise out of, or into, the realm, and only in ships of the king's livery, on pain of forfeiture. This statute was passed at a time when the navy was greatly diminished; but its effects do not appear to have answered the expectations of the legislature; for by statute 6 Richard II. c. 8, the former statute was greatly modified, the merchants being obliged to give English ships the preference, only in case they were able and sufficient.

In 1440, the decline of the English navy was again complained of; and the Commons proposed the enactment of a law, of similar import and force with that of 5 Richard II. c. 3, but it was rejected by Henry VI. In the reign of Henry VII., however, two acts were passed for the encouragement and protection of English shipping, viz. 1 Henry VII. c. 8 (1485), and 4 Henry VII. c. 10 (1489.) Henry VIII. also passed a law for the same purpose in 1541, 32 Henry VIII. c. 14.

In Elizabeth's reign (1562), the carriage by sea of corn, wine, and other articles, and the taking, curing, and conveying by sea, of fish, were regulated with a view "to the maintenance and increase of the navy." And in 1593, the same sovereign granted particular privileges in cases where goods were carried in English vessels.

It appears from Rymer's Fother (xvii. 414.) that James I., in the Commission of Enquiry which he issued, expressly directed the attention of the commissioners to the same subject.

These laws, however, were either evaded or relaxed, for Charles I. found it necessary to revive and confirm them.

We are now arrived at that statute, which is justly regarded as the foundation of the Navigation Act of Charles II. This statute was passed by the Ulurpation Parliament on the 9th of October, 1651. In the year preceding, indeed, the same parliament had sketched a faint and rude outline of the Navigation Act; the sugar islands still adhering to Charles I., the statute of 1650 prohibited all ships of foreign
reign nations from trading with any English plantations without licence from the council of flate. The statute of 1651 arose partly from the same cause, and partly from the circumstance that the English merchants nced to freight Dutch ships to bring home merchandise from America and the Wett Indies, as they could be had at a lower rate of freight than native ships. Till this act passed, it appears, that notwithstanding the existence of former unrepealed acts for the protection and increase of English shipping, all nations in amity with England actually did import into Eng- 201 and what commodities they pleased, and in what ships they pleased; and as the Dutch, at that period, were the principal carriers of Europe, most of the merchandise imported into this country was imported by them.

The law of 1651 enacted that no commodities (colonial or of any other description) should be imported into Eng- land, unless in vessels solely owned, and commanded, and principally manned, by English subjects; and where the commodities were foreign, unless they were entirely con- veyed in such vessels from the place where the commodities grew, or to which they were usually, in the first instance, transported by sea. There were some peculiar exceptions, and one grand and general one, viz., goods originally pro- duced, or first transported by sea from an European state, might be imported thence, into England, in vessels owned by the subjects of that state.

The title of this act was suited to the design which it had in view; it was "Goods from foreign parts, by whom to be imported" (Scobell's Acts, 1651, c. 22. p. 132.), and the consequence was, that the Dutch were cut off from the carrying trade with our colonies, and their importation of fish into this country was laid under great restrictions and heavy burdens.

Before the passing of this law, great jealousy existed and frequent disputes had taken place, between this country and Holland; there were greatly increased and embar- rassed by it; acting in conformity with it, our ships of war insulted on their right to search Dutch vessels, and in several instances made prizes of them, where they found that they contravened the act. The war which broke out in the subsequent year, and which was carried on with great rancour and obstinacy, arose, partly at least, from the Navigation Act of 1651.

The Parliament were entirely and strongly convinced of the necessity and benefit of the Navigation Act, that they sanctioned it, first in 1660, and afterwards in 1662; the 1st, 2d, and 3d of these statutes, 12 Charles II. c. 18. (as has been already observed), is that which is emphatically called the Navigation Act.

The principal dispositions of the Navigation Act are thus summed up by Adam Smith, Wealth of Nations, ii. 192.

First, all ships, of which the owners, masters, and three- fourths of the mariners are not British subjects, are pro- hibited, under pain of forfeiting ship and cargo, from trading to the British settlements and plantations, or from being em- ployed in the coaling trade of Great Britain.

Secondly, a great variety of the most bulky articles of importation can be brought into Great Britain only, either in such ships as are above described, or in ships of the country where those goods are produced, and of which the owners, masters, and three-fourths of the mariners, are of that particular country; and when imported even in ships of this latter kind, they are subject to double alien's duty. If imported in ships of any other country, the penalty is forfeiture of ships and goods.

Thirdly, a great variety of the most bulky articles of importation are prohibited from being imported, even in British ships, from any country but that in which they are produced, under pain of forfeiting ship and cargo.

Fourthly, all fish of all kinds, whale-fins, whale-bone, oil and blubber, not caught by and cured on board British vessels, when imported into Great Britain, are subject to double alien's duty.

This act differed from that of 1651, in its second enacting clause, which did not permit any but English subjects to be factors or agents in English colonies. Before this time the Dutch were the principal factors or agents in our colonies; and the third enacting clause secured the East India, Guinea, and Levant companies, from foreign shipping.

The act 14 Charles II. c. 17. also differed in some respects from the act 12 Charles II. c. 18; by the latter it was sufficient, with respect to the vessel, if the was either owned or built at home; while, by the former of these acts, both these circumstances were declared indispensible.

In commercial writers, the phrases "enumerated and non- enumerated commodities" frequently occur; these expressions took their rise from the Navigation Act. Those are "enumerated commodities," which, by this act, cannot be carried from the colonies to any foreign parts, without being first unladen in Great Britain. Subsequent acts of parliament have enlarged or contracted the number of enum- erated commodities, according to circumstances; and one general exception has been introduced in this branch of the Navigation Act; as some of the enumerated articles are per- mitted to be carried, by a direct course, in ships of the em- pire, to places south of Cape Finisterre.

The principal objects which the Navigation Act, 12 Charles II. c. 18, had in view, will be best explained by its preamble, which declares it to be passed, "not only for the sake of employing and increasing English shipping and seamen, and securing a vent for woollen and other manu- factures; but also to make this kingdom a staple of the com- modities of those plantations, as well as of the commodities of other countries, for the supplying them (it being the usage of other nations to keep their plantation trade to themselves); and farther, if colonial commodities should be taken from any part but the plantations, that the trade of them would thereby in a great measure be deserted from hence, and carried elsewhere; his majesty's customs and other re- venues much lessened; the fair trader prejudiced; and this kingdom not continue a staple of plantation commodities, nor that vent, for the future, of the virtual, and other na- tive commodities of this kingdom."

British built ships are declared to be such as have been built in Great Britain, Ireland, Jersey, Guernsey, or the 16e of Man, or in some colony at the time belonging to Great Britain; any ship whatever, taken and condemned as lawful prize, is to be regarded as a British built ship. Ever since the Navigation Act passed, "Surveyors of the Act of Navigation" have been appointed at the Custom- house, whose duty it is to keep a register of all British built ships.

British seamen are declared to be such as are natural born subjects of the empire; or naturalized by act of parliament; or made denizens; or become subjects by conquest. And by 33 George III. c. 68. foreign seamen, who shall serve three years in the British navy, during the time of war, if they have not taken the oath of allegiance to a foreign state, may be employed, and shall be considered as British seamen. The same statute also introduced the principal modification which has taken place in the Navigation Act, by enacting, that from the conclusion of the war, no goods shall be ex- ported in British vessels, unless the master, and three-fourths
of the crew were British; the Navigation Act not interfering
with the exportation of goods from British ports.
Such a brief history, and general view, of those acts
which have been passed for encouraging and increasing ship-
ning and navigation; before we proceed to the other division
of this article, it may be proper to mention that they are
commonly very much relaxed, and in some particular cafes
discontinued, in time of war; and only rigidly and
uniformly enforced in time of peace.
1. The principle upon which the Navigation Act proceeds
is this, that it is politic and advantageous to burden foreign
in order to encourage domestic industry; this principle has
been very strongly and generally objected to by the most
acute and intelligent writers on political economy; and yet,
befides the cafe in question, there would appear to be other
causes of a more extended nature, in which a deviation from
this principle might prove beneficial to the interests of
the community at large.
There can be no doubt that it is unwise and disadvantageous
to burden foreign industry, merely for the sake of encour-
gaging domestic industry, when, by this means, the latter is
thus diverted from its channel, in which it is exercised with
great effect, into one in which the profit, if it were not thus
protected by monopoly, bounty, or duty, would not be near
to great; but there are undoubtedly cafes, especially in the
ruiner and least enlightened states of commercial activity
and intelligence, in which industry might either be directed to a
more profitable employment, or in which it might be ex-
tended to objects hitherto untouched, and fupposed without
its reach; and yet, unless government leapt forth and laid
a burden on foreign industry, domestic industry might not be
thus directed or extended. But wherever, notwithstanding
the application of a proper degree of industry, capital, and
skill, home produce is inferior in quality, or higher in price,
than foreign produce of the same description, the latter
should be preferred, and no obstacle should be thrown in the
way of its free importation and general use.
Befides this more general exception to the principle of pol-
itical economy, which we have been considering, the cafe of
the navigation laws seems to be one of a more peculiar na-
ture, and more confined character. This exception proceeds
on the idea, that in such a country as Great Britain, its
defence depends very much upon its sailors and shipping; and
that defence is of much more importance than mere opulence;
and ought therefore to be allowed to supercede the operation
of all general principles. The only question is, whether this
encroachment upon other industry be not hereby
has been as effectually and permanently by some other means,
this imposing a burden on foreign industry; it may be
supposed that Great Britain, at the period when the Navigation
Act was passed, stood as fair a chance as Holland of being
the carriers of the produce, at least of its own industry; and
that as the latter country had obtained and preferred a navy
without navigation laws, Great Britain might have done
the same. But we are to recollect that Holland stood in a pecu-
lar situation; having no manufactures or trade of her own,
she was thus enabled to turn nearly her whole attention to the
carrying trade, and to embark nearly her whole capital in it;
and a nation, like an individual, the attention, skill, industry,
and capital of which are directed solely to one undertaking,
will carry on that better, and at a cheaper rate, than any
other nation can do. Great Britain, therefore, had only two
models of preferring herself from the encouragements of the
Dutch on her carrying trade; either by turning her attention
and capital principally, or entirely to that branch, or by ex-
cluding the Dutch from it: the latter, in every point of
view, was preferable; and though it injured the commerce
of Great Britain in some degree, by raising the rate of
freights, it did much less harm than a total change in the
direction of her industry and capital would have done, while
it equally well secured the main object, the encouragement
of sailors and shipping.
2. The necessity of the first enactment of the Navigation
Act flows from the observations which have been already
made; Holland, at that time, was the most formidable rival
of Great Britain by sea; and it was therefore wise to adopt
such measures as should enable the latter to increase her navy,
and cope with, if not overcome, her powerful rival.
3. With respect to the consequences which immediately
resulted from the Navigation Act, there are different state-
ments: at first there were loud complaints that we had not
shipping enough to import from all parts, and yet were
prohibited from getting goods and shipping from foreigners;
while, immediately before the passing of the Navigation Act,
the complaint had been that our shipping were rotting, and
our mariners had gone into the Dutch service. Sir Joshua
Child, who published his treatise on trade in 1668, is so
decidedly and warmly of opinion, that the Navigation Act was
highly beneficial to the nation, that he thinks it ought to be
called Charter Maritima; and in another place he observes,
"that without this act we had not now been owners of one-
half of the shipping or trade, nor should have employed one-
half of the seamen we do at present;" while Sir Roger Coke,
in his "Difcourse of Trade," published 1670, affirms, "that
in two years after the Navigation Act of the Rump Parlia-
ment in 1651, the building of ships in England became one-
third dearer than before, and that seamen's wages became so
excessive dear that we have wholly left the Muscovy and
Greenland trade, whereby we gave the Dutch and other
nations the power of driving the trade of the world."
These opinions and statements, however, may be recon-
ciled; there can be no doubt that the first result of the Na-
vation Act would be to increase the demand for British fea-
men and shipping, and of course to raise the price of ship-
building, seamen's wages, and the rate of freight; this
increased demand would, in time, create an increased supply;
and though the rate of freight probably did not come down
to low, as it had been when the Dutch were allowed to be
our carriers, yet the immediate very great rise would ne-
cessarily be temporary. It may be remarked, however, that
one of the evils complained of by Sir Roger Coke, and which
still exists, would not have been produced had the Reformation
Bill, or act of the Long Parliament, by the latter, liberty was allowed to purchase
ships where they could be procured cheapest; ship-building
of course would not have been so much raised as Sir Roger
Coke complains; while the great object of the Act, the in-
crease of seamen, would have been more completely and
effectually secured; since, if ships had been bought where
they could be procured cheapest, freights would have become
more reasonable, and failors increased in consequence.
4. There can be as little doubt that the Navigation Act has
been beneficial to Great Britain, considered as a nation
dependent for her safety and well-being on her maritime power,
as that it has been prejudicial to her, considered as a nation
purely commercial: the manner in which it operates then, in
two very different ways, has already been pointed out.
"That nation (as Adam Smith well observes) will be most
likely to buy cheap, when, by the most perfect freedom of
trade, it encourages all nations to bring to it the goods
which it has occasion to purchase; and for the same reason
it will be most likely to sell dear, when its markets are thus
filled with the greatest number of buyers." Now, the Na-
vation Act directly and expressly discourages or prevents
foreign
foreign nations from bringing goods into Great Britain; and as the fame author remarks, "if foreigners are hindered from coming to sell, they cannot always afford to come to buy, because coming without a cargo, they must lose the freight from their own country to Great Britain. By diminishing the number of sellers, therefore, we necessarily diminish that of buyers, and are thus likely not only to buy foreign goods dearer, but to sell our own cheaper, than if there was a more perfect freedom of trade."

Lastly, there can be as little doubt that under the circumstances in which Great Britain is at present placed, it would be highly impolitic and unsafe to alter effectually the navigation laws; the lands now more in need of maritime defence than ever did; and the means of that maritime defence require more than ever to be preferred untouched by the encroachments of foreign nations; since, if the Navigation Act was abrogated, the operation of our taxes is such, that foreign ships, in almost every case, would be able to carry goods at a much lower rate of freight than our own shipowners could do. But, on the other hand, it may well be questioned, whether, at present, the regulation of the Long Parliament should not be adopted, and full liberty given to purchase ships wherever they could be found cheapest: as has been already remarked, freight would thus become more reasonable, and consequently the great object of the navigation laws would be more completely answered, while our merchants would have less reason to complain: if this alteration were made, the losses of the merchants would be entirely for the benefit of the nation; now it is only partly for the benefit of the nation, while by benefiting at the same time the ship-builders, that benefit is essentially lessened.

Navigation. Sub-marines, or the art of sailing under water, is mentioned by Mr. Boyle as the defectum of the art of navigation. This was attempted, and successfully, according to him, by Cornelius Drabbel; several persons who were in the boat breathing freely all the time. See Deloffre.

NaviGATOri, in the Sea Language, usually denotes a person capable of conducting or guiding a ship to any place desired.

Navigators is an appellation used for the labourers who work at canal-digging.

Navigators’ Islands, in Geography, a group of islands in the South Pacific ocean. This group, according to La Perouse (Voyage, vol. ii, p. 101.) consists of ten islands, viz. Opunuu, the most easterly, Lione, Fanou, Manunu, Oyolava, Calinaff, Pola, Shika, Offamo and Oucra. This celebrated navigator saw the seven first of these islands, but the position of the third last was unknown; though in the sequel of his voyage, he had reason for concluding that two of the three might be Cooea and Traitor islands, named by Capt. Wallis Bougainville and Keppel. (See Bougainville’s Island.) - These two islands are separated by a channel about three miles wide, intersected by an inlet at the north-easterly point of Traitors Island, which is low and flat, and has only in high tides towards the middle only is divided into two parts by a channel 150 miles wide at the mouth. These three islands form, according to La Perouse, part of the ten that compose the Navigators’ archipelago. The discovery of this group of islands has been repeatedly geographers been attributed to Bougainville in 1724; two of these islands lying in S. lat. 15° W. long. 170°, he called Baunue’s or Beauvais’s islands; and a third island, denominated Single island, lies in S. lat. 13 41° W. long. 171°. These three islands are said to be those which Bougainville calls the Isles of Navigators. But La Perouse is of opinion that neither the historical particulars relating to their inhabitants, nor the geographical position assigned to these islands by the historian of Ropgeignein’s voyage, corroborates the notion that Beauvais’s islands are the same with those to which Bougainville has given the name of Navigators’ islands.

These islands form one of the finest archipelagoes of the South sea, and are as interesting on account of their arts, production, and population, as those of the Society or Friendly islands, well described by the English navigators. As to the morality of the people, La Perouse does not hesitate to affirm, that it would be ineffectual to endeavour to excite by kindness the gratitude of their ferocious souls, which are only to be kept in awe by fear. They are tall and well formed, their usual height being five feet nine, ten, or eleven inches; but their stature is less surprising than the colossal proportions of the different parts of their bodies. Their countenances express the sentiment of disdain, which was not easily subdued. The bodies of the men are painted or tattooed to such a degree, that they seemed to be clothed, although they were almost naked, as they had only a girdle of sea-weeds round their loins, hanging down to their knees. Their hair is very long, which they twirl many times round the head, and thus add to the ferociousness of their countenances, always expressive either of surpise or anger. The leaf dispute among them is followed by blows of sticks, clubs, or paddles, which often cost the combatants their lives; as a consequence of their quarrels, they are covered with scars. The fize of the women corresponds to that of the men; and the grofs effrontery of the greater number of them, the indecency of their motions, and the disgusting offers they made of their favours, rendered them very proper for the mothers or wives of the male inhabitants. These people have certain arts, which they cultivate with success; to their lutes they give an elegant form by means of tools made of very fine clothe kind of bafaltes, in the form of an adze; and polished of these they disdained the implements that were tendered to them. For a few beads, they sold three-footed wooden dishes, cut out of the solid piece, and so polished as to have the appearance of being coated by the finest varnishing. Their subsistence depends on the fruit trees and nutritious roots that grow around them, and also on their pigs, dogs, and fowls. They manufacture extremely fine mats and paper stuffs. They have cloth, composed of real thread procured from some filamentsous plants, such as the nettle or flax; which cloth serves also for the sails of their canoes. Their dialect was similar to that of the people of the Society and Friendly islands; and La Peroue is of opinion that the inhabitants of the different islands of the South sea take their rite from Malay colonies. The descendants of the Malays, in these islands, have acquired a vigour, strength, stature, and proportion which they do not derive from their forfathers, but which is owing to the abundance of food, mildness of climate, and influence of physical causes, which is having a producing effect during a long series of generations. The feudal government is preferred here, and serves to cherish and maintain that ferociousness and perdition of disposition and manners, which characterize the inhabitants.

M. Bougainville has denominated these islands "Navigators" with sufficient reason; as all their voyages are made in canoes, and as they never walk, even from one village to another. Their villages are all situated in creeks on the seaside, and have no paths besides those that serve for penetrating into the interior of the country. The islands visited by La Peroue and his companions were clothed up to the very summit with trees laden with fruit, on which wood-pigeons and turtle-doves of various colours repose; here were
were also some beautiful parrots, or species of black birds, and corn partridges. These islands amuse their leisure hours by taming birds; their houfes were full of wood-pigeons, which they bartered by hundreds, and they likewise fold 300 gallinules of the most beautiful plumage. Their canoes have outriggers, are very small, and hold no more, in general, than five or fix persons. These Indians are such expert swimmers, that their canoes seem only to serve them as floating-places. Their fails are of mat or matted cloth. Their only modes of fishing are with hook and line, and a sweep-net; their baits are curiously wrought of mother-of-pearl and white shell. These islands, says I. Peroulet, appear to be volcanic: the stones on the bank being only pieces of lava, round bafaltes, or coral, by which the whole island is surrounded. Their villages are very agreeably situated: the houfes are built under fruit trees, which keep them delightfully cool. They are seated on the sides of brooks running down from the mountains; and they are surrounded by lattices, which they open to the windward and shut on the sunny side, in order to protect them from the heat.

These islands abound in pigs, dogs, fowls, birds, and fish, and are covered with cocoas, goyava, and banana trees, and another tree bearing a large almond which is eaten roasted, much resembling the chelfnut in flavour. Sugar-canes grow spontaneously on the banks of the rivers. The population of these islands is very considerable. The eastern ones, viz. Opoun, Léoné, and Fanfoüé, are small; the two last are only about five miles in circumference; but Maouna, Oyolava, and Pola, must be reckoned among the largest and most beautiful islands of the South sea. S. lat. 14° 20'. W. long. 169°. See MAOUNA.

NAVIS, Argi NAVIS, or the ship Argo, in Atromony, a constellation of the southern hemisphere. See Argo.

NAUL, in Geography, a small town of the county of Dublin, Ireland, on the confines of the county of Meath, near which is a romantic glen, overhung with rocks, through which the little stream runs which is the boundary of the two counties, and over this glen the old castle of Naul is boldly situated. Naul is in Fingal, and is 14 miles N. of Dublin. Carlile.

NAULUM, in Antiquity, a musical instrument, otherwise called Nhablum; which fee.

NAULUM, among the Romans, properly signified fright, whence it is used to denote a piece of money put into the mouth of a perfon defeased, to pay Charon the ferryman for his passage; this piece was to be of the current coin of the emperor then reigning; so that from it the time of the perfon's death may be known.

NAUMACHIA, NAUMACHY, from ναῦς, ναύς, and μαχαῖς, fight, a spectacle, or show, among the ancient Romans, representing a sea-fight.

NAUMACHIA is also used, by some, for a circus encompassed with seats and porticos; the pit of which, serving as aau arena, was filled with water, by means of pipes, for the exhibiting of sea-fights.

There were several of these naumachias at Rome: three built by Augustus, one by Claudius, and another by Domitian. Nero's naumachia served for the reverie of his medals.

NAUMANN, Johann Amadeus, in Biography, principal maestro di cappella to the Elector of Saxony, born near Drefsen in 1745. This composer had no originality; he had formed himself on the slimy style of Italy in the middle of the last century, before its coalition with the German school had been of service to both. He died at Drefsen in 1801.
NAUPLIUS, in Natural History, a name by which some former authors have called the nautilus, as well the papyrusceous as the chambered kind.

NAURZIM, in Geography, a lake of Russia, about 48 miles in circumference. N. lat. 51° 50'. E. long. 64°

NAUS, a town of the county of Tyrol; 16 miles W. of Bolzano.

NAUSA, a town of South America, in the audience of Quito; 70 miles N.N.E. of Guayaquil.

NAUSARY, a town of Hindostan, about ten leagues from Surat, which is of small extent, but contains a very considerable cotton manufactory. It has a fort which belongs to the Mahattas, and is surrounded with pagodas, gardens, and beautiful flower-plats. In the neighbourhood of this town the only animal used for the saddle is the ox.

NAUSEA, in Medicine, signifies that lighter degree of sickness at the stomach, which does not actually give rise to a discharge of its contents; — a propensity to vomit, which may occur with or without actual purging. The word is usually derived from nau, nautis, a ship, and was probably originally applied to the sickened excited by failure.

Nausea is produced by various causes; sometimes by those circumstances which act directly upon the stomach itself; sometimes by those which influence the stomach indirectly, through the medium of other organs of the body, with which it is connected by sympathy; and sometimes through the medium of the mind.

The nausea which originates from affections of the stomach itself, occurs under various circumstances. It is not unfrequently one of the symptoms of dyspepsia, or indigestion, and arises either from the irritation of the ordinary food, when that is taken in greater quantity than the effered out condition of the stomach is capable of digesting; or from the use of articles of diet which are difficult of solution, which tend to generate acidity or other acrimonious humours, or which offend by some acid or deleterious quality of their own; — or, lastly, from the morbid state of the secreted fluids in the stomach, which irritate its nervous coat, like the offensive substanctes that are taken in. See Indigestion.

But the sympathtic sources of nausea are perhaps still more numerous. The brain is seldom materially affected by any serious irritation or derangement, without deranging the stomach by sympathy: thus, sickness at the stomach is a common symptom of every degree of local injury of the head, in which preflure or concussion of the brain is occasioned; it accompanies inflammation of the brain and its membranes, the preflure of water in the ventricles, or of other morbid effusion or growth within the cranium; as well as the opposite state or inanition of the vessels of the brain, as in syncope, or after great loss of blood. The other organs, with which the stomach is often sympathetically deranged, and sickened, are chiefly the kidneys and the uterus. Thus nausea is a common concomitant of inflammation in the kidneys, or of the irritation of gravel or of a stone lodged in thefse organs, and becomes one of the diagnostic marks, by which diseafe in the kidneys is distinguished from other painful affections of the loins. Sympathtic nausea is also a frequent concomitant of uterine irritation or disorder; thus it is one of the most frequent symptoms of the beginning distention of the uterus in pregnancy, and accompanies inflammation and other painful conditions of that organ.

The influence of the mind alone is likewise capable of exciting nausea and even its ultimate degree, vomiting. The fight, or even the description or imagination, of loathsome and offensive objects and actions, will produce this effect on the stomach of many individuals of refined habits, or who are unacquainted to such objects.

It is not easy to account for that variety of sickness, which is produced by certain kinds of motion of the body, such as twining, whirling, and the undulating motion of a ship at sea. It seems, however, to be referable principally to the sympathetic connection between the stomach and brain; i.e. to the vertigo or dizziness produced in the latter, through the medulla of the organs of vision, by these unusual motions. Sickness and vertigo are mutually productive of each other, like some other affections of the head and stomach. When the stomach is rendered sick by wine, or nauseous drugs, a giddiness is perceived; even with closed eyes, and vice versa. Dr. Darwin mentions a striking fact, illustrative of the effect of this dizziness, produced through the organs of sight, in bringing on and preventing sea-sickness. "In an open boat passing from Leith to Kingshorn in Scotland, a sudden change of wind shook the undisturbed sail, and flopped our boat; from this unusual movement the passengers all vomited except myself. I observed, that the undulation of the ship, and the intability of all visible objects, inclined me strongly to be sick; and this continued or increased, when I closed my eyes, but as often as I bent my attention with energy on the management and mechanism of the ropes and sails, the sickness ceased; and recurred again as often as I relaxed this attention." (Zoornomia, vol. i. p. 5.) Similar nausea, though less in degree, is commonly an attendant on the vertigo produced by looking from a high tower, or attempting to cross a narrow path, unsupported, over a deep chasm.

With respect to the cure of nausea, then, it is obvious, that it will be as various as the causes which induce it; and that it is only in the cafes, where it results primarily from derangement of the stomach, that any material success can be obtained by remedies directed to that organ. In these cafes, the nature of the cause must determine the kind of remedy to be administered. When there is obviously a production of acidity, it will be relieved by the absorbent earths, such as chalk and magnesia, and by the alkalis, as prepared soda, soda-water, or potash. The mixture of an alkali with lemon-juice, taken in the act of effervescence, affords one of the most effectual means of relief in some cafes of sickness, when there is considerable weakness and irritability of the stomach. And in those cafes, in which there is also pain in the stomach, especially after taking food, opiates may be given, in combination with aromatics, with great advantage. In all such cafes, however, it is clear that much must be done by the regulation of diet, both in respect to quantity and quality, — by taking only light and digestible food, in moderate portions, — and by using regular and moderate exercise. Let it be observed, too, that the practice of retorting to emetics on all occasions of nausea, is injudicious; and probably aggravates the evil tenfold, by augmenting the irritability and feehlenf of the stomach, and thus laying the foundation for permanent imbecility in that important organ.

NAUSSA, in Geography, a sea-port town situated on the N.E. coast of the island of Paros, fortified by the Russians when they were in possession of the Archipelago.

NAUSTATHMUS, in Ancient Geography, a port of Sicily. Plin. l. iii. c. 8. — Alto, a port of Africa in the Pentapolis, according to Ptolemy, placed by Mela in the Cyrene. — Alto, a port at the mouth of the river Indus. — Alto, a port of Asia, in the environs of the Tronde, according to Strabo.
NAUSTEDAL, in Geography, a town of Norway, in the province of Bergen; 70 miles N. of Bergen.

NAUTACA, in Ancient Geography, a town of Asia, in Sogdiana. Arrian. i. vii.; the inhabitants of which were called "Nautacens.

NAUTAN, in Geography, a town of Hindostan, in Oude; 30 miles E. of Grocarpoor.

NAUTAPOLL, a town of Bengal; seven miles S. of Burmah.

NAUTICAL PLANISPHERE, a description of the terrestrial globe upon a plane, for the use of mariners. See Planisphere, and Sea-Chart.

NAUTICAL Chart. See Sea-Chart.

NAUTICAL Compass. See Compass.

NAUTICUS, in Anatomy, a muscle, called also tibialis posterior.

NAUTILUS, in Natural History, a genus of the class and order Verrnes Tellacea. The animal is a kind of cephalopod; the shell is univalve, divided into several compartments, communicating with each other by an aperture. This genus, which is sometimes confounded with the argonauta, or paper nautilus, on account of the similarity of their names, includes thirty-one species, which are separated into three divisions; viz. A, of which the shells are spiral, rounded, with contiguous whirls, comprising fifteen species, of which nine are common to our coasts, and found chiefly on the Sandwich shore, or on Sheppy Island. In the division B, the shells are spiral, rounded, with separate whirls; the number of species is three; these are all foreign. In C the shells are all elongated and straightish. There are thirteen species in this division.

A. Spiral, rounded, with contiguous Whirls.

Species.

POMPUILLUS. Aperture of the shell heart-shaped, with obtuse and smooth whirls. This species is found in the Indian and African oceans; it is sometimes very large, and finely variegated with brown flexuous streaks, spots, and marks under the outer covering, which is white. Within it is of a most beautiful pearly gloss. Of this shell the inhabitants of the East make their drinking cups.

* CALCARI. Aperture of the shell linear; the whorls have elevated joints. It is found on Sheppy island; is minute, white, and opaque.

* CRISPUS. Aperture of the shell fimbriate; joints of the whorls crenate. This is an inhabitant of the Mediterranean and of Sheppy Island, and is very minute. Independently of the specific character just given, the shell is opaque, white, umbilicate on each side, granulate and marked with flexuous fringe; the back is carinate; the siphon central, and the chambers a little inflected in the middle.

* BECCARI. Aperture of the shell ovate, the whorls twisted with deep joints. There is a variety, of which the shell is compressed, with a linear aperture and contiguous whorls marked with the elevated frize; many-rayed. This is found on the shores of many countries. The shell is depressed, minute; of a fine pellucid crimson while the fish is alive, but of a dull white when dead.

* LAVIGATULUS. Shell spiral, with smooth joints. This species is found at Sandwich, and is very minute. The shell is semi-ellipsoid, white, and glossy.

* DEPRESSUS. The shell of this species is spiral, slightly umbilicate on each side, with many depressed joints. Found at Reculver, is minute and very rare. The shell is opaque and white.

* UMBILICATUS. Shell spiral, umbilicate, with spiral joints. It is found at Sandwich, is white, opaque, and minute.

B. Spiral, rounded, with separate Whirls.

* CRASSUS. Shell spiral, thick, umbilicate on each side, with fine joints. It is found at Reculver, is very rare, white, opaque, and minute.

* LORATUS. Shell spiral, lobate, the spires rounded on one side and depressed on the other. It is found at Whitstable, is minute, white, and opaque.

* CARINATUS. Shell oblong, carinate, with a narrow oval aperture. It is found at Sandwich, and is rare, minute, white, and opaque.

* SUBURBANTULUS. The shell of this species is a little bending, with raised joints. It is found at Sheppy; minute, opaque, and brown.

* BALISTICUS. Shell white, convex, with a linear aperture; first whorl far exceeding the others in size. It inhabits the Baltic, adhering to the roots of fungi; it resembles the M. beccarii; the shell is sometimes polished and opaque; frequently pellucid.

* HELICITES. In this the whorls of the shells are concealed. It is found, in a fosile plate, on St. Peter's mountain at Maestricht, and is very small; the shell is sometimes convex, sometimes depressed, smooth, or irritable.

* RUGOSUS. Aperture of the shell linear; whorls compressed, with thickened margins. It inhabits the Southern ocean; is very small, white, somewhat depressed; the internal divisions a little prominent outwardly, and appearing like transverse wrinkles.

* UMBILICATUS. Aperture of the shell compressed and linear; the whorls are compressed; the umbilicus concave. It is found in Croatia; is minute, obliquely jointed, with transverse grooves, answering to the divisions within, particularly at the keel.

* SEMILITUS. The shell is incurved, spirally at the tip; the whorls are contiguous. It inhabits Croatia; is minute and convex; the partitions appearing outwardly, sometimes umbilicate.

* LITUS. Shell subconic, with globular divisions growing gradually less; the tip is incurved and spiral. It is found in the Red sea, frequently in a fosile plate.

* OBSCURUS. Shell straight, with a flight curvature; the divisions are obliquely irritable. It inhabits the Mediterranean and Adriatic.

* RAPHANISTRUM. Shell sub-cylindrical, with thick divisions marked with twelve elevated frize; the siphon is central and regular.

* RAPHANUS. Shell jointed, the divisions thick, with seventeen elevated frize; siphon sub-lateral and oblique. It is found in the Mediterranean and Adriatic, and is very minute.

* GRANUM. Shell ovate-oblong, with thick divisions marked with eight interrupted elevated frize; siphon oblique. It is found in the Mediterranean, and distinguished from
NAV

from the list in having prize at the point of the divisions a little contracted.

RADICULA. Shell oblong-ovate, with thick glabrous divisions. It inhabits the Adriatic.

FASCI A. Shell with flat divisions and smooth elevated joints. Found in the Adriatic.

INEQUALIS. Shell cylindrical, with eight divisions; the second and third very short; the aperture margined.

SIPHUNCULUS. Shell smooth, with cylindrical remote divisions; the joints tapering and cylindrical. Inhabits the seas about Sicily, and is found adhering to coral rocks.

LEGUMEN. Shell compressed, jointed, and margined at one end; the siphuncle is lateral. It inhabits the Adriatic.

ORTHOCERA. Whorls of the shell with cincture frizz. It inhabits the ocean, and is frequently found fossil.

BELLERINA; Thunder-bone. The shell is equal, smooth, conic, and acute. It is found in a fossil state in moll parts of Europe, and has derived its English name from a notion that it is a thunder-bolt, and never found but after a storm. The shell varies in size from half an inch to eight inches; it is conical, a little transparent, and when burnt or rubbed it smells like raifined horn. Several fine specimens of the nautilus have been dug out of the hill at Highgate. See the article CONCHOLGY.

NAUTPOUR, in Geography, a town of Bengal, on the Coofah; 36 miles N.W. of Purnear. N. lat. 26° 18'. E. long. 87° 14'.

NAVUK, a town of Persia, in the province of Mecran; 80 miles S. of Arokhla.

NAVY, the fleet or shipping of a prince or state. See FLEET.

The royal navy of England hath ever been its greatest defence and ornament; it is its ancient and natural strength; the floating bulwark and "wooden walls" of the island; an army from which, however strong and powerful, no danger can ever be apprehended to liberty; and accordingly it hath been sufficiently cultivated, even from the earliest ages. (See Laws of Leros.) And yet, so lightly inferior were our ancestors in this respect to the present age, that even in the maritime reign of queen Elizabeth, Sir Edward Coke, (3 Inft. 50.) thinks it matter of boast, that the royal navy of England then consisted of thirty-three ships. The present condition of our marine is in great measure owing to the halutary provisions of the statutes called the navigation acts, by which the conflagrant increase of British shipping and seamen was not only encouraged, but rendered absolutely necessary. See Navigation Acts.

Several articles and orders for the government of the navy are elabbed by 13 Car. II. c. 9, and 22 Geo. II. c. 22, and amended by 19 Geo. III. c. 17, which are as follow:

1. Officers are to cause public worship, according to the liturgy of the church of England, to be solemnly performed in their ships, and take care that prayers and preaching by the chaplains be performed diligently, and that the Lord's day be observed. 2. Perfons guilty of profane oaths, cursing, drunkenness, uncleanness, &c. to be punished as a court martial shall think fit. 3. If any person shall give or hold intelligence to or with an enemy without leave, he shall suffer death. 4. If any letter or missive from an enemy be conveyed to any in the fleet, and he shall not in twelve hours acquaint his superior officer with it, or if the superior officer, being acquainted therewith, shall not reveal it to the commander-in-chief, the officer shall suffer death, or such punishment as a court martial shall impose. 5. Spies and persons endeavouring to corrupt any one in the fleet, shall suffer death, or such punishment as a court martial shall impose. 6. No person shall relieve an enemy with money, victuals, or ammunition, on like penalty. 7. All papers taken on board a prize shall be sent to the court of admiralty, &c. on penalty of forfeiting the slide of the prize, and such punishment as a court martial shall impose. 8. No person shall take out of any prize any money or goods, unless for better securing the same, or for the necessary use of any of his Majesty's ships, before the prize shall be condemned; upon penalty of forfeiting his share, and such punishment as shall be imposed by a court martial. 9. No person on board a prize shall be dressed with the clothes, pillaged, beaten, or ill-treated, upon pain of such punishment as a court martial shall impose.

E
NAVY.

federation or mutiny shall suffer death, or such punishment as a court martial shall deem him to deserve. If any officer, mariner, or soldier, in or belonging to the fleet shall behave himself with contempt to his superior officer, being in the execution of his office, he shall be punished according to the nature of his offence by the judgment of a court martial.

20. Any person concealing any traitorous or mutinous practice or design, shall suffer death, or such punishment as a court martial shall think fit. Any person concealing any traitorous or mutinous words, or any words, practice, or design, tending to the hindrance of the service, and not forthwith revealing the same to the commanding officer; or being present at any mutiny or federation, shall not use his utmost endeavours to suppress the same, he shall be punished as a court martial shall think he deserves. 21. Any person finding cause of complaint of the unwholomeenefs of victuals, or upon other just ground, shall instantly make the same known to his superior, who, as far as he is able, shall cause the same to be presently remedied; and no person upon any such or other pretence shall attempt to stir up any disturbance, upon pain of such punishment as a court martial shall think fit to inflict. 22. Any person striking any of his superior officer, or drawing or offering to draw or lift up any weapon against him, being in the execution of his office, shall suffer death. And any person presuming to quarrel with any of his superior officer, being in the execution of his office, or disobeying any lawful command of any of his superior officer, shall suffer death, or such other punishment as shall be inflicted upon him by a court martial.

23. Any person quarrelling or fighting with any other person in the fleet, or using reproachful or provoking speeches or gestures, shall suffer such punishment as a court martial shall impose. 24. There shall be no wasteful expense or embezzelement of any powder, shot, &c. upon penalty of such punishment as a by a court martial shall be found just. 25. Every person burning or setting fire to any magazine, or store of powder, ship, &c. or furniture thereunto belonging, not then appertaining to an enemy, shall suffer death. 26. Care is to be taken that through wilfulness or negligence no ship be stranded, run upon rocks or sands, or split or hazarded; upon pain of death, or such punishment as a court martial shall deem the offence to deserve. 27. No person shall sleep upon his watch, or negligently perform his duty, or forsake his post, upon pain of death, or such punishment as, &c. 28. Murder; 29. And burglary or theft shall be punished with death. 30. Robbery shall be punished with death, or otherwise, as a court martial shall find meet. 31. Every person knowingly making or signifying, or commanding, counselling, or procuring the making or signifying any false matter, shall be cashiered, and rendered incapable of farther employment. 32. Provoked martial refusal to apprehend or receive any criminal, or suffering him to escape, shall suffer such punishment as a court martial shall deem him to deserve. And all others shall do their endeavours to detect and apprehend all offenders, upon pain of being punished by a court martial. 33. If any flag-officer, captain, commander, or lieutenant, shall behave in a scandalous, infamous, cruel, opprobrious, or fraudulent manner, unbecoming his character, he shall be dismissed. 34. Every person in actual service and full pay, guilty of mutiny, desertion, or disobedience, in any part of his major's dominions on shore, when in actual service, relative to the fleet, shall be liable to be tried by a court martial, and suffer the like punishment as if the offence had been committed at sea. 35. Every person in actual service and full pay, committing upon shore, in any place out of his major's dominions, any crime punishable by these articles, shall be liable to be tried and punished as if the crime had been committed at sea. 36. All other crimes not capital, not mentioned in this act, shall be punished according to the laws and customs used at sea. No perfon to be imprisoned for longer than two years. Court martial not to try any offence (except the 5th, 34th, and 35th articles) not committed upon the main sea, or in great rivers beneath the bridges, or in any haven, &c. within the jurisdiction of the admiralty, or by perons in actual service and full pay, except such perons and officers, as in the 5th article; nor to try a land-officer or soldier on board a transport ship. The lord high admiral, &c. may grant commissions to any officer commanding in chief any fleet, &c. to call courts martial, confuting of commanders and captains. And if the commander-in-chief shall die or be removed, the officer next in command may call courts martiaL No commander-in-chief of a fleet, &c. of more than five ships, shall preside at any court martial in foreign parts, but the officer next in command shall preside. If a commander-in-chief shall detach any part of his fleet, &c. he may impower the chief commander of the detachment to hold courts martial during the separative service. If five or more ships shall meet in foreign parts, the senior officer may hold courts martial and preside thereon. Where it is improper for the officer next to the commander-in-chief to hold or preside at a court martial, the third officer in command may be empowered to preside at or hold a court martial. No court martial shall consist of more than thirteen, or less than five perons. Where there shall not be less than three, and yet not so many as five of the degree of a post captain, or superior rank, the officer who is to preside may call to his assistance as many commanders under the degree of a post captain, as, together with the post captains, shall make up the number five, to hold the court martial. After trial begun, no member of a court martial shall go to shore, until sentence, except in case of sickness, upon pain of being cashiered. Proceedings shall not be delayed, if a sufficient number remain to compose the court, which shall sit from day to day (except Sunday), till sentence be given. The judge advocate, and all officers constituting a court martial, shall be upon oath. Perons refusing to give evidence may be imprisoned. Sentence of death within the Narrow Seas (except in case of mutiny) shall not be put in execution till a report be made to the lord high admiral, &c. Sentence of death beyond the Narrow Seas, shall not be put in execution but by order of the commander-in-chief of the fleet, &c. Sentence of death in any squadron, detached from the fleet, shall not be put in execution (except in case of mutiny), but by order of the commander of the fleet, or lord high admiral, &c. And sentence of death passed in a court martial, held by the senior officer of five or more ships met in foreign parts (except in case of mutiny) shall not be put in execution but by order of the lord high admiral, &c.

The powers given by the said articles shall remain in force with respect to crews of ships wrecked, looted, or destroyed until they be discharged or removed into another ship, or a court martial shall be held to inquire of the cause of the loss of the ship. And if upon inquiry it shall appear, that all or any of the officers and seamen did their utmost to save the ship, and behaved obediently to their superior officers, their pay shall go on: as also shall the pay of officers and seamen taken by the enemy, having done their best to defend the ship, and behaved obediently. If any officer shall receive any goods on board contrary to the 18th article, he shall further forfeit the value of such goods, or 500l. at the election of
of the informer; one moiety to the informer, the other to Greenwich hospital. For other regulations relating to the navy, see Marines.

For the method of supplying the navy, see Manning the Fleet.

The royal navy of Great Britain is conducted, under the direction of the lords of the admiralty, by seven commissioners, and the following principal officers, who compose the board for managing the business of the navy-office, viz. comptroller of the navy, who attends and compiles the payment of all wages, is to know the rates of stores, &c. There is also a deputy comptroller. Surveyor of the navy, who is to know the state of all stores, to supply what is wanting, to estimate repairs, charge boatswains, &c., with the stores they receive, &c. There have been generally two joint-surveyors. Clerk of the acts, whose business is to record all orders, contracts, bills, warrants, &c. Comptroller of the treasurer's accounts. Comptroller of the victualling accounts. Comptroller of the store-keeper's accounts. In time of war, or great naval exertion, there are other additional extra-commissioners. There are also commissioners for Deptford and Woolwich, and also others for the out-ports, refiding at Chatham, Sheerness, Portmouth, and Plymouth; and in time of war commissioners are appointed to reside at some of the principal yare's abroad, as Gibraltar, Halifax in Nova Scotia, Malta, Antigau, Jamaica, Cape of Good Hope, Madras, Bombay, &c. The treasurer of the navy is an officer, whose business is the receive money out of the exchequer, and to pay all the charges of the navy, by warrant from the principal officers. Each of these commissioners and officers has a number of subordinate clerks, with various salaries.

The navy was anciently victualled by contract; but the victualling is now under commissioners who keep their office in Somerset house. See Victualling Office.

For the several yards belonging to his majesty's navy, see Dock Yards.

NAVY and also VicTuallAX bills, are bills or orders for the payment of money, issued by the commissioners of the navy and victualling offices, on the treasurer of the navy, &c. for stores and provisions purchased for the service of the navy.

That the contractors may not be losers by receiving these bills in payment, the current discount, at the time of making them out, is added to the amount of the goods delivered. The inconveniences arising from too great a number of these bills remaining undischarged at any time, have induced government, at different periods, to allow the proprietors to exchange them for a certain proportion of redeemable stock; and thus they become pollexed of at least an equal security, with the advantage, that any part of it can be dispofed of, as occasion may require, instead of being limited in this respect by the amount of the bills, which is generally considerable; the interest also becomes, by this mode of management, payable at certain periods; whereas the time of payment of the interest on the unfunded bills, previously to the regulation which took place in 1794, was always uncertain; no payment being made till the principal and the interest due upon it were discharged together. In 1794, all navy and victualling bills were made payable on a certain day, to be expressed in each particular bill, which day was not to exceed 15 months from the date of the bill, but the bills now issued from the navy and victualling offices are at 90 days' date, bearing interest at 3d. per cent. per diem, commencing from the date of the bill, and payable with it; and these bills being negotiated as bills of exchange, of course cannot be bought and sold at a discount. In negotiating these bills, the whole property-tax on the 90 days' interest is deducted, and the interest for the time they have to run is taken on the nett sum.

The navy-office is the place where the chief business of the navy is transacted by the officers and commissioners.

NAVY, in Geography, a township of America, in Orleans county, state of Vermont.

NAVY-Hall, a settlement of Upper Canada, on the S. side of Lake Ontario, at the head and W. side of Niagara river, which last separates it from Fort Niagara on the E. side, in thestate of New York; 20 miles N. by W. of Fort Erie.

NAVY island, an island in the middle of Niagara river, which separates it from Fort St. Lifer, on the E. bank of the river, and also from Grand island on the S. and S.E.; it is about one mile long, and of the same breadth, and 13 miles N. by E. from Navy-hall.

NAXIA, formerly Naxos, the largest of the Cyclades, and now the most agreeable, and the most tranquil island of the Grecian archipelago. Its fertility, more than its extent, being about 18 miles in circuit, has given occasion for its being called the "Queen." The ancients called it "Stron-gyle," and it is said to have been first peopled by Thracians, who being in want of women stole them from Thellafy, and among others lphidemia and her daughter Pancrates. Al- vus sent his sons Otus and Ophiotes to recover their mother Phidemia; these brothers vanquished the Thracians, made themselves masters of the island, and called it "Dia." The Carians established themselves in this island, and gave it the name of Naxos, their king. Naxos, like the other islands of the archipelago, has experienced all the vicissitudes of fortune. It was formerly a powerful republic, but unable to maintain its independence; it was successively in alliance with the Athenians, conquered and ravaged by the Persians, tributary to the Romans, ceded by Marc Antony, after the battle of Philippi, to the Rhodians, afterwards subject to the emperors of the East, a long time governed by Venetian princes, and at length united to the Ottoman empire, under the reign of Solim II. The Naxians have retained a singular privilege of being governed by their own laws and customs; they have a municipal administration and judges of their own election. The inconceivable importance of this island, and its remoteness from the coast of Asia, have not induced the Turks to establish themselves there. The Porto is content to feed them a war-worce to exercise the police, to gather the taxes, and to remit them to Conflantinople. This island, more free and more independent than "Scio," is, nevertheless, far from having attained the same degree of prosperity. Trade is not sufficiently brisk, the culture of the lands is too much neglected, and the inhabitants possess little or no industry. Poor and haughty, and proud of their ancient nobility, they disdain commerce and agriculture; and thus these noble persons, boasting of their descent from the first Italian families, can bear to see their manfions pass into the hands of Plebeians, and their lands almost destitute of culture. The population of this island is said to exceed 10,000 persons: The capital contains nearly 2000; and the rest are scattered through 41 villages. The taxes which it pays for the lands, the karach, and the customs, amount to about 1660l. sterling; exclusively of some other occasional diffi- burments. Although the number of Catholics is diminishing, so that they have scarcely 600 settled in the town, they have an archbishop, a coadjutor, six canons, a rector, and several curates. They have also a house of Lazarists for the education of youth, a convent of Capuchins, another of Cordeliers, and another of cloistered nuns. The number of the Greeks, on the contrary, is increasing, and their clergy
are much less numerous, and more rich than those of the Latins. The priests of these two forms of religion govern this country with a rod of iron, and, without intending it, render the inhabitants more malicious than devout, more litigious and quarrelsome, than just or humane.

Such is Olivier's account; but Somini's is very different. He says, that the principal inhabitants have preferred the urbaneity, and noble and generous manners of their origin, and that they are distinguished by their affability and politeness, the fruits of a careful education. The women are no less amiable on account of their personal charms, than their other qualities.

This island is covered with high mountains, whose base is felicitate or granitale. White marble, and hard calcareous stones, lie every where on the felicitate, and give rise to a great number of springs, which water and fertilize the plains. The highest of these mountains is that of Jupiter, which the inhabitants call "Dias" or "Zia." In this mountain is a grotto of beautiful white marble, which has been much visited. The inhabitants regard it as a sacred spot, whether the Bacchants of the country came to celebrate their festivals and their mysteries. It presents now nothing very remarkable. Tournefort has described it in the "Voyage au Levant," vol. i. The summit of the mountains affords an extensive and interesting prospect. On the back of the mountains are some flocks of the little sheep of Italy and Provence, with short and coarse wool, and of a small species of goats, the flesh of which is eaten by the poor. The shepherds are peculiarly wild, and the women indefatigable. The females of Naxia, like those of Scio, take pleasure in holding in their mouths and chewing an inodorous sublance, which is furnished by a plant known to botanists under the name of "atraclysis gunnifera." The root of the plant affords an aliment equally wholesome and nutritious. The hills and rising grounds of this island are covered with myrtle, arbustes, lentikas, hypericums, favors, thorny brooms, leguminous shrubs, and several species of rock refus, particularly that which furnishes the labdanum. The rivulets are bordered by olenanders, agnus-casts, and plane-trees. In the east part of the island is a rocked of cliffs. The inhabitants of Naxos procure the caprification of the fig, and they cultivate the vine. Their wine has been generally commended. Athenæus, speaking of it in ancient times, compares it to the nectar of the gods. Olivier says, that it is generally of an indifferent quality, because they know neither how to make nor how to preserve it. The island furnishes wheat, kidney-beans, garden-beans, and a few other legumes for the home consumption. Barley, which is much more abundant, is annually exported. The oil is of an indifferent quality. Oranges, lemons, and bergamot-citrons, are less plentiful than they might be, as there is no town sufficiently near that furnishes a great consumption. The peaches, apricots, pomegranates, pines, plums, walnuts, almonds, and figs, are consumed in the island. Naxos has sheep and goats for the wants of the inhabitants, a few small-flinded oxen for husbandry, together with mules and asses for draught. The wool is of bad quality, and wholly consumed in the country. Cheese is an article of exportation. Cotton is but little cultivated, which is also the case with flax and flax. The honey and wax are consumed in the island. To the south of the town is a small falcon, whence the cattle is supplied with salt.

Although Naxia has no ports for the reception of vessels of a certain size, its coasts, nevertheless, afford tolerably good places of shelter against contrary winds; and the small craft of the archipelage are continually pulling into several of its coves. On the other hand, the principal town called Naxia, and off which vessels may call anchor in a roadstead, is at a very small distance from the much frequented harbours of the eastern side of the island of Paros, and in particular of the capital road of Naufa. N. lat. 37° 6'. E long. 25° 32'.

NAXIA, the capital of the above island, and one of the most beautiful towns in the Grecian archipelage. The town stands on an eminence by the sea-side, on the W. coast of the island, opposite to Paros. It was defended, under the Venetian princes, by a citadel, and by walls, which the Turks have in a great measure destroyed. The Latins, who were formerly masters of the country, are all lodged within their enclofure. The Greeks occupy that part which extends to the eastward of the caflle, known by the name of the "New Town," Naxos-Kou. The ancient city extended to the north, towards the fountain which bears the name of Ariadne. There are also, below the caflle, some remains of a subterranean aqueduct, that probably brought to the town the waters of a copious spring, which is seen four or five miles to the E., and which at this day serves to water part of the plain of Naxia. Bacchus had formerly a temple at Naxos. The gate and the foundation of it are still visible on a small rocky island, in the vicinity of Ariadne's foun- tain. A bridge built on a chain of rocks, it is said, joined this island to the large one, and conducted an aqueduct for conveying water for the priests who inhabited the enclofure of the temple. On the N. side of the island is found a colossal statue of Apollo, which is an imperfect piece of sculpture. The harbour, facing the island of Paros, was formerly capable of containing 30 galleys, was closed by a jetty, now to be divitently perceived when the sea is smooth. It is at present several feet under water, and yet the small craft of the country lie safely there in all seafons. Ships of burden may anchor, in summer, off the harbour, under shelter of the rock, on which are the remains of the temple of Bacchus. N. lat. 37° 7'. E. long. 25° 26'. Somini. Olivier.

NAXOS, or NAXUS, in Ancient Geography, an ancient town of Sicily, on the east side of the island, on a small promontory to the south of "Apollinis Archageta arā." and to the eaf of "Veneris Famus." It was near the mouth of the small river "Ariones." Upon the deftruction of this town, its inhabitants were removed to mount Taurus, on which they built the town of "Taurominimum," called "Naxos-Taurominimum."—Also, a town of the island of Crete,—Alfo, a town of Arcasia.

NAXUANA. a town of the Greater Armenia.

NAY, in Geography, a town of France, in the department of the Lower Pyrénées, and chief place of a canton, in the diocëse of Pau; 9 miles S.S.E. of Pau. The place contains 2358, and the canton 10,036 inhabitants, on a territory of 145 kilometres, in 10 communes.—Alfo, a town of Africa, in the kingdom of Galam; 25 miles S. of Galam.

NAYE, or NAYEOUT, a town of Africa, in Bondou; 12 miles S.W. of Fattimonda.

NAYLAND, or NEYLAND, a market-town in the hundred of Babergh, and county of Suffolk, England, is situated in a valley on the north bank of the river Stour. This place was formerly remarkable for its woollen manufacturers, but this branch of trade is now reduced to a very low ebb, only a small portion of yarn being made to supply the coarse and bombezen manufactory of Norwich. Some white and brown loof, of a very superior quality, is made here; and is also a considerable quantity of meal, which is sent to London. The church of Nayland, the principal ornamen- tation of the town, is almost in its centre, and is surmounted by a lofty spire. The porch is a very handsome piece.
piece of architecture, said to have been erected by one Abel, a clothier, whose monument appears in the wall. Various other monuments in memory of clothiers are dispersed throughout the interior of this edifice, but they are no otherwise worthy of regard, except as tokens of the early manufacturing opulence of the place. The market day is on Friday, and there is a fair annually on the second of October. According to the parliamentary returns of 1811, the houses in Nayland amounted to 184 in number, and the inhabitants to 933.

The manor here was one of those given by Henry III. to Hubert de Bango, his justiciary, when he created him earl of Kenm. It afterwards came into the possession of sir Rich- ard Wotton, who, on Charles I.'s reign, was elevated to the dignity of lord Wotton of Neyland, for his signal services as ambassador to several of the courts of Germany. This nobleman was subsequently made earl of Portland, and a knight of the Garter. Adjoining to Neyland is the parish called Stoke-Neyland, which is distinguished by a very noble church and beeple. This place was the site of a monastery of great note previous to the conquest, but it seems to have been long since it fell to decay after that event. Gifford's hall, the seat of the Monnocks, who have been proprietors of it since the time of Henry VI., is a conspicuous example of the fine old mansions. The shape of this house is quadrangular, with an open court in the middle, and the chief entrance under a tower gateway, said to have been built in the reign of Henry VIII. by Peter Gifford, esq. a distant relation of queen Anne Bullen. The whole is constructed of brick, and the mOULDings of the doors and windows are of the same material. Opposite to the gateway are the remains of an old chapel. A part of the gateway may be seen in Britton's Architectural Antiquities, vol. ii. 420. See also Kirby's Antiquities of the county of Suffolk.

NAYLER, James, in Biography, an English Quaker of the seventeenth century, who disgraced that harmless and, in general, exemplary sect, by the extravagance and fanaticism of his conduct, was born at Ardley, near Wakefield, in Yorkshire, about the year 1616. He received the elements of a very common education, and was refusing at Wakefield when the civil wars broke out in 1641. He then entered into the parliamentary army, and served as a soldier in the ranks several years; at first under Lord Fairfax, and afterwards as quarter-master in major-general Lambert's troop in Scotland, till he returned home, about the year 1649. At this period he was member of the Independent party, and continued so till the year 1651, when the preaching of George Fox at Wakefield, made him a convert to the communion of Quakers, or, as they are more properly called, of Friends, among whom he soon commenced preacher, with much acceptability. In the beginning of 1652, he fancied he heard a voice calling upon him to renounce his kindred and father's house, and to go into the west of England, promising that God would be with him. He was obedient to what, in the fervour of enthusiasm, he believed was a heavenly monition, and went about preaching from place to place, making profelytes in abundance. In 1654-5, he came to the metropolis, where he found a meeting of Friends, which had been established by Edward Burrough, and Francis Howgill, among whom he greatly distinguished himself by his preaching, and so highly did he rank in popularity, that he drew the people from the services of the other preachers, who were foppooped to be less gifted in spiritual things. He became intoxicated by the notice taken of him, and going again into the west, he was, in 1656, committed to the prison of Exeter for propagating his opinions. Here, as is very natural, his friends fowied him every mark of respect and attachment, and some zealots in his cause addressed him in terms that were frightful to consider, calling him the "everlasting son of righteousness;" the "prince of peace;" the "only begotten son of God," &c. He received the homage with the compofure of one who thought he deserved it; but Fox, and the other leading men among the Friends, disdained him, after they had attempted, in vain, to reclaim him to the rational principles of religion. When Nayler was released from imprisonment he intended to return to London, and taking Bristol in his way, his deluded adherents in Glositanbury, Wells, and other places, burned their garments before him, and formed a procession, in imitation of our Saviour's entrance into Jerusalem, and in this way he made his entrance into Bristol. Such conduct was not likely to be overlooked by the existing government, and a committee was appointed by parliament to examine witnesses against Nayler, upon a charge of blasphemy, for admitting religious worship to be paid him, and for assuming the names and incommunicable titles and attributes of Christ. When charged in this way, he admitted the truth of the allegations, but contended, that the honours which he received were not paid to him, but to Christ, who dwelt in him. He was, however, found guilty, as it should seem, not legally, by a jury of his country, but, contrary to law, by a committee of parliament, who resolved that "James Nayler is guilty of horrid blasphemy, and that he is a grand impostor, and a great seducer of the people." To receive his sentence he was brought to the bar of the house; and as the punishment of this madman was as cruel as could well be inflicted by the malice of man, it is necessary to observe that the house was not unanimous in its decisions; it occupied the debates of the commons for more than a week; many of the members of that body entertained the opinion of putting him to death, and some few totally disapproved of the sentence which was used against him. At length, on the seventeenth of December, it was carried by a majority, that "James Nayler be fet in the pillory in the Palace-yard, Weelmin-iter, during the space of two hours, on Thursday next, and be whipt by the hangman through the streets, from Weelminiter to the Old Exchange, and there likewise be set on the pillory for two hours, on Saturday next, in each place wearing a paper containing an inscription of his crimes. And that at the Old Exchange his tongue be bored through with a hot iron, and that he be there itigmatized in the forehead with the letter B." That he be afterwards sent to Bristol, and be conveyed into and through the said city on horseback, with his face backwards, and there also to be publicly whipt; and that from thence he be committed to the prison in Bridewell, London, and there restrained from the society of all people, and there to labour hard till he be released by parliament; and during that time he be debared the use of pen, ink, and paper; and shall have no relief, but what he earns by his daily labour." Such a sentence, which was executed without mercy, deferedly hands down to infamy all those who took a part in it: the parliament, who pronounced this sentence; the protector, who could have prevented it; and the pious divines, as they are sometimes called, Caryl, Manton, Nye, Griffith and Reynolds, who were sent to reclaim him, but who, when they were unable to effect their purpose, were the cruel executors of his sufferings. Hereafter let no Christian look into the works of these men, nor think of their names, without connecting with them their brutal conduct towards a deluded madman, who was an object of pity, not of indignation, and who ought to have been affigned to the care of a physician for the cure of his phrensy, and not to the iron fource of Cromwell's hang-
man. After the Protector's death, Nayler was released from prison, and he took the earliest opportunity of going to Bristol, which had been the principal scene of his mis-
nerable scenes, and of making a confession of his offences, which he uttered with too much feeling, and real sorrow, as to draw tears from all who heard it. Nayler did not long survive his enlargement; he died as he was on his journey into York-
shire, to receive there the welcome gratulations of his wife and children. When he was within two hours of his death, he exclaimed, in a spirit of piety which probably none of his preachers ever felt, "I see a spirit which I feel, that de-
thopes to do no evil, nor to revenge any wrong, but delights to endure all things, in the hope to enjoy its own in the end. Its hope is to outlive all wrath and contention, and to weary out all exaltation and cruelty, or whatever is of a nature contrary to itself." After his death, his "Recantation" of those errors which had brought him into suffering, and his other pieces, were published in an octavo volume. Biog. Brit. Toulin's Ed. of Neal's Hist. of Puritans, vol. iv. p. 152-7.

NAVO, in Geography, a small island in the East Indian sea, near the north coast of Celebes. N. lat. 1° 24'. E. long. 124° 24'.

NAIRES, or NAJRES. See Calicut.

NAZARETE, or Nazarethus. The flate and con-
dition of a Nazarite or Nazarean among the Jews. See Nazarite.

The Nazarene was a small settlement from the rest of mankind; particularly in three things. 1. In that the peron devoted to it drank no wine. 2. In that they did not shave their heads, but let the hair grow. 3. In avoiding the touch of dead people, which they held a de-

 Nazarite was of two kinds; the one temporary, or for a certain number of days; the other for life. The rab-

The Nazareth, in Ancient Geography, a town of Palesti-

tine, in the tribe of Zebulun, seated on the declivity of a mount, at some distance W. from mount Tabor. Here our Lefted Saviour spent the first thirty-three years of his life. Among the antiquities of Palestine, travellers mention a flate church, under ground, built, as it is reported, in the cave where the Virgin Mary received the Angel's hail, and where, just at the section of the crypts, are erected two pillars of granite, each f-mweight: above two feet in diameter, and about three feet distant from each other. These are sup-
poded to stand where the angel and the Virgin were stationed at the time of the annunciation. Near this are seen some no-

NAZARETH, in Geography, now called Najf, formerly so much celebrated, is at present an inconceivable village of Syria, in the pachal of Sade, or of Acre, inhabited by one-third of Mahometans, and two-thirds Greek Catholics. The fathers of the Holy Land, who are dependent on the great convent of Jerusalem, have an hospitium and a church here. They are usually the farmers of the country. In the
time of Daher, they were obliged to make a present to every

NAZARETH, a town of France, in the department of the Seheldt, and chief place of a canton, in the district of Gand. The place contains 4574, and the canton 12,742 inhabitants, on a territory of 126½ kilometres, in seven communes.

NAZARETH, a beautiful port-town of America, in North-
ampton county, Pennsylvania, inhabited by Moravians or United Brethren; 63 miles N. by W. of Philadelphia. It is
situated on the central part of a tract of land, containing about 5000 acres, bought by the brethren, near a small creek, which flows itself in the ground, about one mile and a half east of the town; and consists of two principal streets that form a square. The principal building, called Nazare-

NAZARETH, a river of Africa, which runs into the Atlan-
tic, near Cape Lopez Gonfalvo.

NAZARETE, or Nazarene, in the Old Testament, is used for a person distinguished and separated from the rest, by something extraordinary, either his sanctity, dignity, or vows.

The word comes from the Hebrew נזיר, nazir, to dlgin-
gue, separate; in which it differs from Nazarean, an inhabit-
ant of the country called Nazareth, which comes from נצר, nazar, or nazer, to save, preserve.

The first person to whom the title נזר, nazir, is applied, is Joseph. (Gen. xlix. 26. See also Deut. xxxiii. 16.) He was so called, either because he was separated from the society of his brethren by their malice towards him, or from their evil practices by the grace of God, or because he was advanced by providence to highly above them in dignity and honour. But whatever was the reason of Joseph's being called נזר, nazir, the term was afterwards used to denote a particular sort of separation or devotedness to God, and on that account was applied to the Nazarenes. Accordingly there were of two sorts, viz. such as were by their parents devoted to God in their maner, or even sometimes before they were born: and such as devoted themselves. The former are called "Nazareni nati," and were Nazarenes for life; and the latter "Nazareni votivi," who ordinarily bound themselves to observe the laws of the Nazarenes only for a limited time. In the number of perpetual Nazarenes, were S campaigners, Samuel, and John the Baptist. (Judg. xiii. 5. 1 Sam. i. 11. Luke, i. 15.) Thee, or the "Nazareni nati," were not bound to the same strictness as the "votivi," who must not touch any dead carcass, nor so much as enter the doors of a house where a deceased person was. At for the "Nazareni votivi," who bound themselves by a vow to observe
observe the law of the Nazarites for a certain time, their laws are contained in Numb. chap. vi. The institution of Nazarism was, without doubt, partly religious, and partly civil and prudential. That it was partly religious, is concluded from the book of Amos, chap. ii. 11. Moreover, the frivolity and temperance which the Nazarites were bound to observe very much conduced to health; and thus the institution had its civil and prudential use. (See Lam iv. 7.) That the law of the Nazarites was observed among the Jews at the time of the evangelical history, is evident from what Josephus says of Bence, A.D. 66. (De Bell. lib. ii. c. 15.) A difficulty has been raised with respect to St. Paul's vow at Cenchrea (Acts, xviii. 18.); because the Jewish writers say, that a Nazarite ought not to be out of the land of Israel; and in the law of Moses it is said (Numb. vi. 18.) "the Nazarite shall have the head of his preparation at the door of the tabernacle of the congregation." Dr. Lardner, in resolving this difficulty, inclines to think, that notwithstanding all the zeal of the Jews, they did at this time dispense with the exactness of many things required in the law of Moses. This seems to have been the necessary consequence of their living, as numbers of them now did, at a great distance from Jerusalem. Besides, it seems to have been a rule in the Jewish books, "that they who make the vow of the Nazarite out of the land of Israel, shall go into it to complete the vow." The learned writer now cited suggests, that it will much contribute to the solution of this difficulty, if it be allowed, that this was the reason of the Paul's great concern to keep the next feast at Jerusalem. See Acts, xvii. o—22.

In the second verse of the term Nazarite, derived from נazaar, whence Nazareth, our Saviour himself was called a Nazarene, or Nazarite (Matt. ii. 23.); for this name, or title, as applied to Christ, is sometimes written נזרה (Mark, iv. 67. xvi. 6. Luke, iv. 34.), sometimes נזרה (Matt. xxvi. 71. John, xviii. 7. Acts, ii. 22.), which words seem to be used by the Evangelists precisely in the same sense; accordingly, the Syriac version renders both by the word "Notario."

The evangelist Matthew's allusion as the reason for our Saviour's being called נזרה, that he came and dwelt in the city of Nazareth (Matt. ii. 23.), and referring to some prophecy, which, at least in express words, is no where to be found in the whole Old Testament, hath given critics and commentators no little trouble; "that it might be fulfilled," faith in, "which was spoken by the prophets, he shall be called a Nazarene." Among the different solutions that have been given of this difficulty, the most probable are, either that the passage here referred to is lost, as Chrysolomus sugggests, or that the two first chapters of St. Matthew's gospel are not genuine (see Matthew), or, as St. Jerom intimates, that the evangelist does not here refer to any one particular passage, but to what several of the prophets have in effect said. As he uses the word prophets in the plural number, it is evident, said that father, that he did not take the words from the scripture, but the sense only. (See Whitby on Matt. ii. 23.) Being called a Nazarene is the same thing as being one, the Hebrews expressing word and thing by the same term. The meaning then of Christ's being called נזרה may be, that he shall be despised and reproached, according to a variety of predictions (Is. xxii. 6. lxix. 9. If. ii. 3—5. Zech. xi. 12, 13.), which were accomplished, in one instance at least, by his being called a Nazarene, from his having dwelt at Nazareth, that being a town of such ill repute, that it was commonly thought no good thing could come out of it (John, i. 66.), and our Saviour's being supposed to come out of it being one occasion of his being despised and rejected by the Jews. (John, vii. 52.) Nevertheless, the appellation נזרה of Nazareth, being added to Jesus, in order to distinguish him from all others of the same name, is sometimes applied to him when no reproach was intended, as by St. Peter (Acts, ii. 22. iii. 6. iv. 10.), and by an angel (Mark, xvi. 6.) It is, however, generally used by the Jews as a term of reproach, not only in respect to our Saviour himself, but to his disciples after his ascension. They stigmatized them of the seed of the Nazarene, (Acts, xv. 5.) Nevertheless, the disciples of Christ, after they had generally taken the name of Christians, reverted upon the Jews, giving this title of reproach (as some have supposed) to the Judaizing Christians, as we learn from Epiphanius. See the next article.

Nazarites, Nazarenes, or Nazarines, were likewise a kind of sectaries in the church, in the first ages of Christianity; or, as others describe them, the first believers in Christianity, profelyted from the Jews, and therefore called Jewish believers.

St. Epiphanius tells us, that the Nazarenes were the same with the Jews in every thing relating to the doctrine and ceremonies of the Old Testament; and only differed from them in this, that they added Christianity to their; professing to believe, that Jefus Christ was the Messiah.

There were two kinds of Nazarenes, the one pure, who kept the law of Moses and Christianity together, and who were not placed by the ancient Christians in the register of heretics, but first ranked in this class by Epiphanius, in the fourth century; the other, real Ebionites; see this article.

Ecclesiastical writers tell us, that St. Matthew preached the Gospel to the Jews at Jerusalem, and the rest of Palestine, in their own language; and that accordingly they had his Gospel written in the Hebrew of that time. And St. Epiphanius adds, that this Gospel was preferred among the Jews; and only doubts whether they might not have refuted the genealogy of Jesus Christ, which was not in the copy of the Ebionites. St. Jerom, who translated it out of Hebrew into Greek and Latin, says, a great many people took the Hebrew Gospel, used by the Nazarenes and Ebionites, to be the original of St. Matthew. See St. Matthew.

Hence Baronius, in his Annals, says, if the Vulgate Latin version were to be reformed, it should rather be done by the Hebrew original, than by the Greek, which is but a copy. Caiusbon treats this opinion of Baronius as highly impious; as not being able to conceive how the authority of the Greek version should depend on a text quite lost. He adds, that it was never used by any but the Nazarenes, the Ebionites, and some other heretics; and that it was full of fables, as having been altered and corrupted by those heretics.

The reader will find an accurate and satisfactory account of this Gospel in Mr. Jones's Method of settling the canonical Authority of the New Testament.

Moilema observes, that the term Nazarenes was not originally the name of a sect, but that which distinguished the disciples of Jesus in general. Nevertheless, those who, after their separation from their brethren, retained the title of Nazarenes, differed much from the true disciples of Christ, to whom that name had been originally given. They held that Christ was born of a virgin, and was also in a certain manner united to the divine nature; they refused to abandon the ceremonies prescribed by the law of Moses, but were far from attempting to impose the observance of these ceremonies upon the Gentile Christians; they rejected also those additions that were made to the Mosaic institutions.
ocations by the Pharisees, and the doctors of the law; and from hence we see the reason why the greatest part of the Christians treated the Nazarenes with a more than ordinary degree of gentleness and forbearance.

This writer says, that after the destruction of Jerusalem, under the emperor Adrian, the zealots for the Jewish rites defected the ordinary assemblies of Christians, and established separate meetings among themselves; and were thereover numbered with those sects which had departed from the pure doctrine of Christ. Hence, he says, arose the names of Nazarenes and Ebionites, by which the judaizing Christians were distinguished from those who looked upon the Mosaic worship and ceremonies as entirely abhorred by the appearance of Christ upon earth. Hence he concludes, that though the Nazarenes and Ebionites are generally placed among the sects of the apostolic age, they really belong to the second century, which was the earliest period of their existence as a sect. At the beginning of Christianity, says Beaufobre, (Hill. Manich. t. ii.) there arose two opposite errors concerning the person of our Saviour. The first obtained among the Christians who came out of Judaism. Many perfused themselves that the Christ was but a mere man, distinguished from others by the abundance of divine gifts conferred upon him, and by his incompareable virtues.

In the time of the apostles, according to Athanasius, the Jews were in this error, and drew the Gentiles into it; that the Christ is only a mere man, that he is not God, and that the Word was not made flesh. These Jews were not the unbelieving Jews, but such as made profession of Christianity. But though they agreed so far, they were not all of the same mind concerning the nativity of our Saviour. Some believed that he was the son of Joseph and Mary. Others acknowledged, that he was born of a virgin, and conceived by the sole operation of the Holy Spirit. Neither the one nor the other refused him the title of the Son of God; but they imagined that it was given him on account of the eminence of his office, the excellency of his gifts, his glorious resurrection, the sovereign authority and dominion to which he was advanced by the Father; to all which, they added his miraculous nativity. These kept the name of Nazarenes, which had been given to the first believers; the others were called Ebionites. These two, says this author, were the most ancient heresies of Christianity. Origen and Eusebius speak of two sects of Ebionites, including in these, as we may suppose, those that are sometimes called Nazarenes, and who were the descendents of the Jewish believers at Jerusalem. These latter believed Jesus to be born of a virgin by an especial inspiration of the power of God, or by the Holy Ghost. They also received the apostle Paul and all the other apostles of Christ. While, with the other chiefs of Ebionites, they adhered to the injunctions of the law of Moses, after they had received the gospel of Christ, they did not like them, impose legal obervers upon all men as necessary to salvation. They were evidently of the same opinion with the believers in the church of Jerusalem.

(See Acts, ch. xx.) Whilest on their part they observed them as descendants of Israel and Abraham, they did not impose the ordinances of the law upon others. Of these Nazarenes, Eusebius says, that though they believed Jesus to be born of a virgin by the Holy Ghost, they did not acknowledge his pre-existence as God the word; but Dr. Lardner presumes, that they believed Jesus Christ to be the word, and wisdom, and power of God; but they did not believe the pre-existence of the word as a distinct person and separate from God the father. St. Jerome says, that in his time there were many all over the East called Nazarenes, upon whom the Jews pronounced their curties as heretics. For further particulars respecting these Nazarenes, see Ebionites, Gospel, and St. Matthew.

NAZE, in Geography, a cape in the county of Essex, S of Harwich; near which has been erected a tower for a light-house, eighty feet high. N. lat. 51° 57'. E. long. 1° 11'.

NAZIANZES, in Ancient Geography, a town of Asia, in Cappadocia, towards the S.W., near mount Athan. It was the fee of Gregory, the father of St. Gregory, known to the world by his writings.

NAZIMOV, in Geography, a town of Russia, in the government of Tobolsk, on the Enisei; 68 miles N. of Enisei.

NAZIN, a river of Russia, which runs into the Oby, N. lat. 60° 20'. E. long. 68° 20'.

NAZZARETO, a town of Persea, in the province of Irak; 130 miles S.S.W. of Hamadan.

NEA, a river of Norway, which runs into the Seelbo lake, in the province of Dronthen.

NEA, in Ancient Geography. See NEAPOLIS.—Allo, a town of the Troade, according to Pliny, but placed by Steph. Byz. in Myfia.—Allo, an island of the Ægean sea, placed by Pliny between Lemnos and the Hellepont, and consecrated to Minerva.

Nea Paphos, a town of the island of Cyprus, 60 itadia from Palæ Paphos, according to Strabo. It was situated in the S.W. part of the island, in a gulf formed by the promontory of Zephyrwm.

NE ADMITTA, in Law, a writ directed to the bishop, in behalf of the plaintiff, or defendant, in a cause where a quare impedit, or aiface of darren defendant, is depending; when either party fears, that the bishop will admit the other's clerk during the fight between them.

This writ should be brought within six months after the church becomes void, before the bishop may preface by lape; and upon granting it, another writ is sufficed to the chief justice of the common pleas, to certify the king in chancery, whether there be any plea before him and the other justices, between the parties, &c.

NEAGH, LOUGH, in Geography, a lake of Ireland of considerable extent, lying between the counties of Armagh, Tyrone, Londonderry, and Antrim. According to Dr. Beaufort, it is 15 miles long, seven broad, and covers 582,200 Irish acres, equal to 935,602 English ones. It was formerly latted to cover a plain of 100,000 acres, but Mr. Lendrick's Survey corrected this error. The river called the Lower Bann, flowing from south to north, is the only outlet for seven rivers and innumerable streams that pour their tributary waters into this great inland sea, yet inundations seldom occur; "perhaps a great overflow," says Sir Charles Coote, "will not occur above once in fifteen years." There are, however, tracts of very low marshy ground, especially on the south of it, which are usually flooded, and are considered incapable of being reclaimed. Lough Neagh is the largest of the Irish lakes, but much inferior to many of them in point of beauty. Its shores are molly formed either by the marshy grounds already mentioned, or by an inanimate strand. They are of course deficient in those varied banks and bold promontories, without which such extensive sheets of water cannot have a picturesque effect, unless when the uniformity is broken by frequent islands of different size and character. There are hut two in this lake, a very small one near the mouth of the Blackwater, and Ram island, within a short distance of the Antrim shore, remarkable only for an ancient round tower. The views are more pleasing in lough Beg, into which these waters again expand, after the course of about a mile through a very
NEAL, DANIEL, in Biography, a learned English Protestant dissenting divine, who flourished in the eighteenth century, was born in London in the year 1678. Having lost his parents when very young, the care of his education devolved on his maternal uncle, who sent him to Merchant Taylors’ School to be instructed in grammar and classical learning. On this public foundation he continued till he became the bead scholar, but, from an unwillingness to subscribe to the articles, he declined an offer made him of an exhibition to St. John’s college, Oxford. About the year 1697 he entered himself as student in a dissenting academy under the direction of Mr. Row. After spending three years in this seminary he went for farther improvement to Holland, where he prosecuted his studies during two years at the university of Utrecht, under the celebrated profeffor d’Uries, Gravenius, and Burman, and then he removed to Leipsic, where he remained another year. In 1703 he returned to his native country, in company with Mr. Martin Tomkins, and Mr., afterwards Dr., Nathaniel Lardner, and soon began to officiate as a preacher. In 1704 he was chosen fellow to Dr. Singleton, minister of an independent congregation in Alderfitge street, upon whose death, in 1706, he was elected to the pastoral office among them. In this connection he continued thirty-six years, discharging the duties of his office with the greatest affability and zeal. The small portion of time which he allowed himself from his official services, as a preacher and pastor, he devoted to the study of history, and in 1720 he published his first work under the title of “The History of New England, being an impartial Account of the civil and ecclesiastical history of the Country,” which consisted of two volumes octavo, contains an entertaining and instructive narrative of the first planting of the gospel in a foreign heathen land, and of the rise of an infant commonwealth, struggling with a thousand difficulties; but triumphing over them all, together with biographical memoirs of the principal persons in church and state. In 1722 Mr. Neal published “A Letter to Dr. Francis Hare, Dean of Worcester,” occasioned by his Reflections on the Dissenters, &c., and in the same year he gave the public “A Narrative of the Method and Success of inoculating the Small-pox in New England, by Mr. Benjamin Colman, &c.” On the appearance of this piece her royal highness Caroline, princess of Wales, sent for Mr. Neal to obtain from him some farther account of the actual practice of inoculation. From this period he published only some single sermons till the year 1732, when he sent into the world the first volume of his great work, “The History of the Puritans, or Protestant Non-conformists, from the Reformation to the Death of Queen Elizabeth, with an Account of their Principles, &c.” The circumstances that gave rise to this publication were as follow: Some years before, Dr. Edmund Calamy, in his “Abridgment of the Life of Baxter,” had laid before the public a view of the state of non-conformity, and of the characters and sufferings of its principal adherents during the period immediately succeeding the Act of Uniformity in 1662. This work suggested to Dr. John Neal the design of “A History of New England, from the reformation to the commencement of the civil wars in England in 1640. Mr. Neal was requested to take up the history from that period, and to carry it on to the Act of Uniformity. Dr. Evans had not by any means accomplished his work at the time of his death in 1730, but before this Mr. Neal had finished his intended labour, and had rendered his MS., in every respect, ready for the press. The decease of Dr. Evans obliged him to take up the history from the reformation to the year 1640, in order to render his own work complete and more generally interesting. Mr. Neal had not long published his first volume when he saw he had abundant encouragement to proceed with the undertaking, and in the year 1733 he published a second volume. It was not till the year 1736 that he gave the public his third volume, but during the interval, he engaged with other ministers in certain lectures preached in London, justifying and recommending the principal topics of the Christian religion; and exposing the erroneous tenets of the church of Rome. In 1738 Mr. Neal published his fourth volume, which contained his “Defences of Non-conformity to the Act of Toleration in 1689.” By this work he has secured to himself a permanent and unfading reputation; it is thus described by Dr. Jennings. “The style is most easy and perspicuous; and the judicious remarks which he leads his readers to make upon facts as they go along, make his history to be not only more entertaining, but to be more instructive and useful than most books of that kind.” In a controversy which he had with Dr. Maddox, Mr. Neal published “A Review of the principal Facts objected to in the first Volume of the History of the Puritans,” which was considered to be written with great judgment, and to establish the author’s character as an accurate and diligent historian. His health now began to decline, or he would, probably, have vindicated the other volumes from the animadversions of Dr. Zachary Grey. This talk has been very judiciously performed by Dr. Toulmin, in notes to a new edition of Mr. Neal’s History. Mr. Neal, after a long series of illness, died at Bath in 1743. “He had,” says his biographer, “filled the relations of domestic life with interest and honour, and his loss occasioned a deep regret in the hearts of his family. In his public connections, he was a prudent counsellor, and a faithful steadie friend.” He was probably a Calvinist in his religious faith, but neither his charity nor his friendships were confined to men of his own opinions. The Bible alone was his standard for religious truth,
NEA

truth, and he was willing and deforous that others should have the fame liberty of judging of its contents as he claimed for himself. He had married a sister of the celebrated Lardner, by whom he left a son and two daughters. His son, Mr. Nathaniel Neal, an eminent attorney, was author of "A free and ferious Remontrance to Protestant Diffenting Ministers on occasion of the Decay of Religion," which was republished by Mr. Jeb Orton in the year 1775.

One of the daughters married the son of Dr. David Jennings, and the other the Rev. Mr. Litter, of Ware, in Hertfordshire, whose sons are the eminent Dr. William Litter, of London, and Mr. Daniel Litter, to whom Dr. Toulmin has dedicated his edition of "The History of the Puritans," to which we refer our readers for more information on the subject of this article.

NEALED, at Sea, is used when the founding is deep water close to the shore: it is then said to be nealed to; as also when the shore is sandy, clayey, oozy, or foul and rocky.

NEALING, or Annealing, in the arts, consists in making metals red-hot, which have become hard and brittle by working, in order to restore their former malleability and tractability. All metals have the property of becoming more or less hard and malleable, after undergoing the operation of the hammer. Metals thus affected are more elastic than they were before, but, at the same time, they become more brittle. They are the more sensibly affected in this manner in proportion as the metals are naturally harder. Copper is so much affected, and even gold and silver, by hammering and compression, that they soon cease to be malleable, and instead of being extended under the hammer they crack and split. Hence the necessity of annealing the common coins of the country, to which we have referred under the article MINT. In all cases the labour of hammering, when it is to be long continued, must occasionally be interrupted to soften and restore malleability to metals; this is effected by making them red-hot, and suffering them to cool gradually. Thus heat produces the same effect on metals, in the flate deformed, as it does upon tempered steel, for, if the hardest tempered steel be made red-hot and cooled slowly, it becomes as tractable and ductile as the softest iron. Articles of glass are also nealed before they are fit for use, by placing them in a furnace, and after they have been raised to a due degree of temperature, they are suffered to cool gradually. Without this operation glass vessels would be entirely useless, as they would not admit of the least change of temperature from cold to heat, nor would they bear the slightest blow. See Glass.

Nealing of Glass is the baking of glass, to dry, harden, and give it the due consistence, after it has been blown, and fashioned into the proper works.

This is usually performed in a kind of tower, called the kiln, built over the melting furnace. See Glass.

Nealing of Glass is also used for the art of staining of glass with metallic colours.

One fine use of silver, says Mr. Boyle, was only discovered since the art of annealing upon glass came to be practised. For prepared silver, or even the crude metal, being burnt on a glass plate, will tinge it of a fine yellow, or golden colour. And there are several mineral earths, and other coarce matters, of use in this art, which by means of fire impart transparent colours to glasses, and sometimes different ones from those of the bodies themselves.

Nealing of Steel is the heating it in the fire to a blood-red heat; and then taking it out, and letting it cool gently of itself.

This is done to make it softer, in order to engrave or punch upon it. See Tempering, and Engraving. See also Steel.

Nealing is also used for the art or act of burning or baking earthen or other ware in an oven.

The miners at Mendip, when they meet with a rock they cannot cut through, anneal it, by laying on wood and coal, and contriving the fire so that they quit the mine before the operation begins, it being dangerous to enter it again before it be quite cleared of the smoke. Phil. Trans. N. 39. p. 769.

Nealing of Tile is used for ancient statues for the burning of tiles.

The word is formed of the Saxon ondan, ascendere, to light, burn.

Neander, Michael, in Biography, a German physiciain, who was more celebrated, however, for his mathematical knowledge, was born in the year 1520, at Joachimsthal, a town of Mifnia, on the borders of Bohemia. After the usual studies, he received the degree of master of arts at the university of Wittenberg, in 1550. He afterwards settled at Jena, as a teacher of Greek and mathematics, and filled these duties for the space of seven years, during which he also applied himself to the study of medicine; and in 1558 he was admitted to the degree of M.D. Two years after he was appointed professor of medicine in the same university, of which he also twice filled the office of rector. He died in 1581, at the age of fifty-two, leaving behind him several learned publications. The titles of these are, "Synopsis Menfuruarum et Ponderum, &c." 4to. Balle, 1555; "Methodorum in omni genere Artium breves et succinctae," 1556; "Physica, seu Syloge Phylicorum," 1567; "Remonftrance ad omnem Vitam utilium," Partibus Duabus ex principio in Michaelis Neander, 1785 and 1791; "Sphera Elementa, cum Computo Ecclefiastico, &c." Gen. Biol.

Neandria, or Neandrium, in Ancient Geography, a town of the Troade, upon the Hellespont, according to Strabo. The inhabitants of this town were transferred to Alexandria.

Neap, or Neer-Tides, are those tides which happen when the moon is in the middle of the second and fourth quarters.

The neap-tides are low tides, in respect to their opposite, the spring-tides. As the highest of the spring tides is three days after the full or change, so the lowest of the neap is four days before the full or change. On which occasion the seamen say, that it is deep neap. See Tide.

Neaped, when a ship wants water, so that she cannot get out of the harbour, off the ground, or out of the dock; the seamen say, she is watered, or housed.

Neapolis, in Ancient Geography, Naples, a town of Italy. In Campania, upon a gulf to which it has given its name. This town was built by the Cumæans, who called it Neapoli Cumana, or the new Cumæ. This city became municipal, and obtained the privilege of a borough by the Julian law. Strabo says, that in his time many Romans resortd hither to pass a voluptuous life after the manner of the Greeks, whose language they adopted. Alaric, after having sacked Rome, A.D. 498, pillaged before Naples without damaging it, and the same conduct was pursued by Genefeci. Hither the young Augustus retired, when he was dethroned by Odoacer. The town was taken by this prince, and afterwards by Theodoric, who gave it the name of a county. See Naples.—Allo, a town mentioned in the Acts of the Apostles, chap. xvi. v. 11. This was a town of Macedonia, where St. Paul arrived from the island of Samothrace.—Allo, a town in the interior of the Tauric Cherson—
Cheroneus, according to Strabo; but its situation is not ascertained.—Alfo, a town of Caria, placed by Ptolemy between Niarandas and Carysta.—Alfo, a town of Afa Minor, in Ionia, according to Strabo. It was situated N.E. of the isle of Samos, N. of mount Mycale, and S.S.E. of Ephesus. This town belonged to the Samians, who had received it in exchange of the inhabitants of Ephesus.—Alfo, a town of Afa, in Ifauria, according to Suidas, probably the same which Ptolemy places in Phidia.—Alfo, a town of Egypt, in the Thebaid, called alfo Nea, and placed by Herodotus in the vicinity of Chemnis.—Alfo, a town of Africa, now Nabal, situated five leagues S.W. of Curobis. It was near the sea-coast, and seems to have been a considerable place.—Alfo, a name given to one of the ports of Alexandria.—Alfo, a town on the western coast of the island of Sardinia.—Alfo, a town of the Colchide, placed by Ptolemy between Siganem and Acapol. —Alfo, a town of Cyrenaica, placed by Ptolemy between Chareia and Artaim.

NEAPOLITAN DISEASE, a name given by many authors to the venereal disease (see Lues Venerea); and from hence came the name of the Neapolitan ointment, which is a mixture of quicksilver, and other things, into an ointment intended as a cure for it.

NEAR, or Ne Near, at Sen, a word of command from him that comds the ship, to the man at the helm, requiring him to let her fall to leeward. See No nearer.

NEARCHUS, in Biography, one of Alexander's captains, was employed by that conqueror in conducting his fleet of India, by the ocean to the Persian gulf. This expedition proved so tedious and fatiguing, that the leader, on his return, was not recognized by his friends until he had made himself known. His service was so much esteemed, that he was crowned with a garland by Alexander at Sufa, and wherever he went through the camp flowers were thrown upon him. He is reckoned among the historians of Alexander, and is referred to as such by Strabo, Suidas, and Arrian, the latter of whom has copied much from him in his Indica. The relation of his voyage is extant, and is a very curious and valuable piece. It is published among HUDSON'S "Geographi Minoris." Gen. Biog.

NEARD, NHAARD, or Neaard, in Ancient Geography, a town of Afa, on the right bank of the Euphrates, S.E. of Anatho. This, according to Josephus, was one of the most celebrated of the Jewish schools.

NEAT, or Nett-weight, the weight of a commodity alone, clear of the cask, bag, case, and even fifth. See Net, and Weight.

NEAT-Cattle, in Agriculture, a term applied to all sorts of cattle of the cow kind.

NEATH, in Geography, in the hundred of Neath, and county of Glamorgan, South Wales, is a market town, seated in a valley on the eastern bank of a river which gave name to the place, and which is navigable for small vessels. Here was formerly a Roman station, called Nidum. In the reign of king Henry I. a castle was built here by Richard de Granville, or Grauvili, who was lord of Neath, and who is said to have come to this part of the country to cooperate with Robert Fitzhamon and others against Rhys-ap-Tudor. Having subdued this prince, Richard de Granville seems to have letted it here; and from him have sprung the present noble family of Granville.

Neath is a borough by prescription. The corporation consists of a portreeve, twelve aldermen, a recorder, and an indefinite number of burgesses. The portreeve, and the constable of the castle, hold a court of pleas once every month, and a court leet twice a year. Here are likewise held the petty sessions for the hundred, and there is a court of quarter sessions once in twelve months. This is one of the contributory boroughs with Cardiff, which sends one member to parliament. The market days are Wednesday and Thursday in each week. A legacy has been lately left for the endowment of a free school, but it is not yet established. This parish, according to the parliamentary returns of 1811, contained 533 houses, and 2740 inhabitants.

No manufactures of any consequence are carried on within the limits of the borough of Neath, but its vicinity is crowded with iron works, some of which are conducted upon a very extensive scale. Here are likewise several copper works, a large chemical work, and a very productive colliery. The produce of these several establishments is conveyed to Neath and Swansea by means of canals, and from thence shipped to different parts of the kingdom. Much of the copper from Paris mountain in Anglesey is smelted in this neighbourhood; where, enveloped in the cloud of smoke which issues from the numerous furnaces, stands the ruins of Neath Abbey, built by Richard de Granville, in the reign of Henry I. It was dedicated to the Holy Trinity, and filled with monks of the order of St. Sauveur, of France. At this monastery the unfortunate Edward II. sheltered himself, when driven back from Ireland by contrary winds, till he was taken by one of his barons, and confined in the castle of Kenilworth. The remains yet standing are very considerable, and form the north side of a quadrangle. In front of the gates are the arms of England, and of John of Gaunt. At a short distance north from Neath, on the summit of a hill, is the Knoll, a curious curvated seat of the Morkworths. The views from this mansion are peculiarly fine, and the pleasure grounds around are laid out in perfect conformity to the nature of the country in which it is situated. Adjoining to these on the north, at a hamlet called Cwyn-y-Bryn, is a flat expanse of twenty tons weight, which is denominated Arthur's-ystone, but how it became to be so designated is uncertain. At Llychwhir, eight miles distant from Neath, are the remains of a strong castle destroyed by Rhys-ap-Gwilydd, in the year 1215; and about half way on the road to Bridgend is Margam-park, celebrated for its orangery. Here are also some ruins of an ancient abbey founded by Robert, earl of Gloucester, in the year 1177. This abbey, according to the accounts of those who visited it in the last century, must have been, in the time of its prosperity, a very large and magnificent building, and we cannot help deploiring the want of taste, not to say the worse of it, that could defrey this ancient fabric for the sake of using its materials in the construction of the newly erected mansion of Penrice.” In the village of Margam stands a very curious ancient crofs, and in the adjoining field are several inscribed and monumental stones. The following is one of the inscriptions, “Senatus populusque vermanus divo Tito, divi Vespasiani, F. Vespasiano Augusta.” On the north-wet side of a hill, on the left of the village, is a Roman encampment of great extent, and contiguous to this several smaller entrenchments. The summit of the hill is distinguished by a single stone monument called Y-Maen-Llythyrwg, and supposed to be one of the remotest relics of antiquity in Great Britain. It is a massive parallelopiped, fourteen feet in height, and bears an inscription which has been differently read. Near it stands the “Tower,” or heap of stones, supposed to cover the grave of some ancient chief. Cambrian Traveller’s Guide, 8vo. Carlile’s Topographical Dictionary of Wales, 4to. Malkin’s Scenery, Antiquities, &c. of South Wales, 2 vols. 8vo, 1807.
NEATIMERI, a town of Hindoostan, in Travancore; 15 miles E. of Anjengo.

NEB, a river of the Isle of Man, which runs into the sea at Peel town.

NEB, or Nebo, in Ancient Geography, a town of Paleface, in the tribe of Benjamin.

NEBIO, or Nebo, in Geography, a town of the island of Corisco, and the see of a bishop, in ruins; nine miles S.W. of Ballia.

NEBANSKOI, a town of Russia, in the province of Ulling, on the Sola; 24 miles S. of Ut Sisofik.

NEBB, or Nevel, in the Jews' Antiquities, a kind of musical instrument. See Nabulm.

NEBERYBIS, in Geography, a town of Poland, in the palatinate of Kiev; 60 miles S. of Balacerkiew.

NEBIO, a town of European Turkey, in the Morea; 20 miles W. of Misitra.

NEBITAU, a town of Bohemia, in the circle of Pilzen; 22 miles W.N.W. of Pilien.

NEBO, or Nab, in Ancient Geography, a mountain situated N. of the torrent of Amon, between the country of the Amorites, and that of the Moabites. The Israelites, in the 40th year of their Exodus, encamped at the foot of this mountain; and Moses, having executed the commission which he was entrusted, and having pronounced his blessing on the 12 tribes assembled to receive his last charges, ascended this mountain, from the summit of which, called Pisgah, he had a view of the promised land, into which he was not permitted to enter. On this mountain he soon afterwards died. Nebio forms a part of the chain of mountains called Abran.

NEBOUSAN, in Geography, a province of France before the revolution, of which St. Gaudens was the capital; now the department of the Upper Garonne.

NEBRA, a town of Saxony, in Thuringia; 12 miles N.W. of Naumburg. N. lat. 51° 18'. E. long. 11° 45'.

NEBRISIA, in Ancient Geography, Librixia, a town of Spain, in Bocica, towards the north in ascending the river Beuts.

NEBRITES, in Natural History, a name given by the ancients to a bone held sacred to Bacchus. It was of the brownish-yellow colour of the skin of the young fawn, with some variegations, and was semi-pellucid; it seems to have been the same with some of our agates, with a yellow ground; the ancients, however, do not appear to have been very determinate in the accounts of it; for Pliny mentions another kind of it, which was black.

NEBRUS, a name given by the ancients to the humilenus, a deer of one year old. In the next year it is called patahata; in the third, dicraia; and in the fourth, claddi; the word cerafr is used as the name of this animal when of a greater age than this.

NEBSTICH, in Geography, a town of Moravia; nine miles N.E. of Brunn.

NEBULAS, or Nebulae, derived from nebulus, a cloud, signifies, in Surgery, a fluid opacity of the cornea of the eye.

NEBULAE, in Astronomy, a term applied to those fixed stars, which exhibit a dim, hazy light, being less than those of the sixth magnitude; and, therefore, scarcely, or not at all visible to the naked eye, to which, if seen at all, they appear like dusty specks or clouds through telescopes; these nebulous stars plainly appear to be conglomerations or clusters of several small or distant stars. By the skill and ability of Dr. Herchel, and by means of those instruments of great space-penetrating power which he has employed, our knowledge of these nebulae has been very much extended. Of his account of their nature and formation, and of their different variety, we have already given a somewhat detailed account, under the articles Double Stars, Galaxy, and Nebulae. It was our intention to have enlarged this head, and to have transcribed the catalogue of Nebulae, with which he has furnished the astronomer; but finding that we should thus exceed our prescribed limits, we must content ourselves with referring for further particulars to his own account, in the Philosophical Transactions for 1800, 1802, and 1804, as well as to the article Stars, besides those articles that are above cited. We shall here, however, subjoin the following observations in reference to this subject. Nebulae, which on account of their great distance can be seen only by instruments such as we have above described, may probably be all resolved, says Dr. Herchel, into clustering stars, such as are profusely scattered over the galaxy, groups of stars or collections of closely, and almost equally compressed stars, of any figure or outline, and clusters of stars which differ from those last mentioned, in their beautiful and artificial arrangement. Clustering collections of stars may easily be supposed sufficiently removed to present us with the appearance of a nebula of any shape, which, like the real object of which it is a miniature, will seem to be gradually brighter in the middle. Groups of stars also may, by distance, assume the semblance of nebulous patches; and real clusters of stars, for the same reason, when this composition is beyond the reach of our most powerful instruments to resolve them, will appear like round nebulae that are gradually much brighter in the middle. With instruments of high space-penetrating power, such as Herchel's 40-feet telescope, nebulae are the objects that may be perceived at the greatest distance. Clustering collections of stars may easily contain 50,000 of them. See HEAVENS.

NEBULOSA LINSA, in Heraldry. See Line and Nebuly.

NEBULOSITY, Milky, a phenomenon of a very interesting nature, noticed by Dr. Herchel. (See HEAVENS.) This, he says, is probably of two different kinds, one deceptive, or such as arises from widely extended regions of closely connected clustering stars, contiguous to each other, like the collections that construct our milky way; and the other, on the contrary, real, and possibly at no great distance from us. "The changes (says Dr. Herchel,) I have observed in the great milky nebulousness of Orion, 25 years ago, and which have also been noticed by other astronomers, cannot permit us to look upon this phenomenon as arising from immensely distant regions of fixed stars. Even Huygens, the discoverer of it, was already of opinion, that in viewing it, we saw, as it were, through an opening into a region of light. (Systinae Saturninum, p. 8, 9.) Much more would he be convinced now, when changes in its shape and lustre have been seen, that its light is not, like that of the milky way, composed of stars. To attempt even at a guess at what this light may be would be preposterous. If it should be furnised, for instance, that this nebulousness is of the nature of the zodiacal light, we should then be obliged to admit the existence of an effect without its cause. An idea of its phosphorescent condition is not more philosophical, unless we could fly from what source of phosphorescent matter such immeasurable tracts of luminous phenomena could draw their existence, and permanence; for through minute changes have been observed, yet a general resemblance, allowing for the difference of telescopes, is still to be perceived in the great nebulousness of Orion, ever since the time of its first discovery." The nature of nebulous stars is, according to Dr. Herchel, involved in much obscurity. That stars should have visible atmospheres of great extent is surely surprising, unless we attribute to such atmospheres the
NEC

the quality of self-luminous milky nebulosity. Of the flarri nature of the central point we can have no doubt; for its appearance does not differ in any respect from that of a star of an equal magnitude; but when the great distance of such stars is taken into consideration, the real extent of the surrounding nebulosity is truly wonderful. The planetary nebulae (see Heavens) seem to be allied, in Dr. Herschel's opinion, to nebulous stars; and the planetary nebulae with centres seem to be of the same kind.

NEBULY. Nebulae, in Heraldry, when a coat is charged with several little figures, in form of clouds, running within one another; or when the outline of a bordon, ordinary, &c. is indented or waved. See Line, in Heraldry.

NEBUSCHEL, in Geography, a town of Bohemia, in the circle of Bohemia; six miles N.E. of Melnik.

NECAU, a town of Africa, in the country of Bkedulgerid; 150 miles S.E. of Beni-Merzah.

NECacus, a town of Africa, in Algiers; 100 miles S.W. of Constantiople.

NECESSARIANS denote those, who are advocates for the doctrine of philosophical necessity.

NECESSARIO. in the Italian Music. The word is prefixed to certain parts in music, as a due violini necessario, i.e. that must be played by two violins; canto necessario is used to signify much the same as concertante.

Every mode has certain chords, which may be called its necessary, or essential chords.

NECESSARY, in a philosophical sense, that which cannot but be, or cannot be otherwise.

The schoolmen make a great many kinds or divisions hereof: as, necessary in causing: when there is a cause from which an effect must necessarily follow: necessary in predicating: necessary in being, &c.

There is also a logical necessity: physical necessity; and there are metaphysical and moral necessaries: all which it is sufficient to mention.

NECESSITY, what is produced by a necessary cause, or a power that is irresistible.

In this sense necessity stands opposed to liberty.

Necessity is usually confounded with constraint; yet, in effect, necessity, according to Rochebouc, differs from constraint in this, that the former is joined with the pleasure and inclination of the will, to which constraint is contrary.

Simplicius, after Plato and Epictetus, distinguishes two kinds of necessity: the one, natural or operative, which is opposite to liberty; the other spontaneus or voluntary, very conficent with it: this latter, adds he, is that, which necessitates all things conficent with their nature, as being conncntual to them; since, according to them, a thing that is self-moved, must of necessity be moved according to its own nature, i.e. spontaneously. This distinction is admitted by many of the divine, particularly by St. Augustin, who urges it against the Pelagians, as it is shewn by Janfenus.

The schools distinguish a physical necessity, and a moral necessity; and a simple absolute necessity, and a relative one.

Necessity, Physical, is the want of a principle, or of a natural means necessary to act; which is otherwise called a physical or natural impotence.

Necessity, Moral, is only a great difficulty; such as that arising from a long habit, a strong inclination, or violent passion.

Necessity, Simple, or Absolute, is that which has no dependence on any state or conjuncture, or any particular situation of things, but is found everywhere, and in all the circumstances in which the agent can be supposed.

Such is, in a blind man, the necessity he is under of not distinguishing colours.

Necessity, Relative, is that which places a man in a real incapacity of acting or not acting in those circumstances, and that situation he is found in; though in other circumstances, and another state of things, he might act, or not act.

Such, in the opinion of the Jansenists, is the necessity of doing evil in a man, who, with a violent passion, has only a feeble grace to resist it; or the necessity of doing well in a man, who, having grace of seven or eight degrees of strength, has only coniunctive of two or three degrees to withstand.

All these kinds of necessity are opposite to liberty; since, even in the last, it is as impossible for a man to act, or not act, as if he were in a state of absolute, simple, and physical necessity.

The schoolmen admit other species of necessity: antecedent, concomitant, consequent, &c.: antecedent, is that arising from an antecedent cause, necessarily operating; such is the necessity of the sun's rising to-morrow morning: concomitant arises from an antecedent and necessary cause, but depends on the circumstances of the effect; the effect all the while being free. Thus it is necessity Peter fits, supposing he is fitting.

Necessity, Metaphysical or Philosophical, is a term that has been much used by modern writers; and which some have defined to be, that by which a thing cannot but be, or whereby it cannot be otherwise. But much a more approved author on this subject objects against this definition, and observes, that philosophical necessity is really nothing else than the fall and fixed connection between the things signified by the subject and predicate of a proposition, which affirms something to be true; so that it is in no respect different from their certainty. When there is such a connection, then the thing affirmed in the proposition is necessary in a philosophical sense; whether any opposition or contrary effort be supposed or suppressible in the case, or not. When the subject and predicate of the proposition, which affirms the existence of any thing, either substance, quality, act, or circumstance, have a full and certain connection, then the existence of that thing is said to be necessary in a metaphysical sense.

Those that are commonly called Necessarians, allow no other liberty to man, that is not reframed by this kind of necessity: and when they consider intelligent beings as the subjects of it, some of them differ with it in meta physical and natural necessity.

Moral necessity is used in a variety of senses: sometimes for a necessity of moral obligation; and often for great obligation in point of interest; sometimes, by moral necessity is meant that apparent connection of things, which is the ground of moral evidence; and so it is distinguished from absolute necessity, or that sure connection of things, that is a foundation for infallible certainty: and sometimes, by moral necessity is meant that necessity of connection and confederation, which arises from such moral causes as the strength of inclination or motives, and the connection, subsisting in many cases, between these and certain volitions and actions. By natural necessity, as applied to men, they understand such necessity as men are under, through the force of natural causes; in contradiction to those that are called moral causes, such as habits and dispositions of the heart, and moral inducements and motives.

The advocates for the doctrine of necessity maintain, that the will is never determined without a motive, and that motives always influence the will in a definite and invariable
variable manner, so that it is impossible to choose the action A, and its contrary a; the motives or previous circumstances remaining the same. Necessity is essentially different from compulsion, which is external force operating in opposition to judgment or inclination; whereas necessity excludes all foreign control, and allows no influence besides that of motive, as including the bias of the mind as well as the end in view.

The fact contended for by the Necessarians is, that the same volitions certainly and invariably follow the same motives or previous circumstances, and that there can be no change in the volition, but in consequence of a corresponding change in the previous circumstances, that is, in the views or state of the mind. If, they say, definite volitions be the invariable result of definite previous circumstances, there must be some reason for, some cause of this constant conjunction of motive and volition: this cause, known or unknown, is called necessity: and therefore, the word necessity, like the words gravitation, electricity, magnetism, and many others, is a term invented to express the undefined cause of a known effect. It is also said, that the doctrine of necessity, affording simply the constant invariable conjunction of motive with volition, might with equal propriety have been denominated by the less invidious name of certainty. See Cause and Motive.

Mr. Hobbes, who is said to have been the first who understood and maintained the proper doctrine of philosophical necessity, gives the following account of it, in his Leviathan, p. 108. Liberty and necessity are confiuent: as in the water, that hath not the liberty but a necessity of defending in the channel: so likewise in the actions, which men voluntarily do, which, because they proceed from their will, proceed from liberty; and yet, because every act of man’s will, and every desire and inclination, proceedeth from some cause, and that from another cause, in a continual chain (whole first link is in the hand of God, the first of all causes), proceed from necessity: so that to him, who could see the connections of those causes, the necessity of all men’s voluntary actions would appear manifest; and, therefore, God, that feeth and fippothoth all things, feeth also, that the liberty of man, in doing what he will, is accompanied with the necessity of doing that which God will, and no more or less; for though men may do many things, which God does not command, nor is, therefore, the author of them, yet they can have no passion, will, or appetite to any thing, of which appetite God’s will is not the cause: and did not his will allure the necessity of man’s will, and consequently, of all that on man’s will dependeth, the liberty of men would be a contradiction and impediment to the omnipotence and liberty of God.

Mr. Collins, one of the most admired writers on the subject of necessity, has flated the question concerning human liberty in the following manner: man, he says, is a necessary agent, if all his actions are so determined by the causes preceding each action, that not one past action could possibly not have come to pass, or have been otherwise than it hath been; nor one future action can possibly not come to pass, or be otherwise than it shall be. But he is a free agent, if he is able, at any time, under the circumstances and causes he then is, to do different things; or, in other words, if he is not unavoidably determined, in every point of time, by the circumstances he is in, and causes he is under, to do that one thing he does, and not possibly to do any other. According to this state of the question, he undertakes to prove, that man is a necessary agent; and that there neither is, nor can be such thing as liberty.

He appeals to experience; alleging, that though the vulgar urge this in proof of liberty, it is not a proof of it: that many celebrated philosophers and theologers, both ancient and modern, have given definitions of liberty, that are consistent with fate or necessity: that some great patrons of liberty do, by their concessions in this matter, destroy all arguments from experience; that all the actions of men may be ranked under the four heads of perception, judging, willing, and doing as we will; and that experience does not prove any of these to be free; and that experience not only does not prove liberty, but, on the contrary, men may be, by experience, that they are necessary agents. It is, says he, matter of experience, that man is ever determined in his willing: we experience perfect necessity; and they, who think liberty a matter of experience, yet, all-w, that the will follows the judgment of the understanding, and that when two objects are presented to a man’s choice, one whereof appears better than the other, he cannot choose the worst.

This argument from experience or conjunctions, which the Libertarians urge in favour of their scheme with peculiar force, supposes that we never do nor can form a volition, or perform a voluntary motion without an ascribable motive; that the vigour of the action is uniformly proportioned to the vigour of the motive: and that all motives approach to equality, the choice becomes more difficult; whence it is thought reasonable to conclude, that if the motives were perfectly equal no choice could be made. In this connection it is proper to remark, that all the appeals to conjunctions in favour of the doctrine of necessity apply to voluntary operations of the mind, to suspending the choice, comparing, deliberating, and such like, as well as to external actions. See Liberty and Motive.

2. Man is a necessary agent, because all his actions have a beginning; for whatever has a beginning must have a cause, and every cause is a necessary cause: and if any action whatsoever can be done without a cause, then effects and causes have no necessary relation; and, consequently, we should not be necessarily determined in any case at all. Much it has been laid by the Necessarians on the argument deduced from the relation of cause and effect. An ingenious and ardent defender of the doctrine of necessity illustrates this argument by the following observations. Certain consequences are found in fact invariably to follow certain antecedents. The antecedent circumstances are said to be the cause, and the consequents the effect. Philosophers, it is said, who study with attention the phenomena of nature, are better acquainted with antecedent circumstances than ignorant persons, and form a different and more correct judgment of the causes of those phenomena; and the circumstances really previous to the effect, whether known or unknown, are considered as the proper causes of the effect. (See Cause.) The invariable connection between antecedents and consequents gradually produces an affection of ideas so fixed, as to excite a firm, unhesitating expectation of the consequents wherever the antecedents are observed to occur. From the uniform conjunction of antecedents and consequents, we always infer that there must be some sufficient reason for this conjunction; or, in other words, that constant conjunction implies necessary connection, whether we perceive it or not. If the effect produced is different from what we have been used to expect, we immediately conclude that there is some change in the previous circumstances. Definite volitions are found by experience to follow definite states of mind, as invariably as natural phenomena follow their known antecedents. The observation of this fact generates the same unhesitating expectations of definite actions in definite circumstances, as in the case of natural phenomena. Hence
it follows, that upon principles precisely the same with those upon which the reason and judge in the case of natural phenomena, "flucts of mind and motion" may be called "causes," and "volitions," "effects," "necessary connection" may be argued from "confiant conjunction," and a variation in the volition, when the previous circumstances remain precisely the same, is either a "miracle," or an "impossibility." From this kind of reasoning it has been inferred, that liberty of action is impossible, because it implies an "effect without a cause." On the other hand, it has been replied, that a free action is an effect produced by a being who has power and will to produce it; and therefore it is not an effect without a cause. If, indeed, we allow, with the author above cited, and other Necessitarian writers, that a "causal" is justly defined to be "such previous circumstances as are constantly followed by a certain effect," it would follow, that an event not preceded by circumstances that determined it to be what it was, would be, as Dr. Reid says, not an effect without a cause, which is a contradiction in terms, but an event without a cause, which he holds to be impossible. It is necessarly impossible, whether that above above hinted he the only definition that can be given of a cause." For the result of this inquiry, see the article CAUSE.

3. Liberty, says Mr. Collins, would not be a perfection, but an imperfection; whereas, on the contrary, necessity is an advantage and a perfection. It is allowed, however, by an acute and zealous advocate for the doctrine of necessity, to whose statement of the controversy on this subject we often refer, that philosophical liberty, liberty of indifference, or the power of choosing where objects or motives are equal, is a perfection; and that it may exist in the Supreme Being, and that he has in some cases already exercised this liberty. Without it, in certain irrefutable cases, the Deity could not act at all, or must necessarily choose the inferior object when the superior was equally in his view, for want of power to make a choice amongst equals. But this liberty of indifference, it is said, though a perfection, is only a natural attribute, and not a moral excellence. There can be no merit, though there may be great advantage, in a power of choosing out of equal things. Admitting that this is a natural attribute in God, it must obviously follow, that every argument adduced to prove it to be a contradiction, or to imply the existence of an effect without a cause, is fallacious; and that there appears to be no reasonable ground for denying the possibility of its being communicated to the intelligent creatures of God. Nevertheles, the Necessitarians contend, that this possibility, if conceded, will by no means prove that such a power has actually been communicated to any; much less that the possession of it is essential to moral agency and responsibility. On the other hand, it may be strongly and not improperly urged, that, if philosophical liberty be a "communicable perfection," this view of it affords a presumption that the Creator has actually communicated it to his intelligent, moral, and accountable offspring; more especially if it can be evinced from other considerations that so far from being inconsistent with the security and improvement of virtue, it contributes to promote them.

Whether philosophical necessity be a perfection and beneficial or not, is a question which has been very differently determined by Libertarians and Necessitarians; the former contending that it degrades the dignity of man, that it is inconsistent with proper agency, that it annihilates virtue and vice, merit and demerit, that it is inconsistent with moral discipline, and with the justice of reward and punishment, that it confounds natural and moral qualities, both being upon this hypothesis constitutional and unavoidable, that it is an encouragement to vice, by tranquillizing the guilty mind and supererogating all motives we have reason to believe that it differentiates all attempts for the reformation of others, and that it involves predestination and fatalism, checks virtuous exertion and activity, makes God the author of sin, and is inconsistent with his veracity in the declarations and promises, the invitations and threatenings of the Scriptures. Such are the consequences charged on the doctrine of necessity by the Libertarians, whence they conclude, that it is neither an excellence nor a benefit. Whereas the Necessitarians contend, that philosophical liberty confounds the distinction between virtue and vice, that it is dangerous to virtue, by encouraging inexperienced and thoughtless perfons, confiding in a self-determining power, to venture into circumstances of temptation, that it is inconsistent with moral discipline, confounds all moral distinctions, and subverts the foundation of approbation and disapprobation, of praise and blame, of reward and punishment, that it leads to atheism, by fapping the foundation of the principal argument for proving the existence of God, viz. the connection between cause and effect, and that it is inconsistent with all moral perfections of any being, and particularly with the necessary rectitude of God. On the other hand, philosophical necessity, as its advocates maintain, is the only theory which is reconcilable to the existence of virtue and of moral obligation, in connection with the theory of association, of which it is an essential part; it accounts satisfactorily for the phenomena of habit in general, and, in particular, of moral habits, it lays the only proper foundation for moral discipline, and gives meaning and propriety to the judgments which men form, and the language by which they express the merit or demerit of action and character; and, in short, that it is attended with many beneficial practical conclusions.

Mr. Edwards, an acute writer on this subject, has endeavoured to prove, that liberty of indifference is not only not necessary to virtue, but utterly inconsistent with it; and that: all habits and inclinations, whether virtuous or vicious, are inconsistent with the Arminian notions of liberty and moral agency. And Dr. Priestley observes, that the sense of ill-reproach and shame is excited by our finding that there is no disposition of mind leading to vice, and on which motives to virtue, in particular among men, that arises from the consideration of a spectator. If we ask, however, how this comes to pass, that motives to virtue had not a greater influence, we must ultimately ascribe the inefficacy of the one, and the evil tendency of the other, to God, who made us what we are, and placed us in the situation which we occupy. Dr. Priestley overcomes this difficulty by alleging, that the distinction between things natural and moral entirely caeses in the scheme of necessity, that the vices of men come under the class of common evils, producing misery for a time, but like all other evils, in the same great system, ultimately suberving to greater good. In this light, he says, every thing without distinction may be ascribed to God. And hence it has been concluded, that the doctrine of philosophical necessity is inseparably connected with that of omnium. It teaches us to see God in every thing, and every thing in God. However, Dr. Priestley acknowledges, that this is a view of moral evil, which, though innocent and even useful in speculation, no wise man can or would choose to act upon himself, because our understandings are too limited for the application of such a means of good; though a being of infinite knowledge may introduce it with the greatest advantage. If there be any foundation for the doctrine of necessity, i.e. if all events arise from preceding
NECESSITY.

4. Liberty is inconsistent with the divine predestination: for if God foreknows the existence of any thing, as it depends on its own causes, that existence is no less necessary than if it were the effect of his decree; for it no more implies a contradiction, that causes should not produce their effects, than that an event should not come to pass that is decreed by God.

A contingent event, says Mr. Bellam, to whom we have already referred, depending upon the choice of an agent, whose volitions are formed by a self-determining power, independent of motive, having no certain or necessary connection with previous circumstances, must consequently be uncertain till the previous volition, which ordains its existence, actually takes place. Till that infant it either may, or may not, come to pass. Therefore certainly to foreknow a contingent event, which is, in other words, to know that a future contingent event will certainly take place, would be the same as to know that an event, which is in its own nature uncertain, is at the same time certain, that is, to know a thing to be what it is not; which is a contradiction in terms.

The predestination of God, says the same author, excludes the liberty of indifference from all his rational creatures, as well as from mankind: for under the government of God no action is determined virtuous, that is not voluntary, or that does not proceed from some good motive. And this reasoning he applies to the Deity, who purifies the happiness of his creatures by such means as are best calculated to secure that end, and which are sanctioned by it. And he farther adds, that the Deity may adopt some things, which he would not have chosen on their own account, but for the sake of other things, with which they were necessarily connected.

With respect to the practical influence of the different speculative opinions which have been maintained on this subject, Dr. Reid has introduced into the discussion of the controversy following proper remarks. In the present state, we see some who zealously maintain the doctrine of necessity; others who as zealously maintain that of liberty. One would be apt to think, that a practical belief of these contrary sentiments should produce very different conduct in them that hold them; yet we see no such difference in the affairs of common life. The fatalist deliberates, and resolves, and飞行s his faith. He lays down a plan of conduct, and proceeds with vigour and industry. He exerts himself, and commands, and holds those to be answerable for their conduct to whom he hath committed any charge. He blames those that are false or unfaithful to him, as other men do. He perceives dignity and worth in some characters and actions, and in others discourtesy and turpitude. He refrains injuries, and is grateful for good offices. If any man should plead the doctrine of necessity to exculpate murder, theft, or robbery, or even wilful negligence in the discharge of his duty, his judge, though a fatalist, if he had common sense, would laugh at such a plea, and would not allow it even to alleviate the crime. In all such cases, he feels that it would be absurd not to act and judge as those ought to do who believe themselves and other men to be free agents; just as the sceptic, to avoid absurdity, must, when he goes into the world, act and judge like other men who are not sceptics. 1 'If the fatalist be as little influenced by the opinion of necessity in his moral and religious concerns, and in his expectations concerning another world, as he is in the common affairs of life, his speculative opinion will probably do him little hurt. But if he trust too far to the doctrine of necessity, as to indulg e fl eet and inactivity in his duty, and hope to exculpate himself to his maker by that doctrine, let him consider whether he fails in this excuse from his servants and dependents, when they are negligent or unfaithful in what is committed to their charge.

Upon the opinion of necessity considered as influencing practice, we refer to an excellent chapter in the "Analogy" of Bishop Butler.
NECESSITY.

fley acquainted with, will in certain circumstances do; and at an age, with little much less degree of error, may have a farther prospect into men's future actions: so it is very reasonable to apprehend, that God, without influencing men's wills by his power, yet by his foreknowledge cannot but have as much more certain a knowledge of future as free events than either men or angels can possibly have, as the perfection of his nature is greater than that of theirs. The certainty of foreknowledge, says this excellent writer, does not cause the certainty of things, but is itself founded on the reality of their existence; nor does it imply any other certainty than such as would be equally in things, though there was no foreknowledge; nor again does this certainty of event, in any sort, imply necessity. To the same purpose, Origen has long ago observed, that preface is not the cause of things future, but their being future is the cause of God's preface that they will be.

Dr. Reid, in defculling the argument deduced from the preface of God in favour of necessity, observes that the necessity of the event, foreseen by the Deity, may be thought to be of two confequences, either from its being certainly future, or barely from its being foreseen, or from the impossibility of its being foreseen, if it was not necessary. The first mode of representing this argument is proved by the authority of Aristotle, who held the doctrine of liberty, but believing, at the same time, that whatever is certainly future must be necessary, in order to defend the liberty of human actions, maintained, that certain great events have no certain futurity; an opinion which is not maintained by any modern advocate for liberty. It does not follow by any rule of reasoning, that because an event shall certainly be, therefore its production must be necessary. The manner of its production, whether free or necessary, cannot be concluded from the time of its production, whether it be past, present, or future. That it shall be, no more implies that it shall be necessarily, than that it shall be freely produced; for neither present, past, nor future, have any more connection with necessity than they have with freedom. Although it be granted, that from events being foreseen, we may justly conclude that they are certainly future, it does not follow from their being certainly future, that they are necessary. If by the argument above stated it be meant, that an event must be necessary, merely because it is foreseen, this is not a just confequence: for it has often been observed, that preface and knowledge of every kind, being an immanent act, has no effect upon the thing known. Its mode of existence, whether it be free or necessary, is not in the least affected by its being known to be future, any more than by its being known to be past or present. The Deity foresees his own future free actions, but neither his foresight nor his purpose makes them necessary. If the argument be thus understood, it is impossible that an event which is not necessary should be foreseen, and therefore every event that is certainly foreseen must be necessary, it will be requisite before we draw the conclusion to prove, that no free action can be certainly foreseen. With regard to this Dr. Reid observes, 1. That every man, who believes the Deity to be a free agent, must believe that the proposition, so far from being capable of proof, is certainly false. 2. That every man, who believes that it is an absurdity or contradiction that any free action shall be certainly foreseen, must believe, if he would be consistent, either that the Deity is not a free agent, or that he does not foresee his own actions; nor can we foresee that he will do what is right, and will fulfill his promises. Dr. Pricley has taken great pains to prove this proposition, and indeed the neceffarian system very materially depends upon it. As certainly, says this learned writer, as nothing can be known to exist but what does exist; so certainly can nothing be known to arise from what does exist, but what does arise from it, or depend upon it. But, according to the definition of the terms, a contingent event does not depend upon any previous known circumstances, since some other event might have arisen in the same circumstances. Here the thing to be proved, says Dr. Reid, is not that a contingent event cannot be known to arise necessarily from what exists, but that a contingent future event cannot be the object of knowledge. To draw the argument to this conclusion, it must be put thus: Nothing can be known to arise from what does exist, but what arises necessarily from it; but a contingent event does not necessarily arise from what does exist; therefore a contingent event cannot be known to arise from what does exist. In this legitimate conclusion, the first proposition affirms the thing to be proved; and, therefore, the argument is what logicians call "petitio principii." After pointing out some other defects in Dr. Pricley's argument, Dr. Reid suggests the following reflections, with a view of showing that it is not impossible that the future free actions of men may be certainly foreknown. He begins with observing, that as man does not possess this kind of knowledge, we find it difficult to conceive how it can belong to any other being. The preface of the Deity must be different, not only in degree, but in kind, from any knowledge we can attain of futurity. But though we may have no concepion how the future free actions of men may be known by the Deity, this is not a sufficient reason for concluding that they cannot be known. Of the knowledge and operations of the Deity, in other respects, we must be content to confess our ignorance. Can we conceive how we ourselves have certain knowledge by those faculties with which God has endowed us? The analogy that suffices between the preface of future contingents and the memory of past contingents deferves attention. The fact we possess in some degree, and therefore do not hesitate to acknowledge that it may be perfect in the Deity; but the fact we have in no degree, and therefore we are apt to think it impossible. In both, the object of knowledge is neither what presently exists, nor has any necessary connection with what presently exists. Every argument, brought to prove the impossibility of preface, proves, with equal force, the impossibility of memory. If it be true that nothing can be known to arise from what does exist, but what necessarily arises from it, it must be equally true, that nothing can be known to have gone before what does exist, but what must necessarily have gone before it. If it be true that nothing future can be known, unless its necessary cause exist at present, it must be equally true that nothing past can be known, unless something consequent, with which it is necessarily connected, exist at present. If the fatalist should say, that past events are indeed necessarily connected with the present, he will not surely venture to say, that it is by tracing this necessary connection that we remember the past. Why then should we think preface impossible in the Almighty, when he has given us a faculty which bears a strong analogy to it, and which is no less accountable to the human understanding than preface is. It is more reasonable, as well as more agreeable to the sacred writings, to conclude with a pious father of the church: "Quo circa nullo modo cognoscam, aut retentam prestantiam Dei tollere voluntatis arbitrium, aut retentum voluntatis arbitrio. Deum, quod nefas est, negare prestantiam futurorum; sed utrumque amplectimur, utrumque fideliter et veraciter confitemur; illud ut bene credamus; hoc ut bene vivamus." It cannot reasonably be disputed, that there is an essen-
tial difference between the foreknowledge and permission of events, and the preordination and production of them; and the scheme of necessity seems directly to charge God with being the efficient cause or author of those vices and evils, which arise from circumstances and connections of his previous and absolute appointment. Indeed, many of the advocates of this scheme will not admit the consequence that seems to be fairly deductible from their opinion: however, Dr. Priestley very candidly allows it. It certainly (says he) founds harsh to vulgar ears to say, that in all those crimes that men charge themselves with, and reproach themselves for, God is the agent; and that, in such cases, they are in reality no more agents than a sword is an instrument when employed to commit a murder. It does require strength of mind not to startle at such a conclusion; but then it requires nothing but strength of mind; i.e. such a view of things as shall carry us beyond false and fallacious appearances.

When the Libertarians have pleaded, that if the doctrine of necessity be true, they are under a perpetual and unavoidable delusion, inconsistent with the moral perfections of God, because all men believe, and cannot but believe, that they profess liberty of choice; it is answered, that the ideas of men in general extend no farther than to practical liberty, or the power of doing what they please; and that men are led to believe that they could have acted differently in the same circumstances merely by superficial views of human nature. The Necessarians, however, as we have had occasion to notice in the preceding part of this article, allege, that the doctrine of philosophical necessity does not make God the “approver” of evil, nor represent him as choosing it for its own sake; though the libertarian finds it difficult to conceive how the Supreme Being should not approve what he ordains, and that evil, natural and moral, of which he is the author. They indeed suppose, that a certain quantity of evil of both kinds was unavoidable in a system upon the whole most worthy of the Supreme Being, and eventually productive of the greatest good. Whereas the libertarian cannot reconcile his ideas with the wisdom, rectitude, benevolence, and power of the Creator of the world, the establishment of a system, out of which sin and suffering necessarily arise. The advocates for necessity have alleged, and urged with seeming confidence and triumph over the Libertarians, that all these consequences follow from the divine preference which was thought molt alluring in the scheme of necessity: and particularly God’s being the cause of moral evil. For, as they say, if suppoze God to foresee and permit what it was in his power to have prevented is the very same thing, as to suppoze him to will, and directly to cause it. He directly foresees all the actions of a man’s life, and all the consequences of them: if, therefore, he did not think any particular man and his conduct proper for his plan of creation and providence, he certainly would not have introduced him into being at all. In this reasoning, says Dr. Reid, we may observe, that a supposition is made which seems to contradict itself. That all the actions of a particular man should be distinctly foreseen, and, at the same time, that that man should never be brought into existence, seems to be a contradiction; and there is the same contradiction in supposing any action to be distinctly foreseen and yet prevented. For if it be foreseen, w’t shall happen, and if it be prevented, it shall not happen, and therefore could not be foreseen. The knowledge here suppozed is nothing previous nor science, but something very different from both; and called by some metaphysical divines “scientia media,” in order to distinguish it from prevision. (See Scientia Medii.) However, waiving all disputes about “scientia media,” it is acknowledged that nothing can happen under the administration of the Deity, which he does not see fit to permit. The permission of natural and moral evil is a phenomenon which cannot be disputed. To account for this phenomenon under the government of a Being of infinite goodness, justice, wisdom, and power, has, in all ages, been considered as difficult to human reason, whether we embrace the system of liberty, or that of necessity. But, if the difficulty of accounting for this phenomenon upon the system of liberty be as great as it is upon the system of liberty, it can have no weight when used as an argument against liberty. The manner in which the defenders of necessity reconcile their scheme to the principles of theism, has been already stated. Virtue is acceptable to God, and vice displeasing, as the first tends to produce happiness, and the last misery. He is the proper cause and agent of all moral evil as well as good; but it is for a good end, or in order to produce the greater happiness to his creatures. He does evil that good may come, and this end sanctifies the worst actions that contribute to it. All the wickedness of men being the work of God, he will, when he surveys it, pronounce it, as well as his other works, to be very good. "This view of the divine nature, the only one consistent with the scheme of necessity, appears to me," says Dr. Reid, "much more shocking than the permission of evil upon the scheme of liberty." It is said, that it requires only “a strength of mind" to embrace it; to me it seems to require much strength of countenance to profess it. If other moral evils, says this author, may be attributed to the Deity, as the means of promoting general good, why may not false declarations and false promises? And then what ground have we left to believe the truth of what he reveals, or to rely upon what he promises? The defenders of the doctrine of necessity are charged by our author with adopting two hypotheses, the one limiting the moral character of the Deity, and the other limiting his power; and he observes, that if some advocates of liberty, by limiting too rashly the divine preexistence, in order to defend that system, have raised high indignation in their opponents, they have equal ground of indignation against those, who, to defend necessity, limit the moral perfection of the Deity, and his almighty power. Let us suppose, however, that amidst the variety of beings, to whom God has given existence in different gradations of rank and of faculties, man should occupy a certain station, and be endued with that liberty, which the Necessarians allow to be a communicable excellence; and then consider, what consequences may be fairly drawn from God’s permitting the abuse of liberty in those agents on whom he has bestowed it. If it be asked, Why does God permit so much fin in his creation? This is a question which no finite imperfect being can presume to answer, nor can any mortal lay to him, Why doest thou thus? The ingenious and inquisitive may frame hypotheses for solving this difficulty; but whilst we have satisfactory reasons for believing, that the Judge of the earth doeth what is right, it becomes us to acknowledge that the reasons and ends of his universal government are beyond our knowledge, and perhaps beyond the comprehension of human understanding. This kind of diflference is not inconsistent with the character either of a divine or a philosopher. After this general concession, suitable both to our nature and state, we may proceed in our attempts to reconcile the permission of evil with the perfections of the Sovereign of the universe. To permit, it is said, hath two meanings. It signifies not to forbid: and also not to hinder by superior power. In the first sense God never permits sin. His law forbids every moral evil. By his laws and by his government he gives every encouragement to good conduct, and every
NECESSITY.

every discouragement to bad. But he does not always, by his superior power, hinder it from being committed. This is the ground of the accusatior, on the part of the Necessarians: and this, as they say, is the very same thing as directly to will and to cause it. The only moral attributes that can be supposed inconsistent with the permission of sin are either goodnecis or justice. The defenders of necessity muft, it is said, agreeably to their own principles, maintain, that to will and directly to cause sin, much more not to hinder it, is inconsistent with perfect goodnecis: nay, that goodnecis is a sufficient motive to justify the willing and directly causing it. Therefore, the attempt to reconcile the permission of sin with the infinuid of God is altogether unnecessary. If the causiing of moral evil, and being the real author of it, be consistent with perfect goodnecis, there can be no pretence for saying, that not to hinder it is inconsistent with perfect goodnecis. Moreover, what pretence can there be to say, that the permission of sin is perfectly consistent with the Deity, but inconsistent with justice? Is it not as easy to conceive, that he should permit sin, though virtue be his delight, as that he inflicts misery, when his sole delight is to below happiness? Should it appear incredible, that the permission of sin may tend to promote virtue, to them who believe that the infliction of misery is necessary to promote happiness? Of the justice, as well as the goodnecis of God’s moral government of mankind, we have ample evidence in his laws, in his promises, and in all his dispensations. On this part of the subject it is needless now to enlarge.

5. Another argument in favour of necessity is the following: if a man was not a necessary agent, determined by pleasure and pain, there would be no foundation of rewards and punishments, which are the essential supports of society. These would be ufelefs, because if men were free or indifferent to pleasure and pain, they could be no motives to a man to do or forbear any action.

6. Another argument of the fame kind is deduced from the nature of morality: for if a man was not a necessary agent, determined by pleasure and pain, he would have no notion of morality, or motive to practice it; and if he were indifferent to pleasure and pain, he would have no rule to go by, and might never judge, will, and practice right. Every act of the will, it is said, is excited by some motive, which motive is the cause of that act: and if volitions are properly the effect of motives, then they are necessary connected with their motives: whence it is inferred, that volition is necessary, and doth not proceed from any self-determining power in the will. This argument has been illustrated and urged in all its force by many modern writers, from M. Leibnitz to Dr. Priestley, the laft and molt zealous advocate for necessity; and it has often been anfwered by Dr. Clarke and others, who have fireniously maintained, that liberty is perfectly consistent with men’s acting from a regard to motives. See Motive. See also the preceding part of this article.

7. The doctrine of necessity has fewer difficulties and such as are more easy of solution than those which are peculiar to liberty. It supercedes remorse, so far as it is founded on the belief that it was possible in the fame previous circumstances to have acted otherwise. This doctrine counteracts the expectation of the ultimate reformation of all the rational creatures of God to virtue and to happiness, an expectation dear to every virtuous and benevolent mind, and uncontradicted, by either the phenomena of nature, or the declarations of revelation. But this conclusion is not a deduction from the doctrine of necessity exclusively of that of liberty. This theory of necessity, it is said, leems also to connect the complex ideas of praise and blame, reward and pmiishment, and the supposition of intrinsic merit or demerit of actions independent of their consequences. It is moreover afferted, that the objections against the hypothesis of philosophical liberty are much more difficult of solution than those against the doctrine of necessity: and that founded on the precedence of God, already considered, has been selected as an instance.

8. The doctrine of necessity is a direct inference from that of materialism; so that if the power of thinking be the result of a certain modification of matter, and a certain configuration of brain make a soul, man must be a mechanical subject to the law of necessity. But this argument can have no weight with those who do not see reason to embrace the system of materialism; and even with those who do. Dr. Reid conceives it to be a mere sophism.

The scriptures, according to Dr. Priestley, are favourable to the doctrine of necessity; though he does not think that the sacred writers were, strictly speaking, Necessarians, for they were not philosophers: but their habitual devotion led them to refer all things to God, without reflecting on the rigorous meaning of their language; and very probably, had they been interrogated on the subject, they would have appeared not to be apprized of the proper extent of the Necessarian scheme, and would have answered in a manner unfaourable to it. It has been laid by some, that the doctrine of philosophical necessity, if true, ought to be concealed, because it is difficult of comprehension, and liable to abuse. This, however, is not the language of a liberal and found philosophy. Perhaps, in modern times, a greater stress has been laid upon this metaphysical speculation than it deserves; and that it has, in some few cafes, and when not duly understood, been perverted to injurious purposes. Some indeed have said, that its tendency is incendiary, not to be exhibited in public places, as we have seen in this article, repreffed it as peculiarly favourable to perty and virtue. Thofe who adopted it are held up to view as perfons of difiergished penetration, and as constituting a class of philosophers, who occupy a superior rank to the vulgar, and who manifest discriminating powers, and a freedom from prejudice peculiar to themselves, there may be some danger left weak minds should be misled by such representations, and that they may serve to excite and cherish conceit and pride. But we are of opinion, that whether the doctrine be true or false, the investigation of it, with thofe dispositions which ought ever to accompany a becoming fluid of every kind of subject, and more especially of fuch subjects as are immediately connected with our duty and happiness, can do no injury. We are ready to allow with one of its molt zealous advocates, that Necessarians, whatever may be the supposed tendency of their opinions, are not less virtuous, nor worse members of society, nor less attentive to discharge the duties of life, than the loudest declaimers for natural liberty.
the Philosophy of the Mind, &c. 8vo. chap. ix. See Leib- 
nitzian Philosophy, and Liberty.

NECESSITY Fort, in Geography, an American fort situated in the Great Meadow, Virginia, within four miles of the W. branch of Maryland, and on the N. side of the head-water of Red-lone creek, which discharges itself from the E. into the Monongahela, in N. lat. 39° 43'; above 16 miles from the spot where this fort was erected; 238 miles W. by N. from Alexandria, and 258 N.W. of Frederickburg. This post deferves notice as it was the first scene on which general Washington displayed his abilities as a commander. In 1753 this gallant officer, in the 22d year of his age, being then a colonel, having the command of 300 men, defeated the French, and when M. de Vildere sent a force, amounting to 900 men besides Indians, Washington, in this uninitiated fort, with his small body of troops, defended himself so well as to contrain the French officer to grant him honourable terms of capitulation.

NECESSITY, in Law, is one of the causes that occasions a defect of will. See Will.

NECESSITY, Homicide by. See Homicide.

NECHANETZ, in Geography, a town of Bohemia, in the circle of Koniggratz; eight miles W. of Konig- 
gratz.

NECK, the part or point of an animal to which the head 
is attached. In the horse it should be neat, thin, and have but little flesh upon it. To be well shaped it should, at its growing from the withers, rise with a slope upwards, dimin- 
hishing by degrees toward the head. In mares, it is sup- 
pofed by force a good quality to have their necks somewhat 
grofs, and charged with flesh, as they are generally too fine 
and slender.

The neck contributes much to the making a horse light 
or heavy on the hand, according as it is fine and well-shaped 
or coarse. And in horses as well as cattle it is of much con- 
sequence to have the neck falling well into the shoulder.

NECK. The parts composing this division of the body 
are described in various articles of the Cyclopædia. The principal bulk of the neck is made up of the cervical vertebrae, covered by numerous muscles concerned in moving the head bones, in the motions of the head and of the shoulder. The pharynx and esophagus lie in contact with the front of the vertebral column, and the larynx and trachea in front of 
thefe. The anterior part of the thyroid cartilage makes that 
remarkable prominence in the neck of the male, called the 
ponum Adam. The large blood-vessels of the head pass 
through the neck on the front of the spine, and fome im- 
portant nerves take nearly the fame course. The organs just 
enumerated, connected rather loosely to each other by cell- 
ular subftance, and surrounded by the integuments, compose 
the neck. See SPINE, LARYNX, PHARYNX, ESOPHAGUS, 
&c.

NECK, Derby. See BRONCHOECELL.

NECK, Deformity of. See WHYNCK.

NECK, Dislocation of. See LUXATION.

NECK, Wounds of. See WOUNDS.

NECKS, the, of quadrupeds. Dr. Derham observes, are al- 
ways equal to the length of their legs: this is contrived by 
nature, to enable them to reach the ground for their food 
without dropping the body.

Indeed the elephant is an exception from the rule; its neck 
is very short; but then it has a peculiar provision by a pro- 
bofe or trunk.

Another thing remarkable in the necks of graminiferous 
quadrupeds is a strong, tendinous, and inelastic aponeurosis, 
or ligament, braced from the head to the middle of the back; 
by means of which they are enabled constantly to hold down 
the head, though very heavy, to gather their food without 
pain or labour.

NECKS, the, of birds, are longer than those of any other 
animal; and longer in such as have long legs than in those 
that have short, either for gathering up their meat from the 
ground, or forking their prey in the water, except in web- 
footed fowl, which are, by reverting their bodies, defined 
to search for food, at the bottom of waters: birds, and 
especially thofe that have long necks, have the power of re- 
tracting, fending, or stretching them out in order to change 
their centre of gravity, from their legs to their wings. See 
Anatomy of Birds.

NECK Verfs, the Latin sentence, Misere re mi Deus, was 
thus called, because the reading of it was made a test, by 
which to delfinguish those who, in prefebution of law, were 
qualified in point of learning, and admissible to benefit of 
clergy: but this ground of distinction was let ubide by 5 Ann. 
cap. 6. See CLEVER.

NECK, in the Manege. See CARRYING.

NECK of the cafedel, in Artillery, is that part between 
the breech mouldings and the cæfadel.

NECKAR, in Geography, a river of Germany, which 
rites in the Black Forell, and joins the Rhine at Manheim.

NECKER, JAMES, in Biography, a flatesman and 
financier, who acted a very distinguished part during the early 
part of the French revolution, was born at Geneva, in the 
year 1732, where his father was professor of the civil law in 
the college. He received a good education, and when he 
was in his fiftenth year he was sent to Paris, where he was 
employed, fiit in the banking-house of Vernet, and then in 
that of Theloffon. Such were the ability and affinitj 
which he displayed in this station, that he rote rather hali- 
y to the poft of fiit caflher, and afterwards to be a partner in 
the house. His speculations turned out highly advantageous 
for the concern, and he accumulated a fortune in a very short 
time. Upon the death of Theloffon he established a bank of 
his own, in partnership with Girardot and Haller, the fon 
of the great Haller. His reputation for financial knowledge 
canted him, in 1776, when the French finances were in a 
difordercd state, to be appointed director, and foon after 
comptroller-general of that department of state. He had, 
in the preceding reign, been flected as the proper perfon to 
adjut fome differences fubfifting between the East India 
company and the crown, and had discharged his trust with 
such rare defcretion as to challenge the approbation of both 
parties. At the period we are now speaking of he was pro- 
fessed of the moft distinguished and acknowledged prudence, 
that his appointment would have excited no surprize, had 
it not been the constant policy of the court of France care- 
fully to exclude aliens from the country, and established 
faith, from the control of their revenue. This, therefore, was 
an influence of enlargement of mind and liberality of sentiment, 
that has been frequently held up to mark the prominent fea- 
tures of the reign of Lewis XVI. Necker was in fact the 
first Protestant, since the revocation of the edict of Nantes, 
who had held any important place in the French administra- 
tion. Economy and regularity were the leading points of 
this gentleman's financial government. He suppressed many 
unclefs offices, abolished provincial assemblies, and refurred 
public credit, though his enemies afcrinted that his reforms, or 
rather pretended reforms, were made at the expense of un- 
provocative laws, which left a great additional burden on the 
flate. Whether his meafures were really wise and fiit, or 
merely fpecious, may perhaps be matter of dispute, but it 
cannot be denied that his intentions were pure, and his con- 
duct
NECKER.

duct disinterested. He refused all emolument for his services, and advanced a large sum to government from his private property, which he never drew from the public funds. His administration was generally popular, but in proportion to the regard and attachment of the people, his enemies at court increased, and after having filled the office of minister of finance for five years, he resigned. Previously to this he had published his "Compte Rendu," which was a statement of what he had done in the financial department, and what were his views of this important branch of public policy. It was written to intertell the feelings, and had a conciliatory effect upon the public mind. This was followed by a work entitled "De l'Administration des Finances," which treated the subject more at large, and which was read and circulated with great avidity, and it had, unquestionably, a powerful influence in exciting the popular attention to matters of government. When M. Calonne was appointed to the office which Necker resigned, he made an attack, before the assembly of Notables, upon the veracity of Necker's statements. The latter drew up a reply, which he transmitted to the king, who intimated that if he would forbear making it public, he should shortly be restored to his place. This he refused, and appealed to the nation by publishing his defence, which was so displeasing to the court, that he was exiled to his country seat at St. Ouen, at the distance of 120 miles from the capital. During his retreat from the busy world he wrote his work entitled "De l' Importance des Opinions Religieuses," in which he speaks of religion like one who felt its power operating on his own mind, and who was fully convinced of its importance both to individuals and society. When the boisterous exertions of Calonne had only augmented the deficiencies of the revenue, and the insufficiency of the resources, Brest had become notorious, nothing was left to the court but to recall Necker, whose diminution and banishment had rendered him more popular, and whose virtues had confirmed the confidence which his talents had inspired. It was in August 1788 that this gentleman was reinstated in his former post, to the apparent satisfaction of the court, as well as to the real joy of the people. If the talents of this great man had been severely exercised amidst a war which agitated almost the whole of Europe, when he occupied the post of controller-general, his situation was not less delicate and arduous, when on the eve of civil commotions he was again called to direct the finances of France. At this time the nation groaned under a debt of more than two hundred millions sterling, which even twenty-five years ago was thought sufficient to overwhelm any nation, though now we, in this country, can contemplate a debt of three times its magnitude without alarm or apprehension. The acclamations which welcomed monseigneur Necker to the capital could not but distress his mind, the difficulties with which he had to struggle. He was aware that de Calonne and the archbishop of Sens had both sunk under the public distrust, and the impracticability of raising the necessary supplies; and he well knew that the evil was not diminished, and unless some expedient could be hit on to re-establish public credit, he foresaw his own fate must be similar to that of his predecessor. His first intentions were to recall the banished members of the parliament of Paris, and to re-establish that body to its functions; to replenish the treasury, which he found almost empty; and to relieve the necessity of corn under which the kingdom, and the capital in particular, then laboured. His next plan was the conversation of the States-General, which had been already promised by the king, and which, in fact, proved the immediate forerunner of the revolution. Necker was particularly blamed by his adversaries, who were watching for an opportunity of reproaching his conduct, for having confounded that the number of members of the Tiéres État should be equal to that of the nobles and clergy united. It was soon foreseen by those who considered with attention the situation of the two parties, that the nobility and clergy would, to preserve their influence, urge their claim to vote by orders, while the representatives of the great mass of the people would be equally furious that every question should be decided by a phalanx of voices. At the opening of the States, Necker delivered an elaborate speech, in which it was his misfortune to be deficient in pleasing both parties, and of consequence he obtained the permanent confidence of neither; the exclusive rights of the multitude still attended him, but several of the deputies of the Tiéres État, as the representatives of the people were denominated, regarded already with suspicion the minister who represented the meeting of the States General, merely as the effect of royal grace, instead of a constitutional right. They were still less satisfied with the system to which he inclined, viz. to decide every question by a majority of orders, instead of voices, while the clergy and nobles recollected with indignation, that his counsels had already shaken their former superiority, and had swelled the commons to an equality, in number, with the other two states. After this he proposed a royal sitting, and drew up a plan of government to be recommended by the king in a speech, which underwent so many alterations as to displease the minister who wrote it, and who accordingly signified his disapprobation by his absence when it was delivered. In the course of events, the king was persuaded to reéstablish the increasing claims of the popular party, and he determined upon the assembling of troops round the cities of Paris and Versailles; this was the signal for the dismission of Necker, who had raised his voice in the most resolute tone against these measures. On the eleventh of July 1789, a sudden order was brought him, while sitting at table with company, that he should quit the kingdom within twenty-four hours. The manner in which he submitted to this decree fully acquismed him of any wish to raise a commotion on his own account. Pretending a sudden indisposition, he retired from company after dinner, took a post-chaise, and with his wife drove first to his country seat, and from thence to Brussels, with all possible expedition. As soon as his dismission was known, the whole city was in a flame. The destruction of that fortress of despotism, the Bastille, soon followed; and such symptoms of popular fury appeared that the king was glad to lend an express urging his return, with even greater celerity than he had censured his banishment. This overtook him at Bafl, which he had been first apprized of the revolutionary events at Paris. He determined upon compliance with the invitation, and his return was a scene of triumph, familiar, it was said, to that of Cicero from his banishment. On his approach to the capital he was hailed by the enthusiastic shouts of the people, and his entrance into Paris was regarded as a day of public rejoicing. An immense concourse of people pressed to meet him, a numerous guard conducted him with military honours through the city; the air resounded with acclamations of "Long live the Nation! Long live Necker." Every house was illuminated, but it was said that those perors were most distinguished by their demonstrations of joy who had most largely profited by the loans of the minister. The plaudits of the multitude are never of very long duration, and the popularity of Necker had reached its summit, and it was coerced now to decline. As a minister of finance he was obliged to propose expedients which of necessity were galling to the people, and his feelings with respect to the principles of government were far remote from those which now began to be avowed by the popular leaders, and he soon became, in the
the eyes of the revolutionists, an aristocrat, and, as violence predominated, his personal safety was endangered. Mortified, and perhaps alarmed, at the loss of his influence, and at the symptoms of discontent which began to manifest themselves strongly against almost all his measures, he desired to resign, offering to leave, as pledges for his integrity, the money which he had advanced to government, viz. about 80,000l. fleering, and his house and furniture. His resignation was accepted with much fang-froid, and he left Paris with the poignant reflexions of a man, certainly unequal to the duties which he had undertaken, and who had seen that popularity fade away which had supported him in his former trials. In this retreat he was more than once infurited by the very people who, but a few months before, had hailed him as their favourite. He might well exclaim "My happiness has been of very short duration." Gibbon, who passed four days with him at this period, says, "I could have wished to have exhibited him as a warning to any aspiring youth poftessed with the demon of ambition. With all the means of private happiness in his power, he is the most miserable of human beings; the past, the present, and the future, are equally odious to him. When I suggested some domestic amusements, he answered, with a deep tone of despair, 'in the state in which I am, I can feel nothing but the blast which has overthrown me.'" Shortly after this, his mind was diverted from public disappointment by the more poignant grief of domestic calamity; his wife died, after a long illness, in which he had attended her with the most affectionate fidelity. He now recalled the native energies of his mind, and had recourse to his favourite occupation of writing, and several works of different kinds were the product of his solitary hours. His principal pieces are entitled "Sur l'Administration de M. Necker, par lui-même," "Réflexions, &c." which were intended to benedict the king during his captivity and trial: "Du Pouvoir Exécutif," being an essay that contained his own ideas on the executive part of government: "Dernières Vués de Politiques, et de Finance," of which the chief object was to diffuse what was the best form of government France was capable of receiving. Besides the above, he published a "Courte de Religious Morality," and a novel, written at the suggestion of his daughter, entitled "The Fatal Consequences of a Single Fault." Though deprived of three-fourths of his fortune, he had sufficient for all his wants, and able to indulge his benevolent disposition. He had been placed on the list of emigrants, but the directory unanimously erased his name, and when the French army entered Swifferland, he was treated by the generals with every mark of respect. His talents and conduct have been alike the subject of dispute; but it may be affirmed that though unfit for the florid scenes of a revolution, he would have been eminently great in common times. Though, for a time, overwhelmed with the shock that lurked from the pinnacle of greatness, he spent the latter years of his life, in the rational pursuits of a philosopher and man of sound judgment and true taste. His only daughter, who married the baron de Stael, ambassador from Sweden to France, has made herself known to the literary world by several publications, particularly by "Memoires de the Character and Private Life of her Father," written in a high style of panegyric; and of a novel entitled "Delphine," in which she has inferred her desire of working strongly on the feelings, to overpower, in a great measure, the true notions of good taste and morality. New Ann. Railp. History of the Fr. Rev. by Rabaud de St. Etienne. Hist. of France, 1790.

NECKER'S ISLAND, in Geography, one of the smaller Virgin islands, near the N. coast of Virgin Gorda.

NECKER'S ISLE, a small island in the Pacific ocean, consisting of an almost barren rock about 500 toises in length and 65 in height, without a single tree, but having on it a good deal of graps. M. La Peroufe points it out to navigators, that they may avoid the danger of approaching it: within a space of ten miles from it, no other ground was found besides coral and broken shells. N. lat. 23° 31'. W. long. 164° 32'.

NECKER ISLANDS, a cluster of nine small islands or rocks in the North Pacific ocean, on the W. coast of America, about a league off Cape Blasen; so called by La Peroufe. N. lat. 42° 58' 56". W. long. 124° 45' 20'.

NECKERIA, in Botany, received its name from Hedwig, "in memory of the most eminent oppofer of the doctrine of the sexual propagation of mosses, to whom nevertheless botany is not a little indebted." This was Dr. Natalis Joseph de Necker, botanist to the Elector Palatine, who was born in 1730 and died in 1793. He published a Linnesean Flora of French Flanders in 1768; Methodus Myurorum in 1771; Physiologia Myurorum in 1774; Elementa Botanica, teaching the principles of natural arrangement, in 1790; and some other works. We have sufficiently noticed his determined opposition to the fexes of mosses; see Musci. He also extended his difbelief to other plants, in some measure confounding, like many other writers, their increase by roots or buds, with sexual propagation, as in Lema and Scopelium tectorum. He even contended that the seeds of Hemp and Mercury were perfected without impregnation; but this is refuted by Linnaeus, who proves that no seeds of Hemp are formed, unless the suddenly withered stigma flows it to have been acted upon by the pollen. When the vitality of the part is exhausted, by the accomplishment of its natural purpose, it dies. (See FEUORIZATION OF PLANTS.) The name in question was originally written, as it ought, Neckeria; but the accidental or designed alteration, in Hedwig's great work, has now universally prevailed.—Hedw. Fund. v. 2. 93. t. 8. f. 47—50. Crypt. v. 3. 38—55. Sp. Musc. 200. Schreb. 762. Mart. Mill. Dief. v. 3. Sm. Fl. Brit. 1727. Turn. Musc. Hib. 101. Sibth. 304. Michaux Boreal-Amer. v. 2. 307.—Clafa and order, Cryptogarum Maijfi Nat Ord. Mufci. Eff. Cl. Capsule oblong, from a lateral scaly sheath. Outer fringe of sixteen acute teeth; inner of as many intermediate thread-shaped teeth. Veil smooth.

The habit of Neckeria is like that of Hypnum, under which genus fome of its species have been described by Linnaeus; but still nearer to Fontinalis in the shortness of the fruit-halk. Accordingly several of the species, more recently discovered, have been referred to the latter genus. (See HYNUM and FONTINALIS.) Neckeria differs, in essential character, from both in its inner fringe, which consists of dilated and separate leaves or bristles; not combined by a membranous base, as in the former; nor connected by transverse lattice-work, as in the latter. Sixteen species are described in the Species Myurorum of Hedwig, five of which are British. They are diploid in two sections, and these are each subdivided into two more; according as the leaves are two-ranked or scattered.

Section 1. Fruit-halk shorter than the capsule.

In this section seven of Hedwig's species have the frum irregularly branched; and three of these the leaves elegantly diploid in two ranks, making a flat feather-like figure; which from their polish and transparency, and especially from the crisp or corrugated nature of the fpecies, affords a beautiful spectacle. An example of this is N. pennata. Hedw. Crypt. v. 3. 47. t. 19. (Fontinalis pennata; Linn. Sp. Fl. 1571. Ehrh. Crypt. 13. Sphagnum
num pennatum undulatum, vaginæ quamosa; Dill. Mufc. 250. t. 32. f. 9. Mucoseris terresris major, &c.; Vaill. Par. t. 27. f. 4.—Stem thread-shaped, decumbent, branched. Branches somewhat compound. Leaves imbricated, two-ranked, lanceolate, corrugated, with an oblique point. Capsule immersed in the sheath.—Native of trunks of trees, in Sweden, Switzerland, France and various parts of Germany, but not in England. Grew it however from the Capsule of Good Hope, as well as from Nova Scotia, and the west coast of North America, gathered by Mr. Menzies, so that it appears to be widely dispersed over the globe. This moss is perennial, ripening the capsules in spring. The flars are three or four inches long, with numerous unequal taper-pointed branches, lying flat over each other, all thickly bevet with leaves spreading likewise in two ranks. Each leaf has three or four transverse plats towards the end, but no ribs, veins, nor ferratures. The whole is of a light shining green. Capsules light brown, lateral, axillary, solitary, on very short stalks, enveloped by the numerous lanceolate, taper-pointed, scales of the sheath, which extend considerably beyond the top of each capsule. Lid convex, with a sharply curved point, about half as long as the capsule. Fringe pale and delicate. Veil slender, reddish.

N. difficile. Lateral Neckera. Hedw. Crypt. v. 3. t. 22; and undulata, t. 21; two West Indian species, have blunter foliage, with petacous scales to the sheath, but otherwise they have much of the aspect of the above. The leaves in the form of Gerey even in the latter transversely corrugated. —N. globula, Sw. Ind. Oec. 1753, (Lejeux globella, Hedw. Sp. Mufc. t. 59. f. 1—5.) a native of Jamaica, requires to be here added.

Among those with scattered leaves is N. kternor. Lateral Neckera. Hedw. Crypt. v. 3. 38. t. 15. Engl. Bot. t. 1180. (Sphagnum arborescens; Linn. Sp. Pl. 1570. Hudf. 465. S. heteromallum polycephalum; Dill. Mufc. 248. t. 32. f. 6. Fontinalis secunda; Linn. Meth. Mufc. 30. Dickl. Dr. Pl. 183.) Stem branched, diffuse. Leaves ovate, concave, imbricated every way. Capsules turned to one side. Native of England and Ireland, but, as far as has hitherto been observed, of no other country. Sherard first found it at Bedfordton, Gloucestershire. This grows in tufts closely pressed to the trunks of trees, and is not uncommon in Norfolk. The flars are about 1 inch long, diffuse, rigid, with pinnate branches, thickly clothed with small, dull-green, ovate, concave, acute, single-ribbed leaves, imbricated every way. Capsules at the end of short lateral branches, all leaning one way, over-topped by the leaves of their sheaths, which are lanceolate and taper-pointed. Lid conical, acute, erect. Veil torn at the margin.

The rest of this division are N. filiformis, Hedw. Crypt. v. 3. t. 16; hypnoides, t. 17; composita, Hedw. Sp. Mufc. 203. t. 46. f. 8—13; and filicina, Hedw. Crypt. v. 3. t. 18; all West Indian mutes, discovered by Dr. Swartz. The last has an erect habit, with a naked stem, like a little tree. Their discoverer adds another in his Fl. Ind. Oec. 1704, by the name of polytrichoides. (Hypnum, Hedw. Sp. Mufc. t. 61.) but suspects it, as well as the third last, having hairy veins, may belong to some other genus, perhaps Orthotrichum. Thus we are able to followed.

Section 2. Fruit-flalk longer than the capsule. Six of this section have two-ranked leaves; and two have scattered ones. Among the former are

N. pulula. Small Feathery Neckera. Hedw. Crypt. v. 3. 49. t. 20. Engl. Bot. t. 1443. (Hypnum pennatulum; Dickl. Crypt. fac. 1. 5. t. 1. 8. H. Sicc. fac. t. 22. Fontinalis pennata; Hudf. 408, excluding the fynonyms.) —Branches pinnate. Leaves two-ranked, ovate, obliquely pointed, transversely corrugated. Fruit-flalk scarcely longer than the sheath. Native of trunks of trees in WiltmoreLand, Suffex and Scotland, nor has it been observed in any other country. No wonder that this moss was mid-kens by Mr. HUDSON for the first species, or Fontinalis pennata of Linnæus. None but himself had ever gathered it, till the writer of this, by a diligent search, in the summer of 1782, found it on trees near Ambleside, as indicated in the Fl. Angl. but without capsules. These Mr. Dickson met with in Suffolk, and gave, as we believe, to Mr. Lightfoot. They decided the character between the present plant and pennata, and Hedwig's work estabhlished the species. The habits of the two plants are much alike, but this is smaller and less strikingly beautiful; the leaves are more ovate; and the fruit-flalk is about as long, sometimes longer, than the close tapering sheath, being twice or thrice the length of its capsule. The teeth of the inner fring, in both these species, are very slender, and but half the length of the outer.

N. crispa. Crisped Neckera. Hedw. Sp. Mufc. 206. Sm. Fl. Brit. 1273. (Hypnum crispm; Linn. Sp. Pl. 1589. Engl. Bot. t. 617. H. pennatum, undulatum crispm, setis et capulis brevibus; Dill. Mufc. 273. t. 36. f. 12.)—Branches pinnate. Leaves two-ranked, oblong, transversely corrugated. Fruit-flalk twice the length of the sheath.—Native of chalky or lime-lime countries, in dry woods, very abundant, bearing large capsules in April. The writer of this, by a diligent search, in the summer of 1782, discovered it on the roadside of British mosses. The branched flars, leafy throughout, lie over each other in thick elastic horizontal mutes, and are excellent for package. The capsules are not constantly produced, but when they do occur are abundant, springing from axillary tapering close sheaths, which their italks greatly exceed in length, especially when the capsule is fully ripe.

N. planifolia. Knobbed Neckera. Hedw. Sp. Mufc. t. 48. f. 1—3, and maragoda, Hedw. Crypt. v. 3. t. 235; natives of the South sea islands; with eladorbicans, Hedw. Sp. Mufc. t. 47. f. 1—7, and pedicellata f. 8—13; discovered by the Rev. Dr. Moungen. near Lancaster, in Pennsylvania; are the only remaining species of this section deferbed with two-ranked leaves, which character however their figures hardly express, nor do we find it in our specimens, at least of the latter.

Those of this second section with leaves imbricated in every direction, are only two in Hedwig, both of British growth of plants.

NEC

Mufc. 307. t. 39. f. 43.)—Stem creeping. Branches erect, cylindrical. Leaves lanceolate, imbricated, spreading, flatly turned to one side. Capsules erect.—Found about the roots of trees, in old dry woods, throughout Europe, bearing fruit plentifully enough in the spring. The wiry creeping
flax throw up numerous, erect, crowded, level-topped, simple or divided branches, thickly clothed with dark-green or yellowish leaves, which though imbricated every way, are curved toward one side. Fruit-flakls an inch or more in length, from very short 
flachs. Capsule erect, cylindrical.

Three new species have been added to this genus by Mr. W. Hooper, in his paper on the Mooses found by Dr. Buchanan in Nepal. These are
N. fischeriana, Hooper Tr. of Linn. Soc. v. 9. 312. t. 27. f. 1—Stem pinnate, with short branches. Leaves ovate, pointed, single-ribbed at the base. Capsules nearly seseible, almost globular, turned one way.—On trees at Kargoo in Nepal, bearing fruit in March. Nearly akin to N. betronalia, next to which it ought to be inferred; but the more lax and spreading habit, and especially the spherical capsule, unlike every other known Neckera, distinguih it.

N. flowensf. ibid. 314. t. 27. f. 2.—Stem erect, pinnate. Branches mostly simple. Leaves ovate, ribbed. Capsule cylindrical, erect. Lid awl-shaped.—Gathered at Narain betty. This forms silky tufts of a tawny yellow. It belongs to the last section of the genus, along with curvil-gendula and vitisiciola; but differs widely from both in its fine, crowded branches; from the former in its long capillary fruit-flakls; from the latter in its still more slender capsules, and leaves not turned to one side.

N. tenus. ibid. 315. t. 27. f. 3.—Stem doubly pinnate. Leaves imbricated, serrated; those of the stem roundish—heart-shaped, with two furrows at the base. Capsule erect. Lid incurved.—Gathered at Narain betty in January. This belongs to the same division as the lat, with which it agrees in colour, but its habit, and growth in broad dense silky tufts, is like some of the feathery species of Hyphnum. Besides the marks indicated in the specific characters, the long dark capillary fruit-flakls, and turgid capsules, are peculiar. S.

NECKERHAUSEN, in Geography, a town of the duchy of Baden; five miles E. of Mannheim.

NECKHAM, Alexander, in Biography, an English abbot, who flourished in the thirteenth century, was born at St. Alban's in Hertfordshire. He had imbued a very early inclination for acquiring knowledge, and that he might indulge it, he embraced the religious life among the canons regular of the order of St. Augustine. He profected his studies with great earnestness not only in his native country, but on the continent, and directed his mind to all the various branches of learning and science then known. He became, in the elimation of the age in which he lived, an excellent divine, an able philosopher, an accomplished orator, and an elegant poet. In 1215 he was elected abbot of the monastery of Cirencester, where he died three years afterwards. He was author of "Commentaries" on Ecclesiaeftes, the Song of Songs, the Psalms, and the creed of Athanasius, and of other theological and moral pieces; of which a lift is given in Lelandi Comment. de Scrip. Brit.

NEKBIL—el-sherif, in Egypt, the head of the sherif, or relations of Mahomet, who has the great cognizance of their actions, and the power of inflicting punishments upon them.

In Arabia, Nekeb denotes an officer of inferior decent, some of whom had been slaves in their youth. This title is the highest which 1 man can confer; and it differs from that of Scheich, which is a title that can only come by de-

fent, and is peculiar to sovereign princes and independent lords.

NECKLACE Snake. See Snake.

NECROLOGY, NECROMANCY, formed of neskog, dead, and moraica, incantation or divination, the art or act of communicating with devils, and doing surprizing feats by their afflance; particularly of calling up the dead, and extorting answers from them. See Magic.

NECROSIS, in Medicine, from neskog, dead, is properly synonymous with the term mortification; but it has been applied by Sauvages, and some other writers, to that disease which has been called dry gangrene, mal des ardens, St. Anthony's fire, &c.; namely, the ignis facer of Lucretius and the ancients, and the ergot, &c. of the moderns. This disease, which terminated in the mortification and dropping off of the limbs, after they had been converted into a dry and mummy-like flate, originated from starruation, but has been supposed to arise from poisonous vegetables taken with the food, and not from its deficiency.

Sauvages makes three species of necrosis, which are varieties of the same affection: viz. 1. Necrosis plantaginis, the ergot, as described by the French academicians; 2. N. à vina, the "gangrene deche" of Quesnay; and, 3. N. febrilis, which appears to have been the endemic desribed by the professors of Marpurj, and other German writers, under the appellation of Krzel Krankheit. See Sauvages, NofoL Method. Clas. x. Gen. 39. See also Ergot, Ignis Sacer, Kriebel Krankheit, and Raphania.

Necrosis denotes, in Surgery, the death, or mortification of a part, or the whole of a bone. The term is derived from the Greek verb neskog, to dry or.

Were any rude and uninstructed person to take a hasty view of the bones of the human body, he might easily fall into the error of fancying them to be a mere mass of flony, unorganised, lifeless matter; while to others, who have attentionfully studied the flrst formation of these parts, their increase, their decrasons, and their states both in health and disease, it is a most certain and manifest truth, that the bones, as well as the soft parts, are endued with vitality.

In the earliest period of their growth, as the celebrated Weidmann takes occasion to observe, we may admire the principle of life, by which their first rudiments are begun, and what now exhibits the appearance of a soft gelatinous kind of matter gradually changes into cartilages and membranes, in the middle of which the flenser specks of ossification arise, and increasing in length, breadth, and thickness, at last acquire, in an inexplicable manner, a fixed and durable external form and internal structure.

In their cavities, interlaces, canals, cells, &c. there are various fluids, contained in proper vesicles and receptacles; either blood, lymph, or marrow. These are not liable to putrefy from being stagnant, but undergo a continual renovation, being spots derived from the common mass of the circulation, and afterwards carried back into it again.

But what most still more excite our admiration of nature, is the fact, that even those earthly elements, which give strength and compactness to the bones, do not last without any mutation, but have a particular circulation of their own, and whenever a part of the carthy matter is lofd, from causes not
not necessary for us to particularise here, it is well known to admit of regeneration.

The bones, being then endowed with vitality, must be liable to be acted upon by a variety of stimulating causes, and to become affected with inflammation.

Should the exciting cause of the inflammation continue to operate, the soft parts also inflame and suppurate.

When the inflammation and suppuration are confined to the surface of the bone, the pericement being detached, without, however, any deeper injury of the structure of the bone, or the inflammation extending far internally, writers term the disease _exsudatio officis_, which differs from _denudation_, inasmuch as the latter is caused by external violence, while the former always arises from preceding inflammation.

When the inflammation affects the bone more deeply, and excavations are formed in it, in consequence of its elementary parts having been absorbed, the disorder is named by Latin writers _caries_, by the Greeks _καρίω_, and by the Germans _beinfräts_. If we examine the different notions entertained by surgical authors concerning caries, we shall find that they are little consistent either with each other, or with the affection to which they relate. As Weidmann observes, Sauvages has confounded caries with necrosis; while Linnaeus has set down, as the marks of a caries, some which occasionally attend ulcers, without any such difference of the bone, and do not invariably exist when caries prevails. Vogel and Sagar have, indeed, rightly expressed the disorder; but what they have stated is rendered somewhat obscure by the addition of several superfluous insignificant circumstances to their definitions.

Weidmann contends, however, that these writers need not have had any difficulty in defining caries, since the celebrated Cullen conveyed a just idea of what this disease was, by two words, _officis ulcers_.

It deserves attention also, that ulcers of the bones chiefly differ from those which affect the soft parts, in being much slower in their formation and termination, the vital powers of the bones being very inferior to those which are possessed by the generality of other parts of the body.

Just in the same manner, as the like soft parts, are liable to inflammation and suppuration, so, like the flesh, they may be attacked with gangrene and phaceous; but, in this instance, the case is not usually explicated by these terms, surgeons having agreed to call the disease _necrosis_.

Necrosis of the bones was a disease which did not escape the observation of the ancient medical writers (Hippocrates, Aph. sect. vii. 77. Celsus, lib. iii. cap. 2, &c.) Many of them, however, were accustomed to confound necrosis indiscriminately with several other analogous affections, so that the consequence is, great confusion prevails in their details of the subject, truth and error being often found blended together in their statements. Some of these old writers sometimes employed the term caries, while others used the apppellations _spina ventosa_, _cancer officis_, &c. synonymously with mortification of the bones.

As Weidmann remarks, however, it ought to be understood, that caries, _spina ventosa_, and _pedarthrocose_ are, all ulcers of the bones, differing merely in their nature and situation. Caries, according to this author, is a simple ulcer affecting the outer part of a bone: _spina ventosa_ is a worse species of the same disorder, affecting the interior texture of the bones, and occurring with particular frequency in the joints of children; by Marcus Aurelius Severinus it is called _pedarthrocose_. These ulcerative diseases of the bones differ from necrosis, in the same respects as an ulcer of the soft parts differs from gangrene and _spina ventosa_. In Vol. XXIV.

The celebrated M. Louis, secretary of the Royal Academy of Surgery at Paris, first applied the term _necrosis_ to the disorder of which we are speaking. He differs from Weidmann, however, in signifying by this expression the death of the whole thickness of a bone, whereas this latter writer, in common with all surgeons of the present day, admits different degrees of the affection, from the death of a whole bone to that of a few bony lamelle, and uses the word _necrosis_ to express the disease in all its states.

There have been some writers, amongst whom is the eminent M. David, who have implied by _necrosis_ a disease, in which a part of a bone perishes, and is then reproduced. (See David's Obf. fur une Maladie connue sous le Nom de Necrofe, Paris, 1782.) But since it does not constantly follow, when part of a bone dies and is separated, that new bone is formed, and since, in both these circumstances, the disease only differs in its form and degree, and not in its nature, it is manifest that the signification of necrosis should not be so limited. We must therefore with Weidmann in the propriety of calling every case a true necrosis, whenever a fragment of bone perishes, and is detached, or about to be detached, from the other part, which continues alive.

_Necrofe_ Offizium, p. 7.

In every climate, age, sex, mode of life, habit, and condition, necrosis may occur; but it is observed that youth, the middle age, and persons who suffer laborious employments, and are exposed to external injuries, are most subject to the disease. None of the bones of the human body are altogether exempt from the danger of its attack: yet it is remarked, that the malady most frequently affects those which are situated superfcially and towards the extreme part of the limb, while such as lie more deeply hidden are left apt to be the seat of the disorder. The spongy portions of the bones are seldom affected; the disease is more commonly seen prevailing in the hard, compact texture of these parts: and it may take place either in the long bones, or such as are broad and flat; in those which are large, or the finer ones; or even in the very least, the officula of the ear being known to perish and be discharched. Allain de Morbis Veneres, lib. iv. cap. 1. Henry, Journal de Med. tom. xv. p. 362.

Besides the difference, in regard to the bones which are exposed to necrosis, the disease itself is attended with variety. Sometimes only a small slender portion of bone dies; sometimes the piece is large and of considerable thickness. The disease is simple, when it is simple and only in one bone, and the patient is well in all other respects. The complaint puts on a more complicated form, when several parts of the same bone are affected with necrosis, when different bones are diseased together, or when the health in general is impaired, or other complaints exist. The forms, in which necrosis presents itself, vary according to the disease happens to occur in the external or the internal layers of the bones; in their extremities, or their central parts. The dead piece may merely consist of a small slender scale; or it may be of considerable thickness, and even comprehend the whole particles of the bone. Sometimes the portion affected with necrosis lies between the particles. In certain cases, a whole epiphysis perishes, or, what is exceedingly rare, the diapole of the flat bones. In particular instances, the cylindrical parts of the
long bones are attacked with necros in such a manner, that
the external lamella, which are covered by the perios-
teaum, are preserved, while the internal part dies, and is
detached from the middle of the parietes of the bone.
Sometimes several bones, contiguous to each other, are de-
stroyed and separated at the same time. Nor is it unworthy
of notice, that the ravages of necros may spread over the
bones in every possible direction, longitudinally, transverse
ly, internally, &c.

In order also to have proper ideas respecting the treat-
ment of this disease, it ought to be known, that necros
admits of being divided into different stages; in the first,
the injured part of the bone dies; in the second it is dead,
and the process of separation, is taking place; and, in the
third, the separation is completed.

The various forms of necros having been noticed, the
next thing for us to consider is the causes of this disorder.
Thefe, indeed, are not altogether different from such as pro-
duce ulcers and gangrene in the soft parts. As, however,
the vital power of the bones is less than that of the
flesh, it is probable that necros may be brought on by
lighter causes than tho'fe which induce the preceding af-
fections of the soft parts; and it seems likely, that such
causes as would only give rise to suppuration of the flesli,
may produce necros of the bones.

We may consider, as the cause of necros, whatever ex-
 distinguishes the nutrition of a bone, in the perios-
teaum, the medullary membrane, or the texture of the bone itefelf, so as
to annihilate all the vitality of the part affected. But it
merits attention, that if such causes should only extend their
action to a certain small part either of the perios-<ref>teum, the
medullary structure, or the bone itself, the bone does not
suffer necros of the bones.

The causes of necros may either be of an external or in-
ternal nature, or both. Sometimes the vitality of the bones
is suddenly destroyed by them, while, in other examples,
the bone undergoes the process of inflammation before it
perishes. The outward cause, producing necros, are
wounds, contusions, preflure, fractures, comminuted injuries
of the bones, luxations, acrid caudic applications, fire, cold,
&c. If the external part of a bone be affected by them,
the necros is external; internal, when they extend their
operation to the interior of the part.

When the perios-teum has been injured by external violence,
so that it becomes affected with considerable inflammation,
and flogous, or when it has been more hastily killed by the
action of caudic, fire, cold, or other causes, such vessels
as give nourishment to the bone are cut and destroyed, so
that it must inevitably follow, that the portion of bone,
which is deprived of the perios-teum, must die. But when
the separated piece of the perios-teum, and the exposed por-
tion of bone, are of trivial size; the patient young, and in
other respects healthy; proper antiphlogistic treatment been
purfued; and the vessels ramifying within the texture of the
bone preserved; hope may be entertained that granulations
will arise from the surface of the bone, and an union to the
adjoining flesh be established.

The larger the portion of perios-teum is which is de-
stroyed, while the bone itself has been bruised, and long
exposed to the air, the greater chance is there of a necros
taking place. The reason to be apprehensive of such mischief
is fully stronger, when the patient is advanced in years,
his vital powers on the decline, or his constitution bad.

The layer of bone that dies and separates may either be
small, or of some thickness; or the whole paries of the
bone may die; according as the portion of the perios-teum,
torn away or destroyed by the inflammation, happens to be
small or extensive; according to the degree of injury suf-
tained by the interior structure of the bone; and according
as the treatment has been rightly or injudiciously conducted.

Although internal necros, extending into the spongy
parts of the bones, mostly originate from constitutional
causes, yet such disease may sometimes proceed from injury
of the internal membranes of the bones, occasioned by out-
ward violence. In external injuries of the skull, where the
pericranium is detached, or otherwise spoild, and the ex-
ternal table and diploe have been hurt, the inflammation
often spreads to the internal table, from which the dura
mater separates. Upon the latter membrane matter accum-
ulates, and the symptoms are of a most dangerous de-
scription: if the patient survive without being trephined, a
part of both tables of the skull exfoliates. (See Pott's
Chirurgical Works, vol. i. p. 32. edit. 1779.) The same
thing, says Weidmann, may take place in other bones be-
ides the cranium, and he refers us for proof of the affec-
tion to a cafe recorded by Bromfield, where the spongy
texture of the upper and internal part of the head of
the tibia became affected with necros, in consequence of
violent preflure having been made on it in an flue in that

Neque est quod miremur; ex eo enim, quod vafa, quae
ex perioeto magna copia in t a ipsum offis contextum de-
sesfunt, et in medallas dispargarunt, et reciprocis fre-
quenter analomocibus rejuagantur, pronom eft colligere,
inflammationes, quae ab initio morbi in extemis, tantum offium
cacibis inflagreIcent, per vafa illa, veluti todtte conduet
ctoribus, profundius infligere, sique longe et late frages
fias exerere potet. Weidmann, p. 10.

Another more formidable train of caufes which may be
productive of necros, are of a constitutional nature, and
they affect the bones either in a sudden or gradual manner.

According to Weidmann, it is proved by frequent obser-
vations, that the vitality of the bones may be destroyed by
the effeets of acute malignant fevers, exanmhamata, small-
pox, and meafles.

When the habit is feerulous, or affected with lues venerea,
or fevrus, writers also inform us that a necros may more
readily occur.

It is remarked, that quicksilver, which, when judiciously
employed, is capable of preventing necros in venereal cafes,
may become a caufe of such mischief, particularly in the
lower jaw, if too much of the ointment has been rubbed in,
or the friotions have been made, without fufficient intervals,
or the patient has exposed himfelf to the cold, lived impror-
perly, &c. See Memòires de l'Acad. de Chirurgie, tom. v.
p. 356.

In treating of the caufes of necros, Weidmann, with
much judgment, cautions us not to employ fuch applica-
tions as were in vogue amongst the ancient furgeons, who
were ignorant of the nature of the bones, and the diftinctions
of the difeases to which thofe parts are liable. Remedies
of the fame kind, fays he, have been too much referred to in
modern times, and portions of bone have been not unfre-
frequently destroyed, in confequence of fpirituous, acrid,
caudic applications having been made to injuries of the
bones, or even cutting instruments had recourse to, while the
remedies ought to have been of the leaft irritating kind,
and things left principally to the operation of nature. Many
furgeons are afraid of applying to an exposed and injured
bone emollient ointments; and yet, for what reafon is dif-
ficult of determination, they have no hesitation in putting
upon the part aerid, drying, fpirituous drenchings. But, continuing
Weidmann, I have learned from certain and repeated ex-
perience, that emollient ointments may be advantageously
applied
applied to an uncovered or injured bone. Why, says he, should that kind of dressing which is known to be beneficial to the soft parts be hurtful to the bones? Indeed this writer argues with much truth, that, as the vesicles which nourish the bones are less numerous and smaller than those with which the soft parts in general are furnished, irritating, drying, spirituous applications must be likely to produce more extensive mischief in the former than in the latter parts. Weidmann, therefore, enjoins us never to make such applications to exposed portions of bone, lest necroses should be occasioned by the mode of treatment: he is strongly in favour of using emollient dressings.

It has been a prevailing opinion amongst practitioners, that pus, collected in the vicinity of a bone, may by inflammation acquire irritating properties, so as to lengthen the erode the bone, and cause necroses. This being the doctrine, the common advice has been to make an opening into all such abscesses without delay. Weidmann, however, and the generality of the best informed surgical writers of the present day, do not admit the accuracy of these tenets. It appears to Weidmann, that erroneous ideas on this subject have been induced by the circumstance of the bones in the neighborhood of abscesses being frequently found bare, carious, or affatted with necroses. The inference here drawn is, that the collected purulent matter has occasioned an erosion of the bone. The truth is, however, that the inflammation which has excited suppuration has not been confined to the soft parts, but has also extended both to the periosteum and bone. Weidmann asks, whether any abscesses ever really contained pus of so acrid and eroding a nature, as to be capable of destroying living parts? He observes, that if you take a drop of purulent matter, and infill it into the eye, an organ of exquisite fineness, you will feel no irritation nor inconvenience. When pus is situated in the anterior chamber of the eye, in contact with the iris and inner surface of the cornea, do we find that it erodes the parts? "Muloties ab oculi et extremitates visus, illud hic diu morari neque tamen tenellas habet partes corrodere, tamdemque et funfum fefervum, disprefare, quia determimentum his partibus inftiitum est. Vidimus ego et dilecti mecum dicifipuli, inter quos frateres Josephum et Carolum Wenzell, nunc medicini doctores nominale fufficitat, in ulceribus, mias, et periosis fratus orbis, offium superficibus cum contus, et per longum fatis tempus alui, ipsum vero, applicato inter umgum diglivo mollifimo, illo illuxit perfluitate, neque fufficat impedimentum, quoniam funpaffificias, illa nova carne, tamdemque cicatrice obducereitur; video infuper emortua offa per annos puri intra ulcerum cava explofita, lavam superficiem ret Turkey, nullamque arboronis notam; quod cum in offe emortuo ita evenerit, multo adue minuit in vivo fieri poftcume eft."

Weidmann, De Necrofi Offium, p. 12.

But although Weidmann avers his entire dissent from the doctrine, that pus even erodes the periosteum and bones, he admits, that this fluid, collected in a certain quantity, may, by the preflure which it occasions, produce inflammation and absorption of the adjoining parts. He also distinctly allows, that purulent matter, when collected between a bone and the periosteum, may, by the dilation which it causes, destroy the vesicles which connect that membrane with the bone, and thus, according to circumstances, give rise either to caries or necrosis.

The inflammation which the causes of necrosis excite in a bone, is either chronic or acute; chronic, inasmuch as it manifests itself slowly, increases in the same way, changes from one state to another with equal tardiness, and, on account of the mildness of the symptoms, is apt to deceive the practitioner. Such inflammation is particularly disposed to occur in languid constitutions, in which a tendency to acute inflammatory diseases does not prevail; in which the affection originates from a chronic cause, as ferofula, lues venerea, the freru, &c., and in which only the superficial part of a bone is attacked. But when the inflammation affects the interior of a bone, and the patient is of a robust, irritable, and plethoric temperament, the symptoms are of the most acute description, intolerable pain, acute fever, loss of reft, delirium, and other nervous disorders. Chronic inflammation produces less suffering, but it is longer in forming: while that which is acute occasions excessive pain, and more quickly arrives at its termination.

The part in which necroses is taking place swells, and the tumour, like the inflammation of which we have just now been speaking, most frequently arises slowly, though sometimes it increafes with great rapidity. In the first circumstance, the pain is obscure and trivial; in the last, it is severe and vehement. The tumour is not conical, as that of a simple abscess, but wide and diffufed. Hence its boundaries cannot readily be definguished, particularly when the affected bone is covered with much fufh. The swelling is fo extensive, that the whole region of the bone, or the entire member, may become enlarged.

From the very beginning the swelling augments, and continues to do fo until pus is formed; but at length the matter makes its way outward, and, by its discharge, the tumour somewhat subsides. Another fort of tumefaction, of the edematous kind, is also apt to occur in such patients as have long laboured under the difeafe, and whose confitution has been impaired by the violence of the pain, and the tediousness and large quantity of the discharge.

When acute inflammation has prevailed, pus of a good quality soon collects round the dead portion of bone; but when the inflammation has been of a chronic species, the matter is not produced fo quickly, and is crude and thin.

An abscess around a necrosis, originating from intense inflammation, and situated near the skin, soon bursts; but if the defeased bone be covered with much flesh, or thick tendinous expansions, and the inflammation be of a chronic kind, the pus daily increases in quantity and continues to diffuse in every direction. The bones, tendons, muscles, and vesicles refift the effüets of the difeafe a confiderable time; but the cellular membrane cannot do this equally well. Hence large and various sinufes take place; some of them extending in the cellular membrane near the main cavity of the abscess; others sometimes being in quite a different situation, especially when the matter is confined under any tendinous expansion. In this lat circumftance, the inner surface of the abscesses daily increafes in a surprizing degree, the source of suppuration is extended, and confiderable obfacles to the cure are produced.

After matter has continued for some time to be abundantly discharged from the openings, by which such abfcesses burft, the fores become fihulous, being surrounded with callous margins, emitting fungs granulations, and having no disposition to heal. The impediment to cicatrization here entirely depends upon the dead portion of bone, whether loose or adherent, which acts like any other extraneous body, and hinders the bottom of the ulcers from healing.

The number of these fufitae is different in different cafes; the lefs furious the difeafe is the fewer of them generally occur; while, in more confiderable cafes, there are many of fuch apertures, which may be very near together, or at a confiderable distance from one another. When the whole circumference of a bone is affected with necroses, fufitae may
Necrosis.

be formed in the integuments on every side of the limb; though it occasionally happens that one particular side is quite free from them.

There is no necessity for any comment here upon the urgent necessity of paying close attention to all the circumstances on which the diagnosis of the present disease is founded; the maxims of Celsus should never be out of recollection; "Cuius certa notitia non est, ejus certum reperi re medicum non potest."

There is something in the fort of inflammation with which the disease commences, that might excite suspicions of the approaching occurrence of necrosis. The inflammation is in its progress, deeply seated, lasts a long while, and is accompanied with grievous symptoms; the colour of the skin remains a long while unchanged; but at last it assumes a reddish purple, or leaden hue; the pus, after a time, makes its way to the surface, and, on its being discharged, the inflammatory symptoms and the disease undergo some remission. When the inflammation is acute, the pain continues to be severe a long while.

It is another sign of necrosis, when the swelling accompanying the inflammation seems to comprehend the bone itself, is extensively diffused, and not particularly prominent, and when the matter, after it is formed, lies deeply, and can only be obscurely felt.

The ulcers which occur over a necrosis emit a large quantity of matter; their edges are shelving; and granulations arise which are yellowish, or intensely red, irregular, and generally insensible, though sometimes excessively painful, and, on being touched, readily bleed.

An old opinion prevails amongst some practitioners, that the matter of ulcers, in which there is a dead piece of bone, is always thin, factitious, and fanious, and such qualities of the discharge have been regarded as a proof of the bone being affected. Weidmann, however, enjoins us not to put any confidence in this criterion. He affirms us he has learned, from frequent observation, that ulcers, accompanying necrosis, often secrete white, thick, inodorous matter, while other ulcers, unattended with any disease of the bone, have a thin factitious discharge. Weidmann does not mean to deny, that when the bone is affected with necrosis, the accompanying ulcers never emit unhealthy matter; and his chief intention seems to be, that of ascertaining that the circumstances is far from being sufficiently conlant to serve as a criterion of the disease of the bone.

Nor is it any certain mark of a diseased bone when the dressings, with which the ulcers have been covered, turn black; for this occurrence often takes place when a necrosis does not exist, and is absent when a portion of bone is known to be dead.

From circumstances like the preceding, no certain information can be drawn, in respect to the diagnosis. Much may be learned, however, from manual examination, if the bone be not too deeply concealed, the fistula not very winding, and the fores not entirely filled up with fungous granulations.

When the ulcers are large and open, the finger should be carefully introduced, and by this means the dead part of the bone will be felt and ascertained to be bare, and deprived of its periosteum. That the bone is actually dead, will be a matter of greater certainty, if its surface should be rough as well as bare, for there is always a chance of a bone becoming covered with granulations, even though the periosteum may be detached.

Examinations made with the naked finger always give the fullest information, and consequently ought to be precluded. The ulcers, however, are frequently so narrow, that the finger cannot be easily introduced, in which circumstance a common silver probe must be employed. This should be passed down to the bone, and moved about in all directions, in order to ascertain how much of the periosteum is detached, whether the surface of the bone is rough, and whether the dead portion is loose, or likely to become so quickly, &c.

Sometimes the dead piece of bone projects out of the ulcer, or, on opening the fore, may be distinctly seen. When the visible bone is of a black colour, it is unquestionably dead; but when its appearance is whiter than natural, it is more difficult to form a judgment.

It is worthy of notice, that the blackness of a bone does not depend upon the necrosis itself, but upon the exposure of the part to the air, and the drying up of the pus. It is even said, that portions of bone which are exfoliating are whiter than natural, provided they have always been covered with fluid purulent matter, and defended from the air.

In order to distinguish cases from necroses, it ought to be understood, that the former diseased, for the most part, arises in the spongy parts of the bones, and from an internal cause, in young subjects of debilitated and bad constitutions, the discharge being fetid, copious, thin, and fanious. If the bone itself be touched with a probe, it does not feel dry, as in necroses, but excavated by ulceration, and, as it were, worm-eaten.

It is a remarkable circumstance in the history of necroses, that in favourable instances of the disease, the inflexibility and firmness of the limb are preferred during the whole of the process, by which the new bone is formed. Consequently, the new bone must have begun to grow, and must have acquired firmness before the old bone separates, or is absorbed. Were this not the case, the limb must become flexible and unfelts the moment the dead bone is removed. Another consequence of the new bone being formed before the removal of the old one, is, that the former must surround and include the latter. For, since the ulcers portion of bone completely occupies the space between the two living ends, these cannot be immediately connected by the new bony matter. The connection can alone be completed by the new bone being deposited on the outside of the old one, from one end to the other, and attaching itself to the portions which still remain alive. The new bone must also be necessarily larger than the old one, because externally flattened, and hence the affected limb, after the cure is complete, will always continue larger, clumsier, and less shapely than the other. The length of it, however, remains unaltered, because the old bone retains its attachments, while the rudiments of the new bone are lying on its outside, and connect the living ends of the old one by an inflexible mass, equal in length to the portion which is destroyed.

Thus we see, that in the processes which nature follows in the formation of the new osseous shell, the old bone leaves as a mould for the new one; and the first step of the processes is to surround the old bone with an effusion of coagulating lymph. Ruffell on Necrosis, p. 2—7.

This author adduces many arguments to prove, that the pulpy mass, which extends from one portion of the bone to the other, and is itself at last converted into bone, is formed quite independently of the original bone, or the periosteum. P. 27.

On the other hand, Mr. Crowther has published a letter, written by Mr. Macartney, in which the periosteum is described as being the organ producing the new bony matter. Mr. Macartney remarks, that the first and most import
ant circumstance is the change which takes place in the organization of the periosteum; this membrane acquires the highest degree of vascularity, becomes considerably thickened, soft, spongy, and loosely adherent to the bone. The cellular substance, also, which is immediately connected with the periosteum, suffers a similar alteration: it puts on the appearance of being inflamed, its vessels enlarge, lymph is shed into its interstices, and it becomes confounded with the periosteum. These changes are preparatory to the absorption of the old bone, and the secretion of new osseous matter, and even previous to the death of the bone which is to be removed. In one instance, I found the periosteum vascular and pulpy, when the only affection was a small abcess of the medulla, the bone still retaining its connection with the neighbouring parts, as it readily received injection. The newly organized periosteum, &c. separates entirely from the bone, after which it begins to remove the latter by absorption; and, while this is going on, its inner surface becomes covered with little eminences, resembling granulations. In proportion as the old bone is removed, new osseous matter is deposited in the substance of the granulations, whilt they continue to grow upon the old bone, until the whole, or a part of it, is completely absorbed, according to the circumstances of the case. What remains of the involvment, after the absorption of the old bone, and the formation of the osseous tube which is to replace it, degenerates, loses its vascularity, and appears like a lacerated membrane. I have never had an opportunity of examining a limb a sufficient time after the termination of the disease, to ascertain whether the involvment be at last totally absorbed, but, in some instances, I have seen very little remaining. During the progress of the disease, the thickened cellular substance which surroonded the original periosteum becomes gradually thinner; its vessels diminish, and it adheres strictly to the new formed bone, to which it ultimately serves as a periosteum. Mr. Macartney states, that the anatomical preparations which authenticate the above observations, are preferred at St. Bartholomew's Hospital. See Crowther on White Swelling, p. 183, edit. 2.

According to Mr. Ruffell, an incipient case of necrosis is characterized by a deep-seated excruciating pain, not at first aggravated by pressure, and which is soon followed by a rapid enlargement of the parts along the course of the bone. Soon, however, after the commencement of the attack, an external inflammation succeeds, which quickly ends in the formation of matter. The abscess at length bursts by a small opening. The extent of this inflammation is not in general great. Mott commonly several inflammations of a circumfered kind occur about the same time the abscesses burst by small openings, which do not close, but continue discharging matter as florid forces. The apertures are generally situated over the most superficial part of the affected bone. The pus is usually of good quality, and large in quantity, issuing from extensive cavities, into which the fistula leads. Such abscesses, being situated within the newly formed osseous shell, cannot be discharged by pressure, nor can any fluctuation be felt. A probe can seldom be introduced far into the fistulous openings, or discover any loose piece of bone. In this stage, the dead bone, technically called the quefllum, can seldom be felt; though, in a few instances, small spicules make their way outward, together with the discharge. Fistulous openings may be regarded as necessarily attendant on all cases of necrosis; though to mild a case may be conceived, that the new bone may be generated without any outward ulceration. No such influence, however, is on record. Ruffell.

After the openings have formed, the case may take one of the following courses. The ulcerations may in time heal up, the sequestrum never be seen, and no vestige of the diseased bone remain, except a permanent enlargement and induration along the course of the bone. This is the most favourable manner in which a necrosis may terminate. In the other instance, the sequestrum makes its appearance externally, through the new bone and the integuments, attended with different degrees of pain, inflammation and suppuration, in different cases. The sequestrum may at first be moved by palpation; but is too firmly wedged in the surrounding parts to be completely taken out. In time, however, it becomes loose enough to be removed.

Sometimes the middle portion of the sequestrum prefers itself externally, while its sides are every where wedged in the substance of the new bone. The natural end of such a case would be very tedious of accomplishment, and the interference of art is essentially serviceable in accelerating the separation of the dead bone, thus circumstanced. After the sequestrum has been either absorbed or thrown off, in one of the above ways, the cavity of the new bone becomes filled up with granulations, which are, at length, converted into bony matter. Thus the new bone differs from the original one, in being solid instead of hollow. Ruffell.

When the sequestrum is thrown off slowly, the inflammation is moderate; but when it separates quickly, while the new bone is in a soft state, the detachment is always preceded by severe inflammatory symptoms, and followed by a temporary lysis of the natural firmness of the limb. This premature separation of the sequestrum often occurs in necroses of the lower jaw, and the chin consequently falls down on the neck. In certain cases, the sequestrum separates at each end from the living portions of the old bone, before the new osseous shell has acquired firmness, so that the limb feels as if it were broken in two places. Ruffell.

When the dead bone is removed by absorption, the process is tedious, and attended with a profuse discharge of matter, which gradually ceases, and at last stops altogether. In young subjects, this work is more quickly perfected than in old ones. There are some chronic cases of necrosis, in which the sequestrum remains unab sorbed for an indefinite length of time, producing no violent irritation, yet always enough to tease the patient, and disturb his health.

In necrosis of the long bones, there are always round apertures in the new osseous shell, corresponding with the external fistulous openings, as long as the sequestrum remains enclosed in it. Ruffell.

The tibia, femur, lower jaw, clavicle, humerus, fibula, radius, and ulna, are most frequently affected with necrosis. Excluding the lower jaw and clavicle, the process of regeneration has only been noticed in the cylindrical bones. From twelve to eighteen years of age is the time of life most susceptible to necrosis. The necrosis of the lower jaw, however, seldom occurs before the age of thirty. In some persons, two bones are affected at once, owing to constitutional causes.

The process of cure is said to take place with more celerity in the lower jaw than any other bone, and may be completed in three months. Mr. Ruffell has never known a case of necrosis of the tibia get well in less than a year; but, in general, nearly two years elapse first; sometimes the cure is protracted to a much greater length of time.

When the constitution is predisposed to necrosis, any cause, capable of exciting inflammation, may occasion an attack of it. Often, however, the disease is purely sporadical, and not referrible to outward causes. Cases which occur from...
from external injury, are generally those of the lower jaw, which are frequently imputable to blows, the application of acid fulminations to carious teeth, effects of mercury, &c.

Necroses of the lower jaw and clavicle never prove fatal: that of the lower extremities, which is the worst case, does so very seldom, and only from the violence of the first inflammatory symptoms, which rapidly bring on a hectic fever, which proves incurable, without removing its local cause by a timely amputation. When the violence of the first flare, however, has abated, the irritation ceases, and the hectic symptoms, if there are any, are generally moderate. Nor is this rate of tranquillity diluviated, till the fequestrum, in making its way outward, again produces irritation. At this second period of urgency, extensive inflammation may originate, ulceration spread all over the surface of the limb, affume an unhealthy appearance, violent fever succeed, and the patient either perish, or sink into a flate, in which he must content to amputation as the only means of saving his life. This is the last crisis of imminent danger; but, in general, it is less perilous, than when the inflammation comes on in the incipient stage of necrosis. Ruffell.

The following case of necrosis of the thigh-bone is related by Dr. Mackenzie.—William Baxter, a boy thirteen years old, received a blow on his thigh at school, of which he at first hardly complained; but in a few months he began to have pain in the thigh, which inflamed, swelled, and appeared to have matter in it. The parents being poor, no surgeon was called, and the boy was allowed to linger for a great while. At length the matter made its way through the skin, by a small opening on the interior part of the thigh, about three inches above the knee, and a thin fanes continued to be discharged for eighteen or twenty months. At length, the hole in the skin enlarged, and the point of a bone began to protrude, and give a good deal of pain when the clothes rubbed against it. After suffering in this manner for two years and a half, the boy, as he lay in bed one morning, felt the bone looser, and projecting more than ordinary. He gave it a strong pull, and brought the piece away entirely, which proved to be seven inches and a half of the thigh-bone. A good deal of bleeding followed; but the wound soon healed, and he has never since found the least inconvenience. Dr. Mackenzie, hearing of this singular case, sent for the boy, carefully examined his thigh, and found it as firm as the other. The only difference was, that it was somewhat thicker, and a little more curved. The muscles retained their natural softness and looseness on the bone. The detached piece of bone was a portion of its whole circumference.

In confirmation of this case, Dr. Hunter mentions a tibia, which was sent to him by a Mr. Inset, after amputation. On examination, the case at first sight seemed to be a swelling of the whole bone, with a loose internal exfoliation. However, it proved to be a remarkable instance of the separation of the greatest part of the original bone, whose place was suppplied by a callus. The external surface of the inclosed loose piece of bone was smooth. A small part of the surrounding bony substance being removed, the contained piece was taken out, and found to be the whole body of the tibia. It had separated from the epiphysis at each extremity. The middle part of the bone had perished, consequently had lost its connection with the pedicle, and was gradually thrown off from the living parts of the bone at each end. A callus extended from end to end, united the two extremities of the original tibia, preferred the length, and gave firmness and inflexibility to the part. The exfoliation was so encompassed by the new bony case, that, though quite loose, it could not be thrown out. (Med. Obs. and Enquiries, vol. iii.) In the fifth volume of the Mem. de l'Acad. de Chirurgie, is the history of a man, the whole of whose clavicles came away, without his being deprived of any of the motions of the arm. The death of this patient, which happened shortly afterwards, afforded an opportunity of examining how nature had repaired the loss. Another clavicle was found regenerated, which neither differed from the original one in length or solidity; but only in shape, being flatter, and not so round. It was connected with the acromion and sternum, just like the primitive bone. Though necrosis mostly attacks the cylindrical bones, the flat ones are not exempt from the difeafe. Pott makes mention of a parietal bone, the whole of which was detached, and of an os frontis, the greatest part of which came away. In a thesis on necrosis, in 1776, aux epistles de chirurgie, may be found the case of a young man, a very large part of whose scapula perished and came away. Choppard, who relates the case, mentions, that he saw the patient quite recovered, and felt a new triangular movable bone, firmly supporting the clavicle, but smaller and flatter than natural, and without any spinous processes. The gaze has happened to the lower jaw, as may be seen by referring to the Ephemerides Germaniae, and Mem. de l'Acad. de Chirurgie. In the fifth volume of the latter work is an account of a woman who applied to be relieved of some venereal complaints. From the beginning of the treatment, the bone was discovered to be loose just under the gums, and seemed shortly afterwards to move backwards and forwards with a tooth. Mr. Geeney took hold of the tooth with a key-instrument, and found it firmly inserted in the movable piece of the jaw; he made with caution the necessary manoeuvres for extracting the portion of bone; but was greatly surprised on finding what an extensive part yielded to his very moderate efforts. It was the whole of the lower jaw, above its right angle, from its division into the coronoid and condyloid processes to the space between the first and second of the front grinders of the left side. On the right, there only remained the condyle in the articular cavity of the temporal bone. This destruction left a considerable empty space, from which great deformity was apprehended, in consequence of the unsupported soft parts falling down. The woman, however, got well in two months, and had the most perfect use of a new jaw. A similar fact is recorded in the Journal de Medecine, 1791.

In cases of necrosis, the surgical indications are few and obvious; viz. 1. When inflammation attends any stage of the disease, to have recourse to common antiphlogistic means. 2. To promote the separation, or absorption of the dead bone, according as it tends to make its way outward, or to become completely inclosed with new bony matter; and, in this situation, to be invissibly and gradually removed by a natural process. 3. When the constitution seems unable to sustain any longer the effects of the local disease, to amputate, if the situation of the affection will permit.

During the first inflammatory attack, the patient's life is often endangered from the extent and violence of the inflammation, before the new shell is formed, or the fequestra loose, and ready to separate. In this state, art can do little more than employ topical bleeding, and poultices, and poultices. If, notwithstanding such treatment, a new danger is likely to peril of the hectic symptoms, which rapidly follow, unless the limb be immediately removed, the operation should then not be delayed.

But if the patient get over the first inflammatory stage, the grand object is to get rid of the fequestra. When they, however,
however, are undergoing a gradual absorption, without ever making their appearance externally, or giving any considerable disturbance to the constitution; or when the dead bone is making its way outward, without occasioning urgent inconveniences; the surgeon should interfere very little with the natural progress of the case. When the dead bone does not tend to make its way through the skin; but lies quietly incased in the new osseous shell, the occurrence of extensive suppurations may be prevented, by occasionally applying leeches, and keeping open a blister with the finev cerate, as recommended by Mr. Abernethy in his lectures, and Mr. Crowther, in his work on the White Swelling. The blister will, at the same time, have great effect in promoting the absorption of the lequement, and, of course, in accelerating the process of cure.

When the dead bone, however, creates considerable irritation, when its middle portion is very superficial, or quite exposed, while its ends or edges are overlapped by the surrounding new bony matter, consequentely the piece to be wedged in, that its separation cannot be expected in any moderate time, the operation of cutting it out is, certainly, not only feasible, but highly proper and commendable. In this kind of case, Mr. Hey's saws would be found the most convenient instruments.

Alto, were the dead bone, though quite covered and incased in the new one, to be tedious long in being absorbed, productive of great irritation and impairment of the health, and the affected bone superficial, like the tibia, no candid man could condemn making an incision, and removing a part of the osseous shell, in order to take the chance of being able at once to extract the sequestrum lodged in its cavity. Mr. Ruffell mentions successful attempts of this kind, which fully justify the practice. The state of the bone may be examined, without proceeding to any severe operation, by laying bare small portions of the bone in the vicinity of the fistulous openings, introducing a probe, if possible; or, if that be impracticable, drilling small holes with a perforator, for the purpose of examining the state of the cavity. If the cavity should fill seem extensive, and to contain a sequestrum of considerable size, the necessity of operating is apparent. On the contrary, if the whole cavity be filled up with offensive matter, and no dead bone found there, the progress of the case must, of course, be left to nature. (Ruffell) When the surgeon knows, that his object is to make an opening large enough to allow the dead piece to be extracted, he need not directition how to act about making it. The skin must be divided with a common scalpel, and the bone cut with small trephines, a gouge and mallet, or what are in most cases both, Mr. Hey's saws. Conduit Ruffell on Necrosis, 1794. Mem. de l'Acad. de Chirurgie, tom. V. Boyer on the Diseases of the Bones, vol. i. Encyclopédie Méthodique ; Partie Chirurgicale ; Art. Necrofie. Thes. de Ollium Necrof. 1776. Crowther on White Swelling, &c. edit. 2. Cooper's Dictionary of Practical Surgery.

Some remarks on necrosis may be found in Richerand's Nofographic Chirurgicale, tom. iii. Leveillé has also been very diffuse upon this subject, in his work, entitled Nouvelle Doctrine Chirurgicale, tom. iv. By far the most instructive book on necrosis, is Weidmann's De Necrofio Ollium, with plates, folio ; Francofurts, 1793.

NECTANDRA, in Botany, so called from necy, honey, and and, a man, because the supposed necerties have the appearance of anthers or male organs. Berg. Cap. 131. Jull. 77. This genus is thus characterized by Bergius.

Nectareous scales about eight, (rarely four,) prominent, seated upon the margin of the tube of the funnel-shaped corolla, and resembling anthers. Stamens included within the tube.

The three species described by him are Gymnadenia, with Struthiola erecta, of Lindl. But Juiffic seems not to admit more than the first, the second, having but four of the nectariferous scales, being, in his estimation, a Gymnadenia; and the third, having but four filaments, a Struthiola. The parts in question seem to us too variable, to authorize the establishment of a genus on such a character, for one single species, which has nothing about it besides to support the distinction.

NECTAR, Miss., among the Ancient Poets, the drink of the fabulous deities of the heathens. See AMBROSIA.

NECTAR is also used, by some of the ancients, to express honey: this signification of the word was owing to the supposition, that honey was the drink of the bees, as they effemed the yellow matter collected on their thighs to be their food. They called the latter ambrosia. It seems, that the ancients have been more in the right, as to their opinion of the ambrosia, than other authors, who have usually esteemed that yellow substance to be true wax; but it appears from experiments, that it is not really so; nor can wax be separated from it by any of the known processes of chemistry. It seems rather that the bees eat it, agreeably to the opinion of the ancients, and that after having derived them as nourishment, it is converted in the bowels into the substance we call wax.

NECTARINE, a fruit greatly esteemed for its delicious flavour, and supposed to have its name from the nectar of the gods, in heathen stories.

It differs in nothing from the peach, but in having a smoother skin and a firmer pulp.

We have ten kinds of nectarine cultivated by the curious in gardening; viz. Fairchild's early nectarine, ripening in the end of July; the Ebruge, Newington, scarlet, Brugnon or Stahan, and Roman, which ripen in August; the morry, golden, and Temple's, which ripen in September; and the Peterborough, or late green nectarine, which ripens about the middle of October.

The insects in nectarines may be destroyed in the same manner as those of peach trees.

The prunus, planting, and whole culture of this plant, are the same with that of the peach.

NECTARIUM, in Botany, the nectar or honey-cup, so denominated by Linnaeus, according to the metaphorical sense in which the word Nectar is often elegantly applied, by the Latin writers, to honey. This in Linnaean language is refrained to some part of the flower, and is defined an organ which contains, or which secretes, honey. Similar organs are found on the stalks or leaves of several plants, which produce a liquid, differing, in no respect, from what is found in flowers; but such are termed nectariferous glands. They are met with on the footstalks of Passion-flowers. The Meliae fragrans of Linnaeus (Dracaena fragrans, Ker in Curt. Mag. t. 1881.) exudes, from various parts of its flower-stalks, without any particular apparatus, a great quantity of very sweet concrete honey. In like manner the tube or claws of the corolla, perhaps even the filaments, in many flowers, appear to produce the copious honey lodged around or within them, without any distinct organ, or even a gland, being, as far as we can discover, appropriated to that purpose. Such it generally the case in the ringent flowers, or clays Didymium. Honey indeed is nearly universal in flowers, being designed, in a secondary way, to promote their fecundation, by means of the insects which depend upon it for food, and in searching for it, either by the pollen from the anthers, upon the stigma of
of the same blossom, or convey it from one to another. The more we scrutinize and watch the fecundation of flowers, the more proofs we shall find that even in those which, as usual, have flaments and pistils in the same individual, the former are often more vigorous in one of the same species, even on the same stem, than in another, whose pistil, on the other hand, is more perfect or vigorous than its own flaments. It very often happens also that the anthers of a flower are ripe, not precociously at the same moment with its stigma. In these cases the ministry of insects becomes peculiarly useful. Their operations are among the infinite and rich variety of means, by which similar purposes are accomplished under the superintendance of Divine Wisdom. These force even the most incredulous and fastidious observer, to admit the evidence of a design in Nature. Shall we microscopically admire them, and overlook the infinitely transcending design of the revealed will of God?

The shape and structure of the Nectarium in different plants are extremely various, but commonly quite conformatd and uniform in flowers of the same genus; very frequently indeed supplying the most clear and decisive marks, by which one genus is distinguished from another. In the Crown Imperial the nectary is a mere cup or depression, in the Lily a bordered furrow in the claw of each petal; in the Violet the base of one petal is elongated into a spur, or bag, containing the honey; in the Nafturtium, or Tropæolum, the nectariferous spur is an elongation of the calyx. The nectary is of the nature and texture of petals in the Epimedium, Engl. Bot. t. 438, but perfectly distinct from them, as well as from the calyx; while the Larkspur, Columbine, Aconite, and Helleborous, have likewise nectarines more or less agreeing with their petals, but no calyx. Hence some botanists reckon their petals, though coloured, the calyx, and their nectarines the only corolla. The neighbouring genus Ranunculus, whose nectarines are pores in the claws of its petals, certainly gives weight to such a determination. In Euphorbia the petals are in some species decided cup-like nectarines, filled with honey, in others of a crecent shape, possibly excuding the same fluid from their upper surface; but this we have in many instances not been able to detect, and there rather appears to be an actual transition in this very natural genus, from petals to nectarines.

Very distinct and certain nectarines, as actually secreting honey, are those of a glandular kind, lodged in the deepest recesses of a flower, and quite of a different substance from its other parts. Such are the green glands, usually four, in the Tetradycon, or Crucifera, clasps, situated at the base of the flaments, either on the inner or outer side. Singular ones, are found in Geranium and Salsify. In the latter genus an abortive germen often seems to become a nectar, which is double, in a strange transition. Urtica exhibits the same phenomenon, at least according to Linnaeus, but we cannot of our own knowledge speak to this.

Some flowers display an elaborate apparatus, which cannot be demonstrated to have any concern in the secreting or holding of the honey. Such are the five green bodies, fringed with bristles, each of which bears a globe, in the elegant Paraphila, Engl. Bot. t. 82. These, not being referable to any other of the usual parts of fructification, all of which are present beside, are by analogy presumed to be nectarines, which it is not probable either to dispute or to confirm. Linnaeus has been much confused for using this compendious term for every such supernumerary part, though it is very convenient for botanical distinctions to do so. The numerous and complex rays which decorate the Balfonflower, are equally inexplicable in their nature. But they crown the cell where the copious honey is lodged, while their cellular texture and vivid variegation of colour, indicate their connection with air and light, two great probable agents in the secretion of that faccharine fluid; nor does it appear to us at all improbable, that they share in its elaboration. In other cases the richly coloured petals of flowers possibly answer the same end. Professor Sprengel has very ingeniously attempted to demonstrate, that many of these, by peculiarly constricted or coloured, appendages to flowers, have a definite and appropriate use, which is to attract certain insects by their beauty or smell, that such insects may seek for the honey, or else to accommodate them while they are procuring it. Such he considers to be the intention of an infinite variety of gorgeous decorations about many flowers, which he calls macula indicantes, or spots that indicate the precise situation of the honey. Perhaps, in the rich benevolence of the Creator, he has indulged this tribe of beings with a taste for the beauty of these objects, thus tempting them to frequent the flowers for an important purpose in the economy of nature. So it seems, he has formed some flowers in the strong likenesses of particular butterflies, that the latter may be attracted to deposit their eggs on the plants so adorned, which are requisite for the fulfilment of the future brood of caterpillars.

See Sm. Infers of Georgia, t. 5, where this hypothesis is skilfully illustrated in Papilio Ebule and Caffia Chama-crifta; see also Pholana Gauze, t. 99 of the same work.

That Linnaeus, or other sylleptic botanists, may not sometimes have erred, in giving the name of nectarium, either to incomplete flaments, or to some fringe or other appendage not strictly such, we will not deny; but who can expect to avoid these occasional inaccuracies? He first named the part in question, and illustrated its use, which is no less extensive in the scientific discrimination of plants, than in the economy of their fructification; and if he was now and then led astray by a favourite hypothesis, he is more excusable than others, who could not see the use of the nectarium at all, either in vegetable physiology or sytematic botany.

Gen. Ch. Cal. Perianth inferior, of one leaf, fix-cleft; the three outer segments ovate, acute, coloured on the inside; the three alternate inner ones ovate, obtuse, smaller, coloured on both sides. Cor. none. Stam. Filaments fix, capillary, inserted at the base of the segments of the calyx; anthers ovate. Phyl. Gernenis superior, two, oblong; illices short; filaments obtuse. Peric. Capsules two, ovate, rather fleshy, crowned with the permanent illices of one cell. Seeds numerous, very small.

Ob. We are somewhat inclined to subscribe to Juvenius' opinion of this plant belonging to his Ranunculaceae, and, in that case, the three inner segments of the calyx must be considered as petals.

Ecl. Calyx fix-cleft, the three inner segments smaller and obtuse. Corolla none. Capsules two, rather fleshy, crowned with the illices, of one cell, many-feeded.

1. N. aquatica. Linn. Syll. ed. Gmel. v. 2. 380. Wild. (Cabomba aquatica. Aml. Guian. t. 124.)-Found in pools and gentle rivulets at Guiana, and in the island of Cape Verde. Stems long, branched, jointed, fiddle-shaped, with a pair of leaves at each joint. Lower leaves immerged, in five, capillary segments, repeatedly three-forked, with taper points,
NEC

points, the outline of the whole circular; upper ones floating, alternate, peltate, orbicular, undivided, with concentric ribs. *Footfalls* very long. *Flowers* on long solitary flasks, at the axils of the upper leaves, yellow.

NECUIA, a name given by the ancient Greeks to a species of mullein.

The Greeks and Romans both used the flasks of a peculiar kind of mullein, called *thyra* by Nicander. For the making of wicks of lamps, we have a kind of mullein, called *lychnites*, and candlewick mullein, from the *lychnites* of Dioscorides; but it is not certain that our's is the same plant.

The ancients used the flasks of many different plants for the wicks of their candles and lamps. The rushes, stripped of its bark, was as commonly in use with them as with us for this purpose; and they also used the nettle, this mullein, and many other plants, whose flanks were composed of tough filaments, for the same purpose; beating them out like hemp, and when dry, dipping them in melted resin, and other such inflammable substances. When thus prepared, they are readily inflammable, like our flambex, and this mullein, having flanks more long and large, and more firm than all the others, was used to make those lights, with which they set fire to the funeral pile for confounding the ashes of their dead friends.

*NECYDALIS*, Carrion-Eater, *in Natural History*, a genus of insects of the Coleoptera order. The generic character is this; antennae tesselaceous or filiform; four feelers that are filiform; shells less than the wings, and either narrower or shorter than the abdomen; the tail is simple. Of this genus there are 39 species, separated into two divisions, as follows.

A. *Antennae* tesselaceous; shells shorter than the wings and abdomen.

Species.

* Major. The shells of this species are ferruginous and immaculate; the antennae short. It is found in many parts of Europe. The head is black, and the wings are longer than the body.

* VARIEGATA. Abdomen black, with fulvous bands. It inhabits New Holland.

* Minor. Shells tesselaceous, with a small white line at the tip; the antennae are long. This species is found in several parts of Europe.

* UMBELLARUM. The shells of this species are tesselaceous and immaculate; the antennae are long. This also is an European insect.
